1 Review Of Advanced Calculus  
1.1 Set Theory  
1.1.1 Basic Definitions  
1.1.2 The Schroder Bernstein Theorem  
1.1.3 Equivalence Relations  
1.1.4 Partially Ordered Sets  
2 Continuous Functions Of One Variable  
2.1 Exercises  
2.2 Theorems About Continuous Functions  
3 The Riemann Stieltjes Integral  
3.1 Upper And Lower Riemann Stieltjes Sums  
3.2 Exercises  
3.3 Functions Of Riemann Integrable Functions  
3.4 Properties Of The Integral  
3.5 Fundamental Theorem Of Calculus  
3.6 Exercises  
4 Some Important Linear Algebra  
4.1 Algebra In $\mathbb{F}^n$  
4.2 Exercises  
4.3 The Inner Product And Distance In $\mathbb{C}^n$  
4.4 Subspaces Spanned And Bases  
4.5 An Application To Matrices  
4.6 The Mathematical Theory Of Determinants  
4.6.1 The Function $\text{sgn}$  
4.7 The Determinant  
4.7.1 The Definition  
4.7.2 Permuting Rows Or Columns  
4.7.3 A Symmetric Definition  
4.7.4 The Alternating Property Of The Determinant  
4.7.5 Linear Combinations And Determinants  
4.7.6 The Determinant Of A Product

## 15 Banach Spaces

15.1 Theorems Based On Baire Category

- 15.1.1 Baire Category Theorem
- 15.1.2 Uniform Boundedness Theorem
- 15.1.3 Open Mapping Theorem
- 15.1.4 Closed Graph Theorem

15.2 Hahn Banach Theorem

- 15.2.1 Partially Ordered Sets
- 15.2.2 Gauge Functions And Hahn Banach Theorem
- 15.2.3 The Complex Version Of The Hahn Banach Theorem
- 15.2.4 The Dual Space And Adjoint Operators

15.3 Uniform Convexity Of $L^p$

15.4 Closed Subspaces

15.5 Weak And Weak $^*$ Topologies

- 15.5.1 Basic Definitions
- 15.5.2 Banach Alaoglu Theorem
- 15.5.3 Eberlein Smulian Theorem

15.6 Operators With Closed Range

15.7 Exercises

## 16 Locally Convex Topological Vector Spaces

16.1 Fundamental Considerations

16.2 Separation Theorems

- 16.2.1 Convex Functionals
- 16.2.2 More Separation Theorems

16.3 The Weak And Weak $^*$ Topologies

16.4 Mean Ergodic Theorem

16.5 The Tychonoff And Schauder Fixed Point Theorems

16.6 A Variational Principle of Ekeland

- 16.6.1 Cariste Fixed Point Theorem
- 16.6.2 A Density Result

16.7 Quotient Spaces

## 17 Hilbert Spaces

17.1 Basic Theory

17.2 The Hilbert Space $L^2(U)$

17.3 Approximations In Hilbert Space

17.4 The Muntz Theorem

17.5 Orthonormal Sets

17.6 Fourier Series, An Example

17.7 Compact Operators

- 17.7.1 Compact Operators In Hilbert Space

17.8 Sturm Liouville Problems

- 17.8.1 Nuclear Operators
- 17.8.2 Hilbert Schmidt Operators

## CONTENTS

### 20.9 Mixed Partial Derivatives

### 20.10 Implicit Function Theorem

### 20.11 More Derivatives

### 20.12 Lyapunov Schmidt Procedure

### 20.13 Analytic Functions

### 20.14 Ordinary Differential Equations

### 20.15 Exercises

### 21 Degree Theory, An Introduction

#### 21.1 Sard's Lemma

#### 21.2 Preliminary Results

#### 21.3 Definitions And Elementary Properties

- 21.3.1 The Degree For $C^\infty (\Omega; \mathbb{R}^n)$
- 21.3.2 Definition Of The Degree For Continuous Functions

#### 21.4 Borsuk's Theorem

#### 21.5 Applications

#### 21.6 The Product Formula

#### 21.7 A Function With Values In Smaller Dimensions

#### 21.8 The Leray Schauder Degree

#### 21.9 Exercises

### 22 Critical Points

#### 22.1 Mountain Pass Theorem In Hilbert Space

- 22.1.1 A Locally Lipschitz Selection, Pseudogradients
- 22.1.2 Mountain Pass Theorem In Banach Space

### 23 Nonlinear Operators

#### 23.1 Some Nonlinear Single Valued Operators

#### 23.2 Duality Maps

#### 23.3 Penalization And Projection Operators

#### 23.4 Set-Valued Maps, Pseudomonotone Operators

#### 23.5 Sum Of Pseudomonotone Operators

#### 23.6 Generalized Gradients

#### 23.7 Maximal Monotone Operators

- 23.7.1 The min max Theorem
- 23.7.2 Equivalent Conditions For Maximal Monotone
- 23.7.3 Surjectivity Theorems
- 23.7.4 Approximation Theorems
- 23.7.5 Sum Of Maximal Monotone Operators
- 23.7.6 Convex Functions, An Example

#### 23.8 Perturbation Theorems

28 Differentiation Of Radon Measures  
28.1 Besicovitch Covering Theorem ....................................... 1059  
28.2 Fundamental Theorem Of Calculus For Radon Measures ........... 1064  
28.3 Slicing Measures .................................................. 1067  
28.4 Vitali Coverings .................................................... 1074  
28.5 Differentiation Of Radon Measures .................................... 1076  
28.6 The Radon Nikodym Theorem For Radon Measures .................. 1079

29 Fourier Transforms  
29.1 An Algebra Of Special Functions ................................. 1083  
29.2 Fourier Transforms Of Functions In $G$ .......................... 1084  
29.3 Fourier Transforms Of Just About Anything ...................... 1086  
29.3.1 Fourier Transforms Of $G_1$ ..................................... 1086  
29.3.2 Fourier Transforms Of Functions In $L^1(\mathbb{R}^n)$ ............. 1090  
29.3.3 Fourier Transforms Of Functions In $L^2(\mathbb{R}^n)$ ............. 1093  
29.3.4 The Schwartz Class ........................................... 1097  
29.3.5 Convolution .................................................... 1099  
29.4 Exercises ......................................................... 1101

30 Fourier Analysis In $\mathbb{R}^n$: An Introduction .................... 1107  
30.1 The Marcinkiewicz Interpolation Theorem ......................... 1107  
30.2 The Calderon Zygmund Decomposition ............................ 1110  
30.3 Mihlin’s Theorem .................................................. 1112  
30.4 Singular Integrals .................................................. 1125  
30.5 Helmholtz Decomposition .......................................... 1135

31 Gelfand Triples And Related Stuff  
31.1 An Unnatural Example .............................................. 1145  
31.2 Standard Techniques In Evolution Equations ...................... 1150  
31.3 An Important Formula ............................................. 1161  
31.4 The Implicit Case .................................................. 1168  
31.5 The Implicit Case, $B = B(t)$ ..................................... 1187  
31.6 Another Approach ................................................ 1200  
31.7 Some Imbedding Theorems ......................................... 1207  
31.8 Some Evolution Inclusions ........................................ 1216

32 Maximal Monotone Operators, Hilbert Space ......................... 1221  
32.1 Basic Theory ...................................................... 1221  
32.2 Evolution Inclusions .............................................. 1228  
32.3 Subgradients ....................................................... 1233  
32.3.1 General Results .............................................. 1233  
32.3.2 Hilbert Space .................................................. 1247  
32.4 A Perturbation Theorem .......................................... 1253  
32.5 An Evolution Inclusion ............................................ 1254  
32.6 A More Complicated Perturbation Theorem ....................... 1257  
32.7 An Evolution Inclusion ............................................ 1259
III Sobolev Spaces 1267

33 Weak Derivatives 1269
33.1 Weak * Convergence ........................................... 1269
33.2 Test Functions And Weak Derivatives ......................... 1270
33.3 Weak Derivatives In $L^p_{loc}$ ................................. 1274
33.4 Morrey's Inequality ............................................. 1277
33.5 Rademacher's Theorem ......................................... 1280
33.6 Change Of Variables Formula Lipschitz Maps ................. 1283

34 The Area And Coarea Formulas 1293
34.1 The Area Formula Again ....................................... 1293
34.2 Mappings That Are Not One To One ............................ 1296
34.3 The Coarea Formula ............................................. 1300
34.4 A Nonlinear Fubini's Theorem ................................. 1311

35 Integration On Manifolds 1313
35.1 Partitions Of Unity ............................................. 1313
35.2 Integration On Manifolds ...................................... 1317
35.3 Comparison With $H^n$ .......................................... 1323

36 Basic Theory Of Sobolev Spaces 1325
36.1 Embedding Theorems For $W^{m,p}(\mathbb{R}^n)$ .................. 1334
36.2 An Extension Theorem ......................................... 1348
36.3 General Embedding Theorems .................................. 1355
36.4 More Extension Theorems ...................................... 1358

37 Sobolev Spaces Based On $L^p$ 1365
37.1 Fourier Transform Techniques .................................. 1365
37.2 Fractional Order Spaces ....................................... 1370
37.3 An Intrinsic Norm .............................................. 1372
37.4 Embedding Theorems .......................................... 1379
37.5 The Trace On The Boundary Of A Half Space ................. 1380
37.6 Sobolev Spaces On Manifolds .................................. 1388
   37.6.1 General Theory ........................................... 1388
   37.6.2 The Trace On The Boundary ............................... 1393

38 Weak Solutions 1399
38.1 The Lax Milgram Theorem ..................................... 1399
38.2 An Application Of The Mountain Pass Theorem ............... 1404

39 Korn's Inequality 1411
39.1 A Fundamental Inequality .................................... 1411
39.2 Korn's Inequality ............................................. 1417

Chapter 1

Set Theory

1.1 Basic Definitions

A set is a collection of things called elements of the set. For example, the set of integers, the collection of signed whole numbers such as 1, 2, −4, etc. This set whose existence will be assumed is denoted by \( \mathbb{Z} \). Other sets could be the set of people in a family or the set of donuts in a display case at the store. Sometimes parentheses, \( \{ \} \) specify a set by listing the things which are in the set between the parentheses. For example, the set of integers between −1 and 2, including these numbers could be denoted as \( \{-1, 0, 1, 2\} \). The notation signifying \( x \) is an element of a set \( S \), is written as \( x \in S \). Thus, \( 1 \in \{-1, 0, 1, 2\} \). Here are some axioms about sets.

Axioms are statements which are accepted, not proved.

1. Two sets are equal if and only if they have the same elements.

2. To every set \( A \), and to every condition \( S(x) \) there corresponds a set, \( B \), whose elements are exactly those elements \( x \) of \( A \) for which \( S(x) \) holds.

3. For every collection of sets there exists a set that contains all the elements that belong to at least one set of the given collection.

4. The Cartesian product of a nonempty family of nonempty sets is nonempty.

5. If \( A \) is a set there exists a set, \( \mathcal{P}(A) \) such that \( \mathcal{P}(A) \) is the set of all subsets of \( A \). This is called the power set.

These axioms are referred to as the axiom of extension, axiom of specification, axiom of unions, axiom of choice, and axiom of powers respectively.

It seems fairly clear you should want to believe in the axiom of extension. It is merely saying, for example, that \( \{1, 2, 3\} = \{2, 3, 1\} \) since these two sets have the same elements in them. Similarly, it would seem you should be able to specify a new set from a given set using some “condition” which can be used as a test to
determine whether the element in question is in the set. For example, the set of all integers which are multiples of 2. This set could be specified as follows.

\[ \{ x \in \mathbb{Z} : x = 2y \text{ for some } y \in \mathbb{Z} \} . \]

In this notation, the colon is read as “such that” and in this case the condition is being a multiple of 2.

Another example of political interest, could be the set of all judges who are not judicial activists. I think you can see this last is not a very precise condition since there is no way to determine to everyone’s satisfaction whether a given judge is an activist. Also, just because something is grammatically correct does not mean it makes any sense. For example consider the following nonsense.

\[ S = \{ x \in \text{set of dogs} : \text{it is colder in the mountains than in the winter} \} . \]

So what is a condition?

We will leave these sorts of considerations and assume our conditions make sense. The axiom of unions states that for any collection of sets, there is a set consisting of all the elements in each of the sets in the collection. Of course this is also open to further consideration. What is a collection? Maybe it would be better to say “set of sets” or, given a set whose elements are sets there exists a set whose elements consist of exactly those things which are elements of at least one of these sets. If \( S \) is such a set whose elements are sets,

\[ \bigcup \{ A : A \in S \} \text{ or } \bigcup S \]

signify this union.

Something is in the Cartesian product of a set or “family” of sets if it consists of a single thing taken from each set in the family. Thus \( (1, 2, 3) \in \{1, 4, 2\} \times \{1, 2, 7\} \times \{4, 3, 7, 9\} \) because it consists of exactly one element from each of the sets which are separated by \( \times \). Also, this is the notation for the Cartesian product of finitely many sets. If \( S \) is a set whose elements are sets,

\[ \prod_{A \in S} A \]

signifies the Cartesian product.

The Cartesian product is the set of choice functions, a choice function being a function which selects exactly one element of each set of \( S \). You may think the axiom of choice, stating that the Cartesian product of a nonempty family of nonempty sets is nonempty, is innocuous but there was a time when many mathematicians were ready to throw it out because it implies things which are very hard to believe, things which never happen without the axiom of choice.

\( A \) is a subset of \( B \), written \( A \subseteq B \), if every element of \( A \) is also an element of \( B \). This can also be written as \( B \supseteq A \). \( A \) is a proper subset of \( B \), written \( A \subset B \) or \( B \supset A \) if \( A \) is a subset of \( B \) but \( A \) is not equal to \( B \), \( A \neq B \). \( A \cap B \) denotes the intersection of the two sets, \( A \) and \( B \) and it means the set of elements of \( A \) which
are also elements of $B$. The axiom of specification shows this is a set. The empty set is the set which has no elements in it, denoted as $\emptyset$. $A \cup B$ denotes the union of the two sets, $A$ and $B$ and it means the set of all elements which are in either of the sets. It is a set because of the axiom of unions.

The complement of a set, (the set of things which are not in the given set ) must be taken with respect to a given set called the universal set which is a set which contains the one whose complement is being taken. Thus, the complement of $A$, denoted as $A^C$ (or more precisely as $X \setminus A$) is a set obtained from using the axiom of specification to write

$$A^C \equiv \{x \in X : x \notin A\}$$

The symbol $\notin$ means: “is not an element of”. Note the axiom of specification takes place relative to a given set. Without this universal set it makes no sense to use the axiom of specification to obtain the complement.

Words such as “all” or “there exists” are called quantifiers and they must be understood relative to some given set. For example, the set of all integers larger than 3. Or there exists an integer larger than 7. Such statements have to do with a given set, in this case the integers. Failure to have a reference set when quantifiers are used turns out to be illogical even though such usage may be grammatically correct. Quantifiers are used often enough that there are symbols for them. The symbol $\forall$ is read as “for all” or “for every” and the symbol $\exists$ is read as “there exists”. Thus $\forall \exists \exists$ could mean for every upside down $A$ there exists a backwards $E$.

DeMorgan’s laws are very useful in mathematics. Let $S$ be a set of sets each of which is contained in some universal set, $U$. Then

$$\bigcup \{A^C : A \in S\} = (\bigcap \{A : A \in S\})^C$$

and

$$\bigcap \{A^C : A \in S\} = (\bigcup \{A : A \in S\})^C.$$
the most basic of conditions you could imagine, that of being an element of, is meaningless and so allowing such a set causes the whole theory to be meaningless. The solution is to not allow a universal set. As mentioned by Halmos in Naive set theory, “Nothing contains everything”. Always beware of statements involving quantifiers wherever they occur, even this one.

1.2 The Schroder Bernstein Theorem

It is very important to be able to compare the size of sets in a rational way. The most useful theorem in this context is the Schroder Bernstein theorem which is the main result to be presented in this section. The Cartesian product is discussed above. The next definition reviews this and defines the concept of a function.

Definition 1.2.1 Let $X$ and $Y$ be sets.

$$X \times Y \equiv \{ (x, y) : x \in X \text{ and } y \in Y \}$$

A relation is defined to be a subset of $X \times Y$. A function, $f$, also called a mapping, is a relation which has the property that if $(x, y)$ and $(x, y_1)$ are both elements of the $f$, then $y = y_1$. The domain of $f$ is defined as

$$D(f) \equiv \{ x : (x, y) \in f \},$$

written as $f : D(f) \to Y$.

It is probably safe to say that most people do not think of functions as a type of relation which is a subset of the Cartesian product of two sets. A function is like a machine which takes inputs, $x$ and makes them into a unique output, $f(x)$. Of course, that is what the above definition says with more precision. An ordered pair, $(x, y)$ which is an element of the function or mapping has an input, $x$ and a unique output, $y$, denoted as $f(x)$ while the name of the function is $f$. “mapping” is often a noun meaning function. However, it also is a verb as in “$f$ is mapping $A$ to $B$”. That which a function is thought of as doing is also referred to using the word “maps” as in: $f$ maps $X$ to $Y$. However, a set of functions may be called a set of maps so this word might also be used as the plural of a noun. There is no help for it. You just have to suffer with this nonsense.

The following theorem which is interesting for its own sake will be used to prove the Schroder Bernstein theorem.

Theorem 1.2.2 Let $f : X \to Y$ and $g : Y \to X$ be two functions. Then there exist sets $A, B, C, D$, such that

$$A \cup B = X, \ C \cup D = Y, \ A \cap B = \emptyset, \ C \cap D = \emptyset, \ f(A) = C, \ g(D) = B.$$
1.2. THE SCHRODER BERNSTEIN THEOREM

The following picture illustrates the conclusion of this theorem.

\[ X \]

\[ A \]

\[ B = g(D) \]

\[ f \]

\[ C = f(A) \]

\[ D \]

\[ Y \]

**Proof:** Consider the empty set, \( \emptyset \subseteq X \). If \( y \in Y \setminus f(\emptyset) \), then \( g(y) \notin \emptyset \) because \( \emptyset \) has no elements. Also, if \( A, B, C, \) and \( D \) are as described above, \( A \) also would have this same property that the empty set has. However, \( A \) is probably larger. Therefore, say \( A_0 \subseteq X \) satisfies \( \mathcal{P} \) if whenever \( y \in Y \setminus f(A_0) \), \( g(y) \notin A_0 \).

Let \( A = \cup \mathcal{A} \). If \( y \in Y \setminus f(A) \), then for each \( A_0 \subseteq A \), \( y \in Y \setminus f(A_0) \) and so \( g(y) \notin A_0 \). Since \( g(y) \notin A_0 \) for all \( A_0 \subseteq A \), it follows \( g(y) \notin A \). Hence \( A \) satisfies \( \mathcal{P} \) and is the largest subset of \( X \) which does so. Now define

\[ C = f(A), \ D = Y \setminus C, \ A_0 \subseteq X : A_0 \text{ satisfies } \mathcal{P} \].

It only remains to verify that \( g(D) = B \).

Suppose \( x \in B = X \setminus A \). Then \( A \cup \{x\} \) does not satisfy \( \mathcal{P} \) and so there exists \( y \in Y \setminus f(A \cup \{x\}) \subseteq D \) such that \( g(y) \notin A \cup \{x\} \). But \( y \notin f(A) \) and so since \( A \) satisfies \( \mathcal{P} \), it follows \( g(y) \notin A \). Hence \( g(y) = x \) and so \( x \in g(D) \) and this proves the theorem.

**Theorem 1.2.3 (Schroder Bernstein)** If \( f : X \to Y \) and \( g : Y \to X \) are one to one, then there exists \( h : X \to Y \) which is one to one and onto.

**Proof:** Let \( A, B, C, D \) be the sets of Theorem 1.2.2 and define

\[ h(x) = \begin{cases} f(x) & \text{if } x \in A \\ g^{-1}(x) & \text{if } x \in B \end{cases} \]

Then \( h \) is the desired one to one and onto mapping.

Recall that the Cartesian product may be considered as the collection of choice functions.

**Definition 1.2.4** Let \( I \) be a set and let \( X_i \) be a set for each \( i \in I \). \( f \) is a choice function written as

\[ f \in \prod_{i \in I} X_i \]

if \( f(i) \in X_i \) for each \( i \in I \).
The axiom of choice says that if $X_i \neq \emptyset$ for each $i \in I$, for $I$ a set, then

$$\prod_{i \in I} X_i \neq \emptyset.$$ 

Sometimes the two functions, $f$ and $g$ are onto but not one to one. It turns out that with the axiom of choice, a similar conclusion to the above may be obtained.

**Corollary 1.2.5** If $f : X \to Y$ is onto and $g : Y \to X$ is onto, then there exists $h : X \to Y$ which is one to one and onto.

**Proof:** For each $y \in Y$, $f^{-1}(y) \equiv \{x \in X : f(x) = y\} \neq \emptyset$. Therefore, by the axiom of choice, there exists $f_0^{-1} \in \prod_{y \in Y} f^{-1}(y)$ which is the same as saying that for each $y \in Y$, $f_0^{-1}(y) \in f^{-1}(y)$. Similarly, there exists $g_0^{-1}(x) \in g^{-1}(x)$ for all $x \in X$. Then $f_0^{-1}$ is one to one because if $f_0^{-1}(y_1) = f_0^{-1}(y_2)$, then

$$y_1 = f(f_0^{-1}(y_1)) = f(f_0^{-1}(y_2)) = y_2.$$ 

Similarly $g_0^{-1}$ is one to one. Therefore, by the Schroder Bernstein theorem, there exists $h : X \to Y$ which is one to one and onto.

**Definition 1.2.6** A set $S$, is finite if there exists a natural number $n$ and a map $\theta$ which maps $\{1, \cdots, n\}$ one to one and onto $S$. $S$ is infinite if it is not finite. A set $S$, is called countable if there exists a map $\theta$ mapping $\mathbb{N}$ one to one and onto $S$. (When $\theta$ maps a set $A$ to a set $B$, this will be written as $\theta : A \to B$ in the future.) Here $\mathbb{N} \equiv \{1, 2, \cdots \}$ the natural numbers. $S$ is at most countable if there exists a map $\theta : \mathbb{N} \to S$ which is onto.

The property of being at most countable is often referred to as being countable because the question of interest is normally whether one can list all elements of the set, designating a first, second, third etc. in such a way as to give each element of the set a natural number. The possibility that a single element of the set may be counted more than once is often not important.

**Theorem 1.2.7** If $X$ and $Y$ are both at most countable, then $X \times Y$ is also at most countable. If either $X$ or $Y$ is countable, then $X \times Y$ is also countable.

**Proof:** It is given that there exists a mapping $\eta : \mathbb{N} \to X$ which is onto. Define $\eta(i) \equiv x_i$ and consider $X$ as the set $\{x_1, x_2, x_3, \cdots \}$. Similarly, consider $Y$ as the set $\{y_1, y_2, y_3, \cdots \}$. It follows the elements of $X \times Y$ are included in the following rectangular array.

$$(x_1, y_1) \quad (x_1, y_2) \quad (x_1, y_3) \quad \cdots \quad \leftarrow \text{Those which have } x_1 \text{ in first slot.}$$
$$(x_2, y_1) \quad (x_2, y_2) \quad (x_2, y_3) \quad \cdots \quad \leftarrow \text{Those which have } x_2 \text{ in first slot.}$$
$$(x_3, y_1) \quad (x_3, y_2) \quad (x_3, y_3) \quad \cdots \quad \leftarrow \text{Those which have } x_3 \text{ in first slot.}$$
$$\vdots \quad \vdots \quad \vdots \quad \cdots \quad \vdots$$
1.3. EQUIVALENCE RELATIONS

Follow a path through this array as follows.

\[
\begin{align*}
(x_1, y_1) & \rightarrow (x_1, y_2) & (x_1, y_3) & \rightarrow \\
(x_2, y_1) & \downarrow & (x_2, y_2) & \\
(x_3, y_1) & \rightarrow & \end{align*}
\]

Thus the first element of \(X \times Y\) is \((x_1, y_1)\), the second element of \(X \times Y\) is \((x_1, y_2)\), the third element of \(X \times Y\) is \((x_2, y_1)\) etc. This assigns a number from \(\mathbb{N}\) to each element of \(X \times Y\). Thus \(X \times Y\) is at most countable.

It remains to show the last claim. Suppose without loss of generality that \(X\) is countable. Then there exists \(\alpha : \mathbb{N} \rightarrow X\) which is one to one and onto. Let \(\beta : X \times Y \rightarrow \mathbb{N}\) be defined by \(\beta((x,y)) = \alpha^{-1}(x)\). Thus \(\beta\) is onto \(\mathbb{N}\). By the first part there exists a function from \(\mathbb{N}\) onto \(X \times Y\). Therefore, by Corollary \ref{cor:countable}, there exists a one to one and onto mapping from \(X \times Y\) to \(\mathbb{N}\). This proves the theorem.

**Theorem 1.2.8** If \(X\) and \(Y\) are at most countable, then \(X \cup Y\) is at most countable. If either \(X\) or \(Y\) are countable, then \(X \cup Y\) is countable.

**Proof:** As in the preceding theorem,

\[
X = \{x_1, x_2, x_3, \ldots\}
\]

and

\[
Y = \{y_1, y_2, y_3, \ldots\}.
\]

Consider the following array consisting of \(X \cup Y\) and path through it.

\[
\begin{align*}
x_1 & \rightarrow x_2 & x_3 & \rightarrow \\
y_1 & \rightarrow y_2 & \end{align*}
\]

Thus the first element of \(X \cup Y\) is \(x_1\), the second is \(x_2\) the third is \(y_1\) the fourth is \(y_2\) etc.

Consider the second claim. By the first part, there is a map from \(\mathbb{N}\) onto \(X \times Y\). Suppose without loss of generality that \(X\) is countable and \(\alpha : \mathbb{N} \rightarrow X\) is one to one and onto. Then define \(\beta(y) = 1\), for all \(y \in Y\), and \(\beta(x) = \alpha^{-1}(x)\). Thus, \(\beta\) maps \(X \times Y\) onto \(\mathbb{N}\) and this shows there exist two onto maps, one mapping \(X \cup Y\) onto \(\mathbb{N}\) and the other mapping \(\mathbb{N}\) onto \(X \cup Y\). Then Corollary \ref{cor:countable} yields the conclusion. This proves the theorem.

1.3 Equivalence Relations

There are many ways to compare elements of a set other than to say two elements are equal or the same. For example, in the set of people let two people be equivalent
if they have the same weight. This would not be saying they were the same person, just that they weighed the same. Often such relations involve considering one characteristic of the elements of a set and then saying the two elements are equivalent if they are the same as far as the given characteristic is concerned.

**Definition 1.3.1** Let $S$ be a set. $\sim$ is an equivalence relation on $S$ if it satisfies the following axioms.

1. $x \sim x$ for all $x \in S$. (Reflexive)
2. If $x \sim y$ then $y \sim x$. (Symmetric)
3. If $x \sim y$ and $y \sim z$, then $x \sim z$. (Transitive)

**Definition 1.3.2** $[x]$ denotes the set of all elements of $S$ which are equivalent to $x$ and $[x]$ is called the equivalence class determined by $x$ or just the equivalence class of $x$.

With the above definition one can prove the following simple theorem.

**Theorem 1.3.3** Let $\sim$ be an equivalence class defined on a set, $S$ and let $\mathcal{H}$ denote the set of equivalence classes. Then if $[x]$ and $[y]$ are two of these equivalence classes, either $x \sim y$ and $[x] = [y]$ or it is not true that $x \sim y$ and $[x] \cap [y] = \emptyset$.

### 1.4 Partially Ordered Sets

**Definition 1.4.1** Let $\mathcal{F}$ be a nonempty set. $\mathcal{F}$ is called a partially ordered set if there is a relation, denoted here by $\leq$, such that

- $x \leq x$ for all $x \in \mathcal{F}$.
- If $x \leq y$ and $y \leq z$ then $x \leq z$.

$\mathcal{C} \subseteq \mathcal{F}$ is said to be a chain if every two elements of $\mathcal{C}$ are related. This means that if $x, y \in \mathcal{C}$, then either $x \leq y$ or $y \leq x$. Sometimes a chain is called a totally ordered set. $\mathcal{C}$ is said to be a maximal chain if whenever $\mathcal{D}$ is a chain containing $\mathcal{C}$, $\mathcal{D} = \mathcal{C}$.

The most common example of a partially ordered set is the power set of a given set with $\subseteq$ being the relation. It is also helpful to visualize partially ordered sets as trees. Two points on the tree are related if they are on the same branch of the tree and one is higher than the other. Thus two points on different branches would not be related although they might both be larger than some point on the trunk. You might think of many other things which are best considered as partially ordered sets. Think of food for example. You might find it difficult to determine which of two favorite pies you like better although you may be able to say very easily that you would prefer either pie to a dish of lard topped with whipped cream and mustard. The following theorem is equivalent to the axiom of choice. For a discussion of this, see the appendix on the subject.

**Theorem 1.4.2** (Hausdorff Maximal Principle) Let $\mathcal{F}$ be a nonempty partially ordered set. Then there exists a maximal chain.
Chapter 2

Continuous Functions Of One Variable

There is a theorem about the integral of a continuous function which requires the notion of uniform continuity. This is discussed in this section. Consider the function \( f(x) = \frac{1}{x} \) for \( x \in (0, 1) \). This is a continuous function because, it is continuous at every point of \((0, 1)\). However, for a given \( \varepsilon > 0 \), the \( \delta \) needed in the \( \varepsilon, \delta \) definition of continuity becomes very small as \( x \) gets close to 0. The notion of uniform continuity involves being able to choose a single \( \delta \) which works on the whole domain of \( f \). Here is the definition.

**Definition 2.0.1** Let \( f : D \subseteq \mathbb{R} \to \mathbb{R} \) be a function. Then \( f \) is uniformly continuous if for every \( \varepsilon > 0 \), there exists a \( \delta \) depending only on \( \varepsilon \) such that if \( |x - y| < \delta \) then \( |f(x) - f(y)| < \varepsilon \).

It is an amazing fact that under certain conditions continuity implies uniform continuity.

**Definition 2.0.2** A set, \( K \subseteq \mathbb{R} \) is sequentially compact if whenever \( \{a_n\} \subseteq K \) is a sequence, there exists a subsequence, \( \{a_{n_k}\} \) such that this subsequence converges to a point of \( K \).

The following theorem is part of the Heine Borel theorem.

**Theorem 2.0.3** Every closed interval, \([a, b]\) is sequentially compact.

**Proof:** Let \( \{x_n\} \subseteq [a, b] \equiv I_0 \). Consider the two intervals \([a, \frac{a+b}{2}]\) and \([\frac{a+b}{2}, b]\) each of which has length \((b-a)/2\). At least one of these intervals contains \( x_n \) for infinitely many values of \( n \). Call this interval \( I_1 \). Now do for \( I_1 \) what was done for \( I_0 \). Split it in half and let \( I_2 \) be the interval which contains \( x_n \) for infinitely many values of \( n \). Continue this way obtaining a sequence of nested intervals \( I_0 \supseteq I_1 \supseteq I_2 \supseteq I_3 \cdots \) where the length of \( I_n \) is \((b-a)/2^n\). Now pick \( n_1 \) such that \( x_{n_1} \in I_1 \), \( n_2 \) such that
CHAPTER 2. CONTINUOUS FUNCTIONS OF ONE VARIABLE

$n_2 > n_1$ and $x_{n_2} \in I_2, n_3$ such that $n_3 > n_2$ and $x_{n_3} \in I_3$, etc. (This can be done because in each case the intervals contained $x_n$ for infinitely many values of $n$.) By the nested interval lemma there exists a point, $c$ contained in all these intervals. Furthermore,

$$|x_{n_k} - c| < (b - a) 2^{-k}$$

and so $\lim_{k \to \infty} x_{n_k} = c \in [a, b]$. This proves the theorem.

**Theorem 2.0.4** Let $f : K \to \mathbb{R}$ be continuous where $K$ is a sequentially compact set in $\mathbb{R}$. Then $f$ is uniformly continuous on $K$.

**Proof:** If this is not true, there exists $\varepsilon > 0$ such that for every $\delta > 0$ there exists a pair of points, $x_\delta$ and $y_\delta$ such that even though $|x_\delta - y_\delta| < \delta$, $|f(x_\delta) - f(y_\delta)| \geq \varepsilon$. Taking a succession of values for $\delta$ equal to $1, 1/2, 1/3, \cdots$, and letting the exceptional pair of points for $\delta = 1/n$ be denoted by $x_n$ and $y_n$,

$$|x_n - y_n| < \frac{1}{n}, |f(x_n) - f(y_n)| \geq \varepsilon.$$ 

Now since $K$ is sequentially compact, there exists a subsequence, $\{x_{n_k}\}$ such that $x_{n_k} \to z \in K$. Now $n_k \geq k$ and so

$$|x_{n_k} - y_{n_k}| < \frac{1}{k}.$$ 

Consequently, $y_{n_k} \to z$ also. ( $x_{n_k}$ is like a person walking toward a certain point and $y_{n_k}$ is like a dog on a leash which is constantly getting shorter. Obviously $y_{n_k}$ must also move toward the point also. You should give a precise proof of what is needed here.) By continuity of $f$

$$0 = |f(z) - f(z)| = \lim_{k \to \infty} |f(x_{n_k}) - f(y_{n_k})| \geq \varepsilon,$$

an obvious contradiction. Therefore, the theorem must be true.

The following corollary follows from this theorem and Theorem 2.0.3.

**Corollary 2.0.5** Suppose $I$ is a closed interval, $I = [a, b]$ and $f : I \to \mathbb{R}$ is continuous. Then $f$ is uniformly continuous.

### 2.1 Exercises

1. A function, $f : D \subseteq \mathbb{R} \to \mathbb{R}$ is Lipschitz continuous or just Lipschitz for short if there exists a constant, $K$ such that

$$|f(x) - f(y)| \leq K|x - y|$$

for all $x, y \in D$. Show every Lipschitz function is uniformly continuous.

2. If $|x_n - y_n| \to 0$ and $x_n \to z$, show that $y_n \to z$ also.
2.2. THEOREMS ABOUT CONTINUOUS FUNCTIONS

3. Consider \( f : (1, \infty) \to \mathbb{R} \) given by \( f(x) = \frac{1}{x} \). Show \( f \) is uniformly continuous even though the set on which \( f \) is defined is not sequentially compact.

4. If \( f \) is uniformly continuous, does it follow that \(|f|\) is also uniformly continuous? If \(|f|\) is uniformly continuous does it follow that \( f \) is uniformly continuous? Answer the same questions with “uniformly continuous” replaced with “continuous”. Explain why.

2.2 Theorems About Continuous Functions

In this section, proofs of some theorems which have not been proved yet are given.

Theorem 2.2.1 The following assertions are valid

1. The function, \( af + bg \) is continuous at \( x \) when \( f, g \) are continuous at \( x \in D(f) \cap D(g) \) and \( a, b \in \mathbb{R} \).

2. If and \( f \) and \( g \) are each real valued functions continuous at \( x \), then \( fg \) is continuous at \( x \). If, in addition to this, \( g(x) \neq 0 \), then \( f/g \) is continuous at \( x \).

3. If \( f \) is continuous at \( x \), \( f(x) \in D(g) \subseteq \mathbb{R} \), and \( g \) is continuous at \( f(x) \), then \( g \circ f \) is continuous at \( x \).

4. The function \( f : \mathbb{R} \to \mathbb{R} \), given by \( f(x) = |x| \) is continuous.

Proof: First consider 1.) Let \( \varepsilon > 0 \) be given. By assumption, there exist \( \delta_1 > 0 \) such that whenever \( |x - y| < \delta_1 \), it follows \( |f(x) - f(y)| < \frac{\varepsilon}{2(|a| + |b| + 1)} \) and there exists \( \delta_2 > 0 \) such that whenever \( |x - y| < \delta_2 \), it follows that \( |g(x) - g(y)| < \frac{\varepsilon}{2(|a| + |b| + 1)} \). Then let \( 0 < \delta \leq \min(\delta_1, \delta_2) \). If \( |x - y| < \delta \), then everything happens at once. Therefore, using the triangle inequality

\[
|af(x) + bf(x) - (af(y) + bf(y))| \\
\leq |a||f(x) - f(y)| + |b||g(x) - g(y)| \\
< |a|\left(\frac{\varepsilon}{2(|a| + |b| + 1)}\right) + |b|\left(\frac{\varepsilon}{2(|a| + |b| + 1)}\right) < \varepsilon.
\]

Now consider 2.) There exists \( \delta_1 > 0 \) such that if \( |y - x| < \delta_1 \), then

\[
|f(x) - f(y)| < 1.
\]

Therefore, for such \( y \),

\[
|f(y)| < 1 + |f(x)|.
\]

It follows that for such \( y \),

\[
|fg(x) - fg(y)| \leq |f(x)g(x) - g(x)f(y)| + |g(x)f(y) - f(y)g(y)|
\]
which implies

and so by the triangle inequality, above and let

so

Now let \( 0 < \delta \leq \min(\delta_1, \delta_2, \delta_3) \). Then if \( |x - y| < \delta \), all the above hold at once and so

\[
|f g(x) - f g(y)| \leq (1 + |g(x)| + |f(y)|) |g(x) - g(y)| + |f(x) - f(y)|
\]

\[
< (1 + |g(x)| + |f(y)|) \left( \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)} + \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)} \right) = \varepsilon.
\]

This proves the first part of 2.) To obtain the second part, let \( \delta_1 \) be as described above and let \( \delta_0 > 0 \) be such that for \( |x - y| < \delta_0 \),

\[ |g(x) - g(y)| < |g(x)|/2 \]

and so by the triangle inequality,

\[ -|g(x)|/2 \leq |g(y)| - |g(x)| \leq |g(x)|/2 \]

which implies \(|g(y)| \geq |g(x)|/2\), and \(|g(y)| < 3|g(x)|/2\).

Then if \( |x - y| < \min(\delta_0, \delta_1) \),

\[
\left| \frac{f(x)}{g(x)} - \frac{f(y)}{g(y)} \right| = \left| \frac{f(x) g(y) - f(y) g(x)}{g(x) g(y)} \right| \leq \frac{|f(x) g(y) - f(y) g(x)|}{|g(x)|^2} \leq \frac{2 |f(x) g(y) - f(y) g(x)|}{|g(x)|^2}
\]

\[
\leq \frac{2}{|g(x)|^2} \left[ |f(x) g(y) - f(y) g(y) + f(y) g(y) - f(y) g(x)| \right]
\]

\[
\leq \frac{2}{|g(x)|^2} \left[ |g(y)| |f(x) - f(y)| + |f(y)| |g(y) - g(x)| \right]
\]

\[
\leq \frac{2}{|g(x)|^2} \left[ \frac{3}{2} |g(x)| |f(x) - f(y)| + (1 + |f(x)|) |g(y) - g(x)| \right]
\]

\[
\leq \frac{2}{|g(x)|^2} (1 + 2 |f(x)| + 2 |g(x)|) |f(x) - f(y)| + |g(y) - g(x)|
\]

\[ \equiv M |f(x) - f(y)| + |g(y) - g(x)| \]
2.2. THEOREMS ABOUT CONTINUOUS FUNCTIONS

where $M$ is defined by

$$
M = \frac{2}{|g(x)|^2} (1 + 2|f(x)| + 2|g(x)|)
$$

Now let $\delta_2$ be such that if $|x-y| < \delta_2$, then

$$
|f(x) - f(y)| < \frac{\varepsilon}{2}M^{-1}
$$

and let $\delta_3$ be such that if $|x-y| < \delta_3$, then

$$
|g(y) - g(x)| < \frac{\varepsilon}{2}M^{-1}.
$$

Then if $0 < \delta \leq \min (\delta_0, \delta_1, \delta_2, \delta_3)$, and $|x-y| < \delta$, everything holds and

$$
\left| \frac{f(x)}{g(x)} - \frac{f(y)}{g(y)} \right| \leq M \left[ |f(x) - f(y)| + |g(y) - g(x)| \right]
$$

$$
< M \left[ \frac{\varepsilon}{2}M^{-1} + \frac{\varepsilon}{2}M^{-1} \right] = \varepsilon.
$$

This completes the proof of the second part of 2.)

Note that in these proofs no effort is made to find some sort of “best” $\delta$. The problem is one which has a yes or a no answer. Either it is or it is not continuous.

Now consider 3.). If $f$ is continuous at $x$, then $g \circ f$ is continuous at $x$. Let $\varepsilon > 0$ be given. Then there exists $\eta > 0$ such that if $|y-f(x)| < \eta$ and $y \in D(g)$, it follows that $|g(y) - g(f(x))| < \varepsilon$. From continuity of $f$ at $x$, there exists $\delta > 0$ such that if $|x-z| < \delta$ and $z \in D(f)$, then $|f(z) - f(x)| < \eta$. Then if $|x-z| < \delta$ and $z \in D(g \circ f) \subseteq D(f)$, all the above hold and so

$$
|g(f(z)) - g(f(x))| < \varepsilon.
$$

This proves part 3.)

To verify part 4.), let $\varepsilon > 0$ be given and let $\delta = \varepsilon$. Then if $|x-y| < \delta$, the triangle inequality implies

$$
|f(x) - f(y)| = ||x| - |y||
$$

$$
\leq |x-y| < \delta = \varepsilon.
$$

This proves part 4.) and completes the proof of the theorem.

Next here is a proof of the intermediate value theorem.

**Theorem 2.2.2** Suppose $f : [a,b] \to \mathbb{R}$ is continuous and suppose $f(a) < c < f(b)$. Then there exists $x \in (a,b)$ such that $f(x) = c$.

**Proof:** Let $d = \frac{a+b}{2}$ and consider the intervals $[a,d]$ and $[d,b]$. If $f(d) \geq c$, then on $[a,d]$, the function is $\leq c$ at one end point and $\geq c$ at the other. On the other hand, if $f(d) \leq c$, then on $[d,b]$ $f \geq 0$ at one end point and $\leq 0$ at the
other. Pick the interval on which \( f \) has values which are at least as large as \( c \) and values no larger than \( c \). Now consider that interval, divide it in half as was done for the original interval and argue that on one of these smaller intervals, the function has values at least as large as \( c \) and values no larger than \( c \). Continue in this way. Next apply the nested interval lemma to get \( x \) in all these intervals. In the \( n^{th} \) interval, let \( x_n, y_n \) be elements of this interval such that \( f(x_n) \leq c, f(y_n) \geq c \). Now \(|x_n - x| \leq (b - a)2^{-n} \) and \(|y_n - x| \leq (b - a)2^{-n} \) and so \( x_n \to x \) and \( y_n \to x \). Therefore,

\[
f(x) - c = \lim_{n \to \infty} (f(x_n) - c) \leq 0
\]

while

\[
f(x) - c = \lim_{n \to \infty} (f(y_n) - c) \geq 0.
\]

Consequently \( f(x) = c \) and this proves the theorem.

**Lemma 2.2.3** Let \( \phi : [a, b] \to \mathbb{R} \) be a continuous function and suppose \( \phi \) is \( 1-1 \) on \( (a, b) \). Then \( \phi \) is either strictly increasing or strictly decreasing on \( [a, b] \).

**Proof:** First it is shown that \( \phi \) is either strictly increasing or strictly decreasing on \( (a, b) \).

If \( \phi \) is not strictly decreasing on \( (a, b) \), then there exists \( x_1 < y_1, x_1, y_1 \in (a, b) \) such that

\[
(\phi(y_1) - \phi(x_1))(y_1 - x_1) > 0.
\]

If for some other pair of points, \( x_2 < y_2 \) with \( x_2, y_2 \in (a, b) \), the above inequality does not hold, then since \( \phi \) is \( 1-1 \),

\[
(\phi(y_2) - \phi(x_2))(y_2 - x_2) < 0.
\]

Let \( x_t \equiv tx_1 + (1 - t)x_2 \) and \( y_t \equiv ty_1 + (1 - t)y_2 \). Then \( x_t < y_t \) for all \( t \in [0, 1] \) because

\[
Tx_1 \leq Ty_1 \text{ and \ } (1 - t)x_2 \leq (1 - t)y_2
\]

with strict inequality holding for at least one of these inequalities since not both \( t \) and \( (1 - t) \) can equal zero. Now define

\[
h(t) \equiv (\phi(y_t) - \phi(x_t))(y_t - x_t).
\]

Since \( h \) is continuous and \( h(0) < 0 \), while \( h(1) > 0 \), there exists \( t \in (0, 1) \) such that \( h(t) = 0 \). Therefore, both \( x_t \) and \( y_t \) are points of \( (a, b) \) and \( \phi(y_t) - \phi(x_t) = 0 \) contradicting the assumption that \( \phi \) is one to one. It follows \( \phi \) is either strictly increasing or strictly decreasing on \( (a, b) \).

This property of being either strictly increasing or strictly decreasing on \( (a, b) \) carries over to \([a, b] \) by the continuity of \( \phi \). Suppose \( \phi \) is strictly increasing on \( (a, b) \), a similar argument holding for \( \phi \) strictly decreasing on \( (a, b) \). If \( x > a \), then pick \( y \in (a, x) \) and from the above, \( \phi(y) < \phi(x) \). Now by continuity of \( \phi \) at \( a \),

\[
\phi(a) = \lim_{x \to a^+} \phi(z) \leq \phi(y) < \phi(x).
\]

Therefore, \( \phi(a) < \phi(x) \) whenever \( x \in (a, b) \). Similarly \( \phi(b) > \phi(x) \) for all \( x \in (a, b) \). This proves the lemma.
Corollary 2.2.4 Let \( f : (a, b) \to \mathbb{R} \) be one to one and continuous. Then \( f(a, b) \) is an open interval, \((c, d)\) and \( f^{-1} : (c, d) \to (a, b) \) is continuous.

Proof: Since \( f \) is either strictly increasing or strictly decreasing, it follows that \( f(a, b) \) is an open interval, \((c, d)\). Assume \( f \) is decreasing. Now let \( x \in (a, b) \).

Why is \( f^{-1} \) is continuous at \( f(x) \)? Since \( f \) is decreasing, if \( f(x) < f(y) \), then \( y \equiv f^{-1}(f(y)) < x \equiv f^{-1}(f(x)) \) and so \( f^{-1} \) is also decreasing. Let \( \varepsilon > 0 \) be given. Let \( \varepsilon > \eta > 0 \) and \((x-\eta, x+\eta) \subseteq (a, b) \). Then \( f(x) \in (f(x+\eta), f(x-\eta)) \). Let \( \delta = \min(f(x) - f(x+\eta), f(x-\eta) - f(x)) \). Then if
\[
|f(z) - f(x)| < \delta,
\]
it follows
\[
z \equiv f^{-1}(f(z)) \in (x-\eta, x+\eta) \subseteq (x-\varepsilon, x+\varepsilon)
\]
so
\[
|f^{-1}(f(z)) - x| = |f^{-1}(f(z)) - f^{-1}(f(x))| < \varepsilon.
\]
This proves the theorem in the case where \( f \) is strictly decreasing. The case where \( f \) is increasing is similar.
CHAPTER 2. CONTINUOUS FUNCTIONS OF ONE VARIABLE
Chapter 3

The Riemann Stieltjes Integral

The integral originated in attempts to find areas of various shapes and the ideas involved in finding integrals are much older than the ideas related to finding derivatives. In fact, Archimedes\footnote{Archimedes 287-212 B.C. found areas of curved regions by stuffing them with simple shapes which he knew the area of and taking a limit. He also made fundamental contributions to physics. The story is told about how he determined that a gold smith had cheated the king by giving him a crown which was not solid gold as had been claimed. He did this by finding the amount of water displaced by the crown and comparing with the amount of water it should have displaced if it had been solid gold.} was finding areas of various curved shapes about 250 B.C. using the main ideas of the integral. What is presented here is a generalization of these ideas. The main interest is in the Riemann integral but if it is easy to generalize to the so-called Stieltjes integral in which the length of an interval, $[x, y]$ is replaced with an expression of the form $F(y) - F(x)$ where $F$ is an increasing function, then the generalization is given. However, there is much more that can be written about Stieltjes integrals than what is presented here. A good source for this is the book by Apostol, \cite{Apostol}.\footnote{Apostol, T. M. (1957). Mathematical Analysis. Addison-Wesley.}

3.1 Upper And Lower Riemann Stieltjes Sums

The Riemann integral pertains to bounded functions which are defined on a bounded interval. Let $[a, b]$ be a closed interval. A set of points in $[a, b]$, $\{x_0, \ldots, x_n\}$ is a partition if

$$a = x_0 < x_1 < \cdots < x_n = b.$$ 

Such partitions are denoted by $P$ or $Q$. For $f$ a bounded function defined on $[a, b]$, let

$$M_i (f) = \sup \{ f(x) : x \in [x_{i-1}, x_i] \},$$

$$m_i (f) = \inf \{ f(x) : x \in [x_{i-1}, x_i] \}. $$

[126x520]
Definition 3.1.1 Let $F$ be an increasing function defined on $[a,b]$ and let $\Delta F_i = F(x_i) - F(x_{i-1})$. Then define upper and lower sums as

$$U(f,P) = \sum_{i=1}^{n} M_i(f) \Delta F_i \quad \text{and} \quad L(f,P) = \sum_{i=1}^{n} m_i(f) \Delta F_i$$

respectively. The numbers, $M_i(f)$ and $m_i(f)$, are well defined real numbers because $f$ is assumed to be bounded and $\mathbb{R}$ is complete. Thus the set $S = \{ f(x) : x \in [x_{i-1}, x_i] \}$ is bounded above and below.

In the following picture, the sum of the areas of the rectangles in the picture on the left is a lower sum for the function in the picture and the sum of the areas of the rectangles in the picture on the right is an upper sum for the same function which uses the same partition. In these pictures the function, $F$ is given by $F(x) = x$ and these are the ordinary upper and lower sums from calculus.

What happens when you add in more points in a partition? The following pictures illustrate in the context of the above example. In this example a single additional point, labeled $z$ has been added in.

Note how the lower sum got larger by the amount of the area in the shaded rectangle and the upper sum got smaller by the amount in the rectangle shaded by dots. In general this is the way it works and this is shown in the following lemma.

Lemma 3.1.2 If $P \subseteq Q$ then

$$U(f,Q) \leq U(f,P), \quad \text{and} \quad L(f,P) \leq L(f,Q).$$
Proof: This is verified by adding in one point at a time. Thus let

\[ P = \{x_0, \ldots, x_n\} \]

and let

\[ Q = \{x_0, \ldots, x_k, y, x_{k+1}, \ldots, x_n\}. \]

Thus exactly one point, \( y \), is added between \( x_k \) and \( x_{k+1} \). Now the term in the upper sum which corresponds to the interval \([x_k, x_{k+1}]\) in \( U(f, P)\) is

\[ \sup \{ f(x) : x \in [x_k, x_{k+1}] \} (F(x_{k+1}) - F(x_k)) \] (3.1.1)

and the term which corresponds to the interval \([x_k, x_{k+1}]\) in \( U(f, Q)\) is

\[
\begin{align*}
&\sup \{ f(x) : x \in [x_k, y] \} (F(y) - F(x_k)) \\
&+ \sup \{ f(x) : x \in [y, x_{k+1}] \} (F(x_{k+1}) - F(y)) \\
&\equiv M_1 (F(y) - F(x_k)) + M_2 (F(x_{k+1}) - F(y))
\end{align*}
\] (3.1.2)

All the other terms in the two sums coincide. Now \( \sup \{ f(x) : x \in [x_k, x_{k+1}] \} \geq \max(M_1, M_2) \) and so the expression in (3.1.2) is no larger than

\[
\begin{align*}
&\sup \{ f(x) : x \in [x_k, x_{k+1}] \} (F(x_{k+1}) - F(y)) \\
&+ \sup \{ f(x) : x \in [x_k, x_{k+1}] \} (F(y) - F(x_k)) \\
&\equiv \sup \{ f(x) : x \in [x_k, x_{k+1}] \} (F(x_{k+1}) - F(x_k)),
\end{align*}
\]

the term corresponding to the interval, \([x_k, x_{k+1}]\) and \( U(f, P)\). This proves the first part of the lemma pertaining to upper sums because if \( Q \supseteq P \), one can obtain \( Q \) from \( P \) by adding in one point at a time and each time a point is added, the corresponding upper sum either gets smaller or stays the same. The second part about lower sums is similar and is left as an exercise.

**Lemma 3.1.3** If \( P \) and \( Q \) are two partitions, then

\[ L(f, P) \leq U(f, Q). \]

**Proof:** By Lemma 3.1.2,

\[ L(f, P) \leq L(f, P \cup Q) \leq U(f, P \cup Q) \leq U(f, Q). \]

**Definition 3.1.4**

\[ T = \inf \{ U(f, Q) \ where \ Q \ is \ a \ partition \} \]

\[ L = \sup \{ L(f, P) \ where \ P \ is \ a \ partition \}. \]

Note that \( L \) and \( T \) are well defined real numbers.
CHAPTER 3. THE RIEMANN–STIELTJES INTEGRAL

Theorem 3.1.5 \( I \leq \overline{T} \).

Proof: From Lemma 3.1.3,

\[ I = \sup \{ L(f, P) \mid P \text{ is a partition} \} \leq U(f, Q) \]

because \( U(f, Q) \) is an upper bound to the set of all lower sums and so it is no smaller than the least upper bound. Therefore, since \( Q \) is arbitrary,

\[ I = \sup \{ L(f, P) \mid P \text{ is a partition} \} \leq \inf \{ U(f, Q) \mid Q \text{ is a partition} \} = \overline{T} \]

where the inequality holds because it was just shown that \( I \) is a lower bound to the set of all upper sums and so it is no larger than the greatest lower bound of this set. This proves the theorem.

Definition 3.1.6 A bounded function \( f \) is Riemann–Stieltjes integrable, written as

\[ f \in R([a, b]) \]

if

\[ I = \overline{T} \]

and in this case,

\[ \int_{a}^{b} f(x) \, dF = I = \overline{T}. \]

When \( F(x) = x \), the integral is called the Riemann integral and is written as

\[ \int_{a}^{b} f(x) \, dx. \]

Thus, in words, the Riemann integral is the unique number which lies between all upper sums and all lower sums if there is such a unique number.

Recall the following Proposition which comes from the definitions.

Proposition 3.1.7 Let \( S \) be a nonempty set and suppose \( \sup (S) \) exists. Then for every \( \delta > 0 \),

\[ S \cap (\sup (S) - \delta, \sup (S)] \neq \emptyset. \]

If \( \inf (S) \) exists, then for every \( \delta > 0 \),

\[ S \cap [\inf (S), \inf (S) + \delta) \neq \emptyset. \]

This proposition implies the following theorem which is used to determine the question of Riemann–Stieltjes integrability.

Theorem 3.1.8 A bounded function \( f \) is Riemann integrable if and only if for all \( \varepsilon > 0 \), there exists a partition \( P \) such that

\[ U(f, P) - L(f, P) < \varepsilon. \] (3.1.3)
3.2. Exercises

Proof: First assume \( f \) is Riemann integrable. Then let \( P \) and \( Q \) be two partitions such that

\[
U(f, Q) < \bar{I} + \varepsilon/2, \quad L(f, P) > \underline{I} - \varepsilon/2.
\]

Then since \( \bar{I} = \underline{I} \),

\[
U(f, Q \cup P) - L(f, P \cup Q) \leq U(f, Q) - L(f, P) < \bar{I} + \varepsilon/2 - (\underline{I} - \varepsilon/2) = \varepsilon.
\]

Now suppose that for all \( \varepsilon > 0 \) there exists a partition such that \( \text{(3.1.3)} \) holds. Then for given \( \varepsilon \) and partition \( P \) corresponding to \( \varepsilon = \frac{1}{2} \),

\[
\bar{I} - \underline{I} \leq U(f, P) - L(f, P) \leq \varepsilon.
\]

Since \( \varepsilon \) is arbitrary, this shows \( \bar{I} = \underline{I} \) and this proves the theorem.

The condition described in the theorem is called the Riemann criterion.

Not all bounded functions are Riemann integrable. For example, let \( F(x) = x \) and \( f(x) \) given in \( \text{(3.1.4)} \),

\[
f(x) = \begin{cases} 1 & \text{if } x \in \mathbb{Q} \\ 0 & \text{if } x \in \mathbb{R} \setminus \mathbb{Q} \end{cases}
\]

Then if \([a, b] = [0, 1]\) all upper sums for \( f \) equal 1 while all lower sums for \( f \) equal 0. Therefore the Riemann criterion is violated for \( \varepsilon = 1/2 \).

3.2 Exercises

1. Prove the second half of Lemma \( \text{(3.1.2)} \) about lower sums.

2. Verify that for \( f \) given in \( \text{(3.1.4)} \), the lower sums on the interval \([0, 1]\) are all equal to zero while the upper sums are all equal to one.

3. Let \( f(x) = 1 + x^2 \) for \( x \in [-1, 3] \) and let \( P = \{-1, -1/3, 0, 1/3, 1, 2\} \). Find \( U(f, P) \) and \( L(f, P) \) for \( F(x) = x \) and for \( F(x) = x^3 \).

4. Show that if \( f \in R([a, b]) \) for \( F(x) = x \), there exists a partition, \( \{x_0, \ldots, x_n\} \) such that for any \( z_k \in [x_k, x_{k+1}] \),

\[
\left| \int_a^b f(x) \, dx - \sum_{k=1}^n f(z_k) (x_k - x_{k-1}) \right| < \varepsilon
\]

This sum, \( \sum_{k=1}^n f(z_k) (x_k - x_{k-1}) \), is called a Riemann sum and this exercise shows that the Riemann integral can always be approximated by a Riemann sum. For the general Riemann Stieltjes case, does anything change?

5. Let \( P = \{1, 1/3, 1/2, 1/3, 2\} \) and \( F(x) = x \). Find upper and lower sums for the function, \( f(x) = \frac{1}{2} \) using this partition. What does this tell you about \( \ln(2) \)?

6. If \( f \in R([a, b]) \) with \( F(x) = x \) and \( f \) is changed at finitely many points, show the new function is also in \( R([a, b]) \). Is this still true for the general case where \( F \) is only assumed to be an increasing function? Explain.
7. In the case where 

\[ F(x) = x; \]

define a “left sum” as

\[ \sum_{k=1}^{n} f(x_{k-1}) (x_k - x_{k-1}) \]

and a “right sum”,

\[ \sum_{k=1}^{n} f(x_k) (x_k - x_{k-1}) \]

Also suppose that all partitions have the property that \( x_k - x_{k-1} \) equals a constant, \((b - a)/n\) so the points in the partition are equally spaced, and define the integral to be the number these right and left sums get close to as \( n \) gets larger and larger. Show that for \( f \) given in 3.1.4,

\[ \int_0^x f(t) \, dt = 1 \text{ if } x \text{ is rational and } \int_0^x f(t) \, dt = 0 \text{ if } x \text{ is irrational.} \]

It turns out that the correct answer should always equal zero for that function, regardless of whether \( x \) is rational. This is shown when the Lebesgue integral is studied. This illustrates why this method of defining the integral in terms of left and right sums is total nonsense. Show that even though this is the case, it makes no difference if \( f \) is continuous.

### 3.3 Functions Of Riemann Integrable Functions

It is often necessary to consider functions of Riemann integrable functions and a natural question is whether these are Riemann integrable. The following theorem gives a partial answer to this question. This is not the most general theorem which will relate to this question but it will be enough for the needs of this book.

**Theorem 3.3.1** Let \( f, g \) be bounded functions and let \( f ([a, b]) \subseteq [c_1, d_1], \ g ([a, b]) \subseteq [c_2, d_2] \).

Let \( H : [c_1, d_1] \times [c_2, d_2] \to \mathbb{R} \) satisfy,

\[ |H(a_1, b_1) - H(a_2, b_2)| \leq K [|a_1 - a_2| + |b_1 - b_2|] \]

for some constant \( K \). Then if \( f, g \in R([a, b]) \) it follows that \( H \circ (f, g) \in R([a, b]) \).

**Proof:** In the following claim, \( M_i (h) \) and \( m_i (h) \) have the meanings assigned above with respect to some partition of \([a, b]\) for the function, \( h \).

**Claim:** The following inequality holds.

\[ |M_i (H \circ (f, g)) - m_i (H \circ (f, g))| \leq K [|M_i (f) - m_i (f)| + |M_i (g) - m_i (g)|]. \]

**Proof of the claim:** By the above proposition, there exist \( x_1, x_2 \in [x_{i-1}, x_i] \) be such that

\[ H (f(x_1), g(x_1)) + \eta > M_i (H \circ (f, g)), \]
and
\[ H(f(x_2), g(x_2)) - \eta < m_i (H \circ (f, g)) . \]

Then
\[ |M_i (H \circ (f, g)) - m_i (H \circ (f, g))| \]
\[ < 2\eta + |H(f(x_1), g(x_1)) - H(f(x_2), g(x_2))| \]
\[ < 2\eta + K ||f(x_1) - f(x_2)| + |g(x_1) - g(x_2)|| \]
\[ \leq 2\eta + K ||M_i (f) - m_i (f)| + |M_i (g) - m_i (g)|| . \]

Since \( \eta > 0 \) is arbitrary, this proves the claim.

Now continuing with the proof of the theorem, let \( P \) be such that
\[ \sum_{i=1}^{n} (M_i (f) - m_i (f)) \Delta F_i < \frac{\varepsilon}{2K}, \quad \sum_{i=1}^{n} (M_i (g) - m_i (g)) \Delta F_i < \frac{\varepsilon}{2K} . \]

Then from the claim,
\[ \sum_{i=1}^{n} (M_i (H \circ (f, g)) - m_i (H \circ (f, g))) \Delta F_i \]
\[ < \sum_{i=1}^{n} K ||M_i (f) - m_i (f)| + |M_i (g) - m_i (g)|| \Delta F_i < \varepsilon . \]

Since \( \varepsilon > 0 \) is arbitrary, this shows \( H \circ (f, g) \) satisfies the Riemann criterion and hence \( H \circ (f, g) \) is Riemann integrable as claimed. This proves the theorem.

This theorem implies that if \( f, g \) are Riemann Stieltjes integrable, then so is \( af + bg, |f|, f^2 \), along with infinitely many other such continuous combinations of Riemann Stieltjes integrable functions. For example, to see that \( |f| \) is Riemann integrable, let \( H(a, b) = |a| \). Clearly this function satisfies the conditions of the above theorem and so \( |f| = H(f, f) \in R([a, b]) \) as claimed. The following theorem gives an example of many functions which are Riemann integrable.

**Theorem 3.3.2** Let \( f : [a, b] \to \mathbb{R} \) be either increasing or decreasing on \([a, b]\) and suppose \( F \) is continuous. Then \( f \in R([a, b]) \).

**Proof:** Let \( \varepsilon > 0 \) be given and let
\[ x_i = a + i \left( \frac{b - a}{n} \right), \quad i = 0, \ldots, n. \]

Since \( F \) is continuous, it follows from Corollary on Page 45 that it is uniformly continuous. Therefore, if \( n \) is large enough, then for all \( i \),
\[ F(x_i) - F(x_{i-1}) < \frac{\varepsilon}{f(b) - f(a) + 1} . \]
CHAPTER 3. THE RIEMANN STIELTJES INTEGRAL

Then since \( f \) is increasing,

\[
U(f, P) - L(f, P) = \sum_{i=1}^{n} (f(x_i) - f(x_{i-1})) (F(x_i) - F(x_{i-1})) \leq \frac{\varepsilon}{f(b) - f(a) + 1} \sum_{i=1}^{n} (f(x_i) - f(x_{i-1})) = \frac{\varepsilon}{f(b) - f(a) + 1} (f(b) - f(a)) < \varepsilon.
\]

Thus the Riemann criterion is satisfied and so the function is Riemann Stieltjes integrable. The proof for decreasing \( f \) is similar.

**Corollary 3.3.3** Let \([a, b]\) be a bounded closed interval and let \( \phi : [a, b] \to \mathbb{R} \) be Lipschitz continuous and suppose \( F \) is continuous. Then \( \phi \in R([a, b]) \). Recall that a function, \( \phi \), is Lipschitz continuous if there is a constant, \( K \), such that for all \( x, y \),

\[
|\phi(x) - \phi(y)| < K |x - y|.
\]

**Proof:** Let \( f(x) = x \). Then by Theorem 3.3.2, \( f \) is Riemann Stieltjes integrable. Let \( H(a, b) \equiv \phi(a) \). Then by Theorem 3.3.1, \( H \circ (f, f) = \phi \circ f = \phi \) is also Riemann Stieltjes integrable. This proves the corollary. In fact, it is enough to assume \( \phi \) is continuous, although this is harder. This is the content of the next theorem which is where the difficult theorems about continuity and uniform continuity are used. This is the main result on the existence of the Riemann Stieltjes integral for this book.

**Theorem 3.3.4** Suppose \( f : [a, b] \to \mathbb{R} \) is continuous and \( F \) is just an increasing function defined on \([a, b]\). Then \( f \in R([a, b]) \).

**Proof:** By Corollary 2.0.5 on Page 34, \( f \) is uniformly continuous on \([a, b]\). Therefore, if \( \varepsilon > 0 \) is given, there exists a \( \delta > 0 \) such that if \( |x_i - x_{i-1}| < \delta \), then \( M_i - m_i < \frac{\varepsilon}{F(b) - F(a) + 1} \). Let

\[
P \equiv \{x_0, \ldots, x_n\}
\]

be a partition with \( |x_i - x_{i-1}| < \delta \). Then

\[
U(f, P) - L(f, P) < \sum_{i=1}^{n} (M_i - m_i) (F(x_i) - F(x_{i-1})) < \frac{\varepsilon}{F(b) - F(a) + 1} (F(b) - F(a)) < \varepsilon.
\]

By the Riemann criterion, \( f \in R([a, b]) \). This proves the theorem.
3.4 Properties Of The Integral

The integral has many important algebraic properties. First here is a simple lemma.

**Lemma 3.4.1** Let $S$ be a nonempty set which is bounded above and below. Then if $-S \equiv \{-x : x \in S\}$,

$$\sup(-S) = -\inf(S) \quad (3.4.5)$$

and

$$\inf(-S) = -\sup(S). \quad (3.4.6)$$

**Proof:** Consider $3.4.5$. Let $x \in S$. Then $-x \leq \sup(-S)$ and so $x \geq -\sup(-S)$. This implies $\sup(-S) \geq -\inf(S)$. Now let $x \in -S$. Then $x \in S$ and so $x \geq \inf(S)$ which implies $-x \leq -\inf(S)$. Therefore, $-\inf(S)$ is an upper bound for $-S$ and so $-\inf(S) \geq \sup(-S)$. This shows $3.4.5$. Formula $3.4.6$ is similar and is left as an exercise.

In particular, the above lemma implies that for $M_i(f)$ and $m_i(f)$ defined above $M_i(-f) = -m_i(f)$, and $m_i(-f) = -M_i(f)$.

**Lemma 3.4.2** If $f \in R([a,b])$ then $-f \in R([a,b])$ and

$$-\int_a^b f(x) \, dF = \int_a^b -f(x) \, dF.$$

**Proof:** The first part of the conclusion of this lemma follows from Theorem 3.3.2 since the function $\phi(y) \equiv -y$ is Lipschitz continuous. Now choose $P$ such that

$$\int_a^b -f(x) \, dF - L(-f, P) < \varepsilon.$$

Then since $m_i(-f) = -M_i(f)$,

$$\varepsilon > \int_a^b f(x) \, dF - \sum_{i=1}^n m_i(-f) \Delta F_i = \int_a^b -f(x) \, dF + \sum_{i=1}^n M_i(f) \Delta F_i$$

which implies

$$\varepsilon > \int_a^b -f(x) \, dF + \sum_{i=1}^n M_i(f) \Delta F_i \geq \int_a^b -f(x) \, dF + \int_a^b f(x) \, dF.$$

Thus, since $\varepsilon$ is arbitrary,

$$\int_a^b f(x) \, dF \leq -\int_a^b f(x) \, dF$$

whenever $f \in R([a,b])$. It follows

$$\int_a^b -f(x) \, dF \leq -\int_a^b f(x) \, dF = -\int_a^b (-f(x)) \, dF \leq \int_a^b -f(x) \, dF$$

and this proves the lemma.
Theorem 3.4.3 The integral is linear,
\[ \int_a^b (\alpha f + \beta g) (x) \, dF = \alpha \int_a^b f (x) \, dF + \beta \int_a^b g (x) \, dF. \]
whenever \( f, g \in R([a, b]) \) and \( \alpha, \beta \in \mathbb{R} \).

Proof: First note that by Theorem 3.3.1, \( \alpha f + \beta g \in R([a, b]) \). To begin with, consider the claim that if \( f, g \in R([a, b]) \) then
\[ \int_a^b (f + g) (x) \, dF = \int_a^b f (x) \, dF + \int_a^b g (x) \, dF. \]  
(3.4.7)
Let \( P_1, Q_1 \) be such that
\[ U(f, Q_1) - L(f, Q_1) < \varepsilon/2, \quad U(g, P_1) - L(g, P_1) < \varepsilon/2. \]
Then letting \( P = P_1 \cup Q_1, \) Lemma 3.1.2 implies
\[ U(f, P) - L(f, P) < \varepsilon/2, \quad \text{and} \quad U(g, P) - U(g, P) < \varepsilon/2. \]
Next note that
\[ m_i(f + g) \geq m_i(f) + m_i(g), \quad M_i(f + g) \leq M_i(f) + M_i(g). \]
Therefore,
\[ L(g + f, P) \geq L(f, P) + L(g, P), \quad U(g + f, P) \leq U(f, P) + U(g, P). \]
For this partition,
\[ \int_a^b (f + g) (x) \, dF \in [L(f + g, P), U(f + g, P)] \]
\[ \subseteq [L(f, P) + L(g, P), U(f, P) + U(g, P)] \]
and
\[ \int_a^b f (x) \, dF + \int_a^b g (x) \, dF \in [L(f, P) + L(g, P), U(f, P) + U(g, P)]. \]
Therefore,
\[ \left| \int_a^b (f + g) (x) \, dF - \left( \int_a^b f (x) \, dF + \int_a^b g (x) \, dF \right) \right| \leq \]
\[ U(f, P) + U(g, P) - (L(f, P) + L(g, P)) < \varepsilon/2 + \varepsilon/2 = \varepsilon. \]
This proves (3.4.7) since \( \varepsilon \) is arbitrary.
It remains to show that
\[ \alpha \int_a^b f(x) \, dF = \int_a^b \alpha f(x) \, dF. \]
Suppose first that \( \alpha \geq 0 \). Then
\[ \int_a^b \alpha f(x) \, dF \equiv \sup \{ L(\alpha f, P) : P \text{ is a partition} \} = \]
\[ \alpha \sup \{ L(f, P) : P \text{ is a partition} \} \equiv \alpha \int_a^b f(x) \, dF. \]
If \( \alpha < 0 \), then this and Lemma 3.4.2 imply
\[ \int_a^b \alpha f(x) \, dF = \int_a^b (-\alpha) (-f(x)) \, dF \]
\[ = (-\alpha) \int_a^b (-f(x)) \, dF = \alpha \int_a^b f(x) \, dF. \]
This proves the theorem.

In the next theorem, suppose \( F \) is defined on \([a, b] \cup [b, c] \).

**Theorem 3.4.4** If \( f \in R([a, b]) \) and \( f \in R([b, c]) \), then \( f \in R([a, c]) \) and
\[ \int_a^c f(x) \, dF = \int_a^b f(x) \, dF + \int_b^c f(x) \, dF. \]  

**Proof:** Let \( P_1 \) be a partition of \([a, b] \) and \( P_2 \) be a partition of \([b, c] \) such that
\[ U(f, P_i) - L(f, P_i) < \varepsilon/2, \quad i = 1, 2. \]
Let \( P \equiv P_1 \cup P_2 \). Then \( P \) is a partition of \([a, c] \) and
\[ U(f, P) - L(f, P) = U(f, P_1) - L(f, P_1) + U(f, P_2) - L(f, P_2) < \varepsilon/2 + \varepsilon/2 = \varepsilon. \]
Thus, \( f \in R([a, c]) \) by the Riemann criterion and also for this partition,
\[ \int_a^b f(x) \, dF + \int_b^c f(x) \, dF \in [L(f, P_1) + L(f, P_2), U(f, P_1) + U(f, P_2)] \]
\[ = [L(f, P), U(f, P)] \]
and
\[ \int_a^c f(x) \, dF \in [L(f, P), U(f, P)]. \]
Hence by (3.4.8),
\[ \left| \int_a^c f(x) \, dF - \left( \int_a^b f(x) \, dF + \int_b^c f(x) \, dF \right) \right| < U(f, P) - L(f, P) < \varepsilon \]
which shows that since \( \varepsilon \) is arbitrary, (3.4.8) holds. This proves the theorem.
Corollary 3.4.5 Let $F$ be continuous and let $[a, b]$ be a closed and bounded interval and suppose that

$$a = y_1 < y_2 < \cdots < y_l = b$$

and that $f$ is a bounded function defined on $[a, b]$ which has the property that $f$ is either increasing on $[y_j, y_{j+1}]$ or decreasing on $[y_j, y_{j+1}]$ for $j = 1, \ldots, l - 1$. Then $f \in R([a, b])$.

**Proof:** This follows from Theorem 3.4.4 and Theorem 3.4.2. The symbol, $\int_a^b f(x) \, dF$ when $a > b$ has not yet been defined.

Definition 3.4.6 Let $[a, b]$ be an interval and let $f \in R([a, b])$. Then

$$\int_b^a f(x) \, dF \equiv - \int_a^b f(x) \, dF.$$ 

Note that with this definition,

$$\int_a^a f(x) \, dF = - \int_a^a f(x) \, dF$$

and so

$$\int_a^a f(x) \, dF = 0.$$ 

Theorem 3.4.7 Assuming all the integrals make sense,

$$\int_a^b f(x) \, dF + \int_b^c f(x) \, dF = \int_a^c f(x) \, dF.$$ 

**Proof:** This follows from Theorem 3.4.4 and Definition 3.4.6. For example, assume

$$c \in (a, b).$$

Then from Theorem 3.4.4,

$$\int_a^c f(x) \, dF + \int_c^b f(x) \, dF = \int_a^b f(x) \, dF$$

and so by Definition 3.4.6,

$$\int_a^c f(x) \, dF = \int_a^b f(x) \, dF - \int_c^b f(x) \, dF$$

$$= \int_a^b f(x) \, dF + \int_b^c f(x) \, dF.$$ 

The other cases are similar.
The following properties of the integral have either been established or they follow quickly from what has been shown so far.

If \( f \in R([a,b]) \) then if \( c \in [a,b], \ f \in R([a,c]) \),

\[
\int_a^b f(x) \, dx = (F(b) - F(a)),
\]

\[
\int_a^b (\alpha f + \beta g)(x) \, dx = \alpha \int_a^b f(x) \, dx + \beta \int_a^b g(x) \, dx,
\]

\[
\int_a^c f(x) \, dx + \int_a^b f(x) \, dx = \int_a^b f(x) \, dx,
\]

\[
\int_a^b f(x) \, dx \geq 0 \text{ if } f(x) \geq 0 \text{ and } a < b,
\]

\[
\left| \int_a^b f(x) \, dx \right| \leq \int_a^b |f(x)| \, dx.
\]

The only one of these claims which may not be completely obvious is the last one. To show this one, note that

\[
|f(x)| - f(x) \geq 0, \ |f(x)| + f(x) \geq 0.
\]

Therefore, by (3.4.12) and (3.4.13) if \( a < b \),

\[
\int_a^b |f(x)| \, dx \geq \int_a^b f(x) \, dx
\]

and

\[
\int_a^b |f(x)| \, dx \geq -\int_a^b f(x) \, dx.
\]

Therefore,

\[
\int_a^b |f(x)| \, dx \geq \left| \int_a^b f(x) \, dx \right|.
\]

If \( b < a \) then the above inequality holds with \( a \) and \( b \) switched. This implies (3.4.15).

3.5 Fundamental Theorem Of Calculus

In this section \( F(x) = x \) so things are specialized to the ordinary Riemann integral. With these properties, it is easy to prove the fundamental theorem of calculus.²

²This theorem is why Newton and Liebnitz are credited with inventing calculus. The integral had been around for thousands of years and the derivative was by their time well known. However, the connection between these two ideas had not been fully made although Newton’s predecessor, Isaac Barrow had made some progress in this direction.
Let \( f \in R([a,b]) \). Then by \( 3.4.10 \), \( f \in R([a,x]) \) for each \( x \in [a,b] \). The first version of the fundamental theorem of calculus is a statement about the derivative of the function

\[ x \to \int_{a}^{x} f(t) \, dt. \]

**Theorem 3.5.1** Let \( f \in R([a,b]) \) and let

\[ F(x) \equiv \int_{a}^{x} f(t) \, dt. \]

Then if \( f \) is continuous at \( x \in (a,b) \),

\[ F'(x) = f(x). \]

**Proof:** Let \( x \in (a,b) \) be a point of continuity of \( f \) and let \( h \) be small enough that \( x + h \in [a,b] \). Then by using \( 3.4.13 \),

\[ h^{-1}(F(x+h) - F(x)) = h^{-1}\int_{x}^{x+h} f(t) \, dt. \]

Also, using \( 3.4.11 \),

\[ f(x) = h^{-1}\int_{x}^{x+h} f(x) \, dt. \]

Therefore, by \( 3.4.15 \),

\[ |h^{-1}(F(x+h) - F(x)) - f(x)| = \left| h^{-1}\int_{x}^{x+h} (f(t) - f(x)) \, dt \right| \]

\[ \leq \left| h^{-1}\int_{x}^{x+h} |f(t) - f(x)| \, dt \right|. \]

Let \( \varepsilon > 0 \) and let \( \delta > 0 \) be small enough that if \( |t-x| < \delta \), then

\[ |f(t) - f(x)| < \varepsilon. \]

Therefore, if \( |h| < \delta \), the above inequality and \( 3.4.11 \) shows that

\[ |h^{-1}(F(x+h) - F(x)) - f(x)| \leq |h|^{-1}\varepsilon|h| = \varepsilon. \]

Since \( \varepsilon > 0 \) is arbitrary, this shows

\[ \lim_{h \to 0} h^{-1}(F(x+h) - F(x)) = f(x) \]

and this proves the theorem.

Note this gives existence for the initial value problem,

\[ F'(x) = f(x), \quad F(a) = 0 \]
whenever \( f \) is Riemann integrable and continuous.\(^3\)

The next theorem is also called the fundamental theorem of calculus.

**Theorem 3.5.2** Let \( f \in R([a,b]) \) and suppose there exists an antiderivative for \( f,G \), such that

\[
G'(x) = f(x)
\]

for every point of \((a,b)\) and \( G \) is continuous on \([a,b]\). Then

\[
\int_a^b f(x) \, dx = G(b) - G(a). \tag{3.5.16}
\]

**Proof:** Let \( P = \{x_0, \ldots, x_n\} \) be a partition satisfying

\[
U(f,P) - L(f,P) < \varepsilon.
\]

Then

\[
G(b) - G(a) = G(x_n) - G(x_0)
= \sum_{i=1}^n G(x_i) - G(x_{i-1}).
\]

By the mean value theorem,

\[
G(b) - G(a) = \sum_{i=1}^n G'(z_i)(x_i - x_{i-1})
= \sum_{i=1}^n f(z_i) \Delta x_i
\]

where \( z_i \) is some point in \([x_{i-1}, x_i] \). It follows, since the above sum lies between the upper and lower sums, that

\[
G(b) - G(a) \in [L(f,P), U(f,P)],
\]

and also

\[
\int_a^b f(x) \, dx \in [L(f,P), U(f,P)].
\]

Therefore,

\[
\left| G(b) - G(a) - \int_a^b f(x) \, dx \right| < U(f,P) - L(f,P) < \varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, \((3.5.16)\) holds. This proves the theorem.

The following notation is often used in this context. Suppose \( F \) is an antiderivative of \( f \) as just described with \( F \) continuous on \([a,b]\) and \( F' = f \) on \((a,b)\).

Then

\[
\int_a^b f(x) \, dx = F(b) - F(a) \equiv F(b) - F(a) \big|_a^b.
\]

\(^3\)Of course it was proved that if \( f \) is continuous on a closed interval, \([a,b]\), then \( f \in R([a,b]) \) but this is a hard theorem using the difficult result about uniform continuity.
DEFINITION 3.5.3 Let $f$ be a bounded function defined on a closed interval $[a, b]$ and let $P = \{x_0, \ldots, x_n\}$ be a partition of the interval. Suppose $z_i \in [x_{i-1}, x_i]$ is chosen. Then the sum

$$\sum_{i=1}^{n} f(z_i) (x_i - x_{i-1})$$

is known as a Riemann sum. Also,

$$||P|| \equiv \max \{ |x_i - x_{i-1}| : i = 1, \ldots, n \}.$$ 

PROPOSITION 3.5.4 Suppose $f \in R([a, b])$. Then there exists a partition, $P = \{x_0, \ldots, x_n\}$ with the property that for any choice of $z_k \in [x_{k-1}, x_k]$,

$$\int_{a}^{b} f(x) \, dx - \sum_{k=1}^{n} f(z_k) (x_k - x_{k-1}) < \varepsilon.$$

Proof: Choose $P$ such that $U(f, P) - L(f, P) < \varepsilon$ and then both $\int_{a}^{b} f(x) \, dx$ and $\sum_{k=1}^{n} f(z_k) (x_k - x_{k-1})$ are contained in $[L(f, P), U(f, P)]$ and so the claimed inequality must hold. This proves the proposition.

It is significant because it gives a way of approximating the integral.

The definition of Riemann integrability given in this chapter is also called Darboux integrability and the integral defined as the unique number which lies between all upper sums and all lower sums which is given in this chapter is called the Darboux integral. The definition of the Riemann integral in terms of Riemann sums is given next.

DEFINITION 3.5.5 A bounded function, $f$ defined on $[a, b]$ is said to be Riemann integrable if there exists a number, $I$ with the property that for every $\varepsilon > 0$, there exists $\delta > 0$ such that if

$$P \equiv \{x_0, x_1, \ldots, x_n\}$$

is any partition having $||P|| < \delta$, and $z_i \in [x_{i-1}, x_i]$,

$$|I - \sum_{i=1}^{n} f(z_i) (x_i - x_{i-1})| < \varepsilon.$$

The number $\int_{a}^{b} f(x) \, dx$ is defined as $I$.

Thus, there are two definitions of the Riemann integral. It turns out they are equivalent which is the following theorem of Darboux.

THEOREM 3.5.6 A bounded function defined on $[a, b]$ is Riemann integrable in the sense of Definition 3.5.5 if and only if it is integrable in the sense of Darboux. Furthermore the two integrals coincide.
The proof of this theorem is left for the exercises in Problems 11 - 12. It isn’t essential that you understand this theorem so if it does not interest you, leave it out. Note that it implies that given a Riemann integrable function \( f \) in either sense, it can be approximated by Riemann sums whenever \( ||P|| \) is sufficiently small. Both versions of the integral are obsolete but entirely adequate for most applications and as a point of departure for a more up to date and satisfactory integral. The reason for using the Darboux approach to the integral is that all the existence theorems are easier to prove in this context.

### 3.6 Exercises

1. Let \( F(x) = \int_{x^2}^{x^3} \frac{t^5+7}{1+t^5} \, dt \). Find \( F'(x) \).

2. Let \( F(x) = \int_{2}^{x} \frac{1}{1+t^7} \, dt \). Sketch a graph of \( F \) and explain why it looks the way it does.

3. Let \( a \) and \( b \) be positive numbers and consider the function,

\[
F(x) = \int_{0}^{ax} \frac{1}{a^2+t^2} \, dt + \int_{b}^{a/x} \frac{1}{a^2+t^2} \, dt.
\]

Show that \( F \) is a constant.

4. Solve the following initial value problem from ordinary differential equations which is to find a function \( y \) such that

\[
y'(x) = \frac{x^7+1}{x^6+97x^5+7}, \quad y(10) = 5.
\]

5. If \( F, G \in \int f(x) \, dx \) for all \( x \in \mathbb{R} \), show \( F(x) = G(x) + C \) for some constant, \( C \). Use this to give a different proof of the fundamental theorem of calculus which has for its conclusion \( \int_{a}^{b} f(t) \, dt = G(b) - G(a) \) where \( G'(x) = f(x) \).

6. Suppose \( f \) is Riemann integrable on \( [a,b] \) and continuous. (In fact continuous implies Riemann integrable.) Show there exists \( c \in (a,b) \) such that

\[
f(c) = \frac{1}{b-a} \int_{a}^{b} f(x) \, dx.
\]

**Hint:** You might consider the function \( F(x) \equiv \int_{a}^{x} f(t) \, dt \) and use the mean value theorem for derivatives and the fundamental theorem of calculus.

7. Suppose \( f \) and \( g \) are continuous functions on \( [a,b] \) and that \( g(x) \neq 0 \) on \( (a,b) \). Show there exists \( c \in (a,b) \) such that

\[
f(c) \int_{a}^{b} g(x) \, dx = \int_{a}^{b} f(x) g(x) \, dx.
\]

**Hint:** Define \( F(x) \equiv \int_{a}^{x} f(t) g(t) \, dt \) and let \( G(x) \equiv \int_{a}^{x} g(t) \, dt \). Then use the Cauchy mean value theorem on these two functions.
8. Consider the function

\[ f(x) = \begin{cases} 
\sin \left( \frac{1}{x} \right) & \text{if } x \neq 0 \\
0 & \text{if } x = 0
\end{cases} \]

Is \( f \) Riemann integrable? Explain why or why not.

9. Prove the second part of Theorem 3.3.2 about decreasing functions.

10. Suppose \( f \) is a bounded function defined on \([a, b]\) and \( |f(x)| < M \) for all \( x \in [a, b] \). Now let \( Q \) be a partition having \( n \) points, \( \{x_0^*, \ldots, x_n^*\} \) and let \( P \) be any other partition. Show that

\[ |U(f, P) - L(f, P)| \leq 2Mn \|P\| + |U(f, Q) - L(f, Q)|. \]

**Hint:** Write the sum for \( U(f, P) - L(f, P) \) and split this sum into two sums, the sum of terms for which \([x_{i-1}, x_i]\) contains at least one point of \( Q \), and terms for which \([x_{i-1}, x_i]\) does not contain any points of \( Q \). In the latter case, \([x_{i-1}, x_i]\) must be contained in some interval, \([x_{k-1}^*, x_k^*]\). Therefore, the sum of these terms should be no larger than \( |U(f, Q) - L(f, Q)| \).

11. If \( \varepsilon > 0 \) is given and \( f \) is a Darboux integrable function defined on \([a, b]\), show there exists \( \delta > 0 \) such that whenever \( \|P\| < \delta \), then

\[ |U(f, P) - L(f, P)| < \varepsilon. \]

12. Prove Theorem 3.5.6.
This chapter contains some important linear algebra as distinguished from that which is normally presented in undergraduate courses consisting mainly of uninteresting things you can do with row operations.

The notation, $\mathbb{C}^n$ refers to the collection of ordered lists of $n$ complex numbers. Since every real number is also a complex number, this simply generalizes the usual notion of $\mathbb{R}^n$, the collection of all ordered lists of $n$ real numbers. In order to avoid worrying about whether it is real or complex numbers which are being referred to, the symbol $\mathbb{F}$ will be used. If it is not clear, always pick $\mathbb{C}$.

**Definition 4.0.1** Define

$$F^n \equiv \{(x_1, \cdots, x_n) : x_j \in \mathbb{F} \text{ for } j = 1, \cdots, n\}.$$  

$(x_1, \cdots, x_n) = (y_1, \cdots, y_n)$ if and only if for all $j = 1, \cdots, n$, $x_j = y_j$. When

$$(x_1, \cdots, x_n) \in F^n,$$

it is conventional to denote $(x_1, \cdots, x_n)$ by the single bold face letter, $x$. The numbers, $x_j$ are called the coordinates. The set

$$\{(0, \cdots, 0, t, 0, \cdots, 0) : t \in \mathbb{F}\}$$

for $t$ in the $i^{th}$ slot is called the $i^{th}$ coordinate axis. The point $0 \equiv (0, \cdots, 0)$ is called the origin.

Thus $(1, 2, 4i) \in \mathbb{F}^3$ and $(2, 1, 4i) \in \mathbb{F}^3$ but $(1, 2, 4i) \neq (2, 1, 4i)$ because, even though the same numbers are involved, they don’t match up. In particular, the first entries are not equal.

The geometric significance of $\mathbb{R}^n$ for $n \leq 3$ has been encountered already in calculus or in precalculus. Here is a short review. First consider the case when
$n = 1$. Then from the definition, $\mathbb{R}^1 = \mathbb{R}$. Recall that $\mathbb{R}$ is identified with the points of a line. Look at the number line again. Observe that this amounts to identifying a point on this line with a real number. In other words a real number determines where you are on this line. Now suppose $n = 2$ and consider two lines which intersect each other at right angles as shown in the following picture.

Notice how you can identify a point shown in the plane with the ordered pair, $(2, 6)$. You go to the right a distance of 2 and then up a distance of 6. Similarly, you can identify another point in the plane with the ordered pair $(-8, 3)$. Go to the left a distance of 8 and then up a distance of 3. The reason you go to the left is that there is a $-$ sign on the eight. From this reasoning, every ordered pair determines a unique point in the plane. Conversely, taking a point in the plane, you could draw two lines through the point, one vertical and the other horizontal and determine unique points, $x_1$ on the horizontal line in the above picture and $x_2$ on the vertical line in the above picture, such that the point of interest is identified with the ordered pair, $(x_1, x_2)$. In short, points in the plane can be identified with ordered pairs similar to the way that points on the real line are identified with real numbers. Now suppose $n = 3$. As just explained, the first two coordinates determine a point in a plane. Letting the third component determine how far up or down you go, depending on whether this number is positive or negative, this determines a point in space. Thus, $(1, 4, -5)$ would mean to determine the point in the plane that goes with $(1, 4)$ and then to go below this plane a distance of 5 to obtain a unique point in space. You see that the ordered triples correspond to points in space just as the ordered pairs correspond to points in a plane and single real numbers correspond to points on a line.

You can’t stop here and say that you are only interested in $n \leq 3$. What if you were interested in the motion of two objects? You would need three coordinates to describe where the first object is and you would need another three coordinates to describe where the other object is located. Therefore, you would need to be considering $\mathbb{R}^6$. If the two objects moved around, you would need a time coordinate as well. As another example, consider a hot object which is cooling and suppose you want the temperature of this object. How many coordinates would be needed? You would need one for the temperature, three for the position of the point in the object and one more for the time. Thus you would need to be considering $\mathbb{R}^5$. Many other examples can be given. Sometimes $n$ is very large. This is often the case in applications to business when they are trying to maximize profit subject
to constraints. It also occurs in numerical analysis when people try to solve hard problems on a computer.

There are other ways to identify points in space with three numbers but the one presented is the most basic. In this case, the coordinates are known as Cartesian coordinates after Descartes\textsuperscript{1} who invented this idea in the first half of the seventeenth century. I will often not bother to draw a distinction between the point in n dimensional space and its Cartesian coordinates.

The geometric significance of $\mathbb{C}^n$ for $n > 1$ is not available because each copy of $\mathbb{C}$ corresponds to the plane or $\mathbb{R}^2$.

4.1 Algebra In $\mathbb{F}^n$

There are two algebraic operations done with elements of $\mathbb{F}^n$. One is addition and the other is multiplication by numbers, called scalars. In the case of $\mathbb{C}^n$ the scalars are complex numbers while in the case of $\mathbb{R}^n$ the only allowed scalars are real numbers. Thus, the scalars always come from $\mathbb{F}$ in either case.

**Definition 4.1.1** If $x \in \mathbb{F}^n$ and $a \in \mathbb{F}$, also called a scalar, then $ax \in \mathbb{F}^n$ is defined by

$$ax = a (x_1, \cdots, x_n) \equiv (ax_1, \cdots, ax_n).$$

This is known as scalar multiplication. If $x, y \in \mathbb{F}^n$ then $x + y \in \mathbb{F}^n$ and is defined by

$$x + y = (x_1, \cdots, x_n) + (y_1, \cdots, y_n)$$
$$\equiv (x_1 + y_1, \cdots, x_n + y_n)$$

With this definition, the algebraic properties satisfy the conclusions of the following theorem.

**Theorem 4.1.2** For $v, w \in \mathbb{F}^n$ and $\alpha, \beta$ scalars, (real numbers), the following hold.

$$v + w = w + v,$$

the commutative law of addition,

$$(v + w) + z = v + (w + z),$$

the associative law for addition,

$$v + 0 = v,$$

the existence of an additive identity,

$$v + (-v) = 0,$$

\textsuperscript{1}René Descartes 1596-1650 is often credited with inventing analytic geometry although it seems the ideas were actually known much earlier. He was interested in many different subjects, physiology, chemistry, and physics being some of them. He also wrote a large book in which he tried to explain the book of Genesis scientifically. Descartes ended up dying in Sweden.
the existence of an additive inverse, Also

\[ \alpha (v + w) = \alpha v + \alpha w, \quad (4.1.7) \]
\[ (\alpha + \beta) v = \alpha v + \beta v, \quad (4.1.8) \]
\[ \alpha (\beta v) = \alpha \beta (v), \quad (4.1.9) \]
\[ 1v = v. \quad (4.1.10) \]

In the above \( \mathbf{0} = (0, \cdots, 0) \).

You should verify these properties all hold. For example, consider \( \mathbf{4.1.7} \)

\[ \alpha (v + w) = \alpha (v_1 + w_1, \cdots, v_n + w_n) \]
\[ = (\alpha (v_1 + w_1), \cdots, \alpha (v_n + w_n)) \]
\[ = (\alpha v_1 + \alpha w_1, \cdots, \alpha v_n + \alpha w_n) \]
\[ = (\alpha v_1, \cdots, \alpha v_n) + (\alpha w_1, \cdots, \alpha w_n) \]
\[ = \alpha v + \alpha w. \]

As usual subtraction is defined as \( x - y \equiv x + (-y) \).

### 4.2 Exercises

1. Verify all the properties \( \mathbf{4.1.3-4.1.10} \).

2. Compute \( 5 (1, 2 + 3i, 3, -2) + 6 (2 - i, 1, -2, 7) \).

3. Draw a picture of the points in \( \mathbb{R}^2 \) which are determined by the following ordered pairs.

   (a) \( (1, 2) \)
   (b) \( (-2, -2) \)
   (c) \( (-2, 3) \)
   (d) \( (2, -5) \)

4. Does it make sense to write \( (1, 2) + (2, 3, 1) \)? Explain.

5. Draw a picture of the points in \( \mathbb{R}^3 \) which are determined by the following ordered triples.

   (a) \( (1, 2, 0) \)
   (b) \( (-2, -2, 1) \)
   (c) \( (-2, 3, -2) \)
4.3. THE INNER PRODUCT AND DISTANCE IN $\mathbb{C}^n$

It is necessary to give a generalization of the dot product for vectors in $\mathbb{C}^n$. This is often called the inner product. It reduces to the definition of the dot product in the case the components of the vector are real.

**Definition 4.3.1** Let $x, y \in \mathbb{C}^n$. Thus $x = (x_1, \cdots, x_n)$ where each $x_k \in \mathbb{C}$ and a similar formula holding for $y$. Then the inner product of these two vectors is defined to be

$$x \cdot y \equiv \sum_j x_j \overline{y_j} \equiv x_1 \overline{y_1} + \cdots + x_n \overline{y_n}.$$ 

The inner product is often denoted as $(x, y)$ or $\langle x, y \rangle$.

Notice how you put the conjugate on the entries of the vector $y$. It makes no difference if the vectors happen to be real vectors but with complex vectors you must do it this way. The reason for this is that when you take the inner product of a vector with itself, you want to get the square of the length of the vector, a positive number. Placing the conjugate on the components of $y$ in the above definition assures this will take place. Thus

$$x \cdot x = \sum_j x_j \overline{x_j} = \sum_j |x_j|^2 \geq 0.$$ 

If you didn’t place a conjugate as in the above definition, things wouldn’t work out correctly. For example,

$$(1 + i)^2 + 2^2 = 4 + 2i$$

and this is not a positive number.

The following properties of the inner product follow immediately from the definition and you should verify each of them.

**Properties of the inner product:**

1. $u \cdot v = v \cdot u$.

2. If $a, b$ are numbers and $u, v, z$ are vectors then $(au + bv) \cdot z = a(u \cdot z) + b(v \cdot z)$.

3. $u \cdot u \geq 0$ and it equals 0 if and only if $u = 0$.

Note this implies $(x \cdot \alpha y) = \overline{\alpha} (x \cdot y)$ because

$$(x \cdot \alpha y) = (\alpha y \cdot x) = \overline{\alpha} (y \cdot x) = \overline{\alpha} (x \cdot y)$$

The norm is defined in the usual way.

**Definition 4.3.2** For $x \in \mathbb{C}^n$,

$$|x| \equiv \left( \sum_{k=1}^n |x_k|^2 \right)^{1/2} = (x \cdot x)^{1/2}.$$
Here is a fundamental inequality called the **Cauchy Schwarz inequality** which is stated here in \( \mathbb{C}^n \). First here is a simple lemma.

**Lemma 4.3.3** If \( z \in \mathbb{C} \) there exists \( \theta \in \mathbb{C} \) such that \( \theta z = |z| \) and \( |	heta| = 1 \).

**Proof:** Let \( \theta = 1 \) if \( z = 0 \) and otherwise, let \( \theta = \frac{\overline{z}}{|z|} \). Recall that for \( z = x + iy, \overline{z} = x - iy \) and \( \overline{zz} = |z|^2 \).

I will give a proof of this important inequality which depends only on the above list of properties of the inner product. It will be slightly different than the earlier proof.

**Theorem 4.3.4** *(Cauchy Schwarz)* The following inequality holds for \( x \) and \( y \in \mathbb{C}^n \).

\[
|(x \cdot y)| \leq (|x| \cdot |y|)^{1/2} \tag{4.3.11}
\]

Equality holds in this inequality if and only if one vector is a multiple of the other.

**Proof:** Let \( \theta \in \mathbb{C} \) such that \( |	heta| = 1 \) and

\[
\theta (x \cdot y) = |(x \cdot y)|
\]

Consider \( p(t) = (x + \overline{\theta}y, x + t\overline{\theta}y) \) where \( t \in \mathbb{R} \). Then from the above list of properties of the dot product,

\[
0 \leq p(t) = (x \cdot x) + t\theta (x \cdot y) + t\overline{\theta} (y \cdot x) + t^2 (y \cdot y) \\
= (x \cdot x) + 2t \text{Re}(\theta (x \cdot y)) + t^2 (y \cdot y) \\
= (x \cdot x) + 2t |(x \cdot y)| + t^2 (y \cdot y) \tag{4.3.12}
\]

and this must hold for all \( t \in \mathbb{R} \). Therefore, if \( (y \cdot y) = 0 \) it must be the case that \( |(x \cdot y)| = 0 \) also since otherwise the above inequality would be violated. Therefore, in this case,

\[
|(x \cdot y)| \leq (|x| \cdot |y|)^{1/2} \tag{4.3.11}
\]

On the other hand, if \( (y \cdot y) \neq 0 \), then \( p(t) \geq 0 \) for all \( t \) means the graph of \( y = p(t) \) is a parabola which opens up and it either has exactly one real zero in the case its vertex touches the \( t \) axis or it has no real zeros.

From the quadratic formula this happens exactly when

\[
4 |(x \cdot y)|^2 - 4 (x \cdot x) (y \cdot y) \leq 0
\]

which is equivalent to \((4.3.11)\).
4.4. SUBSPACES SPANS AND BASES

It is clear from a computation that if one vector is a scalar multiple of the other that equality holds in \[ 4.3.11 \]. Conversely, suppose equality does hold. Then this is equivalent to saying

\[ 4 \cdot j(x \cdot y) - 4(x \cdot x)(y \cdot y) = 0 \]

and so \( p(t) = 0 \). Call it \( t_0 \). Then

\[ p(t_0) = ((x + \bar{t}_0y) \cdot (x + t_0\bar{y})) = |x + \bar{t}y|^2 = 0 \]

and so \( x = -\bar{t}_0y \). ■

Note that I only used part of the above properties of the inner product. It was not necessary to use the one which says that if \((x \cdot x) = 0\) then \(x = 0\).

By analogy to the case of \(\mathbb{R}^n\), length or magnitude of vectors in \(\mathbb{C}^n\) can be defined.

**Definition 4.3.5** Let \( z \in \mathbb{C}^n \). Then \( |z| \equiv (z \cdot z)^{1/2} \).

The conclusions of the following theorem are also called the **axioms for a norm**.

**Theorem 4.3.6** For length defined in **Definition 4.3.5**, the following hold.

\[ |z| \geq 0 \text{ and } |z| = 0 \text{ if and only if } z = 0 \] (4.3.13)

If \( \alpha \) is a scalar, \( |\alpha z| = |\alpha| |z| \) (4.3.14)

\[ |z + w| \leq |z| + |w|. \] (4.3.15)

**Proof:** The first two claims are left as exercises. To establish the third, you use the same argument which was used in \(\mathbb{R}^n\).

\[ |z + w|^2 = (z + w) \cdot (z + w) = z \cdot z + w \cdot w + w \cdot z + z \cdot w = |z|^2 + |w|^2 + 2 \text{Re}(w \cdot z) \leq |z|^2 + |w|^2 + 2 |w| |z| = (|z| + |w|)^2. \] ■

This dot product is often denoted as \((x, y)\). It is also called an inner product. An inner product space is a vector space which has an inner product. More is given on this later. If an inner product space is complete, meaning that Cauchy sequences converge, then it is called a Hilbert space. More is given on this later.

### 4.4 Subspaces, Spans, And Bases

**Definition 4.4.1** Let \( \{x_1, \cdots, x_p\} \) be vectors in \(\mathbb{F}^n\). A **linear combination** is any expression of the form

\[ \sum_{i=1}^{p} c_i x_i \]
where the $c_i$ are scalars. The set of all linear combinations of these vectors is called span$(x_1, \ldots, x_n)$. If $V \subseteq \mathbb{F}^n$, then $V$ is called a subspace if whenever $\alpha, \beta$ are scalars and $u$ and $v$ are vectors of $V$, it follows $\alpha u + \beta v \in V$. That is, it is “closed under the algebraic operations of vector addition and scalar multiplication”.

A linear combination of vectors is said to be trivial if all the scalars in the linear combination equal zero. A set of vectors is said to be linearly independent if the only linear combination of these vectors which equals the zero vector is the trivial linear combination. Thus $\{x_1, \ldots, x_n\}$ is called linearly independent if whenever

$$\sum_{k=1}^{p} c_k x_k = 0$$

it follows that all the scalars, $c_k$ equal zero. A set of vectors, $\{x_1, \ldots, x_p\}$, is called linearly dependent if it is not linearly independent. Thus the set of vectors is linearly dependent if there exist scalars, $c_i, i = 1, \ldots, n$, not all zero such that $\sum_{k=1}^{p} c_k x_k = 0$.

**Lemma 4.4.2** A set of vectors $\{x_1, \ldots, x_p\}$ is linearly independent if and only if none of the vectors can be obtained as a linear combination of the others.

**Proof:** Suppose first that $\{x_1, \ldots, x_p\}$ is linearly independent. If

$$x_k = \sum_{j \neq k} c_j x_j,$$

then

$$0 = 1x_k + \sum_{j \neq k} (-c_j) x_j,$$

a nontrivial linear combination, contrary to assumption. This shows that if the set is linearly independent, then none of the vectors is a linear combination of the others.

Now suppose no vector is a linear combination of the others. Is $\{x_1, \ldots, x_p\}$ linearly independent? If it is not there exist scalars, $c_i$, not all zero such that

$$\sum_{i=1}^{p} c_i x_i = 0.$$

Say $c_k \neq 0$. Then you can solve for $x_k$ as

$$x_k = \sum_{j \neq k} (-c_j) / c_k x_j$$

contrary to assumption. This proves the lemma.

The following is called the exchange theorem.

**Theorem 4.4.3** (Exchange Theorem) Let $\{x_1, \ldots, x_r\}$ be a linearly independent set of vectors such that each $x_i$ is in span$(y_1, \ldots, y_s)$. Then $r \leq s$. 

Proof: Define \( \text{span}\{y_1, \ldots, y_s\} = V \), it follows there exist scalars, \( c_1, \ldots, c_s \) such that
\[
x_1 = \sum_{i=1}^{s} c_i y_i. \tag{4.4.16}
\]
Not all of these scalars can equal zero because if this were the case, it would follow that \( x_1 = 0 \) and so \( \{x_1, \ldots, x_r\} \) would not be linearly independent. Indeed, if \( x_1 = 0 \), \( 1x_1 + \sum_{i=2}^{r} 0x_i = x_1 = 0 \) and so there would exist a nontrivial linear combination of the vectors \( \{x_1, \ldots, x_r\} \) which equals zero.

Say \( c_k \neq 0 \). Then solve (4.4.16) for \( y_k \) and obtain
\[
y_k \in \text{span} \left( x_1, y_1, \ldots, y_{k-1}, y_{k+1}, \ldots, y_s \right).
\]
Define \( \{z_1, \ldots, z_{s-1}\} \) by
\[
\{z_1, \ldots, z_{s-1}\} = \{y_1, \ldots, y_{k-1}, y_{k+1}, \ldots, y_s\}
\]
Therefore, \( \text{span}\{x_1, z_1, \ldots, z_{s-1}\} = V \) because if \( v \in V \), there exist constants \( c_1, \ldots, c_s \) such that
\[
v = \sum_{i=1}^{s-1} c_i z_i + c_s y_k. \tag{4.4.17}
\]
Now replace the \( y_k \) in the above with a linear combination of the vectors,
\[
\{x_1, z_1, \ldots, z_{s-1}\}
\]
to obtain
\[
v \in \text{span} \{x_1, z_1, \ldots, z_{s-1}\}.
\]
The vector \( y_k \), in the list \( \{y_1, \ldots, y_s\} \), has now been replaced with the vector \( x_1 \) and the resulting modified list of vectors has the same span as the original list of vectors, \( \{y_1, \ldots, y_s\} \).

Now suppose that \( r > s \) and that
\[
\text{span} (x_1, \ldots, x_l, z_1, \ldots, z_p) = V
\]
where the vectors, \( z_1, \ldots, z_p \) are each taken from the set, \( \{y_1, \ldots, y_s\} \) and \( l + p = s \). This has now been done for \( l = 1 \) above. Then since \( r > s \), it follows that \( l \leq s < r \) and so \( l + 1 \leq r \). Therefore, \( x_{l+1} \) is a vector not in the list, \( \{x_1, \ldots, x_l\} \) and since \( \text{span} \{x_1, \ldots, x_l, z_1, \ldots, z_p\} = V \), there exist scalars, \( c_i \) and \( d_j \) such that
\[
x_{l+1} = \sum_{i=1}^{l} c_i x_i + \sum_{j=1}^{p} d_j z_j. \tag{4.4.17}
\]
Now not all the \( d_j \) can equal zero because if this were so, it would follow that \( \{x_1, \ldots, x_r\} \) would be a linearly dependent set because one of the vectors would
equal a linear combination of the others. Therefore, (4.4.17) can be solved for one of the \( z_i \), say \( z_k \), in terms of \( x_{l+1} \) and the other \( z_i \) and just as in the above argument, replace that \( z_i \) with \( x_{l+1} \) to obtain

\[
\text{span} \left( x_1, \ldots, x_l, x_{l+1}, \overbrace{z_1, \ldots, z_{k-1}, z_{k+1}, \ldots, z_p}^{\text{p-1 vectors here}} \right) = V.
\]

Continue this way, eventually obtaining

\[
\text{span} (x_1, \ldots, x_s) = V.
\]

But then \( x_r \in \text{span} (x_1, \ldots, x_s) \) contrary to the assumption that \( \{x_1, \ldots, x_r\} \) is linearly independent. Therefore, \( r \leq s \) as claimed.

**Definition 4.4.4** A finite set of vectors, \( \{x_1, \ldots, x_r\} \) is a basis for \( \mathbb{F}^n \) if

\[
\text{span} (x_1, \ldots, x_r) = \mathbb{F}^n
\]

and \( \{x_1, \ldots, x_r\} \) is linearly independent.

**Corollary 4.4.5** Let \( \{x_1, \ldots, x_r\} \) and \( \{y_1, \ldots, y_s\} \) be two bases of \( \mathbb{F}^n \). Then \( r = s = n \).

**Proof:** From the exchange theorem, \( r \leq s \) and \( s \leq r \). Now note the vectors,

\[
e_i = (0, \ldots, 0, 1, 0 \ldots, 0)
\]

for \( i = 1, 2, \ldots, n \) are a basis for \( \mathbb{F}^n \). This proves the corollary.

**Lemma 4.4.6** Let \( \{v_1, \ldots, v_r\} \) be a set of vectors. Then \( V = \text{span} (v_1, \ldots, v_r) \) is a subspace.

**Proof:** Suppose \( \alpha, \beta \) are two scalars and let \( \sum_{k=1}^r c_k v_k \) and \( \sum_{k=1}^r d_k v_k \) are two elements of \( V \). What about

\[
\alpha \sum_{k=1}^r c_k v_k + \beta \sum_{k=1}^r d_k v_k?
\]

Is it also in \( V \)?

\[
\alpha \sum_{k=1}^r c_k v_k + \beta \sum_{k=1}^r d_k v_k = \sum_{k=1}^r (\alpha c_k + \beta d_k) v_k \in V
\]

so the answer is yes. This proves the lemma.

---

2This is the plural form of basis. We could say basiss but it would involve an inordinate amount of hissing as in “The sixth shiek’s sixth sheep is sick”. This is the reason that bases is used instead of basiss.
**Definition 4.4.7** A finite set of vectors, \( \{x_1, \ldots, x_r\} \) is a basis for a subspace, \( V \) of \( \mathbb{F}^n \) if \( \text{span} (x_1, \ldots, x_r) = V \) and \( \{x_1, \ldots, x_r\} \) is linearly independent.

**Corollary 4.4.8** Let \( \{x_1, \ldots, x_r\} \) and \( \{y_1, \ldots, y_s\} \) be two bases for \( V \). Then \( r = s \).

**Proof:** From the exchange theorem, \( r \leq s \) and \( s \leq r \). Therefore, this proves the corollary.

**Definition 4.4.9** Let \( V \) be a subspace of \( \mathbb{F}^n \). Then \( \dim (V) \) read as the dimension of \( V \) is the number of vectors in a basis.

Of course you should wonder right now whether an arbitrary subspace even has a basis. In fact it does and this is in the next theorem. First, here is an interesting lemma.

**Lemma 4.4.10** Suppose \( v \notin \text{span} (u_1, \ldots, u_k) \) and \( \{u_1, \ldots, u_k\} \) is linearly independent. Then \( \{u_1, \ldots, u_k, v\} \) is also linearly independent.

**Proof:** Suppose \( \sum_{i=1}^k c_i u_i + d v = 0 \). It is required to verify that each \( c_i = 0 \) and that \( d = 0 \). But if \( d \neq 0 \), then you can solve for \( v \) as a linear combination of the vectors, \( \{u_1, \ldots, u_k\} \),

\[
    v = -\frac{1}{d} \sum_{i=1}^k c_i u_i,
\]

contrary to assumption. Therefore, \( d = 0 \). But then \( \sum_{i=1}^k c_i u_i = 0 \) and the linear independence of \( \{u_1, \ldots, u_k\} \) implies each \( c_i = 0 \) also. This proves the lemma.

**Theorem 4.4.11** Let \( V \) be a nonzero subspace of \( \mathbb{F}^n \). Then \( V \) has a basis.

**Proof:** Let \( v_1 \in V \) where \( v_1 \neq 0 \). If \( \text{span} \{v_1\} = V \), stop. \( \{v_1\} \) is a basis for \( V \). Otherwise, there exists \( v_2 \in V \) which is not in \( \text{span} \{v_1\} \). By Lemma 4.4.10, \( \{v_1, v_2\} \) is a linearly independent set of vectors. If \( \text{span} \{v_1, v_2\} = V \), stop. \( \{v_1, v_2\} \) is a basis for \( V \). If \( \text{span} \{v_1, v_2\} \neq V \), then there exists \( v_3 \notin \text{span} \{v_1, v_2\} \) and \( \{v_1, v_2, v_3\} \) is a larger linearly independent set of vectors. Continuing this way, the process must stop before \( n + 1 \) steps because if not, it would be possible to obtain \( n + 1 \) linearly independent vectors contrary to the exchange theorem. This proves the theorem.

In words the following corollary states that any linearly independent set of vectors can be enlarged to form a basis.

**Corollary 4.4.12** Let \( V \) be a subspace of \( \mathbb{F}^n \) and let \( \{v_1, \ldots, v_r\} \) be a linearly independent set of vectors in \( V \). Then either it is a basis for \( V \) or there exist vectors, \( v_{r+1}, \ldots, v_s \) such that \( \{v_1, \ldots, v_r, v_{r+1}, \ldots, v_s\} \) is a basis for \( V \).

**Proof:** This follows immediately from the proof of Theorem 4.4.11. You do exactly the same argument except you start with \( \{v_1, \ldots, v_r\} \) rather than \( \{v_1\} \).

It is also true that any spanning set of vectors can be restricted to obtain a basis.
**Theorem 4.4.13** Let \( V \) be a subspace of \( \mathbb{F}^n \) and suppose \( \text{span} \left( u_1 \cdots u_p \right) = V \) where the \( u_i \) are nonzero vectors. Then there exist vectors, \( \{ v_1 \cdots v_r \} \subseteq \{ u_1 \cdots u_p \} \) and \( \{ v_1 \cdots v_r \} \) is a basis for \( V \).

**Proof:** Let \( r \) be the smallest positive integer with the property that for some set, \( \{ v_1 \cdots v_r \} \subseteq \{ u_1 \cdots u_p \} \),
\[
\text{span} (v_1 \cdots v_r) = V.
\]
Then \( r \leq p \) and it must be the case that \( \{ v_1 \cdots v_r \} \) is linearly independent because if it were not so, one of the vectors, say \( v_k \), would be a linear combination of the others. But then you could delete this vector from \( \{ v_1 \cdots v_r \} \) and the resulting list of \( r-1 \) vectors would still span \( V \) contrary to the definition of \( r \). This proves the theorem.

### 4.5 An Application To Matrices

The following is a theorem of major significance.

**Theorem 4.5.1** Suppose \( A \) is an \( n \times n \) matrix. Then \( A \) is one to one if and only if \( A \) is onto. Also, if \( B \) is an \( n \times n \) matrix and \( AB = I \), then it follows \( BA = I \).

**Proof:** First suppose \( A \) is one to one. Consider the vectors, \( \{ Ae_1 \cdots Ae_n \} \) where \( e_k \) is the column vector which is all zeros except for a 1 in the \( k^{th} \) position. This set of vectors is linearly independent because if
\[
\sum_{k=1}^{n} c_k Ae_k = 0,
\]
then since \( A \) is linear,
\[
A \left( \sum_{k=1}^{n} c_k e_k \right) = 0
\]
and since \( A \) is one to one, it follows
\[
\sum_{k=1}^{n} c_k e_k = \mathbf{0}
\]
which implies each \( c_k = 0 \). Therefore, \( \{ Ae_1 \cdots Ae_n \} \) must be a basis for \( \mathbb{F}^n \) because if not there would exist a vector, \( y \notin \text{span} \left( Ae_1 \cdots Ae_n \right) \) and then by Lemma 4.4.10, \( \{ Ae_1 \cdots Ae_n, y \} \) would be an independent set of vectors having \( n+1 \) vectors in it, contrary to the exchange theorem. It follows that for \( y \in \mathbb{F}^n \) there exist constants, \( c_i \) such that
\[
y = \sum_{k=1}^{n} c_k Ae_k = A \left( \sum_{k=1}^{n} c_k e_k \right)
\]
showing that, since \( y \) was arbitrary, \( A \) is onto.

Next suppose \( A \) is onto. This means the span of the columns of \( A \) equals \( F^n \). If these columns are not linearly independent, then by Lemma 4.4.2 on Page 66, one of the columns is a linear combination of the others and so the span of the columns of \( A \) equals the span of the \( n - 1 \) other columns. This violates the exchange theorem because \( \{e_1, \ldots, e_n\} \) would be a linearly independent set of vectors contained in the span of only \( n - 1 \) vectors. Therefore, the columns of \( A \) must be independent and this equivalent to saying that \( Ax = 0 \) if and only if \( x = 0 \). This implies \( A \) is one to one because if \( Ax = Ay \), then \( A(x - y) = 0 \) and so \( x - y = 0 \).

Now suppose \( AB = I \). Why is \( BA = I \)? Since \( AB = I \) it follows \( B \) is one to one since otherwise, there would exist, \( x \neq 0 \) such that \( Bx = 0 \) and then \( ABx = A0 = 0 \neq Ix \). Therefore, from what was just shown, \( B \) is also onto. In addition to this, \( A \) must be one to one because if \( Ay = 0 \), then \( y = Bx \) for some \( x \) and then \( x = ABx = Ay = 0 \) showing \( y = 0 \). Now from what is given to be so, it follows \( (AB)A = A \) and so using the associative law for matrix multiplication,

\[
A(BA) - A = A(BA - I) = 0.
\]

But this means \( (BA - I)x = 0 \) for all \( x \) since otherwise, \( A \) would not be one to one. Hence \( BA = I \) as claimed. This proves the theorem.

This theorem shows that if an \( n \times n \) matrix, \( B \) acts like an inverse when multiplied on one side of \( A \) it follows that \( B = A^{-1} \) and it will act like an inverse on both sides of \( A \).

The conclusion of this theorem pertains to square matrices only. For example, let

\[
A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & -1 \\ 1 & 0 & 0 \end{pmatrix}
\]

(4.5.18)

Then

\[
BA = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}
\]

but

\[
AB = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & -1 \\ 1 & 0 & 0 \end{pmatrix}.
\]

### 4.6 The Mathematical Theory Of Determinants

#### 4.6.1 The Function \( \text{sgn} \)

The following Lemma will be essential in the definition of the determinant.

**Lemma 4.6.1** There exists a function, \( \text{sgn}_n \), which maps each ordered list of numbers from \( \{1, \ldots, n\} \) to one of the three numbers, \( 0, 1, \) or \( -1 \) which also has the following properties.

\[
\text{sgn}_n (1, \ldots, n) = 1
\]

(4.6.19)
\[ \text{sgn}_n (i_1, \ldots, p, \ldots, q, \ldots, i_n) = - \text{sgn}_n (i_1, \ldots, q, \ldots, p, \ldots, i_n) \quad (4.6.20) \]

In words, the second property states that if two of the numbers are switched, the value of the function is multiplied by \(-1\). Also, in the case where \(n > 1\) and \(\{i_1, \ldots, i_n\} = \{1, \ldots, n\}\) so that every number from \(\{1, \ldots, n\}\) appears in the ordered list, \((i_1, \ldots, i_n)\),

\[ \text{sgn}_n (i_1, \ldots, i_{\theta - 1}, n, i_{\theta + 1}, \ldots, i_n) \equiv \]

\[ (-1)^{n-\theta} \text{sgn}_{n-1} (i_1, \ldots, i_{\theta - 1}, i_{\theta + 1}, \ldots, i_n) \quad (4.6.21) \]

where \(n = i_\theta\) in the ordered list, \((i_1, \ldots, i_n)\).

**Proof:** Define \(\text{sgn} (x) = 1\) if \(x > 0\), \(-1\) if \(x < 0\) and \(0\) if \(x = 0\). If \(n = 1\), there is only one list and it is just the number 1. Thus one can define \(\text{sgn}_1 (1) \equiv 1\). For the general case where \(n > 1\), simply define

\[ \text{sgn}_n (i_1, \ldots, i_n) \equiv \text{sign} \left( \prod_{r<s} (i_s - i_r) \right) \]

This delivers either \(-1, 1\), or 0 by definition. What about the other claims? Suppose you switch \(i_p\) with \(i_q\) where \(p < q\) so two numbers in the ordered list \((i_1, \ldots, i_n)\) are switched. Denote the new ordered list of numbers as \((j_1, \ldots, j_n)\). Thus \(j_p = i_q\) and \(j_q = i_p\) and if \(r \notin \{p, q\}, j_r = i_r\). See the following illustration

\[
\begin{array}{ccccccc}
  i_1 & i_2 & \ldots & i_p & \ldots & i_q & \ldots & i_n \\
  1 & 2 & \ldots & p & \ldots & q & \ldots & n \\

  i_1 & i_2 & \ldots & i_q & \ldots & i_p & \ldots & i_n \\
  1 & 2 & \ldots & q & \ldots & p & \ldots & n \\

  j_1 & j_2 & \ldots & j_p & \ldots & j_q & \ldots & j_n \\
  1 & 2 & \ldots & p & \ldots & q & \ldots & n \\
\end{array}
\]

Then

\[ \text{sgn}_n (j_1, \ldots, j_n) \equiv \text{sign} \left( \prod_{r<s} (j_s - j_r) \right) \]

\[ = \text{sign} \left( \prod_{p,q \text{ both } p,q} (i_p - i_q) \prod_{p,q \text{ one of } p,q} (i_j - i_q) \prod_{p,q \text{ neither } p \text{ nor } q} (i_p - i_j) \prod_{r<s, r,s \notin \{p,q\}} (i_s - i_r) \right) \]

The last product consists of the product of terms which were in the un-switched product \(\prod_{r<s} (i_s - i_r)\) so produces no change in sign, while the two products in the middle both introduce \(q - p - 1\) minus signs. Thus their product produces no
change in sign. The first factor is of opposite sign to the $i_q - i_p$ which occurred in $\text{sgn}_n (i_1, \cdots, i_n)$. Therefore, this switch introduced a minus sign and

$$\text{sgn}_n (j_1, \cdots, j_n) = - \text{sgn}_n (i_1, \cdots, i_n)$$

Now consider the last claim. In computing $\text{sgn}_n (i_1, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_n)$ there will be the product of $n - \theta$ negative terms

$$(i_{\theta+1} - n) \cdots (i_n - n)$$

and the other terms in the product for computing $\text{sgn}_n (i_1, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_n)$ are those which are required to compute $\text{sgn}_{n-1} (i_1, \cdots, i_{\theta-1}, i_{\theta+1}, \cdots, i_n)$ multiplied by terms of the form $(n - i_j)$ which are nonnegative. It follows that

$$\text{sgn}_n (i_1, \cdots, i_{\theta-1}, n, i_{\theta+1}, \cdots, i_n) = (-1)^{n-\theta} \text{sgn}_{n-1} (i_1, \cdots, i_{\theta-1}, i_{\theta+1}, \cdots, i_n)$$

It is obvious that if there are repeats in the list the function gives 0.  

\textbf{Lemma 4.6.2} Every ordered list of distinct numbers from \{1, 2, $\cdots$, n\} can be obtained from every other such ordered list by a finite number of switches. Also, \text{sgn}_n is unique.

\textbf{Proof:} This is obvious if $n = 1$ or 2. Suppose then that it is true for sets of $n - 1$ elements. Take two ordered lists of numbers, $P_1$, $P_2$. Make one switch in both to place $n$ at the end. Call the result $P_1^n$ and $P_2^n$. Then using induction, there are finitely many switches in $P_1^n$ so that it will coincide with $P_2^n$. Now switch the $n$ in what results to where it was in $P_2$.

To see \text{sgn}_n is unique, if there exist two functions, $f$ and $g$ both satisfying \ref{4.6.19} and \ref{4.6.20}, you could start with $f (1, \cdots, n) = g (1, \cdots, n) = 1$ and applying the same sequence of switches, eventually arrive at $f (i_1, \cdots, i_n) = g (i_1, \cdots, i_n)$. If any numbers are repeated, then \ref{4.6.20} gives both functions are equal to zero for that ordered list.  

\textbf{Definition 4.6.3} When you have an ordered list of distinct numbers from \{1, 2, $\cdots$, n\}, say

$$(i_1, \cdots, i_n),$$

this ordered list is called a permutation. The symbol for all such permutations is $S_n$. The number $\text{sgn}_n (i_1, \cdots, i_n)$ is called the sign of the permutation.

A permutation can also be considered as a function from the set

\{1, 2, $\cdots$, n\} to \{1, 2, $\cdots$, n\}

as follows. Let $f (k) = i_k$. Permutations are of fundamental importance in certain areas of math. For example, it was by considering permutations that Galois was able to give a criterion for solution of polynomial equations by radicals, but this is a different direction than what is being attempted here.

In what follows \text{sgn} will often be used rather than $\text{sgn}_n$ because the context supplies the appropriate $n$.  

\textbf{4.6. THE MATHEMATICAL THEORY OF DETERMINANTS} 73
4.7 The Determinant

**Definition 4.7.1** Let \( f \) be a function which has the set of ordered lists of numbers from \( \{1, \cdots, n\} \) as its domain. Define

\[
\sum_{(k_1, \cdots, k_n)} f(k_1 \cdots k_n)
\]

to be the sum of all the \( f(k_1 \cdots k_n) \) for all possible choices of ordered lists \( (k_1, \cdots, k_n) \) of numbers of \( \{1, \cdots, n\} \). For example,

\[
\sum_{(k_1, k_2)} f(k_1, k_2) = f(1,2) + f(2,1) + f(1,1) + f(2,2).
\]

**4.7.1 The Definition**

**Definition 4.7.2** Let \((a_{ij}) = A\) denote an \( n \times n \) matrix. The determinant of \( A \), denoted by \( \det(A) \) is defined by

\[
\det(A) \equiv \sum_{(k_1, \cdots, k_n)} \text{sgn}(k_1, \cdots, k_n) a_{1k_1} \cdots a_{nk_n}
\]

where the sum is taken over all ordered lists of numbers from \( \{1, \cdots, n\} \). Note it suffices to take the sum over only those ordered lists in which there are no repeats because if there are, \( \text{sgn}(k_1, \cdots, k_n) = 0 \) and so that term contributes 0 to the sum.

**4.7.2 Permuting Rows Or Columns**

Let \( A \) be an \( n \times n \) matrix, \( A = (a_{ij}) \) and let \( (r_1, \cdots, r_n) \) denote an ordered list of \( n \) numbers from \( \{1, \cdots, n\} \). Let \( A(r_1, \cdots, r_n) \) denote the matrix whose \( k^{th} \) row is the \( r_k \) row of the matrix \( A \). Thus

\[
\det(A(r_1, \cdots, r_n)) = \sum_{(k_1, \cdots, k_n)} \text{sgn}(k_1, \cdots, k_n) a_{r_1k_1} \cdots a_{r_nk_n} \quad (4.7.22)
\]

and

\[
A(1, \cdots, n) = A.
\]

**Proposition 4.7.3** Let

\[
(r_1, \cdots, r_n)
\]

be an ordered list of numbers from \( \{1, \cdots, n\} \). Then

\[
\text{sgn}(r_1, \cdots, r_n) \det(A)
\]

\[
= \sum_{(k_1, \cdots, k_n)} \text{sgn}(k_1, \cdots, k_n) a_{r_1k_1} \cdots a_{r_nk_n} \quad (4.7.23)
\]

\[
= \det(A(r_1, \cdots, r_n)). \quad (4.7.24)
\]
**Proof:** Let \((1, \cdots, n) = (1, \cdots, r, \cdots, s, \cdots, n)\) so \(r < s\).

\[
\det (A(1, \cdots, r, \cdots, s, \cdots, n)) = \sum_{(k_1, \cdots, k_n)} \text{sgn} (k_1, \cdots, k_r, \cdots, k_s, \cdots, k_n) a_{1k_1} \cdots a_{rk_r} \cdots a_{sk_s} \cdots a_{nk_n},
\]

and renaming the variables, calling \(k_s, k_r\) and \(k_r, k_s\), this equals

\[
= \sum_{(k_1, \cdots, k_n)} \text{sgn} (k_1, \cdots, k_s, \cdots, k_r, \cdots, k_n) a_{1k_1} \cdots a_{rk_r} \cdots a_{sk_s} \cdots a_{nk_n}
\]

These got switched

\[
= -\det (A(1, \cdots, s, \cdots, r, \cdots, n)).
\]

Consequently,

\[
\det (A(1, \cdots, s, \cdots, r, \cdots, n)) = -\det (A(1, \cdots, r, \cdots, s, \cdots, n)) = -\det (A)
\]

Now letting \(A(1, \cdots, s, \cdots, r, \cdots, n)\) play the role of \(A\), and continuing in this way, switching pairs of numbers,

\[
\det (A(r_1, \cdots, r_n)) = (-1)^p \det (A)
\]

where it took \(p\) switches to obtain \((r_1, \cdots, r_n)\) from \((1, \cdots, n)\). By Lemma \[4.6.1\], this implies

\[
\det (A(r_1, \cdots, r_n)) = (-1)^p \det (A) = \text{sgn} (r_1, \cdots, r_n) \det (A)
\]

and proves the proposition in the case when there are no repeated numbers in the ordered list, \((r_1, \cdots, r_n)\). However, if there is a repeat, say the \(r^{th}\) row equals the \(s^{th}\) row, then the reasoning of \[4.7.25\] to \[4.7.26\] shows that \(\det A(r_1, \cdots, r_n) = 0\) and also \(\text{sgn} (r_1, \cdots, r_n) = 0\) so the formula holds in this case also. \[\square\]

**Observation 4.7.4** \textit{There are} \(n!\) \textit{ordered lists of distinct numbers from} \(\{1, \cdots, n\}\).

To see this, consider \(n\) slots placed in order. There are \(n\) choices for the first slot. For each of these choices, there are \(n - 1\) choices for the second. Thus there are \(n (n - 1)\) ways to fill the first two slots. Then for each of these ways there are \(n - 2\) choices left for the third slot. Continuing this way, there are \(n!\) ordered lists of distinct numbers from \(\{1, \cdots, n\}\) as stated in the observation.
4.7.3 A Symmetric Definition

With the above, it is possible to give a more symmetric description of the determinant from which it will follow that \( \det(A) = \det(A^T) \).

**Corollary 4.7.5** The following formula for \( \det(A) \) is valid.

\[
\det(A) = \frac{1}{n!} \sum_{(r_1, \cdots, r_n) (k_1, \cdots, k_n)} \text{sgn}(r_1, \cdots, r_n) \text{sgn}(k_1, \cdots, k_n) a_{r_1 k_1} \cdots a_{r_n k_n}. \quad (4.7.27)
\]

And also \( \det(A^T) = \det(A) \) where \( A^T \) is the transpose of \( A \). (Recall that for \( A^T = (a_{ij}^T) \), \( a_{ij}^T = a_{ji} \).)

**Proof:** From Proposition 4.7.3, if the \( r_i \) are distinct,

\[
\det(A) = \sum_{(k_1, \cdots, k_n)} \text{sgn}(k_1, \cdots, k_n) a_{r_1 k_1} \cdots a_{r_n k_n}.
\]

Summing over all ordered lists, \( (r_1, \cdots, r_n) \) where the \( r_i \) are distinct. (If the \( r_i \) are not distinct, \( \text{sgn}(r_1, \cdots, r_n) = 0 \) and so there is no contribution to the sum.)

\[
n! \det(A) = \sum_{(r_1, \cdots, r_n) (k_1, \cdots, k_n)} \text{sgn}(r_1, \cdots, r_n) \text{sgn}(k_1, \cdots, k_n) a_{r_1 k_1} \cdots a_{r_n k_n}.
\]

This proves the corollary since the formula gives the same number for \( A \) as it does for \( A^T \).}

4.7.4 The Alternating Property Of The Determinant

**Corollary 4.7.6** If two rows or two columns in an \( n \times n \) matrix \( A \), are switched, the determinant of the resulting matrix equals \( (-1) \) times the determinant of the original matrix. If \( A \) is an \( n \times n \) matrix in which two rows are equal or two columns are equal then \( \det(A) = 0 \). Suppose the \( i^{th} \) row of \( A \) equals \( (xa_1 + yb_1, \cdots, xa_n + yb_n) \). Then

\[
\det(A) = x \det(A_1) + y \det(A_2)
\]

where the \( i^{th} \) row of \( A_1 \) is \( (a_1, \cdots, a_n) \) and the \( i^{th} \) row of \( A_2 \) is \( (b_1, \cdots, b_n) \), all other rows of \( A_1 \) and \( A_2 \) coinciding with those of \( A \). In other words, \( \det \) is a linear function of each row \( A \). The same is true with the word “row” replaced with the word “column”.

**Proof:** By Proposition 4.7.3 when two rows are switched, the determinant of the resulting matrix is \( (-1) \) times the determinant of the original matrix. By Corollary 4.7.5 the same holds for columns because the columns of the matrix equal the rows.
4.7. THE DETERMINANT

of the transposed matrix. Thus if $A_1$ is the matrix obtained from $A$ by switching two columns,
\[
\det(A) = \det(A^T) = -\det(A_1^T) = -\det(A_1)
\]
If $A$ has two equal columns or two equal rows, then switching them results in the same matrix. Therefore, $\det(A) = -\det(A)$ and so $\det(A) = 0$.

It remains to verify the last assertion.
\[
\det(A) = \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) a_{1k_1} \cdots (xa_{k_i} + yb_{k_i}) \cdots a_{nk_n}
\]
\[
= x \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) a_{1k_1} \cdots a_{k_i} \cdots a_{nk_n} + y \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) a_{1k_1} \cdots b_{k_i} \cdots a_{nk_n}
\]
\[
= x \det(A_1) + y \det(A_2).
\]
The same is true of columns because $\det(A^T) = \det(A)$ and the rows of $A^T$ are the columns of $A$.

4.7.5 Linear Combinations And Determinants

Linear combinations have been discussed already. However, here is a review and some new terminology.

**Definition 4.7.7** A vector $w$, is a linear combination of the vectors \( \{v_1, \ldots, v_r\} \) if there exists scalars, $c_1, \ldots, c_r$ such that $w = \sum_{k=1}^{r} c_k v_k$. This is the same as saying $w \in \text{span}(v_1, \ldots, v_r)$.

The following corollary is also of great use.

**Corollary 4.7.8** Suppose $A$ is an $n \times n$ matrix and some column (row) is a linear combination of $r$ other columns (rows). Then $\det(A) = 0$.

**Proof:** Let $A = (a_1, \ldots, a_n)$ be the columns of $A$ and suppose the condition that one column is a linear combination of $r$ of the others is satisfied. Then by using Corollary 4.7.6 the determinant of $A$ is zero if and only if the determinant of the matrix $B$, which has this special column placed in the last position, equals zero. Thus $a_n = \sum_{k=1}^{r} c_k a_k$ and so
\[
\det(B) = \det( a_1, \ldots, a_r, \sum_{k=1}^{r} c_k a_k ) = \det(B)
\]
By Corollary 4.7.6
\[
\det(B) = \sum_{k=1}^{r} c_k \det( a_1, \ldots, a_r, a_{n-1} ) = 0.
\]
because there are two equal columns. The case for rows follows from the fact that $\det(A) = \det(A^T)$. ■
4.7.6 The Determinant Of A Product

Recall the following definition of matrix multiplication.

**Definition 4.7.9** If $A$ and $B$ are $n \times n$ matrices, $A = (a_{ij})$ and $B = (b_{ij})$, $AB = (c_{ij})$ where

$$c_{ij} = \sum_{k=1}^{n} a_{ik} b_{kj}.$$ 

One of the most important rules about determinants is that the determinant of a product equals the product of the determinants.

**Theorem 4.7.10** Let $A$ and $B$ be $n \times n$ matrices. Then

$$\det(AB) = \det(A) \det(B).$$

**Proof:** Let $c_{ij}$ be the $ij^{th}$ entry of $AB$. Then by Proposition 4.7.3,

$$\det(AB) = \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) c_{1k_1} \cdots c_{nk_n}$$

$$= \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) \left( \sum_{r_1} a_{1r_1} b_{r_1 k_1} \right) \cdots \left( \sum_{r_n} a_{nr_n} b_{r_n k_n} \right)$$

$$= \sum_{(r_1 \cdots r_n)} \sum_{(k_1, \ldots, k_n)} \text{sgn}(k_1, \ldots, k_n) b_{r_1 k_1} \cdots b_{r_n k_n} (a_{1r_1} \cdots a_{nr_n})$$

$$= \sum_{(r_1 \cdots r_n)} \text{sgn}(r_1 \cdots r_n) a_{1r_1} \cdots a_{nr_n} \det(B) = \det(A) \det(B).$$

4.7.7 Cofactor Expansions

**Lemma 4.7.11** Suppose a matrix is of the form

$$M = \begin{pmatrix} A & * \\ 0 & a \end{pmatrix} \quad (4.7.28)$$

or

$$M = \begin{pmatrix} A & 0 \\ * & a \end{pmatrix} \quad (4.7.29)$$

where $a$ is a number and $A$ is an $(n-1) \times (n-1)$ matrix and $*$ denotes either a column or a row having length $n-1$ and the $0$ denotes either a column or a row of length $n-1$ consisting entirely of zeros. Then $\det(M) = a \det(A)$. 
4.7. THE DETERMINANT

Proof: Denote $M$ by $(m_{ij})$. Thus in the first case, $m_{nn} = a$ and $m_{ni} = 0$ if $i \neq n$ while in the second case, $m_{nn} = a$ and $m_{in} = 0$ if $i \neq n$. From the definition of the determinant,

$$\det(M) = \sum_{(k_1, \cdots, k_n)} \text{sgn}(k_1, \cdots, k_n) m_{1k_1} \cdots m_{nk_n}$$

Letting $\theta$ denote the position of $n$ in the ordered list, $(k_1, \cdots, k_n)$ then using Lemma 4.6.1, $\det(M)$ equals

$$\sum_{(k_1, \cdots, k_n)} (-1)^{n-\theta} \text{sgn}_{n-1}(k_1, \cdots, k_{\theta-1}, k_{\theta+1}, \cdots, k_n) m_{1k_1} \cdots m_{nk_n}$$

Now suppose $k_n \neq n$. Then if $k_n \neq n$, the term involving $m_{nk_n}$ in the above expression equals zero. Therefore, the only terms which survive are those for which $\theta = n$ or in other words, those for which $k_n = n$. Therefore, the above expression reduces to

$$a \sum_{(k_1, \cdots, k_{n-1})} \text{sgn}_{n-1}(k_1, \cdots, k_{n-1}) m_{1k_1} \cdots m_{(n-1)k_{n-1}} = a \det(A).$$

To get the assertion in the situation of $k_n = n$, use Corollary 4.7.5 and 4.7.29 to write

$$\det(M) = \det(M^T) = \det\left(\begin{pmatrix} A^T & 0 \\ * & a \end{pmatrix}\right) = a \det(A^T) = a \det(A).$$

In terms of the theory of determinants, arguably the most important idea is that of Laplace expansion along a row or a column. This will follow from the above definition of a determinant.

Definition 4.7.12 Let $A = (a_{ij})$ be an $n \times n$ matrix. Then a new matrix called the cofactor matrix, $\text{cof}(A)$ is defined by $\text{cof}(A) = (c_{ij})$ where to obtain $c_{ij}$ delete the $i$th row and the $j$th column of $A$, take the determinant of the $(n-1) \times (n-1)$ matrix which results, (This is called the ijth minor of $A$, ) and then multiply this number by $(-1)^{i+j}$. To make the formulas easier to remember, $\text{cof}(A)_{ij}$ will denote the ijth entry of the cofactor matrix.

The following is the main result. Earlier this was given as a definition and the outrageous totally unjustified assertion was made that the same number would be obtained by expanding the determinant along any row or column. The following theorem proves this assertion.

Theorem 4.7.13 Let $A$ be an $n \times n$ matrix where $n \geq 2$. Then

$$\det(A) = \sum_{j=1}^{n} a_{ij} \text{cof}(A)_{ij} = \sum_{i=1}^{n} a_{ij} \text{cof}(A)_{ij}. \quad (4.7.30)$$

The first formula consists of expanding the determinant along the $i$th row and the second expands the determinant along the $j$th column.
**Proof:** Let \((a_{i1}, \cdots, a_{in})\) be the \(i^{th}\) row of \(A\). Let \(B_j\) be the matrix obtained from \(A\) by leaving every row the same except the \(i^{th}\) row which in \(B_j\) equals

\[
(0, \cdots, 0, a_{ij}, 0, \cdots, 0).
\]

Then by Corollary 4.7.6,

\[
\det(A) = \sum_{j=1}^{n} \det(B_j)
\]

Denote by \(A^{ij}\) the \((n-1) \times (n-1)\) matrix obtained by deleting the \(i^{th}\) row and the \(j^{th}\) column of \(A\). Thus \(\text{cof}(A)_{ij} = (-1)^{i+j} \det(A^{ij})\). At this point, recall that from Proposition 4.7.3, when two rows or two columns in a matrix \(M\), are switched, this results in multiplying the determinant of the old matrix by \(-1\) to get the determinant of the new matrix. Therefore, by Lemma 4.7.11,

\[
\det(B_j) = (-1)^{n-j} (-1)^{n-i} \det \left( \begin{pmatrix} A^{ij} & * \\ 0 & a_{ij} \end{pmatrix} \right) = (-1)^{i+j} \det \left( \begin{pmatrix} A^{ij} & * \\ 0 & a_{ij} \end{pmatrix} \right) = a_{ij} \cdot \text{cof}(A)_{ij}.
\]

Therefore,

\[
\det(A) = \sum_{j=1}^{n} a_{ij} \cdot \text{cof}(A)_{ij}
\]

which is the formula for expanding \(\det(A)\) along the \(i^{th}\) row. Also,

\[
\det(A) = \det(A^T) = \sum_{j=1}^{n} a_{ij} \cdot \text{cof}(A^T)_{ij} = \sum_{j=1}^{n} a_{ji} \cdot \text{cof}(A)_{ji}
\]

which is the formula for expanding \(\det(A)\) along the \(i^{th}\) column. ■

### 4.7.8 Formula For The Inverse

Note that this gives an easy way to write a formula for the inverse of an \(n \times n\) matrix.

**Theorem 4.7.14** \(A^{-1}\) exists if and only if \(\det(A) \neq 0\). If \(\det(A) \neq 0\), then \(A^{-1} = (a^{-1}_{ij})\) where

\[
a^{-1}_{ij} = \det(A)^{-1} \cdot \text{cof}(A)_{ji}
\]

for \(\text{cof}(A)_{ij}\) the \(ij^{th}\) cofactor of \(A\).
4.7. THE DETERMINANT

Proof: By Theorem 4.7.13 and letting \((a_{ir}) = A\), if \(\det(A) \neq 0\),
\[
\sum_{i=1}^{n} a_{ir} \cof(A)_{ir} \det(A)^{-1} = \det(A) \det(A)^{-1} = 1.
\]
Now consider
\[
\sum_{i=1}^{n} a_{ir} \cof(A)_{ik} \det(A)^{-1}
\]
when \(k \neq r\). Replace the \(k^{th}\) column with the \(r^{th}\) column to obtain a matrix \(B_k\) whose determinant equals zero by Corollary 4.7.6. However, expanding this matrix along the \(k^{th}\) column yields
\[
0 = \det(B_k) \det(A)^{-1} = \sum_{i=1}^{n} a_{ir} \cof(A)_{ik} \det(A)^{-1}
\]
Summarizing,
\[
\sum_{i=1}^{n} a_{ir} \cof(A)_{ik} \det(A)^{-1} = \delta_{rk}.
\]
Using the other formula in Theorem 4.7.13 and similar reasoning,
\[
\sum_{j=1}^{n} a_{rj} \cof(A)_{kj} \det(A)^{-1} = \delta_{rk}
\]
This proves that if \(\det(A) \neq 0\), then \(A^{-1}\) exists with \(A^{-1} = (a_{ij}^{-1})\), where
\[
a_{ij}^{-1} = \cof(A)_{ji} \det(A)^{-1}.
\]
Now suppose \(A^{-1}\) exists. Then by Theorem 4.7.10,
\[
1 = \det(I) = \det(AA^{-1}) = \det(A) \det(A^{-1})
\]
so \(\det(A) \neq 0\). 

The next corollary points out that if an \(n \times n\) matrix \(A\) has a right or a left inverse, then it has an inverse.

Corollary 4.7.15 Let \(A\) be an \(n \times n\) matrix and suppose there exists an \(n \times n\) matrix \(B\) such that \(BA = I\). Then \(A^{-1}\) exists and \(A^{-1} = B\). Also, if there exists \(C\) an \(n \times n\) matrix such that \(AC = I\), then \(A^{-1}\) exists and \(A^{-1} = C\).

Proof: Since \(BA = I\), Theorem 4.7.11 implies
\[
\det(B \det A) = 1
\]
and so \(\det A \neq 0\). Therefore from Theorem 4.7.11, \(A^{-1}\) exists. Therefore,
\[
A^{-1} = (BA) A^{-1} = B (AA^{-1}) = BI = B.
\]
The case where $CA = I$ is handled similarly.

The conclusion of this corollary is that left inverses, right inverses and inverses are all the same in the context of $n \times n$ matrices.

Theorem 4.7.14 says that to find the inverse, take the transpose of the cofactor matrix and divide by the determinant. The transpose of the cofactor matrix is called the adjugate or sometimes the classical adjoint of the matrix $A$. It is an abomination to call it the adjoint although you do sometimes see it referred to in this way. In words, $A^{-1}$ is equal to one over the determinant of $A$ times the adjugate matrix of $A$.

### 4.7.9 Cramer’s Rule

In case you are solving a system of equations, $Ax = y$ for $x$, it follows that if $A^{-1}$ exists,

$$x = (A^{-1}A)x = A^{-1}(Ax) = A^{-1}y$$

thus solving the system. Now in the case that $A^{-1}$ exists, there is a formula for $A^{-1}$ given above. Using this formula,

$$x_i = \sum_{j=1}^{n} a^{-1}_{ij}y_j = \sum_{j=1}^{n} \frac{1}{\det(A)} \text{cof}(A)_{ji}y_j.$$ 

By the formula for the expansion of a determinant along a column,

$$x_i = \frac{1}{\det(A)} \text{det} \begin{pmatrix} * & \cdots & y_1 & \cdots & * \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ * & \cdots & y_n & \cdots & * \end{pmatrix},$$

where here the $i^{th}$ column of $A$ is replaced with the column vector $(y_1, \ldots, y_n)^T$, and the determinant of this modified matrix is taken and divided by $\det(A)$. This formula is known as Cramer’s rule.

### 4.7.10 Upper Triangular Matrices

**Definition 4.7.16** A matrix $M$, is upper triangular if $M_{ij} = 0$ whenever $i > j$.

Thus such a matrix equals zero below the main diagonal, the entries of the form $M_{ii}$ as shown.

$$\begin{pmatrix} * & * & \cdots & * \\ 0 & * & \cdots & * \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & * \end{pmatrix}$$

A lower triangular matrix is defined similarly as a matrix for which all entries above the main diagonal are equal to zero.

With this definition, here is a simple corollary of Theorem 4.7.13.
Corollary 4.7.17 Let M be an upper (lower) triangular matrix. Then det (M) is obtained by taking the product of the entries on the main diagonal.

4.8 The Cayley Hamilton Theorem*

Definition 4.8.1 Let A be an n×n matrix. The characteristic polynomial is defined as

\[ q_A(t) \equiv \det(tI - A) \]

and the solutions to \( q_A(t) = 0 \) are called eigenvalues. For A a matrix and \( p(t) = t^n + a_{n-1}t^{n-1} + \cdots + a_1t + a_0 \), denote by \( p(A) \) the matrix defined by

\[ p(A) \equiv A^n + a_{n-1}A^{n-1} + \cdots + a_1A + a_0I. \]

The explanation for the last term is that \( A^0 \) is interpreted as \( I \), the identity matrix.

The Cayley Hamilton theorem states that every matrix satisfies its characteristic equation, that equation defined by \( q_A(t) = 0 \). It is one of the most important theorems in linear algebra\(^4\). The proof in this section is not the most general proof, but works well when the field of scalars is \( \mathbb{R} \) or \( \mathbb{C} \). The following lemma will help with its proof.

Lemma 4.8.2 Suppose for all \(|\lambda|\) large enough,

\[ A_0 + A_1\lambda + \cdots + A_m\lambda^m = 0, \]

where the \( A_i \) are \( n \times n \) matrices. Then each \( A_i = 0 \).

Proof: Multiply by \( \lambda^{-m} \) to obtain

\[ A_0\lambda^{-m} + A_1\lambda^{-m+1} + \cdots + A_{m-1}\lambda^{-1} + A_m = 0. \]

Now let \(|\lambda| \to \infty\) to obtain \( A_m = 0 \). With this, multiply by \( \lambda \) to obtain

\[ A_0\lambda^{-m+1} + A_1\lambda^{-m+2} + \cdots + A_{m-1} = 0. \]

Now let \(|\lambda| \to \infty\) to obtain \( A_{m-1} = 0 \). Continue multiplying by \( \lambda \) and letting \( \lambda \to \infty \) to obtain that all the \( A_i = 0 \). \( \blacksquare \)

With the lemma, here is a simple corollary.

Corollary 4.8.3 Let \( A_i \) and \( B_i \) be \( n \times n \) matrices and suppose

\[ A_0 + A_1\lambda + \cdots + A_m\lambda^m = B_0 + B_1\lambda + \cdots + B_m\lambda^m \]

for all \(|\lambda|\) large enough. Then \( A_i = B_i \) for all \( i \). If \( A_i = B_i \) for each \( A_i, B_i \) then one can substitute an \( n \times n \) matrix \( M \) for \( \lambda \) and the identity will continue to hold.

\(^4\)A special case was first proved by Hamilton in 1853. The general case was announced by Cayley some time later and a proof was given by Frobenius in 1878.
Proof: Subtract and use the result of the lemma. The last claim is obvious by matching terms.

With this preparation, here is a relatively easy proof of the Cayley Hamilton theorem.

**Theorem 4.8.4** Let $A$ be an $n \times n$ matrix and let $q(\lambda) \equiv \det(\lambda I - A)$ be the characteristic polynomial. Then $q(A) = 0$.

**Proof:** Let $C(\lambda)$ equal the transpose of the cofactor matrix of $(\lambda I - A)$ for $|\lambda|$ large. (If $|\lambda|$ is large enough, then $\lambda$ cannot be in the finite list of eigenvalues of $A$ and so for such $\lambda$, $(\lambda I - A)^{-1}$ exists.) Therefore, by Theorem 4.7.14

$$C(\lambda) = q(\lambda)(\lambda I - A)^{-1}.$$

Say

$$q(\lambda) = a_0 + a_1 \lambda + \cdots + \lambda^n$$

Note that each entry in $C(\lambda)$ is a polynomial in $\lambda$ having degree no more than $n - 1$. For example, you might have something like

$$C(\lambda) = \begin{pmatrix} 9 & 3 & 0 \\ -6 & 0 & 0 \\ -1 & -1 & 2 \end{pmatrix} + \lambda \begin{pmatrix} -6 & -1 & 0 \\ 2 & -3 & 0 \\ 1 & 1 & -3 \end{pmatrix} + \lambda^2 \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Therefore, collecting the terms in the general case,

$$C(\lambda) = C_0 + C_1 \lambda + \cdots + C_{n-1} \lambda^{n-1}$$

for $C_j$ some $n \times n$ matrix. Then

$$C(\lambda)(\lambda I - A) = (C_0 + C_1 \lambda + \cdots + C_{n-1} \lambda^{n-1})(\lambda I - A) = q(\lambda)I$$

Then multiplying out the middle term, it follows that for all $|\lambda|$ sufficiently large,

$$a_0 I + a_1 I \lambda + \cdots + I \lambda^n = C_0 \lambda + C_1 \lambda^2 + \cdots + C_{n-1} \lambda^n$$

Then

$$- [C_0 A + C_1 A \lambda + \cdots + C_{n-1} A \lambda^{n-1}]$$

$$= -C_0 A + (C_0 - C_1 A) \lambda + (C_1 - C_2 A) \lambda^2 + \cdots + (C_{n-2} - C_{n-1} A) \lambda^{n-1} + C_{n-1} \lambda^n$$

Then, using Corollary 4.8.3, one can replace $\lambda$ on both sides with $A$. Then the right side is seen to equal 0. Hence the left side, $q(A)I$ is also equal to 0. ■
4.9 An Identity Of Cauchy

There is a very interesting identity for determinants due to Cauchy.

**Theorem 4.9.1** The following identity holds.

\[
\prod_{i,j} (a_i + b_j) \left| \begin{array}{ccc}
\frac{1}{a_1 + b_1} & \cdots & \frac{1}{a_1 + b_n} \\
\vdots & \ddots & \vdots \\
\frac{1}{a_n + b_1} & \cdots & \frac{1}{a_n + b_n}
\end{array} \right| = \prod_{j<i} (a_i - a_j) (b_i - b_j). \tag{4.9.31}
\]

**Proof:** What is the exponent of \(a_2\) on the right? It occurs in \((a_2 - a_1)\) and in \((a_m - a_2)\) for \(m > 2\). Therefore, there are exactly \(n - 1\) factors which contain \(a_2\). Therefore, \(a_2\) has an exponent of \(n - 1\). Similarly, each \(a_k\) is raised to the \(n - 1\) power and the same holds for the \(b_k\) as well. Therefore, the right side of (4.9.31) is of the form

\[c a_1^{n-1} a_2^{n-1} \cdots a_n^{n-1} b_1^{n-1} \cdots b_n^{n-1}\]

where \(c\) is some constant. Now consider the left side of (4.9.31).

This is of the form

\[
\frac{1}{n!} \prod_{i,j} (a_i + b_j) \sum_{i_1 \cdots i_n, j_1 \cdots j_n} \frac{1}{a_{i_1} + b_{j_1}} \frac{1}{a_{i_2} + b_{j_2}} \cdots \frac{1}{a_{i_n} + b_{j_n}}.
\]

For a given \(i_1 \cdots i_n, j_1 \cdots j_n\), let

\[S(i_1 \cdots i_n, j_1 \cdots j_n) \equiv \{(i_1, j_1), (i_2, j_2), \ldots, (i_n, j_n)\}.
\]

This equals

\[
\frac{1}{n!} \sum_{i_1 \cdots i_n, j_1 \cdots j_n} \text{sgn}(i_1 \cdots i_n) \text{sgn}(j_1 \cdots j_n) \prod_{(i,j) \notin \{(i_1,j_1),(i_2,j_2),\ldots,(i_n,j_n)\}} (a_i + b_j)
\]

where you can assume the \(i_k\) are all distinct and the \(j_k\) are also all distinct because otherwise \(\text{sgn}\) will produce a 0. Therefore, in

\[
\prod_{(i,j) \notin \{(i_1,j_1),(i_2,j_2),\ldots,(i_n,j_n)\}} (a_i + b_j),
\]

there are exactly \(n - 1\) factors which contain \(a_k\) for each \(k\) and similarly, there are exactly \(n - 1\) factors which contain \(b_k\) for each \(k\). Therefore, the left side of (4.9.31) is of the form

\[da_1^{n-1} a_2^{n-1} \cdots a_n^{n-1} b_1^{n-1} \cdots b_n^{n-1}\]
and it remains to verify that \( c = d \). Using the properties of determinants, the left side of (4.9.31) is of the form

\[
\prod_{i \neq j} (a_i + b_j)
\]

Let \( a_k \to -b_k \). Then this converges to \( \prod_{i \neq j} (-b_i + b_j) \). The right side of (4.9.31) converges to

\[
\prod_{j < i} (-b_i + b_j) (b_i - b_j) = \prod_{i \neq j} (-b_i + b_j).
\]

Therefore, \( d = c \) and this proves the identity.

### 4.10 Block Multiplication Of Matrices

Consider the following problem

\[
\begin{pmatrix}
A & B \\
C & D
\end{pmatrix}
\begin{pmatrix}
E & F \\
G & H
\end{pmatrix}
\]

You know how to do this. You get

\[
\begin{pmatrix}
AE + BG & AF + BH \\
CE + DG & CF + DH
\end{pmatrix}.
\]

Now what if instead of numbers, the entries, \( A, B, C, D, E, F, G \) are matrices of a size such that the multiplications and additions needed in the above formula all make sense. Would the formula be true in this case? I will show below that this is true.

Suppose \( A \) is a matrix of the form

\[
A = \begin{pmatrix}
A_{11} & \cdots & A_{1m} \\
\vdots & \ddots & \vdots \\
A_{r1} & \cdots & A_{rm}
\end{pmatrix}
\]

where \( A_{ij} \) is a \( s_i \times p_j \) matrix where \( s_i \) is constant for \( j = 1, \cdots, m \) for each \( i = 1, \cdots, r \). Such a matrix is called a block matrix, also a partitioned matrix. How do you get the block \( A_{ij} \)? Here is how for \( A \) an \( m \times n \) matrix:

\[
\begin{pmatrix}
\underbrace{0}_{s_i \times m} & I_{s_i \times s_i} & \underbrace{0}_{n \times p_j}
\end{pmatrix}A
\]

\[
\begin{pmatrix}
\underbrace{I_{p_j \times p_j}}_{n \times p_j} & \underbrace{0}_{n \times p_j}
\end{pmatrix}.
\]
4.10. BLOCK MULTIPLICATION OF MATRICES

In the block column matrix on the right, you need to have $c_j - 1$ rows of zeros above the small $p_j \times p_j$ identity matrix where the columns of $A$ involved in $A_{ij}$ are $c_j, \ldots, c_j + p_j$ and in the block row matrix on the left, you need to have $r_i - 1$ columns of zeros to the left of the $s_i \times s_i$ identity matrix where the rows of $A$ involved in $A_{ij}$ are $r_i, \ldots, r_i + s_i$. An important observation to make is that the matrix on the right specifies columns to use in the block and the one on the left specifies the rows used. There is no overlap between the blocks of $A$: Thus the identity $n \times n$ identity matrix corresponding to multiplication on the right of $A$ is of the form

$$
\begin{pmatrix}
I_{p_1 \times p_1} & 0 \\
& \ddots \\
& & I_{p_m \times p_m}
\end{pmatrix}
$$

these little identity matrices don’t overlap. A similar conclusion follows from consideration of the matrices $I_{s_i \times s_i}$.

Next consider the question of multiplication of two block matrices. Let $B$ be a block matrix of the form

$$
\begin{pmatrix}
B_{11} & \cdots & B_{1p} \\
\vdots & \ddots & \vdots \\
B_{r1} & \cdots & B_{rp}
\end{pmatrix}
$$

and $A$ is a block matrix of the form

$$
\begin{pmatrix}
A_{11} & \cdots & A_{1m} \\
\vdots & \ddots & \vdots \\
A_{p1} & \cdots & A_{pm}
\end{pmatrix}
$$

and that for all $i, j$, it makes sense to multiply $B_{is}A_{sj}$ for all $s \in \{1, \ldots, p\}$. (That is the two matrices, $B_{is}$ and $A_{sj}$ are conformable.) and that for fixed $ij$, it follows $B_{is}A_{sj}$ is the same size for each $s$ so that it makes sense to write $\sum_s B_{is}A_{sj}$.

The following theorem says essentially that when you take the product of two matrices, you can do it two ways. One way is to simply multiply them forming $BA$. The other way is to partition both matrices, formally multiply the blocks to get another block matrix and this one will be $BA$ partitioned. Before presenting this theorem, here is a simple lemma which is really a special case of the theorem.

**Lemma 4.10.1** Consider the following product.

$$
\begin{pmatrix}
0 \\
I \\
0
\end{pmatrix}
\begin{pmatrix}
0 & I & 0 \\
0 & I & 0 \\
0 & 0 & 0
\end{pmatrix}
$$

where the first is $n \times r$ and the second is $r \times n$. The small identity matrix $I$ is an $r \times r$ matrix and there are $l$ zero rows above $I$ and $l$ zero columns to the left of $I$ in the right matrix. Then the product of these matrices is a block matrix of the form

$$
\begin{pmatrix}
0 & 0 & 0 \\
0 & I & 0 \\
0 & 0 & 0
\end{pmatrix}
$$
Proof: From the definition of the way you multiply matrices, the product is

\[
\begin{pmatrix}
0 & 0 & \cdots & 0 \\
I & I & \cdots & I \\
0 & 0 & \cdots & 0 \\
\end{pmatrix}
\begin{pmatrix}
e_1 \\
e_r \\
e_1 \\
\end{pmatrix}
\begin{pmatrix}
e_1 \\
e_r \\
e_1 \\
\end{pmatrix}
\]

which yields the claimed result. In the formula $e_j$ refers to the column vector of length $r$ which has a 1 in the $j$th position. This proves the lemma.

Theorem 4.10.2 Let $B$ be a $q \times p$ block matrix as in 4.10.34 and let $A$ be a $p \times n$ block matrix as in 4.10.35 such that $B_{is}$ is conformable with $A_{sj}$ and each product, $B_{is}A_{sj}$ for $s = 1, \cdots, p$ is of the same size so they can be added. Then $BA$ can be obtained as a block matrix such that the $ij$th block is of the form

\[
\sum_s B_{is}A_{sj}.
\]  

(4.10.36)

Proof: From 4.10.33

\[
B_{is}A_{sj} = \begin{pmatrix}
0 & I_{r_i \times r_i} & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{pmatrix} \begin{pmatrix}
I_{p_s \times p_s} \\
0 \\
0 \\
\end{pmatrix} \begin{pmatrix}
0 & I_{p_s \times p_s} & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{pmatrix} A \begin{pmatrix}
0 & 0 & 0 \\
I_{q_j \times q_j} \\
I_{q_j \times q_j} \\
0 & 0 & 0 \\
\end{pmatrix}
\]

where here it is assumed $B_{is}$ is $r_i \times p_s$ and $A_{sj}$ is $p_s \times q_j$. The product involves the $s$th block in the $i$th row of blocks for $B$ and the $s$th block in the $j$th column of $A$. Thus there are the same number of rows above the $I_{p_s \times p_s}$ as there are columns to the left of $I_{p_s \times p_s}$ in those two inside matrices. Then from Lemma 4.10.1

\[
\begin{pmatrix}
I_{p_s \times p_s} \\
0 \\
0 \\
\end{pmatrix} \begin{pmatrix}
0 & I_{p_s \times p_s} & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{pmatrix} = \begin{pmatrix}
0 & 0 & 0 \\
I_{p_s \times p_s} \\
I_{p_s \times p_s} \\
\end{pmatrix}
\]

Since the blocks of small identity matrices do not overlap,

\[
\sum_s \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & I_{p_s \times p_s} & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{pmatrix} = \begin{pmatrix}
I_{p_1 \times p_1} & 0 & \cdots & 0 \\
0 & \cdots & 0 \\
0 & \cdots & 0 \\
I_{p_p \times p_p} & \cdots & 0 \\
\end{pmatrix}
\]

and so

\[
\sum_s B_{is}A_{sj} =
\]

\[
\sum_s \begin{pmatrix}
0 & I_{r_i \times r_i} & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{pmatrix} B A \begin{pmatrix}
0 & 0 & 0 \\
I_{q_j \times q_j} \\
I_{q_j \times q_j} \\
0 & 0 & 0 \\
\end{pmatrix} = \begin{pmatrix}
0 & I_{r_i \times r_i} & 0 \\
0 & 0 & 0 \\
0 & 0 & 0 \\
\end{pmatrix} B A \begin{pmatrix}
0 & 0 & 0 \\
I_{q_j \times q_j} \\
I_{q_j \times q_j} \\
0 & 0 & 0 \\
\end{pmatrix}
\]
Hence the $ij$th block of $BA$ equals the formal multiplication according to matrix multiplication,

$$
\sum_s B_{is} A_{sj}.
$$

This proves the theorem.

**Example 4.10.3** Let an $n \times n$ matrix have the form

$$
A = \begin{pmatrix}
a & b \\
c & P
\end{pmatrix}
$$

where $P$ is $n - 1 \times n - 1$. Multiply it by

$$
B = \begin{pmatrix}
p & q \\
r & Q
\end{pmatrix}
$$

where $B$ is also an $n \times n$ matrix and $Q$ is $n - 1 \times n - 1$.

You use block multiplication

$$
\begin{pmatrix}
a & b \\
c & P
\end{pmatrix}
\begin{pmatrix}
p & q \\
r & Q
\end{pmatrix}
= \begin{pmatrix}
ap + br & aq + bQ \\
pc + Pr & cq + PQ
\end{pmatrix}
$$

Note that this all makes sense. For example, $b = 1 \times n - 1$ and $r = n - 1 \times 1$ so $br$ is a $1 \times 1$. Similar considerations apply to the other blocks.

Here is an interesting and significant application of block multiplication. In this theorem, $p_M(t)$ denotes the characteristic polynomial, $\det(tI - M)$. Thus the zeros of this polynomial are the eigenvalues of the matrix, $M$.

**Theorem 4.10.4** Let $A$ be an $m \times n$ matrix and let $B$ be an $n \times m$ matrix for $m \leq n$. Then

$$
p_{BA}(t) = t^{n-m}p_{AB}(t),
$$

so the eigenvalues of $BA$ and $AB$ are the same including multiplicities except that $BA$ has $n - m$ extra zero eigenvalues.

**Proof:** Use block multiplication to write

$$
\begin{pmatrix}
AB & 0 \\
B & 0
\end{pmatrix}
\begin{pmatrix}
I & A \\
0 & I
\end{pmatrix}
= \begin{pmatrix}
AB & ABA \\
B & BA
\end{pmatrix},
$$

$$
\begin{pmatrix}
I & A \\
0 & I
\end{pmatrix}^{-1}
\begin{pmatrix}
AB & 0 \\
B & 0
\end{pmatrix}
\begin{pmatrix}
I & A \\
0 & I
\end{pmatrix}
= \begin{pmatrix}
0 & 0 \\
B & BA
\end{pmatrix}.
$$
Since the two matrices above are similar it follows that 
\[
\begin{pmatrix}
0 & 0 \\
B & BA
\end{pmatrix}
\] 
and
\[
\begin{pmatrix}
AB & 0 \\
B & 0
\end{pmatrix}
\] 
have the same characteristic polynomials. Therefore, noting that \(BA\) is an \(n \times n\) matrix and \(AB\) is an \(m \times m\) matrix,
\[
t^m \det (tI - BA) = t^n \det (tI - AB)
\]
and so \(\det (tI - BA) = p_{BA}(t) = t^{n-m} \det (tI - AB) = t^{n-m}p_{AB}(t)\). This proves the theorem.

### 4.11 Exercises

1. Show that matrix multiplication is associative. That is, \((AB)C = A(BC)\).

2. Show the inverse of a matrix, if it exists, is unique. Thus if \(AB = BA = I\), then \(B = A^{-1}\).

3. In the proof of Theorem 4.7.14 it was claimed that \(\det (I) = 1\). Here \(I = (\delta_{ij})\). Prove this assertion. Also prove Corollary 4.7.17.

4. Let \(v_1, \ldots, v_n\) be vectors in \(\mathbb{F}^n\) and let \(M(v_1, \ldots, v_n)\) denote the matrix whose \(i^{th}\) column equals \(v_i\). Define
\[
d(v_1, \ldots, v_n) \equiv \det (M(v_1, \ldots, v_n))
\]
Prove that \(d\) is linear in each variable, (multilinear), that
\[
d(v_1, \ldots, v_i, \ldots, v_j, \ldots, v_n) = -d(v_1, \ldots, v_j, \ldots, v_i, \ldots, v_n),
\]
and
\[
d(e_1, \ldots, e_n) = 1
\]
where here \(e_j\) is the vector in \(\mathbb{F}^n\) which has a zero in every position except the \(j^{th}\) position in which it has a one.

5. Suppose \(f : \mathbb{F}^n \times \cdots \times \mathbb{F}^n \rightarrow \mathbb{F}\) satisfies Lemma 4.11.37 and 4.11.38 and is linear in each variable. Show that \(f = d\).

6. Show that if you replace a row (column) of an \(n \times n\) matrix \(A\) with itself added to some multiple of another row (column) then the new matrix has the same determinant as the original one.

7. If \(A = (a_{ij})\), show \(\det (A) = \sum_{(k_1, \ldots, k_n) sgn (k_1, \ldots, k_n) a_{k_1} \cdots a_{k_n}}\).

8. Use the result of Problem 4 to evaluate by hand the determinant
\[
\det \begin{pmatrix}
1 & 2 & 3 & 2 \\
-6 & 3 & 2 & 3 \\
5 & 2 & 2 & 3 \\
3 & 4 & 6 & 4
\end{pmatrix}.
\]
9. Find the inverse if it exists of the matrix,
\[
\begin{pmatrix}
e^t & \cos t & \sin t \\
e^t & -\sin t & \cos t \\
e^t & -\cos t & -\sin t
\end{pmatrix}.
\]

10. Let \( Ly = y^{(n)} + a_{n-1}(x)y^{(n-1)} + \cdots + a_1(x)y' + a_0(x)y \) where the \( a_i \) are given continuous functions defined on a closed interval, \((a, b)\) and \( y \) is some function which has \( n \) derivatives so it makes sense to write \( Ly \). Suppose \( Ly_k = 0 \) for \( k = 1, 2, \cdots, n \). The Wronskian of these functions, \( y_i \) is defined as
\[
W(y_1, \cdots, y_n)(x) \equiv \det \begin{pmatrix} y_1(x) & \cdots & y_n(x) \\
y_1'(x) & \cdots & y_n'(x) \\
\vdots & & \vdots \\
y_1^{(n-1)}(x) & \cdots & y_n^{(n-1)}(x) \end{pmatrix}
\]
Show that for \( W(x) = W(y_1, \cdots, y_n)(x) \) to save space,
\[
W'(x) = \det \begin{pmatrix} y_1(x) & \cdots & y_n(x) \\
y_1'(x) & \cdots & y_n'(x) \\
\vdots & & \vdots \\
y_1^{(n)}(x) & \cdots & y_n^{(n)}(x) \end{pmatrix}
\]
Now use the differential equation, \( Ly = 0 \) which is satisfied by each of these functions, \( y_i \) and properties of determinants presented above to verify that \( W' + a_{n-1}(x)W = 0 \). Give an explicit solution of this linear differential equation, Abel’s formula, and use your answer to verify that the Wronskian of these solutions to the equation, \( Ly = 0 \) either vanishes identically on \((a, b)\) or never.

11. Two \( n \times n \) matrices, \( A \) and \( B \), are similar if \( B = S^{-1}AS \) for some invertible \( n \times n \) matrix, \( S \). Show that if two matrices are similar, they have the same characteristic polynomials.

12. Suppose the characteristic polynomial of an \( n \times n \) matrix, \( A \) is of the form
\[
t^n + a_{n-1}t^{n-1} + \cdots + a_1t + a_0
\]
and that \( a_0 \neq 0 \). Find a formula \( A^{-1} \) in terms of powers of the matrix, \( A \). Show that \( A^{-1} \) exists if and only if \( a_0 \neq 0 \).

13. In constitutive modeling of the stress and strain tensors, one sometimes considers sums of the form \( \sum_{k=0}^{\infty} a_k A^k \) where \( A \) is a \( 3 \times 3 \) matrix. Show using the Cayley Hamilton theorem that if such a thing makes any sense, you can always obtain it as a finite sum having no more than \( n \) terms.
CHAPTER 4. SOME IMPORTANT LINEAR ALGEBRA

4.12 Shur’s Theorem

Every matrix is related to an upper triangular matrix in a particularly significant way. This is Shur’s theorem and it is the most important theorem in the spectral theory of matrices.

Lemma 4.12.1 Let

\[ \{ x_1, \cdots, x_n \} \]

be a basis for \( \mathbb{F}^n \). Then there exists an orthonormal basis for \( \mathbb{F}^n \),

\[ \{ u_1, \cdots, u_n \} \]

which has the property that for each \( k \leq n \),

\[ \text{span} (x_1, \cdots, x_k) = \text{span} (u_1, \cdots, u_k). \]

Proof: Let \( \{ x_1, \cdots, x_n \} \) be a basis for \( \mathbb{F}^n \). Let \( u_1 \equiv x_1 / |x_1| \). Thus for \( k = 1 \),

\[ \text{span} (u_1) = \text{span} (x_1) \]

and \( \{ u_1 \} \) is an orthonormal set. Now suppose for some \( k < n \),

\( u_1, \cdots, u_k \) have been chosen such that \( (u_j \cdot u_l) = \delta_{jl} \) and \( \text{span} (x_1, \cdots, x_k) = \text{span} (u_1, \cdots, u_k) \). Then define

\[ u_{k+1} \equiv \frac{x_{k+1} - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) u_j}{|x_{k+1} - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) u_j|}, \quad (4.12.39) \]

where the denominator is not equal to zero because the \( x_j \) form a basis and so

\[ x_{k+1} \notin \text{span} (x_1, \cdots, x_k) = \text{span} (u_1, \cdots, u_k) \]

Thus by induction,

\[ u_{k+1} \in \text{span} (u_1, \cdots, u_k, x_{k+1}) = \text{span} (x_1, \cdots, x_k, x_{k+1}). \]

Also, \( x_{k+1} \in \text{span} (u_1, \cdots, u_k, u_{k+1}) \) which is seen easily by solving \( \|x_{k+1}\|^2 \) for \( x_{k+1} \) and it follows

\[ \text{span} (x_1, \cdots, x_k, x_{k+1}) = \text{span} (u_1, \cdots, u_k, u_{k+1}). \]

If \( l \leq k \),

\[ (u_{k+1} \cdot u_l) = C \left( (x_{k+1} \cdot u_l) - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) (u_j \cdot u_l) \right) \]

\[ = C \left( (x_{k+1} \cdot u_l) - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) \delta_{lj} \right) \]

\[ = C ((x_{k+1} \cdot u_l) - (x_{k+1} \cdot u_l)) = 0. \]

The vectors, \( \{ u_l \}_{l=1}^{n} \), generated in this way are therefore an orthonormal basis because each vector has unit length.

The process by which these vectors were generated is called the Gram Schmidt process. Recall the following definition.
Definition 4.12.2 An \( n \times n \) matrix, \( U \), is unitary if \( UU^* = I = U^*U \) where \( U^* \) is defined to be the transpose of the conjugate of \( U \).

Theorem 4.12.3 Let \( A \) be an \( n \times n \) matrix. Then there exists a unitary matrix, \( U \) such that

\[
U^*AU = T, \tag{4.12.40}
\]

where \( T \) is an upper triangular matrix having the eigenvalues of \( A \) on the main diagonal listed according to multiplicity as roots of the characteristic equation.

Proof: Let \( v_1 \) be a unit eigenvector for \( A \). Then there exists \( \lambda_1 \) such that

\[
Av_1 = \lambda_1 v_1, \quad |v_1| = 1.
\]

Extend \( \{v_1\} \) to a basis and then use Lemma 4.12.1 to obtain \( \{v_1, \cdots, v_n\} \), an orthonormal basis in \( F^n \). Let \( U_0 \) be a matrix whose \( i^{th} \) column is \( v_i \). Then from the above, it follows \( U_0 \) is unitary. Then \( U_0^*AU_0 \) is of the form

\[
\begin{pmatrix}
\lambda_1 & * & \cdots & * \\
0 & & & \\
\vdots & & A_1 \\
0 & & & 
\end{pmatrix}
\]

where \( A_1 \) is an \( n - 1 \times n - 1 \) matrix. Repeat the process for the matrix, \( A_1 \) above. There exists a unitary matrix \( U_1 \) such that \( U_1^*A_1 \) is of the form

\[
\begin{pmatrix}
\lambda_2 & * & \cdots & * \\
0 & & & \\
\vdots & & A_2 \\
0 & & & 
\end{pmatrix}.
\]

Now let \( U_1 \) be the \( n \times n \) matrix of the form

\[
\begin{pmatrix}
1 & 0 \\
0 & U_1 
\end{pmatrix}.
\]

This is also a unitary matrix because by block multiplication,

\[
\begin{pmatrix}
1 & 0 \\
0 & U_1 
\end{pmatrix}^* \begin{pmatrix}
1 & 0 \\
0 & U_1 
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & U_1^* 
\end{pmatrix} \begin{pmatrix}
1 & 0 \\
0 & U_1 
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & U_1^*U_1 
\end{pmatrix} = \begin{pmatrix}
1 & 0 \\
0 & I 
\end{pmatrix}
\]

Then using block multiplication, \( U_1^*U_0^*AU_0U_1 \) is of the form

\[
\begin{pmatrix}
\lambda_1 & * & \cdots & * \\
0 & \lambda_2 & \cdots & * \\
0 & 0 & & \\
\vdots & \vdots & & A_2 \\
0 & 0 & & 
\end{pmatrix}
\]
where $A_2$ is an $n - 2 \times n - 2$ matrix. Continuing in this way, there exists a unitary matrix, $U$ given as the product of the $U_i$ in the above construction such that

$$U^*AU = T$$

where $T$ is some upper triangular matrix. Since the matrix is upper triangular, the characteristic equation is $\prod_{i=1}^{n} (\lambda_i - \lambda_i)$ where the $\lambda_i$ are the diagonal entries of $T$. Therefore, the $\lambda_i$ are the eigenvalues.

What if $A$ is a real matrix and you only want to consider real unitary matrices?

**Theorem 4.12.4** Let $A$ be a real $n \times n$ matrix. Then there exists a real unitary matrix, $Q$ and a matrix $T$ of the form

$$T = \begin{pmatrix} P_1 & \cdots & * \\ \vdots & \ddots & \vdots \\ 0 & \cdots & P_r \end{pmatrix} \quad (4.12.41)$$

where $P_i$ equals either a real $1 \times 1$ matrix or $P_i$ equals a real $2 \times 2$ matrix having two complex eigenvalues of $A$ such that $Q^T AQ = T$. The matrix, $T$ is called the real Schur form of the matrix $A$.

**Proof:** Suppose

$$Av_1 = \lambda_1 v_1, \quad |v_1| = 1$$

where $\lambda_1$ is real. Then let $\{v_1, \ldots, v_n\}$ be an orthonormal basis of vectors in $\mathbb{R}^n$. Let $Q_0$ be a matrix whose $i^{th}$ column is $v_i$. Then $Q_0^*AQ_0$ is of the form

$$\begin{pmatrix} \lambda_1 & * & \cdots & * \\ 0 & \ddots & \vdots & \vdots \\ \vdots & \ddots & A_1 \\ 0 & \cdots & \cdots & \cdots \end{pmatrix}$$

where $A_1$ is a real $n - 1 \times n - 1$ matrix. This is just like the proof of Theorem 4.12.3 up to this point.

Now in case $\lambda_1 = \alpha + i\beta$, it follows since $A$ is real that $v_1 = z_1 + i w_1$ and that $v_1 = z_1 - i w_1$ is an eigenvector for the eigenvalue, $\alpha - i\beta$. Here $z_1$ and $w_1$ are real vectors. It is clear that $\{z_1, w_1\}$ is an independent set of vectors in $\mathbb{R}^n$. Indeed, $\{v_1, v_1\}$ is an independent set and it follows span $(v_1, v_1) = \text{span} (z_1, w_1)$. Now using the Gram Schmidt theorem in $\mathbb{R}^n$, there exists $\{u_1, u_2\}$, an orthonormal set of real vectors such that span $(u_1, u_2) = \text{span} (v_1, v_1)$. Now let $\{u_1, u_2, \ldots, u_n\}$ be an orthonormal basis in $\mathbb{R}^n$ and let $Q_0$ be a unitary matrix whose $i^{th}$ column is $u_i$. Then $Au_j$ are both in span $(u_1, u_2)$ for $j = 1, 2$ and so $u_k^T Au_j = 0$ whenever $k \geq 3$. It follows that $Q_0^*AQ_0$ is of the form

$$\begin{pmatrix} * & * & \cdots & * \\ * & * & \vdots & \vdots \\ \vdots & \ddots & A_1 \\ 0 & \cdots & \cdots & \cdots \end{pmatrix}$$
where \( A_1 \) is now an \( n \times 2n \times 2 \) matrix. In this case, find \( \bar{Q}_1 \) an \( n \times 2n \times 2 \) matrix to put \( A_1 \) in an appropriate form as above and come up with \( A_2 \) either an \( n \times 4n \times 4 \) matrix or an \( n \times 3n \times 3 \) matrix. Then the only other difference is to let
\[
Q_1 = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
& & & & \\
& & & \ddots & \\
& & & & & \bar{Q}_1 \\
0 & 0 & & & 
\end{pmatrix}
\]
thus putting a \( 2 \times 2 \) identity matrix in the upper left corner rather than a one. Repeating this process with the above modification for the case of a complex eigenvalue leads eventually to
\[
\begin{pmatrix}
\lambda & 0 & \cdots & 0 \\
0 & \lambda & \cdots & 0 \\
& & \ddots & \\
0 & 0 & & \lambda 
\end{pmatrix}
\]
where \( Q \) is the product of real unitary matrices \( Q_i \) above. Finally,
\[
\lambda I - T = \begin{pmatrix}
\lambda I_1 - P_1 & \cdots & * \\
0 & \ddots & \vdots \\
0 & 0 & \lambda I_r - P_r 
\end{pmatrix}
\]
where \( I_k \) is the \( 2 \times 2 \) identity matrix in the case that \( P_k \) is \( 2 \times 2 \) and is the number 1 in the case where \( P_k \) is a \( 1 \times 1 \) matrix. Now, it follows that \( \det (\lambda I - T) = \prod_{k=1}^{r} \det (\lambda I_k - P_k) \). Therefore, \( \lambda \) is an eigenvalue of \( T \) if and only if it is an eigenvalue of some \( P_k \). This proves the theorem since the eigenvalues of \( T \) are the same as those of \( A \) because they have the same characteristic polynomial due to the similarity of \( A \) and \( T \).

**Definition 4.12.5** When a linear transformation, \( A \), mapping a linear space, \( V \) to \( V \) has a basis of eigenvectors, the linear transformation is called non defective. Otherwise it is called defective. An \( n \times n \) matrix, \( A \), is called normal if \( AA^* = A^*A \). An important class of normal matrices is that of the Hermitian or self adjoint matrices. An \( n \times n \) matrix, \( A \) is self adjoint or Hermitian if \( A = A^* \).

The next lemma is the basis for concluding that every normal matrix is unitarily similar to a diagonal matrix.

**Lemma 4.12.6** If \( T \) is upper triangular and normal, then \( T \) is a diagonal matrix.

**Proof:** Since \( T \) is normal, \( T^*T = TT^* \). Writing this in terms of components and using the description of the adjoint as the transpose of the conjugate, yields the following for the \( ik^{th} \) entry of \( T^*T = TT^* \).
\[
\sum_j t_{ij}t^*_{jk} = \sum_j t_{ij}\overline{t}_{kj} = \sum_j t^*_{ij}t_{jk} = \sum_j t_{ji}\overline{t}_{jk}.
\]
Now use the fact that \( T \) is upper triangular and let \( i = k = 1 \) to obtain the following from the above.
\[
\sum_j |t_{1j}|^2 = \sum_j |t_{j1}|^2 = |t_{11}|^2
\]
You see, $t_{j1} = 0$ unless $j = 1$ due to the assumption that $T$ is upper triangular. This shows $T$ is of the form
\[
\begin{pmatrix}
* & 0 & \cdots & 0 \\
0 & * & \cdots & * \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & *
\end{pmatrix}.
\]

Now do the same thing only this time take $i = k = 2$ and use the result just established. Thus, from the above,
\[
\sum_j |t_{2j}|^2 = \sum_j |t_{j2}|^2 = |t_{22}|^2,
\]
showing that $t_{2j} = 0$ if $j > 2$ which means $T$ has the form
\[
\begin{pmatrix}
* & 0 & 0 & \cdots & 0 \\
0 & * & 0 & \cdots & 0 \\
0 & 0 & * & \cdots & * \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & 0 & *
\end{pmatrix}.
\]

Next let $i = k = 3$ and obtain that $T$ looks like a diagonal matrix in so far as the first 3 rows and columns are concerned. Continuing in this way it follows $T$ is a diagonal matrix.

**Theorem 4.12.7** Let $A$ be a normal matrix. Then there exists a unitary matrix, $U$ such that $U^*AU$ is a diagonal matrix.

**Proof:** From Theorem 4.12.3 there exists a unitary matrix, $U$ such that $U^*AU$ equals an upper triangular matrix. The theorem is now proved if it is shown that the property of being normal is preserved under unitary similarity transformations. That is, verify that if $A$ is normal and if $B = U^*AU$, then $B$ is also normal. But this is easy.

\[
B^*B = U^*A^*UU^*AU = U^*A^*AU \\
= U^*AA^*U = U^*AUU^*A^*U = BB^*.
\]

Therefore, $U^*AU$ is a normal and upper triangular matrix and by Lemma 4.12.6 it must be a diagonal matrix. This proves the theorem.

**Corollary 4.12.8** If $A$ is Hermitian, then all the eigenvalues of $A$ are real and there exists an orthonormal basis of eigenvectors.

**Proof:** Since $A$ is normal, there exists unitary, $U$ such that $U^*AU = D$, a diagonal matrix whose diagonal entries are the eigenvalues of $A$. Therefore, $D^* = U^*A^*U = U^*AU = D$ showing $D$ is real.
Finally, let
\[ U = \begin{pmatrix} u_1 & u_2 & \cdots & u_n \end{pmatrix} \]
where the \( u_i \) denote the columns of \( U \) and
\[ D = \begin{pmatrix} \lambda_1 & & & \\ & \ddots & & \\ & & \ddots & \\ 0 & & & \lambda_n \end{pmatrix} \]
The equation, \( U^*AU = D \) implies
\[ AU = \begin{pmatrix} Au_1 & Au_2 & \cdots & Au_n \end{pmatrix} = UD = \begin{pmatrix} \lambda_1 u_1 & \lambda_2 u_2 & \cdots & \lambda_n u_n \end{pmatrix} \]
where the entries denote the columns of \( AU \) and \( UD \) respectively. Therefore, \( Au_i = \lambda_i u_i \) and since the matrix is unitary, the \( ij \)th entry of \( U^*U \) equals \( \delta_{ij} \) and so
\[ \delta_{ij} = u_i^T u_j = u_i^T u_j = u_i u_j. \]
This proves the corollary because it shows the vectors \( \{ u_i \} \) form an orthonormal basis.

**Corollary 4.12.9** If \( A \) is a real symmetric matrix, then \( A \) is Hermitian and there exists a real unitary matrix, \( U \) such that \( U^T A U = D \) where \( D \) is a diagonal matrix.

**Proof:** This follows from Theorem 4.12.4 and Corollary 4.12.8.

### 4.13 The Right Polar Decomposition

The right polar decomposition involves writing a matrix as a product of two other matrices, one which preserves distances and the other which stretches and distorts. First here are some lemmas.

**Lemma 4.13.1** Let \( A \) be a Hermitian matrix such that all its eigenvalues are non-negative. Then there exists a Hermitian matrix, \( A^{1/2} \) such that \( A^{1/2} \) has all non-negative eigenvalues and \( (A^{1/2})^2 = A \).

**Proof:** Since \( A \) is Hermitian, there exists a diagonal matrix \( D \) having all real nonnegative entries and a unitary matrix \( U \) such that \( A = U^*DU \). Then denote by \( D^{1/2} \) the matrix which is obtained by replacing each diagonal entry of \( D \) with its square root. Thus \( D^{1/2}D^{1/2} = D \). Then define
\[ A^{1/2} \equiv U^*D^{1/2}U. \]
Then
\[ (A^{1/2})^2 = U^*D^{1/2}UU^*D^{1/2}U = U^*DU = A. \]
CHAPTER 4. SOME IMPORTANT LINEAR ALGEBRA

Since \( D^{1/2} \) is real,
\[
\left( U^* D^{1/2} U \right)^* = U^* \left( D^{1/2} \right)^* (U^*)^* = U^* D^{1/2} U
\]

so \( A^{1/2} \) is Hermitian. This proves the lemma.

There is also a useful observation about orthonormal sets of vectors which is stated in the next lemma.

**Lemma 4.13.2** Suppose \( \{x_1, x_2, \ldots, x_r\} \) is an orthonormal set of vectors. Then if \( c_1, \ldots, c_r \) are scalars,
\[
\left\| \sum_{k=1}^r c_k x_k \right\|^2 = \sum_{k=1}^r |c_k|^2.
\]

**Proof:** This follows from the definition. From the properties of the dot product and using the fact that the given set of vectors is orthonormal,
\[
\left\| \sum_{k=1}^r c_k x_k \right\|^2 = \left( \sum_{k=1}^r c_k x_k, \sum_{j=1}^r c_j x_j \right) = \sum_{k,j} c_k \overline{c_j} (x_k, x_j) = \sum_{k=1}^r |c_k|^2.
\]
This proves the lemma.

Next it is helpful to recall the Gram Schmidt algorithm and observe a certain property stated in the next lemma.

**Lemma 4.13.3** Suppose \( \{w_1, \ldots, w_r, v_{r+1}, \ldots, v_p\} \) is a linearly independent set of vectors such that \( \{w_1, \ldots, w_r\} \) is an orthonormal set of vectors. Then when the Gram Schmidt process is applied to the vectors in the given order, it will not change any of the \( w_1, \ldots, w_r \).

**Proof:** Let \( \{u_1, \ldots, u_p\} \) be the orthonormal set delivered by the Gram Schmidt process. Then \( u_1 = w_1 \) because by definition, \( u_1 \equiv w_1/|w_1| = w_1 \). Now suppose \( u_j = w_j \) for all \( j \leq k \leq r \). Then if \( k < r \), consider the definition of \( u_{k+1} \).
\[
u_{k+1} \equiv \frac{w_{k+1} - \sum_{j=1}^{k+1} (w_{k+1} - u_j) u_j}{w_{k+1} - \sum_{j=1}^{k+1} (w_{k+1} - u_j) u_j}
\]
By induction, \( u_j = w_j \) and so this reduces to \( w_{k+1}/|w_{k+1}| = w_{k+1} \). This proves the lemma.

This lemma immediately implies the following lemma.

**Lemma 4.13.4** Let \( V \) be a subspace of dimension \( p \) and let \( \{w_1, \ldots, w_r\} \) be an orthonormal set of vectors in \( V \). Then this orthonormal set of vectors may be extended to an orthonormal basis for \( V \),
\[
\{w_1, \ldots, w_r, y_{r+1}, \ldots, y_p\}
\]
4.13. THE RIGHT POLAR DECOMPOSITION

Proof: First extend the given linearly independent set \( \{w_1, \ldots, w_r\} \) to a basis for \( V \) and then apply the Gram Schmidt theorem to the resulting basis. Since \( \{w_1, \ldots, w_r\} \) is orthonormal it follows from Lemma 4.13.3 the result is of the desired form, an orthonormal basis extending \( \{w_1, \ldots, w_r\} \). This proves the lemma.

Here is another lemma about preserving distance.

Lemma 4.13.5 Suppose \( R \) is an \( m \times n \) matrix with \( m > n \) and \( R \) preserves distances. Then \( R^*R = I \).

Proof: Since \( R \) preserves distances, \( |Rx| = |x| \) for every \( x \). Therefore from the axioms of the dot product,

\[
\begin{align*}
|x|^2 + |y|^2 + (x,y) + (y,x) &= |x + y|^2 \\
&= (Rx,Ry) + (Ry,Rx)
\end{align*}
\]

and so for all \( x, y \),

\[
(R^*Rx - x,y) + (y,R^*Rx - x) = 0
\]

Hence for all \( x, y \),

\[
\text{Re} (R^*Rx - x,y) = 0
\]

Now for a \( x, y \) given, choose \( \alpha \in \mathbb{C} \) such that

\[
\alpha (R^*Rx - x,y) = |(R^*Rx - x,y)|
\]

Then

\[
0 = \text{Re} (R^*Rx - x,\overline{\alpha}y) = \text{Re} \alpha (R^*Rx - x,y)
\]

Thus \( |(R^*Rx - x,y)| = 0 \) for all \( x, y \) because the given \( x, y \) were arbitrary. Let \( y = R^*Rx - x \) to conclude that for all \( x \),

\[
R^*Rx - x = 0
\]

which says \( R^*R = I \) since \( x \) is arbitrary. This proves the lemma.

With this preparation, here is the big theorem about the right polar decomposition.

Theorem 4.13.6 Let \( F \) be an \( m \times n \) matrix where \( m \geq n \). Then there exists a Hermitian \( n \times n \) matrix, \( U \) which has all nonnegative eigenvalues and an \( m \times n \) matrix, \( R \) which preserves distances and satisfies \( R^*R = I \) such that

\[
F = RU.
\]
**Proof:** Consider $F^*F$. This is a Hermitian matrix because

$$(F^*F)^* = F^* (F^*)^* = F^* F$$

Also the eigenvalues of the $n \times n$ matrix $F^*F$ are all nonnegative. This is because if $x$ is an eigenvalue,

$$\lambda(x, x) = (F^*Fx, x) = (Fx, Fx) \geq 0.$$  

Therefore, by Lemma 4.13.1, there exists an $n \times n$ Hermitian matrix, $U$ having all nonnegative eigenvalues such that

$$U^2 = F^* F.$$  

Consider the subspace $U(F^n)$. Let $\{UX_1, \ldots, UX_r\}$ be an orthonormal basis for $U(F^n) \subseteq F^n$. Note that $U(F^n)$ might not be all of $F^n$. Using Lemma 4.13.4, extend to an orthonormal basis for all of $F^n$,

$$\{UX_1, \ldots, UX_r, y_{r+1}, \ldots, y_n\}.$$  

Next observe that $\{FX_1, \ldots, FX_r\}$ is also an orthonormal set of vectors in $F^m$. This is because

$$\langle FX_k, FX_j\rangle = \langle F^*FX_k, x_j\rangle = \langle UX_k, U^*x_j\rangle = \langle UX_k, UX_j\rangle = \delta_{jk}.$$  

Therefore, from Lemma 4.13.4 again, this orthonormal set of vectors can be extended to an orthonormal basis for $F^m$,

$$\{FX_1, \ldots, FX_r, z_{r+1}, \ldots, z_m\}.$$  

Thus there are at least as many $z_k$ as there are $y_j$. Now for $x \in F^n$, since

$$\{UX_1, \ldots, UX_r, y_{r+1}, \ldots, y_n\}$$

is an orthonormal basis for $F^n$, there exist unique scalars,

$$c_1, \ldots, c_r, d_{r+1}, \ldots, d_n$$

such that

$$x = \sum_{k=1}^r c_k UX_k + \sum_{j=r+1}^n d_k y_k.$$  

Define

$$Rx = \sum_{k=1}^r c_k FX_k + \sum_{j=r+1}^n d_k z_k \quad (4.13.42)$$

Then also there exist scalars $b_k$ such that

$$UX = \sum_{k=1}^r b_k UX_k.$$
4.13. **THE RIGHT POLAR DECOMPOSITION**

and so from (4.13.42), applied to $U\mathbf{x}$ in place of $\mathbf{x}$

$$RU\mathbf{x} = \sum_{k=1}^{r} b_k F \mathbf{x}_k = F \left( \sum_{k=1}^{r} b_k \mathbf{x}_k \right)$$

Is $F \left( \sum_{k=1}^{r} b_k \mathbf{x}_k \right) = F \left( \mathbf{x} \right)$?

$$\left( F \left( \sum_{k=1}^{r} b_k \mathbf{x}_k \right) - F \left( \mathbf{x} \right), F \left( \sum_{k=1}^{r} b_k \mathbf{x}_k \right) - F \left( \mathbf{x} \right) \right)$$

$$= \left( (F^* F) \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right), \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right) \right)$$

$$= \left( U^2 \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right), \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right) \right)$$

$$= \left( U \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right), U \left( \sum_{k=1}^{r} b_k \mathbf{x}_k - \mathbf{x} \right) \right)$$

$$= \left( \sum_{k=1}^{r} b_k U \mathbf{x}_k - U \mathbf{x}, \sum_{k=1}^{r} b_k U \mathbf{x}_k - U \mathbf{x} \right) = 0$$

Therefore, $F \left( \sum_{k=1}^{r} b_k \mathbf{x}_k \right) = F \left( \mathbf{x} \right)$ and this shows

$$RU\mathbf{x} = F\mathbf{x}.$$

From (4.13.42) and Lemma 4.13.2, $R$ preserves distances. Therefore, by Lemma 4.13.3, $R^* R = I$. This proves the theorem.
Chapter 5

Multi-variable Calculus

5.1 Continuous Functions

In what follows, \( F \) will denote either \( \mathbb{R} \) or \( \mathbb{C} \). It turns out it is more efficient to not make a distinction. However, the main interest is in \( \mathbb{R} \) so if you like, you can think \( \mathbb{R} \) whenever you see \( F \).

5.2 Open And Closed Sets

Eventually, one must consider functions which are defined on subsets of \( \mathbb{F}^n \) and their properties. The next definition will end up being quite important. It describe a type of subset of \( \mathbb{F}^n \) with the property that if \( x \) is in this set, then so is \( y \) whenever \( y \) is close enough to \( x \). In all of this, for \( x \) a vector, \( |x| \) is given by \((x,x)^{1/2}\) where this denotes the square root of the inner product of the vector with itself as described earlier. Then the distance between the vectors \( x \) and \( y \) is defined as \(|x - y|\).

**Definition 5.2.1** Let \( U \subseteq \mathbb{F}^n \). \( U \) is an open set if whenever \( x \in U \), there exists \( r > 0 \) such that \( B(x,r) \subseteq U \). More generally, if \( U \) is any subset of \( \mathbb{F}^n \), \( x \in U \) is an interior point of \( U \) if there exists \( r > 0 \) such that \( x \in B(x,r) \subseteq U \). In other words \( U \) is an open set exactly when every point of \( U \) is an interior point of \( U \).

If there is something called an open set, surely there should be something called a closed set and here is the definition of one.

**Definition 5.2.2** A subset, \( C \), of \( \mathbb{F}^n \) is called a closed set if \( \mathbb{F}^n \setminus C \) is an open set. They symbol, \( \mathbb{F}^n \setminus C \) denotes everything in \( \mathbb{F}^n \) which is not in \( C \). It is also called the complement of \( C \). The symbol, \( S^C \) is a short way of writing \( \mathbb{F}^n \setminus S \).

To illustrate this definition, consider the following picture.
You see in this picture how the edges are dotted. This is because an open set, can not include the edges or the set would fail to be open. For example, consider what would happen if you picked a point out on the edge of $U$ in the above picture. Every open ball centered at that point would have in it some points which are outside $U$. Therefore, such a point would violate the above definition. You also see the edges of $B(x, r)$ dotted suggesting that $B(x, r)$ ought to be an open set. This is intuitively clear but does require a proof. This will be done in the next theorem and will give examples of open sets. Also, you can see that if $x$ is close to the edge of $U$, you might have to take $r$ to be very small.

It is roughly the case that open sets don’t have their skins while closed sets do. Here is a picture of a closed set, $C$.

Note that $x \notin C$ and since $\mathbb{R}^n \setminus C$ is open, there exists a ball, $B(x, r)$ contained entirely in $\mathbb{R}^n \setminus C$. If you look at $\mathbb{R}^n \setminus C$, what would its skin? It can’t be in $\mathbb{R}^n \setminus C$ and so it must be in $C$. This is a rough heuristic explanation of what is going on with these definitions. Also note that $\mathbb{R}^n$ and $\emptyset$ are both open and closed. Here is why. If $x \in \emptyset$, then there must be a ball centered at $x$ which is also contained in $\emptyset$. This must be considered to be true because there is nothing in $\emptyset$ so there can be no example to show it false. Therefore, from the definition, it follows $\emptyset$ is open.

\footnote{To a mathematician, the statement: Whenever a pig is born with wings it can fly must be taken as true. We do not consider biological or aerodynamic considerations in such statements. There is no such thing as a winged pig and therefore, all winged pigs must be superb flyers since there can be no example of one which is not. On the other hand we would also consider the statement: Whenever a pig is born with wings it can’t possibly fly, as equally true. The point is, you can say...}
It is also closed because if \( x \notin \emptyset \), then \( B(x, 1) \) is also contained in \( \mathbb{F}^n \setminus \emptyset = \mathbb{F}^n \). Therefore, \( \emptyset \) is both open and closed. From this, it follows \( \mathbb{F}^n \) is also both open and closed.

**Theorem 5.2.3** Let \( x \in \mathbb{F}^n \) and let \( r \geq 0 \). Then \( B(x, r) \) is an open set. Also,

\[
D(x, r) \equiv \{ y \in \mathbb{F}^n : |y - x| \leq r \}
\]

is a closed set.

**Proof:** Suppose \( y \in B(x, r) \). It is necessary to show there exists \( r_1 > 0 \) such that \( B(y, r_1) \subseteq B(x, r) \). Define \( r_1 \equiv r - |x - y| \). Then if \( |z - y| < r_1 \), it follows from the above triangle inequality that

\[
|z - x| = |z - y + y - x| \\
\leq |z - y| + |y - x| \\
< r_1 + |y - x| = r - |x - y| + |y - x| = r.
\]

Note that if \( r = 0 \) then \( B(x, r) = \emptyset \), the empty set. This is because if \( y \in \mathbb{F}^n \), \( |x - y| \geq 0 \) and so \( y \notin B(x, 0) \). Since \( \emptyset \) has no points in it, it must be open because every point in it, (There are none.) satisfies the desired property of being an interior point.

Now suppose \( y \notin D(x, r) \). Then \( |x - y| > r \) and defining \( \delta \equiv |x - y| - r \), it follows that if \( z \in B(y, \delta) \), then by the triangle inequality,

\[
|x - z| \geq |x - y| - |y - z| > |x - y| - \delta \\
= |x - y| - (|x - y| - r) = r
\]

and this shows that \( B(y, \delta) \subseteq \mathbb{F}^n \setminus D(x, r) \). Since \( y \) was an arbitrary point in \( \mathbb{F}^n \setminus D(x, r) \), it follows \( \mathbb{F}^n \setminus D(x, r) \) is an open set which shows from the definition that \( D(x, r) \) is a closed set as claimed.

A picture which is descriptive of the conclusion of the above theorem which also implies the manner of proof is the following.

---

anything you want about the elements of the empty set and no one can gainsay your statement. Therefore, such statements are considered as true by default. You may say this is a very strange way of thinking about truth and ultimately this is because mathematics is not about truth. It is more about consistency and logic.
CHAPTER 5. MULTI-VARIABLE CALCULUS

5.3 Continuous Functions

With the above definition of the norm in \( \mathbb{F}^p \), it becomes possible to define continuity.

**Definition 5.3.1** A function \( f : D(f) \subseteq \mathbb{F}^p \to \mathbb{F}^q \) is continuous at \( x \in D(f) \) if for each \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that whenever \( y \in D(f) \) and \( |y - x| < \delta \) it follows that
\[
|f(x) - f(y)| < \varepsilon.
\]

\( f \) is continuous if it is continuous at every point of \( D(f) \).

Note the total similarity to the scalar valued case.

5.3.1 Sufficient Conditions For Continuity

The next theorem is a fundamental result which will allow us to worry less about the \( \varepsilon \delta \) definition of continuity.

**Theorem 5.3.2** The following assertions are valid.

1. The function, \( af + bg \) is continuous at \( x \) whenever \( f, g \) are continuous at \( x \in D(f) \cap D(g) \) and \( a, b \in \mathbb{F} \).

2. If \( f \) is continuous at \( x \), \( f(x) \in D(g) \subseteq \mathbb{F}^p \), and \( g \) is continuous at \( f(x) \), then \( g \circ f \) is continuous at \( x \).

3. If \( f = (f_1, \ldots, f_q) : D(f) \to \mathbb{F}^q \), then \( f \) is continuous if and only if each \( f_k \) is a continuous \( \mathbb{F} \) valued function.

4. The function \( f : \mathbb{F}^p \to \mathbb{F} \), given by \( f(x) = |x| \) is continuous.

The proof of this theorem is in the last section of this chapter. Its conclusions are not surprising. For example the first claim says that \( (af + bg)(y) \) is close to \( (af + bg)(x) \) when \( y \) is close to \( x \) provided the same can be said about \( f \) and \( g \). For the second claim, if \( y \) is close to \( x \), \( f(x) \) is close to \( f(y) \) and so by continuity of \( g \) at \( f(x) \), \( g(f(y)) \) is close to \( g(f(x)) \). To see the third claim is likely, note that closeness in \( \mathbb{F}^p \) is the same as closeness in each coordinate. The fourth claim is immediate from the triangle inequality.

For functions defined on \( \mathbb{F}^n \), there is a notion of polynomial just as there is for functions defined on \( \mathbb{R} \).

**Definition 5.3.3** Let \( \alpha \) be an \( n \) dimensional multi-index. This means
\[
\alpha = (\alpha_1, \ldots, \alpha_n)
\]
where each $\alpha_i$ is a natural number or zero. Also, let

$$|\alpha| \equiv \sum_{i=1}^{n} |\alpha_i|$$

The symbol, $x^\alpha$, means

$$x^\alpha \equiv x_1^{\alpha_1}x_2^{\alpha_2} \cdots x_n^{\alpha_n}.$$  

An $n$ dimensional polynomial of degree $m$ is a function of the form

$$p(x) = \sum_{|\alpha| \leq m} d_\alpha x^\alpha.$$  

where the $d_\alpha$ are complex or real numbers.

The above theorem implies that polynomials are all continuous.

5.4 Exercises

1. Let $f(t) = (t, \sin t)$. Show $f$ is continuous at every point $t$.

2. Suppose $|f(x) - f(y)| \leq K |x - y|$ where $K$ is a constant. Show that $f$ is everywhere continuous. Functions satisfying such an inequality are called Lipschitz functions.

3. Suppose $|f(x) - f(y)| \leq K |x - y|^\alpha$ where $K$ is a constant and $\alpha \in (0,1)$. Show that $f$ is everywhere continuous.

4. Suppose $f : \mathbb{F}^3 \to \mathbb{F}$ is given by $f(x) = 3x_1x_2 + 2x_3^2$. Use Theorem 5.3.2 to verify that $f$ is continuous. **Hint:** You should first verify that the function, $\pi_k : \mathbb{F}^3 \to \mathbb{F}$ given by $\pi_k(x) = x_k$ is a continuous function.

5. Generalize the previous problem to the case where $f : \mathbb{F}^q \to \mathbb{F}$ is a polynomial.

6. State and prove a theorem which involves quotients of functions encountered in the previous problem.

5.5 Limits Of A Function

As in the case of scalar valued functions of one variable, a concept closely related to continuity is that of the limit of a function. The notion of limit of a function makes sense at points, $x$, which are limit points of $D(f)$ and this concept is defined next.

**Definition 5.5.1** Let $A \subseteq \mathbb{F}^m$ be a set. A point, $x$, is a limit point of $A$ if $B(x,r)$ contains infinitely many points of $A$ for every $r > 0$. 
Definition 5.5.2 Let \( f: D(f) \subseteq \mathbb{R}^n \to \mathbb{R}^q \) be a function and let \( x \) be a limit point of \( D(f) \). Then
\[
\lim_{y \to x} f(y) = L
\]
if and only if the following condition holds. For all \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that if
\[
0 < |y - x| < \delta, \text{ and } y \in D(f)
\]
then,
\[
|L - f(y)| < \varepsilon.
\]

Theorem 5.5.3 If \( \lim_{y \to x} f(y) = L \) and \( \lim_{y \to x} f(y) = L_1 \), then \( L = L_1 \).

Proof: Let \( \varepsilon > 0 \) be given. There exists \( \delta > 0 \) such that if \( 0 < |y - x| < \delta \) and \( y \in D(f) \), then
\[
|f(y) - L| < \varepsilon, \text{ } |f(y) - L_1| < \varepsilon.
\]
Pick such a \( y \). There exists one because \( x \) is a limit point of \( D(f) \). Then
\[
|L - L_1| \leq |L - f(y)| + |f(y) - L_1| < \varepsilon + \varepsilon = 2\varepsilon.
\]
Since \( \varepsilon > 0 \) was arbitrary, this shows \( L = L_1 \).

As in the case of functions of one variable, one can define what it means for \( \lim_{y \to x} f(x) = \pm \infty \).

Definition 5.5.4 If \( f(x) \in \mathbb{F} \), \( \lim_{y \to x} f(x) = \infty \) if for every number \( L \), there exists \( \delta > 0 \) such that whenever \( |y - x| < \delta \) and \( y \in D(f) \), then \( f(x) > L \).

The following theorem is just like the one variable version presented earlier.

Theorem 5.5.5 Suppose \( \lim_{y \to x} f(y) = L \) and \( \lim_{y \to x} g(y) = K \) where \( K, L \in \mathbb{F}^q \). Then if \( a, b \in \mathbb{F} \),
\[
\lim_{y \to x} (af(y) + bg(y)) = aL + bK, \quad (5.5.1)
\]
\[
\lim_{y \to x} f \cdot g(y) = LK \quad (5.5.2)
\]
and if \( g \) is scalar valued with \( \lim_{y \to x} g(y) = K \neq 0 \),
\[
\lim_{y \to x} f(y) g(y) = LK. \quad (5.5.3)
\]
Also, if \( h \) is a continuous function defined near \( L \), then
\[
\lim_{y \to x} h \circ f(y) = h(L). \quad (5.5.4)
\]
Suppose \( \lim_{y \to x} f(y) = L \). If \( |f(y) - b| \leq r \) for all \( y \) sufficiently close to \( x \), then \( |L - b| \leq r \) also.
5.5. LIMITS OF A FUNCTION

Proof: The proof of Theorem 5.5.1 is left for you. It is like a corresponding theorem for continuous functions. Now Theorem 5.5.2 is to be verified. Let \( \varepsilon > 0 \) be given. Then by the triangle inequality,

\[
|f \cdot g(y) - L \cdot K| \leq |f(g(y) - f(y)) \cdot K| + |f(y) \cdot K - L \cdot K| \\
\leq |f(y)||g(y) - K| + |K||f(y) - L|.
\]

There exists \( \delta_1 \) such that if \( 0 < |y - x| < \delta_1 \) and \( y \in D(f) \), then

\[
|f(y) - L| < 1,
\]

and so for such \( y \), the triangle inequality implies, \( |f(y)| < 1 + |L| \). Therefore, for \( 0 < |y - x| < \delta_1 \),

\[
|f \cdot g(y) - L \cdot K| \leq (1 + |K| + |L|)||g(y) - K| + |f(y) - L|.
\]  

(5.5.5)

Now let \( 0 < \delta_2 \) be such that if \( y \in D(f) \) and \( 0 < |x - y| < \delta_2 \),

\[
|f(y) - L| < \frac{\varepsilon}{2(1 + |K| + |L|)}, \quad |g(y) - K| < \frac{\varepsilon}{2(1 + |K| + |L|)}.
\]

Then letting \( 0 < \delta \leq \min(\delta_1, \delta_2) \), it follows from (5.5.2) that

\[
|f \cdot g(y) - L \cdot K| < \varepsilon
\]

and this proves (5.5.2).

The proof of (5.5.3) is left to you.

Consider (5.5.3). Since \( h \) is continuous near \( L \), it follows that for \( \varepsilon > 0 \) given, there exists \( \eta > 0 \) such that if \( |y - L| < \eta \), then

\[
|h(y) - h(L)| < \varepsilon.
\]

Now since \( \lim_{y \to x} f(y) = L \), there exists \( \delta > 0 \) such that if \( 0 < |y - x| < \delta \), then

\[
|f(y) - L| < \eta.
\]

Therefore, if \( 0 < |y - x| < \delta \),

\[
|h(f(y)) - h(L)| < \varepsilon.
\]

It only remains to verify the last assertion. Assume \( |f(y) - b| \leq r \) for all \( y \) close enough to \( x \). It is required to show that \( |L - b| \leq r \). If this is not true, then \( |L - b| > r \). Consider \( B(L, |L - b| - r) \). Since \( L \) is the limit of \( f \), it follows \( f(y) \in B(L, |L - b| - r) \) whenever \( y \in D(f) \) is close enough to \( x \). Thus, by the triangle inequality,

\[
|f(y) - L| < |L - b| - r
\]

and so

\[
r < |L - b| - |f(y) - L| \leq ||b - L| - |f(y) - L||
\]

\[
\leq |b - f(y)|,
\]

a contradiction to the assumption that \( |b - f(y)| \leq r \).
CHAPTER 5. MULTI-VARIABLE CALCULUS

Theorem 5.5.6 For \( f : D(f) \to \mathbb{R}^q \) and \( x \in D(f) \) a limit point of \( D(f) \), \( f \) is continuous at \( x \) if and only if

\[
\lim_{y \to x} f(y) = f(x).
\]

Proof: First suppose \( f \) is continuous at \( x \) a limit point of \( D(f) \). Then for every \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that if \( |y - x| < \delta \) and \( y \in D(f) \), then \( |f(x) - f(y)| < \varepsilon \). In particular, this holds if \( 0 < |x - y| < \delta \) and this is just the definition of the limit. Hence \( f(x) = \lim_{y \to x} f(y) \).

Next suppose \( x \) is a limit point of \( D(f) \) and \( \lim_{y \to x} f(y) = f(x) \). This means that if \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that for \( 0 < |x - y| < \delta \) and \( y \in D(f) \), it follows \( |f(y) - f(x)| < \varepsilon \). However, if \( y = x \), then \( |f(y) - f(x)| = |f(x) - f(x)| = 0 \) and so whenever \( y \in D(f) \) and \( |x - y| < \delta \), it follows \( |f(x) - f(y)| < \varepsilon \), showing \( f \) is continuous at \( x \).

The following theorem is important.

Theorem 5.5.7 Suppose \( f : D(f) \to \mathbb{R}^q \). Then for \( x \) a limit point of \( D(f) \),

\[
\lim_{y \to x} f(y) = L
\]

if and only if

\[
\lim_{y \to x} f_k(y) = L_k
\]

where \( f(y) = (f_1(y), \cdots, f_p(y)) \) and \( L = (L_1, \cdots, L_p) \).

Proof: Suppose (5.5.6). Then letting \( \varepsilon > 0 \) be given there exists \( \delta > 0 \) such that if \( 0 < |y - x| < \delta \), it follows

\[
|f_k(y) - L_k| \leq |f(y) - L| < \varepsilon
\]

which verifies (5.5.7).

Now suppose (5.5.7) holds. Then letting \( \varepsilon > 0 \) be given, there exists \( \delta_k \) such that if \( 0 < |y - x| < \delta_k \), then

\[
|f_k(y) - L_k| < \frac{\varepsilon}{\sqrt{p}}.
\]

Let \( 0 < \delta < \min(\delta_1, \cdots, \delta_p) \). Then if \( 0 < |y - x| < \delta \), it follows

\[
|f(y) - L| = \left( \sum_{k=1}^{p} |f_k(y) - L_k|^2 \right)^{1/2} < \left( \sum_{k=1}^{p} \frac{\varepsilon^2}{p} \right)^{1/2} = \varepsilon.
\]

This proves the theorem.

This theorem shows it suffices to consider the components of a vector valued function when computing the limit.
Example 5.5.8 Find \( \lim_{(x,y)\to(3,1)} \left( \frac{x^2 - 9}{x^2 - 3}, y \right) \).

It is clear that \( \lim_{(x,y)\to(3,1)} \frac{x^2 - 9}{x^2 - 3} = 6 \) and \( \lim_{(x,y)\to(3,1)} y = 1 \). Therefore, this limit equals \((6,1)\).

Example 5.5.9 Find \( \lim_{(x,y)\to(0,0)} \frac{xy}{x^2 + y^2} \).

First of all observe the domain of the function is \( \mathbb{R}^2 \setminus \{(0,0)\} \), every point in \( \mathbb{R}^2 \) except the origin. Therefore, \((0,0)\) is a limit point of the domain of the function so it might make sense to take a limit. However, just as in the case of a function of one variable, the limit may not exist. In fact, this is the case here. To see this, take points on the line \( y = 0 \). At these points, the value of the function equals 0. Now consider points on the line \( y = x \) where the value of the function equals 1/2. Since arbitrarily close to \((0,0)\) there are points where the function equals 1/2 and points where the function has the value 0, it follows there can be no limit. Just take \( \varepsilon = 1/10 \) for example. You can’t be within 1/10 of 1/2 and also within 1/10 of 0 at the same time.

Note it is necessary to rely on the definition of the limit much more than in the case of a function of one variable and it is the case there are no easy ways to do limit problems for functions of more than one variable. It is what it is and you will not deal with these concepts without agony.

### 5.6 Exercises

1. Find the following limits if possible

   (a) \( \lim_{(x,y)\to(0,0)} \frac{x^2 - y^2}{x^2 + y^2} \)

   (b) \( \lim_{(x,y)\to(0,0)} \frac{x(x^2 - y^2)}{(x^2 + y^2)} \)

   (c) \( \lim_{(x,y)\to(0,0)} \frac{(x^2 - y^2)^2}{(x^2 + y^2)^2} \) \textbf{Hint:} Consider along \( y = 0 \) and along \( x = y^2 \).

   (d) \( \lim_{(x,y)\to(0,0)} x \sin \left( \frac{1}{x^2 + y^2} \right) \)

   (e) The limit as \( (x,y) \to (1,2) \) of the expression

   \[
   \frac{-2yx^2 + 8yx + 34y + 3y^4 - 18y^2 + 6x^2 - 13x - 20 - xy^2 - x^3}{-y^2 + 4y - 5 - x^2 + 2x}.
   \]

   \textbf{Hint:} It might help to write this in terms of the variables \((s,t) = (x - 1, y - 2)\).

2. In the definition of limit, why must \( x \) be a limit point of \( D(f) \)? \textbf{Hint:} If \( x \) were not a limit point of \( D(f) \), show there exists \( \delta > 0 \) such that \( B(x, \delta) \) contains no points of \( D(f) \) other than possibly \( x \) itself. Argue that 33.3 is a limit and that so is 22 and 7 and 11. In other words the concept is totally worthless.
CHAPTER 5. MULTI-VARIABLE CALCULUS

5.7 The Limit Of A Sequence

As in the case of real numbers, one can consider the limit of a sequence of points in $\mathbb{F}^p$.

**Definition 5.7.1** A sequence $\{a_n\}_{n=1}^\infty$ converges to $a$, and write

$$\lim_{n \to \infty} a_n = a \quad \text{or} \quad a_n \to a$$

if and only if for every $\varepsilon > 0$ there exists $n_\varepsilon$ such that whenever $n \geq n_\varepsilon$,

$$|a_n - a| < \varepsilon.$$

In words the definition says that given any measure of closeness, $\varepsilon$, the terms of the sequence are eventually all this close to $a$. There is absolutely no difference between this and the definition for sequences of numbers other than here bold face is used to indicate $a_n$ and $a$ are points in $\mathbb{F}^p$.

**Theorem 5.7.2** If $\lim_{n \to \infty} a_n = a$ and $\lim_{n \to \infty} a_n = a_1$ then $a_1 = a$.

**Proof:** Suppose $a_1 \neq a$. Then let $0 < \varepsilon < |a_1 - a| / 2$ in the definition of the limit. It follows there exists $n_\varepsilon$ such that if $n \geq n_\varepsilon$, then $|a_n - a| < \varepsilon$ and $|a_n - a_1| < \varepsilon$. Therefore, for such $n$,

$$|a_1 - a| \leq |a_1 - a_n| + |a_n - a| < \varepsilon + \varepsilon = |a_1 - a| / 2 + |a_1 - a| / 2 = |a_1 - a|,$$

a contradiction.

As in the case of a vector valued function, it suffices to consider the components. This is the content of the next theorem.

**Theorem 5.7.3** Let $a_n = (a_1^n, \ldots, a_p^n) \in \mathbb{F}^p$. Then $\lim_{n \to \infty} a_n = \mathbf{a} \equiv (a_1, \cdots, a_p)$ if and only if for each $k = 1, \cdots, p$,

$$\lim_{n \to \infty} a_k^n = a_k. \quad (5.7.8)$$

**Proof:** First suppose $\lim_{n \to \infty} a_n = a$. Then given $\varepsilon > 0$ there exists $n_\varepsilon$ such that if $n > n_\varepsilon$, then

$$|a_n^k - a_k| \leq |a_n - a| < \varepsilon$$

which establishes $(5.7.8)$.

Now suppose $(5.7.8)$ holds for each $k$. Then letting $\varepsilon > 0$ be given there exist $n_k$ such that if $n > n_k$,

$$|a_k^n - a_k| < \varepsilon / \sqrt{p}.$$

Therefore, letting $n_\varepsilon = \max(n_1, \cdots, n_p)$, it follows that for $n > n_\varepsilon$,

$$|a_n - a| = \left( \sum_{k=1}^n |a_k^n - a_k|^2 \right)^{1/2} < \left( \sum_{k=1}^n \frac{\varepsilon^2}{p} \right)^{1/2} = \varepsilon,$$

showing that $\lim_{n \to \infty} a_n = a$. This proves the theorem.
Example 5.7.4 Let \( a_n = \left( \frac{1}{n+1}, \frac{1}{n} \sin (n), \frac{n^2+3}{3n^2+5n} \right) \).

It suffices to consider the limits of the components according to the following theorem. Thus the limit is \((0, 0, 1/3)\).

Theorem 5.7.5 Suppose \( \{a_n\} \) and \( \{b_n\} \) are sequences and that
\[
\lim_{n \to \infty} a_n = a \quad \text{and} \quad \lim_{n \to \infty} b_n = b.
\]
Also suppose \( x \) and \( y \) are numbers in \( \mathbb{F} \). Then
\[
\lim_{n \to \infty} xa_n + yb_n = xa + yb \tag{5.7.9}
\]
\[
\lim_{n \to \infty} a_n \cdot b_n = a \cdot b \tag{5.7.10}
\]
If \( b_n \in \mathbb{F} \), then
\[
a_n b_n \to ab.
\]

**Proof:** The first of these claims is left for you to do. To do the second, let \( \varepsilon > 0 \) be given and choose \( n_1 \) such that if \( n \geq n_1 \) then
\[
|a_n - a| < 1.
\]
Then for such \( n \), the triangle inequality and Cauchy Schwarz inequality imply
\[
|a_n \cdot b_n - a \cdot b| \leq |a_n \cdot b_n - a_n \cdot b| + |a_n \cdot b - a \cdot b| \\
\leq |a_n||b_n - b| + |b||a_n - a| \\
\leq (|a| + 1)|b_n - b| + |b||a_n - a|.
\]
Now let \( n_2 \) be large enough that for \( n \geq n_2 \),
\[
|b_n - b| < \frac{\varepsilon}{2(|a| + 1)} \quad \text{and} \quad |a_n - a| < \frac{\varepsilon}{2(|b| + 1)}.
\]
Such a number exists because of the definition of limit. Therefore, let
\[
n_\varepsilon = \max (n_1, n_2).
\]
For \( n \geq n_\varepsilon \),
\[
|a_n \cdot b_n - a \cdot b| \leq (|a| + 1)|b_n - b| + |b||a_n - a| \\
< (|a| + 1)\frac{\varepsilon}{2(|a| + 1)} + |b|\frac{\varepsilon}{2(|b| + 1)} \leq \varepsilon.
\]
This proves 5.7.9. The proof of 5.7.10 is entirely similar and is left for you.
5.7.1 Sequences And Completeness

Recall the definition of a Cauchy sequence.

**Definition 5.7.6** \( \{a_n\} \) is a Cauchy sequence if for all \( \varepsilon > 0 \), there exists \( n_\varepsilon \) such that whenever \( n, m \geq n_\varepsilon \),

\[
|a_n - a_m| < \varepsilon.
\]

A sequence is Cauchy means “bunching up to each other” as \( m, n \) get large.

**Theorem 5.7.7** Let \( \{a_n\}_{n=1}^\infty \) be a Cauchy sequence in \( \mathbb{F}^p \). Then there exists a unique \( a \in \mathbb{F}^p \) such that \( a_n \to a \).

**Proof:** Let \( a_n = (a^n_1, \ldots, a^n_p) \). Then

\[
|a^n_k - a^m_k| \leq |a_n - a_m|
\]

which shows for each \( k = 1, \ldots, p \), it follows \( \{a^n_k\}_{n=1}^\infty \) is a Cauchy sequence in \( \mathbb{F} \). This requires that both the real and imaginary parts of \( a^n_k \) are Cauchy sequences in \( \mathbb{R} \) which means the real and imaginary parts converge in \( \mathbb{R} \). This shows \( \{a^n_k\}_{n=1}^\infty \) must converge to some \( a_k \). That is \( \lim_{n \to \infty} a^n_k = a_k \). Letting \( a = (a_1, \ldots, a_p) \), it follows from Theorem 5.7.3 that

\[
\lim_{n \to \infty} a_n = a.
\]

This proves the theorem.

**Theorem 5.7.8** The set of terms in a Cauchy sequence in \( \mathbb{F}^p \) is bounded in the sense that for all \( n \), \( |a_n| < M \) for some \( M < \infty \).

**Proof:** Let \( \varepsilon = 1 \) in the definition of a Cauchy sequence and let \( n > n_1 \). Then from the definition,

\[
|a_n - a_{n_1}| < 1.
\]

It follows that for all \( n > n_1 \),

\[
|a_n| < 1 + |a_{n_1}|.
\]

Therefore, for all \( n \),

\[
|a_n| \leq 1 + |a_{n_1}| + \sum_{k=1}^{n_1} |a_k|.
\]

This proves the theorem.

**Theorem 5.7.9** If a sequence \( \{a_n\} \) in \( \mathbb{F}^p \) converges, then the sequence is a Cauchy sequence.
5.8. PROPERTIES OF CONTINUOUS FUNCTIONS

Proof: Let \( \varepsilon > 0 \) be given and suppose \( a_n \to a \). Then from the definition of convergence, there exists \( n_\varepsilon \) such that if \( n > n_\varepsilon \), it follows that

\[
|a_n - a| < \frac{\varepsilon}{2}
\]

Therefore, if \( m, n \geq n_\varepsilon + 1 \), it follows that

\[
|a_n - a_m| \leq |a_n - a| + |a - a_m| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon
\]

showing that, since \( \varepsilon > 0 \) is arbitrary, \( \{a_n\} \) is a Cauchy sequence.

5.7.2 Continuity And The Limit Of A Sequence

Just as in the case of a function of one variable, there is a very useful way of thinking of continuity in terms of limits of sequences found in the following theorem. In words, it says a function is continuous if it takes convergent sequences to convergent sequences whenever possible.

Theorem 5.7.10 A function \( f : D(f) \to \mathbb{R}^q \) is continuous at \( x \in D(f) \) if and only if, whenever \( x_n \to x \) with \( x_n \in D(f) \), it follows \( f(x_n) \to f(x) \).

Proof: Suppose first that \( f \) is continuous at \( x \) and let \( x_n \to x \). Let \( \varepsilon > 0 \) be given. By continuity, there exists \( \delta > 0 \) such that if \( |y - x| < \delta \), then \( |f(y) - f(x)| < \varepsilon \). However, there exists \( n_\delta \) such that if \( n \geq n_\delta \), then \( |x_n - x| < \delta \) and so for all \( n \) this large,

\[
|f(x) - f(x_n)| < \varepsilon
\]

which shows \( f(x_n) \to f(x) \).

Now suppose the condition about taking convergent sequences to convergent sequences holds at \( x \). Suppose \( f \) fails to be continuous at \( x \). Then there exists \( \varepsilon > 0 \) and \( x_n \in D(f) \) such that \( |x - x_n| < \frac{1}{n} \), yet

\[
|f(x) - f(x_n)| \geq \varepsilon.
\]

But this is clearly a contradiction because, although \( x_n \to x \), \( f(x_n) \) fails to converge to \( f(x) \). It follows \( f \) must be continuous after all. This proves the theorem.

5.8 Properties Of Continuous Functions

Functions of \( p \) variables have many of the same properties as functions of one variable. First there is a version of the extreme value theorem generalizing the one dimensional case.

Theorem 5.8.1 Let \( C \) be closed and bounded and let \( f : C \to \mathbb{R} \) be continuous. Then \( f \) achieves its maximum and its minimum on \( C \). This means there exist, \( x_1, x_2 \in C \) such that for all \( x \in C \),

\[
f(x_1) \leq f(x) \leq f(x_2).
\]
There is also the long technical theorem about sums and products of continuous functions. These theorems are proved in the next section.

**Theorem 5.8.2** The following assertions are valid

1. The function, \( af + bg \) is continuous at \( x \) when \( f, g \) are continuous at \( x \in D(f) \cap D(g) \) and \( a, b \in \mathbb{F} \).

2. If and \( f \) and \( g \) are each \( \mathbb{F} \) valued functions continuous at \( x \), then \( fg \) is continuous at \( x \). If, in addition to this, \( g(x) \neq 0 \), then \( f/g \) is continuous at \( x \).

3. If \( f \) is continuous at \( x \), \( f(x) \in D(g) \subseteq \mathbb{F}^p \), and \( g \) is continuous at \( f(x) \), then \( g \circ f \) is continuous at \( x \).

4. If \( f = (f_1, \ldots, f_q) : D(f) \to \mathbb{F}^q \), then \( f \) is continuous if and only if each \( f_k \) is a continuous \( \mathbb{F} \) valued function.

5. The function \( f : \mathbb{F}^p \to \mathbb{F} \), given by \( f(x) = |x| \) is continuous.

### 5.9 Exercises

1. \( f : D \subseteq \mathbb{F}^p \to \mathbb{F}^q \) is Lipschitz continuous or just Lipschitz for short if there exists a constant, \( K \) such that

   \[ |f(x) - f(y)| \leq K|x - y| \]

   for all \( x, y \in D \). Show every Lipschitz function is uniformly continuous which means that given \( \varepsilon > 0 \) there exists \( \delta > 0 \) independent of \( x \) such that if \( |x - y| < \delta \), then \( |f(x) - f(y)| < \varepsilon \).

2. If \( f \) is uniformly continuous, does it follow that \( |f| \) is also uniformly continuous? If \( |f| \) is uniformly continuous does it follow that \( f \) is uniformly continuous? Answer the same questions with “uniformly continuous” replaced with “continuous”. Explain why.

### 5.10 Proofs Of Theorems

This section contains the proofs of the theorems which were just stated without proof.

**Theorem 5.10.1** The following assertions are valid

1. The function, \( af + bg \) is continuous at \( x \) when \( f, g \) are continuous at \( x \in D(f) \cap D(g) \) and \( a, b \in \mathbb{F} \).
2. If and $f$ and $g$ are each $F$ valued functions continuous at $x$, then $fg$ is continuous at $x$. If, in addition to this, $g(x) \neq 0$, then $f/g$ is continuous at $x$.

3. If $f$ is continuous at $x$, $f(x) \in D(g) \subseteq F^p$, and $g$ is continuous at $f(x)$, then $g \circ f$ is continuous at $x$.

4. If $f = (f_1, \ldots, f_n) : D(f) \to F^n$, then $f$ is continuous if and only if each $f_k$ is a continuous $F$ valued function.

5. The function $f : F^p \to F$, given by $f(x) = |x|$ is continuous.

**Proof:** Begin with 1.) Let $\varepsilon > 0$ be given. By assumption, there exist $\delta_1 > 0$ such that whenever $|x - y| < \delta_1$, it follows $|f(x) - f(y)| < \frac{\varepsilon}{2(|a| + |b| + 1)}$ and there exists $\delta_2 > 0$ such that whenever $|x - y| < \delta_2$, it follows $|g(x) - g(y)| < \frac{\varepsilon}{2(|a| + |b| + 1)}$. Then let $0 < \delta \leq \min(\delta_1, \delta_2)$. If $|x - y| < \delta$, then everything happens at once. Therefore, using the triangle inequality

$$|af(x) + bf(y) - (ag(y) + bg(y))|$$

$$\leq |a| |f(x) - f(y)| + |b| |g(x) - g(y)|$$

$$< |a| \left( \frac{\varepsilon}{2(|a| + |b| + 1)} \right) + |b| \left( \frac{\varepsilon}{2(|a| + |b| + 1)} \right) < \varepsilon.$$

Now begin on 2.) There exists $\delta_1 > 0$ such that if $|y - x| < \delta_1$, then

$$|f(x) - f(y)| < 1.$$

Therefore, for such $y$,

$$|f(y)| < 1 + |f(x)|.$$

It follows that for such $y$,

$$|fg(x) - fg(y)| \leq |f(x)g(x) - g(x)f(y)| + |g(x)f(y) - f(y)g(y)|$$

$$\leq |g(x)| |f(x) - f(y)| + |f(y)| |g(x) - g(y)|$$

$$\leq (1 + |g(x)| + |f(y)|) [ |g(x) - g(y)| + |f(x) - f(y)| ].$$

Now let $\varepsilon > 0$ be given. There exists $\delta_2$ such that if $|x - y| < \delta_2$, then

$$|g(x) - g(y)| < \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)},$$

and there exists $\delta_3$ such that if $|x - y| < \delta_3$, then

$$|f(x) - f(y)| < \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)}.$$
Now let $0 < \delta \leq \min (\delta_1, \delta_2, \delta_3)$. Then if $|x - y| < \delta$, all the above hold at once and

$$|f g(x) - f g(y)| \leq (1 + |g(x)| + |f(y)|)(|g(x) - g(y)| + |f(x) - f(y)|)$$

$$< (1 + |g(x)| + |f(y)|) \left( \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)} + \frac{\varepsilon}{2(1 + |g(x)| + |f(y)|)} \right) = \varepsilon.$$  

This proves the first part of 2.) To obtain the second part, let $\delta_1$ be as described above and let $\delta_2 > 0$ be such that for $|x - y| < \delta_0$,

$$|g(x) - g(y)| < |g(x)|/2$$

and so by the triangle inequality,

$$-|g(x)|/2 \leq |g(y)| - |g(x)| \leq |g(x)|/2$$

which implies $|g(y)| \geq |g(x)|/2$, and $|g(y)| < 3|g(x)|/2$.

Then if $|x - y| < \min (\delta_0, \delta_1),$

$$\left| \frac{f(x)}{g(x)} - \frac{f(y)}{g(y)} \right| = \left| \frac{f(x)g(y) - f(y)g(x)}{g(x)g(y)} \right|$$

$$\leq \left| \frac{f(x)g(y) - f(y)g(x)}{\frac{1}{2}|g(x)|^2} \right|$$

$$= \frac{2}{|g(x)|^2} \left| [f(x)g(y) - f(y)g(x)] + [f(y)g(x) - f(x)g(y)] \right|$$

$$\leq \frac{2}{|g(x)|^2} \left[ |f(x)| |g(y)| + |f(y)| |g(x)| \right]$$

$$\leq \frac{2}{|g(x)|^2} \left[ \frac{3}{2} |g(x)| |f(x) - f(y)| + (1 + |f(x)|) |g(y) - g(x)| \right]$$

$$\leq \frac{2}{|g(x)|^2} \left( 1 + 2 |f(x)| + 2 |g(x)| \right) \left( |f(x) - f(y)| + |g(y) - g(x)| \right)$$

$$= M \left( |f(x) - f(y)| + |g(y) - g(x)| \right)$$

where

$$M = \frac{2}{|g(x)|^2} \left( 1 + 2 |f(x)| + 2 |g(x)| \right)$$

Now let $\delta_2$ be such that if $|x - y| < \delta_2$, then

$$|f(x) - f(y)| < \frac{\varepsilon}{2} M^{-1}$$
5.10. PROOFS OF THEOREMS

and let \( \delta_3 \) be such that if \( |x - y| < \delta_3 \), then

\[
|g(y) - g(x)| < \frac{\varepsilon}{2} M^{-1}.
\]

Then if \( 0 < \delta \leq \min(\delta_0, \delta_1, \delta_2, \delta_3) \), and \( |x - y| < \delta \), everything holds and

\[
\left| \frac{f(x) - f(y)}{g(x)} \right| \leq M \left[ |f(x) - f(y)| + |g(y) - g(x)| \right]
\]

\[
< M \left[ \frac{\varepsilon}{2} M^{-1} + \frac{\varepsilon}{2} M^{-1} \right] = \varepsilon.
\]

This completes the proof of the second part of 2.) Note that in these proofs no effort is made to find some sort of “best” \( \delta \). The problem is one which has a yes or a no answer. Either it is or it is not continuous.

Now begin on 3.). If \( f \) is continuous at \( x \), \( f(x) \in D(g) \subseteq F^p \), and \( g \) is continuous at \( f(x) \), then \( g \circ f \) is continuous at \( x \). Let \( \varepsilon > 0 \) be given. Then there exists \( \eta > 0 \) such that if \( |y - f(x)| < \eta \) and \( y \in D(g) \), it follows that \( |g(y) - g(f(x))| < \varepsilon \). It follows from continuity of \( f \) at \( x \) that there exists \( \delta > 0 \) such that if \( |x - z| < \delta \) and \( z \in D(f) \), then \( |f(z) - f(x)| < \eta \). Then if \( |x - z| < \delta \) and \( z \in D(g \circ f) \subseteq D(f) \), all the above hold and so

\[
|g(f(z)) - g(f(x))| < \varepsilon.
\]

This proves part 3.)

Part 4.) says: If \( f = (f_1, \ldots, f_q) : D(f) \to F^q \), then \( f \) is continuous if and only if each \( f_k \) is a continuous \( F \) valued function. Then

\[
|f_k(x) - f_k(y)| \leq |f(x) - f(y)|
\]

\[
\equiv \left( \sum_{i=1}^{q} |f_i(x) - f_i(y)|^2 \right)^{1/2}
\]

\[
\leq \sum_{i=1}^{q} |f_i(x) - f_i(y)|. \quad (5.10.11)
\]

Suppose first that \( f \) is continuous at \( x \). Then there exists \( \delta > 0 \) such that if \( |x - y| < \delta \), then \( |f(x) - f(y)| < \varepsilon \). The first part of the above inequality then shows that for each \( k = 1, \ldots, q \), \( |f_k(x) - f_k(y)| < \varepsilon \). This shows the only if part. Now suppose each function, \( f_k \) is continuous. Then if \( \varepsilon > 0 \) is given, there exists \( \delta_k > 0 \) such that whenever \( |x - y| < \delta_k \)

\[
|f_k(x) - f_k(y)| < \varepsilon/q.
\]

Now let \( 0 < \eta \leq \min(\delta_1, \ldots, \delta_q) \). For \( |x - y| < \delta \), the above inequality holds for all \( k \) and so the last part of 5.10.11 implies

\[
|f(x) - f(y)| \leq \sum_{i=1}^{q} |f_i(x) - f_i(y)|
\]

\[
< \sum_{i=1}^{q} \frac{\varepsilon}{q} = \varepsilon.
\]
This proves part 4.)

To verify part 5.), let \( \varepsilon > 0 \) be given and let \( \delta = \varepsilon \). Then if \( |x - y| < \delta \), the triangle inequality implies

\[
|f(x) - f(y)| = |x| - |y| 
\leq |x - y| < \delta = \varepsilon.
\]

This proves part 5.) and completes the proof of the theorem.

Here is a multidimensional version of the nested interval lemma.

The following definition is similar to that given earlier. It defines what is meant by a sequentially compact set in \( \mathbb{F}^p \):

**Definition 5.10.2** A set, \( K \subseteq \mathbb{F}^p \) is sequentially compact if and only if whenever \( \{x_n\}_{n=1}^\infty \) is a sequence of points in \( K \), there exists a point, \( x \in K \) and a subsequence, \( \{x_{n_k}\}_{k=1}^\infty \) such that \( x_{n_k} \to x \).

It turns out the sequentially compact sets in \( \mathbb{F}^p \) are exactly those which are closed and bounded. Only half of this result will be needed in this book and this is proved next. First note that \( C \) can be considered as \( \mathbb{R}^2 \). Therefore, \( C^p \) may be considered as \( \mathbb{R}^{2p} \).

**Theorem 5.10.3** Let \( C \subseteq \mathbb{F}^p \) be closed and bounded. Then \( C \) is sequentially compact.

**Proof:** Let \( \{a_n\} \subseteq C \). Then let \( a_n = (a^n_1, \cdots, a^n_p) \). It follows the real and imaginary parts of the terms of the sequence, \( \{a^n_j\}_{n=1}^\infty \), are each contained in some sufficiently large closed bounded interval. By Theorem 2.0.3 on Page 33, there is a subsequence of the sequence of real parts of \( \{a^n_j\}_{n=1}^\infty \) which converges. Also there is a further subsequence of the imaginary parts of \( \{a^n_j\}_{n=1}^\infty \) which converges. Thus there is a subsequence, \( n_k \), with the property that \( a^{n_k}_j \) converges to a point, \( a_j \in \mathbb{F} \). Taking further subsequences, one obtains the existence of a subsequence, still called \( n_k \) such that for each \( r = 1, \cdots, p \), \( a^{n_k}_r \) converges to a point, \( a_r \in \mathbb{F} \) as \( k \to \infty \). Therefore, letting \( a = (a_1, \cdots, a_p) \), \( \lim_{k \to \infty} a^{n_k} = a \). Since \( C \) is closed, it follows \( a \in C \). This proves the theorem.

Here is a proof of the extreme value theorem.

**Theorem 5.10.4** Let \( C \) be closed and bounded and let \( f : C \to \mathbb{R} \) be continuous. Then \( f \) achieves its maximum and its minimum on \( C \). This means there exist \( x_1, x_2 \in C \) such that for all \( x \in C \),

\[
f(x_1) \leq f(x) \leq f(x_2).
\]

**Proof:** Let \( M = \sup \{ f(x) : x \in C \} \). Recall this means \( +\infty \) if \( f \) is not bounded above and it equals the least upper bound of these values of \( f \) if \( f \) is bounded above. Then there exists a sequence, \( \{x_n\} \) such that \( f(x_n) \to M \). Since \( C \) is sequentially compact, there exists a subsequence, \( x_{n_k} \), and a point, \( x \in C \) such that \( x_{n_k} \to x \).
5.11. THE SPACE $\mathcal{L}(F^N, F^M)$

But then since $f$ is continuous at $x$, it follows from Theorem 5.7.10 on Page 115 that $f(x) = \lim_{k\to\infty} f(x_n) = M$. This proves $f$ achieves its maximum and also shows its maximum is less than $\infty$. Let $x_2 = x$. The case of a minimum is handled similarly.

Recall that a function is uniformly continuous if the following definition holds.

**Definition 5.10.5** Let $f : D(f) \to F$. Then $f$ is uniformly continuous if for every $\varepsilon > 0$ there exists $\delta > 0$ such that whenever $|x - y| < \delta$, it follows $|f(x) - f(y)| < \varepsilon$.

**Theorem 5.10.6** Let $f : C \to F$ be continuous where $C$ is a closed and bounded set in $F$. Then $f$ is uniformly continuous on $C$.

**Proof:** If this is not so, there exists $\varepsilon > 0$ and pairs of points, $x_n$ and $y_n$ satisfying $|x_n - y_n| < 1/n$ but $|f(x_n) - f(y_n)| \geq \varepsilon$. Since $C$ is sequentially compact, there exists $x \in C$ and a subsequence, $\{x_{n_k}\}$ satisfying $x_{n_k} \to x$. But $|x_{n_k} - y_{n_k}| < 1/k$ and so $y_{n_k} \to x$ also. Therefore, from Theorem 5.7.10 on Page 115,

$$
\varepsilon \leq \lim_{k \to \infty} |f(x_{n_k}) - f(y_{n_k})| = |f(x) - f(x)| = 0,
$$

a contradiction. This proves the theorem.

5.11 The Space $\mathcal{L}(F^N, F^M)$

**Definition 5.11.1** The symbol, $\mathcal{L}(F^N, F^M)$ will denote the set of linear transformations mapping $F^n$ to $F^m$. Thus $L \in \mathcal{L}(F^n, F^m)$ means that for $\alpha, \beta$ scalars and $x, y$ vectors in $F^n$,

$$
L(\alpha x + \beta y) = \alpha L(x) + \beta L(y).
$$

It is convenient to give a norm for the elements of $\mathcal{L}(F^n, F^m)$. This will allow the consideration of questions such as whether a function having values in this space of linear transformations is continuous.

5.11.1 The Operator Norm

How do you measure the distance between linear transformations defined on $F^n$? It turns out there are many ways to do this but I will give the most common one here.

**Definition 5.11.2** $\mathcal{L}(F^n, F^m)$ denotes the space of linear transformations mapping $F^n$ to $F^m$. For $A \in \mathcal{L}(F^n, F^m)$, the operator norm is defined by

$$
\|A\| \equiv \max \{ |Ax|_{F^m} : |x|_{F^n} = 1 \} < \infty.
$$

**Theorem 5.11.3** Denote by $\|\cdot\|$ the norm on either $F^n$ or $F^m$. Then $\mathcal{L}(F^n, F^m)$ with this operator norm is a complete normed linear space of dimension $nm$ with

$$
\|Ax\| \leq \|A\| |x|.
$$

Here Completeness means that every Cauchy sequence converges.
Proof: It is necessary to show the norm defined on \( L(\mathbb{F}^n, \mathbb{F}^m) \) really is a norm. This means it is necessary to verify

\[ ||A|| \geq 0 \text{ and equals zero if and only if } A = 0. \]

For \( \alpha \) a scalar,

\[ ||\alpha A|| = |\alpha||A||, \]

and for \( A, B \in L(\mathbb{F}^n, \mathbb{F}^m) \),

\[ ||A + B|| \leq ||A|| + ||B|| \]

The first two properties are obvious but you should verify them. It remains to verify the norm is well defined and also to verify the triangle inequality above. First if \( |x| \leq 1 \), and \((A_{ij})\) is the matrix of the linear transformation with respect to the usual basis vectors, then

\[
||A|| = \max \left\{ \left( \sum_i |(A_{ij})|^2 \right)^{1/2} : |x| \leq 1 \right\}
\]

\[
= \max \left\{ \left( \sum_i \sum_j A_{ij}x_j^2 \right)^{1/2} : |x| \leq 1 \right\}
\]

which is a finite number by the extreme value theorem.

It is clear that a basis for \( L(\mathbb{F}^n, \mathbb{F}^m) \) consists of linear transformations whose matrices are of the form \( E_{ij} \) where \( E_{ij} \) consists of the \( m \times n \) matrix having all zeros except for a 1 in the \( ij^{th} \) position. In effect, this considers \( L(\mathbb{F}^n, \mathbb{F}^m) \) as \( \mathbb{F}^{nm} \). Think of the \( m \times n \) matrix as a long vector folded up.

If \( x \neq 0 \),

\[
|Ax| \frac{1}{|x|} = \left| A \frac{x}{|x|} \right| \leq ||A|| \tag{5.11.12}
\]

It only remains to verify completeness. Suppose then that \( \{A_k\} \) is a Cauchy sequence in \( L(\mathbb{F}^n, \mathbb{F}^m) \). Then from 5.11.12 \( \{A_kx\} \) is a Cauchy sequence for each \( x \in \mathbb{F}^n \). This follows because

\[
|A_kx - A_lx| \leq ||A_k - A_l|| |x|
\]

which converges to 0 as \( k, l \to \infty \). Therefore, by completeness of \( \mathbb{F}^m \), there exists \( Ax \), the name of the thing to which the sequence, \( \{A_kx\} \) converges such that

\[
\lim_{k \to \infty} A_kx = Ax.
\]
5.11. THE SPACE \( \mathcal{L}(\mathbb{F}^N, \mathbb{F}^M) \)

Then \( A \) is linear because

\[
A(ax + by) = \lim_{k \to \infty} A_k(ax + by) = \lim_{k \to \infty} (aA_kx + bA_ky) = a \lim_{k \to \infty} A_kx + b \lim_{k \to \infty} A_ky = aAx + bAy.
\]

By the first part of this argument, \( ||A|| < \infty \) and so \( A \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m) \). This proves the theorem.

**Proposition 5.11.4** Let \( A(x) \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m) \) for each \( x \in U \subseteq \mathbb{F}^p \). Then letting \( (A_{ij}(x)) \) denote the matrix of \( A(x) \) with respect to the standard basis, it follows \( A_{ij} \) is continuous at \( x \) for each \( i, j \) if and only if for all \( \varepsilon > 0 \), there exists a \( \delta > 0 \) such that if \( |x - y| < \delta \), then \( ||A(x) - A(y)|| < \varepsilon \). That is, \( A \) is a continuous function having values in \( \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m) \) at \( x \).

**Proof:** Suppose first the second condition holds. Then from the material on linear transformations,

\[
|A_{ij}(x) - A_{ij}(y)| = |e_i \cdot (A(x) - A(y))e_j| \\
\leq |e_i| ||(A(x) - A(y))e_j|| \\
\leq ||A(x) - A(y)||.
\]

Therefore, the second condition implies the first.

Now suppose the first condition holds. That is each \( A_{ij} \) is continuous at \( x \). Let \( |v| \leq 1 \).

\[
|(A(x) - A(y))(v)| = \left( \sum_i \left| \sum_j (A_{ij}(x) - A_{ij}(y))v_j \right|^2 \right)^{1/2} \tag{5.11.13}
\]

\[
\leq \left( \sum_i \left( \sum_j |A_{ij}(x) - A_{ij}(y)||v_j|^2 \right) \right)^{1/2}.
\]

By continuity of each \( A_{ij} \), there exists a \( \delta > 0 \) such that for each \( i, j \)

\[
|A_{ij}(x) - A_{ij}(y)| < \frac{\varepsilon}{n\sqrt{m}}
\]
whenever $|x - y| < \delta$. Then from (5.11.13), if $|x - y| < \delta$,

$$|(A(x) - A(y))(v)| < \left( \sum_i \left( \sum_j \frac{\varepsilon}{n^{1/m}} |v| \right)^2 \right)^{1/2}$$

$$\leq \left( \sum_i \left( \sum_j \frac{\varepsilon}{n^{1/m}} \right)^2 \right)^{1/2} = \varepsilon$$

This proves the proposition.

5.12 The Frechet Derivative

Let $U$ be an open set in $\mathbb{F}^n$, and let $f : U \to \mathbb{F}^m$ be a function.

Definition 5.12.1 A function $g$ is $o(v)$ if

$$\lim_{|v| \to 0} \frac{g(v)}{|v|} = 0$$

(5.12.14)

A function $f : U \to \mathbb{F}^m$ is differentiable at $x \in U$ if there exists a linear transformation $L \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m)$ such that

$$f(x + v) = f(x) + Lv + o(v)$$

This linear transformation $L$ is the definition of $Df(x)$. This derivative is often called the Frechet derivative.

Usually no harm is occasioned by thinking of this linear transformation as its matrix taken with respect to the usual basis vectors.

The definition (5.12.14) means that the error,

$$f(x + v) - f(x) - Lv$$

converges to 0 faster than $|v|$. Thus the above definition is equivalent to saying

$$\lim_{|v| \to 0} \frac{|f(x + v) - f(x) - Lv|}{|v|} = 0$$

(5.12.15)

or equivalently,

$$\lim_{y \to x} \frac{|f(y) - f(x) - Df(x)(y - x)|}{|y - x|} = 0.$$

(5.12.16)

Now it is clear this is just a generalization of the notion of the derivative of a function of one variable because in this more specialized situation,

$$\lim_{|v| \to 0} \frac{|f(x + v) - f(x) - f'(x)v|}{|v|} = 0,$$
5.12. THE FRECHET DERIVATIVE

due to the definition which says

\[ f'(x) = \lim_{v \to 0} \frac{f(x + v) - f(x)}{v}. \]

For functions of \( n \) variables, you can’t define the derivative as the limit of a difference quotient like you can for a function of one variable because you can’t divide by a vector. That is why there is a need for a more general definition.

The term \( o(v) \) is notation that is descriptive of the behavior in \( \mathbb{R}^n \) and it is only this behavior that is of interest. Thus, if \( t \) and \( k \) are constants,

\[ o(v) = o(v) + o(v), \quad o(tv) = o(v), \quad ko(v) = o(v) \]

and other similar observations hold. The sloppiness built in to this notation is useful because it ignores details which are not important. It may help to think of \( o(v) \) as an adjective describing what is left over after approximating \( f(x + v) \) by \( f(x) + Df(x)v \).

**Theorem 5.12.2** The derivative is well defined.

**Proof:** First note that for a fixed vector, \( v \), \( o(tv) = o(t) \). Now suppose both \( L_1 \) and \( L_2 \) work in the above definition. Then let \( v \) be any vector and let \( t \) be a real scalar which is chosen small enough that \( tv \in U \). Then

\[ f(x + tv) = f(x) + L_1 tv + o(tv), \quad f(x + tv) = f(x) + L_2 tv + o(tv). \]

Therefore, subtracting these two yields \( (L_2 - L_1)(tv) = o(tv) = o(t) \). Therefore, dividing by \( t \) yields \( (L_2 - L_1)(v) = \frac{o(t)}{t} \). Now let \( t \to 0 \) to conclude that \( (L_2 - L_1)(v) = 0 \). Since this is true for all \( v \), it follows \( L_2 = L_1 \). This proves the theorem.

**Lemma 5.12.3** Let \( f \) be differentiable at \( x \). Then \( f \) is continuous at \( x \) and in fact, there exists \( K > 0 \) such that whenever \( |v| \) is small enough,

\[ |f(x + v) - f(x)| \leq K |v| \]

**Proof:** From the definition of the derivative, \( f(x + v) - f(x) = Df(x)v + o(v) \). Let \( |v| \) be small enough that \( \frac{o(|v|)}{|v|} < 1 \) so that \( |o(v)| \leq |v| \). Then for such \( v \),

\[ |f(x + v) - f(x)| \leq |Df(x)v| + |v| \leq (|Df(x)| + 1)|v| \]

This proves the lemma with \( K = |Df(x)| + 1 \).

**Theorem 5.12.4** *(The chain rule)* Let \( U \) and \( V \) be open sets, \( U \subseteq \mathbb{F}^n \) and \( V \subseteq \mathbb{F}^m \). Suppose \( f : U \to V \) is differentiable at \( x \in U \) and suppose \( g : V \to \mathbb{F}^q \) is differentiable at \( f(x) \in V \). Then \( g \circ f \) is differentiable at \( x \) and

\[ D(g \circ f)(x) = Dg(f(x))Df(x). \]
Proof: This follows from a computation. Let $B(x,r) \subseteq U$ and let $r$ also be small enough that for $|v| \leq r$, it follows that $f(x+v) \in V$. Such an $r$ exists because $f$ is continuous at $x$. For $|v| < r$, the definition of differentiability of $g$ and $f$ implies

$$g(f(x+v)) - g(f(x)) =$$

$$Dg(f(x))(f(x+v) - f(x)) + o(f(x+v) - f(x))$$

$$= Dg(f(x))[Df(x)v + o(v)] + o(f(x+v) - f(x))$$

$$= Dg(f(x))Df(x)v + o(v) + o(f(x+v) - f(x)).$$  \hspace{1cm} (5.12.17)

It remains to show $o(f(x+v) - f(x)) = o(v)$.

By Lemma \ref{lemma:linear_transform}, with $K$ given there, letting $\varepsilon > 0$, it follows that for $|v|$ small enough,

$$|o(f(x+v) - f(x))| \leq (\varepsilon/K)|f(x+v) - f(x)| \leq (\varepsilon/K)K |v| = \varepsilon |v|.$$

Since $\varepsilon > 0$ is arbitrary, this shows $o(f(x+v) - f(x)) = o(v)$ because whenever $|v|$ is small enough,

$$\frac{|o(f(x+v) - f(x))|}{|v|} \leq \varepsilon.$$

By \ref{lemma:linear_transform}, this shows

$$g(f(x+v)) - g(f(x)) = Dg(f(x))Df(x)v + o(v)$$

which proves the theorem.

The derivative is a linear transformation. What is the matrix of this linear transformation taken with respect to the usual basis vectors? Let $e_i$ denote the vector of $\mathbb{R}^n$ which has a one in the $i^{th}$ entry and zeroes elsewhere. Then the matrix of the linear transformation is the matrix whose $i^{th}$ column is $Df(x)e_i$. What is this? Let $t \in \mathbb{R}$ such that $|t|$ is sufficiently small.

$$f(x+te_i) - f(x) = Df(x)te_i + o(te_i)$$

$$= Df(x)te_i + o(t).$$

Then dividing by $t$ and taking a limit,

$$Df(x)e_i = \lim_{t \to 0} \frac{f(x+te_i) - f(x)}{t} = \frac{\partial f}{\partial x_i}(x).$$

Thus the matrix of $Df(x)$ with respect to the usual basis vectors is the matrix of the form

$$
\begin{pmatrix}
  f_{1,x_1}(x) & f_{1,x_2}(x) & \cdots & f_{1,x_n}(x) \\
  \vdots & \vdots & & \vdots \\
  f_{m,x_1}(x) & f_{m,x_2}(x) & \cdots & f_{m,x_n}(x)
\end{pmatrix}.
$$

As mentioned before, there is no harm in referring to this matrix as $Df(x)$ but it may also be referred to as $Jf(x)$.

This is summarized in the following theorem.
Theorem 5.12.5 Let \( f : \mathbb{F}^n \to \mathbb{F}^m \) and suppose \( f \) is differentiable at \( \mathbf{x} \). Then all the partial derivatives \( \frac{\partial f_i}{\partial x_j} (\mathbf{x}) \) exist and if \( \mathbf{J}f (\mathbf{x}) \) is the matrix of the linear transformation with respect to the standard basis vectors, then the \( ij \)th entry is given by \( f_{i,j} \) or \( \frac{\partial f_i}{\partial x_j} (\mathbf{x}) \).

What if all the partial derivatives of \( f \) exist? Does it follow that \( f \) is differentiable? Consider the following function:

\[
f(\mathbf{x}, \mathbf{y}) = \begin{cases} 
\frac{xy}{x^2 + y^2} & \text{if } (\mathbf{x}, \mathbf{y}) \neq (0, 0) \\
0 & \text{if } (\mathbf{x}, \mathbf{y}) = (0, 0)
\end{cases}
\]

Then from the definition of partial derivatives,

\[
\lim_{h \to 0} \frac{f(h, 0) - f(0, 0)}{h} = \lim_{h \to 0} \frac{0 - 0}{h} = 0
\]

and

\[
\lim_{h \to 0} \frac{f(0, h) - f(0, 0)}{h} = \lim_{h \to 0} \frac{0 - 0}{h} = 0
\]

However \( f \) is not even continuous at \((0, 0)\) which may be seen by considering the behavior of the function along the line \( y = x \) and along the line \( x = 0 \). By Lemma 5.12.3, this implies \( f \) is not differentiable. Therefore, it is necessary to consider the correct definition of the derivative given above if you want to get a notion which generalizes the concept of the derivative of a function of one variable in such a way as to preserve continuity whenever the function is differentiable.

5.13 \( C^1 \) Functions

However, there are theorems which can be used to get differentiability of a function based on existence of the partial derivatives.

**Definition 5.13.1** When all the partial derivatives exist and are continuous the function is called a \( C^1 \) function.

Because of Proposition 5.11.3 on Page 123 and Theorem 5.12.5 which identifies the entries of \( \mathbf{J}f \) with the partial derivatives, the following definition is equivalent to the above.

**Definition 5.13.2** Let \( U \subseteq \mathbb{F}^n \) be an open set. Then \( f : U \to \mathbb{F}^m \) is \( C^1 \) \((U)\) if \( f \) is differentiable and the mapping

\[
\mathbf{x} \to \mathbf{D}f (\mathbf{x})
\]

is continuous as a function from \( U \) to \( \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m) \).

The following is an important abstract generalization of the familiar concept of partial derivative.
CHAPTER 5. MULTI-VARIABLE CALCULUS

Definition 5.13.3 Let \( g : U \subseteq \mathbb{F}^n \times \mathbb{F}^m \to \mathbb{F}^q \), where \( U \) is an open set in \( \mathbb{F}^n \times \mathbb{F}^m \). Denote an element of \( \mathbb{F}^n \times \mathbb{F}^m \) by \((x, y)\) where \( x \in \mathbb{F}^n \) and \( y \in \mathbb{F}^m \). Then the map \( x \to g(x, y) \) is a function from the open set in \( \mathbb{F}^n \),

\[
\{ x : (x, y) \in U \}
\]
to \( \mathbb{F}^q \). When this map is differentiable, its derivative is denoted by

\[
D_1g(x, y) \quad \text{or sometimes by} \quad D_xg(x, y).
\]

Thus,

\[
g(x + v, y) - g(x, y) = D_1g(x, y)v + o(v).
\]

A similar definition holds for the symbol \( D_yg \) or \( D_2g \). The special case seen in beginning calculus courses is where \( g : U \to \mathbb{F}^q \) and

\[
g_{x_i}(x) = \frac{\partial g(x)}{\partial x_i} = \lim_{h \to 0} \frac{g(x + he_i) - g(x)}{h}.
\]

The following theorem will be very useful in much of what follows. It is a version of the mean value theorem. You might call it the mean value inequality.

Theorem 5.13.4 Suppose \( U \) is an open subset of \( \mathbb{F}^n \) and \( f : U \to \mathbb{F}^m \) has the property that \( Df(x) \) exists for all \( x \) in \( U \) and that, \( x + t(y - x) \in U \) for all \( t \in [0, 1] \). (The line segment joining the two points lies in \( U \).) Suppose also that for all points on this line segment,

\[
||Df(x + t(y - x))|| \leq M.
\]

Then

\[
|f(y) - f(x)| \leq M |y - x|.
\]

Proof: Let

\[
S = \{ t \in [0, 1] : \text{for all} \ s \in [0, t],
|f(x + s(y - x)) - f(x)| \leq (M + \varepsilon) s |y - x| \}.
\]

Then \( 0 \in S \) and by continuity of \( f \), it follows that if \( t = \sup S \), then \( t \in S \) and if \( t < 1 \),

\[
|f(x + t(y - x)) - f(x)| = (M + \varepsilon) t |y - x|. \quad (5.13.18)
\]

If \( t < 1 \), then there exists a sequence of positive numbers, \( \{h_k\}_{k=1}^{\infty} \) converging to 0 such that

\[
|f(x + (t + h_k)(y - x)) - f(x)| > (M + \varepsilon)(t + h_k) |y - x|
\]

which implies that

\[
|f(x + (t + h_k)(y - x)) - f(x + t(y - x))| + |f(x + t(y - x)) - f(x)| > (M + \varepsilon)(t + h_k) |y - x|.
\]
5.13. \textit{C}^1 \textit{FUNCTIONS}

By Proposition this inequality implies

\[ |f(x + (t + h_k)(y - x)) - f(x + t(y - x))| > (M + \varepsilon)h_k|y - x| \]

which yields upon dividing by \( h_k \) and taking the limit as \( h_k \to 0 \),

\[ |Df(x + t(y - x))(y - x)| \geq (M + \varepsilon)|y - x|. \]

Now by the definition of the norm of a linear operator,

\[ M|y - x| \geq |Df(x + t(y - x))||y - x| \]
\[ \geq |Df(x + t(y - x))(y - x)| \geq (M + \varepsilon)|y - x|, \]

a contradiction. Therefore, \( t = 1 \) and so

\[ |f(x + (y - x)) - f(x)| \leq (M + \varepsilon)|y - x|. \]

Since \( \varepsilon > 0 \) is arbitrary, this proves the theorem.

The next theorem proves that if the partial derivatives exist and are continuous, then the function is differentiable.

\textbf{Theorem 5.13.5} Let \( g : U \subseteq \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}^q \). Then \( g \) is \( C^1(U) \) if and only if \( D_1 g \) and \( D_2 g \) both exist and are continuous on \( U \). In this case,

\[ Dg(x, y)(u, v) = D_1 g(x, y)u + D_2 g(x, y)v. \]

\textbf{Proof:} Suppose first that \( g \in C^1(U) \). Then if \( (x, y) \in U \),

\[ g(x + u, y) - g(x, y) = Dg(x, y)(u, 0) + o(u). \]

Therefore, \( D_1 g(x, y)u = Dg(x, y)(u, 0) \). Then

\[ |(D_1 g(x, y) - D_1 g(x', y'))(u)| = \]
\[ |Dg(x, y) - Dg(x', y')(u, 0)| \leq \]
\[ ||Dg(x, y) - Dg(x', y')|||u, 0||. \]

Therefore,

\[ |D_1 g(x, y) - D_1 g(x', y')| \leq ||Dg(x, y) - Dg(x', y')||. \]

A similar argument applies for \( D_2 g \) and this proves the continuity of the function,

\[ (x, y) \to D_1 g(x, y) \text{ for } i = 1, 2. \]

The formula follows from

\[ Dg(x, y)(u, v) = Dg(x, y)(u, 0) + Dg(x, y)(0, v) \equiv D_1 g(x, y)u + D_2 g(x, y)v. \]

Now suppose \( D_1 g(x, y) \) and \( D_2 g(x, y) \) exist and are continuous.

\[ g(x + u, y + v) - g(x, y) = g(x + u, y + v) - g(x, y + v) \]
\[ + g(x, y + v) - g(x, y) \]
\[ = g(x + u, y) - g(x, y) + g(x, y + v) - g(x, y) + \]
\[ [g(x + u, y + v) - g(x, y + v) - (g(x, y + v) - g(x, y)))] \]
\[ = D_1 g(x, y) u + D_2 g(x, y) v + o(v) + o(u) + \]
\[ [g(x + u, y + v) - g(x + u, y) - (g(x, y + v) - g(x, y))]. \] (5.13.19)

Let \( h(x, u) \equiv g(x + u, y + v) - g(x + u, y) \). Then the expression in \( [ \) is of the form,
\[ h(x, u) - h(x, 0). \]

Also
\[ D_2 h(x, u) = D_1 g(x + u, y + v) - D_1 g(x + u, y) \]
and so, by continuity of \( (x, y) \rightarrow D_1 g(x, y), \)
\[ ||D_2 h(x, u)|| < \varepsilon \]
whenever \( ||(u, v)|| \) is small enough. By Theorem 5.13.2 on Page 128, there exists \( \delta > 0 \) such that if \( ||(u, v)|| < \delta \), the norm of the last term in 5.13.19 satisfies the inequality,
\[ ||g(x + u, y + v) - g(x + u, y) - (g(x, y + v) - g(x, y))|| < \varepsilon ||u||. \] (5.13.20)

Therefore, this term is \( o((u, v)) \). It follows from 5.13.20 and 5.13.14 that
\[ g(x + u, y + v) = g(x, y) + D_1 g(x, y) u + D_2 g(x, y) v + o(u) + o(v) + o((u, v)) \]
\[ = g(x, y) + D_1 g(x, y) u + D_2 g(x, y) v + o((u, v)) \]

Showing that \( Dg(x, y) \) exists and is given by
\[ Dg(x, y)(u, v) = D_1 g(x, y) u + D_2 g(x, y) v. \]

The continuity of \( (x, y) \rightarrow Dg(x, y) \) follows from the continuity of \( (x, y) \rightarrow D_1 g(x, y) \). This proves the theorem.

Not surprisingly, it can be generalized to many more factors.

**Definition 5.13.6** Let \( g : U \subseteq \prod_{i=1}^{n} F^{r_i} \rightarrow F^q \), where \( U \) is an open set. Then the map \( x_i \rightarrow g(x) \) is a function from the open set in \( F^{r_i} \),
\[ \{ x : x = (x_1, \cdots, x_{i-1}, x_i, x_{i+1}, \cdots, x_n) \in U \} \]
to \( F^q \). When this map is differentiable, its derivative is denoted by \( D_1 g(x) \). To aid in the notation, for \( v \in F^{r_i} \), let \( \theta_i v \in \prod_{i=1}^{n} F^{r_i} \) be the vector \( (0, \cdots, v, \cdots, 0) \) where the \( v \) is in the \( i^{th} \) slot and for \( v \in \prod_{i=1}^{n} F^{r_i} \), let \( v_i \) denote the entry in the \( i^{th} \) slot of \( v \). Thus, by saying \( x_i \rightarrow g(x) \) is differentiable is meant that for \( v \in F^{r_i} \) sufficiently small,
\[ g(x + \theta_i v) - g(x) = D_1 g(x) v + o(v). \]

Note \( D_1 g(x) \in L(F^{r_i}, \prod_{i=1}^{n} F^{r_i}) \).
Here is a generalization of Theorem $5.13.7$.

**Theorem 5.13.7** Let $g, U, \prod_{i=1}^{n} \mathbb{R}^{i}$, be given as in Definition $5.13.7$. Then $g$ is $C^1(U)$ if and only if $D_i g$ exists and is continuous on $U$ for each $i$. In this case,

$$Dg(x)(v) = \sum_{k} D_k g(x)v_k$$

where $v = (v_1, \cdots, v_n)$.

**Proof:** Suppose then that $D_i g$ exists and is continuous for each $i$. Note that $\sum_{j=1}^{k} \theta_j v_j = (v_1, \cdots, v_k, 0, \cdots, 0)$. Thus $\sum_{j=1}^{k} \theta_j v_j = v$ and define $\sum_{j=1}^{k} \theta_j v_j = v$. Therefore,

$$g(x + v) - g(x) = \sum_{k=1}^{n} \left[ g\left(x + \sum_{j=1}^{k} \theta_j v_j\right) - g\left(x + \sum_{j=1}^{k-1} \theta_j v_j\right) \right]$$

Consider the terms in this sum.

$$g\left(x + \sum_{j=1}^{k} \theta_j v_j\right) - g\left(x + \sum_{j=1}^{k-1} \theta_j v_j\right) = g(x + \theta_k v_k) - g(x) +$$

and the expression in $5.13.24$ is of the form $h(v_k) - h(0)$ where for small $w \in \mathbb{R}^n$,

$$h(w) = g\left(x + \sum_{j=1}^{k-1} \theta_j v_j + \theta_k w\right) - g(x + \theta_k w).$$

Therefore,

$$Dh(w) = D_k g\left(x + \sum_{j=1}^{k-1} \theta_j v_j + \theta_k w\right) - D_k g(x + \theta_k w)$$

and by continuity, $||Dh(w)|| < \varepsilon$ provided $|v|$ is small enough. Therefore, by Theorem $5.13.24$, whenever $|v|$ is small enough, $|h(v_k) - h(0)| \leq \varepsilon |v_k| \leq \varepsilon |v|$ which shows that since $\varepsilon$ is arbitrary, the expression in $5.13.24$ is $o(v)$. Now in $5.13.24$,

$$g(x + \theta_k v_k) - g(x) = D_k g(x)v_k + o(v_k) = D_k g(x)v_k + o(v).$$

Therefore, referring to $5.13.24$,

$$g(x + v) - g(x) = \sum_{k=1}^{n} D_k g(x)v_k + o(v).$$
which shows \( Dg \) exists and equals the formula given in \( 5.13.21 \).

Next suppose \( g \) is \( C^1 \). I need to verify that \( D_kg(x) \) exists and is continuous. Let \( \mathbf{v} \in \mathbb{F}^r \) sufficiently small. Then

\[
\begin{align*}
g(x + \theta_k \mathbf{v}) - g(x) &= Dg(x) \theta_k \mathbf{v} + o(\theta_k \mathbf{v}) \\
&= Dg(x) \theta_k \mathbf{v} + o(\mathbf{v})
\end{align*}
\]

since \( |\theta_k \mathbf{v}| = |\mathbf{v}| \). Then \( D_kg(x) \) exists and equals

\[
Dg(x) \circ \theta_k
\]

Since \( x \rightarrow Dg(x) \) is continuous and \( \theta_k : \mathbb{F}^r \rightarrow \prod_{i=1}^n \mathbb{F}^r_i \) is also continuous, this proves the theorem.

The way this is usually used is in the following corollary, a case of Theorem 5.13.7 obtained by letting \( F \) in the above theorem.

**Corollary 5.13.8** Let \( U \) be an open subset of \( \mathbb{F}^n \) and let \( f : U \rightarrow \mathbb{F}^m \) be \( C^1 \) in the sense that all the partial derivatives of \( f \) exist and are continuous. Then \( f \) is differentiable and

\[
f(x + \mathbf{v}) = f(x) + \sum_{k=1}^n \frac{\partial f}{\partial x_k}(x) v_k + o(\mathbf{v}).
\]

### 5.14 \( C^k \) Functions

Recall the notation for partial derivatives in the following definition.

**Definition 5.14.1** Let \( g : U \rightarrow \mathbb{F}^n \). Then

\[
g_{x_k}(x) = \frac{\partial g}{\partial x_k}(x) = \lim_{h \to 0} \frac{g(x + h e_k) - g(x)}{h}
\]

Higher order partial derivatives are defined in the usual way.

\[
g_{x_k x_l}(x) = \frac{\partial^2 g}{\partial x_l \partial x_k}(x)
\]

and so forth.

To deal with higher order partial derivatives in a systematic way, here is a useful definition.

**Definition 5.14.2** \( \alpha = (\alpha_1, \cdots, \alpha_n) \) for \( \alpha_1 \cdots \alpha_n \) positive integers is called a multi-index. For \( \alpha \) a multi-index, \( |\alpha| = \alpha_1 + \cdots + \alpha_n \) and if \( x \in \mathbb{F}^n \),

\[
x = (x_1, \cdots, x_n),
\]

and \( f \) a function, define

\[
x^\alpha = x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n}, \quad D^\alpha f(x) = \frac{\partial^{|\alpha|} f(x)}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2} \cdots \partial x_n^{\alpha_n}}.
\]
The following is the definition of what is meant by a \( C^k \) function.

**Definition 5.14.3** Let \( U \) be an open subset of \( \mathbb{F}^n \) and let \( f : U \to \mathbb{F}^m \). Then for \( k \) a nonnegative integer, \( f \) is \( C^k \) if for every \( |\alpha| \leq k \), \( D^\alpha f \) exists and is continuous.

### 5.15 Mixed Partial Derivatives

Under certain conditions the **mixed partial derivatives** will always be equal. This astonishing fact is due to Euler in 1734.

**Theorem 5.15.1** Suppose \( f : U \subseteq \mathbb{F}^2 \to \mathbb{R} \) where \( U \) is an open set on which \( f_x, f_y, f_{xy}, \) and \( f_{yx} \) exist. Then if \( f_{xy} \) and \( f_{yx} \) are continuous at the point \((x, y) \in U\), it follows

\[
f_{xy}(x, y) = f_{yx}(x, y).
\]

**Proof:** Since \( U \) is open, there exists \( r > 0 \) such that \( B((x, y), r) \subseteq U \). Now let \( |t|, |s| < r/2, t, s \) real numbers and consider

\[
\Delta(s, t) \equiv \frac{1}{st} \left( f(x + t, y + s) - f(x + t, y) - (f(x, y + s) - f(x, y)) \right). \tag{5.15.25}
\]

Note that \((x + t, y + s) \in U\) because

\[
|(x + t, y + s) - (x, y)| = |(t, s)| = (t^2 + s^2)^{1/2} \leq \left( \frac{r^2}{4} + \frac{r^2}{4} \right)^{1/2} = \frac{r}{\sqrt{2}} < r.
\]

As implied above, \( h(t) = f(x + t, y + s) - f(x + t, y) \). Therefore, by the mean value theorem from calculus and the (one variable) chain rule,

\[
\Delta(s, t) = \frac{1}{st} \left( h(t) - h(0) \right) = \frac{1}{st} h'(\alpha t) t
\]

for some \( \alpha \in (0, 1) \). Applying the mean value theorem again,

\[
\Delta(s, t) = f_{xy}(x + \alpha t, y + \beta s)
\]

where \( \alpha, \beta \in (0, 1) \).

If the terms \( f(x + t, y) \) and \( f(x, y + s) \) are interchanged in \( \Delta(s, t) \), \( \Delta(s, t) \) is unchanged and the above argument shows there exist \( \gamma, \delta \in (0, 1) \) such that

\[
\Delta(s, t) = f_{yx}(x + \gamma t, y + \delta s).
\]

Letting \((s, t) \to (0, 0)\) and using the continuity of \( f_{xy} \) and \( f_{yx} \) at \((x, y)\),

\[
\lim_{(s, t) \to (0, 0)} \Delta(s, t) = f_{xy}(x, y) = f_{yx}(x, y).
\]
This proves the theorem.

The following is obtained from the above by simply fixing all the variables except for the two of interest.

**Corollary 5.15.2** Suppose $U$ is an open subset of $\mathbb{R}^n$ and $f : U \to \mathbb{R}$ has the property that for two indices, $k, l$, $f_{x_k}, f_{x_l}, f_{x_k x_l}$, and $f_{x_k x_l}$ exist on $U$ and $f_{x_k x_l}$ and $f_{x_l x_k}$ are both continuous at $x \in U$. Then $f_{x_k x_l}(x) = f_{x_l x_k}(x)$.

By considering the real and imaginary parts of $f$ in the case where $f$ has values in $\mathbb{F}$ you obtain the following corollary.

**Corollary 5.15.3** Suppose $U$ is an open subset of $\mathbb{F}^n$ and $f : U \to \mathbb{F}$ has the property that for two indices, $k, l$, $f_{x_k}, f_{x_l}, f_{x_k x_l}$, and $f_{x_k x_l}$ exist on $U$ and $f_{x_k x_l}$ and $f_{x_l x_k}$ are both continuous at $x \in U$. Then $f_{x_k x_l}(x) = f_{x_l x_k}(x)$.

Finally, by considering the components of $f$ you get the following generalization.

**Corollary 5.15.4** Suppose $U$ is an open subset of $\mathbb{F}^n$ and $f : U \to \mathbb{F}^m$ has the property that for two indices, $k, l$, $f_{x_k}, f_{x_l}, f_{x_k x_l}$, and $f_{x_k x_l}$ exist on $U$ and $f_{x_k x_l}$ and $f_{x_l x_k}$ are both continuous at $x \in U$. Then $f_{x_k x_l}(x) = f_{x_l x_k}(x)$.

It is necessary to assume the mixed partial derivatives are continuous in order to assert they are equal. The following is a well known example [3].

**Example 5.15.5** Let

$$f(x, y) = \begin{cases} \frac{xy(x^2-y^2)}{x^2+y^2} & \text{if } (x, y) \neq (0, 0) \\ 0 & \text{if } (x, y) = (0, 0) \end{cases}$$

From the definition of partial derivatives it follows immediately that $f_x(0, 0) = f_y(0, 0) = 0$. Using the standard rules of differentiation, for $(x, y) \neq (0, 0)$,

$$f_x = y \frac{x^4 - y^4 + 4x^2y^2}{(x^2 + y^2)^2}, \quad f_y = x \frac{x^4 - y^4 - 4x^2y^2}{(x^2 + y^2)^2}$$

Now

$$f_{xy}(0, 0) = \lim_{y \to 0} \frac{f_x(0, y) - f_x(0, 0)}{y} = \lim_{y \to 0} \frac{-y^4}{(y^2)^2} = -1$$

while

$$f_{yx}(0, 0) = \lim_{x \to 0} \frac{f_y(x, 0) - f_y(0, 0)}{x} = \lim_{x \to 0} \frac{x^4}{(x^2)^2} = 1$$

showing that although the mixed partial derivatives do exist at $(0, 0)$, they are not equal there.
5.16. IMPLICIT FUNCTION THEOREM

5.16 Implicit Function Theorem

The implicit function theorem is one of the greatest theorems in mathematics. There are many versions of this theorem. However, I will give a very simple proof valid in finite dimensional spaces.

**Theorem 5.16.1** (implicit function theorem) Suppose $U$ is an open set in $\mathbb{R}^n \times \mathbb{R}^m$. Let $f : U \to \mathbb{R}^n$ be in $C^1(U)$ and suppose

$$f(x_0, y_0) = 0, \quad D_1 f (x_0, y_0)^{-1} \in \mathcal{L} (\mathbb{R}^n, \mathbb{R}^n).$$

(5.16.26)

Then there exist positive constants, $\delta, \eta$, such that for every $y \in B(y_0, \eta)$ there exists a unique $x(y) \in B(x_0, \delta)$ such that

$$f(x(y), y) = 0.$$  

(5.16.27)

Furthermore, the mapping, $y \to x(y)$ is in $C^1(B(y_0, \eta))$.

**Proof:** Let

$$f(x, y) = \begin{pmatrix} f_1(x, y) \\ f_2(x, y) \\ \vdots \\ f_n(x, y) \end{pmatrix}.$$  

Define for $(x^1, \cdots, x^n) \in \overline{B(x_0, \delta)}^n$ and $y \in B(y_0, \eta)$ the following matrix.

$$J(x^1, \cdots, x^n, y) = \begin{pmatrix} f_{1,x_1}(x^1, y) & \cdots & f_{1,x_n}(x^1, y) \\ \vdots & & \vdots \\ f_{n,x_1}(x^n, y) & \cdots & f_{n,x_n}(x^n, y) \end{pmatrix}.$$  

Then by the assumption of continuity of all the partial derivatives, there exists $\delta_0 > 0$ and $\eta_0 > 0$ such that if $\delta < \delta_0$ and $\eta < \eta_0$, it follows that for all $(x^1, \cdots, x^n) \in \overline{B(x_0, \delta)}^n$ and $y \in B(y_0, \eta)$,

$$\det (J(x^1, \cdots, x^n, y)) > r > 0.$$  

(5.16.28)

and $\overline{B(x_0, \delta_0)} \times \overline{B(y_0, \eta_0)} \subseteq U$. Pick $y \in B(y_0, \eta)$ and suppose there exist $x, z \in \overline{B(x_0, \delta)}$ such that $f(x, y) = f(z, y) = 0$. Consider $f_i$ and let

$$h(t) \equiv f_i(x + t(z - x), y).$$

Then $h(1) = h(0)$ and so by the mean value theorem, $h'(t_i) = 0$ for some $t_i \in (0, 1)$. Therefore, from the chain rule and for this value of $t_i$,

$$h'(t_i) = D f_i (x + t_i(z - x), y)(z - x) = 0.$$  

(5.16.29)

Then denote by $x^i$ the vector, $x + t_i(z - x)$. It follows from 5.16.28 that

$$J(x^1, \cdots, x^n, y)(z - x) = 0.$$
and so from (5.16.28) \( z - x = 0 \). Now it will be shown that if \( \eta \) is chosen sufficiently small, then for all \( y \in B(y_0, \eta) \), there exists a unique \( x(y) \in B(x_0, \delta) \) such that \( f(x(y), y) = 0 \).

**Claim:** If \( \eta \) is small enough, then the function, \( h_y(x) = |f(x, y)|^2 \) achieves its minimum value on \( B(x_0, \delta) \) at a point of \( B(x_0, \delta) \).

**Proof of claim:** Suppose this is not the case. Then there exists a sequence \( \eta_k \to 0 \) and for some \( y_k \) having \( |y_k - y_0| < \eta_k \), the minimum of \( h_y \) occurs on a point of the boundary of \( B(x_0, \delta) \), \( x_k \) such that \( |x_0 - x_k| = \delta \). Now taking a subsequence, still denoted by \( k \), it can be assumed that \( x_k \to x \) with \( |x - x_0| = \delta \) and \( y_k \to y_0 \). Let \( \varepsilon > 0 \). Then for \( k \) large enough, \( h_{y_k}(x_0) < \varepsilon \) because \( f(x_0, y_0) = 0 \). Therefore, from the definition of \( x_k \), \( h_{y_k}(x_k) < \varepsilon \). Passing to the limit yields \( h_{y_0}(x) \leq \varepsilon \). Since \( \varepsilon > 0 \) is arbitrary, it follows that \( h_{y_0}(x) = 0 \) which contradicts the first part of the argument in which it was shown that for \( y \in B(y_0, \eta) \) there is at most one point, \( x \) of \( B(x_0, \delta) \) where \( f(x, y) = 0 \). Here two have been obtained, \( x_0 \) and \( x \). This proves the claim.

Choose \( \eta < \eta_0 \) and also small enough that the above claim holds and let \( x(y) \) denote a point of \( B(x_0, \delta) \) at which the minimum of \( h_y \) on \( B(x_0, \delta) \) is achieved. Since \( x(y) \) is an interior point, you can consider \( h_y(x(y) + tv) \) for \( |t| \) small and conclude this function of \( t \) has a zero derivative at \( t = 0 \). Thus

\[
Dh_x(x(y))v = 0 = 2f(x(y), y)^TD_1f(x(y), y)v
\]

for every vector \( v \). But from (5.16.28) and the fact that \( v \) is arbitrary, it follows \( f(x(y), y) = 0 \). This proves the existence of the function \( y \to x(y) \) such that \( f(x(y), y) = 0 \) for all \( y \in B(y_0, \eta) \).

It remains to verify this function is a \( C^1 \) function. To do this, let \( y_1 \) and \( y_2 \) be points of \( B(y_0, \eta) \). Then as before, consider the \( i^{th} \) component of \( f \) and consider the same argument using the mean value theorem to write

\[
0 = f_i(x(y_1), y_1) - f_i(x(y_2), y_2)
= f_i(x(y_1), y_1) - f_i(x(y_2), y_1) + f_i(x(y_2), y_1) - f_i(x(y_2), y_2)
= D_1f_i(x^i, y_1)(x(y_1) - x(y_2)) + D_2f_i(x(y_2), y^i)(y_1 - y_2).
\]

Therefore,

\[
J(x^1, \ldots, x^n, y_1)(x(y_1) - x(y_2)) = -M(y_1 - y_2)
\]

where \( M \) is the matrix whose \( i^{th} \) row is \( D_2f_i(x(y_2), y^i) \). Then from (5.16.28) there exists a constant, \( C \) independent of the choice of \( y \in B(y_0, \eta) \) such that

\[
||J(x^1, \ldots, x^n, y)|| < C
\]

whenever \( (x^1, \ldots, x^n) \in B(x_0, \delta) \). By continuity of the partial derivatives of \( f \) it also follows there exists a constant, \( C_1 \) such that \( ||D_2f_i(x, y)|| < C_1 \) whenever, \( (x, y) \in B(x_0, \delta) \times B(y_0, \eta) \). Hence \( ||M|| \) must also be bounded independent of the
5.16. IMPLICIT FUNCTION THEOREM

choice of \( y_1 \) and \( y_2 \) in \( B (y_0, \eta) \). From \( D \), it follows there exists a constant, \( C \)
such that for all \( y_1, y_2 \) in \( B (y_0, \eta) \),

\[
| x (y_1) - x (y_2) | \leq C | y_1 - y_2 | .
\]

(5.16.31)

It follows as in the proof of the chain rule that

\[
o (x (y + v) - x (y)) = o (v) .
\]

(5.16.32)

Now let \( y \in B (y_0, \eta) \) and let \( |v| \) be sufficiently small that \( y + v \in B (y_0, \eta) \).
Then

\[
0 = f (x (y + v), y + v) - f (x (y), y) = f (x (y + v), y + v) - f (x (y + v), y) + f (x (y + v), y) - f (x (y), y)
\]

\[
= D_2 f (x (y + v), y) v + D_1 f (x (y), y) (x (y + v) - x (y)) + o ((x (y + v) - x (y))]
\]

\[
= D_2 f (x (y), y) v + D_1 f (x (y), y) (x (y + v) - x (y)) + o ((x (y + v) - x (y))
\]

\[
= D_2 f (x (y), y) v + D_1 f (x (y), y) (x (y + v) - x (y)) + o (v)
\]

Therefore,

\[
x (y + v) - x (y) = -D_1 f (x (y), y)^{-1} D_2 f (x (y), y) v + o (v)
\]

which shows that \( Dx (y) = -D_1 f (x (y), y)^{-1} D_2 f (x (y), y) \) and \( y \to Dx (y) \) is continuous. This proves the theorem.

In practice, how do you verify the condition, \( D_1 f (x_0, y_0)^{-1} \in \mathcal{L} (\mathbb{F}^n, \mathbb{F}^n) \)?

\[
f (x, y) = \begin{pmatrix}
f_1 (x_1, \ldots, x_n, y_1, \ldots, y_n) \\
\vdots \\
f_n (x_1, \ldots, x_n, y_1, \ldots, y_n)
\end{pmatrix}
\]

The matrix of the linear transformation, \( D_1 f (x_0, y_0) \) is then

\[
\begin{pmatrix}
\frac{\partial f_1 (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_1} & \cdots & \frac{\partial f_1 (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_n} \\
\vdots & \ddots & \vdots \\
\frac{\partial f_n (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_1} & \cdots & \frac{\partial f_n (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_n}
\end{pmatrix}
\]

and from linear algebra, \( D_1 f (x_0, y_0)^{-1} \in \mathcal{L} (\mathbb{F}^n, \mathbb{F}^n) \) exactly when the above matrix has an inverse. In other words when

\[
\det \begin{pmatrix}
\frac{\partial f_1 (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_1} & \cdots & \frac{\partial f_1 (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_n} \\
\vdots & \ddots & \vdots \\
\frac{\partial f_n (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_1} & \cdots & \frac{\partial f_n (x_1, \ldots, x_n, y_1, \ldots, y_n)}{\partial x_n}
\end{pmatrix} \neq 0
\]
at \((x_0, y_0)\). The above determinant is important enough that it is given special notation. Letting \(z = f(x, y)\), the above determinant is often written as
\[
\frac{\partial (z_1, \ldots, z_n)}{\partial (x_1, \ldots, x_n)}.
\]

Of course you can replace \(\mathbb{R}\) with \(\mathbb{F}\) in the above by applying the above to the situation in which each \(\mathbb{F}\) is replaced with \(\mathbb{R}^2\).

**Corollary 5.16.2 (implicit function theorem)** Suppose \(U\) is an open set in \(\mathbb{F}^n \times \mathbb{F}^m\). Let \(f : U \to \mathbb{F}^n\) be in \(C^1(U)\) and suppose
\[
f(x_0, y_0) = 0, \quad D_f(x_0, y_0)^{-1} \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^m).
\] (5.16.33)

Then there exist positive constants, \(\delta, \eta\), such that for every \(y \in B(y_0, \eta)\) there exists a unique \(x(y) \in B(x_0, \delta)\) such that
\[
f(x(y), y) = 0.
\] (5.16.34)

Furthermore, the mapping, \(y \to x(y)\) is in \(C^1(B(y_0, \eta))\).

The next theorem is a very important special case of the implicit function theorem known as the inverse function theorem. Actually one can also obtain the implicit function theorem from the inverse function theorem. It is done this way in \(\text{[76]}\) and in \(\text{[3]}\).

**Theorem 5.16.3 (inverse function theorem)** Let \(x_0 \in U \subseteq \mathbb{F}^n\) and let \(f : U \to \mathbb{F}^n\). Suppose
\[
f \text{ is } C^1(U), \quad \text{and } Df(x_0)^{-1} \in \mathcal{L}(\mathbb{F}^n, \mathbb{F}^n).
\] (5.16.35)

Then there exist open sets, \(W\), and \(V\) such that
\[
x_0 \in W \subseteq U, \quad \text{(5.16.36)}
f : W \to V \text{ is one to one and onto,} \quad \text{(5.16.37)}
f^{-1} \text{ is } C^1. \quad \text{(5.16.38)}
\]

**Proof:** Apply the implicit function theorem to the function
\[
F(x, y) \equiv f(x) - y
\]
where \(y_0 = f(x_0)\). Thus the function \(y \to x(y)\) defined in that theorem is \(f^{-1}\). Now let
\[
W \equiv B(x_0, \delta) \cap f^{-1}(B(y_0, \eta))
\] and
\[
V \equiv B(y_0, \eta).
\]

This proves the theorem.
5.16. IMPLICIT FUNCTION THEOREM

5.16.1 More Continuous Partial Derivatives

Corollary 5.16.2 will now be improved slightly. If \( f \) is \( C^k \), it follows that the function which is implicitly defined is also in \( C^k \), not just \( C^1 \). Since the inverse function theorem comes as a case of the implicit function theorem, this shows that the inverse function also inherits the property of being \( C^k \).

**Theorem 5.16.4** (implicit function theorem) Suppose \( U \) is an open set in \( \mathbb{F}^n \times \mathbb{F}^m \). Let \( f : U \to \mathbb{F}^n \) be in \( C^k (U) \) and suppose

\[
f (x_0, y_0) = 0, \quad D_1 f (x_0, y_0)^{-1} \in \mathcal{L} (\mathbb{F}^n, \mathbb{F}^m).
\]  

(5.16.39)

Then there exist positive constants, \( \delta, \eta \), such that for every \( y \in B (y_0, \eta) \) there exists a unique \( x (y) \in B (x_0, \delta) \) such that

\[
f (x (y), y) = 0.
\]  

(5.16.40)

Furthermore, the mapping, \( y \to x (y) \) is in \( C^k (B (y_0, \eta)) \).

**Proof:** From Corollary 5.16.2 \( y \to x (y) \) is \( C^1 \). It remains to show it is \( C^k \) for \( k > 1 \) assuming that \( f \) is \( C^k \). From 5.16.40

\[
\frac{\partial x}{\partial y^p} = -D_1 (x, y)^{-1} \frac{\partial f}{\partial y^p}.
\]

Thus the following formula holds for \( q = 1 \) and \( |\alpha| = q \).

\[
D^\alpha x (y) = \sum_{|\beta| \leq q} M_\beta (x, y) D^\beta f (x, y)
\]  

(5.16.41)

where \( M_\beta \) is a matrix whose entries are differentiable functions of \( D^\gamma (x) \) for \( |\gamma| < q \) and \( D^\tau f (x, y) \) for \( |\tau| \leq q \). This follows easily from the description of \( D_1 (x, y)^{-1} \) in terms of the cofactor matrix and the determinant of \( D_1 (x, y) \). Suppose 5.16.41 holds for \( |\alpha| = q < k \). Then by induction, this yields \( x \) is \( C^q \). Then

\[
\frac{\partial D^\alpha x (y)}{\partial y^p} = \sum_{|\beta| \leq |\alpha|} \frac{\partial M_\beta (x, y)}{\partial y^p} D^\beta f (x, y) + M_\beta (x, y) \frac{\partial D^\beta f (x, y)}{\partial y^p}.
\]

By the chain rule \( \frac{\partial M_\beta (x, y)}{\partial y^p} \) is a matrix whose entries are differentiable functions of \( D^\tau f (x, y) \) for \( |\tau| \leq q + 1 \) and \( D^\gamma (x) \) for \( |\gamma| < q + 1 \). It follows since \( y^p \) was arbitrary that for any \( |\alpha| = q + 1 \), a formula like 5.16.41 holds with \( q \) being replaced by \( q + 1 \).

By induction, \( x \) is \( C^k \). This proves the theorem.

As a simple corollary this yields an improved version of the inverse function theorem.

**Theorem 5.16.5** (inverse function theorem) Let \( x_0 \in U \subseteq \mathbb{F}^n \) and let \( f : U \to \mathbb{F}^n \). Suppose for \( k \) a positive integer, \( f \) is \( C^k (U) \), and \( Df (x_0)^{-1} \in \mathcal{L} (\mathbb{F}^n, \mathbb{F}^n) \).

(5.16.42)
Then there exist open sets, \( W \) and \( V \) such that
\[
x_0 \in W \subseteq U, \quad (5.16.43)
\]
\[
f : W \to V \text{ is one to one and onto}, \quad (5.16.44)
\]
\[
f^{-1} \text{ is } C^k. \quad (5.16.45)
\]

5.17 The Method Of Lagrange Multipliers

As an application of the implicit function theorem, consider the method of Lagrange multipliers from calculus. Recall the problem is to maximize or minimize a function subject to equality constraints. Let \( f : U \to \mathbb{R} \) be a \( C^1 \) function where \( U \subseteq \mathbb{R}^n \) and let
\[
g_i(x) = 0, \quad i = 1, \ldots, m \quad (5.17.46)
\]
be a collection of equality constraints with \( m < n \). Now consider the system of nonlinear equations
\[
f(x) = a
\]
\[
g_i(x) = 0, \quad i = 1, \ldots, m.
\]
\( x_0 \) is a local maximum if \( f(x_0) \geq f(x) \) for all \( x \) near \( x_0 \) which also satisfies the constraints (5.17.46). A local minimum is defined similarly. Let \( F : U \times \mathbb{R} \to \mathbb{R}^{m+1} \) be defined by
\[
F(x,a) \equiv \begin{pmatrix}
f(x) - a \\
g_1(x) \\
\vdots \\
g_m(x)
\end{pmatrix}.
\]

Now consider the \( m + 1 \times n \) Jacobian matrix,
\[
\begin{pmatrix}
f_{x_1}(x_0) & \cdots & f_{x_n}(x_0) \\
g_{1x_1}(x_0) & \cdots & g_{1x_n}(x_0) \\
\vdots & \ddots & \vdots \\
g_{mx_1}(x_0) & \cdots & g_{mx_n}(x_0)
\end{pmatrix}.
\]
If this matrix has rank \( m + 1 \) then some \( m + 1 \times m + 1 \) submatrix has nonzero determinant. It follows from the implicit function theorem that there exist \( m + 1 \) variables, \( x_{i_1}, \ldots, x_{i_{m+1}} \) such that the system
\[
F(x,a) = 0 \quad (5.17.48)
\]
specifies these \( m + 1 \) variables as a function of the remaining \( n - (m + 1) \) variables and \( a \) in an open set of \( \mathbb{R}^{n-m} \). Thus there is a solution \( (x,a) \) to (5.17.48) for some \( x \) close to \( x_0 \) whenever \( a \) is in some open interval. Therefore, \( x_0 \) cannot be either a local minimum or a local maximum. It follows that if \( x_0 \) is either a local maximum
or a local minimum, then the above matrix must have rank less than \( m + 1 \) which requires the rows to be linearly dependent. Thus, there exist \( m \) scalars,

\[
\lambda_1, \ldots, \lambda_m,
\]

and a scalar \( \mu \), not all zero such that

\[
\mu \begin{pmatrix}
  f_{x_1}(x_0) \\
  \vdots \\
  f_{x_n}(x_0)
\end{pmatrix} = \lambda_1 \begin{pmatrix}
  g_{1x_1}(x_0) \\
  \vdots \\
  g_{1x_n}(x_0)
\end{pmatrix} + \cdots + \lambda_m \begin{pmatrix}
  g_{mx_1}(x_0) \\
  \vdots \\
  g_{mx_n}(x_0)
\end{pmatrix}. \quad (5.17.49)
\]

If the column vectors

\[
\begin{pmatrix}
  g_{1x_1}(x_0) \\
  \vdots \\
  g_{1x_n}(x_0)
\end{pmatrix}, \ldots, \begin{pmatrix}
  g_{mx_1}(x_0) \\
  \vdots \\
  g_{mx_n}(x_0)
\end{pmatrix} \quad (5.17.50)
\]

are linearly independent, then, \( \mu \neq 0 \) and dividing by \( \mu \) yields an expression of the form

\[
\begin{pmatrix}
  f_{x_1}(x_0) \\
  \vdots \\
  f_{x_n}(x_0)
\end{pmatrix} = \lambda_1 \begin{pmatrix}
  g_{1x_1}(x_0) \\
  \vdots \\
  g_{1x_n}(x_0)
\end{pmatrix} + \cdots + \lambda_m \begin{pmatrix}
  g_{mx_1}(x_0) \\
  \vdots \\
  g_{mx_n}(x_0)
\end{pmatrix}. \quad (5.17.51)
\]

at every point \( x_0 \) which is either a local maximum or a local minimum. This proves the following theorem.

**Theorem 5.17.1** Let \( U \) be an open subset of \( \mathbb{R}^n \) and let \( f : U \to \mathbb{R} \) be a \( C^1 \) function. Then if \( x_0 \in U \) is either a local maximum or local minimum of \( f \) subject to the constraints \( 5.17.46 \) then \( 5.17.49 \) must hold for some scalars \( \mu, \lambda_1, \ldots, \lambda_m \) not all equal to zero. If the vectors in \( 5.17.50 \) are linearly independent, it follows that an equation of the form \( 5.17.51 \) holds.
Chapter 6

Metric Spaces And General Topological Spaces

6.1 Metric Space

Definition 6.1.1 A metric space is a set, \( X \) and a function \( d: X \times X \rightarrow [0, \infty) \) which satisfies the following properties.

\[
d(x, y) = d(y, x) \\
d(x, y) \geq 0 \text{ and } d(x, y) = 0 \text{ if and only if } x = y \\
d(x, y) \leq d(x, z) + d(z, y).
\]

You can check that \( \mathbb{R}^n \) and \( \mathbb{C}^n \) are metric spaces with \( d(x, y) = |x - y| \). However, there are many others. The definitions of open and closed sets are the same for a metric space as they are for \( \mathbb{R}^n \).

Definition 6.1.2 A set, \( U \) in a metric space is open if whenever \( x \in U \), there exists \( r > 0 \) such that \( B(x, r) \subseteq U \). As before, \( B(x, r) \equiv \{ y : d(x, y) < r \} \). Closed sets are those whose complements are open. A point \( p \) is a limit point of a set, \( S \) if for every \( r > 0 \), \( B(p, r) \) contains infinitely many points of \( S \). A sequence, \( \{x_n\} \) converges to a point \( x \) if for every \( \varepsilon > 0 \) there exists \( N \) such that if \( n \geq N \), then \( d(x, x_n) < \varepsilon \). \( \{x_n\} \) is a Cauchy sequence if for every \( \varepsilon > 0 \) there exists \( N \) such that if \( m, n \geq N \), then \( d(x_n, x_m) < \varepsilon \).

Lemma 6.1.3 In a metric space, \( X \) every ball, \( B(x, r) \) is open. A set is closed if and only if it contains all its limit points. If \( p \) is a limit point of \( S \), then there exists a sequence of distinct points of \( S, \{x_n\} \) such that \( \lim_{n \to \infty} x_n = p \).

Proof: Let \( z \in B(x, r) \). Let \( \delta = r - d(x, z) \). Then if \( w \in B(z, \delta) \),

\[
d(w, x) \leq d(x, z) + d(z, w) < d(x, z) + r - d(x, z) = r.
\]

Therefore, \( B(z, \delta) \subseteq B(x, r) \) and this shows \( B(x, r) \) is open.

The properties of balls are presented in the following theorem.
Theorem 6.1.4 Suppose \((X, d)\) is a metric space. Then the sets \(\{B(x, r) : r > 0, \ x \in X\}\) satisfy
\[
\bigcup \{B(x, r) : r > 0, \ x \in X\} = X \tag{6.1.1}
\]
If \(p \in B(x, r_1) \cap B(z, r_2)\), there exists \(r > 0\) such that
\[
B(p, r) \subseteq B(x, r_1) \cap B(z, r_2). \tag{6.1.2}
\]

Proof: Observe that the union of these balls includes the whole space, \(X\) so \(6.1.1\) is obvious. Consider \(6.1.2\). Let \(p \in B(x, r_1) \cap B(z, r_2)\). Consider
\[
r \equiv \min (r_1 - d(x, p), r_2 - d(z, p))
\]
and suppose \(y \in B(p, r)\). Then
\[
d(y, x) \leq d(y, p) + d(p, x) < r_1 - d(x, p) + d(x, p) = r_1
\]
and so \(B(p, r) \subseteq B(x, r_1)\). By similar reasoning, \(B(p, r) \subseteq B(z, r_2)\). This proves the theorem.

Let \(K\) be a closed set. This means \(K^C \equiv X \setminus K\) is an open set. Let \(p\) be a limit point of \(K\). If \(p \in K^C\), then since \(K^C\) is open, there exists \(B(p, r) \subseteq K^C\). But this contradicts \(p\) being a limit point because there are no points of \(K\) in this ball. Hence all limit points of \(K\) must be in \(K\).

Suppose next that \(K\) contains its limit points. Is \(K^C\) open? Let \(p \in K^C\). Then \(p\) is not a limit point of \(K\). Therefore, there exists \(B(p, r)\) which contains at most finitely many points of \(K\). Since \(p \notin K\), it follows that by making \(r\) smaller if necessary, \(B(p, r)\) contains no points of \(K\). That is \(B(p, r) \subseteq K^C\) showing \(K^C\) is open. Therefore, \(K\) is closed.

Suppose now that \(p\) is a limit point of \(S\). Let \(x_1 \in (S \setminus \{p\}) \cap B(p, 1)\). If \(x_1, \cdots, x_k\) have been chosen, let
\[
r_{k+1} = \min \left\{d(p, x_i), i = 1, \cdots, k, \frac{1}{k+1}\right\}.
\]
Let \(x_{k+1} \in (S \setminus \{p\}) \cap B(p, r_{k+1})\). This proves the lemma.

Lemma 6.1.5 If \(\{x_n\}\) is a Cauchy sequence in a metric space, \(X\) and if some subsequence, \(\{x_{n_k}\}\) converges to \(x\), then \(\{x_n\}\) converges to \(x\). Also if a sequence converges, then it is a Cauchy sequence.

Proof: Note first that \(n_k \geq k\) because in a subsequence, the indices, \(n_1, n_2, \cdots\) are strictly increasing. Let \(\varepsilon > 0\) be given and let \(N\) be such that for \(k > N, d(x, x_{n_k}) < \varepsilon/2\) and for \(m, n \geq N, d(x_m, x_n) < \varepsilon/2\). Pick \(k > n\). Then if \(n > N\),
\[
d(x_n, x) \leq d(x_n, x_{n_k}) + d(x_{n_k}, x) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
\]
Finally, suppose \(\lim_{n \to \infty} x_n = x\). Then there exists \(N\) such that if \(n > N\), then \(d(x_n, x) < \varepsilon/2\). It follows that for \(m, n > N\),
\[
d(x_n, x_m) \leq d(x_n, x) + d(x, x_m) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
\]
This proves the lemma.

A useful idea is the idea of distance from a point to a set.

**Definition 6.1.6** Let \((X, d)\) be a metric space and let \(S\) be a nonempty set in \(X\). Then

\[
\text{dist}(x, S) \equiv \inf \{d(x, y) : y \in S\}.
\]

The following lemma is the fundamental result.

**Lemma 6.1.7** The function, \(x \rightarrow \text{dist}(x, S)\) is continuous and in fact satisfies

\[
|\text{dist}(x, S) - \text{dist}(y, S)| \leq d(x, y).
\]

**Proof:** Suppose \(\text{dist}(x, y)\) is as least as large as \(\text{dist}(y, S)\). Then pick \(z \in S\) such that \(d(y, z) \leq \text{dist}(y, S) + \varepsilon\). Then

\[
|\text{dist}(x, S) - \text{dist}(y, S)| = \text{dist}(x, S) - \text{dist}(y, S) \\
\leq d(x, z) - (d(y, z) - \varepsilon) \\
= d(x, z) - d(y, z) + \varepsilon \\
\leq d(x, y) + d(y, z) - d(y, z) + \varepsilon \\
= d(x, y) + \varepsilon.
\]

Since \(\varepsilon > 0\) is arbitrary, this proves the lemma.

### 6.2 Compactness In Metric Space

Many existence theorems in analysis depend on some set being compact. Therefore, it is important to be able to identify compact sets. The purpose of this section is to describe compact sets in a metric space.

**Definition 6.2.1** Let \(A\) be a subset of \(X\). \(A\) is compact if whenever \(A\) is contained in the union of a set of open sets, there exists finitely many of these open sets whose union contains \(A\). (Every open cover admits a finite subcover.) \(A\) is “sequentially compact” means every sequence has a convergent subsequence converging to an element of \(A\).

In a metric space compact is not the same as closed and bounded!

**Example 6.2.2** Let \(X\) be any infinite set and define \(d(x, y) = 1\) if \(x \neq y\) while \(d(x, y) = 0\) if \(x = y\).

You should verify the details that this is a metric space because it satisfies the axioms of a metric. The set \(X\) is closed and bounded because its complement is \(\emptyset\) which is clearly open because every point of \(\emptyset\) is an interior point. (There are none.) Also \(X\) is bounded because \(X = \bigcup_{x \in X} B(x, 2)\). However, \(X\) is clearly not compact because \(\{B(x, \frac{1}{2}) : x \in X\}\) is a collection of open sets whose union contains \(X\) but
since they are all disjoint and nonempty, there is no finite subset of these whose union contains \( X \). In fact \( B(x, \frac{1}{2}) = \{x\} \).

From this example it is clear something more than closed and bounded is needed. If you are not familiar with the issues just discussed, ignore them and continue.

**Definition 6.2.3** In any metric space, a set \( E \) is totally bounded if for every \( \varepsilon > 0 \) there exists a finite set of points \( \{x_1, \cdots, x_n\} \) such that

\[
E \subseteq \bigcup_{i=1}^{n} B(x_i, \varepsilon).
\]

This finite set of points is called an \( \varepsilon \) net.

The following proposition tells which sets in a metric space are compact. First here is an interesting lemma.

**Lemma 6.2.4** Let \( X \) be a metric space and suppose \( D \) is a countable dense subset of \( X \). In other words, it is being assumed \( X \) is a separable metric space. Consider the open sets of the form \( B(d, r) \) where \( r \) is a positive rational number and \( d \in D \). Denote this countable collection of open sets by \( \mathcal{B} \). Then every open set is the union of sets of \( \mathcal{B} \). Furthermore, if \( \mathcal{C} \) is any collection of open sets, there exists a countable subset, \( \{U_n\} \subseteq \mathcal{C} \) such that \( \bigcup U_n = \bigcup \mathcal{C} \).

**Proof:** Let \( U \) be an open set and let \( x \in U \). Let \( B(x, \delta) \subseteq U \). Then by density of \( D \), there exists \( d \in D \cap B(x, \delta/4) \). Now pick \( r \in \mathbb{Q} \cap (\delta/4, 3\delta/4) \) and consider \( B(d, r) \). Clearly, \( B(d, r) \) contains the point \( x \) because \( r > \delta/4 \). Is \( B(d, r) \subseteq B(x, \delta) \)? If so, this proves the lemma because \( x \) was an arbitrary point of \( U \). Suppose \( z \in B(d, r) \).

Then

\[
d(z, x) \leq d(z, d) + d(d, x) < r + \frac{\delta}{4} < \frac{3\delta}{4} + \frac{\delta}{4} = \delta.
\]

Now let \( \mathcal{C} \) be any collection of open sets. Each set in this collection is the union of countably many sets of \( \mathcal{B} \). Let \( \mathcal{B}' \) denote the sets of \( \mathcal{B} \) which are contained in some set of \( \mathcal{C} \). Thus \( \bigcup \mathcal{B}' = \bigcup \mathcal{C} \). Then for each \( B \in \mathcal{B}' \), pick \( U_B \in \mathcal{C} \) such that \( B \subseteq U_B \). Then \( \{U_B : B \in \mathcal{B}'\} \) is a countable collection of sets of \( \mathcal{C} \) whose union equals \( \bigcup \mathcal{C} \). Therefore, this proves the lemma.

**Proposition 6.2.5** Let \( (X, d) \) be a metric space. Then the following are equivalent.

\[
(X, d) \text{ is compact,} \quad (6.2.3)
\]

\[
(X, d) \text{ is sequentially compact,} \quad (6.2.4)
\]

\[
(X, d) \text{ is complete and totally bounded.} \quad (6.2.5)
\]

**Proof:** Suppose \( 6.2.3 \) and let \( \{x_k\} \) be a sequence. Suppose \( \{x_k\} \) has no convergent subsequence. If this is so, then no value of the sequence is repeated more than finitely many times. Also \( \{x_k\} \) has no limit point because if it did, there would exist a subsequence which converges. To see this, suppose \( p \) is a limit point of \( \{x_k\} \). Then in \( B(p, 1) \) there are infinitely many points of \( \{x_k\} \). Pick one called \( x_{k_1} \). Now if
6.2. COMPACTNESS IN METRIC SPACE

$x_{k_1}, x_{k_2}, \ldots, x_{k_n}$ have been picked with $x_{k_i} \in B(p, 1/i)$, consider $B(p, 1/(n+1))$. There are infinitely many points of $\{x_k\}$ in this ball also. Pick $x_{k_{n+1}}$ such that $k_{n+1} > k_n$. Then $\{x_{k_n}\}_{n=1}^{\infty}$ is a subsequence which converges to $p$ and it is assumed this does not happen. Thus $\{x_k\}$ has no limit points. It follows the set

$$C_n = \cup \{x_k : k \geq n\}$$

is a closed set because it has no limit points and if

$$U_n = C_n^C,$$

then

$$X = \cup_{n=1}^{\infty} U_n$$

but there is no finite subcovering, because no value of the sequence is repeated more than finitely many times. This contradicts compactness of $(X, d)$. Note $x_k$ is not in $U_n$ whenever $k > n$. Thus $\text{6.2.3}$ implies $\text{6.2.4}$.

Now suppose $\text{6.2.4}$ and let $\{x_n\}$ be a Cauchy sequence. Is $\{x_n\}$ convergent? By sequential compactness $x_{n_k} \to x$ for some subsequence. By Lemma $\text{6.1.5}$ it follows that $\{x_n\}$ also converges to $x$ showing that $(X, d)$ is complete. If $(X, d)$ is not totally bounded, then there exists $\varepsilon > 0$ for which there is no $\varepsilon$ net. Hence there exists a sequence $\{x_k\}$ with $d(x_k, x_l) \geq \varepsilon$ for all $l \neq k$. By Lemma $\text{6.1.5}$ again, this contradicts $\text{6.2.4}$ because no subsequence can be a Cauchy sequence and so no subsequence can converge. This shows $\text{6.2.4}$ implies $\text{6.2.5}$.

Now suppose $\text{6.2.5}$. What about $\text{6.2.4}$? Let $\{p_n\}$ be a sequence and let $\{x_i^n\}_{i=1}^{m_n}$ be a $2^{-n}$ net for $n=1, 2, \ldots$. Let

$$B_n = B(x_i^n, 2^{-n})$$

be such that $B_n$ contains $p_k$ for infinitely many values of $k$ and $B_n \cap B_{n+1} \neq \emptyset$. To do this, suppose $B_n$ contains $p_k$ for infinitely many values of $k$. Then one of the sets which intersect $B_n$, $B(x_i^{n+1}, 2^{-(n+1)})$ must contain $p_k$ for infinitely many values of $k$ because all these indices of points from $\{p_n\}$ contained in $B_n$ must be accounted for in one of finitely many sets, $B(x_i^{n+1}, 2^{-(n+1)})$. Thus there exists a strictly increasing sequence of integers, $n_k$ such that

$$p_{n_k} \in B_k.$$ 

Then if $k \geq l$,

$$d(p_{n_k}, p_{n_l}) \leq \sum_{i=l}^{k-1} d(p_{n_{i+1}}, p_{n_i})$$

$$< \sum_{i=l}^{k-1} 2^{-(i-1)} < 2^{-(l-2)}.$$ 

Consequently $\{p_{n_k}\}$ is a Cauchy sequence. Hence it converges because the metric space is complete. This proves $\text{6.2.4}$.
Now suppose \( \text{and } 6.2.5 \) which have now been shown to be equivalent. Let \( D_n \) be a \( n^{-1} \) net for \( n = 1, 2, \ldots \) and let
\[ D = \bigcup_{n=1}^{\infty} D_n. \]
Thus \( D \) is a countable dense subset of \( (X, d) \).

Now let \( C \) be any set of open sets such that \( \bigcup C \supseteq X \). By Lemma 6.2.4, there exists a countable subset of \( C \),
\[ \tilde{C} = \{ U_n \}_{n=1}^{\infty} \]
such that \( \bigcup \tilde{C} = \bigcup C \). If \( C \) admits no finite subcover, then neither does \( \tilde{C} \) and there exists \( p_n \in X \setminus \bigcup_{k=1}^{n} U_k \). Then since \( X \) is sequentially compact, there is a subsequence \( \{ p_{n_k} \} \) such that \( \{ p_{n_k} \} \) converges. Say
\[ p = \lim_{k \to \infty} p_{n_k}. \]
All but finitely many points of \( \{ p_{n_k} \} \) are in \( X \setminus \bigcup_{k=1}^{n} U_k \). Therefore \( p \in X \setminus \bigcup_{k=1}^{n} U_k \) for each \( n \). Hence
\[ p \notin \bigcup_{k=1}^{\infty} U_k \]
contradicting the construction of \( \{ U_n \}_{n=1}^{\infty} \) which required that \( \bigcup_{n=1}^{\infty} U_n \supseteq X \). Hence \( X \) is compact. This proves the proposition.

Consider \( \mathbb{R}^n \). In this setting totally bounded and bounded are the same. This will yield a proof of the Heine Borel theorem from advanced calculus.

**Lemma 6.2.6** A subset of \( \mathbb{R}^n \) is totally bounded if and only if it is bounded.

**Proof:** Let \( A \) be totally bounded. Is it bounded? Let \( x_1, \ldots, x_p \) be a 1 net for \( A \). Now consider the ball \( B(0, r+1) \) where \( r = \max(|x_i| : i = 1, \ldots, p) \). If \( z \in A \), then \( z \in B(x_j, 1) \) for some \( j \) and so by the triangle inequality,
\[ |z - 0| \leq |z - x_j| + |x_j| < 1 + r. \]
Thus \( A \subseteq B(0, r+1) \) and so \( A \) is bounded.

Now suppose \( A \) is bounded and suppose \( A \) is not totally bounded. Then there exists \( \varepsilon > 0 \) such that there is no \( \varepsilon \) net for \( A \). Therefore, there exists a sequence of points \( \{ a_i \} \) with \( |a_i - a_j| \geq \varepsilon \) if \( i \neq j \). Since \( A \) is bounded, there exists \( r > 0 \) such that
\[ A \subseteq [-r, r]^n. \]
(\( x \in [-r, r]^n \) means \( x_i \in [-r, r] \) for each \( i \).) Now define \( S \) to be all cubes of the form
\[ \prod_{k=1}^{n} (a_k, b_k) \]
where
\[ a_k = -r + i2^{-p}r, \quad b_k = -r + (i + 1)2^{-p}r, \]
6.3. SOME APPLICATIONS OF COMPACTNESS

for \( i \in \{0, 1, \ldots, 2^{p+1} - 1\} \). Thus \( S \) is a collection of \((2^{p+1})^n\) non overlapping cubes whose union equals \([-r, r]^n\) and whose diameters are all equal to \(2^{-p} r \sqrt{n}\). Now choose \( p \) large enough that the diameter of these cubes is less than \(\varepsilon\). This yields a contradiction because one of the cubes must contain infinitely many points of \( \{a_i\} \). This proves the lemma.

The next theorem is called the Heine Borel theorem and it characterizes the compact sets in \( \mathbb{R}^n \).

**Theorem 6.2.7** A subset of \( \mathbb{R}^n \) is compact if and only if it is closed and bounded.

**Proof:** Since a set in \( \mathbb{R}^n \) is totally bounded if and only if it is bounded, this theorem follows from Proposition 6.2.5 and the observation that a subset of \( \mathbb{R}^n \) is closed if and only if it is complete. This proves the theorem.

### 6.3 Some Applications Of Compactness

The following corollary is an important existence theorem which depends on compactness.

**Corollary 6.3.1** Let \( X \) be a compact metric space and let \( f : X \to \mathbb{R} \) be continuous. Then \( \max \{ f(x) : x \in X \} \) and \( \min \{ f(x) : x \in X \} \) both exist.

**Proof:** First it is shown \( f(X) \) is compact. Suppose \( C \) is a set of open sets whose union contains \( f(X) \). Then since \( f \) is continuous \( f^{-1}(U) \) is open for all \( U \in C \). Therefore, \( \{ f^{-1}(U) : U \in C \} \) is a collection of open sets whose union contains \( X \). Since \( X \) is compact, it follows finitely many of these, \( \{ f^{-1}(U_1), \ldots, f^{-1}(U_p) \} \), contains \( X \) in their union. Therefore, \( f(X) \subseteq \bigcup_{k=1}^{p} U_k \) showing \( f(X) \) is compact as claimed.

Now since \( f(X) \) is compact, Theorem 6.2.7 implies \( f(X) \) is closed and bounded. Therefore, it contains its inf and its sup. Thus \( f \) achieves both a maximum and a minimum.

**Definition 6.3.2** Let \( X, Y \) be metric spaces and \( f : X \to Y \) a function. \( f \) is uniformly continuous if for all \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that whenever \( x_1 \) and \( x_2 \) are two points of \( X \) satisfying \( d(x_1, x_2) < \delta \), it follows that \( d(f(x_1), f(x_2)) < \varepsilon \).

A very important theorem is the following.

**Theorem 6.3.3** Suppose \( f : X \to Y \) is continuous and \( X \) is compact. Then \( f \) is uniformly continuous.

**Proof:** Suppose this is not true and that \( f \) is continuous but not uniformly continuous. Then there exists \( \varepsilon > 0 \) such that for all \( \delta > 0 \) there exist points, \( p_\delta \) and \( q_\delta \) such that \( d(p_\delta, q_\delta) < \delta \) and yet \( d(f(p_\delta), f(q_\delta)) \geq \varepsilon \). Let \( p_n \) and \( q_n \) be the points which go with \( \delta = 1/n \). By Proposition 6.2.3 \( \{p_n\} \) has a convergent
subsequence, \( \{ p_{n_k} \} \) converging to a point, \( x \in X \). Since \( d(p_n, q_n) < \frac{1}{n} \), it follows that \( q_{n_k} \to x \) also. Therefore,
\[
\varepsilon \leq d(f(p_{n_k}), f(q_{n_k})) \leq d(f(p_{n_k}), f(x)) + d(f(x), f(q_{n_k}))
\]
but by continuity of \( f \), both \( d(f(p_{n_k}), f(x)) \) and \( d(f(x), f(q_{n_k})) \) converge to 0 as \( k \to \infty \) contradicting the above inequality. This proves the theorem.

Another important property of compact sets in a metric space concerns the finite intersection property.

**Definition 6.3.4** If every finite subset of a collection of sets has nonempty intersection, the collection has the finite intersection property.

**Theorem 6.3.5** Suppose \( \mathcal{F} \) is a collection of compact sets in a metric space, \( X \) which has the finite intersection property. Then there exists a point in their intersection. \((\bigcap \mathcal{F} \neq \emptyset)\).

**Proof:** First I show each compact set is closed. Let \( K \) be a nonempty compact set and suppose \( p \notin K \). Then for each \( x \in K \), let \( V_x = B(x, d(p, x)/3) \) and \( U_x = B(p, d(p, x)/3) \) so that \( U_x \) and \( V_x \) have empty intersection. Then since \( V \) is compact, there are finitely many \( V_{x_i} \) which cover \( K \) say \( V_{x_1}, \ldots, V_{x_n} \). Then let \( U = \bigcap_{i=1}^{n} U_{x_i} \). It follows \( p \in U \) and \( U \) has empty intersection with \( K \). In fact \( U \) has empty intersection with \( \bigcup_{i=1}^{n} V_{x_i} \). Since \( U \) is an open set and \( p \in K^C \) is arbitrary, it follows \( K^C \) is an open set.

Consider now the claim about the intersection. If this were not so,
\[
\bigcup \{ F^C : F \in \mathcal{F} \} = X
\]
and so, in particular, picking some \( F_0 \in \mathcal{F} \),
\[
\{ F^C : F \in \mathcal{F} \}
\]
would be an open cover of \( F_0 \). Since \( F_0 \) is compact, some finite subcover, \( F_1^C, \ldots, F_m^C \) exists. But then
\[
F_0 \subseteq \bigcup_{k=1}^{m} F_k^C
\]
which means \( \bigcap_{k=0}^{m} F_k = \emptyset \), contrary to the finite intersection property. To see this, note that if \( x \in F_0 \), then it must fail to be in some \( F_k \) and so it is not in \( \bigcap_{k=0}^{m} F_k \). Since this is true for every \( x \) it follows \( \bigcap_{k=0}^{m} F_k = \emptyset \).

**Theorem 6.3.6** Let \( X_i \) be a compact metric space with metric \( d_i \). Then \( \prod_{i=1}^{m} X_i \) is also a compact metric space with respect to the metric, \( d(x, y) \equiv \max_i (d_i(x_i, y_i)) \).

**Proof:** This is most easily seen from sequential compactness. Let \( \{ x^k \}_{k=1}^{\infty} \) be a sequence of points in \( \prod_{i=1}^{m} X_i \). Consider the \( i \)th component of \( x^k \), \( x^k_i \). It follows \( \{ x^k \} \) is a sequence of points in \( X_i \) and so it has a convergent subsequence. Compactness of \( X_i \) implies there exists a subsequence of \( x^k \), denoted by \( \{ x^{k_1} \} \) such that
\[
\lim_{k_1 \to \infty} x^{k_1}_{i} \to x_1 \in X_1.
\]
Now there exists a further subsequence, denoted by \( \{ x^{k_2} \} \) such that in addition to this, \( x^{k_2} \rightarrow x_2 \in X_2 \). After taking \( m \) such subsequences, there exists a subsequence, \( \{ x^l \} \) such that \( \lim_{l \to \infty} x^l = x_i \in X_i \) for each \( i \). Therefore, letting \( x \equiv (x_1, \ldots, x_m) \), \( x^l \rightarrow x \) in \( \prod_{i=1}^{m} X_i \). This proves the theorem.

### 6.4 Ascoli Arzela Theorem

**Definition 6.4.1** Let \( (X, d) \) be a complete metric space. Then it is said to be locally compact if \( B(x, r) \) is compact for each \( r > 0 \).

Thus if you have a locally compact metric space, then if \( \{ a_n \} \) is a bounded sequence, it must have a convergent subsequence.

Let \( K \) be a compact subset of \( \mathbb{R}^n \) and consider the continuous functions which have values in a locally compact metric space, \( (X, d) \) where \( d \) denotes the metric on \( X \). Denote this space as \( C(K, X) \).

**Definition 6.4.2** For \( f, g \in C(K, X) \), where \( K \) is a compact subset of \( \mathbb{R}^n \) and \( X \) is a locally compact complete metric space define

\[
\rho_K(f, g) \equiv \sup \{ d(f(x), g(x)) : x \in K \}.
\]

Then \( \rho_K \) provides a distance which makes \( C(K, X) \) into a metric space.

The Ascoli Arzela theorem is a major result which tells which subsets of \( C(K, X) \) are sequentially compact.

**Definition 6.4.3** Let \( A \subseteq C(K, X) \) for \( K \) a compact subset of \( \mathbb{R}^n \). Then \( A \) is said to be uniformly equicontinuous if for every \( \varepsilon > 0 \) there exists a \( \delta > 0 \) such that whenever \( x, y \in K \) with \( |x - y| < \delta \) and \( f \in A \),

\[
d(f(x), f(y)) < \varepsilon.
\]

The set, \( A \) is said to be uniformly bounded if for some \( M < \infty \), and \( a \in X \),

\[
f(x) \in B(a, M)
\]

for all \( f \in A \) and \( x \in K \).

Uniform equicontinuity is like saying that the whole set of functions, \( A \), is uniformly continuous on \( K \) uniformly for \( f \in A \). The version of the Ascoli Arzela theorem I will present here is the following.

**Theorem 6.4.4** Suppose \( K \) is a nonempty compact subset of \( \mathbb{R}^n \) and \( A \subseteq C(K, X) \) is uniformly bounded and uniformly equicontinuous. Then if \( \{ f_k \} \subseteq A \), there exists a function, \( f \in C(K, X) \) and a subsequence, \( f_{k_1} \), such that

\[
\lim_{k \to \infty} \rho_K(f_{k_1}, f) = 0.
\]
To give a proof of this theorem, I will first prove some lemmas.

**Lemma 6.4.5** If $K$ is a compact subset of $\mathbb{R}^n$, then there exists $D \equiv \{x_k\}_{k=1}^{\infty} \subseteq K$ such that $D$ is dense in $K$. Also, for every $\varepsilon > 0$ there exists a finite set of points, \{x_1, \cdots, x_m\} \subseteq K, called an $\varepsilon$ net such that

$$\bigcup_{i=1}^{m} B(x_i, \varepsilon) \supseteq K.$$  

**Proof:** For $m \in \mathbb{N}$, pick $x_1^m \in K$. If every point of $K$ is within $1/m$ of $x_1^m$, stop. Otherwise, pick $x_2^m \in K \setminus B(x_1^m, 1/m)$. If every point of $K$ contained in $B(x_1^m, 1/m) \cup B(x_2^m, 1/m)$, stop. Otherwise, pick $x_3^m \in K \setminus (B(x_1^m, 1/m) \cup B(x_2^m, 1/m))$. If every point of $K$ is contained in $B(x_1^m, 1/m) \cup B(x_2^m, 1/m) \cup B(x_3^m, 1/m)$, stop. Otherwise, pick $x_4^m \in K \setminus (B(x_1^m, 1/m) \cup B(x_2^m, 1/m) \cup B(x_3^m, 1/m))$. Continue this way until the process stops, say at $N(m)$. It must stop because if it didn’t, there would be a convergent subsequence due to the compactness of $K$. Ultimately all terms of this convergent subsequence would be closer than $1/m$, violating the manner in which they are chosen. Then $D = \bigcup_{m=1}^{\infty} \bigcup_{k=1}^{N(m)} \{x_k^m\}$. This is countable because it is a countable union of countable sets. If $y \in K$ and $\varepsilon > 0$, then for some $m, 2/m < \varepsilon$ and so $B(y, \varepsilon)$ must contain some point of $\{x_k^m\}$ since otherwise, the process stopped too soon. You could have picked $y$. $\blacksquare$

**Lemma 6.4.6** Suppose $D$ is defined above and $\{g_m\}$ is a sequence of functions of $A$ having the property that for every $x_k \in D$,

$$\lim_{m \to \infty} g_m(x_k) \text{ exists.}$$

Then there exists $g \in C(K, X)$ such that

$$\lim_{m \to \infty} \rho(g_m, g) = 0.$$

**Proof:** Define $g$ first on $D$.

$$g(x_k) = \lim_{m \to \infty} g_m(x_k).$$

Next I show that $\{g_m\}$ converges at every point of $K$. Let $x \in K$ and let $\varepsilon > 0$ be given. Choose $x_k$ such that for all $f \in A$,

$$d(f(x_k), f(x)) < \frac{\varepsilon}{3}.$$
I can do this by the equicontinuity. Now if \( p, q \) are large enough, say \( p, q \geq M \),
\[
d(g_p(x_k), g_q(x_k)) < \frac{\varepsilon}{3}.
\]
Therefore, for \( p, q \geq M \),
\[
d(g_p(x), g_q(x)) \leq d(g_p(x), g_p(x_k)) + d(g_p(x_k), g_q(x_k)) + d(g_q(x_k), g_q(x)) < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon.
\]
It follows that \( \{g_m(x)\} \) is a Cauchy sequence having values \( X \). Therefore, it converges. Let \( g(x) \) be the name of the thing it converges to.

Let \( \varepsilon > 0 \) be given and pick \( \delta > 0 \) such that whenever \( x, y \in K \) and \( |x - y| < \delta \), it follows \( d(f(x), f(y)) < \frac{\varepsilon}{3} \) for all \( f \in A \). Now let \( \{x_1, \ldots, x_m\} \) be a \( \delta \) net for \( K \) as in Lemma 6.4.5. Since there are only finitely many points in this \( \delta \) net, it follows that there exists \( N \) such that for all \( p, q \geq N \),
\[
d(g_q(x_i), g_p(x_i)) < \frac{\varepsilon}{3}
\]
for all \( \{x_1, \ldots, x_m\} \). Therefore, for arbitrary \( x \in K \), pick \( x_i \in \{x_1, \ldots, x_m\} \) such that \( |x_i - x| < \delta \). Then
\[
d(g_q(x), g_p(x)) \leq d(g_q(x), g_q(x_i)) + d(g_q(x_i), g_p(x_i)) + d(g_p(x_i), g_p(x)) < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon.
\]
Since \( N \) does not depend on the choice of \( x \), it follows this sequence \( \{g_m(x)\} \) is uniformly Cauchy. That is, for every \( \varepsilon > 0 \), there exists \( N \) such that if \( p, q \geq N \), then
\[
\rho(g_p, g_q) < \varepsilon.
\]
Next, I need to verify that the function, \( g \), is a continuous function. Let \( N \) be large enough that whenever \( p, q \geq N \), the above holds. Then for all \( x \in K \),
\[
d(g(x), g_p(x)) \leq \frac{\varepsilon}{3} \quad (6.4.6)
\]
whenever \( p \geq N \). This follows from observing that for \( p, q \geq N \),
\[
d(g_q(x), g_p(x)) < \frac{\varepsilon}{3}
\]
and then taking the limit as \( q \to \infty \) to obtain \( 6.4.6 \). In passing to the limit, you can use the following simple claim.

Claim: In a metric space, if \( a_n \to a \), then \( d(a_n, b) \to d(a, b) \).

Proof of the claim: You note that by the triangle inequality, \( d(a_n, b) - d(a, b) \leq d(a_n, a) \) and \( d(a, b) - d(a_n, b) \leq d(a_n, a) \) and so
\[
|d(a_n, b) - d(a, b)| \leq d(a_n, a).
\]
Now let \( p \) satisfy \( \mathbf{6.4.6} \) for all \( x \) whenever \( p > N \). Also pick \( \delta > 0 \) such that if \( |x - y| < \delta \), then

\[
d(g_p(x), g_p(y)) < \frac{\varepsilon}{3}.
\]

Then if \( |x - y| < \delta \),

\[
d(g(x), g(y)) \leq d(g(x), g_p(x)) + d(g_p(x), g_p(y)) + d(g_p(y), g(y)) < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon.
\]

Since \( \varepsilon \) was arbitrary, this shows that \( g \) is continuous.

It only remains to verify that \( \rho(g_k) \to 0 \). But this follows from \( \mathbf{6.4.6} \).

With these lemmas, it is time to prove Theorem \( \mathbf{6.4.4} \).

**Proof of Theorem \( \mathbf{6.4.4} \)**: Let \( D = \{x_k\} \) be the countable dense set of \( K \) guaranteed by Lemma \( \mathbf{6.4.4} \) and let \( \{(1,1), (1,2), (1,3), (1,4), (1,5), \ldots\} \) be a subsequence of \( \mathbb{N} \) such that

\[
\lim_{k \to \infty} f_{(1,k)}(x_1) \text{ exists.}
\]

This is where the local compactness of \( X \) is being used. Now let

\[
\{(2,1), (2,2), (2,3), (2,4), (2,5), \ldots\}
\]

be a subsequence of \( \{(1,1), (1,2), (1,3), (1,4), (1,5), \ldots\} \) which has the property that

\[
\lim_{k \to \infty} f_{(2,k)}(x_2) \text{ exists.}
\]

Thus it is also the case that

\[
f_{(2,k)}(x_1) \text{ converges to } \lim_{k \to \infty} f_{(1,k)}(x_1).
\]

because every subsequence of a convergent sequence converges to the same thing as the convergent sequence. Continue this way and consider the array

\[
\begin{align*}
f_{(1,1)}, f_{(1,2)}, f_{(1,3)}, f_{(1,4)} & \text{ converges at } x_1 \\
f_{(2,1)}, f_{(2,2)}, f_{(2,3)}, f_{(2,4)} & \text{ converges at } x_1 \text{ and } x_2 \\
f_{(3,1)}, f_{(3,2)}, f_{(3,3)}, f_{(3,4)} & \text{ converges at } x_1, x_2, \text{ and } x_3 \\
& \vdots
\end{align*}
\]

Now let \( g_k \equiv f_{(k,k)} \). Thus \( g_k \) is ultimately a subsequence of \( \{f_{(m,k)}\} \) whenever \( k > m \) and therefore, \( \{g_k\} \) converges at each point of \( D \). By Lemma \( \mathbf{6.4.6} \) it follows there exists \( g \in C(K;X) \) such that

\[
\lim_{k \to \infty} \rho(g, g_k) = 0.
\]

Actually there is an if and only if version of it but the most useful case is what is presented here. The process used to get the subsequence in the proof is called the Cantor diagonalization procedure.
6.5 Another General Version

This will use the characterization of compact metric spaces to give a proof of a general version of the Arzella Ascoli theorem. See Naylor and Sell [11] which is where I saw this general formulation.

Definition 6.5.1 Let \((X, d_X)\) be a compact metric space. Let \((Y, d_Y)\) be another complete metric space. Then \(C(X, Y)\) will denote the continuous functions which map \(X\) to \(Y\). Then \(\rho\) is a metric on \(C(X, Y)\) defined by

\[
\rho(f, g) = \sup_{x \in X} d_Y (f(x), g(x)).
\]

Theorem 6.5.2 \((C(X, Y), \rho)\) is a complete metric space.

Proof: It is first necessary to show that \(\rho\) is well defined. In this argument, I will just write \(d\) rather than \(d_X\) or \(d_Y\). To show this, note that

\[
x \to d(f(x), g(x))
\]

is a continuous function because \(f, g\) are continuous and

\[
|d(f(x), g(x)) - d(f(y), g(y))| \leq d(f(x), f(y)) + d(g(x), g(y))
\]

This follows from the triangle inequality. Say \(d(f(x), g(x)) \geq d(f(y), g(y))\). Otherwise just replace \(x\) with \(y\) and repeat the argument. Then in this case, it reduces to the claim that

\[
d(f(x), g(x)) \leq d(f(x), f(y)) + d(g(x), g(y)) + d(f(y), g(y))
\]

However, by the triangle inequality, the right side of the above is at least as large as

\[
d(f(x), f(y)) + d(g(x), f(y)) \geq d(f(x), g(x)).
\]

It follows that \(\rho(f, g)\) is just the maximum of a continuous function defined on a compact set.

Clearly \(\rho(f, g) = \rho(g, f)\) and

\[
\rho(f, g) + \rho(g, h) = \sup_{x \in X} d(f(x), g(x)) + \sup_{x \in X} d(g(x), h(x))
\]

\[
\geq \sup_{x \in X} (d(f(x), g(x)) + d(g(x), h(x)))
\]

\[
\geq \sup_{x \in X} (d(f(x), h(x))) = \rho(f, h)
\]

so the triangle inequality holds.

It remains to check completeness. Let \(\{f_n\}\) be a Cauchy sequence. Then from the definition, \(\{f_n(x)\}\) is a Cauchy sequence in \(Y\) and so it converges to something called \(f(x)\). I have to verify that \(x \to f(x)\) is continuous. Define

\[
\rho'(f, f_n) = \lim_{m \to \infty} \sup \rho(f_m, f_n).
\]
Then if \( n \) is sufficiently large, \( \rho'(f, f_n) < \varepsilon/3 \). Also,
\[
d(f(x), f_n(x)) = \lim_{m \to \infty} d(f_m(x), f_n(x)) \\
\leq \limsup_{m \to \infty} \rho(f_m, f_n) = \rho'(f, f_n) < \frac{\varepsilon}{3}
\] (6.5.7)

Then picking such an \( n \),
\[
d(f(x), f(y)) \leq d(f(x), f_n(x)) + d(f_n(x), f_n(y)) + d_n(f_n(y), f(y)) \\
\leq \rho'(f, f_n) + d(f_n(x), f_n(y)) + \rho'(f, f_n) < \frac{2\varepsilon}{3} + d(f_n(x), f_n(y))
\]
which is less than \( \varepsilon \) provided \( d(x, y) \) is small enough, this by continuity of \( f_n \). Therefore, \( f \) is continuous. By 6.5.7 this shows that, since \( x \) is arbitrary, \( \rho(f, f_n) < \varepsilon \) whenever \( n \) is large enough. ■

Here is a useful lemma.

**Lemma 6.5.3** Let \( S \) be a totally bounded subset of \((X, d)\) a metric space. Then \( \overline{S} \) is also totally bounded.

**Proof:** Suppose not. Then there exists a sequence \( \{p_n\} \subseteq \overline{S} \) such that \( d(p_m, p_n) \geq \varepsilon \) for all \( m \neq n \). Now let \( q_n \in B(p_n, \frac{\varepsilon}{8}) \cap S \). Then it follows that
\[
\frac{\varepsilon}{8} + d(q_n, q_m) \geq d(p_n, q_n) + d(q_n, q_m) + d(q_m, p_m) \geq d(p_n, q_n) + \varepsilon
\]
and so \( d(q_n, q_m) > \frac{\varepsilon}{2} \). This contradicts total boundedness of \( S \). ■

Next, here is an important definition.

**Definition 6.5.4** Let \( A \subseteq C(X, Y) \) where \((X, d_X)\) and \((Y, d_Y)\) are metric spaces. Thus \( A \) is a set of continuous functions mapping \( X \) to \( Y \). Then \( A \) is said to be equicontinuous if for every \( \varepsilon > 0 \) there exists a \( \delta > 0 \) such that if \( d_X(x_1, x_2) < \delta \) then for all \( f \in A \), \( d_Y(f(x_1), f(x_2)) < \varepsilon \). (This is uniform continuity which is uniform in \( A \).
\( A \) is said to be pointwise compact if \( \{f(x) : f \in A\} \) has compact closure in \( Y \).

Here is the Ascoli Arzela theorem.

**Theorem 6.5.5** Let \( (X, d_X) \) be a compact metric space and let \( (Y, d_Y) \) be a complete metric space. Thus \((C(X, Y), \rho)\) is a complete metric space. Let \( A \subseteq C(X, Y) \) be pointwise compact and equicontinuous. Then \( \overline{A} \) is compact. Here the closure is taken in \((C(X, Y), \rho)\). The converse also holds.

**Proof:** The more useful direction is that the two conditions imply compactness of \( A \). I prove this first. Since \( \overline{A} \) is a closed subset of a complete space, it follows that \( \overline{A} \) will be compact if it is totally bounded. In showing this, it follows from Lemma 6.5.3 that it suffices to verify that \( A \) is totally bounded. Suppose this is
not so. Then there exists \( \varepsilon > 0 \) and a sequence of points of \( \mathcal{A} \), \( \{f_n\} \) such that
\[
\rho(f_n, f_m) \geq \varepsilon \quad \text{whenever} \quad n \neq m.
\]

By equicontinuity, there exists \( \delta > 0 \) such that if \( d(x, y) < \delta \), then \( d(f(x), f(y)) < \varepsilon/8 \) for all \( f \in \mathcal{A} \). Let \( \{x_i\}_{i=1}^m \) be a \( \delta/2 \) net for \( X \). Since there are only finitely many \( x_i \), it follows from pointwise compactness that there exists a subsequence, still denoted by \( \{f_n\} \) which converges at each \( x_i \). There exists \( x_{nm} \) such that
\[
\rho(f_n, f_m) - \frac{\varepsilon}{8} < d(f_n(x_{nm}), f_m(x_{nm}))
\]
\[
\leq d(f_n(x_{nm}), f_n(x_i)) + d(f_n(x_i), f_m(x_i)) + d(f_m(x_i), f_m(x_{nm}))
\]
\[
< \frac{\varepsilon}{8} + d(f_n(x_i), f_m(x_i)) + \frac{\varepsilon}{8}
\]
(6.5.8)
where here \( x_i \) is such that \( x_{nm} \in B(x_i, \delta) \). From the convergence of \( f_n \) at each \( x_i \), there exists \( N \) such that if \( m, n > N \), then for all \( x_i \),
\[
d(f_n(x_i), f_m(x_i)) < \frac{\varepsilon}{8}.
\]

Now this results in the contradiction,
\[
\varepsilon - \frac{\varepsilon}{8} < \frac{\varepsilon}{8} + \frac{\varepsilon}{8} + \frac{\varepsilon}{8}
\]
It follows that \( \mathcal{A} \) and hence \( \overline{\mathcal{A}} \) is totally bounded. This proves the more important direction.

Next suppose \( \overline{\mathcal{A}} \) is compact. Why must \( \mathcal{A} \) be pointwise compact and equicontinuous? If it fails to be pointwise compact, then there exists \( x \in X \) such that \( \{f(x) : f \in \mathcal{A}\} \) is not contained in a compact set of \( Y \). Thus there exists \( \varepsilon > 0 \) and a sequence of functions in \( \mathcal{A} \) \( \{f_n\} \) such that \( d(f_n(x), f_m(x)) \geq \varepsilon \). But this implies \( \rho(f_m, f_n) \geq \varepsilon \) and so \( \overline{\mathcal{A}} \) fails to be totally bounded, a contradiction. Thus \( \mathcal{A} \) must be pointwise compact. Now why must it be equicontinuous? If it is not, then for each \( n \in \mathbb{N} \) there exists \( \varepsilon > 0 \) and \( x_n, y_n \in X \) such that \( d(x_n, y_n) < 1/n \) but for some \( f_n \in \mathcal{A} \), \( d(f_n(x_n), f_n(y_n)) \geq \varepsilon \). However, by compactness, there exists a subsequence \( \{f_{n_k}\} \) such that \( \lim_{k \to \infty} \rho(f_{n_k}, f) = 0 \) and also that \( x_{n_k}, y_{n_k} \to x \in X \). Hence
\[
\varepsilon \leq d(f_{n_k}(x_{n_k}), f_{n_k}(y_{n_k})) \leq d(f_{n_k}(x_{n_k}), f(x_{n_k})) + d(f(x_{n_k}), f_{n_k}(y_{n_k})) + d(f_{n_k}(y_{n_k}), f_{n_k})
\]
and now this is a contradiction because each term on the right converges to 0. The middle term converges to 0 because \( f(x_{n_k}), f(y_{n_k}) \to f(x) \).
The Tietze Extension Theorem

It turns out that if $H$ is a closed subset of a metric space, $(X, d)$ and if $f : H \to [a, b]$ is continuous, then there exists $g$ defined on all of $X$ such that $g = f$ on $H$ and $g$ is continuous. This is called the Tietze extension theorem. First it is well to recall continuity in the context of metric space.

**Definition 6.6.1** Let $(X, d)$ be a metric space and suppose $f : X \to Y$ is a function where $(Y, \rho)$ is also a metric space. For example, $Y = \mathbb{R}$. Then $f$ is continuous at $x \in X$ if for every $\varepsilon > 0$ there exists $\delta > 0$ such that $\rho(f(x), f(z)) < \varepsilon$ whenever $d(x, z) < \delta$. As is usual in such definitions, $f$ is said to be continuous if it is continuous at every point of $X$.

The following lemma gives an important example of a continuous real valued function defined on a metric space, $(X, d)$.

**Lemma 6.6.2** Let $(X, d)$ be a metric space and let $S \subseteq X$ be a nonempty subset. Define

$$\text{dist}(x, S) \equiv \inf \{d(x, y) : y \in S\}.$$ 

Then $x \to \text{dist}(x, S)$ is a continuous function satisfying the inequality,

$$|\text{dist}(x, S) - \text{dist}(y, S)| \leq d(x, y).$$ (6.6.9)

**Proof:** The continuity of $x \to \text{dist}(x, S)$ is obvious if the inequality is established. So let $x, y \in X$. Without loss of generality, assume $\text{dist}(x, S) \geq \text{dist}(y, S)$ and pick $z \in S$ such that $d(y, z) - \varepsilon < \text{dist}(y, S)$. Then

$$|\text{dist}(x, S) - \text{dist}(y, S)| = \text{dist}(x, S) - \text{dist}(y, S) \leq d(x, z) - (d(y, z) - \varepsilon) \leq d(z, y) + d(x, y) - d(y, z) + \varepsilon = d(x, y) + \varepsilon.$$

Since $\varepsilon$ is arbitrary, this proves.

**Lemma 6.6.3** Let $H, K$ be two nonempty disjoint closed subsets of a metric space, $(X, d)$. Then there exists a continuous function, $g : X \to [-1, 1]$ such that $g(H) = -1/3, g(K) = 1/3, g(X) \subseteq [-1/3, 1/3]$.

**Proof:** Let

$$f(x) = \frac{\text{dist}(x, H)}{\text{dist}(x, H) + \text{dist}(x, K)}.$$ 

The denominator is never equal to zero because if $\text{dist}(x, H) = 0$, then $x \in H$ because $H$ is closed. (To see this, pick $h_k \in B(x, 1/k) \cap H$. Then $h_k \to x$ and since $H$ is closed, $x \in H$.) Similarly, if $\text{dist}(x, K) = 0$, then $x \in K$ and so the denominator is never zero as claimed. Hence, by Lemma 6.6.2 $f$ is continuous and from its definition, $f = 0$ on $H$ and $f = 1$ on $K$. Now let $g(x) = \frac{2}{3} f(x) - \frac{1}{3}$. Then $g$ has the desired properties.
6.6. THE Tietze Extension Theorem

**Definition 6.6.4** For $f$ a real or complex valued bounded continuous function defined on a metric space, $M$

$$||f||_M = \sup \{|f(x)| : x \in M\}.$$  

**Lemma 6.6.5** Suppose $M$ is a closed set in $X$ where $(X,d)$ is a metric space and suppose $f : M \to [-1,1]$ is continuous at every point of $M$. Then there exists a function, $g$ which is defined and continuous on all of $X$ such that $||f - g||_M < \frac{2}{3}$.

**Proof:** Let $H = f^{-1}([-1,-1/3]), K = f^{-1}([1/3,1])$. Thus $H$ and $K$ are disjoint closed subsets of $M$. Suppose first $H,K$ are both nonempty. Then by Lemma 6.6.3 there exists $g$ such that $g$ is a continuous function defined on all of $X$ and $g(H) = -1/3$, $g(K) = 1/3$, and $g(X) \subseteq [-1/3,1/3]$. It follows $||f - g||_M < 2/3$. If $H = \emptyset$, then $f$ has all its values in $[-1/3,1]$ and so letting $g \equiv 1/3$, the desired condition is obtained. If $K = \emptyset$, let $g \equiv -1/3$. This proves the lemma.

**Lemma 6.6.6** Suppose $M$ is a closed set in $X$ where $(X,d)$ is a metric space and suppose $f : M \to [-1,1]$ is continuous at every point of $M$. Then there exists a function, $g$ which is defined and continuous on all of $X$ such that $g = f$ on $M$ and $g$ has its values in $[-1,1]$.

**Proof:** Let $g_1$ be such that $g_1(X) \subseteq [-1/3,1/3]$ and $||f - g_1||_M \leq \frac{2}{3}$. Suppose $g_1, \ldots, g_m$ have been chosen such that $g_j(X) \subseteq [-1/3,1/3]$ and

$$\left| \left| f - \sum_{i=1}^{m} \left( \frac{2}{3} \right)^{i-1} g_i \right| \right|_M < \left( \frac{2}{3} \right)^m.$$  

(6.6.10)

Then

$$\left| \left| \left( \frac{2}{3} \right)^m \left( f - \sum_{i=1}^{m} \left( \frac{2}{3} \right)^{i-1} g_i \right) \right| \right|_M \leq 1$$

and so $\left( \frac{2}{3} \right)^m \left( f - \sum_{i=1}^{m} \left( \frac{2}{3} \right)^{i-1} g_i \right)$ can play the role of $f$ in the first step of the proof. Therefore, there exists $g_{m+1}$ defined and continuous on all of $X$ such that its values are in $[-1/3,1/3]$ and

$$\left| \left| \left( \frac{2}{3} \right)^m \left( f - \sum_{i=1}^{m} \left( \frac{2}{3} \right)^{i-1} g_i \right) - g_{m+1} \right| \right|_M \leq \frac{2}{3}.$$  

Hence

$$\left| \left| \left( f - \sum_{i=1}^{m} \left( \frac{2}{3} \right)^{i-1} g_i \right) - \left( \frac{2}{3} \right)^m g_{m+1} \right| \right|_M \leq \left( \frac{2}{3} \right)^{m+1}.$$  

It follows there exists a sequence, $\{g_i\}$ such that each has its values in $[-1/3,1/3]$ and for every $m$. (6.6.10) holds. Then let

$$g(x) = \sum_{i=1}^{\infty} \left( \frac{2}{3} \right)^{i-1} g_i(x).$$
It follows
\[ \left| g(x) \right| \leq \sum_{i=1}^{\infty} \left( \frac{2}{3} \right)^{i-1} g_i(x) \leq \frac{1}{5} \leq 1 \]

and since convergence is uniform, \( g \) must be continuous. The estimate 6.6.10 implies \( f = g \) on \( M \).

The following is the Tietze extension theorem.

**Theorem 6.6.7** Let \( M \) be a closed nonempty subset of a metric space \((X, d)\) and let \( f : M \rightarrow [a, b] \) is continuous at every point of \( M \). Then there exists a function, \( g \) continuous on all of \( X \) which coincides with \( f \) on \( M \) such that \( g(X) \subseteq [a, b] \).

**Proof:** Let \( f_1(x) = 1 + \frac{2}{b-a} (f(x) - b) \). Then \( f_1 \) satisfies the conditions of Lemma 6.6.6 and so there exists \( g_1 : X \rightarrow [-1, 1] \) such that \( g \) is continuous on \( X \) and equals \( f_1 \) on \( M \). Let \( g(x) = (g_1(x) - 1) \left( \frac{b-a}{2} \right) + b \). This works.

### 6.7 Some Simple Fixed Point Theorems

The following is of more interest in the case of normed vector spaces, but there is no harm in stating it in this more general setting. You should verify that the functions described in the following definition are all continuous.

**Definition 6.7.1** Let \( f : X \rightarrow Y \) where \((X, d)\) and \((Y, \rho)\) are metric spaces. Then \( f \) is said to be Lipschitz continuous if for every \( x, \hat{x} \in X \), \( \rho(f(x), f(\hat{x})) \leq rd(x, \hat{x}) \). The function is called a contraction map if \( r < 1 \).

The big theorem about contraction maps is the following.

**Theorem 6.7.2** Let \( f : (X, d) \rightarrow (X, d) \) be a contraction map and let \((X, d)\) be a complete metric space. Thus Cauchy sequences converge and also \( d(f(x), f(\hat{x})) \leq rd(x, \hat{x}) \) where \( r < 1 \). Then \( f \) has a unique fixed point. This is a point \( x \in X \) such that \( f(x) = x \). Also, if \( x_0 \) is any point of \( X \), then
\[ d(x, x_0) \leq \frac{d(x_0, f(x_0))}{1 - r} \]

Also, for each \( n \),
\[ d(f^n(x_0), x_0) \leq \frac{d(x_0, f(x_0))}{1 - r}, \]

and \( x = \lim_{n \rightarrow \infty} f^n(x_0) \).

**Proof:** Pick \( x_0 \in X \) and consider the sequence of iterates of the map,
\[ x_0, f(x_0), f^2(x_0), \ldots. \]
We argue that this is a Cauchy sequence. For \( m < n \), it follows from the triangle inequality,

\[
d(f^n(x_0) - f^m(x_0)) \leq \sum_{k=m}^{n-1} d(f^{k+1}(x_0) - f^k(x_0)) \leq \sum_{k=m}^{\infty} r^k d(f(x_0), x_0)
\]

The reason for this last is as follows.

\[
d(f^2(x_0), f(x_0)) \leq rd(f(x_0), x_0)
\]

\[
d(f^3(x_0), f^2(x_0)) \leq rd(f^2(x_0), f(x_0)) \leq r^2 d(f(x_0), x_0)
\]

and so forth. Therefore,

\[
d(f^n(x_0), f^m(x_0)) \leq d(f(x_0), x_0) \frac{r^m}{1 - r}
\]

which shows that this is indeed a Cauchy sequence. Therefore, there exists \( x \) such that

\[
\lim_{n \to \infty} f^n(x_0) = x
\]

By continuity,

\[
f(x) = f \left( \lim_{n \to \infty} f^n(x_0) \right) = \lim_{n \to \infty} f^{n+1}(x_0) = x.
\]

Also note that this estimate yields

\[
d(x_0, f^n(x_0)) \leq \frac{d(x_0, f(x_0))}{1 - r}
\]

Now \( d(x_0, x) \leq d(x_0, f^n(x_0)) + d(f^n(x_0), x) \) and so

\[
d(x_0, x) - d(f^n(x_0), x) \leq \frac{d(x_0, f(x_0))}{1 - r}
\]

Letting \( n \to \infty \), it follows that

\[
d(x_0, x) \leq \frac{d(x_0, f(x_0))}{1 - r}
\]

It only remains to verify that there is only one fixed point. Suppose then that \( x, x' \) are two. Then

\[
d(x, x') = d(f(x), f(x')) \leq rd(x', x)
\]

and so \( d(x, x') = 0 \) because \( r < 1 \). ■

The above is the usual formulation of this important theorem, but we actually proved a better result.
Corollary 6.7.3  Let $B$ be a closed subset of the complete metric space $(X, d)$ and let $f : B \to X$ be a contraction map

$$d(f(x), f(\tilde{x})) \leq rd(x, \tilde{x}), \ r < 1.$$ 

Also suppose there exists $x_0 \in B$ such that the sequence of iterates $\{f^n(x_0)\}_{n=1}^{\infty}$ remains in $B$. Then $f$ has a unique fixed point in $B$ which is the limit of the sequence of iterates. This is a point $x \in B$ such that $f(x) = x$. In the case that $B = B(x_0, \delta)$, the sequence of iterates satisfies the inequality

$$d(f^n(x_0), x_0) \leq \frac{d(x_0, f(x_0))}{1 - r}$$

and so it will remain in $B$ if

$$\frac{d(x_0, f(x_0))}{1 - r} < \delta.$$ 

**Proof:** By assumption, the sequence of iterates stays in $B$. Then, as in the proof of the preceding theorem, for $m < n$, it follows from the triangle inequality,

$$d(f^m(x_0), f^n(x_0)) \leq \sum_{k=m}^{n-1} d(f^{k+1}(x_0), f^k(x_0))$$

$$\leq \sum_{k=m}^{\infty} r^k d(f(x_0), x_0) = \frac{r^m}{1-r} d(f(x_0), x_0)$$

Hence the sequence of iterates is Cauchy and must converge to a point $x$ in $X$. However, $B$ is closed and so it must be the case that $x \in B$. Then as before,

$$x = \lim_{n \to \infty} f^n(x_0) = \lim_{n \to \infty} f^{n+1}(x_0) = f \left( \lim_{n \to \infty} f^n(x_0) \right) = f(x)$$

As to the sequence of iterates remaining in $B$ where $B$ is a ball as described, the inequality above in the case where $m = 0$ yields

$$d(x_0, f^n(x_0)) \leq \frac{1}{1-r} d(f(x_0), x_0)$$

and so, if the right side is less than $\delta$, then the iterates remain in $B$. As to the fixed point being unique, it is as before. If $x, x'$ are both fixed points in $B$, then $d(x, x') = d(f(x), f(x')) \leq rd(x, x')$ and so $x = x'$. 

Sometimes you have the contraction depending on a parameter $\lambda$. Then there is a principle of uniform contractions.

Corollary 6.7.4 Suppose $f : X \times \Lambda \to X$ where $\Lambda$ is a metric space and $X$ is a complete metric space. Suppose $f$ satisfies

1. $d(f(x, \lambda), f(y, \lambda)) \leq rd(x, y)$ for each $\lambda \in \Lambda$. 

2. $\lambda \rightarrow f(x, \lambda)$ is continuous as a map from $\Lambda$ to $X$.

Then if $x(\lambda)$ is the fixed point, it follows that $\lambda \rightarrow x(\lambda)$ is continuous.

**Proof:** Pick $x_0 \in X$ and consider the above sequence of iterates, $\{f^n(x, \lambda)\}$. Let $\rho$ be the metric on $\Lambda$. Then there is a fixed point and if $x(\lambda)$ is this unique fixed point,

$$d(x(\lambda), x_0) \leq \frac{d(f(x_0, \lambda), x_0)}{1-r}$$

In particular, you could start with $x_0 = x(\mu)$ and conclude that

$$d(x(\lambda), x(\mu)) \leq \frac{d(f(x(\mu), \lambda), x(\mu))}{1-r}$$

$$\leq \frac{d(f(x(\mu), \lambda), f(x(\mu), \mu))}{1-r} + \frac{d(f(x(\mu), \mu), x(\mu))}{1-r}$$

$$= \frac{d(f(x(\mu), \lambda), f(x(\mu), \mu))}{1-r}$$

Now by continuity of $\lambda \rightarrow f(x, \lambda)$, it follows that if $\rho(\lambda, \mu)$ is small enough, the above is no larger than

$$\frac{\varepsilon(1-r)}{1-r} = \varepsilon$$

Hence, if $\rho(\lambda, \mu)$ is small enough, we have

$$d(x(\lambda), x(\mu)) < \varepsilon.$$  

This is called the uniform contraction principle.

The contraction mapping theorem has an extremely useful generalization. In order to get a unique fixed point, it suffices to have some power of $f$ a contraction map.

**Theorem 6.7.5** Let $f : (X, d) \rightarrow (X, d)$ have the property that for some $n \in \mathbb{N}$, $f^n$ is a contraction map and let $(X, d)$ be a complete metric space. Then there is a unique fixed point for $f$. As in the earlier theorem the sequence of iterates $\{f^n(x_0)\}_{n=1}^{\infty}$ also converges to the fixed point.

**Proof:** From Theorem 6.7.2 there is a unique fixed point for $f^n$. Thus

$$f^n(x) = x$$

Then

$$f^n(f(x)) = f^{n+1}(x) = f(x)$$

By uniqueness, $f(x) = x$. 

CHAPTER 6. METRIC SPACES AND GENERAL TOPOLOGICAL SPACES

Now consider the sequence of iterates. Suppose it fails to converge to \( x \). Then there is \( \varepsilon > 0 \) and a subsequence \( n_k \) such that

\[
d(f^{n_k}(x_0), x) \geq \varepsilon
\]

Now \( n_k = p_k n + r_k \) where \( r_k \) is one of the numbers \( \{0, 1, 2, \ldots, n - 1\} \). It follows that there exists one of these numbers which is repeated infinitely often. Call it \( r \) and let the further subsequence continue to be denoted as \( n_k \). Thus

\[
d(f^{p_k n + r}(x_0), x) \geq \varepsilon
\]

In other words,

\[
d(f^{p_k n}(f^r(x_0)), x) \geq \varepsilon
\]

However, from Theorem 6.7.2, as \( k \to \infty \), \( f^{p_k n}(f^r(x_0)) \to x \) which contradicts the above inequality. Hence the sequence of iterates converges to \( x \), as it did for \( f \) a contraction map.

**Definition 6.7.6** Let \( f : (X, d) \to (Y, \rho) \) be a function. Then it is said to be uniformly continuous on \( X \) if for every \( \varepsilon > 0 \) there exists a \( \delta > 0 \) such that whenever \( x, \hat{x} \) are two points of \( X \) with \( d(x, \hat{x}) < \delta \), it follows that \( \rho(f(x), f(\hat{x})) < \varepsilon \).

Note the difference between this and continuity. With continuity, the \( \delta \) could depend on \( x \) but here it works for any pair of points in \( X \).

**Lemma 6.7.7** Suppose \( x_n \to x \) and \( y_n \to y \). Then \( d(x_n, y_n) \to d(x, y) \).

**Proof:** Consider the following.

\[
d(x, y) \leq d(x, x_n) + d(x_n, y) \leq d(x, x_n) + d(x_n, y_n) + d(y_n, y)
\]

so

\[
d(x, y) - d(x_n, y_n) \leq d(x, x_n) + d(y_n, y)
\]

Similarly

\[
d(x_n, y_n) - d(x, y) \leq d(x, x_n) + d(y_n, y)
\]

and so

\[
|d(x_n, y_n) - d(x, y)| \leq d(x, x_n) + d(y_n, y)
\]

and the right side converges to 0 as \( n \to \infty \).

There is a remarkable result concerning compactness and uniform continuity.

**Theorem 6.7.8** Let \( f : (X, d) \to (Y, \rho) \) be a continuous function and let \( K \) be a compact subset of \( X \). Then the restriction of \( f \) to \( K \) is uniformly continuous.

**Proof:** First of all, \( K \) is a metric space and \( f \) restricted to \( K \) is continuous. Now suppose it fails to be uniformly continuous. Then there exists \( \varepsilon > 0 \) and pairs of points \( x_n, \hat{x}_n \) such that \( d(f(x_n), f(\hat{x}_n)) < 1/n \) but \( \rho(f(x_n), f(\hat{x}_n)) \geq \varepsilon \). Since \( K \) is
compact, it is sequentially compact and so there exists a subsequence, still denoted as \( \{x_n\} \) such that \( x_n \to x \in K \). Then also \( \hat{x}_n \to x \) also and so
\[
\rho(f(x), f(x)) = \lim_{n \to \infty} \rho(f(x_n), f(\hat{x}_n)) \geq \varepsilon
\]
which is a contradiction. Note the use of Lemma 6.7.7 in the equal sign. ■

Next is to consider the meaning of convergence of sequences of functions. There are two main ways of convergence of interest here, pointwise and uniform convergence.

**Definition 6.7.9** Let \( f_n : X \to Y \) where \( (X, d), (Y, \rho) \) are two metric spaces. Then \( \{f_n\} \) is said to converge pointwise to a function \( f : X \to Y \) if for every \( x \in X \),
\[
\lim_{n \to \infty} f_n(x) = f(x)
\]
\( \{f_n\} \) is said to converge uniformly if for all \( \varepsilon > 0 \), there exists \( N \) such that if \( n \geq N \), then
\[
\sup_{x \in X} \rho(f_n(x), f(x)) < \varepsilon
\]

Here is a well known example illustrating the difference between pointwise and uniform convergence.

**Example 6.7.10** Let \( f_n(x) = x^n \) on the metric space \([0, 1]\). Then this function converges pointwise to
\[
f(x) = \begin{cases} 0 & \text{on } [0, 1) \\ 1 & \text{at } 1 \end{cases}
\]
but it does not converge uniformly on this interval to \( f \).

Note how the target function \( f \) in the above example is not continuous even though each function in the sequence is. The nice thing about uniform convergence is that it takes continuity of the functions in the sequence and imparts it to the target function. It does this for both continuity at a single point and uniform continuity. Thus uniform convergence is a very superior thing.

**Theorem 6.7.11** Let \( f_n : X \to Y \) where \( (X, d), (Y, \rho) \) are two metric spaces and suppose each \( f_n \) is continuous at \( x \in X \) and also that \( f_n \) converges uniformly to \( f \) on \( X \). Then \( f \) is also continuous at \( x \). In addition to this, if each \( f_n \) is uniformly continuous on \( X \), then the same is true for \( f \).

**Proof:** Let \( \varepsilon > 0 \) be given. Then
\[
\rho(f(x), f(\hat{x})) \leq \rho(f(x), f_n(x)) + \rho(f_n(x), f_n(\hat{x})) + \rho(f_n(\hat{x}), f(\hat{x}))
\]
By uniform convergence, there exists \( N \) such that both \( \rho(f(x), f_n(x)) \) and \( \rho(f_n(\hat{x}), f(\hat{x})) \) are less than \( \varepsilon/3 \) provided \( n \geq N \). Thus picking such an \( n \),
\[
\rho(f(x), f(\hat{x})) \leq \frac{2\varepsilon}{3} + \rho(f_n(x), f_n(\hat{x}))
\]
Now from the continuity of \( f_n\), there exists \( \delta > 0 \) such that if \( d(x, \hat{x}) < \delta \), then \( \rho(f_n(x), f_n(\hat{x})) < \varepsilon/3 \). Hence, if \( d(x, \hat{x}) < \delta \), then

\[
\rho(f(x), f(\hat{x})) \leq \frac{2\varepsilon}{3} + \rho(f_n(x), f_n(\hat{x})) < \frac{2\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon
\]

Hence, \( f \) is continuous at \( x \).

Next consider uniform continuity. It follows from the uniform convergence that if \( x, \hat{x} \) are any two points of \( X \), then if \( n \geq N \), then, picking such an \( n \),

\[
\rho(f(x), f(\hat{x})) \leq \frac{2\varepsilon}{3} + \rho(f_n(x), f_n(\hat{x}))
\]

By uniform continuity of \( f_n \) there exists \( \delta \) such that if \( d(x, \hat{x}) < \delta \), then the term on the right in the above is less than \( \varepsilon/3 \). Hence if \( d(x, \hat{x}) < \delta \), then \( \rho(f(x), f(\hat{x})) < \varepsilon \) and so \( f \) is uniformly continuous as claimed.

### 6.8 General Topological Spaces

It turns out that metric spaces are not sufficiently general for some applications. This section is a brief introduction to general topology. In making this generalization, the properties of balls which are the conclusion of Theorem 6.1.4 on Page 144 are stated as axioms for a subset of the power set of a given set which will be known as a basis for the topology. More can be found in [75] and the references listed there.

**Definition 6.8.1** Let \( X \) be a nonempty set and suppose \( \mathcal{B} \subseteq \mathcal{P}(X) \). Then \( \mathcal{B} \) is a basis for a topology if it satisfies the following axioms.

1.) Whenever \( p \in A \cap B \) for \( A, B \in \mathcal{B} \), it follows there exists \( C \in \mathcal{B} \) such that \( p \in C \subseteq A \cap B \).

2.) \( \cup \mathcal{B} = X \).

Then a subset, \( U \), of \( X \) is an open set if for every point, \( x \in U \), there exists \( B \in \mathcal{B} \) such that \( x \in B \subseteq U \). Thus the open sets are exactly those which can be obtained as a union of sets of \( \mathcal{B} \). Denote these subsets of \( X \) by the symbol \( \tau \) and refer to \( \tau \) as the topology or the set of open sets.

Note that this is simply the analog of saying a set is open exactly when every point is an interior point.

**Proposition 6.8.2** Let \( X \) be a set and let \( \mathcal{B} \) be a basis for a topology as defined above and let \( \tau \) be the set of open sets determined by \( \mathcal{B} \). Then

\[
\emptyset \in \tau, \quad X \in \tau, \quad (6.8.11)
\]

\[
\text{If } C \subseteq \tau, \text{ then } \cup C \in \tau \quad (6.8.12)
\]

\[
\text{If } A, B \in \tau, \text{ then } A \cap B \in \tau. \quad (6.8.13)
\]
Proof: If \( p \notin \emptyset \) then there exists \( B \in \mathcal{B} \) such that \( p \in B \subseteq \emptyset \) because there are no points in \( \emptyset \). Therefore, \( \emptyset \in \tau \). Now if \( p \in X \), then by part 2) of Definition 6.8.1, \( p \in B \subseteq X \) for some \( B \in \mathcal{B} \) and so \( X \in \tau \).

If \( C \subseteq \tau \), and if \( p \in \cup C \), then there exists a set, \( B \in C \) such that \( p \in B \). However, \( B \) is itself a union of sets from \( \mathcal{B} \) and so there exists \( C \in \mathcal{B} \) such that \( p \in C \subseteq B \subseteq \cup C \). This verifies 6.8.12.

Finally, if \( A, B \subseteq \tau \) and \( p \in A \cap B \), then since \( A \) and \( B \) are themselves unions of sets of \( \mathcal{B} \), it follows there exists \( A_1, B_1 \in \mathcal{B} \) such that \( A_1 \subseteq A, B_1 \subseteq B \), and \( p \in A_1 \cap B_1 \). Therefore, by 1) of Definition 6.8.1, there exists \( C \in \mathcal{B} \) such that \( p \in C \subseteq A_1 \cap B_1 \subseteq A \cap B \), showing that \( A \cap B \in \tau \) as claimed. Of course if \( A \cap B = \emptyset \), then \( A \cap B \subseteq \tau \). This proves the proposition.

Definition 6.8.3 A set \( X \) together with such a collection of its subsets satisfying 6.8.11 - 6.8.13 is called a topological space. \( \tau \) is called the topology or set of open sets of \( X \).

Definition 6.8.4 A topological space is said to be Hausdorff if whenever \( p \) and \( q \) are distinct points of \( X \), there exist disjoint open sets \( U, V \) such that \( p \in U, q \in V \). In other words points can be separated with open sets.

\[
\begin{array}{ccc}
U & p & V \\
\text{Hausdorff} & & \\
q
\end{array}
\]

Definition 6.8.5 A subset of a topological space is said to be closed if its complement is open. Let \( p \) be a point of \( X \) and let \( E \subseteq X \). Then \( p \) is said to be a limit point of \( E \) if every open set containing \( p \) contains a point of \( E \) distinct from \( p \).

Note that if the topological space is Hausdorff, then this definition is equivalent to requiring that every open set containing \( p \) contains infinitely many points from \( E \). Why?

Theorem 6.8.6 A subset, \( E \), of \( X \) is closed if and only if it contains all its limit points.

Proof: Suppose first that \( E \) is closed and let \( x \) be a limit point of \( E \). Is \( x \in E \)? If \( x \notin E \), then \( E^C \) is an open set containing \( x \) which contains no points of \( E \), a contradiction. Thus \( x \in E \).

Now suppose \( E \) contains all its limit points. Is the complement of \( E \) open? If \( x \in E^C \), then \( x \) is not a limit point of \( E \) because \( E \) has all its limit points and so there exists an open set, \( U \) containing \( x \) such that \( U \) contains no point of \( E \) other than \( x \). Since \( x \notin E \), it follows that \( x \in U \subseteq E^C \) which implies \( E^C \) is an open set because this shows \( E^C \) is the union of open sets.
Theorem 6.8.7 If \((X, \tau)\) is a Hausdorff space and if \(p \in X\), then \(\{p\}\) is a closed set.

**Proof:** If \(x \neq p\), there exist open sets \(U\) and \(V\) such that \(x \in U, p \in V\) and \(U \cap V = \emptyset\). Therefore, \(\{p\}^C\) is an open set so \(\{p\}\) is closed.

Note that the Hausdorff axiom was stronger than needed in order to draw the conclusion of the last theorem. In fact it would have been enough to assume that if \(x \neq y\), then there exists an open set containing \(x\) which does not intersect \(y\).

**Definition 6.8.8** A topological space \((X, \tau)\) is said to be regular if whenever \(C\) is a closed set and \(p\) is a point not in \(C\), there exist disjoint open sets \(U\) and \(V\) such that \(p \in U, C \subseteq V\). Thus a closed set can be separated from a point not in the closed set by two disjoint open sets.

**Definition 6.8.9** The topological space, \((X, \tau)\) is said to be normal if whenever \(C\) and \(K\) are disjoint closed sets, there exist disjoint open sets \(U\) and \(V\) such that \(C \subseteq U, K \subseteq V\). Thus any two disjoint closed sets can be separated with open sets.

**Definition 6.8.10** Let \(E\) be a subset of \(X\). \(\overline{E}\) is defined to be the smallest closed set containing \(E\).

**Lemma 6.8.11** The above definition is well defined.

**Proof:** Let \(C\) denote all the closed sets which contain \(E\). Then \(C\) is nonempty because \(X \in C\).

\[
(\cap \{A : A \in C\})^C = \cup \{A^C : A \in C\},
\]

an open set which shows that \(\cap C\) is a closed set and is the smallest closed set which contains \(E\).

**Theorem 6.8.12** \(\overline{E} = E \cup \{\text{limit points of } E\}\).
Proof: Let \( x \in E \) and suppose that \( x \notin E \). If \( x \) is not a limit point either, then there exists an open set, \( U \), containing \( x \) which does not intersect \( E \). But then \( U^c \) is a closed set which contains \( E \) which does not contain \( x \), contrary to the definition that \( E \) is the intersection of all closed sets containing \( E \). Therefore, \( x \) must be a limit point of \( E \) after all.

Now \( E \subseteq \overline{E} \) so suppose \( x \) is a limit point of \( E \). Is \( x \notin E \)? If \( H \) is a closed set containing \( E \), which does not contain \( x \), then \( H^c \) is an open set containing \( x \) which contains no points of \( E \) other than \( x \) negating the assumption that \( x \) is a limit point of \( E \).

The following is the definition of continuity in terms of general topological spaces. It is really just a generalization of the \( \epsilon - \delta \) definition of continuity given in calculus.

**Definition 6.8.13** Let \((X, \tau)\) and \((Y, \eta)\) be two topological spaces and let \( f : X \to Y \). \( f \) is continuous at \( x \in X \) if whenever \( V \) is an open set of \( Y \) containing \( f(x) \), there exists an open set \( U \subseteq X \) such that \( x \in U \) and \( f(U) \subseteq V \). \( f \) is continuous if \( f^{-1}(V) \in \tau \) whenever \( V \in \eta \).

You should prove the following.

**Proposition 6.8.14** In the situation of Definition 6.8.13 \( f \) is continuous if and only if \( f \) is continuous at every point of \( X \).

**Definition 6.8.15** Let \((X_i, \tau_i)\) be topological spaces. \( \prod_{i=1}^{n} X_i \) is the Cartesian product. Define a product topology as follows. Let \( B = \prod_{i=1}^{n} A_i \) where \( A_i \in \tau_i \). Then \( B \) is a basis for the product topology.

**Theorem 6.8.16** The set \( B \) of Definition 6.8.15 is a basis for a topology.

**Proof:** Suppose \( x \in \prod_{i=1}^{n} A_i \cap \prod_{i=1}^{n} B_i \) where \( A_i \) and \( B_i \) are open sets. Say \( x = (x_1, \ldots, x_n) \).

Then \( x_i \in A_i \cap B_i \) for each \( i \). Therefore, \( x \in \prod_{i=1}^{n} A_i \cap \prod_{i=1}^{n} B_i \subseteq \prod_{i=1}^{n} A_i \).

The definition of compactness is also considered for a general topological space. This is given next.

**Definition 6.8.17** A subset, \( E \), of a topological space \((X, \tau)\) is said to be compact if whenever \( C \subseteq \tau \) and \( E \subseteq \cup C \), there exists a finite subset of \( C \), \( \{U_1 \cdots U_n \} \), such that \( E \subseteq \cup_{i=1}^{n} U_i \). (Every open covering admits a finite subcovering.) \( E \) is precompact if \( \overline{E} \) is compact. A topological space is called locally compact if it has a basis \( B \), with the property that \( \overline{B} \) is compact for each \( B \in B \).

In general topological spaces there may be no concept of “bounded”. Even if there is, closed and bounded is not necessarily the same as compactness. However, in any Hausdorff space every compact set must be a closed set.
Theorem 6.8.18 If $\langle X, \tau \rangle$ is a Hausdorff space, then every compact subset must also be a closed set.

**Proof**: Suppose $p \notin K$. For each $x \in X$, there exist open sets, $U_x$ and $V_x$ such that
\[ x \in U_x, \quad p \in V_x, \]
and
\[ U_x \cap V_x = \emptyset. \]
If $K$ is assumed to be compact, there are finitely many of these sets, $U_{x_1}, \ldots, U_{x_m}$ which cover $K$. Then let $V \equiv \cap_{i=1}^{m} V_{x_i}$. It follows that $V$ is an open set containing $p$ which has empty intersection with each of the $U_{x_i}$. Consequently, $V$ contains no points of $K$ and is therefore not a limit point of $K$. This proves the theorem.

A useful construction when dealing with locally compact Hausdorff spaces is the notion of the one point compactification of the space.

**Definition 6.8.19** Suppose $\langle X, \tau \rangle$ is a locally compact Hausdorff space. Then let $\bar{X} \equiv X \cup \{\infty\}$ where $\infty$ is just the name of some point which is not in $X$ which is called the point at infinity. A basis for the topology $\bar{\tau}$ for $\bar{X}$ is
\[ \tau \cup \{K^C \text{ where } K \text{ is a compact subset of } X\}. \]
The complement is taken with respect to $\bar{X}$ and so the open sets, $K^C$ are basic open sets which contain $\infty$.

The reason this is called a compactification is contained in the next lemma.

**Lemma 6.8.20** If $\langle X, \tau \rangle$ is a locally compact Hausdorff space, then $\langle \bar{X}, \bar{\tau} \rangle$ is a compact Hausdorff space. Also if $U$ is an open set of $\bar{\tau}$, then $U \setminus \{\infty\}$ is an open set of $\tau$.

**Proof**: Since $\langle X, \tau \rangle$ is a locally compact Hausdorff space, it follows $\langle \bar{X}, \bar{\tau} \rangle$ is a Hausdorff topological space. The only case which needs checking is the one of $p \in X$ and $\infty$. Since $\langle X, \tau \rangle$ is locally compact, there exists an open set of $\tau$, $U$ having compact closure which contains $p$. Then $p \in U$ and $\infty \in U^C$ and these are disjoint open sets containing the points, $p$ and $\infty$ respectively. Now let $C$ be an open cover of $\bar{X}$ with sets from $\bar{\tau}$. Then $\infty$ must be in some set, $U_\infty$ from $C$, which must contain a set of the form $K^C$ where $K$ is a compact subset of $X$. Then there exist sets from $C$, $U_1, \ldots, U_r$ which cover $K$. Therefore, a finite subcover of $\bar{X}$ is $U_1, \ldots, U_r, U_\infty$.

To see the last claim, suppose $U$ contains $\infty$ since otherwise there is nothing to show. Notice that if $C$ is a compact set, then $X \setminus C$ is an open set. Therefore, if $x \in U \setminus \{\infty\}$, and if $\bar{X} \setminus C$ is a basic open set contained in $U$ containing $\infty$, then if $x$ is in this basic open set of $\bar{X}$, it is also in the open set $X \setminus C \subseteq U \setminus \{\infty\}$. If $x$ is not in any basic open set of the form $\bar{X} \setminus C$ then $x$ is contained in an open set of $\tau$ which is contained in $U \setminus \{\infty\}$. Thus $U \setminus \{\infty\}$ is indeed open in $\tau$. 

6.9. CONNECTED SETS

Definition 6.8.21  If every finite subset of a collection of sets has nonempty intersection, the collection has the finite intersection property.

Theorem 6.8.22  Let $\mathcal{K}$ be a set whose elements are compact subsets of a Hausdorff topological space, $(X, \tau)$. Suppose $\mathcal{K}$ has the finite intersection property. Then $\emptyset \neq \cap \mathcal{K}$.

Proof: Suppose to the contrary that $\emptyset = \cap \mathcal{K}$. Then consider
\[
\mathcal{C} = \{ K^C : K \in \mathcal{K} \}.
\]
It follows $\mathcal{C}$ is an open cover of $K_0$ where $K_0$ is any particular element of $\mathcal{K}$. But then there are finitely many $K \in \mathcal{K}$, $K_1, \cdots, K_r$ such that $K_0 \subseteq \cup_{i=1}^r K_i^C$ implying that $\cap_{i=0}^r K_i = \emptyset$, contradicting the finite intersection property.

Lemma 6.8.23  Let $(X, \tau)$ be a topological space and let $\mathcal{B}$ be a basis for $\tau$. Then $K$ is compact if and only if every open cover of basic open sets admits a finite subcover.

Proof: Suppose first that $X$ is compact. Then if $\mathcal{C}$ is an open cover consisting of basic open sets, it follows it admits a finite subcover because these are open sets in $\mathcal{C}$.

Next suppose that every basic open cover admits a finite subcover and let $\mathcal{C}$ be an open cover of $X$. Then define $\mathcal{C}$ to be the collection of basic open sets which are contained in some set of $\mathcal{C}$. It follows $\mathcal{C}$ is a basic open cover of $X$ and so it admits a finite subcover, $\{U_1, \cdots, U_p\}$. Now each $U_i$ is contained in an open set of $\mathcal{C}$. Let $O_i$ be a set of $\mathcal{C}$ which contains $U_i$. Then $\{O_1, \cdots, O_p\}$ is an open cover of $X$. This proves the lemma.

In fact, much more can be said than Lemma 6.8.23. However, this is all which I will present here.

6.9  Connected Sets

Stated informally, connected sets are those which are in one piece. More precisely,

Definition 6.9.1  A set, $S$ in a general topological space is separated if there exist sets, $A, B$ such that
\[
S = A \cup B, \quad A, B \neq \emptyset, \quad \overline{A} \cap B = B \cap \overline{A} = \emptyset.
\]

In this case, the sets $A$ and $B$ are said to separate $S$. A set is connected if it is not separated.

One of the most important theorems about connected sets is the following.

Theorem 6.9.2  Suppose $U$ and $V$ are connected sets having nonempty intersection. Then $U \cup V$ is also connected.
Proof: Suppose \( U \cup V = A \cup B \) where \( \overline{A} \cap B = \overline{B} \cap A = \emptyset \). Consider the sets, \( A \cap U \) and \( B \cap U \). Since

\[
(\overline{A \cap U}) \cap (B \cap U) = (A \cap U) \cap (\overline{B \cap U}) = \emptyset,
\]

it follows one of these sets must be empty since otherwise, \( U \) would be separated. It follows that \( U \) is contained in either \( A \) or \( B \). Similarly, \( V \) must be contained in either \( A \) or \( B \). Since \( U \) and \( V \) have nonempty intersection, it follows that both \( V \) and \( U \) are contained in one of the sets, \( A, B \). Therefore, the other must be empty and this shows \( U \cup V \) cannot be separated and is therefore, connected.

The intersection of connected sets is not necessarily connected as is shown by the following picture.

---

**Theorem 6.9.3** Let \( f : X \to Y \) be continuous where \( X \) and \( Y \) are topological spaces and \( X \) is connected. Then \( f(X) \) is also connected.

Proof: To do this you show \( f(X) \) is not separated. Suppose to the contrary that \( f(X) = A \cup B \) where \( A \) and \( B \) separate \( f(X) \). Then consider the sets, \( f^{-1}(A) \) and \( f^{-1}(B) \). If \( z \in f^{-1}(B) \), then \( f(z) \in B \) and so \( f(z) \) is not a limit point of \( A \). Therefore, there exists an open set, \( U \) containing \( f(z) \) such that \( U \cap A = \emptyset \). But then, the continuity of \( f \) implies that \( f^{-1}(U) \) is an open set containing \( z \) such that \( f^{-1}(U) \cap f^{-1}(A) = \emptyset \). Therefore, \( f^{-1}(A) \) contains no limit points of \( f^{-1}(A) \). Similar reasoning implies \( f^{-1}(A) \) contains no limit points of \( f^{-1}(B) \). It follows that \( X \) is separated by \( f^{-1}(A) \) and \( f^{-1}(B) \), contradicting the assumption that \( X \) was connected.

An arbitrary set can be written as a union of maximal connected sets called connected components. This is the concept of the next definition.

**Definition 6.9.4** Let \( S \) be a set and let \( p \in S \). Denote by \( C_p \) the union of all connected subsets of \( S \) which contain \( p \). This is called the connected component determined by \( p \).

**Theorem 6.9.5** Let \( C_p \) be a connected component of a set \( S \) in a general topological space. Then \( C_p \) is a connected set and if \( C_p \cap C_q \neq \emptyset \), then \( C_p = C_q \).
6.9. CONNECTED SETS

Proof: Let $C$ denote the connected subsets of $S$ which contain $p$. If $C_p = A \cup B$ where

$$\overline{A} \cap B = \overline{B} \cap A = \emptyset,$$

then $p$ is in one of $A$ or $B$. Suppose without loss of generality $p \in A$. Then every set of $C$ must also be contained in $A$ also since otherwise, as in Theorem 6.9.2, the set would be separated. But this implies $B$ is empty. Therefore, $C_p$ is connected. From this, and Theorem 6.9.2, the second assertion of the theorem is proved.

This shows the connected components of a set are equivalence classes and partition the set.

A set, $I$ is an interval in $\mathbb{R}$ if and only if whenever $x, y \in I$ then $(x, y) \subseteq I$. The following theorem is about the connected sets in $\mathbb{R}$.

Theorem 6.9.6 A set, $C$ in $\mathbb{R}$ is connected if and only if $C$ is an interval.

Proof: Let $C$ be connected. If $C$ consists of a single point, $p$, there is nothing to prove. The interval is just $[p, p]$. Suppose $p < q$ and $p, q \in C$. You need to show $(p, q) \subseteq C$.

Let $C \cap (-\infty, x) \equiv A$, and $C \cap (x, \infty) \equiv B$. Then $C = A \cup B$ and the sets, $A$ and $B$ separate $C$ contrary to the assumption that $C$ is connected.

Conversely, let $I$ be an interval. Suppose $I$ is separated by $A$ and $B$. Pick $x \in A$ and $y \in B$. Suppose without loss of generality that $x < y$. Now define the set,

$$S \equiv \{t \in [x, y] : [x, t] \subseteq A\}$$

and let $l$ be the least upper bound of $S$. Then $l \in A$ so $l \notin B$ which implies $l \in A$. But if $l \notin B$, then for some $\delta > 0$,

$$(l, l + \delta) \cap B = \emptyset$$

contradicting the definition of $l$ as an upper bound for $S$. Therefore, $l \in B$ which implies $l \notin A$ after all, a contradiction. It follows $I$ must be connected.

The following theorem is a very useful description of the open sets in $\mathbb{R}$.

Theorem 6.9.7 Let $U$ be an open set in $\mathbb{R}$. Then there exist countably many disjoint open sets, $\{(a_i, b_i)\}_{i=1}^{\infty}$ such that $U = \bigcup_{i=1}^{\infty} (a_i, b_i)$.

Proof: Let $p \in U$ and let $z \in C_p$, the connected component determined by $p$. Since $U$ is open, there exists, $\delta > 0$ such that $(z - \delta, z + \delta) \subseteq U$. It follows from Theorem 6.9.2 that

$$(z - \delta, z + \delta) \subseteq C_p.$$ 

This shows $C_p$ is open. By Theorem 6.9.7 this shows $C_p$ is an open interval, $(a, b)$ where $a, b \in [-\infty, \infty]$. There are therefore at most countably many of these connected components because each must contain a rational number and the rational numbers are countable. Denote by $\{(a_i, b_i)\}_{i=1}^{\infty}$ the set of these connected components. This proves the theorem.
CHAPTER 6. METRIC SPACES AND GENERAL TOPOLOGICAL SPACES

Definition 6.9.8 A topological space, \( E \) is arcwise connected if for any two points, \( p, q \in E \), there exists a closed interval, \([a, b]\) and a continuous function, \( \gamma : [a, b] \to E \) such that \( \gamma(a) = p \) and \( \gamma(b) = q \). \( E \) is locally connected if it has a basis of connected open sets. \( E \) is locally arcwise connected if it has a basis of arcwise connected open sets.

An example of an arcwise connected topological space would be the any subset of \( \mathbb{R}^n \) which is the continuous image of an interval. Locally connected is not the same as connected. A well known example is the following.

\[
\left\{ \left( x, \sin \frac{1}{x} \right) : x \in (0, 1] \right\} \cup \{(0, y) : y \in [-1, 1]\} \quad (6.9.14)
\]

You can verify that this set of points considered as a metric space with the metric from \( \mathbb{R}^2 \) is not locally connected or arcwise connected but is connected.

Proposition 6.9.9 If a topological space is arcwise connected, then it is connected.

Proof: Let \( X \) be an arcwise connected space and suppose it is separated. Then \( X = A \cup B \) where \( A, B \) are two separated sets. Pick \( p \in A \) and \( q \in B \). Since \( X \) is given to be arcwise connected, there must exist a continuous function \( \gamma : [a, b] \to X \) such that \( \gamma(a) = p \) and \( \gamma(b) = q \). But then we would have \( \gamma([a, b]) = (\gamma([a, b]) \cap A) \cup (\gamma([a, b]) \cap B) \) and the two sets, \( \gamma([a, b]) \cap A \) and \( \gamma([a, b]) \cap B \) are separated thus showing that \( \gamma([a, b]) \) is separated and contradicting Theorem 6.9.6 and Theorem 6.9.3. It follows that \( X \) must be connected as claimed.

Theorem 6.9.10 Let \( U \) be an open subset of a locally arcwise connected topological space, \( X \). Then \( U \) is arcwise connected if and only if \( U \) is connected. Also the connected components of an open set in such a space are open sets, hence arcwise connected.

Proof: By Proposition 6.9.9 it is only necessary to verify that if \( U \) is connected and open in the context of this theorem, then \( U \) is arcwise connected. Pick \( p \in U \). Say \( x \in U \) satisfies \( \mathcal{P} \) if there exists a continuous function, \( \gamma : [a, b] \to U \) such that \( \gamma(a) = p \) and \( \gamma(b) = x \).

\[
A \equiv \{ x \in U \text{ such that } x \text{ satisfies } \mathcal{P}. \}
\]

If \( x \in A \), there exists, according to the assumption that \( X \) is locally arcwise connected, an open set, \( V \), containing \( x \) and contained in \( U \) which is arcwise connected. Thus letting \( y \in V \), there exist intervals, \([a, b]\) and \([c, d]\) and continuous functions having values in \( U \), \( \gamma, \eta \) such that \( \gamma(a) = p, \gamma(b) = x, \eta(c) = x \), and \( \eta(d) = y \). Then let \( \gamma_1 : [a, b + d - c] \to U \) be defined as

\[
\gamma_1(t) = \begin{cases} 
\gamma(t) & \text{if } t \in [a, b] \\
\eta(t + c - b) & \text{if } t \in [b, b + d - c]
\end{cases}
\]
Then it is clear that $\gamma_1$ is a continuous function mapping $p$ to $y$ and showing that $V \subseteq A$. Therefore, $A$ is open. $A \neq \emptyset$ because there is an open set, $V$ containing $p$ which is contained in $U$ and is arcwise connected.

Now consider $B \equiv U \setminus A$. This is also open. If $B$ is not open, there exists a point $z \in B$ such that every open set containing $z$ is not contained in $B$. Therefore, letting $V$ be one of the basic open sets chosen such that $z \in V \subseteq U$, there exist points of $A$ contained in $V$. But then, a repeat of the above argument shows $z \in A$ also. Hence $B$ is open and so if $B \neq \emptyset$, then $U = B \cup A$ and so $U$ is separated by the two sets, $B$ and $A$ contradicting the assumption that $U$ is connected.

It remains to verify the connected components are open. Let $z \in C_p$ where $C_p$ is the connected component determined by $p$. Then picking $V$ an arcwise connected open set which contains $z$ and is contained in $U; C_p \cap V$ is connected and contained in $U$ and so it must also be contained in $C_p$. This proves the theorem.

As an application, consider the following corollary.

**Corollary 6.9.11** Let $f : \Omega \to \mathbb{Z}$ be continuous where $\Omega$ is a connected open set. Then $f$ must be a constant.

**Proof:** Suppose not. Then it achieves two different values, $k$ and $l \neq k$. Then $\Omega = f^{-1}(l) \cup f^{-1}(\{m \in \mathbb{Z} : m \neq l\})$ and these are disjoint nonempty open sets which separate $\Omega$. To see they are open, note

$$f^{-1}(\{m \in \mathbb{Z} : m \neq l\}) = f^{-1}\left(\bigcup_{m \neq l} \left[m - \frac{1}{6}, m + \frac{1}{6}\right]\right)$$

which is the inverse image of an open set.

### 6.10 Exercises

1. Let $d(x, y) = |x - y|$ for $x, y \in \mathbb{R}$. Show that this is a metric on $\mathbb{R}$.

2. Now consider $\mathbb{R}^n$. Let $\|x\|_\infty \equiv \max \{|x_i|, i = 1, \cdots, n\}$. Define

$$d(x, y) \equiv \|x - y\|_\infty.$$ 

Show that this is a metric on $\mathbb{R}^n$. In the case of $n = 2$, describe the ball $B(0, r)$. **Hint:** First show that $\|x + y\| \leq \|x\| + \|y\|$.

3. Let $C([0, T])$ denote the space of functions which are continuous on $[0, T]$. Define

$$\|f\| \equiv \sup_{t \in [0, T]} |f(t)| = \max_{t \in [0, T]} |f(t)|$$

Verify the following. $\|f + g\| \leq \|f\| + \|g\|$. Then use to show that $d(f, g) \equiv \|f - g\|$ is a metric and that with this metric, $(C([0, T]), d)$ is a metric space.
4. Recall that \([a, b]\) is compact. This was done in single variable advanced calculus. That is, every sequence has a convergent subsequence. (We will go over it in here as well.) Also recall that a sequence of numbers \(\{x_n\}\) is a Cauchy sequence means that for every \(\varepsilon > 0\) there exists \(N\) such that if \(m, n > N\), then \(|x_n - x_m| < \varepsilon\). First show that every Cauchy sequence is bounded. Next, using the compactness of closed intervals, show that every Cauchy sequence has a convergent subsequence. It is shown later that if this is true, the original Cauchy sequence converges. Thus \(\mathbb{R}\) with the usual metric just described is complete because every Cauchy sequence converges.

5. Using the result of the above problem, show that \((\mathbb{R}^n, \|\cdot\|_\infty)\) is a complete metric space. That is, every Cauchy sequence converges. Here \(d(x, y) \equiv \|x - y\|_\infty\).

6. Suppose you had \((X_i, d_i)\) is a metric space. Now consider the product space

\[ X \equiv \prod_{i=1}^{n} X_i \]

with \(d(x, y) = \max \{d(x_i, y_i), i = 1 \cdots, n\}\). Would this be a metric space? If so, prove that this is the case. Does triangle inequality hold? **Hint:** For each \(i\),

\[ d_i(x_i, z_i) \leq d_i(x_i, y_i) + d_i(y_i, z_i) \leq d(x, y) + d(y, z) \]

Now take max of the two ends.

7. In the above example, if each \((X_i, d_i)\) is complete, explain why \((X, d)\) is also complete.

8. Show that \(C([0, T])\) is a complete metric space. That is, show that if \(\{f_n\}\) is a Cauchy sequence, then there exists \(f \in C([0, T])\) such that \(\lim_{n \to \infty} d(f, f_n) = \lim_{n \to \infty} \|f - f_n\| = 0\). **Hint:** First, you know that \(\{f_n(t)\}\) is a Cauchy sequence for each \(t\). Why? Now let \(f(t)\) be the name of the thing to which \(f_n(t)\) converges. Recall why the uniform convergence implies \(t \to f(t)\) is continuous. Give the proof. It was done in single variable advanced calculus. Review and write down proof. Also show that \(\|f - f_n\| \to 0\).

9. Let \(X\) be a nonempty set of points. Say it has infinitely many points. Define \(d(x, y) = 1\) if \(x \neq y\) and \(d(x, y) = 0\) if \(x = y\). Show that this is a metric. Show that in \((X, d)\) every point is open and closed. In fact, show that every set is open and every set is closed. Is this a complete metric space? Explain why. Describe the open balls.

10. Show that the union of any set of open sets is an open set. Show the intersection of any set of closed sets is closed. Let \(A\) be a nonempty subset of a metric space \((X, d)\). Then the closure of \(A\), written as \(\overline{A}\) is defined to be the
intersection of all closed sets which contain \( A \). Show that \( \overline{A} = A \cup A' \). That is, to find the closure, you just take the set and include all limit points of the set.

11. Let \( A' \) denote the set of limit points of \( A \), a nonempty subset of a metric space \((X, d)\). Show that \( A = A \cap A' \). That is, to find the closure, you just take the set and include all limit points of the set.

12. A theorem was proved which gave three equivalent descriptions of compactness of a metric space. One of them said the following: A metric space is compact if and only if it is complete and totally bounded. Suppose \((X, d)\) is a complete metric space and \( K \subseteq X \). Then \((K, d)\) is also clearly a metric space having the same metric as \( X \). Show that \((K, d)\) is compact if and only if it is closed and totally bounded. Note the similarity with the Heine Borel theorem on \( \mathbb{R} \).

13. A theorem was proved which gave three equivalent descriptions of compactness of a metric space. One of them said the following: A metric space is compact if and only if it is complete and totally bounded. Suppose \((X, d)\) is a complete metric space and \( K \subseteq X \). Then \((K, d)\) is also clearly a metric space having the same metric as \( X \). Show that \((K, d)\) is compact if and only if it is closed and totally bounded. Note the similarity with the Heine Borel theorem on \( \mathbb{R} \).

14. If you have a metric space \((X, d)\) and a compact subset of \((X, d)\) \( K \), suppose that \( L \) is a closed subset of \( K \). Explain why \( L \) must also be compact. \textbf{Hint:} Go right to the definition. Take an open covering of \( L \) and consider this along with the open set \( L^c \) to obtain an open covering of \( K \). Now use compactness of \( K \). Use this to explain why every closed and bounded set in \( \mathbb{R}^n \) is compact. Here the distance is given by \( d(x, y) \equiv \max_{1 \leq i \leq n} \{|x_i - y_i|\} \).

15. Show that compactness is a topological property in the following sense. If \((X, d), (Y, \rho)\) are both metric spaces and \( f : X \to Y \) has the property that \( f \) is one to one, onto, and continuous, and also \( f^{-1} \) is one to one onto and continuous, then
CHAPTER 6. METRIC SPACES AND GENERAL TOPOLOGICAL SPACES

the two metric spaces are compact or not compact together. That is one is compact if and only if the other is.

16. Consider \( \mathbb{R} \) the real numbers. Define a distance in the following way.

\[
\rho(x, y) \equiv |\arctan(x) - \arctan(y)|
\]

Show this is a good enough distance and that the open sets which come from this distance are the same as the open sets which come from the usual distance \( d(x, y) = |x - y| \). Explain why this yields that the identity mapping \( f(x) = x \) is continuous with continuous inverse as a map from \((\mathbb{R}, d)\) to \((\mathbb{R}, \rho)\). To do this, you show that an open ball taken with respect to one of these is also open with respect to the other. However, \((\mathbb{R}, \rho)\) is not a complete metric space while \((\mathbb{R}, d)\) is. Thus, unlike compactness. Completeness is not a topological property. Hint: To show the lack of completeness of \((\mathbb{R}, \rho)\), consider \( x_n = n \).

17. A very useful idea in metric space is the following distance function. Let \((X, d)\) be a metric space and \( S \subseteq X, S \neq \emptyset \). Then \( \text{dist}(x, S) \equiv \inf \{d(x, y) : y \in S\} \).

Show that this always satisfies

\[
|\text{dist}(x, S) - \text{dist}(z, S)| \leq d(x, z)
\]

This is a really neat result.

18. If \( K \) is a compact subset of \((X, d)\) and \( y \notin K \), show that there always exists \( x \in K \) such that \( d(x, y) = \text{dist}(y, K) \). Give an example in \( \mathbb{R} \) to show that this is might not be so if \( K \) is not compact.

19. You know that if \( f : X \to X \) for \( X \) a complete metric space, then if \( d(f(x), f(y)) < rd(x, y) \) it follows that \( f \) has a unique fixed point theorem. Let \( f : \mathbb{R} \to \mathbb{R} \) be given by

\[
f(t) = t + (1 + e^{t})^{-1}
\]

Show that \( |f(t) - f(s)| < |t - s| \), but \( f \) has no fixed point.

20. If \((X, d)\) is a metric space, show that there is a bounded metric \( \rho \) such that the open sets for \((X, d)\) are the same as those for \((X, \rho)\).

21. Let \((X, d)\) be a metric space where \( d \) is a bounded metric. Let \( \mathcal{C} \) denote the collection of closed subsets of \( X \). For \( A, B \in \mathcal{C} \), define

\[
\rho(A, B) \equiv \inf \{\delta > 0 : A_{\delta} \supseteq B \text{ and } B_{\delta} \supseteq A\}
\]

where for a set \( S \),

\[
S_{\delta} \equiv \{x : \text{dist}(x, S) \equiv \inf \{d(x, s) : s \in S\} \leq \delta\}.
\]

Show \( x \to \text{dist}(x, S) \) is continuous and that therefore, \( S_{\delta} \) is a closed set containing \( S \). Also show that \( \rho \) is a metric on \( \mathcal{C} \). This is called the Hausdorff metric.
22. Suppose \((X,d)\) is a compact metric space. Show \((C,\rho)\) is a complete metric space. **Hint:** Show first that if \(W_n \downarrow W\) where \(W_n\) is closed, then \(\rho(W_n,W) \to 0\). Now let \(\{A_n\}\) be a Cauchy sequence in \(C\). Then if \(\varepsilon > 0\) there exists \(N\) such that when \(m,n \geq N\), then \(\rho(A_n,A_m) < \varepsilon\). Therefore, for each \(n \geq N\),
\[
(A_n)_\varepsilon \supseteq \bigcup_{k=n}^\infty A_k.
\]
Let \(A \equiv \cap_{n=1}^\infty \bigcup_{k=n}^\infty A_k\). By the first part, there exists \(N_1 > N\) such that for \(n \geq N_1\),
\[
\rho\left(\bigcup_{k=n}^\infty A_k, A\right) < \varepsilon, \text{ and } (A_n)_\varepsilon \supseteq \bigcup_{k=n}^\infty A_k.
\]
Therefore, for such \(n\), \(A_\varepsilon \supseteq W_n \supseteq A_n\) and \((W_n)_\varepsilon \supseteq (A_n)_\varepsilon \supseteq A\) because
\[
(A_n)_\varepsilon \supseteq \bigcup_{k=n}^\infty A_k \supseteq A.
\]

23. Let \(X\) be a compact metric space. Show \((C,\rho)\) is compact. **Hint:** Let \(D_n\) be a \(2^{-n}\) net for \(X\). Let \(K_n\) denote finite unions of sets of the form \(\bar{B}(p,2^{-n})\) where \(p \in D_n\). Show \(K_n\) is a \(2^{-(n-1)}\) net for \((C,\rho)\).
Chapter 7

Weierstrass Approximation Theorem

7.1 The Bernstein Polynomials

This short chapter is on the important Weierstrass approximation theorem. It is about approximating an arbitrary continuous function uniformly by a polynomial. It will be assumed only that $f$ has values in $\mathbb{C}$ and that all scalars are in $\mathbb{C}$. First here is some notation.

Definition 7.1.1 $\alpha = (\alpha_1, \cdots, \alpha_n)$ for $\alpha_1 \cdots \alpha_n$ positive integers is called a multi-index. For $\alpha$ a multi-index, $|\alpha| = \alpha_1 + \cdots + \alpha_n$ and if $x \in \mathbb{R}^n$,

$$x = (x_1, \cdots, x_n),$$

and $f$ a function, define

$$x^\alpha \equiv x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n}.$$

A polynomial in $n$ variables of degree $m$ is a function of the form

$$p(x) = \sum_{|\alpha| \leq m} a_\alpha x^\alpha.$$

Here $\alpha$ is a multi-index as just described.

The following estimate will be the basis for the Weierstrass approximation theorem. It is actually a statement about the variance of a binomial random variable.

Lemma 7.1.2 The following estimate holds for $x \in [0, 1]$.

$$\sum_{k=0}^{m} \binom{m}{k} (k - mx)^2 x^k (1 - x)^{m-k} \leq \frac{1}{4} m$$

181
CHAPTER 7. WEIERSTRASS APPROXIMATION THEOREM

Proof: By the Binomial theorem,
\[
\sum_{k=0}^{m} \binom{m}{k} (e^t x)^k (1-x)^{m-k} = (1-x+e^t x)^m. \tag{7.1.1}
\]
Differentiating both sides with respect to \( t \) and then evaluating at \( t = 0 \) yields
\[
\sum_{k=0}^{m} \binom{m}{k} k x^k (1-x)^{m-k} = mx.
\]
Now doing two derivatives of (7.1.1) with respect to \( t \) yields
\[
\sum_{k=0}^{m} \binom{m}{k} k^2 (e^t x)^k (1-x)^{m-k} = m (m-1) (1-x+e^t x)^{m-2} e^{2tx} x^2 \\
+ m (1-x+e^t x)^{m-1} xe^t.
\]
Evaluating this at \( t = 0 \),
\[
\sum_{k=0}^{m} \binom{m}{k} k^2 (x)^k (1-x)^{m-k} = m (m-1) x^2 + mx.
\]
Therefore,
\[
\sum_{k=0}^{m} \binom{m}{k} (kmx)^2 x^k (1-x)^{m-k} = m (m-1) x^2 + mx - 2m^2 x^2 + m^2 x^2 \\
= m (x-x^2) \leq \frac{1}{4} m.
\]
This proves the lemma.

Now for \( x = (x_1, \cdots, x_n) \in [0, 1]^n \) consider the polynomial,
\[
p_m (x) \equiv \sum_{k_1=0}^{m} \cdots \sum_{k_n=0}^{m} \binom{m}{k_1} \binom{m}{k_2} \cdots \binom{m}{k_n} x_1^{k_1} (1-x_1)^{m-k_1} x_2^{k_2} (1-x_2)^{m-k_2} \\
\cdots x_n^{k_n} (1-x_n)^{m-k_n} f \left( \frac{k_1}{m}, \cdots, \frac{k_n}{m} \right). \tag{7.1.2}
\]
Also define if \( I \) is a set in \( \mathbb{R}^n \)
\[
||h||_I \equiv \sup \{|h(x)| : x \in I\}.
\]
Thus \( p_m \) converges uniformly to \( f \) on a set, \( I \) if
\[
\lim_{m \to \infty} ||p_m - f||_I = 0.
\]
Also to simplify the notation, let \( k = (k_1, \cdots, k_n) \) where each \( k_i \in [0, m], \ \frac{k}{m} = (\frac{k_1}{m}, \cdots, \frac{k_n}{m}) \), and let
\[
\binom{m}{k} \equiv \binom{m}{k_1} \binom{m}{k_2} \cdots \binom{m}{k_n}.
\]
7.1. THE BERNSTEIN POLYNOMIALS

Also define

\[ ||k||_\infty \equiv \max \{k_i, i = 1, 2, \ldots, n\} \]

\[ x^k (1-x)^{m-k} \equiv x_1^{k_1} (1-x_1)^{m-k_1} x_2^{k_2} (1-x_2)^{m-k_2} \ldots x_n^{k_n} (1-x_n)^{m-k_n} . \]

Thus in terms of this notation,

\[ p_m(x) = \sum_{||k||_\infty \leq m} {m \choose k} x^k (1-x)^{m-k} f \left( \frac{k}{m} \right) \]

**Lemma 7.1.3** For \( x \in [0, 1]^n \), \( f \) a continuous function defined on \([0, 1]^n\), and \( p_m \) given in (7.1.2), \( p_m \) converges uniformly to \( f \) on \([0, 1]^n\) as \( m \to \infty \).

**Proof:** The function, \( f \) is uniformly continuous because it is continuous on a compact set. Therefore, there exists \( \delta > 0 \) such that if \( |x - y| < \delta \), then

\[ |f(x) - f(y)| < \varepsilon. \]

Denote by \( G \) the set of \( k \) such that \( (k_i - mx_i)^2 < \eta^2 m^2 \) for each \( i \) where \( \eta = \delta / \sqrt{n} \). Note this condition is equivalent to saying that for each \( i, |\frac{k_i}{m} - x_i| < \eta \). By the binomial theorem,

\[ \sum_{||k||_\infty \leq m} {m \choose k} x^k (1-x)^{m-k} = 1 \]

and so for \( x \in [0, 1]^n \),

\[ |p_m(x) - f(x)| \leq \sum_{||k||_\infty \leq m} {m \choose k} x^k (1-x)^{m-k} \left| f \left( \frac{k}{m} \right) - f(x) \right| \]

\[ \leq \sum_{k \in G} {m \choose k} x^k (1-x)^{m-k} \left| f \left( \frac{k}{m} \right) - f(x) \right| \]

\[ + \sum_{k \in G^c} {m \choose k} x^k (1-x)^{m-k} \left| f \left( \frac{k}{m} \right) - f(x) \right| \]

(7.1.3)

Now for \( k \in G \) it follows that for each \( i \)

\[ \left| \frac{k_i}{m} - x_i \right| < \frac{\delta}{\sqrt{n}} \]

(7.1.4)

and so

\[ |f \left( \frac{k}{m} \right) - f(x)| < \varepsilon \] because the above implies \( |\frac{k_i}{m} - x_i| < \delta \). Therefore, the first sum on the right in (7.1.3) is no larger than

\[ \sum_{k \in G} {m \choose k} x^k (1-x)^{m-k} \varepsilon \leq \sum_{||k||_\infty \leq m} {m \choose k} x^k (1-x)^{m-k} \varepsilon = \varepsilon. \]
Letting $M \geq \max \{|f(x)| : x \in [0,1]^n\}$ it follows

\[
|p_m(x) - f(x)| \leq \varepsilon + 2M \sum_{k \in \mathbb{G}} m^k x^k (1-x)^m-k
\]

\[
\leq \varepsilon + 2M \left(\frac{1}{n^2m^2}\right)^n \sum_{k \in \mathbb{G}} \left(\frac{m}{k}\right)^n \prod_{j=1}^n (k_j - mx_j)^2 x^k (1-x)^m-k
\]

\[
\leq \varepsilon + 2M \left(\frac{1}{n^2m^2}\right)^n \sum_{||k||_\infty \leq m} \left(\frac{m}{k}\right)^n \prod_{j=1}^n (k_j - mx_j)^2 x^k (1-x)^m-k
\]

because on $G^C$,

\[
\frac{(k_j - mx_j)^2}{n^2m^2} < 1, \quad j = 1, \ldots, n.
\]

Now by Lemma 7.1.3,\]

\[
|p_m(x) - f(x)| \leq \varepsilon + 2M \left(\frac{1}{n^2m^2}\right)^n \left(\frac{m}{k}\right)^n.
\]

Therefore, since the right side does not depend on $x$, it follows

\[
\lim_{m \to \infty} \sup_{x \in [0,1]^n} ||p_m - f||_{[0,1]^n} \leq \varepsilon
\]

and since $\varepsilon$ is arbitrary, this shows $\lim_{m \to \infty} ||p_m - f||_{[0,1]^n} = 0$. This proves the lemma.

The following is not surprising.

**Lemma 7.1.4** Let $f$ be a continuous function defined on $[-M, M]^n$. Then there exists a sequence of polynomials, \{\(p_m\)}\_ converging uniformly to $f$ on $[-M, M]^n$.

**Proof:** Let $h(t) = -M + 2Mt$ so $h : [0,1] \to [-M, M]$ and let $h(t) \equiv (h(t_1), \ldots, h(t_n))$. Therefore, $f \circ h$ is a continuous function defined on $[0,1]^n$. From Lemma 7.1.3 there exists a polynomial, $p(t)$ such that $||p_m - f \circ h||_{[0,1]^n} < \frac{1}{m}$. Now for $x \in [-M, M]^n$, $h^{-1}(x) = (h^{-1}(x_1), \ldots, h^{-1}(x_n))$ and so

\[
||p_m \circ h^{-1} - f||_{[-M, M]^n} = ||p_m - f \circ h||_{[0,1]^n} < \frac{1}{m}.
\]

But $h^{-1}(x) = \frac{x}{2M} + \frac{x}{2}$ and so $p_m$ is still a polynomial. This proves the lemma.

The classical version of the Weierstrass approximation theorem involved showing that a continuous function of one variable defined on a closed and bounded interval is the uniform limit of a sequence of polynomials. This is certainly included as a special case of the above. Now recall the Tietze extension theorem found on Page 160. In the general version about to be presented, the set on which $f$ is defined is just a compact subset of $\mathbb{R}^n$, not the Cartesian product of intervals. For convenience here is the Tietze extension theorem.
Theorem 7.1.5 Let $M$ be a closed nonempty subset of a metric space $(X, d)$ and let $f : M \rightarrow [a, b]$ is continuous at every point of $M$. Then there exists a function, $g$ continuous on all of $X$ which coincides with $f$ on $M$ such that $g(X) \subseteq [a, b]$.

The Weierstrass approximation theorem follows.

Theorem 7.1.6 Let $K$ be a compact set in $\mathbb{R}^n$ and let $f$ be a continuous function defined on $K$. Then there exists a sequence of polynomials $\{p_m\}$ converging uniformly to $f$ on $K$.

Proof: Choose $M$ large enough that $K \subseteq [-M, M]^n$ and let $\tilde{f}$ denote a continuous function defined on all of $[-M, M]^n$ such that $\tilde{f} = f$ on $K$. Such an extension exists by the Tietze extension theorem, Theorem 7.1.5 applied to the real and imaginary parts of $f$. By Lemma there exists a sequence of polynomials, $\{p_m\}$ defined on $[-M, M]^n$ such that $\|\tilde{f} - p_m\|_{[-M,M]^n} \to 0$. Therefore, $\|\tilde{f} - p_m\|_K \to 0$ also. This proves the theorem.

7.2 Stone Weierstrass Theorem

7.2.1 The Case Of Compact Sets

There is a profound generalization of the Weierstrass approximation theorem due to Stone.

Definition 7.2.1 $A$ is an algebra of functions if $A$ is a vector space and if whenever $f, g \in A$ then $fg \in A$.

To begin with assume that the field of scalars is $\mathbb{R}$. This will be generalized later. Theorem 7.1.6 implies the following very special case.

Corollary 7.2.2 The polynomials are dense in $C([a, b])$.

The next result is the key to the profound generalization of the Weierstrass theorem due to Stone in which an interval will be replaced by a compact or locally compact set and polynomials will be replaced with elements of an algebra satisfying certain axioms.

Corollary 7.2.3 On the interval $[-M, M]$, there exist polynomials $p_n$ such that

$$p_n(0) = 0$$

and

$$\lim_{n \to \infty} \|p_n - |\|_\infty = 0.$$ 

Proof: By Corollary 7.2.2 there exists a sequence of polynomials, $\{\tilde{p}_n\}$ such that $\tilde{p}_n \to |\|$ uniformly. Then let $p_n(t) \equiv \tilde{p}_n(t) - \tilde{p}_n(0)$. This proves the corollary.
CHAPTER 7. WEIERSTRASS APPROXIMATION THEOREM

Definition 7.2.4 An algebra of functions, $\mathcal{A}$ defined on $A$, annihilates no point of $A$ if for all $x \in A$, there exists $g \in \mathcal{A}$ such that $g(x) \neq 0$. The algebra separates points if whenever $x_1 \neq x_2$, then there exists $g \in \mathcal{A}$ such that $g(x_1) \neq g(x_2)$.

The following generalization is known as the Stone Weierstrass approximation theorem.

Theorem 7.2.5 Let $A$ be a compact topological space and let $\mathcal{A} \subseteq C(A; \mathbb{R})$ be an algebra of functions which separates points and annihilates no point. Then $\mathcal{A}$ is dense in $C(A; \mathbb{R})$.

Proof: First here is a lemma.

Lemma 7.2.6 Let $c_1$ and $c_2$ be two real numbers and let $x_1 \neq x_2$ be two points of $A$. Then there exists a function $f_{x_1 x_2}$ such that $f_{x_1 x_2}(x_1) = c_1$, $f_{x_1 x_2}(x_2) = c_2$.

Proof of the lemma: Let $g \in \mathcal{A}$ satisfy $g(x_1) \neq g(x_2)$. Such a $g$ exists because the algebra separates points. Since the algebra annihilates no point, there exist functions $h$ and $k$ such that $h(x_1) \neq 0$, $k(x_2) \neq 0$.

Then let $u \equiv gh - g(x_2)h$, $v \equiv gk - g(x_1)k$.

It follows that $u(x_1) \neq 0$ and $u(x_2) = 0$ while $v(x_2) \neq 0$ and $v(x_1) = 0$. Let

$$f_{x_1 x_2} = \frac{c_1 u}{u(x_1)} + \frac{c_2 v}{v(x_2)}.$$  

This proves the lemma. Now continue the proof of Theorem 7.2.5.

First note that $\overline{\mathcal{A}}$ satisfies the same axioms as $\mathcal{A}$ but in addition to these axioms, $\overline{\mathcal{A}}$ is closed. The closure of $\mathcal{A}$ is taken with respect to the usual norm on $C(A)$,

$$\|f\|_{\infty} \equiv \max \{|f(x)| : x \in A\}.$$  

Suppose $f \in \overline{\mathcal{A}}$ and suppose $M$ is large enough that

$$\|f\|_{\infty} < M.$$  

Using Corollary 7.2.3, let $p_n$ be a sequence of polynomials such that

$$\|p_n - f\|_{\infty} \to 0, \ p_n(0) = 0.$$
It follows that \( p_n \circ f \in \overline{A} \) and so \(|f| \in \overline{A}\) whenever \( f \in \overline{A} \). Also note that
\[
\max (f, g) = \frac{|f - g| + (f + g)}{2} \\
\min (f, g) = \frac{(f + g) - |f - g|}{2}.
\]
Therefore, this shows that if \( f, g \in \overline{A} \) then
\[
\max (f, g), \min (f, g) \in \overline{A}.
\]
By induction, if \( f_i, i = 1, 2, \ldots, m \) are in \( \overline{A} \) then
\[
\max (f_i, i = 1, 2, \ldots, m), \min (f_i, i = 1, 2, \ldots, m) \in \overline{A}.
\]
Now let \( h \in C (A; \mathbb{R}) \) and let \( x \in A \). Use Lemma 7.2.6 to obtain \( f_{xy} \), a function of \( \overline{A} \) which agrees with \( h \) at \( x \) and \( y \). Letting \( \varepsilon > 0 \), there exists an open set \( U (y) \) containing \( y \) such that
\[ f_{xy}(z) > h(z) - \varepsilon \quad \text{if} \quad z \in U(y). \]
Since \( A \) is compact, let \( U (y_1), \ldots, U (y_l) \) cover \( A \). Let
\[ f_x \equiv \max (f_{xy_1}, f_{xy_2}, \ldots, f_{xy_l}). \]
Then \( f_x \in \overline{A} \) and
\[ f_x (z) > h(z) - \varepsilon \]
for all \( z \in A \) and \( f_x (x) = h(x) \). This implies that for each \( x \in A \) there exists an open set \( V (x) \) containing \( x \) such that for \( z \in V (x) \),
\[ f_x (z) < h(z) + \varepsilon. \]
Let \( V (x_1), \ldots, V (x_m) \) cover \( A \) and let
\[ f \equiv \min (f_{x_1}, \ldots, f_{x_m}). \]
Therefore,
\[ f (z) < h(z) + \varepsilon \]
for all \( z \in A \) and since \( f_x (z) > h(z) - \varepsilon \) for all \( z \in A \), it follows
\[ f (z) > h(z) - \varepsilon \]
also and so
\[ |f (z) - h(z)| < \varepsilon \]
for all \( z \). Since \( \varepsilon \) is arbitrary, this shows \( h \in \overline{A} \) and proves \( \overline{A} = C (A; \mathbb{R}) \). This proves the theorem.
CHAPTER 7. WEIERSTRASS APPROXIMATION THEOREM

7.2.2 The Case Of Locally Compact Sets

**Definition 7.2.7** Let \((X, \tau)\) be a locally compact Hausdorff space. \(C_0(X)\) denotes the space of real or complex valued continuous functions defined on \(X\) with the property that if \(f \in C_0(X)\), then for each \(\varepsilon > 0\) there exists a compact set \(K\) such that \(|f(x)| < \varepsilon\) for all \(x \notin K\). Define

\[ \|f\|_{\infty} = \sup \{|f(x)| : x \in X\}. \]

**Lemma 7.2.8** For \((X, \tau)\) a locally compact Hausdorff space with the above norm, \(C_0(X)\) is a complete space.

**Proof:** Let \((\tilde{X}, \tilde{\tau})\) be the one point compactification described in Lemma 6.8.20. Define

\[ D = \left\{ f \in C(\tilde{X}) : f(\infty) = 0 \right\}. \]

Then \(D\) is a closed subspace of \(C(\tilde{X})\). For \(f \in C_0(X)\),

\[ \tilde{f}(x) = \begin{cases} f(x) & \text{if } x \in X \\ 0 & \text{if } x = \infty \end{cases} \]

and let \(\theta : C_0(X) \to D\) be given by \(\theta f = \tilde{f}\). Then \(\theta\) is one to one and onto and also satisfies \(\|f\|_{\infty} = \|\theta f\|_{\infty}\). Now \(D\) is complete because it is a closed subspace of a complete space and so \(C_0(X)\) with \(\|\cdot\|_{\infty}\) is also complete. This proves the lemma.

The above refers to functions which have values in \(\mathbb{C}\) but the same proof works for functions which have values in any complete normed linear space.

In the case where the functions in \(C_0(X)\) all have real values, I will denote the resulting space by \(C_0(X; \mathbb{R})\) with similar meanings in other cases.

With this lemma, the generalization of the Stone Weierstrass theorem to locally compact sets is as follows.

**Theorem 7.2.9** Let \(A\) be an algebra of functions in \(C_0(X; \mathbb{R})\) where \((X, \tau)\) is a locally compact Hausdorff space which separates the points and annihilates no point. Then \(A\) is dense in \(C_0(X; \mathbb{R})\).

**Proof:** Let \((\tilde{X}, \tilde{\tau})\) be the one point compactification as described in Lemma 6.8.20. Let \(\tilde{A}\) denote all finite linear combinations of the form

\[ \left\{ \sum_{i=1}^{n} c_i \tilde{f}_i + c_0 : f \in A, \ c_i \in \mathbb{R} \right\}, \]

where for \(f \in C_0(X; \mathbb{R})\),

\[ \tilde{f}(x) = \begin{cases} f(x) & \text{if } x \in X \\ 0 & \text{if } x = \infty \end{cases} \]
Then \( \tilde{A} \) is obviously an algebra of functions in \( C \left( \tilde{X}; \mathbb{R} \right) \). It separates points because this is true of \( A \). Similarly, it annihilates no point because of the inclusion of \( c_0 \) an arbitrary element of \( \mathbb{R} \) in the definition above. Therefore from Theorem 7.2.5, \( A \) is dense in \( C \left( \tilde{X}; \mathbb{R} \right) \). Letting \( f \in C_0 (X; \mathbb{R}) \), it follows \( \tilde{f} \in C \left( \tilde{X}; \mathbb{R} \right) \) and so there exists a sequence \( \{ h_n \} \subseteq \tilde{A} \) such that \( h_n \) converges uniformly to \( f \). Now \( h_n \) is of the form \( \sum_{i=1}^{n} c_i^n \tilde{f}_i^n + c_0^n \) and since \( \tilde{f} (\infty) = 0 \), you can take each \( c_0^n = 0 \) and so this has shown the existence of a sequence of functions in \( A \) such that it converges uniformly to \( f \). This proves the theorem.

7.2.3 The Case Of Complex Valued Functions

What about the general case where \( C_0 (X) \) consists of complex valued functions and the field of scalars is \( \mathbb{C} \) rather than \( \mathbb{R} \)? The following is the version of the Stone Weierstrass theorem which applies to this case. You have to assume that for \( f \in A \) it follows \( \tilde{f} \in A \). Such an algebra is called self adjoint.

**Theorem 7.2.10** Suppose \( A \) is an algebra of functions in \( C_0 (X) \), where \( X \) is a locally compact Hausdorff space, which separates the points, annihilates no point, and has the property that if \( f \in A \), then \( \tilde{f} \in A \). Then \( A \) is dense in \( C_0 (X) \).

**Proof:** Let \( \text{Re} \ A \equiv \{ \text{Re} f : f \in A \} \), \( \text{Im} \ A \equiv \{ \text{Im} f : f \in A \} \). First I will show that \( A = \text{Re} \ A + i \text{Im} \ A = \text{Im} \ A + i \text{Re} \ A \). Let \( f \in A \). Then

\[
f = \frac{1}{2} (f + \overline{f}) + \frac{1}{2} (f - \overline{f}) = \text{Re} f + i \text{Im} f \in \text{Re} \ A + i \text{Im} \ A
\]

and so \( A \subseteq \text{Re} \ A + i \text{Im} \ A \). Also

\[
f = \frac{1}{2i} (if + i \overline{f}) - \frac{i}{2} (if + \overline{if}) = \text{Im} (if) + i \text{Re} (if) \in \text{Im} \ A + i \text{Re} \ A
\]

This proves one half of the desired equality. Now suppose \( h \in \text{Re} \ A + i \text{Im} \ A \). Then

\( h = \text{Re} g_1 + i \text{Im} g_2 \) where \( g_i \in A \). Then since \( \text{Re} g_1 = \frac{1}{2} (g_1 + \overline{g_1}) \), it follows \( \text{Re} g_1 \in A \). Similarly \( \text{Im} g_2 \in A \). Therefore, \( h \in A \). The case where \( h \in \text{Im} \ A + i \text{Re} \ A \) is similar. This establishes the desired equality.

Now \( \text{Re} \ A \) and \( \text{Im} \ A \) are both real algebras. I will show this now. First consider \( \text{Im} \ A \). It is obvious this is a real vector space. It only remains to verify that the product of two functions in \( \text{Im} \ A \) is in \( \text{Im} \ A \). Note that from the first part, \( \text{Re} \ A, \text{Im} \ A \) are both subsets of \( A \) because, for example, if \( u \in \text{Im} \ A \) then \( u + 0 \in \text{Im} \ A + i \text{Re} \ A = A \). Therefore, if \( v, w \in \text{Im} \ A \), both \( iv \) and \( w \) are in \( A \) and so \( \text{Im} (ivw) = vw \) and \( ivw \in A \). Similarly, \( \text{Re} \ A \) is an algebra.

Both \( \text{Re} \ A \) and \( \text{Im} \ A \) must separate the points. Here is why: If \( x_1 \neq x_2 \), then there exists \( f \in A \) such that \( f(x_1) \neq f(x_2) \). If \( \text{Im} f (x_1) \neq \text{Im} f (x_2) \), this shows there is a function in \( \text{Im} \ A \), \( \text{Im} f \) which separates these two points. If \( \text{Im} f \) fails to separate the two points, then \( \text{Re} f \) must separate the points and so you could consider \( \text{Im} (if) \) to get a function in \( \text{Im} \ A \) which separates these points. This shows \( \text{Im} \ A \) separates the points. Similarly \( \text{Re} \ A \) separates the points.
Neither $\text{Re} \mathcal{A}$ nor $\text{Im} \mathcal{A}$ annihilate any point. This is easy to see because if $x$ is a point there exists $f \in \mathcal{A}$ such that $f(x) \neq 0$. Thus either $\text{Re} f(x) \neq 0$ or $\text{Im} f(x) \neq 0$. If $\text{Im} f(x) \neq 0$, this shows this point is not annihilated by $\text{Im} \mathcal{A}$. If $\text{Im} f(x) = 0$, consider $\text{Im} (if)(x) = \text{Re} f(x) \neq 0$. Similarly, $\text{Re} \mathcal{A}$ does not annihilate any point.

It follows from Theorem 7.2.9 that $\text{Re} \mathcal{A}$ and $\text{Im} \mathcal{A}$ are dense in the real valued functions of $C_0(X)$. Let $f \in C_0(X)$. Then there exists $f \in \mathcal{A}$ and $g \in \mathcal{A}$ such that $h_n \to \text{Re} f$ uniformly and $g_n \to \text{Im} f$ uniformly. Therefore, $h_n + ig_n \in \mathcal{A}$ and it converges to $f$ uniformly. This proves the theorem.

### 7.3 The Holder Spaces

We consider these spaces as spaces of functions defined on an interval $[0, 1]$ although one could have $[0, T]$ just as easily. A slightly more general version is in the exercises. They are a very interesting example of spaces which are not separable.

**Definition 7.3.1** Let $p > 1$. Then $f \in C^{1/p}([0, 1])$ means that $f \in C([0, 1])$ and also

$$\rho_p (f) = \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{1/p}} : x, y \in X, x \neq y \right\} < \infty$$

Then the norm is defined as $\|f\|_{C([0,1])} + \rho_p (f) = \|f\|_{1/p}$.

We leave it as an exercise to verify that $C^{1/p}([0, 1])$ is a complete normed linear space.

Let $p > 1$. Then $C^{1/p}([0, 1])$ is not separable. Define uncountably many functions, one for each $\varepsilon$ where $\varepsilon$ is a sequence of $-1$ and 1. Thus $\varepsilon_k \in \{-1, 1\}$. Thus $\varepsilon \neq \varepsilon'$ if the two sequences differ in at least one slot, one giving 1 and the other equaling $-1$. Now define

$$f_{\varepsilon} (t) = \sum_{k=1}^{\infty} \varepsilon_k 2^{-k/p} \sin \left(2^k \pi t\right)$$

Then this is $1/p$ Holder. Let $s < t$.

$$\left| f_{\varepsilon} (t) - f_{\varepsilon} (s) \right| \leq \sum_{k \leq \log_2 (t-s)} \left| 2^{-k/p} \sin \left(2^k \pi t\right) - 2^{-k/p} \sin \left(2^k \pi s\right) \right|$$

$$+ \sum_{k > \log_2 (t-s)} \left| 2^{-k/p} \sin \left(2^k \pi t\right) - 2^{-k/p} \sin \left(2^k \pi s\right) \right|$$

If $t = 1$ and $s = 0$, there is really nothing to show because then the difference equals 0. There is also nothing to show if $t = s$. From now on, $0 < t - s < 1$. Let $k_0$ be
7.3. THE HOLDER SPACES

the largest integer which is less than or equal to \(|\log_2 (t-s)| = -\log_2 (t-s)|.

Note that \(-\log (t-s) > 0\) because \(0 < t-s < 1\). Then

\[
|f_\epsilon (t) - f_\epsilon (s)| \leq \sum_{k \leq k_0} 2^{-k/p} \sin (2^k \pi t) - 2^{-k/p} \sin (2^k \pi s) + \sum_{k > k_0} 2^{-k/p} \sin (2^k \pi t) - 2^{-k/p} \sin (2^k \pi s)
\]

\[
\leq \sum_{k \leq k_0} 2^{-k/p} 2^k \pi |t-s| + \sum_{k > k_0} 2^{-k/p} 2^k \pi
\]

Now \(k_0 \leq -\log_2 (t-s) < k_0 + 1\) and so \(-k_0 \geq \log_2 (t-s) \geq -(k_0 + 1)\). Hence

\[
2^{-k_0} \geq |t-s| \geq 2^{-k_0} 2^{-1/p}
\]

and so

\[
2^{-k_0/p} \geq |t-s|^{1/p} \geq 2^{-k_0/p} 2^{-1/p}
\]

Using this in the sums,

\[
|f_\epsilon (t) - f_\epsilon (s)| \leq |t-s| C_p + \sum_{k > k_0} 2^{-k/p} 2^k \pi (2^{1/p} |t-s|^{1/p}) 2
\]

\[
\leq |t-s| C_p + \sum_{k > k_0} 2^{-(k-k_0)/p} \left(2^{1/p} |t-s|^{1/p}\right) 2
\]

\[
\leq C_p |t-s| + \left(2^{1+1/p}\right) \sum_{k=1}^{\infty} 2^{-k/p} |t-s|^{1/p}
\]

\[
= C_p |t-s| + D_p |t-s|^{1/p} \leq C_p |t-s|^{1/p} + D_p |t-s|^{1/p}
\]

Thus \(f_\epsilon\) is indeed 1/p Holder continuous.

Now consider \(\epsilon \neq \epsilon'.\) Suppose the first discrepancy in the two sequences occurs with \(\epsilon_j\). Thus one is 1 and the other is \(-1\). Let \(t = \frac{i+1}{2j+1}, s = \frac{i}{2j+1}\)

\[
|f_\epsilon (t) - f_\epsilon (s) - (f_{\epsilon'} (t) - f_{\epsilon'} (s))| =
\]

\[
\left| \sum_{k=1}^{\infty} \epsilon_k 2^{-k/p} \sin (2^k \pi t) - \sum_{k=1}^{\infty} \epsilon_k 2^{-k/p} \sin (2^k \pi s) - \sum_{k=1}^{\infty} \epsilon' k 2^{-k/p} \sin (2^k \pi t) + \sum_{k=1}^{\infty} \epsilon' k 2^{-k/p} \sin (2^k \pi s) \right|
\]

Now consider what happens for \(k > j\)

\[
\sin \left(2^k \pi \frac{i}{2j+1}\right) = \sin \left(m \pi\right) = 0
\]
for some integer $m$. Thus the whole mess reduces to
\[
\left(\varepsilon_j - \varepsilon_j' \right) 2^{-j/p} \sin \left( \frac{2^j \pi (i+1)}{2^{j+1}} \right) - \left(\varepsilon_j - \varepsilon_j' \right) 2^{-j/p} \sin \left( \frac{2^j \pi i}{2^{j+1}} \right) \\
= \left(\varepsilon_j - \varepsilon_j' \right) 2^{-j/p} \left[ \pi \frac{(i+1)}{2} \right] - \left(\varepsilon_j - \varepsilon_j' \right) 2^{-j/p} \left( \frac{\pi i}{2} \right) \\
= 2 \left(2^{-j/p} \right)
\]
In particular, $|t - s| = \frac{1}{2^{j+1}}$ so $2^{1/p} |t - s|^{1/p} = 2^{-j/p}$
\[
|f_t(t) - f_t(s) - (f_t'(t) - f_t'(s))| = 2 \left(2^{1/p} \right) |t - s|^{1/p}
\]
which shows that
\[
\sup_{0 \leq s < t \leq 1} \frac{|f_t(t) - f_t'(t) - (f_t(s) - f_t'(s))|}{|t - s|^{1/p}} \geq 2^{1/p} (2)
\]
Thus there exists a set of uncountably many functions in $C^{1/p}([0,T])$ and for any two of them $f,g$, you get
\[
\|f - g\|_{C^{1/p}([0,1])} > 2
\]
so $C^{1/p}([0,1])$ is not separable.

### 7.4 Exercises

1. Let $(X, \tau), (Y, \eta)$ be topological spaces and let $A \subseteq X$ be compact. Then if $f : X \rightarrow Y$ is continuous, show that $f(A)$ is also compact.

2. In the context of Problem 3, suppose $\mathbb{R} = Y$ where the usual topology is placed on $\mathbb{R}$. Show $f$ achieves its maximum and minimum on $A$.

3. Let $V$ be an open set in $\mathbb{R}^n$. Show there is an increasing sequence of compact sets, $K_m$, such that $V = \bigcup_{m=1}^{\infty} K_m$. **Hint:** Let
\[
C_m = \left\{ \mathbf{x} \in \mathbb{R}^n : \text{dist} (\mathbf{x}, V^C) \geq \frac{1}{m} \right\}
\]
where
\[
\text{dist} (\mathbf{x}, S) = \inf \{ |\mathbf{y} - \mathbf{x}| : \mathbf{y} \in S \}.
\]
Consider $K_m = C_m \cap B(0,m)$.

4. Let $B(X; \mathbb{R}^n)$ be the space of functions $f$, mapping $X$ to $\mathbb{R}^n$ such that
\[
\sup \{|f(x)| : x \in X\} < \infty.
\]
Show $B(X; \mathbb{R}^n)$ is a complete normed linear space if
\[
\|f\| = \sup \{|f(x)| : x \in X\}.
\]
5. Let \( \alpha \in [0, 1] \). Define, for \( X \) a compact subset of \( \mathbb{R}^p \),

\[
C^\alpha (X; \mathbb{R}^n) \equiv \{ f \in C(X; \mathbb{R}^n) : \rho_\alpha (f) + ||f|| < \infty \}
\]

where

\[
||f|| = \sup\{|f(x)| : x \in X \}
\]

and

\[
\rho_\alpha (f) = \sup\{ \frac{|f(x) - f(y)|}{|x - y|^{\alpha}} : x, y \in X, x \neq y \}.
\]

Show that \((C^\alpha (X; \mathbb{R}^n), ||\cdot||_\alpha)\) is a complete normed linear space.

6. Let \( \{f_n\}_{n=1}^{\infty} \subseteq C^\alpha (X; \mathbb{R}^n) \) where \( X \) is a compact subset of \( \mathbb{R}^p \) and suppose

\[
||f_n||_\alpha \leq M
\]

for all \( n \). Show there exists a subsequence, \( n_k \), such that \( f_{n_k} \) converges in \( C(X; \mathbb{R}^n) \). The given sequence is called precompact when this happens. (This also shows the embedding of \( C^\alpha (X; \mathbb{R}^n) \) into \( C(X; \mathbb{R}^n) \) is a compact embedding.) Note that it is likely the case that \( C^\alpha (X; \mathbb{R}^n) \) is not separable although it embeds continuously into a nice separable space. In fact, \( C^\alpha ([0, T]; \mathbb{R}^n) \) can be shown to not be separable. See Definition [3431] and the discussion which follows it.

7. Use the general Stone Weierstrass approximation theorem to prove Theorem 7.1.6.
Chapter 8

Brouwer Fixed Point
Theorem $\mathbb{R}^n$

In this short optional chapter, is an elementary proof of the Brouwer fixed point theorem and a discussion of some of the manipulations which are important regarding simplices. The Brouwer fixed point theorem will be presented later using analytical techniques. This here is an approach based on combinatorics or graph theory. It features the famous Sperner’s lemma.

8.1 Simplices And Triangulations

Definition 8.1.1 Define an $n$ simplex, denoted by $[x_0, \cdots, x_n]$, to be the convex hull of the $n + 1$ points, $\{x_0, \cdots, x_n\}$ where $\{x_i - x_0\}_{i=1}^n$ are independent. Thus

$$[x_0, \cdots, x_n] = \left\{ \sum_{i=0}^n t_i x_i : \sum_{i=0}^n t_i = 1, \ t_i \geq 0 \right\}.$$  

Note that $\{x_j - x_m\}_{j \neq m}$ are also independent.

Since $\{x_i - x_0\}_{i=1}^n$ is independent, the $t_i$ are uniquely determined. If two of them are

$$\sum_{i=0}^n t_i x_i = \sum_{i=0}^n s_i x_i$$

Then

$$\sum_{i=0}^n t_i (x_i - x_0) = \sum_{i=0}^n s_i (x_i - x_0)$$

so $t_i = s_i$ for $i \geq 1$ by independence. Since the $s_i$ and $t_i$ sum to 1, it follows that also $s_0 = t_0$. If $n \leq 2$, the simplex is a triangle, line segment, or point. If $n \leq 3$, it is a tetrahedron, triangle, line segment or point. To say that $\{x_i - x_0\}_{i=1}^n$ are
independent is to say that \( \{ x_i - x_r \}_{i \neq r} \) are independent for each fixed \( r \). Indeed, if \( x_i - x_r = \sum_{j \neq i, r} c_j (x_j - x_r) \), then you would have

\[
x_i - x_0 + x_0 - x_r = \sum_{j \neq i, r} c_j (x_j - x_0) + \left( \sum_{j \neq i, r} c_j \right) x_0
\]

and it follows that \( x_i - x_0 \) is a linear combination of the \( x_j - x_0 \) for \( j \neq i \), contrary to assumption.

A simplex \( S \) can be triangulated. This means it is the union of smaller sub-simplices such that if \( S_1, S_2 \) are two simplices in the triangulation, with

\[
S_1 = [z_0, \ldots, z_m], \quad S_2 = [z_0^2, \ldots, z_p^2]
\]

then

\[
S_1 \cap S_2 = [x_{k_0}, \ldots, x_{k_r}]
\]

where \([x_{k_0}, \ldots, x_{k_r}]\) is in the triangulation and

\[
\{x_{k_0}, \ldots, x_{k_r}\} = \{z_0^2, \ldots, z_m\} \cap \{z_0^2, \ldots, z_p^2\}
\]

or else the two simplices do not intersect.

Does there exist a triangulation in which all sub-simplices have diameter less than \( \varepsilon \)? This is obvious if \( n \leq 2 \). Supposing it to be true for \( n - 1 \), is it also so for \( n \)? The barycenter \( b \) of a simplex \([x_0, \ldots, x_n]\) is just \( \frac{1}{n+1} \sum x_i \). This point is not in the convex hull of any of the faces, those simplices of the form \([x_0, \ldots, x_k, \ldots, x_n]\) where the hat indicates \( x_k \) has been left out. Thus \([x_0, \ldots, b, \ldots, x_n]\) is a \( n \) simplex also. Now in general, if you have an \( n \) simplex \([x_0, \ldots, x_n]\), its diameter is the maximum of \(|x_k - x_l|\) for all \( k \neq l \). Consider \([b - x_j]\). It equals

\[
\left| \sum_{i=0}^{n} \frac{1}{n+1} (x_i - x_j) \right| = \left| \sum_{i \neq j} \frac{1}{n+1} (x_i - x_j) \right| \leq \frac{n}{n+1} \text{diam}(S).
\]

Next consider the \( k^{th} \) face of \( S \) \([x_0, \ldots, \hat{x}_k, \ldots, x_n]\). By induction, it has a triangulation into simplices which each have diameter no more than \( \frac{n}{n+1} \text{diam}(S) \). Let these \( n - 1 \) simplices be denoted by \( \{S_i^k\}_{i=1}^{n-1} \). Then the simplices \( \{[S_i^k, b]_{i=1}^{m_n+1} \} \) are a triangulation of \( S \) such that \( \text{diam}([S_i^k, b]) \leq \frac{n}{n+1} \text{diam}(S) \). Do for \( [S_i^k, b] \) what was just done for \( S \) obtaining a triangulation of \( S \) as the union of what is obtained such that each simplex has diameter no more than \( \left( \frac{n}{n+1} \right)^2 \text{diam}(S) \). Continuing this way shows the existence of the desired triangulation.

### 8.2 Labeling Vertices

Next is a way to label the vertices. Let \( p_0, \ldots, p_n \) be the first \( n+1 \) prime numbers. All vertices of a simplex \( S = [x_0, \ldots, x_n] \) having \( \{x_k - x_0\}_{k=1}^{n} \) independent will be labeled with one of these primes. In particular, the vertex \( x_k \) will be labeled as \( p_k \) if the simplex is \([x_0, \ldots, x_n]\). The value of a simplex will be the product of its labels. Triangulate this \( S \). Consider a 1 simplex coming from the original
8.2. LABELING VERTICES

simplex $[x_{i_1}, \ldots, x_{i_k}]$, label one end as $p_{k_1}$ and the other as $p_{k_2}$. Then label all other vertices of this triangulation which occur on $[x_{i_1}, \ldots, x_{i_k}]$ either $p_{k_1}$ or $p_{k_2}$. Note that by independence of $\{x_k - x_r\}_{k \neq r}$, this cannot introduce an inconsistency because the segment cannot contain any other vertex of $S$. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_1}p_{k_2}$, that is a $p_k$ at one end and a $p_k$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $[x_{i_1}, \ldots, x_{i_{j+1}}]$.

$$\{x_{j_1}, \ldots, x_{j_{k+1}}\} \subseteq \{x_0, \ldots, x_n\}$$

any $k$ simplex for $k \leq n - 1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+1} p_{j_i}$ on this simplex. Consider $\tilde{S} \equiv [x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$. Then by induction, there is an odd number of $k$ simplices on the $s^{th}$ face $[x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$ having value $\prod_{i \neq s} p_{j_i}$. In particular the face $[x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$ has an odd number of simplices with value $\prod_{i \leq k+1} p_{j_i}$. Now no simplex in any other face of $\tilde{S}$ can have this value by uniqueness of prime factorization. Label the “interior” vertices, those $u$ having all $s_i > 0$ in $u = \sum_{i=1}^{k+2} s_i x_{j_i}$, (These have not yet been labeled,) with any of the $p_{j_1}, \ldots, p_{j_{k+2}}$. Pick a simplex on the face $[x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$ which has value $\prod_{i \leq k+1} p_{j_i}$ and cross this simplex into $\tilde{S}$. Continue crossing simplices having value $\prod_{i \leq k+1} p_{j_i}$ which have not been crossed till the process ends. It must end because there are an odd number of these simplices having value $\prod_{i \leq k+1} p_{j_i}$. If the process leads to the outside of $\tilde{S}$, then one can always enter it again because there are an odd number of simplices with value $\prod_{i \leq k+1} p_{j_i}$ available and you will have used up an even number. When the process ends, the value of the simplex must be $\prod_{i=1}^{k+2} p_{j_i}$ because it will have the additional label $p_{j_{k+2}}$ on a vertex since if not, there will be another way out of the simplex. This identifies a simplex in the triangulation with value $\prod_{i=1}^{k+2} p_{j_i}$. Then repeat the process with $\prod_{i \leq k+1} p_{j_i}$ valued simplices on $[x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$ which have not been crossed. Repeating the process, entering from the outside, cannot deliver a $\prod_{i \leq k+1} p_{j_i}$ valued simplex encountered earlier. This is because you cross faces labeled $\prod_{i \leq k+1} p_{j_i}$. If the remaining vertex is labeled $p_{j_i}$ where $i \neq k + 2$, then this yields exactly one other face to cross. There are two, the one with the first vertex $p_{j_i}$ and the next one with the new vertex labeled $p_{j_i}$ substituted for the first vertex having this label. Thus there is either one route in to a simplex or two. Thus, starting at a simplex labeled $\prod_{i \leq k+1} p_{j_i}$, one can cross faces having this value till one is led to the $\prod_{i \leq k+1} p_{j_i}$ valued simplex on the selected face of $\tilde{S}$. In other words, the process is one to one in selecting a $\prod_{i \leq k+1} p_{j_i}$ vertex from crossing such a vertex on the selected face of $\tilde{S}$. Continue doing this, crossing a $\prod_{i \leq k+1} p_{j_i}$ simplex on the face of $\tilde{S}$ which has not been crossed previously. This identifies an odd number of simplices having value $\prod_{i=1}^{k+2} p_{j_i}$. These are the ones which are “accessible” from the outside using this process. If there are any which are not accessible from outside, applying the same process starting inside one of these, leads to exactly one other inaccessible simplex with value $\prod_{i=1}^{k+2} p_{j_i}$. Hence these inaccessible simplices occur in pairs and so there are an odd number of simplices in the triangulation having
value $\prod_{i=1}^{k+2} p_j$. We refer to this procedure of labeling as Sperner’s lemma. The system of labeling is well defined thanks to the assumption that $\{x_k - x_0\}_{k=1}^n$ is independent which implies that $\{x_k - x_0\}_{k\neq i}$ is also linearly independent. Thus there can be no ambiguity in the labeling of vertices on any “face” the convex hull of some of the original vertices of $S$. The following is a description of the system of labeling the vertices.

**Lemma 8.2.1** Let $[x_0, \ldots, x_n]$ be an $n$ simplex with $\{x_k - x_0\}_{k=1}^n$ independent, and let the first $n + 1$ primes be $p_0, p_1, \ldots, p_n$. Label $x_k$ as $p_k$ and consider a triangulation of this simplex. Labeling the vertices of this triangulation which occur on $[x_k, \ldots, x_n]$ with any of $p_k, \ldots, p_n$, beginning with all 1 simplices $[x_{k_1}, x_{k_2}]$ and then 2 simplices and so forth, there are an odd number of simplices $[y_{k_1}, \ldots, y_{k_s}]$ of the triangulation contained in $[x_{k_1}, \ldots, x_n]$ which have value $p_{k_1}, \ldots, p_{k_s}$. This for $s = 1, 2, \ldots, n$.

A combinatorial method

We now give a brief discussion of the system of labeling for Sperner’s lemma from the point of view of counting numbers of faces rather than obtaining them with an algorithm. Let $p_0, \ldots, p_n$ be the first $n + 1$ prime numbers. All vertices of a simplex $S = [x_0, \ldots, x_n]$ having $\{x_k - x_0\}_{k=1}^n$ independent will be labeled with one of these primes. In particular, the vertex $x_k$ will be labeled as $p_k$. The value of a simplex will be the product of its labels. Triangulate this $S$. Consider a 1 simplex coming from the original simplex $[x_{k_1}, x_{k_2}]$, label one end as $p_{k_1}$ and the other as $p_{k_2}$. Then label all other vertices of this triangulation which occur on $[x_{k_1}, x_{k_2}]$ either $p_0$ or $p_{k_2}$. The assumption of linear independence assures that no other vertex of $S$ can be in $[x_{k_1}, x_{k_2}]$ so there will be no inconsistency in the labeling. Then obviously there will be an odd number of simplices in this triangulation having value $p_{k_1}p_{k_2}$, that is a $p_{k_1}$ at one end and a $p_{k_2}$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $[x_{j_1}, \ldots, x_{j_{k+1}}]$,

$$\{x_{j_1}, \ldots, x_{j_{k+1}}\} \subseteq \{x_0, \ldots, x_n\}$$

any $k$ simplex for $k \leq n - 1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+2} p_j$. Consider $\tilde{S} = [x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$. Then by induction, there is an odd number of $k$ simplices on the $s$th face

$$[x_{j_1}, \ldots, x_{j_s}, \ldots, x_{j_{k+1}}]$$

having value $\prod_{i\neq s} p_j$. In particular the face $[x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]$ has an odd number of simplices with value $\prod_{i=1}^{k+1} p_j := \hat{P}_k$. We want to argue that some simplex in the triangulation which is contained in $\tilde{S}$ has value $\hat{P}_{k+1} := \prod_{j=1}^{k+2} p_j$. Let $Q$ be the number of $k + 1$ simplices from the triangulation contained in $\tilde{S}$ which have two faces with value $\hat{P}_k$ (A $k + 1$ simplex has either 1 or 2 $\hat{P}_k$ faces.) and let $R$ be the number of $k + 1$ simplices from the triangulation contained in $\tilde{S}$ which have exactly one $\hat{P}_k$ face. These are the ones we want because they have value $\hat{P}_{k+1}$. Thus
the number of faces having value $\hat{P}_k$ which is described here is $2Q + R$. All interior $\hat{P}_k$ faces being counted twice by this number. Now we count the total number of $\hat{P}_k$ faces another way. There are $P$ of them on the face $[x_{j_1}, \ldots, x_{j_{k+1}}, \hat{x}_{j_{k+2}}]$ and by induction, $P$ is odd. Then there are $O$ of them which are not on this face. These faces got counted twice. Therefore,

$$2Q + R = P + 2O$$

and so, since $P$ is odd, so is $R$. Thus there is an odd number of $\hat{P}_{k+1}$ simplices in $\hat{S}$.

We refer to this procedure of labeling as Sperner’s lemma. The system of labeling is well defined thanks to the assumption that $f_{x_k} = x_0$ is independent which implies that $\{x_k - x_i\}_{k \neq i}$ is also linearly independent. Thus there can be no ambiguity in the labeling of vertices on any “face”, the convex hull of some of the original vertices of $S$. Sperner’s lemma is now a consequence of this discussion.

8.3 The Brouwer Fixed Point Theorem

$S \equiv [x_0, \cdots, x_n]$ is a simplex in $\mathbb{R}^n$. Assume $\{x_i - x_0\}_{i=1}^{n}$ are linearly independent. Thus a typical point of $S$ is of the form

$$\sum_{i=0}^{n} t_i x_i$$

where the $t_i$ are uniquely determined and the map $x \to t$ is continuous from $S$ to the compact set $\{t \in \mathbb{R}^{n+1} : \sum t_i = 1, t_i \geq 0\}$.

To see this, suppose $x^k \to x$ in $S$. Let $x^k \equiv \sum_{i=0}^{n} t_i^k x_i$ with $x$ defined similarly with $t_i^k$ replaced with $t_i$, $x \equiv \sum_{i=0}^{n} t_i x_i$. Then

$$x^k - x_0 = \sum_{i=0}^{n} t_i^k x_i - \sum_{i=0}^{n} t_i^k x_0 = \sum_{i=1}^{n} t_i^k (x_i - x_0)$$

Thus

$$x^k - x_0 = \sum_{i=1}^{n} t_i^k (x_i - x_0), \ x - x_0 = \sum_{i=1}^{n} t_i (x_i - x_0)$$

Say $t_i^k$ fails to converge to $t_i$ for all $i \geq 1$. Then there exists a subsequence, still denoted with superscript $k$ such that for each $i = 1, \cdots, n$, it follows that $t_i^k \to s_i$ where $s_i \geq 0$ and some $s_i \neq t_i$. But then, taking a limit, it follows that

$$x - x_0 = \sum_{i=1}^{n} s_i (x_i - x_0) = \sum_{i=1}^{n} t_i (x_i - x_0)$$

which contradicts independence of the $x_i - x_0$. It follows that for all $i \geq 1, t_i^k \to t_i$. Since they all sum to 1, this implies that also $t_0^k \to t_0$. Thus the claim about continuity is verified.
Let \( f : S \to S \) be continuous. When doing \( f \) to a point \( x \), one obtains another point of \( S \) denoted as \( \sum_{i=0}^{n} s_i x_i \).

Label \( x_j \) as \( p_j \) where \( p_0, \ldots, p_n \) are the first \( n + 1 \) prime numbers. Thus the vertices of \( S \) have been labeled. Next triangulate \( S \) so that all simplices have diameter less than \( \varepsilon \). If \( [y_0, \ldots, y_n] \) is one of these small vertices, each is of the form \( \sum_{i=0}^{n} t_i x_i \) where \( t_i \geq 0 \) and \( \sum_i t_i = 1 \). Define \( r_j = s_j / t_j \) if \( t_j > 0 \) and \( \infty \) if \( t_j = 0 \). Then \( p(y_i) \) will be the label placed on \( y_i \). It equals \( p_k \) where \( r_k \) is the smallest of all these extended positive real numbers just described. If there is duplication, pick \( p_k \) where \( k \) is smallest.

Note that this method of labeling does not contradict the original labels placed on the vertices \( x_i \). This is because for \( x_i, t_i = 1 \) and all other \( t_j = 0 \) so the only ratio that is finite will be \( s_i / t_i \). All others are \( \infty \) by definition. As for the vertices which are on the \( k^{th} \) face \( [x_0, \ldots, \hat{x}_k, \ldots, x_n] \), these will be labeled from the list \( \{ p_0, \ldots, p_k, \ldots, p_n \} \) because \( t_k = 0 \) for each of these and so \( r_k = \infty \).

By the Sperner’s lemma procedure described above, there are an odd number of simplices having value \( \prod_{i \neq k} p_i \) on the \( k^{th} \) face and an odd number of simplices in the triangulation of \( S \) for which the product of the labels on their vertices equals \( p_0 p_1 \cdots p_n \equiv P_n \). We call this the value of the simplex. Thus if \( [y_0, \ldots, y_n] \) is one of these simplices, and \( p(y_i) \) is the label for \( y_i \),

\[
\prod_{i=0}^{n} p(y_i) = \prod_{i=0}^{n} p_i \equiv P_n
\]

What is \( r_k \)? Could it be larger than 1? \( r_k \) is certainly finite because at least some \( t_j \neq 0 \) since they sum to 1. Thus, if \( r_k > 1 \), you would have \( s_k > t_k \). The \( s_j \) sum to 1 and so some \( s_j < t_j \) since otherwise, the sum of the \( t_j \) equalling 1 would require the sum of the \( s_j \) to be larger than 1. Hence \( r_k \) was not really the smallest after all and so \( r_k \leq 1 \). Hence \( s_k \leq t_k \).

Let \( S = \{ S_1, \ldots, S_m \} \) denote those simplices whose value is \( P_n \). In other words, if \( \{ y_0, \ldots, y_n \} \) are the vertices of one of these simplices, and

\[
y_s = \sum_{i=0}^{n} t_i^* x_i
\]

\( r_k \leq r_j \) for all \( j \neq k \) and \( \{ k_0, \ldots, k_n \} = \{ 0, \ldots, n \} \). Let \( b \) denote the barycenter of \( S_k \).

Now do this for a sequence \( \varepsilon_k \to 0 \) where \( b_k \) is a barycenter as above for a simplex having value \( P_n \). Thus it is the barycenter of a simplex having diameter less than \( \varepsilon_k \) and value \( P_n \). By compactness, there is a subsequence still denoted with the index \( k \) such that \( b_k \to x \). This \( x \) is a fixed point.

Consider this last claim. \( x = \sum_{i=0}^{n} t_i x_i \) and after applying \( f \), the result is \( \sum_{i=0}^{n} s_i x_i \).

\[
x = \cap_{k=1}^{\infty} \sigma_k
\]

where \( \sigma_k \) is a simplex having vertices \( \{ y_0^k, \ldots, y_n^k \} \) and the value of \( [y_0^k, \ldots, y_n^k] \) is \( P_n \). Re ordering these if necessary, we can assume that the label for \( y_i^k = p_i \) which
implies that, as noted above,
\[ \frac{s_i}{t_i} \leq 1, \quad s_i \leq t_i \]
the \(i^{th}\) coordinate of \(f(y_i^k)\) with respect to the original vertices of \(S\) decreases and each \(i\) is represented for \(i = \{0, 1, \ldots, n\}\). Thus from the diameters of these \(\sigma_k\) converging to 0,
\[ y_i^k \to x \]
and so the \(i^{th}\) coordinate of \(y_i^k, t_i^k\) must converge to \(t_i\). Hence if the \(i^{th}\) coordinate of \(f(y_i^k)\) is denoted by \(s_i^k\),
\[ s_i^k \leq t_i^k \]
By continuity of \(f\), it follows that \(s_i^k \to s_i\). Thus the above inequality is preserved on taking \(k \to \infty\) and so
\[ 0 \leq s_i \leq t_i \]
this for each \(i\). But these \(s_i\) add to 1 as do the \(t_i\) and so in fact, \(s_i = t_i\) for each \(i\) and so \(f(x) = x\). This proves the following theorem which is the Brouwer fixed point theorem.

**Theorem 8.3.1** Let \(S\) be a simplex \([x_0, \ldots, x_n]\) such that \(\{x_i - x_0\}_{i=1}^n\) are independent. Also let \(f : S \to S\) be continuous. Then there exists \(x \in S\) such that \(f(x) = x\).

**Corollary 8.3.2** Let \(K\) be a closed convex bounded subset of \(\mathbb{R}^n\). Let \(f : K \to K\) be continuous. Then there exists \(x \in K\) such that \(f(x) = x\).

**Proof:** Let \(S\) be a large simplex containing \(K\) and let \(P\) be the projection map onto \(K\). Consider \(g(x) \equiv f(Px)\). Then \(g\) satisfies the necessary conditions for Theorem 8.3.1 and so there exists \(x \in S\) such that \(g(x) = x\). But this says \(x \in K\) and so \(g(x) = f(x)\). \(\blacksquare\)

## 8.4 Invariance Of Domain

As an application of the inverse function theorem Weierstrass approximation theorem and so forth is a simple proof of the important invariance of domain theorem.

**Lemma 8.4.1** Let \(f\) be continuous and map \(\overline{B(p,r)} \subseteq \mathbb{R}^n\) to \(\mathbb{R}^n\). Suppose that for all \(x \in \overline{B(p,r)}\),
\[ |f(x) - x| < \varepsilon r \]
Then it follows that
\[ f \left( \overline{B(p,r)} \right) \supseteq B(p, (1 - \varepsilon) r) \]
**Proof:** This is from the Brouwer fixed point theorem, Corollary 8.3.2. Consider for \( y \in B(p, (1 - \varepsilon) r) \)

\[
   h(x) \equiv x - f(x) + y
\]

Then \( h \) is continuous and for \( x \in B(p, r) \),

\[
   |h(x) - p| = |x - f(x) + y - p| < \varepsilon r + |y - p| < \varepsilon r + (1 - \varepsilon) r = r
\]

Hence \( h : B(p, r) \to B(p, r) \) and so it has a fixed point \( x \) by Corollary 8.3.2. Thus

\[
   x - f(x) + y = x
\]

so \( f(x) = y \). \( \blacksquare \)

The notation \( \|f\|_K \) means \( \sup_{x \in K} |f(x)| \).

**Lemma 8.4.2** Let \( K \) be a compact set in \( \mathbb{R}^n \) and let \( g : K \to \mathbb{R}^n, z \in K \). Let \( \delta > 0 \). Then there exists a polynomial \( q \) (each component a polynomial) such that

\[
   \|q - g\|_K < \delta, \quad q(z) = g(z), \quad Dq(z)^{-1}
\]

exists

**Proof:** By the Weierstrass approximation theorem, there exists a polynomial \( \hat{q} \) such that

\[
   \|\hat{q} - g\|_K < \frac{\delta}{3}
\]

Then define for \( y \in K \)

\[
   q(y) \equiv \hat{q}(y) + g(z) - \hat{q}(z)
\]

Then

\[
   q(z) = \hat{q}(z) + g(z) - \hat{q}(z) = g(z)
\]

Also

\[
   |q(y) - g(y)| \leq |(\hat{q}(y) + g(z) - \hat{q}(z)) - g(y)|
\]

\[
   \leq |\hat{q}(y) - g(y)| + |g(z) - \hat{q}(z)| < \frac{2\delta}{3}
\]

and so since \( y \) was arbitrary,

\[
   \|q - g\|_K \leq \frac{2\delta}{3} < \delta
\]

If \( Dq(z)^{-1} \) exists, then this is what is wanted. If not, let

\[
   0 < \eta < \{ |\lambda| : \lambda \text{ is an eigenvalue of } Dq(z), \lambda \neq 0 \}
\]

Then if \( \eta \) is small enough, \( q(y) \) could be replaced with \( q(y) + \eta(y - z) \) and the above inequality would be preserved along with \( q(z) = g(z) \) but now \( Dq(z) \) would have no zero eigenvalues and would therefore be invertible. Simply use the modified \( q \). \( \blacksquare \)
8.4. INVARIANCE OF DOMAIN

**Lemma 8.4.3** Let \( f : \overline{B(p,r)} \to \mathbb{R}^n \) where the ball is also in \( \mathbb{R}^n \). Let \( f \) be one to one. Then there exists \( \delta > 0 \) such that

\[
 f \left( \overline{B(p,r)} \right) \supseteq B(f(p), \delta).
\]

**Proof:** Since \( f \left( \overline{B(p,r)} \right) \) is compact, it follows that \( f^{-1} : f \left( \overline{B(p,r)} \right) \to \overline{B(p,r)} \) is continuous. By Lemma 8.4.2, there exists a polynomial \( q : f \left( \overline{B(p,r)} \right) \to \mathbb{R}^n \) such that

\[
 \| q - f^{-1} \|_{\overline{B(p,r)}} < \varepsilon r, \quad \varepsilon < 1, \quad Dq(f(p))^{-1} \text{ exists, and } q(f(p)) = p
\]

From the first inequality in the above,

\[
 |q(f(x)) - x| = |q(f(x)) - f^{-1}(f(x))| \leq \| q - f^{-1} \|_{\overline{B(p,r)}} < \varepsilon r
\]

By Lemma 8.4.1,

\[
 q \circ f \left( \overline{B(p,r)} \right) \supseteq B(p, (1 - \varepsilon) r)
\]

By the Inverse function theorem, there is an open set containing \( f(p) \) denoted as \( W \) such that on \( W \), \( g \) is one to one and it and its inverse, defined on an open set \( V = g(W) \) both map open sets to open sets. By the construction, \( p \in V \) and so if \( \eta \) is small enough, it follows that \( B(p, \eta) \subseteq B(p, (1 - \varepsilon) r) \cap V \). Thus

\[
 q \circ f \left( \overline{B(p,r)} \right) \supseteq B(p, \eta)
\]

and \( q, q^{-1} \) both map open sets to open sets. Thus \( q^{-1}(B(p,\eta)) \) is an open set containing \( f(p) \). Hence if \( \delta \) is small enough,

\[
 f \left( \overline{B(p,r)} \right) \supseteq B(f(p), \delta)
\]

With this lemma, the invariance of domain theorem comes right away. This remarkable theorem states that if \( f : U \to \mathbb{R}^n \) for \( U \) an open set in \( \mathbb{R}^n \) and if \( f \) is one to one, then \( f(U) \) is also an open set in \( \mathbb{R}^n \).

**Theorem 8.4.4** Let \( U \) be an open set in \( \mathbb{R}^n \) and let \( f : U \to \mathbb{R}^n \) be one to one and continuous. Then \( f(U) \) is also an open subset in \( \mathbb{R}^n \).

**Proof:** It suffices to show that if \( p \in U \) then \( f(p) \) is an interior point of \( f(U) \). Let \( f(U) \) \subseteq U. By Lemma 8.4.3, \( f(U) \supseteq f \left( \overline{B(p,r)} \right) \supseteq B(f(p), \delta) \) so \( f(p) \) is indeed an interior point of \( f(U) \).

Real And Abstract Analysis
Chapter 9

Abstract Measure And Integration

9.1 $\sigma$ Algebras

This chapter is on the basics of measure theory and integration. A measure is a real valued mapping from some subset of the power set of a given set which has values in $[0, \infty]$. Many apparently different things can be considered as measures and also there is an integral defined. By discussing this in terms of axioms and in a very abstract setting, many different topics can be considered in terms of one general theory. For example, it will turn out that sums are included as an integral of this sort. So is the usual integral as well as things which are often thought of as being in between sums and integrals.

Let $\Omega$ be a set and let $\mathcal{F}$ be a collection of subsets of $\Omega$ satisfying

$$\emptyset \in \mathcal{F}, \quad \Omega \in \mathcal{F},$$

$$E \in \mathcal{F} \text{ implies } E^C \equiv \Omega \setminus E \in \mathcal{F},$$

If $\{E_n\}_{n=1}^{\infty} \subseteq \mathcal{F}$, then $\bigcup_{n=1}^{\infty} E_n \in \mathcal{F}$. (9.1.2)

Definition 9.1.1 A collection of subsets of a set, $\Omega$, satisfying Formulas (9.1.1) - (9.1.2) is called a $\sigma$ algebra.

As an example, let $\Omega$ be any set and let $\mathcal{F} = \mathcal{P}(\Omega)$, the set of all subsets of $\Omega$ (power set). This obviously satisfies Formulas (9.1.1) - (9.1.2).

Lemma 9.1.2 Let $\mathcal{C}$ be a set whose elements are $\sigma$ algebras of subsets of $\Omega$. Then $\cap \mathcal{C}$ is a $\sigma$ algebra also.

Be sure to verify this lemma. It follows immediately from the above definitions but it is important for you to check the details.
CHAPTER 9. ABSTRACT MEASURE AND INTEGRATION

Example 9.1.3 Let $\tau$ denote the collection of all open sets in $\mathbb{R}^n$ and let $\sigma(\tau)$ denote the intersection of all $\sigma$ algebras that contain $\tau$. $\sigma(\tau)$ is called the $\sigma$ algebra of Borel sets. In general, for a collection of sets, $\Sigma$, $\sigma(\Sigma)$ is the smallest $\sigma$ algebra which contains $\Sigma$.

This is a very important $\sigma$ algebra and it will be referred to frequently as the Borel sets. Attempts to describe a typical Borel set are more trouble than they are worth and it is not easy to do so. Rather, one uses the definition just given in the example. Note, however, that all countable intersections of open sets and countable unions of closed sets are Borel sets. Such sets are called $G$ sets and $F$ sets respectively.

Definition 9.1.4 Let $F$ be a $\sigma$ algebra of sets of $\Omega$ and let $\mu : F \rightarrow [0, \infty]$. $\mu$ is called a measure if

$$\mu(\bigcup_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} \mu(E_i)$$

whenever the $E_i$ are disjoint sets of $F$. The triple, $(\Omega, F, \mu)$ is called a measure space and the elements of $F$ are called the measurable sets. $(\Omega, F, \mu)$ is a finite measure space when $\mu(\Omega) < \infty$.

Note that the above definition immediately implies that if $E_i \in F$ and the sets $E_i$ are not necessarily disjoint,

$$\mu(\bigcup_{i=1}^{\infty} E_i) \leq \sum_{i=1}^{\infty} \mu(E_i).$$

To see this, let $F_1 \equiv E_1$, $F_2 \equiv E_2 \setminus E_1$, $\cdots$, $F_n \equiv E_n \setminus \bigcup_{i=1}^{n-1} E_i$, then the sets $F_i$ are disjoint sets in $F$ and

$$\mu(\bigcup_{i=1}^{\infty} E_i) = \mu(\bigcup_{i=1}^{\infty} F_i) = \sum_{i=1}^{\infty} \mu(F_i) \leq \sum_{i=1}^{\infty} \mu(E_i)$$

because of the fact that each $E_i \supseteq F_i$ and so

$$\mu(E_i) = \mu(F_i) + \mu(E_i \setminus F_i)$$

which implies $\mu(E_i) \geq \mu(F_i)$.

The following theorem is the basis for most of what is done in the theory of measure and integration. It is a very simple result which follows directly from the above definition.

Theorem 9.1.5 Let $\{E_m\}_{m=1}^{\infty}$ be a sequence of measurable sets in a measure space $(\Omega, F, \mu)$. Then if $\cdots \subseteq E_n \subseteq E_{n+1} \subseteq E_{n+2} \subseteq \cdots$,

$$\mu(\bigcup_{i=1}^{\infty} E_i) = \lim_{n \to \infty} \mu(E_n)$$

(9.1.4)
and if \( \cdots \supseteq E_n \supseteq E_{n+1} \supseteq E_{n+2} \supseteq \cdots \) and \( \mu(E_1) < \infty \), then
\[
\mu(\bigcap_{i=1}^{\infty} E_i) = \lim_{n \to \infty} \mu(E_n). \tag{9.1.5}
\]

Stated more succinctly, \( E_k \uparrow E \) implies \( \mu(E_k) \uparrow \mu(E) \) and \( E_k \downarrow E \) with \( \mu(E_1) < \infty \) implies \( \mu(E_k) \downarrow \mu(E) \).

**Proof:** First note that \( \cap_{i=1}^{\infty} E_i = (\cup_{i=1}^{\infty} E_i^C)^C \in \mathcal{F} \) so \( \cap_{i=1}^{\infty} E_i \) is measurable. Also note that for \( A \) and \( B \) sets of \( \mathcal{F} \), \( A \setminus B \equiv (A^C \cup B)^C \in \mathcal{F} \). To show 9.1.4, note that 9.1.4 is obviously true if \( \mu(E_k) = 1 \) for any \( k \). Therefore, assume \( \mu(E_k) < \infty \) for all \( k \). Thus
\[
\mu(E_{k+1} \setminus E_k) + \mu(E_k) = \mu(E_{k+1})
\]
and so
\[
\mu(E_{k+1} \setminus E_k) = \mu(E_{k+1}) - \mu(E_k).
\]

Also,
\[
\bigcup_{k=1}^{\infty} E_k = E_1 \cup \bigcup_{k=1}^{\infty} (E_{k+1} \setminus E_k)
\]
and the sets in the above union are disjoint. Hence by 9.1.3,
\[
\mu(\bigcup_{i=1}^{\infty} E_i) = \mu(E_1) + \sum_{k=1}^{\infty} \mu(E_{k+1} \setminus E_k) = \mu(E_1)
\]
\[
= \mu(E_1) + \sum_{k=1}^{\infty} \mu(E_{k+1}) - \mu(E_k)
\]
\[
= \mu(E_1) + \lim_{n \to \infty} \sum_{k=1}^{n} \mu(E_{k+1}) - \mu(E_k) = \lim_{n \to \infty} \mu(E_{n+1}).
\]
This shows part 9.1.4.

To verify 9.1.5,
\[
\mu(E_1) = \mu(\cap_{i=1}^{\infty} E_i) + \mu(E_1 \setminus \cap_{i=1}^{\infty} E_i)
\]
since \( \mu(E_1) < \infty \), it follows \( \mu(\cap_{i=1}^{n} E_i) ) < \infty \). Also, \( E_1 \setminus \cap_{i=1}^{n} E_i \uparrow E_1 \setminus \cap_{i=1}^{\infty} E_i \) and so by 9.1.4,
\[
\mu(E_1) - \mu(\cap_{i=1}^{\infty} E_i) = \mu(E_1 \setminus \cap_{i=1}^{\infty} E_i) = \lim_{n \to \infty} \mu(E_1 \setminus \cap_{i=1}^{n} E_i)
\]
\[
= \mu(E_1) - \lim_{n \to \infty} \mu(\cap_{i=1}^{n} E_i) = \mu(E_1) - \lim_{n \to \infty} \mu(E_n),
\]
Hence, subtracting \( \mu(E_1) \) from both sides,
\[
\lim_{n \to \infty} \mu(E_n) = \mu(\cap_{i=1}^{\infty} E_i).
\]
This proves the theorem.
It is convenient to allow functions to take the value $+\infty$. You should think of $+\infty$, usually referred to as $\infty$ as something out at the right end of the real line and its only importance is the notion of sequences converging to it. $x_n \to \infty$ exactly when for all $l \in \mathbb{R}$, there exists $N$ such that if $n \geq N$, then $x_n > l$.

This is what it means for a sequence to converge to $\infty$. Don’t think of $\infty$ as a number. It is just a convenient symbol which allows the consideration of some limit operations more simply. Similar considerations apply to $-\infty$ but this value is not of very great interest. In fact the set of most interest is the complex numbers or some vector space. Therefore, this topic is not considered.

**Lemma 9.1.6** Let $f : \Omega \to (-\infty, \infty]$ where $\mathcal{F}$ is a $\sigma$ algebra of subsets of $\Omega$. Then the following are equivalent.

\[
\begin{align*}
& f^{-1}((d, \infty]) \in \mathcal{F} \text{ for all finite } d, \\
& f^{-1}((\infty, d)) \in \mathcal{F} \text{ for all finite } d, \\
& f^{-1}([d, \infty]) \in \mathcal{F} \text{ for all finite } d, \\
& f^{-1}((\infty, d]) \in \mathcal{F} \text{ for all finite } d, \\
& f^{-1}((a, b)) \in \mathcal{F} \text{ for all } a < b, -\infty < a < b < \infty.
\end{align*}
\]

**Proof:** First note that the first and the third are equivalent. To see this, observe

\[
f^{-1}((d, \infty]) = \cap_{n=1}^{\infty} f^{-1}((d - 1/n, \infty]),
\]

and so if the first condition holds, then so does the third.

\[
f^{-1}((d, \infty]) = \cup_{n=1}^{\infty} f^{-1}([d + 1/n, \infty]),
\]

and so if the third condition holds, so does the first.

Similarly, the second and fourth conditions are equivalent. Now

\[
f^{-1}((\infty, d]) = (f^{-1}((d, \infty]))^C
\]

so the first and fourth conditions are equivalent. Thus the first four conditions are equivalent and if any of them hold, then for $-\infty < a < b < \infty$,

\[
f^{-1}((a, b)) = f^{-1}((\infty, b)) \cap f^{-1}((a, \infty]) \in \mathcal{F}.
\]

Finally, if the last condition holds,

\[
f^{-1}([d, \infty]) = (\cup_{k=1}^{\infty} f^{-1}((-k + d, d)))^C \in \mathcal{F}
\]

and so the third condition holds. Therefore, all five conditions are equivalent. This proves the lemma.

This lemma allows for the following definition of a measurable function having values in $(-\infty, \infty]$.
9.1. σ ALGEBRAS

**Definition 9.1.7** Let \((\Omega, \mathcal{F}, \mu)\) be a measure space and let \(f : \Omega \to (-\infty, \infty]\). Then \(f\) is said to be measurable if any of the equivalent conditions of Lemma 9.1.6 hold. When the σ algebra, \(\mathcal{F}\) equals the Borel σ algebra, \(\mathcal{B}\), the function is called Borel measurable. More generally, if \(f : \Omega \to X\) where \(X\) is a topological space, \(f\) is said to be measurable if \(f^{-1}(U) \in \mathcal{F}\) whenever \(U\) is open.

**Theorem 9.1.8** Let \(f_n\) and \(f\) be functions mapping \(\Omega\) to \((-\infty, \infty]\) where \(\mathcal{F}\) is a σ algebra of measurable sets of \(\Omega\). Then if \(f_n\) is measurable, and \(f(\omega) = \lim_{n \to \infty} f_n(\omega)\), it follows that \(f\) is also measurable. (Pointwise limits of measurable functions are measurable.)

**Proof:** First it is shown \(f^{-1}((a, b)) \in \mathcal{F}\). Let \(V_m = (a + \frac{1}{m}, b - \frac{1}{m})\). Then for all \(m\), \(V_m \subseteq (a, b)\) and

\[
(a, b) = \cup_{m=1}^{\infty} V_m = \cup_{m=1}^{\infty} \overline{V}_m.
\]

Note that \(V_m \neq \emptyset\) for all \(m\) large enough. Since \(f\) is the pointwise limit of \(f_n\),

\[
f^{-1}(V_m) \subseteq \{ \omega : f_k(\omega) \in V_m \text{ for all } k \text{ large enough} \} \subseteq f^{-1}(\overline{V}_m).
\]

You should note that the expression in the middle is of the form

\[
\cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_k^{-1}(V_m).
\]

Therefore,

\[
f^{-1}((a, b)) = \cup_{m=1}^{\infty} f^{-1}(V_m) \subseteq \cup_{m=1}^{\infty} \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_k^{-1}(V_m)
\]

\[
\subseteq \cup_{m=1}^{\infty} f^{-1}(\overline{V}_m) = f^{-1}((a, b)).
\]

It follows \(f^{-1}((a, b)) \in \mathcal{F}\) because it equals the expression in the middle which is measurable. This shows \(f\) is measurable.

The following theorem considers the case of functions which have values in a metric space. Its proof is similar to the proof of the above.

**Theorem 9.1.9** Let \(\{f_n\}\) be a sequence of measurable functions mapping \(\Omega\) to \((X, d)\) where \((X, d)\) is a metric space and \((\Omega, \mathcal{F})\) is a measure space. Suppose also that \(f(\omega) = \lim_{n \to \infty} f_n(\omega)\) for all \(\omega\). Then \(f\) is also a measurable function.

**Proof:** It is required to show \(f^{-1}(U)\) is measurable for all \(U\) open. Let

\[
V_m = \left\{ x \in U : \text{dist}(x, U^C) > \frac{1}{m} \right\}.
\]

Thus

\[
V_m \subseteq \left\{ x \in U : \text{dist}(x, U^C) \geq \frac{1}{m} \right\}
\]

and \(V_m \subseteq V_m \subseteq V_{m+1}\) and \(\cup_{m} V_m = U\). Then since \(V_m\) is open,

\[
f^{-1}(V_m) = \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} f_k^{-1}(V_m).
\]
CHAPTER 9. ABSTRACT MEASURE AND INTEGRATION

and so

\[ f^{-1}(U) = \bigcup_{m=1}^{\infty} f^{-1}(V_m) = \bigcup_{m=1}^{\infty} \bigcap_{n=1}^{\infty} f_k^{-1}(V_m) \subseteq \bigcup_{m=1}^{\infty} f^{-1}(V_m) = f^{-1}(U) \]

which shows \( f^{-1}(U) \) is measurable. This proves the theorem.

Now here is a simple observation.

**Observation 9.1.10** Let \( f : \Omega \to X \) where \( X \) is some topological space. Suppose

\[ f(\omega) = \sum_{k=1}^{m} x_k \mathbb{1}_{A_k}(\omega) \]

where each \( x_k \in X \) and the \( A_k \) are disjoint measurable sets. (Such functions are often referred to as simple functions.) The sum means the function has value \( x_k \) on set \( A_k \). Then \( f \) is measurable.

**Proof:** Letting \( U \) be open, \( f^{-1}(U) = \bigcup \{ A_k : x_k \in U \} \), a finite union of measurable sets.

There is also a very interesting theorem due to Kuratowski which is presented next.

To summarize the proof, you get an increasing sequence of \( 2^{-n} \) nets \( C_n \) and you obtain a corresponding sequence of simple functions \( f_s \) such that \( f_s(\omega) = \lim_{n \to \infty} s_n(\omega) \). Then you let \( f(\omega) = \lim_{n \to \infty} s_n(\omega) \). Thus \( f(\omega) \) is measurable and

\[ \sup_{x \in E} \psi(x, \omega) \geq \psi(f(\omega), \omega) = \lim_{n \to \infty} \psi(s_n(\omega), \omega) \geq \sup_{x \in C_n} \psi(x, \omega) \]

Thus, by continuity in the first entry,

\[ \sup_{x \in E} \psi(x, \omega) \geq \psi(f(\omega), \omega) \geq \lim_{n \to \infty} \psi(s_n(\omega), \omega) \geq \sup_{x \in C_n} \psi(x, \omega) = \sup_{x \in \bigcup_{n \in \mathbb{N}} C_n} \psi(x, \omega) \]

**Theorem 9.1.11** Let \( E \) be a compact metric space and let \((\Omega, \mathcal{F})\) be a measure space. Suppose \( \psi : E \times \Omega \to \mathbb{R} \) has the property that \( x \to \psi(x, \omega) \) is continuous and \( \omega \to \psi(x, \omega) \) is measurable. Then there exists a measurable function, \( f \) having values in \( E \) such that

\[ \psi(f(\omega), \omega) = \sup_{x \in E} \psi(x, \omega) \]

Furthermore, \( \omega \to \psi(f(\omega), \omega) \) is measurable.

**Proof:** Let \( C_1 \) be a \( 2^{-1} \) net of \( E \). Suppose \( C_1, \ldots, C_m \) have been chosen such that \( C_k \) is a \( 2^{-k} \) net and \( C_{i+1} \supseteq C_i \) for all \( i \). Then consider \( E \setminus \bigcup \{ B \{ x, 2^{-(m+1)} : x \in C_m \} \} \).

If this set is empty, let \( C_{m+1} = C_m \). If it is nonempty, let \( \{ y_i \}_{i=1}^{r} \) be a \( 2^{-(m+1)} \) net
for this compact set. Then let \( C_{m+1} = C_m \cup \{ y_i \}_{i=1}^r \). It follows \( \{ C_m \}_{m=1}^\infty \) satisfies \( C_m \) is a \( 2^{-m} \) net and \( C_m \subseteq C_{m+1} \).

Let \( \{ x_k \}_{k=1}^{m(1)} \) equal \( C_1 \). Let

\[
A_1^1 = \left\{ \omega : \psi (x_1^1, \omega) = \max_k \psi (x_k^1, \omega) \right\}
\]

For \( \omega \in A_1^1 \), define \( s_1 (\omega) = x_1^1 \). Next let

\[
A_1^1 = \left\{ \omega \notin A_1^1 : \psi (x_2^1, \omega) = \max_k \psi (x_k^1, \omega) \right\}
\]

and let \( s_1 (\omega) = x_2^1 \) on \( A_2^1 \). Continue in this way to obtain a simple function, \( s_1 \) such that

\[
\psi (s_1 (\omega), \omega) = \max \{ \psi (x, \omega) : x \in C_1 \}
\]

and \( s_1 \) has values in \( C_1 \).

Suppose \( s_1 (\omega), s_2 (\omega), \ldots, s_m (\omega) \) are simple functions with the property that if \( m > 1 \),

\[
d (s_k (\omega), s_{k+1} (\omega)) < 2^{-k}, \\
\psi (s_k (\omega), \omega) = \max \{ \psi (x, \omega) : x \in C_k \}
\]

\( s_k \) has values in \( C_k \)

for each \( k + 1 \leq m \), only the second and third assertions holding if \( m = 1 \). Letting \( C_m = \{ x_k \}_{k=1}^N \), it follows \( s_m (\omega) \) is of the form

\[
s_m (\omega) = \sum_{k=1}^N x_k \chi_{A_k} (\omega), \ A_i \cap A_j = \emptyset. \tag{9.1.6}
\]

meaning that \( s_m (\omega) \) has value \( x_k \) on \( A_k \). Denote by \( \{ y_{1i} \}_{i=1}^{n_1} \) those points of \( C_{m+1} \) which are contained in \( B (x_1, 2^{-m}) \). Letting \( A_k \) play the role of \( \Omega \) in the first step in which \( s_1 \) was constructed, for each \( \omega \in A_1 \) let \( s_{m+1} (\omega) \) be a simple function which has one of the values \( y_{1i} \) and satisfies

\[
\psi (s_{m+1} (\omega), \omega) = \max_{i \leq n_1} \psi (y_{1i}, \omega)
\]

for each \( \omega \in A_1 \). Next let \( \{ y_{2i} \}_{i=1}^{n_2} \) be those points of \( C_{m+1} \) different than \( \{ y_{1i} \}_{i=1}^{n_1} \) which are contained in \( B (x_2, 2^{-m}) \). Then define \( s_{m+1} (\omega) \) on \( A_2 \) to have values taken from \( \{ y_{2i} \}_{i=1}^{n_2} \) and

\[
\psi (s_{m+1} (\omega), \omega) = \max_{i \leq n_2} \psi (y_{2i}, \omega)
\]

for each \( \omega \in A_2 \). Continuing this way defines \( s_{m+1} \) on all of \( \Omega \) and it satisfies

\[
d (s_m (\omega), s_{m+1} (\omega)) < 2^{-m} \text{ for all } \omega \in \Omega \tag{9.1.7}
\]
It remains to verify
\[ \psi(s_{m+1}(\omega), \omega) = \max \{ \psi(x, \omega) : x \in C_{m+1} \}. \quad (9.1.8) \]
To see this is so, pick \( \omega \in \Omega \). Let
\[ \max \{ \psi(x, \omega) : x \in C_{m+1} \} = \psi(y_{rj}, \omega) \quad (9.1.9) \]
where \( y_{rj} \in \{ y_{ri} \}_{i=1}^{r} \subseteq C_{m+1} \) and out of all the balls \( B(x, 2^{-m}) \), let the first one which contains \( y_{rj} \) be \( B(x_k, 2^{-m}) \). Then by the construction, \( s_{m+1}(\omega) = y_{rj} \) because \( \psi(y_{rj}, \omega) \) is at least as large as \( \psi(y_{sj}, \omega) \) for all the other \( y_{sj} \). This and (9.1.9) verifies (9.1.8).

From (9.1.7) it follows \( s_m(\omega) \) converges uniformly on \( \Omega \) to a measurable function, \( f(\omega) \). Then from the construction, \( \psi(f(\omega), \omega) \geq \psi(s_m(\omega), \omega) \) for all \( m \) and \( \omega \). Now pick \( \omega \in \Omega \) and let \( z \) be such that \( \psi(z, \omega) = \max_{x \in E} \psi(x, \omega) \). Letting \( y_k \to z \) where \( y_k \in C_k \), it follows from continuity of \( \psi \) in the first argument that
\[ \max_{x \in E} \psi(x, \omega) = \psi(z, \omega) = \lim_{k \to \infty} \psi(y_k, \omega) \]
\[ \leq \lim_{m \to \infty} \psi(s_m(\omega), \omega) = \psi(f(\omega), \omega) \leq \max_{x \in E} \psi(x, \omega). \]

To show \( \omega \to \psi(f(\omega), \omega) \) is measurable, note that since \( E \) is compact, there exists a countable dense subset, \( D \). Then using continuity of \( \psi \) in the first argument,
\[ \psi(f(\omega), \omega) = \sup_{x \in E} \psi(x, \omega) \]
\[ = \sup_{x \in D} \psi(x, \omega) \]
which equals a measurable function of \( \omega \) because \( D \) is countable. ■

**Theorem 9.1.12** Let \( B \) consist of open cubes of the form
\[ Q_x = \prod_{i=1}^{n} (x_i - \delta, x_i + \delta) \]
where \( \delta \) is a positive rational number and \( x \in Q^n \). Then every open set in \( \mathbb{R}^n \) can be written as a countable union of open cubes from \( B \). Furthermore, \( B \) is a countable set.

**Proof:** Let \( U \) be an open set and let \( y \in U \). Since \( U \) is open, \( B(y, r) \subseteq U \) for some \( r > 0 \) and it can be assumed \( r/\sqrt{n} \in \mathbb{Q} \). Let
\[ x \in B\left(y, \frac{r}{10\sqrt{n}} \right) \cap Q^n \]
and consider the cube, \( Q_x \in B \) defined by
\[ Q_x = \prod_{i=1}^{n} (x_i - \delta, x_i + \delta) \]
where $\delta = r/4\sqrt{n}$. The following picture is roughly illustrative of what is taking place.

Then the diameter of $Q_x$ equals

$$\left( n \left( \frac{r}{2\sqrt{n}} \right)^2 \right)^{1/2} = \frac{r}{2}$$

and so, if $z \in Q_x$, then

$$|z - y| \leq |z - x| + |x - y| < \frac{r}{2} + \frac{r}{2} = r.$$  

Consequently, $Q_x \subseteq U$. Now also,

$$\left( \sum_{i=1}^{n} (x_i - y_i)^2 \right)^{1/2} < \frac{r}{10\sqrt{n}}$$

and so it follows that for each $i$,

$$|x_i - y_i| < \frac{r}{4\sqrt{n}}$$

since otherwise the above inequality would not hold. Therefore, $y \in Q_x \subseteq U$. Now let $B_U$ denote those sets of $B$ which are contained in $U$. Then $\cup B_U = U$.

To see $B$ is countable, note there are countably many choices for $x$ and countably many choices for $\delta$. This proves the theorem.

Recall that $g : \mathbb{R}^n \to \mathbb{R}$ is continuous means $g^{-1}$ (open set) = an open set. In particular $g^{-1}((a, b))$ must be an open set.

**Theorem 9.1.13** Let $f_i : \Omega \to \mathbb{R}$ for $i = 1, \cdots, n$ be measurable functions and let $g : \mathbb{R}^n \to \mathbb{R}$ be continuous where $f \equiv (f_1, \cdots, f_n)^T$. Then $g \circ f$ is a measurable function from $\Omega$ to $\mathbb{R}$.
Proof: First it is shown

\[(g \circ f)^{-1}((a, b)) \in \mathcal{F}.\]

Now \((g \circ f)^{-1}((a, b)) = f^{-1}(g^{-1}((a, b)))\) and since \(g\) is continuous, it follows that \(g^{-1}((a, b))\) is an open set which is denoted as \(U\) for convenience. Now by Theorem 9.1.12 above, it follows there are countably many open cubes, \(\{Q_k\}\) such that

\[U = \bigcup_{k=1}^{\infty} Q_k\]

where each \(Q_k\) is a cube of the form

\[Q_k = \prod_{i=1}^{n} (x_i - \delta, x_i + \delta)\]

Now

\[f^{-1}\left(\prod_{i=1}^{n} (x_i - \delta, x_i + \delta)\right) = \bigcap_{i=1}^{n} f_i^{-1}((x_i - \delta, x_i + \delta)) \in \mathcal{F}\]

and so

\[(g \circ f)^{-1}((a, b)) = f^{-1}(g^{-1}((a, b))) = f^{-1}(U) = f^{-1}(\bigcup_{k=1}^{\infty} Q_k) = \bigcup_{k=1}^{\infty} f^{-1}(Q_k) \in \mathcal{F}.\]

This proves the theorem.

Corollary 9.1.14 Sums, products, and linear combinations of measurable functions are measurable.

Proof: To see the product of two measurable functions is measurable, let \(g(x, y) = xy\), a continuous function defined on \(\mathbb{R}^2\). Thus if you have two measurable functions, \(f_1\) and \(f_2\) defined on \(\Omega\),

\[g \circ (f_1, f_2)(\omega) = f_1(\omega) f_2(\omega)\]

and so \(\omega \to f_1(\omega) f_2(\omega)\) is measurable. Similarly you can show the sum of two measurable functions is measurable by considering \(g(x, y) = x + y\) and you can show a linear combination of two measurable functions is measurable by considering \(g(x, y) = ax + by\). More than two functions can also be considered as well.

The message of this corollary is that starting with measurable real valued functions you can combine them in pretty much any way you want and you end up with a measurable function.

Here is some notation which will be used whenever convenient.

Definition 9.1.15 Let \(f : \Omega \to [-\infty, \infty]\). Define

\[\{\alpha < f\} = \{\omega \in \Omega : f(\omega) > \alpha\} = f^{-1}((\alpha, \infty))\]

with obvious modifications for the symbols \([\alpha \leq f]\), \([\alpha \geq f]\), \([\alpha \geq f \geq \beta]\), etc.
Definition 9.1.16 For a set $E$,

$$\chi_E(\omega) = \begin{cases} 
1 & \text{if } \omega \in E, \\
0 & \text{if } \omega \notin E.
\end{cases}$$

This is called the characteristic function of $E$. Sometimes this is called the indicator function which I think is better terminology since the term characteristic function has another meaning. Note that this “indicates” whether a point, $\omega$ is contained in $E$. It is exactly when the function has the value 1.

Theorem 9.1.17 (Egoroff) Let $(\Omega, \mathcal{F}, \mu)$ be a finite measure space,

$$(\mu(\Omega) < \infty)$$

and let $f_n, f$ be complex valued functions such that $\text{Re} f_n, \text{Im} f_n$ are all measurable and

$$\lim_{n \to \infty} f_n(\omega) = f(\omega)$$

for all $\omega \notin E$ where $\mu(E) = 0$. Then for every $\varepsilon > 0$, there exists a set,

$$F \supseteq E, \; \mu(F) < \varepsilon,$$

such that $f_n$ converges uniformly to $f$ on $F^c$.

Proof: First suppose $E = \emptyset$ so that convergence is pointwise everywhere. It follows then that $\text{Re} f$ and $\text{Im} f$ are pointwise limits of measurable functions and are therefore measurable. Let $E_{km} = \{ \omega \in \Omega : |f_n(\omega) - f(\omega)| \geq 1/m \text{ for some } n > k \}$. Note that

$$|f_n(\omega) - f(\omega)| = \sqrt{(\text{Re} f_n(\omega) - \text{Re} f(\omega))^2 + (\text{Im} f_n(\omega) - \text{Im} f(\omega))^2}$$

and so, by Theorem 9.1.13

$$\left| f_n - f \right| \geq \frac{1}{m}$$

is measurable. Hence $E_{km}$ is measurable because

$$E_{km} = \bigcup_{n=k+1}^{\infty} \left| f_n - f \right| \geq \frac{1}{m}.$$

For fixed $m$, $\bigcap_{k=1}^{\infty} E_{km} = \emptyset$ because $f_n$ converges to $f$. Therefore, if $\omega \in \Omega$ there exists $k$ such that if $n > k$, $|f_n(\omega) - f(\omega)| < \frac{1}{m}$ which means $\omega \notin E_{km}$. Note also that

$$E_{km} \supseteq E_{(k+1)m}.$$

Since $\mu(E_{1m}) < \infty$, Theorem 9.1.13 on Page 208 implies

$$0 = \mu(\bigcap_{k=1}^{\infty} E_{km}) = \lim_{k \to \infty} \mu(E_{km}).$$
Let \( k(m) \) be chosen such that \( \mu(E_{k(m)}m) < \varepsilon 2^{-m} \) and let

\[
F = \bigcup_{m=1}^{\infty} E_{k(m)}m.
\]

Then \( \mu(F) < \varepsilon \) because

\[
\mu(F) \leq \sum_{m=1}^{\infty} \mu(E_{k(m)}m) < \sum_{m=1}^{\infty} \varepsilon 2^{-m} = \varepsilon
\]

Now let \( \eta > 0 \) be given and pick \( m_0 \) such that \( m_0^{-1} < \eta \). If \( \omega \in F^C \), then

\[
\omega \in \bigcap_{m=1}^{\infty} E_{k(m)}^Cm.
\]

Hence \( \omega \in E_{k(m_0)}^{C(m_0)} \) so

\[
|f_n(\omega) - f(\omega)| < 1/m_0 < \eta
\]

for all \( n > k(m_0) \). This holds for all \( \omega \in F^C \) and so \( f_n \) converges uniformly to \( f \) on \( F^C \).

Now if \( E \neq \emptyset \), consider \( \{X_{E^C}f_n\}_{n=1}^{\infty} \). Each \( X_{E^C}f_n \) has real and imaginary parts measurable and the sequence converges pointwise to \( X_{E}f \) everywhere. Therefore, from the first part, there exists a set of measure less than \( \varepsilon, F \) such that on \( F^C \), \( \{X_{E^C}f_n\} \) converges uniformly to \( X_{E^C}f \). Therefore, on \( (E \cup F)^C \), \( \{f_n\} \) converges uniformly to \( f \). This proves the theorem.

Finally here is a comment about notation.

**Definition 9.1.18** Something happens for \( \mu \) a.e. \( \omega \) said as \( \mu \) almost everywhere, if there exists a set \( E \) with \( \mu(E) = 0 \) and the thing takes place for all \( \omega \in E \). Thus \( f(\omega) = g(\omega) \) a.e. if \( f(\omega) = g(\omega) \) for all \( \omega \in E \) where \( \mu(E) = 0 \). A measure space, \( (\Omega, F, \mu) \) is \( \sigma \) finite if there exist measurable sets, \( \Omega_n \) such that \( \mu(\Omega_n) < \infty \) and \( \Omega = \bigcup_{n=1}^{\infty} \Omega_n \).

### 9.2 Exercises

1. Let \( \Omega = \mathbb{N} = \{1, 2, \ldots\} \). Let \( F = \mathcal{P}(\mathbb{N}) \) and let \( \mu(S) = \text{number of elements in } S \). Thus \( \mu(\{1\}) = 1 = \mu(\{2\}) \), \( \mu(\{1, 2\}) = 2 \), etc. Show \( (\Omega, F, \mu) \) is a measure space. It is called counting measure. What functions are measurable in this case?

2. Let \( \Omega \) be any uncountable set and let \( F = \{A \subseteq \Omega : \text{either } A \text{ or } A^C \text{ is countable} \} \). Let \( \mu(A) = 1 \) if \( A \) is uncountable and \( \mu(A) = 0 \) if \( A \) is countable. Show \( (\Omega, F, \mu) \) is a measure space. This is a well known bad example.
3. Let $\mathcal{F}$ be a $\sigma$ algebra of subsets of $\Omega$ and suppose $\mathcal{F}$ has infinitely many elements. Show that $\mathcal{F}$ is uncountable. **Hint:** You might try to show there exists a countable sequence of disjoint sets of $\mathcal{F}$, $\{A_i\}$. It might be easiest to verify this by contradiction if it doesn’t exist rather than a direct construction. Once this has been done, you can define a map, $\theta$, from $\mathcal{P}(\mathbb{N})$ into $\mathcal{F}$ which is one to one by $\theta(S) = \bigcup_{i \in S} A_i$. Then argue $\mathcal{P}(\mathbb{N})$ is uncountable and so $\mathcal{F}$ is also uncountable.

4. Prove Lemma 9.1.2

5. $g$ is Borel measurable if whenever $U$ is open, $g^{-1}(U)$ is Borel. Let $f : \Omega \to \mathbb{R}^n$ and let $g : \mathbb{R}^n \to \mathbb{R}$ and $\mathcal{F}$ is a $\sigma$ algebra of sets of $\Omega$. Suppose $f$ is measurable and $g$ is Borel measurable. Show $g \circ f$ is measurable. To say $g$ is Borel measurable means $g^{-1}$ (open set) = (Borel set) where a Borel set is one of those sets in the smallest $\sigma$ algebra containing the open sets of $\mathbb{R}^n$. See Lemma 9.1.2. **Hint:** You should show, using Theorem 9.1.12 that $f^{-1}$ (open set) $\in \mathcal{F}$. Now let

$$S = \{ E \subseteq \mathbb{R}^n : f^{-1}(E) \in \mathcal{F} \}$$

By what you just showed, $S$ contains the open sets. Now verify $S$ is a $\sigma$ algebra. Argue that from the definition of the Borel sets, it follows $S$ contains the Borel sets.

6. Let $(\Omega, \mathcal{F})$ be a measure space and suppose $f : \Omega \to \mathbb{C}$. Then $f$ is said to be measurable if

$$f^{-1}(\text{open set}) \in \mathcal{F}.$$

Show $f$ is measurable if and only if $\text{Re } f$ and $\text{Im } f$ are measurable real-valued functions. Thus it suffices to define a complex valued function to be measurable if the real and imaginary parts are measurable. **Hint:** Argue that $f^{-1}(((a, b) + i(c, d))) = (\text{Re } f)^{-1}((a, b)) \cap (\text{Im } f)^{-1}((c, d))$. Then use Theorem 9.1.12 to verify that if $\text{Re } f$ and $\text{Im } f$ are measurable, it follows $f$ is. Conversely, argue that $(\text{Re } f)^{-1}((a, b)) = f^{-1}((a, b) + i\mathbb{R})$ with a similar formula holding for $\text{Im } f$.

7. Let $(\Omega, \mathcal{F}, \mu)$ be a measure space. Define $\overline{\mu} : \mathcal{P}(\Omega) \to [0, \infty]$ by

$$\overline{\mu}(A) = \inf \{ \mu(B) : B \supseteq A, B \in \mathcal{F} \}.$$

Show $\overline{\mu}$ satisfies

$$\overline{\mu}(\emptyset) = 0, \text{ if } A \subseteq B, \overline{\mu}(A) \leq \overline{\mu}(B),$$

$$\overline{\mu}(\bigcup_{i=1}^{\infty} A_i) \leq \sum_{i=1}^{\infty} \mu(A_i), \mu(A) = \overline{\mu}(A) \text{ if } A \in \mathcal{F}.$$

If $\overline{\mu}$ satisfies these conditions, it is called an outer measure. This shows every measure determines an outer measure on the power set.
8. Let \( \{E_i\} \) be a sequence of measurable sets with the property that
\[
\sum_{i=1}^{\infty} \mu(E_i) < \infty.
\]
Let \( S = \{ \omega \in \Omega \text{ such that } \omega \in E_i \text{ for infinitely many values of } i \} \). Show \( \mu(S) = 0 \) and \( S \) is measurable. This is part of the Borel Cantelli lemma. **Hint:** Write \( S \) in terms of intersections and unions. Something is in \( S \) means that for every \( n \) there exists \( k > n \) such that it is in \( E_k \). Remember the tail of a convergent series is small.

9. \( \uparrow \) Let \( f_n, f \) be measurable functions. \( f_n \) converges in measure if
\[
\lim_{n \to \infty} \mu(\{x \in \Omega : |f(x) - f_n(x)| \geq \varepsilon\}) = 0
\]
for each fixed \( \varepsilon > 0 \). Prove the theorem of F. Riesz. If \( f_n \) converges to \( f \) in measure, then there exists a subsequence \( \{f_{n_k}\} \) which converges to \( f \) a.e. **Hint:** Choose \( n_1 \) such that
\[
\mu(\{x : |f(x) - f_{n_1}(x)| \geq 1\}) < 1/2.
\]
Choose \( n_2 > n_1 \) such that
\[
\mu(\{x : |f(x) - f_{n_2}(x)| \geq 1/2\}) < 1/2^2,
\]
n_3 > n_2 such that
\[
\mu(\{x : |f(x) - f_{n_3}(x)| \geq 1/3\}) < 1/2^3,
\]
etc. Now consider what it means for \( f_{n_k}(x) \) to fail to converge to \( f(x) \). Then use Problem 8.

### 9.3 The Abstract Lebesgue Integral

#### 9.3.1 Preliminary Observations

This section is on the Lebesgue integral and the major convergence theorems which are the reason for studying it. In all that follows \( \mu \) will be a measure defined on a \( \sigma \) algebra \( \mathcal{F} \) of subsets of \( \Omega \). \( 0 \cdot \infty = 0 \) is always defined to equal zero. This is a meaningless expression and so it can be defined arbitrarily but a little thought will soon demonstrate that this is the right definition in the context of measure theory. To see this, consider the zero function defined on \( \mathbb{R} \). What should the integral of this function equal? Obviously, by an analogy with the Riemann integral, it should equal zero. Formally, it is zero times the length of the set or infinity. This is why this convention will be used.
Lemma 9.3.1 Let \( f(a, b) \in [-\infty, \infty] \) for \( a \in A \) and \( b \in B \) where \( A, B \) are sets. Then

\[
\sup_{a \in A} \sup_{b \in B} f(a, b) = \sup_{b \in B} \sup_{a \in A} f(a, b).
\]

**Proof:** Note that for all \( a, b \), \( f(a, b) \leq \sup_{b \in B} \sup_{a \in A} f(a, b) \) and therefore, for all \( a \),

\[
\sup_{b \in B} f(a, b) \leq \sup_{b \in B} \sup_{a \in A} f(a, b).
\]

Therefore,

\[
\sup_{a \in A} \sup_{b \in B} f(a, b) \leq \sup_{b \in B} \sup_{a \in A} f(a, b).
\]

Repeating the same argument interchanging \( a \) and \( b \), gives the conclusion of the lemma.

Lemma 9.3.2 If \( \{A_n\} \) is an increasing sequence in \([-\infty, \infty]\), then

\[
\sup \{A_n\} = \lim_{n \to \infty} A_n.
\]

The following lemma is useful also and this is a good place to put it. First \( \{b_j\}_{j=1}^\infty \) is an enumeration of the \( a_{ij} \) if

\[
\bigcup_{j=1}^\infty \{b_j\} = \bigcup_{i,j=1} b_{ij}.
\]

In other words, the countable set, \( \{a_{ij}\}_{i,j=1}^\infty \) is listed as \( b_1, b_2, \ldots \).

Lemma 9.3.3 Let \( a_{ij} \geq 0 \). Then \( \sum_{i=1}^\infty \sum_{j=1}^\infty a_{ij} = \sum_{j=1}^\infty \sum_{i=1}^\infty a_{ij} \). Also if \( \{b_j\}_{j=1}^\infty \) is any enumeration of the \( a_{ij} \), then \( \sum_{j=1}^\infty b_j = \sum_{j=1}^\infty \sum_{i=1}^\infty a_{ij} \).

**Proof:** First note there is no trouble in defining these sums because the \( a_{ij} \) are all nonnegative. If a sum diverges, it only diverges to \( \infty \) and so \( \infty \) is written as the answer.

\[
\sum_{j=1}^\infty \sum_{i=1}^\infty a_{ij} \geq \sup_{n} \sum_{j=1}^n \sum_{i=1}^\infty a_{ij} = \sup_{n} \lim_{m \to \infty} \sum_{j=1}^m \sum_{i=1}^n a_{ij}
\]

\[
= \sup_{n} \lim_{m \to \infty} \sum_{i=1}^n \sum_{j=1}^m a_{ij} = \sup_{n} \sum_{i=1}^\infty \sum_{j=1}^\infty a_{ij} = \sum_{i=1}^\infty \sum_{j=1}^\infty a_{ij}.
\] (9.3.10)

Interchanging the \( i \) and \( j \) in the above argument the first part of the lemma is proved.

Finally, note that for all \( p \),

\[
\sum_{j=1}^p b_j \leq \sum_{i=1}^\infty \sum_{j=1}^\infty a_{ij}
\]

and so \( \sum_{j=1}^\infty b_j \leq \sum_{i=1}^\infty \sum_{j=1}^\infty a_{ij} \). Now let \( m, n > 1 \) be given. Then

\[
\sum_{i=1}^m \sum_{j=1}^n a_{ij} \leq \sum_{j=1}^m b_j
\]
where \( p \) is chosen large enough that \( \{b_1, \ldots, b_p\} \supseteq \{a_{ij} : i \leq m \text{ and } j \leq n\} \). Therefore, since such a \( p \) exists for any choice of \( m, n \), it follows that for any \( m, n \),

\[
\sum_{i=1}^{m} \sum_{j=1}^{n} a_{ij} \leq \sum_{j=1}^{\infty} b_{j},
\]

Therefore, taking the limit as \( n \to \infty \),

\[
\sum_{i=1}^{m} \sum_{j=1}^{\infty} a_{ij} \leq \sum_{j=1}^{\infty} b_{j}
\]

and finally, taking the limit as \( m \to \infty \),

\[
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} a_{ij} \leq \sum_{j=1}^{\infty} b_{j}
\]

proving the lemma.

### 9.3.2 The Lebesgue Integral Nonnegative Functions

The following picture illustrates the idea used to define the Lebesgue integral to be like the area under a curve.

\[ \int f \, d\mu \equiv \sup_{h>0} \sum_{i=1}^{\infty} h \mu ([ih < f]) \]

\(^1\text{Note the difference between this picture and the one usually drawn in calculus courses where the little rectangles are upright rather than on their sides. This illustrates a fundamental philosophical difference between the Riemann and the Lebesgue integrals. With the Riemann integral intervals are measured. With the Lebesgue integral, it is inverse images of intervals which are measured.} \]
Lemma 9.3.4  The following inequality holds.

\[ \sum_{i=1}^{\infty} h \mu ([ih < f]) \leq \sum_{i=1}^{\infty} \frac{h}{2} \mu \left( \left[ \frac{i}{2} < f \right] \right). \]

Also, it suffices to consider only \( h \) smaller than a given positive number in the above definition of the integral.

**Proof:**
Let \( N \in \mathbb{N} \).

\[ \sum_{i=1}^{2N} \frac{h}{2} \mu \left( \left[ \frac{i}{2} < f \right] \right) = \sum_{i=1}^{2N} \frac{h}{2} \mu ([ih < 2f]) \]

\[ = \sum_{i=1}^{N} \frac{h}{2} \mu ([2i - 1]h < 2f]) + \sum_{i=1}^{N} \frac{h}{2} \mu ([2i]h < 2f]) \]

\[ = \sum_{i=1}^{N} \frac{h}{2} \mu \left( \left[ \frac{2i - 1}{2} < f \right] \right) + \sum_{i=1}^{N} \frac{h}{2} \mu ([ih < f]) \]

\[ \geq \sum_{i=1}^{N} \frac{h}{2} \mu ([ih < f]) + \sum_{i=1}^{N} \frac{h}{2} \mu ([ih < f]) = \sum_{i=1}^{N} \frac{h}{2} \mu ([ih < f]). \]

Now letting \( N \to \infty \) yields the claim of the lemma.

To verify the last claim, suppose \( M < \int f \, d\mu \) and let \( \delta > 0 \) be given. Then there exists \( h > 0 \) such that

\[ M < \sum_{i=1}^{\infty} h \mu ([ih < f]) \leq \int f \, d\mu. \]

By the first part of this lemma,

\[ M < \sum_{i=1}^{\infty} \frac{h}{2^n} \mu \left( \left[ \frac{i}{2^n} < f \right] \right) \leq \int f \, d\mu \]

and continuing to apply the first part,

\[ M < \sum_{i=1}^{\infty} \frac{h}{2^n} \mu \left( \left[ \frac{i}{2^n} < f \right] \right) \leq \int f \, d\mu. \]

Choose \( n \) large enough that \( h/2^n < \delta \). It follows

\[ M < \sup_{\delta > h > 0} \sum_{i=1}^{\infty} h \mu ([ih < f]) \leq \int f \, d\mu. \]

Since \( M \) is arbitrary, this proves the last claim.
9.3.3 The Lebesgue Integral For Nonnegative Simple Functions

Definition 9.3.5 A function, $s$, is called simple if it is a measurable real valued function and has only finitely many values. These values will never be $±\infty$. Thus a simple function is one which may be written in the form

$$s(\omega) = \sum_{i=1}^{n} c_i \chi_{E_i}(\omega)$$

where the sets, $E_i$ are disjoint and measurable. $s$ takes the value $c_i$ at $E_i$.

Note that by taking the union of some of the $E_i$ in the above definition, you can assume that the numbers, $c_i$ are the distinct values of $s$. Simple functions are important because it will turn out to be very easy to take their integrals as shown in the following lemma.

Lemma 9.3.6 Let $s(\omega) = \sum_{i=1}^{p} a_i \chi_{E_i}(\omega)$ be a nonnegative simple function with the $a_i$ the distinct non zero values of $s$. Then

$$\int s \, d\mu = \sum_{i=1}^{p} a_i \mu(E_i). \quad (9.3.11)$$

Also, for any nonnegative measurable function, $f$, if $\lambda \geq 0$, then

$$\int \lambda f \, d\mu = \lambda \int f \, d\mu. \quad (9.3.12)$$

Proof: Consider first. Without loss of generality, you can assume $0 < a_1 < a_2 < \cdots < a_p$ and that $\mu(E_i) < \infty$. Let $\varepsilon > 0$ be given and let

$$\delta_1 \sum_{i=1}^{p} \mu(E_i) < \varepsilon.$$ 

Pick $\delta < \delta_1$ such that for $h < \delta$ it is also true that

$$h < \frac{1}{2} \min (a_1, a_2 - a_1, a_3 - a_2, \cdots, a_n - a_{n-1}).$$

Then for $0 < h < \delta$

$$\sum_{k=1}^{\infty} h \mu([s > kh]) = \sum_{k=1}^{\infty} h \sum_{i=k}^{\infty} \mu([ih < s \leq (i+1)h])$$

$$= \sum_{i=1}^{\infty} (i \sum_{k=1}^{i} \mu([ih < s \leq (i+1)h]))$$

$$= \sum_{i=1}^{\infty} ih \mu([ih < s \leq (i+1)h]). \quad (9.3.13)$$
Because of the choice of $h$ there exist positive integers, $i_k$ such that $i_1 < i_2 < \cdots < i_p$ and
\[ i_1 h < a_1 \leq (i_1 + 1) h < \cdots < i_2 h < a_2 < \cdots < i_p h < a_p \leq (i_p + 1) h. \]

Then in the sum of Exercise 9.3.13 the only terms which are nonzero are those for which $i \in \{i_1, i_2, \ldots, i_p\}$. To see this, you might consider the following picture.

When $ih$ and $(i+1)h$ are both in between two of the $a_i$ the set $[ih < s \leq (i + 1)h]$ must be empty because the only values of the function are one of the $a_i$. At an $i_k$, $i_k h$ is smaller than $a_k$ while $(i_k + 1)h$ is at least as large. Therefore, the set $[ih < s \leq (i + 1)h]$ equals $E_k$ and so
\[ \mu([i_k h < s \leq (i_k + 1)h]) = \mu(E_k). \]

Therefore,
\[ \sum_{k=1}^{\infty} h \mu([s > kh]) = \sum_{k=1}^{p} i_k h \mu(E_k). \]

It follows that for all $h$ this small,
\[ 0 < \sum_{k=1}^{p} a_k \mu(E_k) - \sum_{k=1}^{\infty} h \mu([s > kh]) = \sum_{k=1}^{p} a_k \mu(E_k) - \sum_{k=1}^{p} i_k h \mu(E_k) \leq h \sum_{k=1}^{p} \mu(E_k) < \varepsilon. \]

Taking the inf for $h$ this small and using Lemma 9.3.4,
\[ 0 \leq \sum_{k=1}^{p} a_k \mu(E_k) - \sup_{\delta > 0} \sum_{k=1}^{\infty} h \mu([s > kh]) = \sum_{k=1}^{p} a_k \mu(E_k) - \int sd\mu \leq \varepsilon. \]

Since $\varepsilon > 0$ is arbitrary, this proves the first part.
To verify note the formula is obvious if \( \lambda = 0 \) because then \( [ih < \lambda f] = \emptyset \) for all \( i > 0 \). Assume \( \lambda > 0 \). Then

\[
\int \lambda f \, d\mu = \sup_{h > 0} \sum_{i=1}^{\infty} h \mu ([ih < \lambda f])
\]

\[
= \sup_{h > 0} \sum_{i=1}^{\infty} h \mu ([ih/\lambda < f])
\]

\[
= \sup_{h > 0} \lambda \sum_{i=1}^{\infty} (h/\lambda) \mu ([i (h/\lambda) < f])
\]

\[
= \lambda \int f \, d\mu.
\]

This proves the lemma.

**Lemma 9.3.7** Let the nonnegative simple function, \( s \) be defined as

\[
s(\omega) = \sum_{i=1}^{n} c_i \chi_{E_i}(\omega)
\]

where the \( c_i \) are not necessarily distinct but the \( E_i \) are disjoint. It follows that

\[
\int s = \sum_{i=1}^{n} c_i \mu(E_i).
\]

**Proof:** Let the values of \( s \) be \( \{a_1, \ldots, a_m\} \). Therefore, since the \( E_i \) are disjoint, each \( a_i \) equal to one of the \( c_j \). Let \( A_i = \bigcup\{E_j : c_j = a_i\} \). Then from Lemma 9.3.6 it follows that

\[
\int s = \sum_{i=1}^{m} a_i \mu(A_i) = \sum_{i=1}^{m} a_i \sum_{\{j : c_j = a_i\}} \mu(E_j)
\]

\[
= \sum_{i=1}^{m} \sum_{\{j : c_j = a_i\}} c_j \mu(E_j) = \sum_{i=1}^{n} c_i \mu(E_i).
\]

This proves the lemma.

Note that \( \int s \) could equal \( +\infty \) if \( \mu(A_k) = \infty \) and \( a_k > 0 \) for some \( k \), but \( \int s \) is well defined because \( s \geq 0 \). Recall that \( 0 \cdot \infty = 0 \).

**Lemma 9.3.8** If \( a, b \geq 0 \) and if \( s \) and \( t \) are nonnegative simple functions, then

\[
\int as + bt = a \int s + b \int t.
\]

**Proof:** Let

\[
s(\omega) = \sum_{i=1}^{n} \alpha_i \chi_{A_i}(\omega), \quad t(\omega) = \sum_{i=1}^{m} \beta_j \chi_{B_i}(\omega)
\]
where \( \alpha_i \) are the distinct values of \( s \) and the \( \beta_j \) are the distinct values of \( t \). Clearly \( as + bt \) is a nonnegative simple function because it is measurable and has finitely many values. Also,

\[
(as + bt)(\omega) = \sum_{j=1}^{m} \sum_{i=1}^{n} (a\alpha_i + b\beta_j) \mathcal{X}_{A_i \cap B_j}(\omega)
\]

where the sets \( A_i \cap B_j \) are disjoint. By Lemma 9.3.7,

\[
\int as + bt = \sum_{j=1}^{m} \sum_{i=1}^{n} (a\alpha_i + b\beta_j) \mu(A_i \cap B_j)
\]

\[
= a \sum_{i=1}^{n} \alpha_i \mu(A_i) + b \sum_{j=1}^{m} \beta_j \mu(B_j)
\]

\[
= a \int s + b \int t.
\]

This proves the lemma.

9.3.4 Simple Functions And Measurable Functions

There is a fundamental theorem about the relationship of simple functions to measurable functions given in the next theorem.

**Theorem 9.3.9** Let \( f \geq 0 \) be measurable. Then there exists a sequence of nonnegative simple functions \( \{s_n\} \) satisfying

\[
0 \leq s_n(\omega)
\]

\[
\cdots s_n(\omega) \leq s_{n+1}(\omega) \cdots
\]

\[
f(\omega) = \lim_{n \to \infty} s_n(\omega) \text{ for all } \omega \in \Omega.
\]

If \( f \) is bounded the convergence is actually uniform.

**Proof:** Letting \( I \equiv \{ \omega : f(\omega) = \infty \} \), define

\[
t_n(\omega) = \sum_{k=0}^{2^n} \frac{k}{n} \mathcal{X}_{[k/n, \infty)}(\omega) + n \mathcal{X}_I(\omega).
\]

Then \( t_n(\omega) \leq f(\omega) \) for all \( \omega \) and \( \lim_{n \to \infty} t_n(\omega) = f(\omega) \) for all \( \omega \). This is because \( t_n(\omega) = n \) for \( \omega \in I \) and if \( f(\omega) \in [0, \frac{2^n + 1}{n}] \), then

\[
0 \leq f(\omega) - t_n(\omega) \leq \frac{1}{n}.
\]

Thus whenever \( \omega \notin I \), the above inequality will hold for all \( n \) large enough. Let

\[
s_1 = t_1, \ s_2 = \max (t_1, t_2), \ s_3 = \max (t_1, t_2, t_3), \cdots.
\]
Then the sequence \( \{s_n\} \) satisfies (9.3.14).

To verify the last claim, note that in this case the term \( n\mathcal{X}_j(\omega) \) is not present. Therefore, for all \( n \) large enough, (9.3.10) holds for all \( \omega \). Thus the convergence is uniform. This proves the theorem.

Although it is not needed here, there is a similar theorem which applies to measurable functions which have values in a separable metric space. In this context, a simple function is one which is of the form

\[
\sum_{k=1}^{m} x_k \chi_{E_k}(\omega)
\]

where the \( E_k \) are disjoint measurable sets and the \( x_k \) are in \( X \). I am abusing notation somewhat by using a sum. You can’t add in a general metric space. The symbol means the function has value \( x_k \) on the set \( E_k \).

**Theorem 9.3.10** Let \((\Omega, F)\) be a measure space and let \( f : \Omega \to X \) where \((X,d)\) is a separable metric space. Then \( f \) is a measurable function if and only if there exists a sequence of simple functions, \( \{f_n\} \) such that for each \( \omega \in \Omega \) and \( n \in \mathbb{N} \),

\[
d(f_n(\omega), f(\omega)) \geq d(f_{n+1}(\omega), f(\omega)) \tag{9.3.17}
\]

and

\[
\lim_{n \to \infty} d(f_n(\omega), f(\omega)) = 0. \tag{9.3.18}
\]

**Proof:** Let \( D = \{x_k\}_{k=1}^{\infty} \) be a countable dense subset of \( X \). First suppose \( f \) is measurable. Then since in a metric space every open set is the countable intersection of closed sets, it follows \( f^{-1}(\text{closed set}) \subset F \). Now let \( D_n = \{x_k\}_{k=1}^{n} \). Let

\[
A_1 = \left\{ \omega : d(x_1, f(\omega)) = \min_{k \leq n} d(x_k, f(\omega)) \right\}
\]

That is, \( A_1 \) are those \( \omega \) such that \( f(\omega) \) is approximated best out of \( D_n \) by \( x_1 \). Why is this a measurable set? It is because \( \omega \to d(x, f(\omega)) \) is a real valued measurable function, being the composition of a continuous function, \( y \to d(x, y) \) and a measurable function, \( \omega \to f(\omega) \). Next let

\[
A_2 = \left\{ \omega \notin A_1 : d(x_2, f(\omega)) = \min_{k \leq n} d(x_k, f(\omega)) \right\}
\]

and continue in this manner obtaining disjoint measurable sets, \( \{A_k\}_{k=1}^{n} \) such that for \( \omega \in A_k \) the best approximation to \( f(\omega) \) from \( D_n \) is \( x_k \). Then

\[
 f_n(\omega) = \sum_{k=1}^{n} x_k \chi_{A_k}(\omega).
\]

Note

\[
\min_{k \leq n+1} d(x_k, f(\omega)) \leq \min_{k \leq n} d(x_k, f(\omega))
\]
and so this verifies (9.3.17). It remains to verify (9.3.18).

Let \( \varepsilon > 0 \) be given and pick \( \omega \in \Omega \). Then there exists \( x_n \in D \) such that \( d(x_n, f(\omega)) < \varepsilon \). It follows from the construction that \( d(f_n(\omega), f(\omega)) \leq d(x_n, f(\omega)) < \varepsilon \). This proves the first half.

Now suppose the existence of the sequence of simple functions as described above. Each \( f_n \) is a measurable function because \( f_1 \) is measurable and \( f_n = \chi_{A_k : x_k \in U} \). Therefore, the conclusion that \( f \) is measurable follows from Theorem (9.1.9) on Page 211.

In the context of this more general notion of measurable function having values in a metric space, here is a version of Egoroff’s theorem.

**Theorem 9.3.11 (Egoroff)** Let \((\Omega, F, \mu)\) be a finite measure space, \((\mu(\Omega) < \infty)\)

and let \( f_n, f \) be \( X \) valued measurable functions where \( X \) is a separable metric space and for all \( \omega \notin E \) where \( \mu(E) = 0 \)

\[
f_n(\omega) \to f(\omega)
\]

Then for every \( \varepsilon > 0 \), there exists a set,

\[
F \supseteq E, \mu(F) < \varepsilon,
\]

such that \( f_n \) converges uniformly to \( f \) on \( F^c \).

**Proof:** First suppose \( E = \emptyset \) so that convergence is pointwise everywhere. Let

\[
E_{km} = \{ \omega \in \Omega : d(f_n(\omega), f(\omega)) \geq 1/m \text{ for some } n > k \}.
\]

**Claim:** \([\omega : d(f_n(\omega), f(\omega)) \geq \frac{1}{m}]\) is measurable.

**Proof of claim:** Let \( \{x_k\}_{k=1}^\infty \) be a countable dense subset of \( X \) and let \( r \) denote a positive rational number, \( \mathbb{Q}^+ \). Then

\[
\bigcup_{k \in \mathbb{N}, r \in \mathbb{Q}^+} f_n^{-1}(B(x_k, r)) \cap f^{-1}

\left(B\left(x_k, \frac{1}{m} - r\right)\right)
\]

\[
= \left[ d(f, f_n) < \frac{1}{m} \right] \quad (9.3.19)
\]

Here is why. If \( \omega \) is in the set on the left, then \( d(f_n(\omega), x_k) < r \) and

\[
d(f(\omega), x_k) < \frac{1}{m} - r.
\]

Therefore,

\[
d(f(\omega), f_n(\omega)) < r + \frac{1}{m} - r = \frac{1}{m}.
\]
Thus the left side is contained in the right. Now let $\omega$ be in the right side. That is $d(f_n(\omega), f(\omega)) < \frac{1}{m}$. Choose $2r < \frac{1}{m} - d(f_n(\omega), f(\omega))$ and pick $x_k \in B(f_n(\omega), r)$. Then

$$d(f(\omega), x_k) \leq d(f(\omega), f_n(\omega)) + d(f_n(\omega), x_k) < \frac{1}{m} - 2r + r = \frac{1}{m} - r$$

Thus $\omega \in f_n^{-1}(B(x_k, r)) \cap f^{-1}(B(x_k, \frac{1}{m} - r))$ and so $\omega$ is in the left side. Thus the two sets are equal. Now the set on the left in 9.3.19 is measurable because it is a countable union of measurable sets. This proves the claim since

$$\left[ \omega : d(f_n(\omega), f(\omega)) \geq \frac{1}{m} \right]$$

is the complement of this measurable set.

Hence $E_{km}$ is measurable because

$$E_{km} = \bigcup_{n=k+1}^{\infty} \left[ \omega : d(f_n(\omega), f(\omega)) \geq \frac{1}{m} \right].$$

For fixed $m$, $\bigcap_{k=1}^{\infty} E_{km} = \emptyset$ because $f_n(\omega)$ converges to $f(\omega)$. Therefore, if $\omega \in \Omega$ there exists $k$ such that if $n > k$, $|f_n(\omega) - f(\omega)| < \frac{1}{m}$ which means $\omega \notin E_{km}$. Note also that

$$E_{km} \supseteq E_{(k+1)m}.$$ 

Since $\mu(E_{1m}) < \infty$, Theorem 9.1.5 on Page 208 implies

$$0 = \mu(\bigcap_{k=1}^{\infty} E_{km}) = \lim_{k \to \infty} \mu(E_{km}).$$

Let $k(m)$ be chosen such that $\mu(E_{k(m)m}) < \varepsilon 2^{-m}$ and let

$$F = \bigcup_{m=1}^{\infty} E_{k(m)m}.$$ 

Then $\mu(F) < \varepsilon$ because

$$\mu(F) \leq \sum_{m=1}^{\infty} \mu(E_{k(m)m}) < \sum_{m=1}^{\infty} \varepsilon 2^{-m} = \varepsilon$$

Now let $\eta > 0$ be given and pick $m_0$ such that $m_0^{-1} < \eta$. If $\omega \in F^C$, then

$$\omega \in \bigcap_{m=1}^{\infty} E_{k(m)m}^C.$$ 

Hence $\omega \in E_{k(m_0)m_0}^C$ so

$$d(f(\omega), f_n(\omega)) < 1/m_0 < \eta$$
for all $n > k(m_0)$. This holds for all $\omega \in F^C$ and so $f_n$ converges uniformly to $f$ on $F^C$.

Now if $E \neq \emptyset$, consider $\{X_{EC} f_n\}_{n=1}^{\infty}$. Then $X_{EC} f_n$ is measurable and the sequence converges pointwise to $X_E f$ everywhere. Therefore, from the first part, there exists a set of measure less than $\varepsilon, F$ such that on $F^C$, $\{X_{EC} f_n\}$ converges uniformly to $X_{EC} f$. Therefore, on $(E \cup F)^C$, $\{f_n\}$ converges uniformly to $f$. This proves the theorem.

9.3.5 The Monotone Convergence Theorem

The following is called the monotone convergence theorem. This theorem and related convergence theorems are the reason for using the Lebesgue integral.

**Theorem 9.3.12 (Monotone Convergence theorem)** Let $f$ have values in $[0, \infty]$ and suppose $\{f_n\}$ is a sequence of nonnegative measurable functions having values in $[0, \infty]$ and satisfying

$$
\lim_{n \to \infty} f_n(\omega) = f(\omega) \text{ for each } \omega.
$$

Then $f$ is measurable and

$$
\int f d\mu = \lim_{n \to \infty} \int f_n d\mu.
$$

**Proof:** From Lemmas 9.3.1 and 9.3.2,

$$
\int f d\mu = \sup_{h > 0} \sum_{i=1}^{\infty} h \mu([ih < f])
= \sup_{h > 0} \sup_{k} \sum_{i=1}^{k} h \mu([ih < f])
= \sup_{k} \sup_{h > 0} \sum_{i=1}^{k} h \mu([ih < f_m])
= \sup_{m} \sup_{h > 0} \sum_{i=1}^{\infty} h \mu([ih < f_m])
= \sup_{m} \int f_m d\mu
= \lim_{m \to \infty} \int f_m d\mu.
$$

The third equality follows from the observation that

$$
\lim_{m \to \infty} \mu([ih < f_m]) = \mu([ih < f])
$$
CHAPTER 9. ABSTRACT MEASURE AND INTEGRATION

which follows from Theorem 9.1.5 since the sets, \([ih < f_n]\) are increasing in \(m\) and their union equals \([ih < f]\). This proves the theorem.

To illustrate what goes wrong without the Lebesgue integral, consider the following example.

**Example 9.3.13** Let \(\{r_n\}\) denote the rational numbers in \([0, 1]\) and let

\[
  f_n(t) = \begin{cases} 
  1 & \text{if } t \notin \{r_1, \ldots, r_n\} \\
  0 & \text{otherwise} 
  \end{cases}
\]

Then \(f_n(t) \uparrow f(t)\) where \(f\) is the function which is one on the rationals and zero on the irrationals. Each \(f_n\) is Riemann integrable (why?) but \(f\) is not Riemann integrable. Therefore, you can’t write \(\int f \, dx = \lim_{n \to \infty} \int f_n \, dx\).

A meta-mathematical observation related to this type of example is this. If you can choose your functions, you don’t need the Lebesgue integral. The Riemann integral is just fine. It is when you can’t choose your functions and they come to you as pointwise limits that you really need the superior Lebesgue integral or at least something more general than the Riemann integral. The Riemann integral is entirely adequate for evaluating the seemingly endless lists of boring problems found in calculus books.

**9.3.6 Other Definitions**

To review and summarize the above, if \(f \geq 0\) is measurable,

\[
\int f \, d\mu = \sup_{k > 0} \sum_{i=1}^{\infty} h \mu ([f > ih])
\]

(9.3.20)

another way to get the same thing for \(\int f \, d\mu\) is to take an increasing sequence of nonnegative simple functions, \(\{s_n\}\) with \(s_n(\omega) \to f(\omega)\) and then by monotone convergence theorem,

\[
\int f \, d\mu = \lim_{n \to \infty} \int s_n
\]

where if \(s_n(\omega) = \sum_{j=1}^{m} c_j \chi_{E_j}(\omega)\),

\[
\int s_n \, d\mu = \sum_{i=1}^{m} c_i m(E_i).
\]

Similarly this also shows that for such nonnegative measurable function,

\[
\int f \, d\mu = \sup \left\{ \int s : 0 \leq s \leq f, \ s \text{ simple} \right\}
\]

which is the usual way of defining the Lebesgue integral for nonnegative simple functions in most books. I have done it differently because this approach led to an easier proof of the Monotone convergence theorem. Here is an equivalent definition of the integral. The fact it is well defined has been discussed above.
9.3. THE ABSTRACT LEBESGUE INTEGRAL

Definition 9.3.14 For $s$ a nonnegative simple function,

$$s(\omega) = \sum_{k=1}^{n} c_k X_{E_k}(\omega), \quad \int s = \sum_{k=1}^{n} c_k \mu(E_k).$$

For $f$ a nonnegative measurable function,

$$\int f d\mu = \sup \left\{ \int s : 0 \leq s \leq f, \ s \text{ simple} \right\}.$$

9.3.7 Fatou’s Lemma

Sometimes the limit of a sequence does not exist. There are two more general notions known as $\limsup$ and $\liminf$ which do always exist in some sense. These notions are dependent on the following lemma.

Lemma 9.3.15 Let $\{a_n\}$ be an increasing (decreasing) sequence in $[\infty, \infty]$. Then $\lim_{n \to \infty} a_n$ exists.

Proof: Suppose first $\{a_n\}$ is increasing. Recall this means $a_n \leq a_{n+1}$ for all $n$. If the sequence is bounded above, then it has a least upper bound and so $a_n \to a$ where $a$ is its least upper bound. If the sequence is not bounded above, then for every $l \in \mathbb{R}$, it follows $l$ is not an upper bound and so eventually, $a_n > l$. But this is what is meant by $a_n \to \infty$. The situation for decreasing sequences is completely similar.

Now take any sequence, $\{a_n\} \subseteq [-\infty, \infty]$ and consider the sequence $\{A_n\}$ where

$$A_n = \inf \{a_k : k \geq n\}.$$ 

Then as $n$ increases, the set of numbers whose inf is being taken is getting smaller. Therefore, $A_n$ is an increasing sequence and so it must converge. Similarly, if $B_n = \sup \{a_k : k \geq n\}$, it follows $B_n$ is decreasing and so $\{B_n\}$ also must converge. With this preparation, the following definition can be given.

Definition 9.3.16 Let $\{a_n\}$ be a sequence of points in $[-\infty, \infty]$. Then define

$$\lim \inf_{n \to \infty} a_n = \lim \inf_{n \to \infty} \{a_k : k \geq n\}$$

and

$$\lim \sup_{n \to \infty} a_n = \lim \sup_{n \to \infty} \{a_k : k \geq n\}$$

In the case of functions having values in $[-\infty, \infty]$,

$$\left(\lim \inf_{n \to \infty} f_n\right)(\omega) = \lim \inf_{n \to \infty} (f_n(\omega)).$$

A similar definition applies to $\lim \sup_{n \to \infty} f_n$. 
Lemma 9.3.17 Let \( \{a_n\} \) be a sequence in \([\infty, \infty]\). Then \( \lim_{n \to \infty} a_n \) exists if and only if
\[
\lim_{n \to \infty} \inf a_n = \lim_{n \to \infty} \sup a_n
\]
and in this case, the limit equals the common value of these two numbers.

Proof: Suppose first \( \lim_{n \to \infty} a_n = a \in \mathbb{R} \). Then, letting \( \varepsilon > 0 \) be given, \( a_n \in (a - \varepsilon, a + \varepsilon) \) for all \( n \) large enough, say \( n \geq N \). Therefore, both \( \inf \{a_k : k \geq n\} \) and \( \sup \{a_k : k \geq n\} \) are contained in \([a - \varepsilon, a + \varepsilon]\) whenever \( n \geq N \). It follows \( \limsup_{n \to \infty} a_n \) and \( \liminf_{n \to \infty} a_n \) are both in \([a - \varepsilon, a + \varepsilon]\), showing
\[
\lim_{n \to \infty} \inf a_n - \limsup_{n \to \infty} a_n < 2\varepsilon.
\]
Since \( \varepsilon \) is arbitrary, the two must be equal and they both must equal \( a \). Next suppose \( \lim_{n \to \infty} a_n = \infty \). Then if \( l \in \mathbb{R} \), there exists \( N \) such that for \( n \geq N \),
\[
l \leq a_n
\]
and therefore, for such \( n \),
\[
l \leq \inf \{a_k : k \geq n\} \leq \sup \{a_k : k \geq n\}
\]
and this shows, since \( l \) is arbitrary that
\[
\lim_{n \to \infty} \inf a_n = \limsup_{n \to \infty} a_n = \infty.
\]
The case for \( -\infty \) is similar.

Conversely, suppose \( \liminf_{n \to \infty} a_n = \limsup_{n \to \infty} a_n = a \). Suppose first that \( a \in \mathbb{R} \). Then, letting \( \varepsilon > 0 \) be given, there exists \( N \) such that if \( n \geq N \),
\[
\sup \{a_k : k \geq n\} - \inf \{a_k : k \geq n\} < \varepsilon
\]
therefore, if \( k, m > N \), and \( a_k > a_m \),
\[
|a_k - a_m| = a_k - a_m \leq \sup \{a_k : k \geq n\} - \inf \{a_k : k \geq n\} < \varepsilon
\]
showing that \( \{a_n\} \) is a Cauchy sequence. Therefore, it converges to \( a \in \mathbb{R} \), and as in the first part, the \( \liminf \) and \( \limsup \) both equal \( a \). If \( \liminf_{n \to \infty} a_n = \limsup_{n \to \infty} a_n = \infty \), then given \( l \in \mathbb{R} \), there exists \( N \) such that for \( n \geq N \),
\[
\inf_{n>N} a_n > l.
\]
Therefore, \( \lim_{n \to \infty} a_n = \infty \). The case for \( -\infty \) is similar. This proves the lemma.

The next theorem, known as Fatou’s lemma is another important theorem which justifies the use of the Lebesgue integral.
**Theorem 9.3.18** *(Fatou's lemma) Let \( f_n \) be a nonnegative measurable function with values in \([0, \infty]\). Let \( g(\omega) = \lim \inf_{n \to \infty} f_n(\omega) \). Then \( g \) is measurable and
\[
\int g d\mu \leq \lim \inf_{n \to \infty} \int f_n d\mu.
\]
In other words,
\[
\int \left( \lim \inf_{n \to \infty} f_n \right) d\mu \leq \lim \inf_{n \to \infty} \int f_n d\mu.
\]

**Proof:** Let \( g_n(\omega) = \inf \{ f_k(\omega) : k \geq n \} \). Then
\[
g_n^{-1}(\{a, \infty]\}) = \bigcap_{k=n}^{\infty} f_k^{-1}(\{a, \infty]\}) \in \mathcal{F}.
\]
Thus \( g_n \) is measurable by Lemma 9.1.6 on Page 210. Also \( g(\omega) = \lim_{n \to \infty} g_n(\omega) \) so \( g \) is measurable because it is the pointwise limit of measurable functions. Now the functions \( g_n \) form an increasing sequence of nonnegative measurable functions so the monotone convergence theorem applies. This yields
\[
\int g d\mu = \lim_{n \to \infty} \int g_n d\mu \leq \lim \inf_{n \to \infty} \int f_n d\mu.
\]
The last inequality holding because
\[
\int g_n d\mu \leq \int f_n d\mu.
\]
(Note that it is not known whether \( \lim_{n \to \infty} \int f_n d\mu \) exists.) This proves the theorem.

### 9.3.8 The Righteous Algebraic Desires Of The Lebesgue Integral

The monotone convergence theorem shows the integral wants to be linear. This is the essential content of the next theorem.

**Theorem 9.3.19** Let \( f, g \) be nonnegative measurable functions and let \( a, b \) be nonnegative numbers. Then
\[
\int (af + bg) d\mu = a \int f d\mu + b \int g d\mu.
\]  

**Proof:** By Theorem 9.3.9 on Page 227 there exist sequences of nonnegative simple functions, \( s_n \to f \) and \( t_n \to g \). Then by the monotone convergence theorem and Lemma 9.3.8,
\[
\int (af + bg) d\mu = \lim_{n \to \infty} \int as_n + bt_n d\mu
\]
\[
= \lim_{n \to \infty} \left( a \int s_n d\mu + b \int t_n d\mu \right)
\]
\[
= a \int f d\mu + b \int g d\mu.
\]
As long as you are allowing functions to take the value $+\infty$, you cannot consider something like $f + (-g)$ and so you can’t very well expect a satisfactory statement about the integral being linear until you restrict yourself to functions which have values in a vector space. This is discussed next.

### 9.4 The Space $L^1$

The functions considered here have values in $\mathbb{C}$, a vector space.

**Definition 9.4.1** Let $(\Omega, S, \mu)$ be a measure space and suppose $f : \Omega \rightarrow \mathbb{C}$. Then $f$ is said to be measurable if both $\text{Re} f$ and $\text{Im} f$ are measurable real valued functions.

**Definition 9.4.2** A complex simple function will be a function which is of the form

$$s(\omega) = \sum_{k=1}^{n} c_k \mathcal{X}_{E_k}(\omega)$$

where $c_k \in \mathbb{C}$ and $\mu(E_k) < \infty$. For $s$ a complex simple function as above, define

$$I(s) = \sum_{k=1}^{n} c_k \mu(E_k).$$

**Lemma 9.4.3** The definition, is well defined. Furthermore, $I$ is linear on the vector space of complex simple functions. Also the triangle inequality holds,

$$|I(s)| \leq I(|s|).$$

**Proof:** Suppose $\sum_{k=1}^{n} c_k \mathcal{X}_{E_k}(\omega) = 0$. Does it follow that $\sum_{k=1}^{n} c_k \mu(E_k) = 0$?

The supposition implies

$$\sum_{k=1}^{n} \text{Re} c_k \mathcal{X}_{E_k}(\omega) = 0, \quad \sum_{k=1}^{n} \text{Im} c_k \mathcal{X}_{E_k}(\omega) = 0. \quad (9.4.22)$$

Choose $\lambda$ large and positive so that $\lambda + \text{Re} c_k \geq 0$. Then adding $\sum_{k=1}^{n} \lambda \mathcal{X}_{E_k}$ to both sides of the first equation above,

$$\sum_{k=1}^{n} (\lambda + \text{Re} c_k) \mathcal{X}_{E_k} (\omega) = \sum_{k=1}^{n} \lambda \mathcal{X}_{E_k}$$

and by Lemma [Section 9.3.8 on Page 224] it follows upon taking $f$ of both sides that

$$\sum_{k=1}^{n} (\lambda + \text{Re} c_k) \mu(E_k) = \sum_{k=1}^{n} \lambda \mu(E_k)$$
which implies $\sum_{k=1}^{n} \text{Re} c_k \mu (E_k) = 0$. Similarly, $\sum_{k=1}^{n} \text{Im} c_k \mu (E_k) = 0$ and so $\sum_{k=1}^{n} c_k \mu (E_k) = 0$. Thus if

$$\sum_{j} c_j \chi_{E_j} = \sum_{k} d_k \chi_{F_k}$$

then $\sum_{j} c_j \chi_{E_j} + \sum_{k} (-d_k) \chi_{F_k} = 0$ and so the result just established verifies $\sum_{j} c_j \mu (E_j) - \sum_{k} d_k \mu (F_k) = 0$ which proves $I$ is well defined.

That $I$ is linear is now obvious. It only remains to verify the triangle inequality. Let $s$ be a simple function,

$$s = \sum_{j} c_j \chi_{E_j}$$

Then pick $\theta \in \mathbb{C}$ such that $\theta I (s) = |I (s)|$ and $|\theta| = 1$. Then from the triangle inequality for sums of complex numbers,

$$|I (s)| = \theta I (s) = I (\theta s) = \sum_{j} \theta c_j \mu (E_j)$$

$$= \left| \sum_{j} \theta c_j \mu (E_j) \right| \leq \sum_{j} |\theta c_j| \mu (E_j) = I (|s|).$$

This proves the lemma.

With this lemma, the following is the definition of $L^1(\Omega)$.

**Definition 9.4.4** $f \in L^1(\Omega)$ means there exists a sequence of complex simple functions, $\{s_n\}$ such that

$$s_n (\omega) \to f (\omega) \text{ for all } \omega \in \Omega$$

$$\lim_{m,n \to \infty} I (|s_n - s_m|) = \lim_{m,n \to \infty} \int |s_n - s_m| \, d\mu = 0 \quad (9.4.23)$$

Then

$$I (f) \equiv \lim_{n \to \infty} I (s_n). \quad (9.4.24)$$

**Lemma 9.4.5** *Definition 9.4.4* is well defined.

**Proof:** There are several things which need to be verified. First suppose $I$ is well defined. Then by Lemma 9.4.3

$$|I (s_n) - I (s_m)| = |I (s_n - s_m)| \leq I (|s_n - s_m|)$$

and for $m, n$ large enough this last is given to be small so $\{I (s_n)\}$ is a Cauchy sequence in $\mathbb{C}$ and so it converges. This verifies the limit in $I$ at least exists. It remains to consider another sequence $\{t_n\}$ having the same properties as $\{s_n\}$ and
verifying $I(f)$ determined by this other sequence is the same. By Lemma [9.4.6] and Fatou’s lemma, Theorem [9.3.18] on Page 235, $\int j I(s_n) I(f) I(t_n) = \int j I(s_n I(f) I(t_n) = \int f f d \mu$

whenever $n$ is large enough. Since $\varepsilon$ is arbitrary, this shows the limit from using the $t_n$ is the same as the limit from using $s_n$. This proves the lemma.

What if $f$ has values in $[0, 1]$? Earlier $\int f d \mu$ was defined for such functions and now $I(f)$ has been defined. Are they the same? If so, $I$ can be regarded as an extension of $\int f d \mu$ to a larger class of functions.

**Lemma 9.4.6** Suppose $f$ has values in $[0, 1]$ and $f \in L^1(\Omega)$. Then $f$ is measurable and

$$ I(f) = \int f d \mu. $$

**Proof:** Since $f$ is the pointwise limit of a sequence of complex simple functions, $\{s_n\}$ having the properties described in Definition [9.4.4], it follows $f(\omega) = \lim_{n \to \infty} \text{Re} s_n(\omega)$ and so $f$ is measurable. Also

$$ \int \left| (\text{Re} s_n)^+ - (\text{Re} s_m)^+ \right| d \mu \leq \int |\text{Re} s_n - \text{Re} s_m| d \mu \leq \int |s_n - s_m| d \mu $$

where $x^+ \equiv \frac{1}{2}(|x| + x)$, the positive part of the real number, $x$. Thus there is no loss of generality in assuming $\{s_n\}$ is a sequence of complex simple functions having values in $[0, 1)$. Then since for such complex simple functions, $I(s) = \int s d \mu$,

$$ |I(f) - \int f d \mu| \leq |I(f) - I(s_n)| + \int s_n d \mu - \int f d \mu $$

$$ < \varepsilon + \int_{[s_n - f \geq 0]} s_n d \mu - \int_{[s_n - f \geq 0]} f d \mu $$

$$ + \int_{[s_n - f < 0]} s_n d \mu - \int_{[s_n - f < 0]} f d \mu $$

$$ \leq \varepsilon + \int_{[s_n - f \geq 0]} (s_n - f) d \mu + \int_{[s_n - f < 0]} (s_n - f) d \mu $$

$^2$The negative part of the real number $x$ is defined to be $x^- \equiv \frac{1}{2}(|x| - x)$. Thus $|x| = x^+ + x^-$ and $x = x^+ - x^-$. .
9.4. THE SPACE $L^1$

\[
\leq \varepsilon + \int_{[s_n-f\geq 0]} |s_n-f| \, d\mu + \int_{[s_n-f>0]} |s_n-f| \, d\mu
\]
\[
= \varepsilon + \int |s_n-f| \, d\mu
\]
whenever $n$ is large enough. But by Fatou’s lemma, Theorem 9.3.18 on Page 239, the last term is no larger than

\[
\lim \inf_{k \to \infty} \int |s_n-s_k| \, d\mu < \varepsilon
\]
whenever $n$ is large enough. Since $\varepsilon$ is arbitrary, this shows $I(f) = \int f \, d\mu$ as claimed.

As explained above, $I$ can be regarded as an extension of $\int d\mu$ so from now on, the usual symbol, $\int d\mu$ will be used. It is now easy to verify $\int d\mu$ is linear on $L^1(\Omega)$.

**Theorem 9.4.7** $\int d\mu$ is linear on $L^1(\Omega)$ and $L^1(\Omega)$ is a complex vector space. If $f \in L^1(\Omega)$, then $\text{Re} f, \text{Im} f,$ and $|f|$ are all in $L^1(\Omega)$. Furthermore, for $f \in L^1(\Omega),$

\[
\int f \, d\mu = \int (\text{Re} f)^+ \, d\mu - \int (\text{Re} f)^- \, d\mu + i \left( \int (\text{Im} f)^+ \, d\mu - \int (\text{Im} f)^- \, d\mu \right)
\]
Also the triangle inequality holds,

\[
\left| \int f \, d\mu \right| \leq \int |f| \, d\mu
\]

**Proof:** First it is necessary to verify that $L^1(\Omega)$ is really a vector space because it makes no sense to speak of linear maps without having these maps defined on a vector space. Let $f, g$ be in $L^1(\Omega)$ and let $a, b \in \mathbb{C}$. Then let $\{s_n\}$ and $\{t_n\}$ be sequences of complex simple functions associated with $f$ and $g$ respectively as described in Definition 9.4.4. Consider $\{as_n + bt_n\}$, another sequence of complex simple functions. Then $as_n(\omega) + bt_n(\omega) \to a f(\omega) + bg(\omega)$ for each $\omega$. Also, from Lemma 9.4.3,

\[
\int |as_n + bt_n - (as_m + bt_m)| \, d\mu \leq |a| \int |s_n-s_m| \, d\mu + |b| \int |t_n-t_m| \, d\mu
\]
and the sum of the two terms on the right converge to zero as $m,n \to \infty$. Thus $af + bg \in L^1(\Omega)$. Also

\[
\int (af + bg) \, d\mu = \lim_{n \to \infty} \int (as_n + bt_n) \, d\mu
\]
\[
= \lim_{n \to \infty} \left( a \int s_n \, d\mu + b \int t_n \, d\mu \right)
\]
\[
= a \lim_{n \to \infty} \int s_n \, d\mu + b \lim_{n \to \infty} \int t_n \, d\mu
\]
\[
= a \int f \, d\mu + b \int g \, d\mu.
\]
If \( \{s_n\} \) is a sequence of complex simple functions described in Definition 9.4.4 corresponding to \( f \), then \( \{|s_n|\} \) is a sequence of complex simple functions satisfying the conditions of Definition 9.4.4 corresponding to \( |f| \). This is because \( |s_n(\omega)| \to |f(\omega)| \) and
\[
\int |s_n - s_m| \, d\mu \leq \int |s_m - s_n| \, d\mu
\]
with this last expression converging to 0 as \( m, n \to \infty \). Thus \( |f| \in L^1(\Omega) \). Also, by similar reasoning, \( \{\text{Re } s_n\} \) and \( \{\text{Im } s_n\} \) correspond to \( \text{Re } f \) and \( \text{Im } f \) respectively in the manner described by Definition 9.4.4 showing that \( \text{Re } f \) and \( \text{Im } f \) are in \( L^1(\Omega) \).

The formula follows from the observation that
\[
f = (\text{Re } f)^+ - (\text{Re } f)^- + i \left( (\text{Im } f)^+ - (\text{Im } f)^- \right)
\]
and the fact shown first that \( \int df \) is linear.

To verify the triangle inequality, let \( \{s_n\} \) be complex simple functions for \( f \) as in Definition 9.4.4. Then
\[
\left| \int f \, d\mu \right| = \lim_{n \to \infty} \left| \int s_n \, d\mu \right| \leq \lim_{n \to \infty} \int |s_n| \, d\mu = \int |f| \, d\mu.
\]
This proves the theorem.

The following description of \( L^1(\Omega) \) is the version most often used because it is easy to verify the conditions for it.

**Corollary 9.4.8** Let \( (\Omega, S, \mu) \) be a measure space and let \( f : \Omega \to \mathbb{C} \). Then \( f \in L^1(\Omega) \) if and only if \( f \) is measurable and \( \int |f| \, d\mu < \infty \).

**Proof:** Suppose \( f \in L^1(\Omega) \). Then from Definition 9.4.4, it follows both real and imaginary parts of \( f \) are measurable. Just take real and imaginary parts of \( s_n \) and observe the real and imaginary parts of \( f \) are limits of the real and imaginary parts of \( s_n \) respectively. Why is \( \int |f| \, d\mu < \infty \)? It follows from Theorem 9.4.7. Recall why this was so. Let \( \{s_n\} \) be a sequence of simple functions attached to \( f \) as in the definition of what it means to be \( L^1 \). Then from the definition of \( I(s) \) for \( s \) simple,
\[
|I(|s_n| - |s_m|)| \leq I(|s_n - s_m|)
\]
which converges to 0. Since \( \{I(|s_n|)\} \) is a Cauchy sequence, it is bounded by a constant \( C \) and also \( \{|s_n|\} \) is a sequence of simple functions of the right sort which converges pointwise to \( |f| \) and so by definition,
\[
\int |f| \, d\mu = I(f) = \lim_{n \to \infty} I(|s_n|) \leq C.
\]
This shows the only if part.
The more interesting part is the if part. Suppose then that \( f \) is measurable and $\int |f| \, d\mu < \infty$. Suppose first that \( f \) has values in \([0, \infty)\). It is necessary to obtain the sequence of complex simple functions. By Theorem \ref{thm:9.3.9}, there exists a sequence of nonnegative simple functions, \( \{s_n\} \) such that \( s_n(\omega) \uparrow f(\omega) \). Then by the monotone convergence theorem,
\[
\lim_{n \to \infty} \int (2f - (f - s_n)) \, d\mu = \int 2f \, d\mu
\]
and so
\[
\lim_{n \to \infty} \int (f - s_n) \, d\mu = 0.
\]
Letting \( m \) be large enough, it follows $\int (f - s_m) \, d\mu < \varepsilon$ and so if $n > m$
\[
\int |s_m - s_n| \, d\mu \leq \int |f - s_m| \, d\mu < \varepsilon.
\]
Therefore, \( f \in L^1(\Omega) \) because \( \{s_n\} \) is a suitable sequence.

The general case follows from considering positive and negative parts of real and imaginary parts of \( f \). These are each measurable and nonnegative and their integral is finite so each is in \( L^1(\Omega) \) by what was just shown. Thus
\[
f = \text{Re} f^+ - \text{Re} f^- + i (\text{Im} f^+ - \text{Im} f^-)
\]
and so \( f \in L^1(\Omega) \). This proves the corollary.

**Theorem 9.4.9 (Dominated Convergence theorem)** Let \( f_n \in L^1(\Omega) \) and suppose
\[
f(\omega) = \lim_{n \to \infty} f_n(\omega),
\]
and there exists a measurable function \( g \), with values in \([0, \infty]\) \footnote{Note that, since \( g \) is allowed to have the value \( \infty \), it is not known that \( g \in L^1(\Omega) \).} such that
\[
|f_n(\omega)| \leq g(\omega) \quad \text{and} \quad \int g(\omega) \, d\mu < \infty.
\]
Then \( f \in L^1(\Omega) \) and
\[
\int f \, d\mu = \lim_{n \to \infty} \int f_n \, d\mu.
\]

**Proof:** \( f \) is measurable by Theorem \ref{thm:9.3.18}. Since $|f| \leq g$, it follows that
\[
f \in L^1(\Omega) \quad \text{and} \quad |f - f_n| \leq 2g.
\]
By Fatou’s lemma (Theorem \ref{thm:9.3.18}),
\[
\int 2g \, d\mu \leq \liminf_{n \to \infty} \int 2g - |f - f_n| \, d\mu
\]
\[
= \int 2g \, d\mu - \limsup_{n \to \infty} \int |f - f_n| \, d\mu.
\]
Subtracting \( \int 2gd\mu \),

\[
0 \leq -\lim_{n \to \infty} \sup \int |f - f_n|d\mu.
\]

Hence

\[
0 \geq \lim_{n \to \infty} \sup \left( \int |f - f_n|d\mu \right) \geq \lim_{n \to \infty} \sup \left| \int f d\mu - \int f_n d\mu \right|
\]

\[
\geq \lim_{n \to \infty} \inf \left| \int f d\mu - \int f_n d\mu \right| \geq 0.
\]

This proves the theorem by Lemma 9.3.17 on Page 234 because the lim sup and lim inf are equal.

**Corollary 9.4.10** Suppose \( f_n \in L^1(\Omega) \) and \( f(\omega) = \lim_{n \to \infty} f_n(\omega) \). Suppose also there exist measurable functions, \( g_n, g \) with values in \([0, \infty]\) such that

\[
\lim_{n \to \infty} \int g_n d\mu = \int gd\mu,
\]

\( g_n(\omega) \to g(\omega) \) \( \mu \) a.e. and both \( \int g_n d\mu \) and \( \int gd\mu \) are finite. Also suppose \( |f_n(\omega)| \leq g_n(\omega) \). Then

\[
\lim_{n \to \infty} \int |f - f_n| d\mu = 0.
\]

**Proof:** It is just like the above. This time \( g + g_n - |f - f_n| \geq 0 \) and so by Fatou’s lemma,

\[
\int 2gd\mu - \lim_{n \to \infty} \sup \int |f - f_n|d\mu =
\]

\[
\lim_{n \to \infty} \inf \int (g_n + g) - \lim_{n \to \infty} \sup \int |f - f_n|d\mu
\]

\[
= \lim_{n \to \infty} \inf \left( (g_n + g) - |f - f_n| \right) d\mu \geq \int 2gd\mu
\]

and so \(-\lim sup_{n \to \infty} \int |f - f_n| d\mu \geq 0\).

**Definition 9.4.11** Let \( E \) be a measurable subset of \( \Omega \).

\[
\int_E f d\mu \equiv \int f \chi_E d\mu.
\]

If \( L^1(E) \) is written, the \( \sigma \) algebra is defined as

\[
\{ E \cap A : A \in \mathcal{F} \}
\]

and the measure is \( \mu \) restricted to this smaller \( \sigma \) algebra. Clearly, if \( f \in L^1(\Omega) \), then

\[
f \chi_E \in L^1(E)
\]

and if \( f \in L^1(E) \), then letting \( \tilde{f} \) be the 0 extension of \( f \) off of \( E \), it follows \( \tilde{f} \) \( \in L^1(\Omega) \).
9.5 Vitali Convergence Theorem

The Vitali convergence theorem is a convergence theorem which in the case of a finite measure space is superior to the dominated convergence theorem.

**Definition 9.5.1** Let $(\Omega, \mathcal{F}, \mu)$ be a measure space and let $\mathcal{S} \subseteq L^1(\Omega)$. $\mathcal{S}$ is uniformly integrable if for every $\varepsilon > 0$ there exists $\delta > 0$ such that for all $f \in \mathcal{S}$

$$| \int_E fd\mu | < \varepsilon$$

whenever $\mu(E) < \delta$.

**Lemma 9.5.2** If $\mathcal{S}$ is uniformly integrable, then $|\mathcal{S}| \equiv \{f : f \in \mathcal{S}\}$ is uniformly integrable. Also $\mathcal{S}$ is uniformly integrable if $\mathcal{S}$ is finite.

**Proof:** Let $\varepsilon > 0$ be given and suppose $\mathcal{S}$ is uniformly integrable. First suppose the functions are real valued. Let $\delta$ be such that if $\mu(E) < \delta$,

$$| \int_E fd\mu | < \frac{\varepsilon}{2}$$

for all $f \in \mathcal{S}$. Let $\mu(E) < \delta$. Then if $f \in \mathcal{S}$,

$$\int_E |f| d\mu \leq \int_{E \cap \{f \leq 0\}} (-f) d\mu + \int_{E \cap \{f > 0\}} f d\mu$$

$$= \left| \int_{E \cap \{f \leq 0\}} f d\mu \right| + \left| \int_{E \cap \{f > 0\}} f d\mu \right|$$

$$< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$

In general, if $\mathcal{S}$ is a uniformly integrable set of complex valued functions, the inequalities,

$$\left| \int_E \text{Re} f d\mu \right| \leq \left| \int_E f d\mu \right|, \left| \int_E \text{Im} f d\mu \right| \leq \left| \int_E f d\mu \right|,$$

imply $\text{Re} \mathcal{S} \equiv \{ \text{Re} f : f \in \mathcal{S} \}$ and $\text{Im} \mathcal{S} \equiv \{ \text{Im} f : f \in \mathcal{S} \}$ are also uniformly integrable. Therefore, applying the above result for real valued functions to these sets of functions, it follows $|\mathcal{S}|$ is uniformly integrable also.

For the last part, is suffices to verify a single function in $L^1(\Omega)$ is uniformly integrable. To do so, note that from the dominated convergence theorem,

$$\lim_{R \to \infty} \int_{|f| > R} |f| d\mu = 0.$$

Let $\varepsilon > 0$ be given and choose $R$ large enough that $\int_{|f| > R} |f| d\mu < \frac{\varepsilon}{2}$. Now let $\mu(E) < \frac{\varepsilon}{2R}$. Then

$$\int_E |f| d\mu = \int_{E \cap \{|f| \leq R\}} |f| d\mu + \int_{E \cap \{|f| > R\}} |f| d\mu$$

$$< R \mu(E) + \frac{\varepsilon}{2} < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$
This proves the lemma.

The following theorem is Vitali’s convergence theorem.

**Theorem 9.5.3** Let \( \{ f_n \} \) be a uniformly integrable set of complex valued functions, \( \mu(\Omega) < \infty \), and \( f_n(x) \to f(x) \) a.e. where \( f \) is a measurable complex valued function. Then \( f \in L^1(\Omega) \) and

\[
\lim_{n \to \infty} \int_{\Omega} |f_n - f| d\mu = 0.
\]

**Proof:** First it will be shown that \( f \in L^1(\Omega) \). By uniform integrability, there exists \( \delta > 0 \) such that if \( \mu(E) < \delta \), then

\[
\int_E |f_n| d\mu < 1
\]

for all \( n \). By Egoroff’s theorem, there exists a set, \( E \) of measure less than \( \delta \) such that on \( E^C \), \( \{ f_n \} \) converges uniformly. Therefore, for \( p \) large enough, and \( n > p \),

\[
\int_{E^C} |f_p - f_n| d\mu < 1
\]

which implies

\[
\int_{E^C} |f_n| d\mu < 1 + \int_\Omega |f_p| d\mu.
\]

Then since there are only finitely many functions, \( f_n \) with \( n \leq p \), there exists a constant, \( M_1 \) such that for all \( n \),

\[
\int_{E^C} |f_n| d\mu < M_1.
\]

But also,

\[
\int_{\Omega} |f_m| d\mu = \int_{E^C} |f_m| d\mu + \int_E |f_m| \\
\leq M_1 + 1 = M.
\]

Therefore, by Fatou’s lemma,

\[
\int_{\Omega} |f| d\mu \leq \liminf_{n \to \infty} \int_{\Omega} |f_n| d\mu \leq M,
\]

showing that \( f \in L^1 \) as hoped.

Now \( \mathcal{S} \cup \{ f \} \) is uniformly integrable so there exists \( \delta_1 > 0 \) such that if \( \mu(E) < \delta_1 \), then \( \int_E |g| d\mu < \varepsilon/3 \) for all \( g \in \mathcal{S} \cup \{ f \} \). By Egoroff’s theorem, there exists a set, \( F \) with \( \mu(F) < \delta_1 \) such that \( f_n \) converges uniformly to \( f \) on \( F^C \). Therefore, there exists \( N \) such that if \( n > N \), then

\[
\int_{F^C} |f - f_n| d\mu < \frac{\varepsilon}{3}.
\]
9.6. EXERCISES

It follows that for $n > N$,

$$
\int_{\Omega} |f - f_n| \, d\mu \leq \int_{F^c} |f - f_n| \, d\mu + \int_F |f| \, d\mu + \int_F |f_n| \, d\mu < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon,
$$

which verifies 9.5.25.

9.6 Exercises

1. Let $\Omega = \mathbb{N} = \{1, 2, \ldots\}$ and $\mu(S) =$ number of elements in $S$. If $f : \Omega \to \mathbb{C}$

what is meant by $\int f \, d\mu$? Which functions are in $L^1(\Omega)$? Which functions are measurable?

2. Show that for $f \geq 0$ and measurable, $\int f \, d\mu \equiv \lim_{h \to 0^+} \sum_{i=1}^{\infty} h \mu([ih < f])$.

3. For the measure space of Problem 2, give an example of a sequence of nonnegative measurable functions $\{f_n\}$ converging pointwise to a function $f$, such that inequality is obtained in Fatou’s lemma.

4. Fill in all the details of the proof of Lemma 9.5.2.

5. Let $\sum_{i=1}^{\infty} c_i \chi_{E_i}(\omega) = s(\omega)$ be a nonnegative simple function for which the $c_i$ are the distinct nonzero values. Show with the aid of the monotone convergence theorem that the two definitions of the Lebesgue integral given in the chapter are equivalent.

6. Suppose $(\Omega, \mu)$ is a finite measure space and $\mathcal{S} \subseteq L^1(\Omega)$. Show $\mathcal{S}$ is uniformly integrable and bounded in $L^1(\Omega)$ if there exists an increasing function $h$ which satisfies

$$
\lim_{t \to \infty} \frac{h(t)}{t} = \infty, \quad \sup \left\{ \int_{\Omega} h(|f|) \, d\mu : f \in \mathcal{S} \right\} < \infty.
$$

$\mathcal{S}$ is bounded if there is some number, $M$ such that

$$
\int |f| \, d\mu \leq M
$$

for all $f \in \mathcal{S}$.

7. Let $\{a_n\}, \{b_n\}$ be sequences in $[-\infty, \infty]$ and $a \in \mathbb{R}$. Show

$$
\lim_{n \to \infty} \inf (a - a_n) = a - \lim_{n \to \infty} \sup a_n.
$$

This was used in the proof of the Dominated convergence theorem. Also show

$$
\lim_{n \to \infty} \sup (-a_n) = -\lim_{n \to \infty} \inf (a_n)
$$
CHAPTER 9. ABSTRACT MEASURE AND INTEGRATION

\[
\limsup_{n \to \infty} (a_n + b_n) \leq \limsup_{n \to \infty} a_n + \limsup_{n \to \infty} b_n
\]

provided no sum is of the form \(\infty - \infty\). Also show strict inequality can hold in the inequality. State and prove corresponding statements for \(\liminf\).

8. Let \((\Omega, \mathcal{F}, \mu)\) be a measure space and suppose \(f, g : \Omega \to (0, \infty]\) are measurable. Prove the sets

\[
\{\omega : f(\omega) < g(\omega)\} \text{ and } \{\omega : f(\omega) = g(\omega)\}
\]

are measurable. **Hint:** The easy way to do this is to write

\[
\{\omega : f(\omega) < g(\omega)\} = \bigcup_{r \in \mathbb{Q}} [f < r] \cap [g > r].
\]

Note that \(l(x, y) = x - y\) is not continuous on \((0, \infty]\) so the obvious idea doesn’t work.

9. Let \(\{f_n\}\) be a sequence of real or complex valued measurable functions. Let \(S = \{\omega : \{f_n(\omega)\} \text{ converges}\}\). Show \(S\) is measurable. **Hint:** You might try to exhibit the set where \(f_n\) converges in terms of countable unions and intersections using the definition of a Cauchy sequence.

10. Let \((\Omega, \mathcal{S}, \mu)\) be a measure space and let \(f\) be a nonnegative measurable function defined on \(\Omega\). Also let \(\phi : [0, \infty) \to [0, \infty)\) be strictly increasing and have a continuous derivative and \(\phi(0) = 0\). Suppose \(f\) is bounded and that \(0 \leq \phi(f(\omega)) \leq M\) for some number, \(M\). Show that

\[
\int_{\Omega} \phi(f) \, d\mu = \int_0^\infty \phi'(s) \mu([s < f]) \, ds,
\]

where the integral on the right is the ordinary improper Riemann integral. **Hint:** First note that \(s \to \phi'(s) \mu([s < f])\) is Riemann integrable because \(\phi'\) is continuous and \(s \to \mu([s < f])\) is a nonincreasing function, hence Riemann integrable. From the second description of the Lebesgue integral and the assumption that \(\phi(f(\omega)) \leq M\), argue that for \([M/h]\) the greatest integer less than \(M/h\),

\[
\int_{\Omega} \phi(f) \, d\mu = \sup_{h > 0} \sum_{i=1}^{[M/h]} h \mu (\{ih < \phi(f)\})
\]

\[
= \sup_{h > 0} \sum_{i=1}^{[M/h]} h \mu \left( \left\lfloor \phi^{-1}(ih) \right\rfloor < f \right) \]

\[
= \sup_{h > 0} \sum_{i=1}^{[M/h]} \frac{h \Delta_i}{\Delta_i} \mu \left( \left\lfloor \phi^{-1}(ih) \right\rfloor < f \right)
\]
where $\Delta_i = (\phi^{-1}(ih) - \phi^{-1}((i-1)h))$. Now use the mean value theorem to write

$$
\Delta_i = (\phi^{-1})'(t_i) h = \frac{1}{\phi' (\phi^{-1}(t_i))} h
$$

for some $t_i$ between $(i-1)h$ and $ih$. Therefore, the right side is of the form

$$
\sup_{h \in [M/h]} \sum_{i=1}^{\lfloor M/h \rfloor} \phi' (\phi^{-1}(t_i)) \Delta_i \mu ([\phi^{-1}(ih) < f])
$$

where $\phi^{-1}(t_i) \in (\phi^{-1}((i-1)h), \phi^{-1}(ih))$. Argue that if $t_i$ were replaced with $ih$, this would be a Riemann sum for the Riemann integral

$$
\int_0^{\phi^{-1}(M)} \phi' (t) \mu ([t < f]) dt = \int_0^{\infty} \phi' (t) \mu ([t < f]) dt.
$$

11. Let $(\Omega, \mathcal{F}, \mu)$ be a measure space and suppose $f_n$ converges uniformly to $f$ and that $f_n$ is in $L^1(\Omega)$. When is

$$
\lim_{n \to \infty} \int f_n d\mu = \int f d\mu?
$$

12. Suppose $u_n(t)$ is a differentiable function for $t \in (a, b)$ and suppose that for $t \in (a, b)$,

$$
|u_n(t)|, |u_n'(t)| < K_n
$$

where $\sum_{n=1}^{\infty} K_n < \infty$. Show

$$
(\sum_{n=1}^{\infty} u_n(t))' = \sum_{n=1}^{\infty} u_n'(t).
$$

**Hint:** This is an exercise in the use of the dominated convergence theorem and the mean value theorem.

13. Show that $\{\sum_{i=1}^{\infty} 2^{-n} \mu ([i2^{-n} < f])\}$ for $f$ a nonnegative measurable function is an increasing sequence. Could you define

$$
\int f d\mu \equiv \lim_{n \to \infty} \sum_{i=1}^{\infty} 2^{-n} \mu ([i2^{-n} < f])
$$

and would it be equivalent to the above definitions of the Lebesgue integral?
14. Suppose \( \{f_n\} \) is a sequence of nonnegative measurable functions defined on a measure space, \((\Omega, \mathcal{S}, \mu)\). Show that

\[
\int \sum_{k=1}^{\infty} f_k d\mu = \sum_{k=1}^{\infty} \int f_k d\mu.
\]

**Hint:** Use the monotone convergence theorem along with the fact the integral is linear.
Chapter 10

The Construction Of Measures

10.1 Outer Measures

What are some examples of measure spaces? In this chapter, a general procedure is discussed called the method of outer measures. It is due to Caratheodory (1918). This approach shows how to obtain measure spaces starting with an outer measure. This will then be used to construct measures determined by positive linear functionals.

Definition 10.1.1 Let \( \Omega \) be a nonempty set and let \( \mu : \mathcal{P}(\Omega) \to [0, \infty] \) satisfy

\[
\mu(\emptyset) = 0,
\]

If \( A \subseteq B \), then \( \mu(A) \leq \mu(B) \),

\[
\mu(\bigcup_{i=1}^{\infty} E_i) \leq \sum_{i=1}^{\infty} \mu(E_i).
\]

Such a function is called an outer measure. For \( E \subseteq \Omega \), \( E \) is \( \mu \) measurable if for all \( S \subseteq \Omega \),

\[
\mu(S) = \mu(S \setminus E) + \mu(S \cap E).
\] (10.1.1)

To help in remembering (10.1.1), think of a measurable set, \( E \), as a process which divides a given set into two pieces, the part in \( E \) and the part not in \( E \) as in (10.1.1). In the Bible, there are four incidents recorded in which a process of division resulted in more stuff than was originally present\(^1\). Measurable sets are exactly

\(^1\)Kings 17, 2 Kings 4, Mathew 14, and Mathew 15 all contain such descriptions. The stuff involved was either oil, bread, flour or fish. In mathematics such things have also been done with sets. In the book by Bruckner Bruckner and Thompson there is an interesting discussion of the Banach Tarski paradox which says it is possible to divide a ball in \( \mathbb{R}^3 \) into five disjoint pieces and
those for which no such miracle occurs. You might think of the measurable sets as the nonmiraculous sets. The idea is to show that they form a \( \sigma \) algebra on which the outer measure, \( \mu \) is a measure.

First here is a definition and a lemma.

**Definition 10.1.2** \((\mu[S])(A) = \mu(S \cap A)\) for all \( A \subseteq \Omega \). Thus \( \mu[S] \) is the name of a new outer measure, called \( \mu \) restricted to \( S \).

The next lemma indicates that the property of measurability is not lost by considering this restricted measure.

**Lemma 10.1.3** If \( A \) is \( \mu \) measurable, then \( A \) is \( \mu[S] \) measurable.

**Proof:** Suppose \( A \) is \( \mu \) measurable. It is desired to show that for all \( T \subseteq \Omega \),

\[
(\mu[S])(T) = (\mu[S])(T \cap A) + (\mu[S])(T \setminus A).
\]

Thus it is desired to show

\[
\mu(S \cap T) = \mu(T \cap A \cap S) + \mu(T \cap S \cap A^C).
\] (10.1.2)

But (10.1.2) holds because \( A \) is \( \mu \) measurable. Apply Definition 10.1.1 to \( S \setminus T \) instead of \( S \).

If \( A \) is \( \mu[S] \) measurable, it does not follow that \( A \) is \( \mu \) measurable. Indeed, if you believe in the existence of non measurable sets, you could let \( A = S \) for such a \( \mu \) non measurable set and verify that \( S \) is \( \mu[S] \) measurable.

The next theorem is the main result on outer measures. It is a very general result which applies whenever one has an outer measure on the power set of any set. This theorem will be referred to as Caratheodory’s procedure in the rest of the book.

**Theorem 10.1.4** The collection of \( \mu \) measurable sets, \( S \), forms a \( \sigma \) algebra and

\[
\text{If } F_i \in S, \ F_i \cap F_j = \emptyset, \text{ then } \mu(\bigcup_{i=1}^{\infty} F_i) = \sum_{i=1}^{\infty} \mu(F_i). \tag{10.1.3}
\]

If \( \cdots F_n \subseteq F_{n+1} \subseteq \cdots \), then if \( F = \bigcup_{n=1}^{\infty} F_n \) and \( F_n \in S \), it follows that

\[
\mu(F) = \lim_{n \to \infty} \mu(F_n). \tag{10.1.4}
\]

If \( \cdots F_n \supseteq F_{n+1} \supseteq \cdots \), and if \( F = \bigcap_{n=1}^{\infty} F_n \) for \( F_n \in S \) then if \( \mu(F_1) < \infty \),

\[
\mu(F) = \lim_{n \to \infty} \mu(F_n). \tag{10.1.5}
\]

Also, \( (S, \mu) \) is complete. By this it is meant that if \( F \in S \) and if \( E \subseteq \Omega \) with \( \mu(E \setminus F) + \mu(F \setminus E) = 0 \), then \( E \in S \).

assemble the pieces to form two disjoint balls of the same size as the first. The details can be found in: The Banach Tarski Paradox by Wagon, Cambridge University press. 1985. It is known that all such examples must involve the axiom of choice.
Proof: First note that $\emptyset$ and $\Omega$ are obviously in $\mathcal{S}$. Now suppose $A, B \in \mathcal{S}$. I will show $A \setminus B \equiv A \cap B^C$ is in $\mathcal{S}$. To do so, consider the following picture.

Since $\mu$ is subadditive,
\[
\mu(S) \leq \mu(S \cap A \cap B^C) + \mu(A \cap B \cap S) + \mu(S \cap B \cap A^C) + \mu(S \cap A^C \cap B^C).
\]
Now using $A, B \in \mathcal{S}$,
\[
\mu(S) \leq \mu(S \cap A \cap B^C) + \mu(S \cap B \cap A) + \mu(S \cap A^C \cap B) + \mu(S \cap A^C \cap B^C) = \mu(S \cap A) + \mu(S \cap A^C) = \mu(S)
\]
It follows equality holds in the above. Now observe using the picture if you like that
\[
(A \cap B \cap S) \cup (S \cap B \cap A^C) \cup (S \cap A^C \cap B^C) = S \setminus (A \setminus B)
\]
and therefore,
\[
\mu(S) = \mu(S \cap A \cap B^C) + \mu(A \cap B \cap S) + \mu(S \cap B \cap A^C) + \mu(S \cap A^C \cap B^C) \geq \mu(S \cap (A \setminus B)) + \mu(S \setminus (A \setminus B)).
\]
Therefore, since $S$ is arbitrary, this shows $A \setminus B \in \mathcal{S}$.

Since $\Omega \in \mathcal{S}$, this shows that $A \in \mathcal{S}$ if and only if $A^C \in \mathcal{S}$. Now if $A, B \in \mathcal{S}$, $A \cup B = (A^C \cap B^C)^C = (A^C \setminus B)^C \in \mathcal{S}$. By induction, if $A_1, \cdots, A_n \in \mathcal{S}$, then so is $\bigcup_{i=1}^n A_i$. If $A, B \in \mathcal{S}$, with $A \cap B = \emptyset$,
\[
\mu(A \cup B) = \mu((A \cup B) \cap A) + \mu((A \cup B) \setminus A) = \mu(A) + \mu(B).
\]
CHAPTER 10. THE CONSTRUCTION OF MEASURES

By induction, if \( A_i \cap A_j = \emptyset \) and \( A_i \in \mathcal{S} \), \( \mu(\bigcup_{i=1}^{n} A_i) = \sum_{i=1}^{n} \mu(A_i) \).

Now let \( A = \bigcup_{i=1}^{\infty} A_i \) where \( A_i \cap A_j = \emptyset \) for \( i \neq j \).

\[
\sum_{i=1}^{\infty} \mu(A_i) \geq \mu(A) \geq \mu(\bigcup_{i=1}^{n} A_i) = \sum_{i=1}^{n} \mu(A_i).
\]

Since this holds for all \( n \), you can take the limit as \( n \to \infty \) and conclude,

\[
\sum_{i=1}^{\infty} \mu(A_i) = \mu(A)
\]

which establishes \( \mathbf{10.1.3} \). Part \( \mathbf{10.1.4} \) follows from part \( \mathbf{10.1.3} \) just as in the proof of Theorem \( \mathbf{9.1.5} \) on Page 208. That is, letting \( F_0 = \emptyset \), use part \( \mathbf{10.1.3} \) to write

\[
\mu(F) = \mu(\bigcup_{k=1}^{\infty} (F_k \setminus F_{k-1})) = \sum_{k=1}^{\infty} \mu(F_k \setminus F_{k-1})
\]

\[
= \lim_{n \to \infty} \sum_{k=1}^{n} (\mu(F_k) - \mu(F_{k-1})) = \lim_{n \to \infty} \mu(F_n).
\]

In order to establish \( \mathbf{10.1.5} \), let the \( F_n \) be as given there. Then from what was just shown,

\[
\mu(F_1 \setminus F_n) + \mu(F_n) = \mu(F_1)
\]

Then, since \( (F_1 \setminus F_n) \) increases to \( (F_1 \setminus F) \), \( \mathbf{10.1.3} \) implies

\[
\lim_{n \to \infty} \mu(F_1 \setminus F_n) = \lim_{n \to \infty} (\mu(F_1) - \mu(F_n)) = \mu(F_1 \setminus F).
\]

Now I don’t know whether \( F \in \mathcal{S} \) and so all that can be said is that

\[
\mu(F_1 \setminus F) + \mu(F) \geq \mu(F_1)
\]

but this implies

\[
\mu(F_1 \setminus F) \geq \mu(F_1) - \mu(F).
\]

Hence

\[
\lim_{n \to \infty} (\mu(F_1) - \mu(F_n)) = \mu(F_1 \setminus F) \geq \mu(F_1) - \mu(F)
\]

which implies

\[
\lim_{n \to \infty} \mu(F_n) \leq \mu(F).
\]

But since \( F \subseteq F_n \),

\[
\mu(F) \leq \lim_{n \to \infty} \mu(F_n)
\]

and this establishes \( \mathbf{10.1.4} \). Note that it was assumed \( \mu(F_1) < \infty \) because \( \mu(F_1) \) was subtracted from both sides.
10.1. OUTER MEASURES

It remains to show $S$ is closed under countable unions. Recall that if $A \in S$, then $A^C \in S$ and $S$ is closed under finite unions. Let $A_i \in S$, $A = \bigcup_{i=1}^{\infty} A_i$, $B_n = \bigcup_{i=1}^{n} A_i$. Then

$$
\mu(S) = \mu(S \cap B_n) + \mu(S \setminus B_n) \quad (10.1.6)
$$

By Lemma 10.1.3 $B_n$ is $(\mu|S)$ measurable and so is $B_n^C$. I want to show $\mu(S) = \mu(S \setminus A) + \mu(S \cap A)$. If $\mu(S) = \infty$, there is nothing to prove. Assume $\mu(S) < \infty$. Then apply Parts 10.1.5 and 10.1.4 to the outer measure, $\mu|S$ in 10.1.6 and let $n \to \infty$. Thus

$$
B_n \uparrow A, \ B_n^C \downarrow A^C
$$

and this yields

$$
\mu(S) = (\mu|S)(A) + (\mu|S)(A^C) = \mu(S \cap A) + \mu(S \setminus A).
$$

Therefore $A \in S$ and this proves Parts 10.1.3, 10.1.4, and 10.1.5. It remains to prove the last assertion about the measure being complete.

Let $F \in S$ and let $\mu(E \setminus F) + \mu(F \setminus E) = 0$. Consider the following picture.

Then referring to this picture and using $F \in S$,

$$
\mu(S) \leq \mu(S \cap E) + \mu(S \setminus E) \\
\leq \mu(S \cap E \cap F) + \mu((S \cap E) \setminus F) + \mu(S \setminus F) + \mu(F \setminus E) \\
\leq \mu(S \cap F) + \mu(E \setminus F) + \mu(S \setminus F) + \mu(F \setminus E) \\
= \mu(S \cap F) + \mu(S \setminus F) = \mu(S)
$$

Hence $\mu(S) = \mu(S \cap E) + \mu(S \setminus E)$ and so $E \in S$. This shows that $(S, \mu)$ is complete and proves the theorem.

Completeness usually occurs in the following form. $E \subseteq F \in S$ and $\mu(F) = 0$. Then $E \in S$.

**Proposition 10.1.5** Let $(\Omega, \mathcal{F}, \mu)$ be a measure space. Let $\bar{\mu}$ be the outer measure determined by $\mu$. Also denote as $\mathcal{F}$, the $\sigma$ algebra of $\bar{\mu}$ measurable sets. Thus $(\Omega, \mathcal{F}, \bar{\mu})$ is a complete measure space in which $\mathcal{F} \supseteq \mathcal{F}$ and $\bar{\mu} = \mu$ on $\mathcal{F}$. Also, in this situation, if $\bar{\mu}(E) = 0$, then $E \in \mathcal{F}$. No new sets are obtained if $(\Omega, \mathcal{F}, \mu)$ is already complete.
Proof: All that remains to show is the last claim. But this is obvious because if \( S \) is a set,
\[
\tilde{\mu}(S) \leq \tilde{\mu}(S \cap E) + \tilde{\mu}(S \setminus E) \\
\leq \tilde{\mu}(E) + \tilde{\mu}(S \setminus E) \\
= \tilde{\mu}(S \setminus E) \leq \tilde{\mu}(S)
\]
and so all inequalities are equal signs.

Suppose now that \((\Omega, \mathcal{F}, \mu)\) is complete. Let \( F \in \mathcal{F} \). Then there exists \( E \supseteq F \) such that \( \mu(E) = \tilde{\mu}(F) \). This is obvious if \( \tilde{\mu}(F) = \infty \). Otherwise, let \( E_n \supseteq F, \tilde{\mu}(F) + \frac{1}{n} > \mu(E_n) \). Just let \( E = \cap_n E_n \). Now \( \tilde{\mu}(E \setminus F) = 0 \). Now also, there exists a set of \( \mathcal{F} \) called \( W \) such that \( \mu(W) = 0 \) and \( W \supseteq E \setminus F \). Thus \( E \setminus F \subseteq W \), a set of measure zero. Hence by completeness of \((\Omega, \mathcal{F}, \mu)\), it must be the case that \( E \setminus F = E \cap F^C = G \in \mathcal{F} \). Then taking complements of both sides, \( E^C \cup F = G^C \in \mathcal{F} \). Now take intersections with \( E \). \( F \in E \cap G^C \in \mathcal{F} \). 

In the case of a Hausdorff topological space, the following lemma gives conditions under which the algebra of measurable sets for an outer measure \( \mu \) contains the Borel sets. In words, it assumes the outer measure is inner regular on open sets and outer regular on all sets. Also it assumes you can approximate the measure of an open set with a compact set and the measure of a compact set with an open set.

Lemma 10.1.6 Let \( \Omega \) be a Hausdorff space and suppose \( \mu \) is an outer measure satisfying \( \mu \) is finite on compact sets and the following conditions,

1. \( \mu(E) = \inf \{ \mu(V), V \supseteq E, V \text{ open} \} \) for all \( E \). (Outer regularity.)

2. For every open set \( V \), \( \mu(V) = \sup \{ \mu(K), K \subseteq V, K \text{ compact} \} \) (Inner regularity on open sets.)

3. If \( A, B \) are compact disjoint sets, then \( \mu(A \cup B) = \mu(A) + \mu(B) \).

Then the following hold.

1. If \( \varepsilon > 0 \) and if \( K \) is compact, there exists \( V \) open such that \( V \supseteq K \) and
\[
\mu(V \setminus K) < \varepsilon
\]

2. If \( \varepsilon > 0 \) and if \( V \) is open with \( \mu(V) < \infty \), there exists a compact subset \( K \) of \( V \) such that
\[
\mu(V \setminus K) < \varepsilon
\]

3. Then the \( \mu \) measurable sets \( S \) contain the Borel sets and also \( \mu \) is inner regular on every open set and for every \( E \in S \) with \( \mu(E) < \infty \). Here \( S \) consists of those subsets of \( \Omega \) \( E \) with the property that for any subset \( S \) of \( \Omega \),
\[
\mu(S) = \mu(S \cap E) + \mu(S \cap E^C)
\]
**Proof:** First we establish 1 and 2 and use them to establish the last assertion. Consider 2. Suppose it is not true. Then there exists an open set $V$ having $\mu(V) < \infty$ but for all $K \subseteq V$, $\mu(V \setminus K) \geq \varepsilon$ for some $\varepsilon > 0$. By inner regularity on open sets, there exists $K_1 \subseteq V, K_1$ compact, such that $\mu(K_1) \geq \varepsilon/2$. Now by assumption, $\mu(V \setminus K_1) \geq \varepsilon$ and so by inner regularity on open sets again, there exists compact $K_2 \subseteq V \setminus K_1$ such that $\mu(K_2) \geq \varepsilon/2$. Continuing this way, there is a sequence of disjoint compact sets contained in $V \{K_i\}$ such that $\mu(K_i) \geq \varepsilon/2$.

Now this is an obvious contradiction because by 3,

\[
\mu(V) \geq \mu(\bigcup_{i=1}^{n} K_i) = \sum_{i=1}^{n} \mu(K_i) \geq n \frac{\varepsilon}{2}
\]

for each $n$, contradicting $\mu(V) < \infty$.

Next consider 1. By outer regularity, there exists an open set $W \supseteq K$ such that $\mu(W) < \mu(K) + 1$. By 4, there exists compact $K_1 \subseteq W \setminus K$ such that $\mu((W \setminus K) \setminus K_1) < \varepsilon$. Then consider $V \equiv W \setminus K_1$. This is an open set containing $K$ and from what was just shown,

\[
\mu((W \setminus K_1) \setminus K) = \mu((W \setminus K) \setminus K_1) < \varepsilon.
\]

Now consider the last assertion.

Define

\[ S_1 = \{ E \in \mathcal{P}(\Omega) : E \cap K \in \mathcal{S} \} \]

for all compact $K$.

First it will be shown the compact sets are in $\mathcal{S}$. From this it will follow the closed sets are in $S_1$. Then you show $S_1 = \mathcal{S}$. Thus $S_1 = \mathcal{S}$ is a $\sigma$ algebra and so it contains the Borel sets. Finally you show the inner regularity assertion.

**Claim 1:** Compact sets are in $\mathcal{S}$.

**Proof of claim:** Let $V$ be an open set with $\mu(V) < \infty$. I will show that for $C$ compact,

\[
\mu(V) \geq \mu(V \setminus C) + \mu(V \cap C).
\]

Here is a diagram to help keep things straight.
By 2 there exists a compact set $K \subseteq V \setminus C$ such that
\[ \mu((V \setminus C) \setminus K) < \varepsilon. \]
and a compact set $H \subseteq V$ such that
\[ \mu(V \setminus H) < \varepsilon. \]
Thus $\mu(V) \leq \mu(V \setminus H) + \mu(H) < \varepsilon + \mu(H)$. Then
\[
\begin{align*}
\mu(V) &\leq \mu(H) + \varepsilon \leq \mu(H \cap C) + \mu(H \setminus C) + \varepsilon \\
&\leq \mu(V \cap C) + \mu(V \setminus C) + \varepsilon \leq \mu(H \cap C) + \mu(K) + 3\varepsilon
\end{align*}
\]
By 3,
\[ \mu(H \cap C) + \mu(K) + 3\varepsilon = \mu((H \cap C) \cup K) + 3\varepsilon \leq \mu(V) + 3\varepsilon. \]
Since $\varepsilon$ is arbitrary, this shows that
\[ \mu(V) = \mu(V \setminus C) + \mu(V \cap C). \quad (10.1.7) \]

Of course 10.1.7 is exactly what needs to be shown for arbitrary $S$ in place of $V$. It suffices to consider only $S$ having $\mu(S) < \infty$. If $S \subseteq \Omega$, with $\mu(S) < \infty$, let $V \supseteq S$, $\mu(S) + \varepsilon > \mu(V)$. Then from what was just shown, if $C$ is compact,
\[
\begin{align*}
\varepsilon + \mu(S) &> \mu(V) = \mu(V \setminus C) + \mu(V \cap C) \\
&\geq \mu(S \setminus C) + \mu(S \cap C).
\end{align*}
\]
Since $\varepsilon$ is arbitrary, this shows the compact sets are in $S$. This proves the claim.

As discussed above, this verifies the closed sets are in $S_1$ because if $H$ is closed and $C$ is compact, then $H \cap C \in S$. If $S_1$ is a $\sigma$ algebra, this will show that $S_1$ contains the Borel sets. Thus I first show $S_1$ is a $\sigma$ algebra.

To see that $S_1$ is closed with respect to taking complements, let $E \in S_1$ and $K$ a compact set.
\[ K = (E^C \cap K) \cup (E \cap K). \]
Then from the fact, just established, that the compact sets are in $S$,
\[ E^C \cap K = K \setminus (E \cap K) \in S. \]
$S_1$ is closed under countable unions because if $K$ is a compact set and $E_n \in S_1$, 

$$K \cap \bigcup_{n=1}^{\infty} E_n = \bigcup_{n=1}^{\infty} (K \cap E_n) \in S$$

because it is a countable union of sets of $S$. Thus $S_1$ is a $\sigma$ algebra.

Therefore, if $E \in S$ and $K$ is a compact set, just shown to be in $S$, it follows $K \cap E \in S$ because $S$ is a $\sigma$ algebra which contains the compact sets and so $S_1 \supseteq S$.

It remains to verify $S_1 \subseteq S$. Recall that

$$S_1 \equiv \{ E : E \cap K \in S \text{ for all } K \text{ compact} \}$$

Let $E \in S_1$ and let $V$ be an open set with $\mu(V) < \infty$ and choose $K \subseteq V$ such that $\mu(V \setminus K) < \varepsilon$. Then since $E \in S_1$, it follows $E \cap K, E^C \cap K \in S$ and so

$$\mu(V) \leq \mu(V \setminus E) + \mu(V \cap E) \leq \underbrace{\mu(K \setminus E)}_{\text{The two sets are disjoint and in } S} + \mu(K \cap E) + \mu(E) + 2\varepsilon$$

$$= \mu(K) + \mu(E) + 2\varepsilon \leq \mu(V) + 3\varepsilon$$

Since $\varepsilon$ is arbitrary, this shows

$$\mu(V) = \mu(V \setminus E) + \mu(V \cap E)$$

which would show $E \in S$ if $V$ were an arbitrary set.

Now let $S \subseteq \Omega$ be such an arbitrary set. If $\mu(S) = \infty$, then

$$\mu(S) = \mu(S \cap E) + \mu(S \setminus E).$$

If $\mu(S) < \infty$, let

$$V \supseteq S, \mu(S) + \varepsilon \geq \mu(V).$$

Then

$$\mu(S) + \varepsilon \geq \mu(V) = \mu(V \setminus E) + \mu(V \cap E) \geq \mu(S \setminus E) + \mu(S \cap E).$$

Since $\varepsilon$ is arbitrary, this shows that $E \in S$ and so $S_1 = S$. Thus $S \supseteq \text{Borel sets as claimed.}$

From $\mu$ is inner regular on all open sets. It remains to show that

$$\mu(F) = \sup \{ \mu(K) : K \subseteq F \}$$

for all $F \in S$ with $\mu(F) < \infty$. It might help to refer to the following crude picture to keep things straight. It also might not help. I am not sure. In the picture, the green marks the boundary of $V$ while red marks $U$ and black marks $F$ and $V^C \cap K$.

This last set is as shown because $K$ is a compact subset of $U$ such that $\mu(U \setminus K) < \epsilon$. 

![Diagram](image-url)
Let $\mu(F) < \infty$ and let $U$ be an open set, $U \supseteq F$, $\mu(U) < \infty$. Let $V$ be open, $V \supseteq U \setminus F$, and

$$
\mu(V \setminus (U \setminus F)) < \varepsilon.
$$

(This can be obtained as follows, because $\mu$ is a measure on $\mathcal{S}$.

$$
\mu(V) = \mu(U \setminus F) + \mu(V \setminus (U \setminus F))
$$

Thus from the outer regularity of $\mu$, above, there exists $V$ such that it contains $U \setminus F$ and

$$
\mu(U \setminus F) + \varepsilon > \mu(V).
$$

and so

$$
\mu(V \setminus (U \setminus F)) = \mu(V) - \mu(U \setminus F) < \varepsilon.
$$

Also,

$$
V \setminus (U \setminus F) = V \cap (U \cap F^C)^C
$$

$$
= V \cap [U^C \cup F]
$$

$$
= (V \cap F) \cup (V \cap U^C)
$$

$$
\supseteq V \cap F
$$

and so

$$
\mu(V \cap U) \leq \mu(V \setminus (U \setminus F)) < \varepsilon.
$$

Since $V \supseteq U \cap F^C$, $V^C \subseteq U^C \cup F$ so $U \cap V^C \subseteq U \cap F = F$. Hence $U \cap V^C$ is a subset of $F$. Now let $K \subseteq U$, $\mu(U \setminus K) < \varepsilon$. Thus $K \cap V^C$ is a compact subset of $F$ and

$$
\mu(F) = \mu(V \cap F) + \mu(F \setminus V)
$$

$$
< \varepsilon + \mu(F \setminus V) \leq \varepsilon + \mu(U \cap V^C) \leq 2\varepsilon + \mu(K \cap V^C).
$$

Since $\varepsilon$ is arbitrary, this proves the second part of the lemma.

Where do outer measures come from? One way to obtain an outer measure is to start with a measure $\mu$, defined on a $\sigma$ algebra of sets, $\mathcal{S}$, and use the following definition of the outer measure induced by the measure.

**Definition 10.1.7** Let $\mu$ be a measure defined on a $\sigma$ algebra of sets, $\mathcal{S} \subseteq \mathcal{P}(\Omega)$. Then the outer measure induced by $\mu$, denoted by $\overline{\mu}$ is defined on $\mathcal{P}(\Omega)$ as

$$
\overline{\mu}(E) = \inf\{\mu(F) : F \in \mathcal{S} \text{ and } F \supseteq E\}.
$$

A measure space, $(\mathcal{S}, \Omega, \mu)$ is $\sigma$ finite if there exist measurable sets, $\Omega_i$, with $\mu(\Omega_i) < \infty$ and $\Omega = \cup_{i=1}^{\infty} \Omega_i$.

You should prove the following lemma.

**Lemma 10.1.8** If $(\mathcal{S}, \Omega, \mu)$ is $\sigma$ finite then there exist disjoint measurable sets, $\{B_n\}$ such that $\mu(B_n) < \infty$ and $\cup_{n=1}^{\infty} B_n = \Omega$. 

The following lemma deals with the outer measure generated by a measure which is $\sigma$ finite. It says that if the given measure is $\sigma$ finite and complete then no new measurable sets are gained by going to the induced outer measure and then considering the measurable sets in the sense of Caratheodory.

**Lemma 10.1.9** Let $(\Omega, S, \mu)$ be any measure space and let $\overline{\mu} : \mathcal{P}(\Omega) \rightarrow [0, \infty]$ be the outer measure induced by $\mu$. Then $\overline{\mu}$ is an outer measure as claimed and if $\overline{\mathcal{S}}$ is the set of $\overline{\mu}$ measurable sets in the sense of Caratheodory, then $\overline{\mathcal{S}} \supseteq S$ and $\overline{\mu} = \mu$ on $S$. Furthermore, if $\mu$ is $\sigma$ finite and $(\Omega, S, \mu)$ is complete, then $\overline{\mathcal{S}} = S$.

**Proof:** It is easy to see that $\overline{\mu}$ is an outer measure. Let $E \in S$. The plan is to show $E \in \overline{\mathcal{S}}$ and $\overline{\mu}(E) = \mu(E)$. To show this, let $S \subseteq \Omega$ and then show

$$\overline{\mu}(S) \geq \overline{\mu}(S \cap E) + \overline{\mu}(S \setminus E).$$

(10.1.8)

This will verify that $E \in \overline{\mathcal{S}}$. If $\overline{\mu}(S) = \infty$, there is nothing to prove, so assume $\overline{\mu}(S) < \infty$. Thus there exists $T \in S$, $T \supseteq S$, and

$$\overline{\mu}(S) > \mu(T) - \varepsilon = \mu(T \cap E) + \mu(T \setminus E) - \varepsilon$$

$$\geq \overline{\mu}(T \cap E) + \overline{\mu}(T \setminus E) - \varepsilon$$

$$\geq \overline{\mu}(S \cap E) + \overline{\mu}(S \setminus E) - \varepsilon.$$ 

Since $\varepsilon$ is arbitrary, this proves $E \in \overline{\mathcal{S}}$ and verifies $S \subseteq \overline{\mathcal{S}}$. Now if $E \in S$ and $V \supseteq E$ with $V \in S$, $\mu(E) \leq \mu(V)$. Hence, taking inf, $\mu(E) \leq \overline{\mu}(E)$. But also $\mu(E) \geq \overline{\mu}(E)$ since $E \in S$ and $E \supseteq E$. Hence

$$\overline{\mu}(E) \leq \mu(E) \leq \overline{\mu}(E).$$

Next consider the claim about not getting any new sets from the outer measure in the case the measure space is $\sigma$ finite and complete.

Suppose first $F \in \mathcal{S}$ and $\overline{\mu}(F) < \infty$. Then there exists $E \in S$ such that $E \supseteq F$ and $\mu(E) = \overline{\mu}(F)$. Since $\overline{\mu}(F) < \infty$,

$$\overline{\mu}(E \setminus F) = \mu(E) - \overline{\mu}(F) = 0.$$  

Then there exists $D \supseteq E \setminus F$ such that $D \in S$ and $\mu(D) = \overline{\mu}(E \setminus F) = 0$. Then by completeness of $S$, it follows $E \setminus F \in S$ and so

$$E = (E \setminus F) \cup F.$$ 

Hence $F = E \setminus (E \setminus F) \in S$. In the general case where $\overline{\mu}(F)$ is not known to be finite, let $\mu(B_n) < \infty$, with $B_n \cap B_m = \emptyset$ for all $n \neq m$ and $\cup_n B_n = \Omega$. Apply what was just shown to $F \cap B_n$, obtaining each of these is in $S$. Then $F = \cup_n F \cap B_n \in S$. This proves the Lemma.

Usually $\Omega$ is not just a set. It is also a topological space. It is very important to consider how the measure is related to this topology. The following definition tells what it means for a measure to be regular.
Definition 10.1.10 Let \( \mu \) be a measure on a \( \sigma \)-algebra \( S \), of subsets of \( \Omega \), where \( (\Omega, \tau) \) is a topological space. \( \mu \) is a Borel measure if \( S \) contains all Borel sets. \( \mu \) is called outer regular if \( \mu \) is Borel and for all \( E \in S \),
\[
\mu(E) = \inf\{\mu(V): V \text{ is open and } V \supseteq E\}.
\]
\( \mu \) is called inner regular if \( \mu \) is Borel and
\[
\mu(E) = \sup\{\mu(K): K \subseteq E, \text{ and } K \text{ is compact}\}.
\]
If the measure is both outer and inner regular, it is called regular.

There is an interesting situation in which regularity is obtained automatically. To save on words, let \( \mathcal{B}(E) \) denote the \( \sigma \)-algebra of Borel sets in \( E \), a closed subset of \( \mathbb{R}^n \). It is a very interesting fact that every finite measure on \( \mathcal{B}(E) \) must be regular.

Lemma 10.1.11 Let \( \mu \) be a finite measure defined on \( \mathcal{B}(E) \) where \( E \) is a closed subset of \( \mathbb{R}^n \). Then for every \( F \in \mathcal{B}(E) \),
\[
\mu(F) = \sup\{\mu(K): K \subseteq F, \text{ and } K \text{ is closed}\}
\]
\[
\mu(F) = \inf\{\mu(V): V \supseteq F, \text{ and } V \text{ is open}\}
\]

Proof: For convenience, I will call a measure which satisfies the above two conditions “almost regular”. It would be regular if closed were replaced with compact. First note every open set is the countable union of compact sets and every closed set is the countable intersection of open sets. Here is why. Let \( V \) be an open set and let
\[
K_k = \{x \in V: \text{dist}(x, V^c) \geq 1/k\}.
\]
Then clearly the union of the \( K_k \) equals \( V \) and each is closed because \( x \rightarrow \text{dist}(x, S) \) is always a continuous function whenever \( S \) is any nonempty set. Next, for \( K \) closed let
\[
V_k = \{x \in E: \text{dist}(x, K) < 1/k\}.
\]
Clearly the intersection of the \( V_k \) equals \( K \). Therefore, letting \( V \) denote an open set and \( K \) a closed set,
\[
\mu(V) = \sup\{\mu(K): K \subseteq V \text{ and } K \text{ is closed}\}
\]
\[
\mu(K) = \inf\{\mu(V): V \supseteq K \text{ and } V \text{ is open}\}.
\]
Also since \( V \) is open and \( K \) is closed,
\[
\mu(V) = \inf\{\mu(U): U \supseteq V \text{ and } V \text{ is open}\}
\]
\[
\mu(K) = \sup\{\mu(L): L \subseteq K \text{ and } L \text{ is closed}\}
\]
In words, \( \mu \) is almost regular on open and closed sets. Let
\[
\mathcal{F} = \{F \in \mathcal{B}(E) \text{ such that } \mu \text{ is almost regular on } F\}.
\]
Then \( \mathcal{F} \) contains the open sets. I want to show \( \mathcal{F} \) is a \( \sigma \) algebra and then it will follow \( \mathcal{F} = \mathcal{B}(E) \).

First I will show \( \mathcal{F} \) is closed with respect to complements. Let \( F \in \mathcal{F} \). Then since \( \mu \) is finite and \( F \) is inner regular, there exists \( K \subseteq F \) such that \( \mu (F \setminus K) < \varepsilon \). But \( K^C \setminus F^C = F \setminus K \) and so \( \mu (K^C \setminus F^C) < \varepsilon \) showing that \( F^C \) is outer regular. I have just approximated the measure of \( F^C \) with the measure of \( K^C \), an open set containing \( F^C \).

A similar argument works to show \( F \) is inner regular. You start with \( V \supseteq F \) such that \( \mu (V \setminus F) < \varepsilon \), note \( F^C \setminus V^C = V \setminus F \), and then conclude \( \mu (F^C \setminus V^C) < \varepsilon \), thus approximating \( F^C \) with the closed subset, \( V^C \).

Next I will show \( \mathcal{F} \) is closed with respect to taking countable unions. Let \( \{F_k\} \) be a sequence of sets in \( \mathcal{F} \). Then since \( \mu \) is finite, there exist \( \{K_k\} \) such that \( K_k \subseteq F_k \) and \( \mu (F_k \setminus K_k) < \varepsilon / 2^{k+1} \). First choose \( m \) large enough that

\[
\mu \left( (\bigcup_{k=1}^{\infty} F_k) \setminus (\bigcup_{k=1}^{m} F_k) \right) < \frac{\varepsilon}{2}.
\]

Then

\[
\mu \left( (\bigcup_{k=1}^{m} F_k) \setminus (\bigcup_{k=1}^{m} K_k) \right) \leq \sum_{k=1}^{m} \frac{\varepsilon}{2^{k+1}} < \frac{\varepsilon}{2}
\]

and so

\[
\mu \left( (\bigcup_{k=1}^{\infty} F_k) \setminus (\bigcup_{k=1}^{m} K_k) \right) \leq \mu \left( (\bigcup_{k=1}^{\infty} F_k) \setminus (\bigcup_{k=1}^{m} F_k) \right) + \mu \left( (\bigcup_{k=1}^{m} F_k) \setminus (\bigcup_{k=1}^{m} K_k) \right) < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon
\]

Since \( \mu \) is outer regular on \( F_k \), there exists \( V_k \) such that \( \mu (V_k \setminus F_k) < \varepsilon / 2^k \). Then

\[
\mu \left( (\bigcup_{k=1}^{\infty} V_k) \setminus (\bigcup_{k=1}^{\infty} F_k) \right) \leq \sum_{k=1}^{\infty} \mu (V_k \setminus F_k) < \sum_{k=1}^{\infty} \frac{\varepsilon}{2^k} = \varepsilon
\]

and this completes the demonstration that \( \mathcal{F} \) is a \( \sigma \) algebra. This proves the lemma.

**Theorem 10.1.12** Let \( \mu \) be a finite measure defined on \( \mathcal{B}(E) \) where \( E \) is a closed subset of \( \mathbb{R}^n \). Then \( \mu \) is regular.

**Proof:** From Lemma 10.1.11 \( \mu \) is outer regular. Now let \( F \in \mathcal{B}(E) \). Then since \( \mu \) is finite, there exists \( K \subseteq F \) such that \( K \) is closed, \( K \subseteq F \), and

\[
\mu (F) < \mu (K) + \varepsilon.
\]

Then let \( K_k = K \cap \overline{B(0,k)} \). Thus \( K_k \) is a closed and bounded, hence compact set.
and $\bigcup_{k=1}^{\infty} K_k = K$. Therefore, for all $k$ large enough,

$$
\mu(F) < \mu(K_k) + \varepsilon < \sup\{\mu(K) : K \subseteq F \text{ and } K \text{ compact}\} + \varepsilon \leq \mu(F) + \varepsilon
$$

Since $\varepsilon$ was arbitrary, it follows

$$
\sup\{\mu(K) : K \subseteq F \text{ and } K \text{ compact}\} = \mu(F).
$$

This proves the theorem.

It will be assumed in what follows that $(\Omega, \tau)$ is a locally compact Hausdorff space. This means it is Hausdorff: If $p, q \in \Omega$ such that $p \neq q$, there exist open sets, $U_p$ and $U_q$ containing $p$ and $q$ respectively such that $U_p \cap U_q = \emptyset$ and Locally compact: There exists a basis of open sets for the topology, $B$ such that for each $U \in B$, $\overline{U}$ is compact. Recall $B$ is a basis for the topology if $\bigcup B = \Omega$ and if every open set in $\tau$ is the union of sets of $B$. Also recall a Hausdorff space is normal if whenever $H$ and $C$ are two closed sets, there exist disjoint open sets, $U_H$ and $U_C$ containing $H$ and $C$ respectively. A regular space is one which has the property that if $p$ is a point not in $H$, a closed set, then there exist disjoint open sets, $U_p$ and $U_H$ containing $p$ and $H$ respectively.

### 10.2 Urysohn’s lemma

Urysohn’s lemma which characterizes normal spaces is a very important result which is useful in general topology and in the construction of measures. Because it is somewhat technical a proof is given for the part which is needed.

**Theorem 10.2.1 (Urysohn)** Let $(X, \tau)$ be normal and let $H \subseteq U$ where $H$ is closed and $U$ is open. Then there exists $g : X \to [0, 1]$ such that $g$ is continuous, $g(x) = 1$ on $H$ and $g(x) = 0$ if $x \notin U$.

**Proof:** Let $D \equiv \{r_n\}_{n=1}^{\infty}$ be the rational numbers in $(0, 1]$. Choose $V_{r_1}$ an open set such that

$$
H \subseteq V_{r_1} \subseteq \overline{V}_{r_1} \subseteq U.
$$

This can be done by applying the assumption that $X$ is normal to the disjoint closed sets, $H$ and $U^C$, to obtain open sets $V$ and $W$ with

$$
H \subseteq V, \quad U^C \subseteq W, \quad \text{and } V \cap W = \emptyset.
$$

Then

$$
H \subseteq V \subseteq \overline{V}, \quad \overline{V} \cap U^C = \emptyset
$$

and so let $V_{r_1} = V$. 
Suppose $V_{r_1}, \ldots, V_{r_k}$ have been chosen and list the rational numbers $r_1, \ldots, r_k$ in order,

$$r_{l_1} < r_{l_2} < \cdots < r_{l_k} \text{ for } \{l_1, \ldots, l_k\} = \{1, \ldots, k\}.$$

If $r_{k+1} > r_{l_k}$ then letting $p = r_{l_k}$, let $V_{r_{k+1}}$ satisfy

$$V_p \subseteq V_{r_{k+1}} \subseteq V_{r_k} \subseteq U.$$

If $r_{k+1} \in (r_{l_i}, r_{l_{i+1}})$, let $p = r_{l_i}$ and let $q = r_{l_{i+1}}$. Then let $V_{r_{k+1}}$ satisfy

$$V_p \subseteq V_{r_{k+1}} \subseteq V_{r_k} \subseteq V_q.$$

If $r_{k+1} < r_{l_1}$, let $p = r_{l_1}$ and let $V_{r_{k+1}}$ satisfy

$$H \subseteq V_{r_{k+1}} \subseteq V_{r_k} \subseteq V_p.$$

Thus there exist open sets $V_r$ for each $r \in \mathbb{Q} \cap (0, 1)$ with the property that if $r < s$,

$$H \subseteq V_r \subseteq V_s \subseteq V_p \subseteq U.$$

Now let

$$f(x) = \min \{\inf \{t \in D : x \in V_t\}, 1\}, \quad f(x) \equiv 1 \text{ if } x \notin \bigcup_{t \in D} V_t.$$

(Recall $D = \mathbb{Q} \cap (0, 1]$.) I claim $f$ is continuous.

$$f^{-1}([0, a)) = \bigcup \{V_t : t < a, t \in D\},$$

an open set.

Next consider $x \in f^{-1}([0, a])$ so $f(x) \leq a$. If $t > a$, then $x \in V_t$ because if not, then

$$f(x) \equiv \inf \{t \in D : x \in V_t\} > a.$$

Thus

$$f^{-1}([0, a]) \subseteq \bigcap \{V_t : t > a\} = \bigcap \{V_t : t > a\}$$

which is a closed set. If $x \in \bigcap \{V_t : t > a\}$, then $x \in \bigcap \{V_t : t > a\}$ and so $f(x) \leq a$.

If $a = 1$, $f^{-1}([0, 1]) = f^{-1}([0, a]) = X$. Therefore,

$$f^{-1}((a, 1]) = X \setminus f^{-1}([0, a]) = \text{open set}.$$ 

It follows $f$ is continuous. Clearly $f(x) = 0$ on $H$. If $x \in U^C$, then $x \notin V_t$ for any $t \in D$ so $f(x) = 1$ on $U^C$. Let $g(x) = 1 - f(x)$. This proves the theorem.

In any metric space there is a much easier proof of the conclusion of Urysohn’s lemma which applies.

**Lemma 10.2.2** Let $S$ be a nonempty subset of a metric space, $(X, d)$. Define

$$f(x) \equiv \text{dist}(x, S) \equiv \inf \{d(x, y) : y \in S\}.$$

Then $f$ is continuous.
**Proof:** Consider \( |f(x) - f(x_1)| \) and suppose without loss of generality that \( f(x_1) \geq f(x) \). Then choose \( y \in S \) such that \( f(x) + \varepsilon > d(x, y) \). Then

\[
|f(x_1) - f(x)| = f(x_1) - f(x) \leq f(x_1) - d(x, y) + \varepsilon \\
\leq d(x_1, y) - d(x, y) + \varepsilon \\
\leq d(x, x_1) + d(x, y) - d(x, y) + \varepsilon \\
= d(x, x_1) + \varepsilon.
\]

Since \( \varepsilon \) is arbitrary, it follows that \( |f(x_1) - f(x)| \leq d(x_1, x) \) and this proves the lemma.

**Theorem 10.2.3** (*Urysohn’s lemma for metric space*) Let \( H \) be a closed subset of an open set, \( U \) in a metric space, \((X, d)\). Then there exists a continuous function, \( g : X \to [0, 1] \) such that \( g(x) = 1 \) for all \( x \in H \) and \( g(x) = 0 \) for all \( x \notin U \).

**Proof:** If \( x \notin C \), a closed set, then \( \text{dist}(x, C) > 0 \) because if not, there would exist a sequence of points of \( C \) converging to \( x \) and it would follow that \( x \in C \). Therefore, \( \text{dist}(x, H) + \text{dist}(x, U^C) > 0 \) for all \( x \in X \). Now define a continuous function, \( g \) as

\[
g(x) = \frac{\text{dist}(x, U^C)}{\text{dist}(x, H) + \text{dist}(x, U^C)}.
\]

It is easy to see this verifies the conclusions of the theorem and this proves the theorem.

**Theorem 10.2.4** Every compact Hausdorff space is normal.

**Proof:** First it is shown that \( X \), is regular. Let \( H \) be a closed set and let \( p \notin H \). Then for each \( h \in H \), there exists an open set \( U_h \) containing \( p \) and an open set \( V_h \) containing \( h \) such that \( U_h \cap V_h = \emptyset \). Since \( H \) must be compact, it follows there are finitely many of the sets \( V_h \), \( V_{h_1} \cdots V_{h_n} \), such that \( H \subseteq \bigcup_{i=1}^{n} V_{h_i} \). Then letting \( U = \bigcap_{i=1}^{n} U_{h_i} \) and \( V = \bigcup_{i=1}^{n} V_{h_i} \), it follows that \( p \in U \), \( H \subseteq V \) and \( U \cap V = \emptyset \). Thus \( X \) is regular as claimed.

Next let \( K \) and \( H \) be disjoint nonempty closed sets. Using regularity of \( X \), for every \( k \in K \), there exists an open set \( U_k \) containing \( k \) and an open set \( V_k \) containing \( H \) such that these two open sets have empty intersection. Thus \( H \cap U_k = \emptyset \). Finitely many of the \( U_k \), \( U_{k_1}, \cdots, U_{k_p} \) cover \( K \) and so \( \bigcup_{i=1}^{p} U_{k_i} \) is a closed set which has empty intersection with \( H \). Therefore, \( K \subseteq \bigcup_{i=1}^{p} U_{k_i} \) and \( H \subseteq \bigcup_{i=1}^{p} U_{k_i} \). This proves the theorem.

A useful construction when dealing with locally compact Hausdorff spaces is the notion of the one point compactification of the space discussed earlier. However, it is reviewed here for the sake of convenience or in case you have not read the earlier treatment.

**Definition 10.2.5** Suppose \((X, \tau)\) is a locally compact Hausdorff space. Then let \( \bar{X} = X \cup \{\infty\} \) where \( \infty \) is just the name of some point which is not in \( X \) which is
called the point at infinity. A basis for the topology \( \bar{\tau} \) for \( \bar{X} \) is

\[
\tau \cup \{K^C \text{ where } K \text{ is a compact subset of } X\}.
\]

The complement is taken with respect to \( \bar{X} \) and so the open sets, \( K^C \) are basic open sets which contain \( \infty \).

The reason this is called a compactification is contained in the next lemma.

**Lemma 10.2.6** If \( (X, \tau) \) is a locally compact Hausdorff space, then \( (\bar{X}, \bar{\tau}) \) is a compact Hausdorff space. Also if \( U \) is an open set of \( \bar{\tau} \), then \( U \setminus \{\infty\} \) is an open set of \( \tau \).

**Proof:** Since \( (X, \tau) \) is a locally compact Hausdorff space, it follows \( (\bar{X}, \bar{\tau}) \) is a Hausdorff topological space. The only case which needs checking is the one of \( p \in X \) and \( \infty \). Since \( (X, \tau) \) is locally compact, there exists an open set of \( \tau \), \( U \) having compact closure which contains \( p \). Then \( p \in U \) and \( \infty \in \overline{U^C} \) and these are disjoint open sets containing the points, \( p \) and \( \infty \) respectively. Now let \( C \) be an open cover of \( X \) with sets from \( \bar{\tau} \). Then \( \infty \) must be in some set, \( U_\infty \) from \( C \), which must contain a set of the form \( K^C \) where \( K \) is a compact subset of \( X \). Then there exist sets from \( C \), \( U_1, \ldots, U_r \) which cover \( K \). Therefore, a finite subcover of \( \bar{X} \) is \( U_1, \ldots, U_r, U_\infty \).

To see the last claim, suppose \( U \) contains \( \infty \) since otherwise there is nothing to show. Notice that if \( C \) is a compact set, then \( X \setminus C \) is an open set. Therefore, if \( x \in U \setminus \{\infty\} \), and if \( \bar{X} \setminus C \) is a basic open set contained in \( U \) containing \( \infty \), then if \( x \) is in this basic open set of \( \bar{X} \), it is also in the open set \( X \setminus C \subseteq U \setminus \{\infty\} \). If \( x \) is not in any basic open set of the form \( \bar{X} \setminus C \) then \( x \) is contained in an open set of \( \tau \) which is contained in \( U \setminus \{\infty\} \). Thus \( U \setminus \{\infty\} \) is indeed open in \( \tau \).

**Theorem 10.2.7** Let \( X \) be a locally compact Hausdorff space, and let \( K \) be a compact subset of the open set \( V \). Then there exists a continuous function, \( f : X \to [0, 1] \), such that \( f \) equals 1 on \( K \) and \( \{x : f(x) \neq 0\} \equiv \text{sgn}(f) \) is a compact subset of \( V \).

**Proof:** Let \( \bar{X} \) be the space just described. Then \( K \) and \( V \) are respectively closed and open in \( \bar{\tau} \). By Theorem 10.2.6 there exist open sets in \( \bar{\tau} \), \( U \), and \( W \) such that \( K \subseteq U, \infty \in V^C \subseteq W \), and \( U \cap W = U \cap (W \setminus \{\infty\}) = 0 \).
Thus $W \setminus \{\infty\}$ is an open set in the original topological space which contains $V^C$, $U$ is an open set in the original topological space which contains $K$, and $W \setminus \{\infty\}$ and $U$ are disjoint.

Now for each $x \in K$, let $U_x$ be a basic open set whose closure is compact and such that

$$x \in U_x \subseteq U.$$ 

Thus $U_x$ must have empty intersection with $V^C$ because the open set, $W \setminus \{\infty\}$ contains no points of $U_x$. Since $K$ is compact, there are finitely many of these sets, $U_{x_1}, U_{x_2}, \ldots, U_{x_n}$ which cover $K$. Now let $H \equiv \bigcup_{i=1}^n U_{x_i}$.

Claim: $\overline{H} = \bigcup_{i=1}^n \overline{U_{x_i}}$.

Proof of claim: Suppose $p \in \overline{H}$. If $p \notin \bigcup_{i=1}^n \overline{U_{x_i}}$, then if follows $p \notin \overline{U_{x_i}}$ for each $i$. Therefore, there exists an open set, $R_i$ containing $p$ such that $R_i$ contains no other points of $U_{x_i}$. Therefore, $R \equiv \bigcap_{i=1}^n R_i$ is an open set containing $p$ which contains no other points of $\bigcup_{i=1}^n U_{x_i} = W$, a contradiction. Therefore, $\overline{H} \subseteq \bigcup_{i=1}^n \overline{U_{x_i}}$.

On the other hand, if $p \in \overline{U_{x_i}}$, then $p$ is obviously in $\overline{H}$ so this proves the claim.

From the claim, $K \subseteq H \subseteq \overline{H} \subseteq V$ and $\overline{H}$ is compact because it is the finite union of compact sets. By Urysohn’s lemma, there exists $f_1$ continuous on $\overline{H}$ which has values in $[0, 1]$ such that $f_1$ equals 1 on $K$ and equals 0 off $H$, let $f$ denote the function which extends $f_1$ to be 0 off $\overline{H}$. Then for $\alpha > 0$, the continuity of $f_1$ implies there exists $U$ open in the topological space such that

$$f^{-1}((-\infty, \alpha)) = f_1^{-1}((-\infty, \alpha)) \cup \overline{H}^C = (U \cap \overline{H}) \cup \overline{H}^C = U \cup \overline{H}^C$$

an open set. If $\alpha \leq 0$,

$$f^{-1}((-\infty, \alpha)) = \emptyset$$

an open set. If $\alpha > 0$, there exists an open set $U$ such that

$$f^{-1}((\alpha, \infty)) = f_1^{-1}((\alpha, \infty)) = U \cap \overline{H} = U \cap H$$

because $U$ must be a subset of $H$ since by definition $f = 0$ off $H$. If $\alpha \leq 0$, then

$$f^{-1}((\alpha, \infty)) = X,$$

an open set. Thus $f$ is continuous and $\text{spt}(f) \subseteq \overline{H}$, a compact subset of $V$. This proves the theorem.

In fact, the conclusion of the above theorem could be used to prove that the topological space is locally compact. However, this is not needed here.

In case you would like a more elementary proof which does not use the one point compactification idea, here is such a proof.

**Theorem 10.2.8** Let $X$ be a locally compact Hausdorff space, and let $K$ be a compact subset of the open set $V$. Then there exists a continuous function, $f : X \rightarrow [0, 1]$, such that $f$ equals 1 on $K$ and $\{x : f(x) \neq 0\} \equiv \text{spt}(f)$ is a compact subset of $V$. 

Proof: To begin with, here is a claim. This claim is obvious in the case of a metric space but requires some proof in this more general case.

Claim: If \( k \in K \) then there exists an open set \( U_k \) containing \( k \) such that \( \overline{U_k} \) is contained in \( V \).

Proof of claim: Since \( X \) is locally compact, there exists a basis of open sets whose closures are compact, \( \mathcal{U} \). Denote by \( \mathcal{C} \) the set of all \( U \in \mathcal{U} \) which contain \( k \) and let \( \mathcal{C}' \) denote the set of all closures of these sets of \( \mathcal{C} \) intersected with the closed set \( V^C \). Thus \( \mathcal{C}' \) is a collection of compact sets. I will argue that there are finitely many of the sets of \( \mathcal{C}' \) which have empty intersection. If not, then \( \mathcal{C}' \) has the finite intersection property and so there exists a point \( p \) in all of them. Since \( X \) is a Hausdorff space, there exist disjoint basic open sets from \( \mathcal{U} \), \( A, B \) such that \( k \in A \) and \( p \in B \). Therefore, \( p \not\in \overline{A} \) contrary to the above requirement that \( p \) be in all such sets. It follows there are sets \( A_1, \ldots, A_m \) in \( \mathcal{C} \) such that

\[
V^C \cap \overline{A_1} \cap \cdots \cap \overline{A_m} = \emptyset
\]

Let \( U_k = A_1 \cap \cdots \cap A_m \). Then \( \overline{U_k} \subseteq \overline{A_1} \cap \cdots \cap \overline{A_m} \) and so it has empty intersection with \( V^C \). Thus it is contained in \( V \). Also \( \overline{U_k} \) is a closed subset of the compact set \( \overline{A_1} \) so it is compact. This proves the claim.

Now to complete the proof of the theorem, since \( K \) is compact, there are finitely many \( U_k \) of the sort just described which cover \( K, U_{k_1}, \ldots, U_{k_r} \). Let

\[
H = \cup_{i=1}^{r} U_{k_i}
\]

so it follows

\[
\overline{H} = \cup_{i=1}^{r} \overline{U_{k_i}}
\]

and so \( K \subseteq H \subseteq \overline{H} \subseteq V \) and \( \overline{H} \) is a compact set. By Urysohn’s lemma, there exists \( f_1 \) continuous on \( \overline{H} \) which has values in \( [0, 1] \) such that \( f_1 \) equals 1 on \( K \) and equals 0 off \( H \). Let \( f \) denote the function which extends \( f_1 \) to be 0 off \( \overline{H} \). Then for \( \alpha > 0 \), the continuity of \( f_1 \) implies there exists \( U \) open in the topological space such that

\[
f^{-1} ((-\infty, \alpha)) = f_1^{-1} ((-\infty, \alpha)) \cup \overline{H}^C = (U \cap \overline{H}) \cup \overline{H}^C = U \cup \overline{H}^C
\]

an open set. If \( \alpha \leq 0 \),

\[
f^{-1} ((-\infty, \alpha)) = \emptyset
\]

an open set. If \( \alpha > 0 \), there exists an open set \( U \) such that

\[
f^{-1} ((\alpha, \infty)) = f_1^{-1} ((\alpha, \infty)) = U \cap \overline{H} = U \cap H
\]

because \( U \) must be a subset of \( H \) since by definition \( f = 0 \) off \( H \). If \( \alpha \leq 0 \), then

\[
f^{-1} ((\alpha, \infty)) = X,
\]

an open set. Thus \( f \) is continuous and \( \text{spt}(f) \subseteq \overline{H} \), a compact subset of \( V \). This proves the theorem.
**Definition 10.2.9** Define \( \text{spt}(f) \) (support of \( f \)) to be the closure of the set \( \{ x : f(x) \neq 0 \} \). If \( V \) is an open set, \( C_c(V) \) will be the set of continuous functions \( f \), defined on \( \Omega \) having \( \text{spt}(f) \subseteq V \). Thus in Theorem 10.2.7 or 10.2.8, \( f \in C_c(V) \).

**Definition 10.2.10** If \( K \) is a compact subset of an open set, \( V \), then \( K \prec \phi \prec V \) if \( \phi \in C_c(V) \), \( \phi(K) = \{ 1 \} \), \( \phi(\Omega) \subseteq [0, 1] \), where \( \Omega \) denotes the whole topological space considered. Also for \( \phi \in C_c(\Omega) \), \( K \prec \phi \) if \( \phi(\Omega) \subseteq [0, 1] \) and \( \phi(K) = 1 \).

**Theorem 10.2.11** (Partition of unity) Let \( K \) be a compact subset of a locally compact Hausdorff topological space satisfying Theorem 10.2.7 or 10.2.8 and suppose \( K \subseteq V = \cup_{i=1}^n V_i \), \( V_i \) open.

Then there exist \( \psi_i \prec V_i \) with

\[
\sum_{i=1}^n \psi_i(x) = 1
\]

for all \( x \in K \).

**Proof:** Let \( K_1 = K \setminus \cup_{i=2}^n V_i \). Thus \( K_1 \) is compact and \( K_1 \subseteq V_1 \). Let \( K_2 \subseteq W_1 \subseteq \overline{W}_1 \subseteq V_1 \) with \( \overline{W}_1 \) compact. To obtain \( W_1 \), use Theorem 10.2.7 or 10.2.8 to get \( f \) such that \( K_1 \prec f \prec V_1 \) and let \( W_1 \equiv \{ x : f(x) \neq 0 \} \). Thus \( W_1, V_2, \ldots, V_n \) covers \( K \) and \( \overline{W}_1 \subseteq V_1 \). Let \( K_2 = K \setminus (\cup_{i=3}^n V_i \cup W_1) \). Then \( K_2 \) is compact and \( K_2 \subseteq V_2 \). Let \( K_2 \subseteq W_2 \subseteq \overline{W}_2 \subseteq V_2 \) compact. Continue this way finally obtaining \( W_1, \ldots, W_n, K \subseteq W_1 \cup \cdots \cup W_n \), and \( \overline{W}_i \subseteq \overline{V}_i \) compact. Now let \( \overline{W}_i \subseteq U_i \subseteq \overline{U}_i \subseteq V_i, \overline{U}_i \) compact.

By Theorem 10.2.7 or 10.2.8, let \( \overline{U}_i \prec \phi_i \prec V_i \), \( \cup_{i=1}^n \overline{W}_i \prec \gamma \prec \cup_{i=1}^n \overline{U}_i \). Define

\[
\psi_i(x) = \begin{cases} 
\gamma(x)\phi_j(x)/\sum_{j=1}^n \phi_j(x) & \text{if } \sum_{j=1}^n \phi_j(x) \neq 0, \\
0 & \text{if } \sum_{j=1}^n \phi_j(x) = 0.
\end{cases}
\]

If \( x \) is such that \( \sum_{j=1}^n \phi_j(x) = 0 \), then \( x \notin \cup_{i=1}^n \overline{U}_i \). Consequently \( \gamma(y) = 0 \) for all \( y \) near \( x \) and so \( \psi_i(y) = 0 \) for all \( y \) near \( x \). Hence \( \psi_i \) is continuous at such \( x \).
If \( \sum_{j=1}^{n} \phi_j(x) \neq 0 \), this situation persists near \( x \) and so \( \psi_i \) is continuous at such points. Therefore \( \psi_i \) is continuous. If \( x \in K \), then \( \gamma(x) = 1 \) and so \( \sum_{j=1}^{n} \psi_j(x) = 1 \). Clearly \( 0 \leq \psi_i(x) \leq 1 \) and \( \text{spt}(\psi_j) \subseteq V_j \). This proves the theorem.

The following corollary won’t be needed immediately but is of considerable interest later.

**Corollary 10.2.12** If \( H \) is a compact subset of \( V_i \), there exists a partition of unity such that \( \psi_i(x) = 1 \) for all \( x \in H \) in addition to the conclusion of Theorem 10.2.11.

**Proof:** Keep \( V_i \) the same but replace \( V_j \) with \( \tilde{V}_j \equiv V_j \setminus H \). Now in the proof above, applied to this modified collection of open sets, if \( j \neq i, \phi_j(x) = 0 \) whenever \( x \in H \). Therefore, \( \psi_i(x) = 1 \) on \( H \).

### 10.3 Positive Linear Functionals

**Definition 10.3.1** Let \((\Omega, \tau)\) be a topological space. \( L : C_c(\Omega) \to \mathbb{C} \) is called a positive linear functional if \( L \) is linear,
\[
L(af_1 + bf_2) = aLf_1 + bLf_2,
\]
and if \( Lf \geq 0 \) whenever \( f \geq 0 \).

**Theorem 10.3.2** (Riesz representation theorem) Let \((\Omega, \tau)\) be a locally compact Hausdorff space and let \( L \) be a positive linear functional on \( C_c(\Omega) \): Then there exists a \( \sigma \) algebra \( S \) containing the Borel sets and a unique measure \( \mu \), defined on \( S \), such that
\[
\begin{align*}
\mu & \text{ is complete,} \\
\mu(K) & < \infty \text{ for all } K \text{ compact,} \\
\mu(F) & = \sup\{\mu(K) : K \subseteq F, \ K \text{ compact}\},
\end{align*}
\]
for all \( F \) open and for all \( F \in S \) with \( \mu(F) < \infty \),
\[
\mu(F) \equiv \inf\{\mu(V) : V \supseteq F, \ V \text{ open}\}
\]
for all \( F \in S \), and
\[
\int f d\mu = Lf \text{ for all } f \in C_c(\Omega).
\]

The plan is to define an outer measure and then to show that it, together with the \( \sigma \) algebra of sets measurable in the sense of Caratheodory, satisfies the conclusions of the theorem. Always, \( K \) will be a compact set and \( V \) will be an open set.

**Definition 10.3.3** \( \mu(V) \equiv \sup\{Lf : f < V\} \) for \( V \) open, \( \mu(\emptyset) = 0 \). \( \mu(E) \equiv \inf\{\mu(V) : V \supseteq E\} \) for arbitrary sets \( E \).

**Lemma 10.3.4** \( \mu \) is a well-defined outer measure.
**Proof:** First it is necessary to verify $\mu$ is well defined because there are two descriptions of it on open sets. Suppose then that $\mu_1 (V) \equiv \inf \{ \mu(U) : U \supseteq V \text{ and } U \text{ is open} \}$. It is required to verify that $\mu_1 (V) = \mu (V)$ where $\mu$ is given as $\sup \{ Lf : f \prec V \}$. If $U \supseteq V$, then $\mu_1 (U) \geq \mu_1 (V)$ directly from the definition. Hence from the definition of $\mu_1$, it follows $\mu_1 (V) \geq \mu (V)$. On the other hand, $V \supseteq V$ and so $\mu_1 (V) \leq \mu (V)$. This verifies $\mu$ is well defined.

It remains to show that $\mu$ is an outer measure. Let $V = \cup_{i=1}^{\infty} V_i$ and let $f \prec V$. Then $\text{spt}(f) \subseteq \cup_{i=1}^{n} V_i$ for some $n$. Let $\psi_i \prec V_i, \sum_{i=1}^{n} \psi_i = 1$ on $\text{spt}(f)$.

$$Lf = \sum_{i=1}^{n} L(f \psi_i) \leq \sum_{i=1}^{n} \mu(V_i) \leq \sum_{i=1}^{\infty} \mu(V_i).$$

Hence

$$\mu(V) \leq \sum_{i=1}^{\infty} \mu(V_i)$$

since $f \prec V$ is arbitrary. Now let $E = \cup_{i=1}^{\infty} E_i$. Is $\mu(E) \leq \sum_{i=1}^{\infty} \mu(E_i)$? Without loss of generality, it can be assumed $\mu(E_i) < \infty$ for each $i$ since if not so, there is nothing to prove. Let $V_i \supseteq E_i$ with $\mu(E_i) + \varepsilon 2^{-i} > \mu(V_i)$.

$$\mu(E) \leq \mu(\cup_{i=1}^{\infty} V_i) \leq \sum_{i=1}^{\infty} \mu(V_i) \leq \varepsilon + \sum_{i=1}^{\infty} \mu(E_i).$$

Since $\varepsilon$ was arbitrary, $\mu(E) \leq \sum_{i=1}^{\infty} \mu(E_i)$ which proves the lemma.

**Lemma 10.3.5** Let $K$ be compact, $g \geq 0, g \in C_c(\Omega)$, and $g = 1$ on $K$. Then $\mu(K) \leq Lg$. Also $\mu(K) < \infty$ whenever $K$ is compact.

**Proof:** Let $\alpha \in (0, 1)$ and $V_{\alpha} = \{ x : g(x) > \alpha \}$ so $V_{\alpha} \supseteq K$ and let $h \prec V_{\alpha}$.

Then $h \leq 1$ on $V_{\alpha}$ while $\alpha^{-1} g^{-1} \geq 1$ on $V_{\alpha}$ and so $g \alpha^{-1} \geq h$ which implies $L(g \alpha^{-1}) \geq Lh$ and that therefore, since $L$ is linear,

$$Lg \geq \alpha Lh.$$ 

Since $h \prec V_{\alpha}$ is arbitrary, and $K \subseteq V_{\alpha}$,

$$Lg \geq \alpha \mu(V_{\alpha}) \geq \alpha \mu(K).$$

Letting $\alpha \uparrow 1$ yields $Lg \geq \mu(K)$. This proves the first part of the lemma. The second assertion follows from this and Theorem [10.2.7]. If $K$ is given, let

$$K \prec g \prec \Omega$$

and so from what was just shown, $\mu(K) \leq Lg < \infty$. This proves the lemma.
Lemma 10.3.6 If $A$ and $B$ are disjoint compact subsets of $\Omega$, then $\mu(A \cup B) = \mu(A) + \mu(B)$.

Proof: By Theorem 10.2.7 or 10.2.8, there exists $h \in C_c(\Omega)$ such that $A \prec h \prec B^C$. Let $U_1 = h^{-1}(\mathbb{I}, 1)$, $V_1 = h^{-1}((0, \frac{1}{2}))$. Then $A \subseteq U_1$, $B \subseteq V_1$ and $U_1 \cap V_1 = \emptyset$.

From Lemma 10.3.5, $\mu(A \cup B) < \infty$ and so there exists an open set, $W$ such that

$$W \supseteq A \cup B, \mu(A \cup B) + \varepsilon > \mu(W).$$

Now let $U = U_1 \cap W$ and $V = V_1 \cap W$. Then

$$U \supseteq A, \ V \supseteq B, \ U \cap V = \emptyset, \text{ and } \mu(A \cup B) + \varepsilon \geq \mu(W) \geq \mu(U \cup V).$$

Let $A \prec f \prec U$, $B \prec g \prec V$. Then by Lemma 10.3.5,

$$\mu(A \cup B) + \varepsilon \geq \mu(U \cup V) \geq L(f + g) = Lf + Lg \geq \mu(A) + \mu(B).$$

Since $\varepsilon > 0$ is arbitrary, this proves the lemma.

From Lemma 10.3.7, the following lemma is obtained.

Lemma 10.3.7 Let $f \in C_c(\Omega)$, $f(\Omega) \subseteq [0, 1]$. Then $\mu(spt(f)) \geq Lf$. Also, every open set, $V$ satisfies

$$\mu(V) = \sup \{\mu(K) : K \subseteq V\}.$$

Proof: Let $V \supseteq spt(f)$ and let $spt(f) \prec g \prec V$. Then $Lf \leq Lg \leq \mu(V)$ because $f \leq g$. Since this holds for all $V \supseteq spt(f)$, $Lf \leq \mu(spt(f))$ by definition of $\mu$.

Finally, let $V$ be open and let $l < \mu(V)$. Then from the definition of $\mu$, there exists $f \prec V$ such that $L(f) > l$. Therefore, $l < \mu(spt(f)) \leq \mu(V)$ and so this shows the claim about inner regularity of the measure on an open set.

At this point, the conditions of Lemma 10.3.11 have been verified. Thus $S$ contains the Borel sets and $\mu$ is inner regular on sets of $S$ having finite measure.

It remains to show $\mu$ satisfies 10.3.11.

Lemma 10.3.8 $\int f \, d\mu = Lf$ for all $f \in C_c(\Omega)$.
CHAPTER 10. THE CONSTRUCTION OF MEASURES

**Proof:** Let \( f \in C_c(\Omega) \), \( f \) real-valued, and suppose \( f(\Omega) \subseteq [a, b] \). Choose \( t_0 < a \) and let \( t_0 < t_1 < \cdots < t_n = b, t_i - t_{i-1} < \varepsilon \). Let

\[
E_i = f^{-1}((t_{i-1}, t_i)) \cap \text{spt}(f). \tag{10.3.12}
\]

Note that \( \bigcup_{i=1}^n E_i \) is a closed set, and in fact

\[
\bigcup_{i=1}^n E_i = \text{spt}(f) \tag{10.3.13}
\]

since \( \Omega = \bigcup_{i=1}^n f^{-1}((t_{i-1}, t_i)) \). Let \( V_i \supseteq E_i, V_i \) is open and let \( V_i \) satisfy

\[
f(x) < t_i + \varepsilon \text{ for all } x \in V_i, \tag{10.3.14}
\]

\[
\mu(V_i \setminus E_i) < \varepsilon/n.
\]

By Theorem [10.2.11] there exists \( h_i \in C_c(\Omega) \) such that

\[
h_i \prec V_i, \quad \sum_{i=1}^n h_i(x) = 1 \text{ on } \text{spt}(f).
\]

Now note that for each \( i, \)

\[
f(x)h_i(x) \leq h_i(x)(t_i + \varepsilon).
\]

(If \( x \in V_i, \) this follows from [10.3.14]. If \( x \notin V_i \) both sides equal 0.) Therefore,

\[
L f = L \left( \sum_{i=1}^n f h_i \right) \leq L \left( \sum_{i=1}^n h_i(t_i + \varepsilon) \right)
\]

\[
= \sum_{i=1}^n (t_i + \varepsilon) L(h_i)
\]

\[
= \sum_{i=1}^n \left( |t_0| + t_i + \varepsilon \right) L(h_i) - |t_0| L \left( \sum_{i=1}^n h_i \right).
\]

Now note that \( |t_0| + t_i + \varepsilon \geq 0 \) and so from the definition of \( \mu \) and Lemma [10.3.12], this is no larger than

\[
\sum_{i=1}^n \left( |t_0| + t_i + \varepsilon \right) \mu(V_i) - |t_0| \mu(\text{spt}(f))
\]

\[
\leq \sum_{i=1}^n \left( |t_0| + t_i + \varepsilon \right) \left( \mu(E_i) + \varepsilon/n \right) - |t_0| \mu(\text{spt}(f))
\]

\[
= |t_0| \sum_{i=1}^n \mu(E_i) + |t_0| \varepsilon + \sum_{i=1}^n t_i \mu(E_i) + \varepsilon(|t_0| + |b|)
\]
From (10.3.13) and (10.3.12), the first and last terms cancel. Therefore this is no larger than

\[ \sum_{i=1}^{n} t_i \frac{\varepsilon}{n} + \varepsilon \sum_{i=1}^{n} \mu(E_i) + \varepsilon^2 - |t_0| \mu(\text{spt}(f)). \]

Since \( \varepsilon > 0 \) is arbitrary,

\[ Lf \leq \int \! fd\mu \quad (10.3.15) \]

for all \( f \in C_c(\Omega) \), \( f \) real. Hence equality holds in (10.3.13) because \( L(-f) \leq -\int \! fd\mu \) so \( L(f) \geq \int \! fd\mu \). Thus \( Lf = \int \! fd\mu \) for all \( f \in C_c(\Omega) \). Just apply the result for real functions to the real and imaginary parts of \( f \). This proves the Lemma.

This gives the existence part of the Riesz representation theorem.

It only remains to prove uniqueness. Suppose both \( \mu_1 \) and \( \mu_2 \) are measures on \( S \) satisfying the conclusions of the theorem. Then if \( K \) is compact and \( V \supseteq K \), let \( K \prec f \prec V \). Then

\[ \mu_1(K) \leq \int \! fd\mu_1 = Lf = \int \! fd\mu_2 \leq \mu_2(V). \]

Thus \( \mu_1(K) \leq \mu_2(K) \) for all \( K \). Similarly, the inequality can be reversed and so it follows the two measures are equal on compact sets. By the assumption of inner regularity on open sets, the two measures are also equal on all open sets. By outer regularity, they are equal on all sets of \( S \). This proves the theorem.

An important example of a locally compact Hausdorff space is any metric space in which the closures of balls are compact. For example, \( \mathbb{R}^n \) with the usual metric is an example of this. Not surprisingly, more can be said in this important special case.

**Theorem 10.3.9** Let \( (\Omega, \tau) \) be a metric space in which the closures of the balls are compact and let \( L \) be a positive linear functional defined on \( C_c(\Omega) \). Then there exists a measure representing the positive linear functional which satisfies all the conclusions of Theorem (10.2.7 or 10.2.8) and in addition the property that \( \mu \) is regular. The same conclusion follows if \( (\Omega, \tau) \) is a compact Hausdorff space.

**Theorem 10.3.10** Let \( (\Omega, \tau) \) be a metric space in which the closures of the balls are compact and let \( L \) be a positive linear functional defined on \( C_c(\Omega) \). Then there exists a measure representing the positive linear functional which satisfies all the conclusions of Theorem (10.2.7 or 10.2.8) and in addition the property that \( \mu \) is regular. The same conclusion follows if \( (\Omega, \tau) \) is a compact Hausdorff space.
Proof: Let $\mu$ and $S$ be as described in Theorem 10.3.2. The outer regularity comes automatically as a conclusion of Theorem 10.3.2. It remains to verify inner regularity. Let $F \in S$ and let $l < k < \mu (F)$. Now let $z \in \Omega$ and $\Omega_n = B(z, n)$ for $n \in \mathbb{N}$. Thus $F \cap \Omega_n \uparrow F$. It follows that for $n$ large enough,

$$k < \mu (F \cap \Omega_n) \leq \mu (F).$$

Since $\mu (F \cap \Omega_n) < \infty$ it follows there exists a compact set, $K$ such that $K \subseteq F \cap \Omega_n \subseteq F$ and $l < \mu (K) \leq \mu (F)$.

This proves inner regularity. In case $(\Omega, \tau)$ is a compact Hausdorff space, the conclusion of inner regularity follows from Theorem 10.3.2. This proves the theorem.

The proof of the above yields the following corollary.

Corollary 10.3.11 Let $(\Omega, \tau)$ be a locally compact Hausdorff space and suppose $\mu$ defined on a $\sigma$ algebra, $S$ represents the positive linear functional $L$ where $L$ is defined on $C_c (\Omega)$ in the sense of Theorem 10.2.7 or 10.2.8. Suppose also that there exist $\Omega_n \in S$ such that $\Omega = \bigcup_{n=1}^{\infty} \Omega_n$ and $\mu (\Omega_n) < \infty$. Then $\mu$ is regular.

The following is on the uniqueness of the $\sigma$ algebra in some cases.

Definition 10.3.12 Let $(\Omega, \tau)$ be a locally compact Hausdorff space and let $L$ be a positive linear functional defined on $C_c (\Omega)$ such that the complete measure defined by the Riesz representation theorem for positive linear functionals is inner regular. Then this is called a Radon measure. Thus a Radon measure is complete, and regular.

Corollary 10.3.13 Let $(\Omega, \tau)$ be a locally compact Hausdorff space which is also $\sigma$ compact meaning

$$\Omega = \bigcup_{n=1}^{\infty} \Omega_n, \Omega_n \text{ is compact},$$

and let $L$ be a positive linear functional defined on $C_c (\Omega)$. Then if $(\mu_1, S_1)$, and $(\mu_2, S_2)$ are two Radon measures, together with their $\sigma$ algebras which represent $L$ then the two $\sigma$ algebras are equal and the two measures are equal.

Proof: Suppose $(\mu_1, S_1)$ and $(\mu_2, S_2)$ both work. It will be shown the two measures are equal on every compact set. Let $K$ be compact and let $V$ be an open set containing $K$. Then let $K \prec f \prec V$. Then

$$\mu_1 (K) = \int_K d\mu_1 \leq \int f d\mu_1 = L (f) = \int f d\mu_2 \leq \mu_2 (V).$$

Therefore, taking the infimum over all $V$ containing $K$ implies $\mu_1 (K) \leq \mu_2 (K)$. Reversing the argument shows $\mu_1 (K) = \mu_2 (K)$. This also implies the two measures are equal on all open sets because they are both inner regular on open sets. It is being assumed the two measures are regular. Now let $F \in S_1$ with $\mu_1 (F) < \infty$. Then there exist sets, $H, G$ such that $H \subseteq F \subseteq G$ such that $H$ is the countable
union of compact sets and \( G \) is a countable intersection of open sets such that \( \mu_1 (G) \neq \mu_1 (H) \) which implies \( \mu_1 (G \setminus H) = 0 \). Now \( G \setminus H \) can be written as the countable intersection of sets of the form \( V_k \setminus K_k \) where \( V_k \) is open, \( \mu_1 (V_k) < \infty \) and \( K_k \) is compact. From what was just shown, \( \mu_2 (V_k \setminus K_k) = \mu_1 (V_k \setminus K_k) \) so it follows \( \mu_2 (G \setminus H) = 0 \) also. Since \( \mu_2 \) is complete, and \( G \) and \( H \) are in \( S_2 \), it follows \( F \in S_2 \) and \( \mu_2 (F) = \mu_1 (F) \). Now for arbitrary \( F \) possibly having \( \mu_1 (F) = \infty \), consider \( F \cap \Omega_n \). From what was just shown, this set is in \( S_2 \) and \( \mu_2 (F \cap \Omega_n) = \mu_1 (F \cap \Omega_n) \).

Taking the union of these \( F \cap \Omega_n \) gives \( F \in S_2 \) and also \( \mu_1 (F) = \mu_2 (F) \). This shows \( S_1 \subseteq S_2 \). Similarly, \( S_2 \subseteq S_1 \).

The following lemma is often useful.

**Lemma 10.3.14** Let \((\Omega, \mathcal{F}, \mu)\) be a measure space where \( \Omega \) is a topological space. Suppose \( \mu \) is a Radon measure and \( f \) is measurable with respect to \( \mathcal{F} \). Then there exists a Borel measurable function, \( g \), such that \( g = f \) a.e.

**Proof:** Assume without loss of generality that \( f \geq 0 \). Then let \( s_n \uparrow f \) pointwise. Say

\[
s_n (\omega) = \sum_{k=1}^{P_n} c_k^n \mathcal{X}_{E_k^n} (\omega)
\]

where \( E_k^n \in \mathcal{F} \). By the outer regularity of \( \mu \), there exists a Borel set, \( F_k^n \supseteq E_k^n \) such that \( \mu (F_k^n) = \mu (E_k^n) \). In fact \( F_k^n \) can be assumed to be a \( G_\delta \) set. Let

\[
t_n (\omega) = \sum_{k=1}^{P_n} c_k^n \mathcal{X}_{F_k^n} (\omega).
\]

Then \( t_n \) is Borel measurable and \( t_n (\omega) = s_n (\omega) \) for all \( \omega \notin N_n \) where \( N_n \in \mathcal{F} \) is a set of measure zero. Now let \( N \equiv \bigcup_{n=1}^{\infty} N_n \). Then \( N \) is a set of measure zero and if \( \omega \notin N \), then \( t_n (\omega) \rightarrow f (\omega) \). Let \( N' \supseteq N \) where \( N' \) is a Borel set and \( \mu (N') = 0 \). Then \( t_n \mathcal{X}_{(N')^c} \) converges pointwise to a Borel measurable function, \( g \), and \( g (\omega) = f (\omega) \) for all \( \omega \notin N' \). Therefore, \( g = f \) a.e. and this proves the lemma.

### 10.4 One Dimensional Lebesgue Measure

To obtain one dimensional Lebesgue measure, you use the positive linear functional \( L \) given by

\[
Lf = \int f (x) \, dx
\]

whenever \( f \in C_c (\mathbb{R}) \). Lebesgue measure, denoted by \( m \) is the measure obtained from the Riesz representation theorem such that

\[
\int f \, dm = Lf = \int f (x) \, dx.
\]

From this it is easy to verify that

\[
m ([a, b]) = m ((a, b)) = b - a. \quad (10.4.16)
\]
This will be done in general a little later but for now, consider the following picture of functions, \( f_k \) and \( g_k \). Note that \( f_k \leq \mathcal{X}_{(a,b)} \leq \mathcal{X}_{[a,b]} \leq g_k \).

Then considering lower sums and upper sums in the inequalities on the ends,

\[
\left( b - a - \frac{2}{k} \right) \leq \int f_k \, dx = \int f_k \, dm \leq m ((a, b)) \leq m ([a, b]) = \int \mathcal{X}_{[a,b]} \, dm \leq \int g_k \, dm = \int g_k \, dx \leq \left( b - a + \frac{2}{k} \right).
\]

From this the claim in 10.4.16 follows.

### 10.5 One Dimensional Lebesgue Stieltjes Measure

This is just a generalization of Lebesgue measure. Instead of the functional,

\[
Lf = \int f(x) \, dx, \quad f \in C_c(\mathbb{R}),
\]

you use the functional

\[
Lf = \int f(x) \, dF(x), \quad f \in C_c(\mathbb{R}),
\]

where \( F \) is an increasing function defined on \( \mathbb{R} \). By Theorem 3.3.4 this functional is easily seen to be well defined. Therefore, by the Riesz representation theorem there exists a unique Radon measure \( \mu \) representing the functional. Thus

\[
\int \mathbb{R} f \, d\mu = \int f \, dF
\]

for all \( f \in C_c(\mathbb{R}) \). Now consider what this measure does to intervals. To begin with, consider what it does to the closed interval, \([a, b] \). The following picture may help.
In this picture \([a_n] \) increases to \(a\) and \([b_n] \) decreases to \(b\). Also suppose \(a, b\) are points of continuity of \(F\). Therefore,

\[
F(b) - F(a) \leq L f_n = \int_R f_n d\mu \leq F(b_n) - F(a_n)
\]

Passing to the limit and using the dominated convergence theorem, this shows

\[
\mu([a, b]) = F(b) - F(a) = F(b^+) - F(a^-).
\]

Next suppose \(a, b\) are arbitrary, maybe not points of continuity of \(F\). Then letting \(a_n\) and \(b_n\) be as in the above picture which are points of continuity of \(F\),

\[
\mu([a, b]) = \lim_{n \to \infty} \mu([a_n, b_n]) = \lim_{n \to \infty} F(b_n) - F(a_n) = F(b^+) - F(a^-).
\]

In particular \(\mu(a) = F(a^+) - F(a^-)\) and so

\[
\mu((a, b)) = F(b^+) - F(a^-) - (F(a^+) - F(a^-)) = F(b^-) - F(a^+).
\]

This shows what \(\mu\) does to intervals. This is stated as the following proposition.

**Proposition 10.5.1** Let \(\mu\) be the measure representing the functional

\[
Lf \equiv \int f dF, \ f \in C_c(R)
\]

for \(F\) an increasing function defined on \(R\). Then

\[
\mu([a, b]) = F(b^+) - F(a^-)
\]

\[
\mu((a, b)) = F(b^-) - F(a^+),
\]

\[
\mu(a) = F(a^+) - F(a^-).
\]

**Observation 10.5.2** Note that all the above would work as well if

\[
Lf \equiv \int f dF, \ f \in C_c([0, \infty))
\]

where \(F\) is continuous at 0 and \(\nu\) is the measure representing this functional. This is because you could just extend \(F(x)\) to equal \(F(0)\) for \(x \leq 0\) and apply the above to the extended \(F\). In this case, \(\nu([0, b]) = F(b^+) - F(0)\).
10.6 The Distribution Function

There is an interesting connection between the Lebesgue integral of a nonnegative function with something called the distribution function.

**Definition 10.6.1** Let \( f \geq 0 \) and suppose \( f \) is measurable. The distribution function is the function defined by

\[
t \rightarrow \mu ([t < f]) .
\]

**Lemma 10.6.2** If \( \{f_n\} \) is an increasing sequence of functions converging pointwise to \( f \) then

\[
\mu ([f > t]) = \lim_{n \to \infty} \mu ([f_n > t])
\]

**Proof:** The sets, \([f_n > t]\) are increasing and their union is \([f > t]\) because if \( f(\omega) > t \), then for all \( n \) large enough, \( f_n(\omega) > t \) also. Therefore, the desired conclusion follows from properties of measures.

**Lemma 10.6.3** Suppose \( s \geq 0 \) is a measurable simple function,

\[
s(\omega) = \sum_{k=1}^{n} a_k \chi_{E_k}(\omega)
\]

where the \( a_k \) are the distinct nonzero values of \( s \), \( 0 < a_1 < a_2 < \cdots < a_n \). Suppose \( \phi \) is a \( C^1 \) function defined on \([0, \infty)\) which has the property that \( \phi(0) = 0 \), \( \phi'(t) > 0 \) for all \( t \). Then

\[
\int_0^\infty \phi'(t) \mu ([s > t]) \, dt = \int \phi(s) \, d\mu.
\]

**Proof:** First note that if \( \mu (E_k) = \infty \) for any \( k \) then both sides equal \( \infty \) and so without loss of generality, assume \( \mu (E_k) < \infty \) for all \( k \). Letting \( a_0 \equiv 0 \), the left side equals

\[
\sum_{k=1}^{n} \int_{a_{k-1}}^{a_k} \phi'(t) \mu ([s > t]) \, dt = \sum_{k=1}^{n} \int_{a_{k-1}}^{a_k} \phi'(t) \sum_{i=k}^{n} \mu (E_i) \, dt
\]

\[
= \sum_{k=1}^{n} \sum_{i=k}^{n} \mu (E_i) \int_{a_{k-1}}^{a_k} \phi'(t) \, dt
\]

\[
= \sum_{k=1}^{n} \sum_{i=k}^{n} \mu (E_i) (\phi(a_k) - \phi(a_{k-1}))
\]

\[
= \sum_{i=1}^{n} \mu (E_i) \sum_{k=1}^{i} (\phi(a_k) - \phi(a_{k-1}))
\]

\[
= \sum_{i=1}^{n} \mu (E_i) \phi(a_i) = \int \phi(s) \, d\mu. \quad \blacksquare
\]

With this lemma the next theorem which is the main result follows easily.
Theorem 10.6.4 Let $f \geq 0$ be measurable and let $\phi$ be a $C^1$ function defined on $[0, \infty)$ which satisfies $\phi' (t) > 0$ for all $t > 0$ and $\phi (0) = 0$. Then
\[
\int \phi (f) \, d\mu = \int_0^\infty \phi' (t) \mu ([f > t]) \, dm.
\]

Proof: By Theorem 9.3.9 on Page 227 there exists an increasing sequence of nonnegative simple functions, $\{s_n\}$ which converges pointwise to $f$. By the monotone convergence theorem and Lemma 10.6.2,
\[
\int \phi (f) \, d\mu = \lim_{n \to \infty} \int \phi (s_n) \, d\mu = \lim_{n \to \infty} \int_0^\infty \phi' (t) \mu ([s_n > t]) \, dm
\]
\[
= \int_0^\infty \phi' (t) \mu ([f > t]) \, dm \quad \blacksquare
\]

This theorem can be generalized to a situation in which $\phi$ is only increasing and continuous. In the generalization I will replace the symbol $\phi$ with $F$ to coincide with earlier notation.

Lemma 10.6.5 Suppose $s \geq 0$ is a measurable simple function,
\[
s (\omega) \equiv \sum_{k=1}^n a_k X_{E_k} (\omega)
\]
where the $a_k$ are the distinct nonzero values of $s, a_1 < a_2 < \cdots < a_n$. Suppose $F$ is an increasing function defined on $[0, \infty), F (0) = 0$, $F$ being continuous at 0 from the right and continuous at every $a_k$. Then letting $\mu$ be a measure and $(\Omega, F, \mu)$ a measure space,
\[
\int_{[0, \infty)} \mu ([s > t]) \, d\nu = \int_\Omega F (s) \, d\mu.
\]
where the integral on the left is the Lebesque integral for the measure $\nu$ given as the Radon measure representing the functional
\[
\int_0^\infty gdF
\]
for $g \in C_c ([0, \infty))$.

Proof: This follows from the following computation and Proposition 10.5.1. Since $F$ is continuous at 0 and the values $a_k$,
\[
\int_0^\infty \mu ([s > t]) \, d\nu (t) = \sum_{k=1}^n \int_{(a_{k-1}, a_k]} \mu ([s > t]) \, d\nu (t)
\]
\[
= \sum_{k=1}^n \int_{(a_{k-1}, a_k]} \sum_{j=k}^n \mu (E_j) \, dF (t) = \sum_{j=1}^n \mu (E_j) \sum_{k=1}^j \nu ([a_{k-1}, a_k])
\]
\[
= \sum_{j=1}^n \mu (E_j) \sum_{k=1}^j (F (a_k) - F (a_{k-1})) = \sum_{j=1}^n \mu (E_j) F (a_j) = \int_\Omega F (s) \, d\mu \quad \blacksquare
\]
CHAPTER 10. THE CONSTRUCTION OF MEASURES

Now here is the generalization to nonnegative measurable \( f \).

**Theorem 10.6.6** Let \( f \geq 0 \) be measurable with respect to \( \mathcal{F} \) where \((\Omega, \mathcal{F}, \mu)\) a measure space, and let \( F \) be an increasing continuous function defined on \([0, \infty)\) and \( F(0) = 0 \). Then

\[
\int_{\Omega} F(f) \, d\mu = \int_{[0, \infty]} \mu([f > t]) \, d\nu(t)
\]

where \( \nu \) is the Radon measure representing

\[
Lg = \int_{0}^{\infty} gdF
\]

for \( g \in C_c([0, \infty)) \).

**Proof:** By Theorem 10.6.3 on Page 227 there exists an increasing sequence of nonnegative simple functions, \( \{s_n\} \) which converges pointwise to \( f \). By the monotone convergence theorem and Lemma 10.6.5,

\[
\int_{\Omega} F(f) \, d\mu = \lim_{n \to \infty} \int_{\Omega} F(s_n) \, d\mu = \lim_{n \to \infty} \int_{[0, \infty]} \mu([s_n > t]) \, d\nu
\]

\[
= \int_{[0, \infty]} \mu([f > t]) \, d\nu
\]

Note that the function \( t \to \mu([f > t]) \) is a decreasing function. Therefore, one can make sense of an improper Riemann Stieltjes integral

\[
\int_{0}^{\infty} \mu([f > t]) \, dF(t).
\]

With more work, one can have this equal to the corresponding Lebesgue integral above.

### 10.7 Good Lambda Inequality

There is a very interesting and important inequality called the good lambda inequality (I am not sure if there is a bad lambda inequality.) which follows from the above theory of distribution functions. It involves the inequality

\[
\mu([f > \beta \lambda] \cap [g \leq \delta \lambda]) \leq \phi(\delta) \mu([f > \lambda])
\]

for \( \beta > 1 \), nonnegative functions \( f, g \) and is supposed to hold for all small positive \( \delta \) and \( \phi(\delta) \to 0 \) as \( \delta \to 0 \). Note the left side is small when \( g \) is large and \( f \) is small. The inequality involves dominating an integral involving \( f \) with one involving \( g \) as described below. As above, \( \nu \) is the measure which comes from the functional \( \int_{\mathbb{R}} gdF \) for \( g \in C_c(\mathbb{R}) \).
Theorem 10.7.1 Let \((\Omega, F, \mu)\) be a finite measure space and let \(F\) be a continuous increasing function defined on \([0, \infty)\) such that \(F(0) = 0\). Suppose also that for all \(\alpha > 1\), there exists a constant \(C_\alpha\) such that for all \(x \in [0, \infty)\),
\[F(ax) \leq C_\alpha F(x).\]
Also suppose \(f, g\) are nonnegative measurable functions and there exists \(\beta > 1, 0 < r < 1\), such that for all \(\lambda > 0\) and \(1 > \delta > 0\),
\[\mu ([f > \beta \lambda] \cap [g \leq r \delta \lambda]) \leq \phi (\delta) \mu ([f > \lambda])\] (10.7.17)
where \(\lim_{\delta \to 0+} \phi (\delta) = 0\) and \(\phi\) is increasing. Under these conditions, there exists a constant \(C\) depending only on \(\beta, \phi, r\) such that
\[\int_{\Omega} F(f(\omega)) \, d\mu (\omega) \leq C \int_{\Omega} F(g(\omega)) \, d\mu (\omega).\]

Proof: Let \(\beta > 1\) be as given above. First suppose \(f\) is bounded.
\[
\int_{\Omega} F(f) \, d\mu = \int_{\Omega} F \left( \frac{f}{\beta} \right) \, d\mu \leq C_\beta \int_{\Omega} F \left( \frac{f}{\beta} \right) \, d\mu
\]
\[= C_\beta \int_0^\infty \mu ([f > \beta \lambda]) \, d\nu\]

Now using the given inequality,
\[= C_\beta \int_0^\infty \mu ([f > \beta \lambda] \cap [g \leq r \delta \lambda]) \, d\nu + C_\beta \int_0^\infty \mu ([f > \beta \lambda] \cap [g > r \delta \lambda]) \, d\nu\]
\[\leq C_\beta \phi (\delta) \int_0^\infty \mu ([f > \lambda]) \, d\nu + C_\beta \int_0^\infty \mu ([g > r \delta \lambda]) \, d\nu\]
\[\leq C_\beta \phi (\delta) \int_{\Omega} F(f) \, d\mu + C_\beta \int_{\Omega} F \left( \frac{g}{r \delta} \right) \, d\mu\]

Now choose \(\delta\) small enough that \(C_\beta \phi (\delta) < \frac{1}{2}\) and then subtract the first term on the right in the above from both sides. It follows from the properties of \(F\) again that
\[\frac{1}{2} \int_{\Omega} F(f) \, d\mu \leq C_\beta C_{(r \delta)^{-1}} \int_{\Omega} F(g) \, d\mu.\]
This establishes the inequality in the case where \(f\) is bounded.

In general, let \(f_n = \min (f, n)\). Then for \(n \leq \lambda\), the inequality
\[\mu ([f > \beta \lambda] \cap [g \leq r \delta \lambda]) \leq \phi (\delta) \mu ([f > \lambda])\]
holds with \(f\) replaced with \(f_n\) because both sides equal 0 thanks to \(\beta > 1\). If \(n > \lambda\), then \([f > \lambda] = [f_n > \lambda]\) and so the inequality still holds because in this case,
\[\mu ([f_n > \beta \lambda] \cap [g \leq r \delta \lambda]) \leq \mu ([f > \beta \lambda] \cap [g \leq r \delta \lambda]) \leq \phi (\delta) \mu ([f > \lambda]) = \phi (\delta) \mu ([f_n > \lambda])\]
Therefore, \(10.7.17\) is valid with \(f\) replaced with \(f_n\). Now pass to the limit as \(n \to \infty\) and use the monotone convergence theorem.

**10.8  The Ergodic Theorem**

I am putting this theorem here because it seems to fit in well with the material of this chapter.

In this section \((\Omega, \mathcal{F}, \mu)\) will be a finite measure space. This means that \(\mu (\Omega) < \infty\). The mapping, \(T : \Omega \to \Omega\) will satisfy the following condition.

\[
T (A), T^{-1} (A) \in \mathcal{F} \text{ whenever } A \in \mathcal{F}, T \text{ is one to one.} \quad (10.8.18)
\]

For example, you could have \(T\) a homeomorphism on some topological space \(X\) and the \(\sigma\) algebra could be the Borel sets.

**Lemma 10.8.1** If \(T\) satisfies \(10.8.18\), then \(f \circ T\) is measurable whenever \(f\) is measurable.

**Proof:** Let \(U\) be an open set. Then

\[
(f \circ T)^{-1} (U) = T^{-1} (f^{-1} (U)) \in \mathcal{F}
\]

by \(10.8.18\).

Now suppose that in addition to \(10.8.18\), \(T\) also satisfies

\[
\mu (T^{-1} A) = \mu (A), \quad (10.8.19)
\]

for all \(A \in \mathcal{F}\). In words, \(T^{-1}\) is measure preserving. Note that also

\[
\mu (TA) = \mu (T^{-1} TA) = \mu (A)
\]

so also \(T\) is measure preserving. Then for \(T\) satisfying \(10.8.18\) and \(10.8.19\), we have the following simple lemma.

**Lemma 10.8.2** If \(T\) satisfies \(10.8.18\) and \(10.8.19\) then whenever \(f\) is nonnegative and measurable,

\[
\int_{\Omega} f (\omega) \, d\mu = \int_{\Omega} f (T \omega) \, d\mu. \quad (10.8.20)
\]

Also \(10.8.20\) holds whenever \(f \in L^1 (\Omega)\).

**Proof:** Let \(f \geq 0\) and \(f\) is measurable. Let \(A \in \mathcal{F}\). Then from \(10.8.19\),

\[
\int_{\Omega} \chi_A (\omega) \, d\mu = \mu (A) = \mu (T^{-1} (A)) = \int_{\Omega} \chi_{T^{-1} (A)} (\omega) \, d\mu = \int_{\Omega} \chi_A (T (\omega)) \, d\mu.
\]

It follows that whenever \(s\) is a simple function,

\[
\int s (\omega) \, d\mu = \int s (T \omega) \, d\mu
\]
10.8. THE ERGODIC THEOREM

If \( f \geq 0 \) and measurable, Theorem [14.3.9] on Page [227] implies there exists an increasing sequence of simple functions, \( \{ s_n \} \) converging pointwise to \( f \). Then the result follows from monotone convergence theorem. Splitting \( f \in L^1 \) into real and imaginary parts we apply this to the positive and negative parts of these and obtain [14.3.20] in this case also.

Definition 10.8.3 A measurable function \( f \), is said to be invariant if

\[ f(T\omega) = f(\omega) \, . \]

A set, \( A \in \mathcal{F} \) is said to be invariant if \( X_A \) is an invariant function. Thus a set is invariant if and only if \( T^{-1}A = A \). \( \mathcal{X}_A(T\omega) = \mathcal{X}_{T^{-1}(A)}(\omega) \) so to say that \( X_A \) is invariant is to say that \( T^{-1}A = A \).

The following theorem, the individual ergodic theorem, is the main result. Define \( T^0(\omega) = \omega \). Let

\[ S_n f(\omega) \equiv \sum_{k=1}^{n} f(T^{k-1}\omega) \, , \quad S_0 f(\omega) \equiv 0. \]

Also define the following maximal type function \( M_\infty f(\omega) \)

\[ M_\infty f(\omega) \equiv \sup \{ S_k f(\omega) : 0 \leq k \} \quad (10.8.21) \]

and let

\[ M_n f(\omega) \equiv \sup \{ S_k f(\omega) : 0 \leq k \leq n \} \quad (10.8.22) \]

Then one can prove the following interesting lemma.

Lemma 10.8.4 Let \( f \in L^1(\mu) \) where \( f \) has real values. Then \( \int_{|M_\infty f| > 0} f \, d\mu \geq 0 \).

Proof: First note that \( M_n f(\omega) \geq 0 \) for all \( n \) and \( \omega \). This follows easily from the observation that by definition, \( S_0 f(\omega) = 0 \) and so \( M_n f(\omega) \) is at least as large. There is certainly something to show here because the integrand is not known to be nonnegative. The integral involves \( f \) not \( M_\infty f \).

Let \( T^*h \equiv h \circ T \). Thus \( T^* \) is linear and maps measurable functions to measurable functions by Lemma [10.8.8]. It is also clear that if \( h \geq 0 \), then \( T^*h \geq 0 \) also. Therefore, for large \( k \leq n \),

\[ S_k f(\omega) \equiv \sum_{j=1}^{k} f(T^{j-1}\omega) = f(\omega) + \sum_{j=2}^{k} f(T^{j-1}\omega) \]

\[ = f(\omega) + T^* \sum_{j=1}^{k-1} f(T^{j-1}\omega) \quad \text{(factored out } T^*) \]

\[ = f(\omega) + T^*S_{k-1} f(\omega) \leq f(\omega) + T^*M_n f \]

and so, taking the supremum for \( k \leq n \),

\[ M_n f(\omega) \leq f(\omega) + T^*M_n f(\omega) \, . \]
CHAPTER 10. THE CONSTRUCTION OF MEASURES

Now since \( M_n f \geq 0 \),
\[
\int f = \int f + \int M_n f \leq \int M_n f \geq 0
\]
by Lemma 10.8.2. It follows that
\[
\int f = \int f + \int M_n f
\]
for each \( n \). Also, since \( M_n f \to M_\infty f \), the following pointwise convergence holds.
\[
X(M_n f > 0) f = X(M_\infty f > 0) f
\]
Since \( f \) is in \( L^1(\Omega) \), the dominated convergence theorem implies
\[
\int f = \lim_{n \to \infty} \int M_n f \geq 0.
\]

**Theorem 10.8.5** Let \((\Omega, \mathcal{F}, \mu)\) be a probability space and let \( T : \Omega \to \Omega \) satisfy
\[
\mu = \mu \quad \text{and} \quad T^{-1} \text{ is measure preserving and } T^{-1} \text{ maps } \mathcal{F} \text{ to } \mathcal{F} \text{ and } T \text{ is one to one.}
\]
Then if \( f \in L^1(\Omega) \) having real or complex values and
\[
S_n f = \sum_{k=1}^{n} f(T^{k-1} \omega), \quad S_0 f = 0, \quad (10.8.23)
\]
it follows there exists a set of measure zero \( N \), and an invariant function \( g \) such that for all \( \omega \notin N \),
\[
\lim_{n \to \infty} \frac{1}{n} S_n f = g(\omega). \quad (10.8.24)
\]
and also
\[
\lim_{n \to \infty} \frac{1}{n} S_n f = g \text{ in } L^1(\Omega)
\]

**Proof:** To begin with, we assume \( f \) has real values. Now if \( A \) is an invariant set, \( X_A(T^n \omega) = X_A(\omega) \) and so
\[
S_n (X_A f) = \sum_{k=1}^{n} f(T^{k-1} \omega) X_A(T^{k-1} \omega) = \sum_{k=1}^{n} f(T^{k-1} \omega) X_A(\omega)
\]
\[
= X_A(\omega) \sum_{k=1}^{n} f(T^{k-1} \omega) = X_A(\omega) S_n f(\omega).
\]
10.8. THE ERGODIC THEOREM

Therefore, for such an invariant set,

\[ M_n (\mathcal{X}_A f) (\omega) = \mathcal{X}_A (\omega) M_n f (\omega), \quad M_\infty (\mathcal{X}_A f) (\omega) = \mathcal{X}_A (\omega) M_\infty f (\omega). \] (10.8.25)

Let \(-\infty < a < b < \infty\) and define

\[ N_{ab} \equiv \left\{ -\infty < \lim_{n \to \infty} \frac{1}{n} S_n f (\omega) < a < b < \lim_{n \to \infty} \sup \frac{1}{n} S_n f (\omega) < \infty \right\} \] (10.8.26)

Observe that from the definition,

\[ \lim_{n \to \infty} \inf \frac{1}{n} S_n f (\omega) = \lim_{n \to \infty} \inf \frac{1}{n} S_n f (T\omega) \]

and

\[ \lim_{n \to \infty} \sup \frac{1}{n} S_n f (\omega) = \lim_{n \to \infty} \sup \frac{1}{n} S_n f (T\omega). \]

Thus if \( \omega \in N_{ab} \), it follows that \( T\omega \in N_{ab} \) and if \( T\omega \in N_{ab} \), then so is \( \omega \). Thus \( N_{ab} \) is an invariant set. Also, if \( \omega \in N_{ab} \), then

\[ a - \lim_{n \to \infty} \frac{1}{n} S_n f (\omega) = \lim_{n \to \infty} \left( a - \frac{1}{n} S_n f (\omega) \right) > 0 \]

and

\[ \lim_{n \to \infty} \left( \frac{1}{n} S_n f (\omega) - b \right) > 0 \]

It follows that

\[ N_{ab} \subseteq [M_\infty (f - b) > 0] \cap [M_\infty (a - f) > 0]. \]

Consequently, since \( N_{ab} \) is invariant, argued above,

\[ \mathcal{X}_{N_{ab}} M_\infty (f - b) = M_\infty (\mathcal{X}_{N_{ab}} (f - b)) \]

and so from Lemma 10.8.3

\[ \int_{N_{ab}} (f (\omega) - b) \, d\mu = \int_{[\mathcal{X}_{N_{ab}} M_\infty (f - b) > 0]} \mathcal{X}_{N_{ab}} (\omega) (f (\omega) - b) \, d\mu \]

\[ = \int_{[M_\infty (\mathcal{X}_{N_{ab}} (f - b)) > 0]} \mathcal{X}_{N_{ab}} (\omega) (f (\omega) - b) \, d\mu \geq 0 \] (10.8.27)

and

\[ \int_{N_{ab}} (a - f (\omega)) \, d\mu = \int_{[\mathcal{X}_{N_{ab}} M_\infty (a - f) > 0]} \mathcal{X}_{N_{ab}} (\omega) (a - f (\omega)) \, d\mu \]

\[ = \int_{[M_\infty (\mathcal{X}_{N_{ab}} (a - f)) > 0]} \mathcal{X}_{N_{ab}} (\omega) (a - f (\omega)) \, d\mu \geq 0 \] (10.8.28)

It follows that

\[ a \mu (N_{ab}) \geq \int_{N_{ab}} f \, d\mu \geq b \mu (N_{ab}). \] (10.8.29)
Since $a < b$, it follows that $\mu (N_{ab}) = 0$.

Now let

$$N \equiv \cup \{ N_{ab} : a < b, \ a, b \in Q \}.$$ 

It follows that $\mu (N) = 0$. Now $TN_{a,b} = N_{a,b}$ and so

$$T (N) = \cup_{a,b} T (N_{a,b}) = \cup_{a,b} N_{a,b} = N.$$ 

Thus, $T^n N = N$ for all $n \in \mathbb{N}$. For $\omega \notin N$, $\lim_{n \to \infty} \frac{1}{n} S_n f (\omega)$ exists. Now let

$$g (\omega) \equiv \begin{cases} 0 & \text{if } \omega \in N \\ \lim_{n \to \infty} \frac{1}{n} S_n f (\omega) & \text{if } \omega \notin N \end{cases}.$$ 

Then it is clear $g$ satisfies the conditions of the theorem because if $\omega \in N$, then $T \omega \in N$ also and so in this case, $g (T \omega) = g (\omega) \equiv 0$. On the other hand, if $\omega \notin N$, then

$$g (T \omega) = \lim_{n \to \infty} \frac{1}{n} S_n f (T \omega) = \lim_{n \to \infty} \frac{1}{n} S_n f (\omega) = g (\omega).$$ 

Which shows that $g$ is invariant. Also, from Lemma [11][18],

$$\int_{\Omega} |g| \, d\mu \leq \liminf_{n \to \infty} \int_{\Omega} \left| \frac{1}{n} S_n f \right| \, d\mu \leq \liminf_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} \left| f (T^{k-1} \omega) \right| \, d\mu = \liminf_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} |f (\omega)| \, d\mu = \| f \|_{L^1},$$

so $g \in L^1 (\Omega, \mu)$.

The last claim about convergence in $L^1$ follows from the Vitali convergence theorem if we verify the sequence, $\{ \frac{1}{n} S_n f \}_{n=1}^{\infty}$ is uniformly integrable. To see this is the case, we know $f \in L^1 (\Omega)$ and so if $\varepsilon > 0$ is given, there exists $\delta > 0$ such that whenever $B \in \mathcal{F}$ and $\mu (B) \leq \delta$, then $| \int_{B} f (\omega) \, d\mu | < \varepsilon$. Taking $\mu (A) < \delta$, it follows

$$\left| \int_{A} \frac{1}{n} S_n f (\omega) \, d\mu \right| = \frac{1}{n} \sum_{k=1}^{n} \int_{A} f (T^{k-1} \omega) \, d\mu = \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \chi_{A} (\omega) f (T^{k-1} \omega) \, d\mu$$

$$= \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \chi_{A} \left( T^{k-1} T^{-(k-1)} \omega \right) f (T^{k-1} \omega) \, d\mu$$

$$= \frac{1}{n} \sum_{k=1}^{n} \int_{\Omega} \chi_{A} \left( T^{-(k-1)} \omega \right) f (\omega) \, d\mu$$

$$= \frac{1}{n} \sum_{k=1}^{n} \int_{T^{k-1} (A)} f (\omega) \, d\mu \leq \frac{1}{n} \sum_{k=1}^{n} \int_{T^{k-1} (A)} f (\omega) \, d\mu < \frac{1}{n} \sum_{k=1}^{n} \varepsilon = \varepsilon.$$
10.9. PRODUCT MEASURES

because \( \mu \left( T^{(k-1)}A \right) = \mu (A) \) by assumption. This proves the above sequence is uniformly integrable and so, by the Vitali convergence theorem,

\[
\lim_{n \to \infty} \int_{\Omega} \left| \frac{1}{n} S_n f - g \right| \, d\mu = 0.
\]

This proves the theorem in the case the function has real values. In the case where \( f \) has complex values, apply the above result to the real and imaginary parts of \( f \).

\[\blacksquare\]

**Definition 10.8.6** The above mapping \( T \) is ergodic if the only invariant sets have measure 0 or 1.

If the map, \( T \) is ergodic, the following corollary holds.

**Corollary 10.8.7** In the situation of Theorem 10.8.5, if \( T \) is ergodic, then

\[
g (\omega) = \int f (\omega) \, d\mu
\]

for a.e. \( \omega \).

**Proof:** Let \( g \) be the function of Theorem 10.8.5 and let \( R_1 \) be a rectangle in \( \mathbb{R}^2 = \mathbb{C} \) of the form \([-a, a] \times [-a, a]\) such that \( g^{-1} (R_1) \) has measure greater than 0. This set is invariant because the function, \( g \) is invariant and so it must have measure 1. Divide \( R_1 \) into four equal rectangles, \( R'_1, R'_2, R'_3, R'_4 \). Then one of these, renamed \( R_2 \) has the property that \( g^{-1} (R_2) \) has positive measure. Therefore, since the set is invariant, it must have measure 1. Continue in this way obtaining a sequence of closed rectangles, \( \{ R_i \} \) such that the diameter of \( R_i \) converges to zero and \( g^{-1} (R_i) \) has measure 1. Then let \( c = \bigcap_{j=1}^{\infty} R_j \). We know \( \mu (g^{-1} (c)) = \lim_{n \to \infty} \mu (g^{-1} (R_i)) = 1 \). It follows that \( g (\omega) = c \) for a.e. \( \omega \). Now from Theorem 10.8.5,

\[
c = \int c \, d\mu = \lim_{n \to \infty} \frac{1}{n} \int S_n f \, d\mu = \int f \, d\mu. \blacksquare
\]

10.9 Product Measures

Let \((X, \mathcal{S}, \mu)\) and \((Y, \mathcal{T}, \nu)\) be two complete measure spaces. In this section consider the problem of defining a product measure, \( \mu \times \nu \) which is defined on a \( \sigma \) algebra of sets of \( X \times Y \) such that \( (\mu \times \nu) (E \times F) = \mu (E) \nu (F) \) whenever \( E \in \mathcal{S} \) and \( F \in \mathcal{T} \).

I found the following approach to product measures in [44] and they say they got it from [47].

**Definition 10.9.1** Let \( \mathcal{R} \) denote the set of countable unions of sets of the form \( A \times B \), where \( A \in \mathcal{S} \) and \( B \in \mathcal{T} \) (Sets of the form \( A \times B \) are referred to as measurable rectangles) and also let

\[
\rho (A \times B) = \mu (A) \nu (B)
\]

(10.9.30)
More generally, define
\[ \rho(E) \equiv \int \int E(x,y) \, d\mu \, d\nu \quad (10.9.31) \]
whenever \( E \) is such that
\[ x \mapsto E(x,y) \text{ is } \mu \text{ measurable for all } y \quad (10.9.32) \]
and
\[ y \mapsto \int E(x,y) \, d\mu \text{ is } \nu \text{ measurable.} \quad (10.9.33) \]

Note that if \( E = A \times B \) as above, then
\[
\int \int E(x,y) \, d\mu \, d\nu = \int \int A \times B(x,y) \, d\mu \, d\nu = \int \int A(x) \times B(y) \, d\mu \, d\nu = \mu(A) \nu(B) = \rho(E)
\]
and so there is no contradiction between (10.9.31) and (10.9.30).

The first goal is to show that for \( Q \in \mathcal{R}, \) (10.9.32) and (10.9.33) both hold. That is, \( x \mapsto E_Q(x,y) \) is \( \mu \) measurable for all \( y \) and \( y \mapsto \int E_Q(x,y) \, d\mu \) is \( \nu \) measurable. This is done so that it is possible to speak of \( \rho(Q) \). The following lemma will be the fundamental result which will make this possible. First here is a picture.

\[ A \]
\[ D \]
\[ C \]
\[ B \]

\[ \text{Lemma 10.9.2} \quad \text{Given } C \times D \text{ and } \{ A_i \times B_i \}_{i=1}^n, \text{ there exist finitely many disjoint rectangles, } \{ C'_i \times D'_i \}_{i=1}^p \text{ such that none of these sets intersect any of the } A_i \times B_i, \text{ each set is contained in } C \times D \text{ and} \]
\[ (\cup_{i=1}^n A_i \times B_i) \cup (\cup_{k=1}^p C'_k \times D'_k) = (C \times D) \cup (\cup_{i=1}^n A_i \times B_i). \]

\[ \text{Proof:} \quad \text{From the above picture, you see that} \]
\[ (C \times D) \setminus (A_1 \times B_1) = C \times (D \setminus B_1) \cup (C \setminus A_1) \times (D \setminus B_1) \]
and these last two sets are disjoint, have empty intersection with \( A_1 \times B_1 \), and
\[ (C \times (D \setminus B_1) \cup (C \setminus A_1) \times (D \setminus B_1)) \cup (\cup_{i=1}^n A_i \times B_i) = (C \times D) \cup (\cup_{i=1}^n A_i \times B_i) \]
Now suppose disjoint sets, \( \{ \bar{C}_i \times \bar{D}_i \}_{i=1}^m \) have been obtained, each being a subset of \( C \times D \) such that
\[
(\bigcup_{i=1}^m A_i \times B_i) \cup \left( \bigcup_{k=1}^m \bar{C}_k \times \bar{D}_k \right) = (\bigcup_{i=1}^m A_i \times B_i) \cup (C \times D)
\]
and for all \( k, \bar{C}_k \times \bar{D}_k \) has empty intersection with each set of \( \{ A_i \times B_i \}_{i=1}^p \). Then using the same procedure, replace each of \( \bar{C}_k \times \bar{D}_k \) with finitely many disjoint rectangles such that none of these intersect the original rectangles and such that none of these intersect \( A_{p+1} \times B_{p+1} \) while preserving the union of all the sets involved. The process stops when you have gotten to \( n \). This proves the lemma.

**Lemma 10.9.3** If \( Q = \bigcup_{i=1}^\infty A_i \times B_i \in \mathcal{R} \), then there exist disjoint sets, of the form \( A'_i \times B'_i \) such that \( Q = \bigcup_{i=1}^\infty A'_i \times B'_i \), each \( A'_i \times B'_i \) is a subset of some \( A_i \times B_i \), and \( A'_i \in \mathcal{S} \) while \( B'_i \in \mathcal{T} \). Also, the intersection of finitely many sets of \( \mathcal{R} \) is a set of \( \mathcal{R} \). For \( \rho \) defined in [10.9.2], it follows that [10.9.3] hold for any element of \( \mathcal{R} \). Furthermore,
\[
\rho(Q) = \sum_i \mu(A'_i) \nu(B'_i) = \sum_i \rho(A'_i \times B'_i).
\]

**Proof:** Let \( Q \) be given as above. Let \( A'_1 \times B'_1 = A_1 \times B_1 \). By Lemma [10.9.2], it is possible to replace \( A_2 \times B_2 \) with finitely many disjoint rectangles, \( \{ A'_i \times B'_i \}_{i=2}^m \), such that none of these rectangles intersect \( A'_1 \times B'_1 \), each is a subset of \( A_2 \times B_2 \), and
\[
\bigcup_{i=1}^\infty A_i \times B_i = (\bigcup_{i=1}^m A'_i \times B'_i) \cup (\bigcup_{k=3}^\infty A_k \times B_k)
\]
Now suppose disjoint rectangles, \( \{ A'_i \times B'_i \}_{i=1}^m \) have been obtained such that each rectangle is a subset of \( A_k \times B_k \) for some \( k \leq p \) and
\[
\bigcup_{i=1}^\infty A_i \times B_i = (\bigcup_{i=1}^m A'_i \times B'_i) \cup (\bigcup_{k=p+1}^\infty A_k \times B_k).
\]
By Lemma [10.9.2] again, there exist disjoint rectangles \( \{ A'_i \times B'_i \}_{i=p+1}^m \) such that each is contained in \( A_{p+1} \times B_{p+1} \), none have intersection with any of \( \{ A'_i \times B'_i \}_{i=1}^m \) and
\[
\bigcup_{i=1}^\infty A_i \times B_i = (\bigcup_{i=1}^{m+p} A'_i \times B'_i) \cup (\bigcup_{k=p+2}^\infty A_k \times B_k).
\]
Note that no change is made in \( \{ A'_i \times B'_i \}_{i=1}^m \). Continuing this way proves the existence of the desired sequence of disjoint rectangles, each of which is a subset of at least one of the original rectangles and such that
\[
Q = \bigcup_{i=1}^\infty A'_i \times B'_i.
\]
It remains to verify \( x \to \chi_Q(x, y) \) is \( \mu \) measurable for all \( y \) and
\[
y \to \int \chi_Q(x, y) \, d\mu
\]
is \( \nu \) measurable whenever \( Q \in \mathcal{R} \). Let \( Q = \bigcup_{i=1}^{\infty} A_i \times B_i \in \mathcal{R} \). Then by the first part of this lemma, there exists \( \{A'_i \times B'_i\}_{i=1}^{\infty} \) such that the sets are disjoint and \( \bigcup_{i=1}^{\infty} A'_i \times B'_i = Q \). Therefore, since the sets are disjoint,

\[
X_Q(x, y) = \sum_{i=1}^{\infty} X_{A'_i \times B'_i}(x, y) = \sum_{i=1}^{\infty} X_{A'_i}(x) X_{B'_i}(y).
\]

It follows \( x \to X_Q(x, y) \) is measurable. Now by the monotone convergence theorem,

\[
\int X_Q(x, y) \, d\mu = \int \sum_{i=1}^{\infty} X_{A'_i}(x) X_{B'_i}(y) \, d\mu
\]

\[
= \sum_{i=1}^{\infty} X_{B'_i}(y) \int X_{A'_i}(x) \, d\mu
\]

\[
= \sum_{i=1}^{\infty} X_{B'_i}(y) \mu(A'_i).
\]

It follows \( y \to \int X_Q(x, y) \, d\mu \) is measurable and so by the monotone convergence theorem again,

\[
\int \int X_Q(x, y) \, d\mu d\nu = \int \sum_{i=1}^{\infty} X_{B'_i}(y) \mu(A'_i) \, d\nu
\]

\[
= \sum_{i=1}^{\infty} \int X_{B'_i}(y) \mu(A'_i) \, d\nu
\]

\[
= \sum_{i=1}^{\infty} \nu(B'_i) \mu(A'_i). \tag{10.9.34}
\]

This shows the measurability conditions, \([10.9.32]\) and \([10.9.33]\) hold for \( Q \in \mathcal{R} \) and also establishes the formula for \( \rho(Q) \), \([10.9.34]\).

If \( \bigcup_i A_i \times B_i \) and \( \bigcup_j C_j \times D_j \) are two sets of \( \mathcal{R} \), then their intersection is

\[
\bigcup_i \bigcup_j (A_i \cap C_j) \times (B_i \cap D_j)
\]

a countable union of measurable rectangles. Thus finite intersections of sets of \( \mathcal{R} \) are in \( \mathcal{R} \). This proves the lemma.

Now note that from the definition of \( \mathcal{R} \) if you have a sequence of elements of \( \mathcal{R} \) then their union is also in \( \mathcal{R} \). The next lemma will enable the definition of an outer measure.

**Lemma 10.9.4** Suppose \( \{R_i\}_{i=1}^{\infty} \) is a sequence of sets of \( \mathcal{R} \) then

\[
\rho(\bigcup_{i=1}^{\infty} R_i) \leq \sum_{i=1}^{\infty} \rho(R_i).
\]
Proof: Let \( R_i = \bigcup_{j=1}^{\infty} A_j^i \times B_j^i \). Using Lemma 10.9.3, let \( \{A'_m \times B'_m\}_{m=1}^{\infty} \) be a sequence of disjoint rectangles each of which is contained in some \( A_j^i \times B_j^i \) for some \( i, j \) such that
\[
\bigcup_{i=1}^{\infty} R_i = \bigcup_{m=1}^{\infty} A'_m \times B'_m.
\]
Now define
\[
S_i \equiv \{ m : A'_m \times B'_m \subseteq A_j^i \times B_j^i \text{ for some } j \}.
\]
It is not important to consider whether some \( m \) might be in more than one \( S_i \). The important thing to notice is that
\[
\bigcup_{m \in S_i} A'_m \times B'_m \subseteq \bigcup_{j=1}^{\infty} A_j^i \times B_j^i = R_i.
\]
Then by Lemma 10.9.3,
\[
\rho \left( \bigcup_{i=1}^{\infty} R_i \right) = \sum_{m} \rho (A'_m \times B'_m)
\leq \sum_{i=1}^{\infty} \sum_{m \in S_i} \rho (A'_m \times B'_m)
\leq \sum_{i=1}^{\infty} \rho \left( \bigcup_{m \in S_i} A'_m \times B'_m \right) \leq \sum_{i=1}^{\infty} \rho (R_i).
\]
This proves the lemma.

So far, there is no measure and no \( \sigma \) algebra. However, the next step is to define an outer measure which will lead to a measure on a \( \sigma \) algebra of measurable sets from the Carathéodory procedure. When this is done, it will be shown that this measure can be computed using \( \rho \) which implies the important Fubini theorem.

Now it is possible to define an outer measure.

Definition 10.9.5 For \( S \subseteq X \times Y \), define
\[
(\mu \times \nu)(S) \equiv \inf \{ \rho (R) : S \subseteq R, R \in \mathcal{R} \}.
\] (10.9.35)

The following proposition is interesting but is not needed in the development which follows. It gives a different description of \( (\mu \times \nu) \).

Proposition 10.9.6 \( (\mu \times \nu)(S) = \inf \{ \sum_{i=1}^{\infty} \mu (A_i) \nu (B_i) : S \subseteq \bigcup_{i=1}^{\infty} A_i \times B_i \} \)

Proof: Let \( \lambda (S) \equiv \inf \{ \sum_{i=1}^{\infty} \mu (A_i) \nu (B_i) : S \subseteq \bigcup_{i=1}^{\infty} A_i \times B_i \} \). Suppose \( S \subseteq \bigcup_{i=1}^{\infty} A_i \times B_i = Q \in \mathcal{R} \). Then by Lemma 10.9.4, \( Q = \bigcup_{i=1}^{\infty} A'_i \times B'_i \) where these rectangles are disjoint. Thus by this lemma, \( \rho (Q) = \sum_{i=1}^{\infty} \mu (A'_i) \nu (B'_i) \geq \lambda (S) \) and so \( \lambda (S) \leq (\mu \times \nu)(S) \). If \( \lambda (S) = \infty \), this shows \( \lambda (S) = (\mu \times \nu)(S) \). Suppose then that \( \lambda (S) < \infty \) and \( \lambda (S) + \epsilon > \sum_{i=1}^{\infty} \mu (A_i) \nu (B_i) \) where \( Q = \bigcup_{i=1}^{\infty} A_i \times B_i \supseteq S \). Then by Lemma 10.9.4 again, \( \bigcup_{i=1}^{\infty} A'_i \times B'_i = \bigcup_{i=1}^{\infty} A'_i \times B'_i \) where the primed rectangles are disjoint, each is a subset of some \( A_i \times B_i \) and so
\[
\lambda (S) + \epsilon \geq \sum_{i=1}^{\infty} \mu (A_i) \nu (B_i) \geq \sum_{i=1}^{\infty} \mu (A'_i) \nu (B'_i) = \rho (Q) \geq (\mu \times \nu)(S).
\]
Since \( \epsilon \) is arbitrary, this shows \( \lambda (S) \geq (\mu \times \nu)(S) \) and this proves the proposition.
Lemma 10.9.7 \( \bar{\mu} \times \bar{\nu} \) is an outer measure on \( X \times Y \) and for \( R \in \mathcal{R} \)

\[
(\bar{\mu} \times \bar{\nu}) (R) = \rho (R) .
\] (10.9.36)

**Proof:** First consider (10.9.36). Since \( R \supseteq R \), it follows \( \rho (R) \geq (\bar{\mu} \times \bar{\nu}) (R) \). On the other hand, if \( Q \in \mathcal{R} \) and \( Q \supseteq R \), then \( \rho (Q) \geq \rho (R) \) and so, taking the infimum on the left yields \( (\bar{\mu} \times \bar{\nu}) (R) \geq \rho (R) \). This shows (10.9.36).

It is necessary to show that if \( S \subseteq T \), then

\[
(\bar{\mu} \times \bar{\nu}) (S) \leq (\bar{\mu} \times \bar{\nu}) (T) ,
\] (10.9.37)

\[
(\bar{\mu} \times \bar{\nu}) (\bigcup_{i=1}^{\infty} S_i) \leq \sum_{i=1}^{\infty} (\bar{\mu} \times \bar{\nu}) (S_i) .
\] (10.9.38)

To do this, note that (10.9.37) is obvious. To verify (10.9.38), note that it is obvious if \( (\bar{\mu} \times \bar{\nu}) (S_i) = \infty \) for any \( i \). Therefore, assume \( (\bar{\mu} \times \bar{\nu}) (S_i) < \infty \). Then letting \( \varepsilon > 0 \) be given, there exist \( R_i \in \mathcal{R} \) such that

\[
(\bar{\mu} \times \bar{\nu}) (S_i) + \frac{\varepsilon}{2^i} > \rho (R_i) , \quad R_i \supseteq S_i .
\]

Then by Lemma (10.9.4), (10.9.36), and the observation that \( \bigcup_{i=1}^{\infty} R_i \in \mathcal{R} \),

\[
(\bar{\mu} \times \bar{\nu}) (\bigcup_{i=1}^{\infty} S_i) \leq (\bar{\mu} \times \bar{\nu}) (\bigcup_{i=1}^{\infty} R_i)
= \rho (\bigcup_{i=1}^{\infty} R_i) \leq \sum_{i=1}^{\infty} \rho (R_i)
\leq \sum_{i=1}^{\infty} (\bar{\mu} \times \bar{\nu}) (S_i) + \frac{\varepsilon}{2^i}
= \left( \sum_{i=1}^{\infty} (\bar{\mu} \times \bar{\nu}) (S_i) \right) + \varepsilon .
\]

Since \( \varepsilon \) is arbitrary, this proves the lemma.

By Caratheodory’s procedure, it follows there is a \( \sigma \) algebra of subsets of \( X \times Y \), denoted here by \( \mathcal{S} \times \mathcal{T} \) such that \( (\bar{\mu} \times \bar{\nu}) \) is a complete measure on this \( \sigma \) algebra. The first thing to note is that every rectangle is in this \( \sigma \) algebra.

**Lemma 10.9.8** Every rectangle is \( (\bar{\mu} \times \bar{\nu}) \) measurable.

**Proof:** Let \( S \subseteq X \times Y \). The following inequality must be established.

\[
(\bar{\mu} \times \bar{\nu}) (S) \geq (\bar{\mu} \times \bar{\nu}) (S \cap (A \times B)) + (\bar{\mu} \times \bar{\nu}) (S \setminus (A \times B)) .
\] (10.9.39)

The following claim will be used to establish this inequality.

**Claim:** Let \( P, A \times B \in \mathcal{R} \). Then

\[
\rho (P \cap (A \times B)) + \rho (P \setminus (A \times B)) = \rho (P) .
\]
10.9. PRODUCT MEASURES

Proof of the claim: From Lemma 10.9.3, \( P = \bigcup_{i=1}^{\infty} A_i' \times B_i' \) where the \( A_i' \times B_i' \) are disjoint. Therefore,

\[
P \cap (A \times B) = \bigcup_{i=1}^{\infty} (A \cap A_i') \times (B \cap B_i')
\]

while

\[
P \setminus (A \times B) = \bigcup_{i=1}^{\infty} (A_i' \setminus A) \times B_i' \cup \bigcup_{i=1}^{\infty} (A \cap A_i') \times (B_i' \setminus B).
\]

Since all of the sets in the above unions are disjoint,

\[
\rho (P \cap (A \times B)) + \rho (P \setminus (A \times B)) = 
\int \int \sum_{i=1}^{\infty} \chi_{(A \cap A_i')} (x) \chi_{B \cap B_i'} (y) \, d\mu \, d\nu + 
\int \int \sum_{i=1}^{\infty} \chi_{(A_i' \setminus A)} (x) \chi_{B_i'} (y) \, d\mu \, d\nu 
\]

\[
+ \int \int \sum_{i=1}^{\infty} \chi_{A \cap A_i'} (x) \chi_{B_i' \setminus B} (y) \, d\mu \, d\nu
\]

\[
= \sum_{i=1}^{\infty} \mu (A \cap A_i') \nu (B \cap B_i') + \mu (A_i' \setminus A) \nu (B_i') + \mu (A \cap A_i') \nu (B_i' \setminus B)
\]

\[
= \sum_{i=1}^{\infty} \mu (A \cap A_i') \nu (B_i') + \mu (A_i' \setminus A) \nu (B_i') = \sum_{i=1}^{\infty} \mu (A_i') \nu (B_i') = \rho (P).
\]

This proves the claim.

Now continuing to verify, without loss of generality, \((\mu \times \nu) (S)\) can be assumed finite. Let \( P \supseteq S \) for \( P \in \mathcal{R} \) and

\[
(\mu \times \nu) (S) + \varepsilon > \rho (P).
\]

Then from the claim,

\[
(\mu \times \nu) (S) + \varepsilon > \rho (P) = \rho (P \cap (A \times B)) + \rho (P \setminus (A \times B))
\]

\[
\geq (\mu \times \nu) (S \cap (A \times B)) + (\mu \times \nu) (S \setminus (A \times B)).
\]

Since \( \varepsilon > 0 \) this shows \( A \times B \) is \( \mu \times \nu \) measurable as claimed.

**Lemma 10.9.9** Let \( \mathcal{R}_1 \) be defined as the set of all countable intersections of sets of \( \mathcal{R} \). Then if \( S \subseteq X \times Y \), there exists \( R \in \mathcal{R}_1 \) for which it makes sense to write \( \rho (R) \) because \( \mu \times \nu \) and \( \mu \times \nu \) hold such that

\[
(\mu \times \nu) (S) = \rho (R). \quad (10.9.40)
\]

Also, every element of \( \mathcal{R}_1 \) is \( \mu \times \nu \) measurable.
CHAPTER 10. THE CONSTRUCTION OF MEASURES

Proof: Consider \( S \subseteq X \times Y \). If \( (\mu \times \nu) (S) = \infty \), let \( R = X \times Y \) and it follows \( \rho (X \times Y) = \infty = (\mu \times \nu) (S) \). Assume then that \( (\mu \times \nu) (S) < \infty \).

Therefore, there exists \( P_n \in \mathcal{R} \) such that \( P_n \supseteq S \) and

\[
(\mu \times \nu) (S) \leq \rho (P_n) < (\mu \times \nu) (S) + 1/n. \tag{10.9.41}
\]

Let \( Q_n = \cap_{i=1}^n P_i \in \mathcal{R} \). Define

\[
P = \cap_{i=1}^\infty Q_i \supseteq S.
\]

Then \( (\mu \times \nu) \) holds with \( Q_n \) in place of \( P_n \). It is clear that

\[
x \mapsto \mathcal{X}_P (x, y) \text{ is } \mu \text{ measurable}
\]

because this function is the pointwise limit of functions for which this is so. It remains to consider whether \( y \mapsto \int \mathcal{X}_P (x, y) d\mu \) is \( \nu \) measurable. First observe \( Q_n \supseteq Q_{n+1} \), \( \mathcal{X}_{Q_n} \leq \mathcal{X}_{P_n} \), and

\[
\rho (Q_1) = \rho (P_1) = \int \int \mathcal{X}_{P_1} (x, y) d\mu d\nu < \infty. \tag{10.9.42}
\]

Therefore, there exists a set of \( \nu \) measure 0, \( N \), such that if \( y \notin N \), then

\[
\int \mathcal{X}_{P_1} (x, y) d\mu < \infty.
\]

It follows from the dominated convergence theorem that

\[
\lim_{n \to \infty} \mathcal{X}_{N \in C} (y) \int \mathcal{X}_{Q_n} (x, y) d\mu = \mathcal{X}_{N \in C} (y) \int \mathcal{X}_P (x, y) d\mu
\]

and so

\[
y \mapsto \mathcal{X}_{N \in C} (y) \int \mathcal{X}_P (x, y) d\mu
\]

is also measurable. By completeness of \( \nu \),

\[
y \mapsto \int \mathcal{X}_P (x, y) d\mu
\]

must also be \( \nu \) measurable and so it makes sense to write

\[
\int \int \mathcal{X}_P (x, y) d\mu d\nu
\]

for every \( P \in \mathcal{R}_1 \). Also, by the dominated convergence theorem,

\[
\int \int \mathcal{X}_P (x, y) d\mu d\nu = \int \int \mathcal{X}_{N \in C} (y) \int \mathcal{X}_P (x, y) d\mu d\nu
\]

\[
= \lim_{n \to \infty} \int \int \mathcal{X}_{N \in C} (y) \int \mathcal{X}_{Q_n} (x, y) d\mu d\nu
\]

\[
= \lim_{n \to \infty} \int \int \mathcal{X}_{Q_n} (x, y) d\mu d\nu
\]

\[
= \lim_{n \to \infty} \rho (Q_n) \in [(\mu \times \nu) (S), (\mu \times \nu) (S) + 1/n]
\]
for all $n$. Therefore,

$$\rho(P) = \int \int X_P(x, y) \, d\mu d\nu = (\mu \times \nu)(S).$$

The sets of $R_1$ are $\mu \times \nu$ measurable because these sets are countable intersections of countable unions of rectangles and Lemma 10.9.8 verifies the rectangles are $\mu \times \nu$ measurable. This proves the Lemma.

The following theorem is the main result.

Theorem 10.9.10 Let $E \subseteq X \times Y$ be $\mu \times \nu$ measurable and suppose $\mu \times \nu(E) < \infty$. Then

$$x \to X_E(x, y)$$

is $\mu$ measurable a.e. $y$. Modifying $X_E$ on a set of measure zero, it is possible to write

$$\int X_E (x, y) \, d\mu.$$ 

The function,

$$y \to \int X_E (x, y) \, d\mu$$

is $\nu$ measurable and

$$(\mu \times \nu)(E) = \int \int X_E (x, y) \, d\mu d\nu.$$ 

Similarly,

$$(\mu \times \nu)(E) = \int \int X_E (x, y) \, d\nu d\mu.$$ 

Proof: By Lemma 10.9.9, there exists $R \in R_1$ such that

$$\rho(R) = (\mu \times \nu)(E), \quad R \supseteq E.$$ 

Therefore, since $R$ is $\mu \times \nu$ measurable and $\rho(R) = (\mu \times \nu)(R)$, it follows

$$(\mu \times \nu)(R \setminus E) = 0.$$ 

By Lemma 10.9.9 again, there exists $P \supseteq R \setminus E$ with $P \in R_1$ and

$$\rho(P) = (\mu \times \nu)(R \setminus E) = 0.$$ 

Thus

$$\int \int X_P (x, y) \, d\mu d\nu = 0.$$ 

(10.9.43)

Since $P \in R_1$ Lemma 10.9.9 implies $x \to X_P(x, y)$ is $\mu$ measurable and it follows from the above there exists a set of $\nu$ measure zero, $N$ such that if $y \notin N$, then

$$\int X_P (x, y) \, d\mu = 0.$$ 

Therefore, by completeness of $\nu$,

$$x \to X_{N^c}(y) X_{R \setminus E}(x, y)$$
is $\mu$ measurable and
\[ \int \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_{R \setminus E} (x, y) \, d\mu = 0. \]  
(10.9.44)

Now also
\[ \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_R (x, y) = \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_{R \setminus E} (x, y) + \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_E (x, y) \]  
(10.9.45)

and this shows that
\[ x \to \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_E (x, y) \]
is $\mu$ measurable because it is the difference of two functions with this property. Then by (10.9.44) it follows
\[ \int \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_E (x, y) \, d\mu = \int \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_R (x, y) \, d\mu. \]

The right side of this equation equals a $\nu$ measurable function and so the left side which equals it is also a $\nu$ measurable function. It follows from completeness of $\nu$ that $y \to \int \mathcal{X}_E (x, y) \, d\mu$ is $\nu$ measurable because for $y$ outside of a set of $\nu$ measure zero, $N_\mathcal{C}$ it equals $\int \mathcal{X}_R (x, y) \, d\mu$. Therefore,
\[
\int \int \mathcal{X}_E (x, y) \, d\mu d\nu = \int \int \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_E (x, y) \, d\mu d\nu \\
= \int \int \mathcal{X}_{N_\mathcal{C}} (y) \mathcal{X}_R (x, y) \, d\mu d\nu \\
= \int \int \mathcal{X}_R (x, y) \, d\mu d\nu \\
= \rho (R) = (\mu \times \nu) (E).
\]

In all the above there would be no change in writing $d\nu d\mu$ instead of $d\mu d\nu$. The same result would be obtained. This proves the theorem.

Now let $f : X \times Y \to [0, \infty]$ be $\mu \times \nu$ measurable and
\[ \int fd(\mu \times \nu) < \infty. \]  
(10.9.46)

Let $s (x, y) \equiv \sum_{i=1}^m c_i \mathcal{X}_{E_i} (x, y)$ be a nonnegative simple function with $c_i$ being the nonzero values of $s$ and suppose
\[ 0 \leq s \leq f. \]

Then from the above theorem,
\[ \int sd(\mu \times \nu) = \int \int sd\mu d\nu \]

In which
\[ \int sd\mu = \int \mathcal{X}_{N_\mathcal{C}} (y) \, sd\mu \]
for $N$ a set of $\nu$ measure zero such that $y \to \int X_C(y) s d\mu$ is $\nu$ measurable. This follows because $\mu \times \nu$ implies $(\mu \times \nu)(E_i) < \infty$. Now let $s_n \uparrow f$ where $s_n$ is a nonnegative simple function and

$$
\int s_n d(\mu \times \nu) = \int \int X_C(y) s_n(x, y) \, d\mu d\nu
$$

where

$$
y \to \int X_C(y) s_n(x, y) \, d\mu
$$

is $\nu$ measurable. Then let $N = \bigcup_{n=1}^{\infty} N_n$. It follows $N$ is a set of $\nu$ measure zero. Thus

$$
\int s_n d(\mu \times \nu) = \int \int X_C(y) s_n(x, y) \, d\mu d\nu
$$

and letting $n \to \infty$, the monotone convergence theorem implies

$$
\int f d(\mu \times \nu) = \int \int X_C(y) f(x, y) \, d\mu d\nu = \int \int f(x, y) \, d\mu d\nu
$$

because of completeness of the measures, $\mu$ and $\nu$. This proves Fubini’s theorem.

**Theorem 10.9.11** (Fubini) Let $(X, S, \mu)$ and $(Y, T, \nu)$ be complete measure spaces and let

$$(\mu \times \nu)(E) \equiv \inf \left\{ \int \int X_R(x, y) \, d\mu d\nu : E \subseteq R \in \mathcal{R} \right\}$$

where $A_i \in S$ and $B_i \in T$. Then $\mu \times \nu$ is an outer measure on the subsets of $X \times Y$ and the $\sigma$ algebra of $\mu \times \nu$ measurable sets, $S \times T$, contains all measurable rectangles. If $f \geq 0$ is a $\mu \times \nu$ measurable function satisfying

$$
\int_{X \times Y} f d(\mu \times \nu) < \infty,
$$

then

$$
\int_{X \times Y} f d(\mu \times \nu) = \int_Y \int_X f \, d\mu d\nu,
$$

where the iterated integral on the right makes sense because for $\nu$ a.e. $y$, $x \to f(x, y)$ is $\mu$ measurable and $y \to \int f(x, y) \, d\mu$ is $\nu$ measurable. Similarly,

$$
\int_{X \times Y} f d(\mu \times \nu) = \int_X \int_Y f \, d\mu d\nu.
$$

$^2$Recall this is the same as

$$
\inf \left\{ \sum_{i=1}^{\infty} \mu(A_i) \nu(B_i) : E \subseteq \bigcup_{i=1}^{\infty} A_i \times B_i \right\}
$$

in which the $A_i$ and $B_i$ are measurable.
In the case where \((X, S, \mu)\) and \((Y, T, \nu)\) are both \(\sigma\) finite, it is not necessary to assume \[10.9.47\].

**Corollary 10.9.12 (Fubini)** Let \((X, S, \mu)\) and \((Y, T, \nu)\) be complete measure spaces such that \((X, S, \mu)\) and \((Y, T, \nu)\) are both \(\sigma\) finite and let

\[\mu \times \nu (E) \equiv \inf \left\{ \int \int X_R (x, y) d\mu d\nu : E \subseteq R \in \mathcal{R} \right\}\]

where \(A_i \in S\) and \(B_i \in T\). Then \(\mu \times \nu\) is an outer measure. If \(f \geq 0\) is a \(\mu \times \nu\) measurable function then

\[\int_{X \times Y} f d(\mu \times \nu) = \int_{Y} \int_{X} f d\mu d\nu,\]

where the iterated integral on the right makes sense because for \(\nu\) a.e. \(y, x \to f(x, y)\) is \(\mu\) measurable and \(y \to \int f(x, y) d\mu\) is \(\nu\) measurable. Similarly,

\[\int_{X \times Y} f d(\mu \times \nu) = \int_{X} \int_{Y} f d\nu d\mu.\]

**Proof:** Let \(\bigcup_{n=1}^{\infty} X_n = X\) and \(\bigcup_{n=1}^{\infty} Y_n = Y\) where \(X_n \in S, Y_n \in T, X_n \subseteq X_{n+1}, Y_n \subseteq Y_{n+1}\) for all \(n\) and \(\mu(X_n) < \infty, \nu(Y_n) < \infty\). From Theorem \[10.9.11\] applied to \(X_n, Y_n\) and \(f_m \equiv \min(f, m)\),

\[\int_{X_n \times Y_n} f_m d(\mu \times \nu) = \int_{Y_n} \int_{X_n} f_m d\mu d\nu\]

Now take \(m \to \infty\) and use the monotone convergence theorem to obtain

\[\int_{X_n \times Y_n} f d(\mu \times \nu) = \int_{Y_n} \int_{X_n} f d\mu d\nu.\]

Then use the monotone convergence theorem again letting \(n \to \infty\) to obtain the desired conclusion. The argument for the other order of integration is similar.

**Corollary 10.9.13** If \(f \in L^1(X \times Y)\), then

\[\int f d(\mu \times \nu) = \int \int f(x, y) d\mu d\nu = \int \int f(x, y) d\nu d\mu.\]

If \(\mu\) and \(\nu\) are \(\sigma\) finite, then if \(f\) is \(\mu \times \nu\) measurable having complex values and either \(\int \int |f| d\mu d\nu < \infty\) or \(\int \int |f| d\nu d\mu < \infty\), then \(\int \int |f| d(\mu \times \nu) < \infty\) so \(f \in L^1(X \times Y)\).

**Proof:** Without loss of generality, it can be assumed that \(f\) has real values. Then

\[f = \frac{|f| + f - (|f| - f)}{2}\]
and both \( f^+ \equiv \frac{|f| + f}{2} \) and \( f^- \equiv \frac{|f| - f}{2} \) are nonnegative and are less than \(|f|\). Therefore, \( \int gd(\mu \times \nu) < \infty \) for \( g = f^+ \) and \( g = f^- \) so the above theorem applies and

\[
\int f d(\mu \times \nu) = \int f^+ d(\mu \times \nu) - \int f^- d(\mu \times \nu) \\
= \int \int f^+ d\mu d\nu - \int \int f^- d\mu d\nu \\
= \int \int f d\mu d\nu.
\]

It remains to verify the last claim. Suppose \( s \) is a simple function,

\[
s(x, y) = \sum_{i=1}^{m} c_i \chi_{E_i} \leq |f|(x, y)
\]

where the \( c_i \) are the nonzero values of \( s \). Then

\[
s\chi_{R_n} \leq |f|\chi_{R_n}
\]

where \( R_n \equiv X_n \times Y_n \) where \( X_n \uparrow X \) and \( Y_n \uparrow Y \) with \( \mu(X_n) < \infty \) and \( \nu(Y_n) < \infty \). It follows, since the nonzero values of \( s\chi_{R_n} \) are achieved on sets of finite measure,

\[
\int s\chi_{R_n} d(\mu \times \nu) = \int \int s\chi_{R_n} d\mu d\nu.
\]

Letting \( n \to \infty \) and applying the monotone convergence theorem, this yields

\[
\int sd(\mu \times \nu) = \int \int sd\mu d\nu. \tag{10.9.48}
\]

Now let \( s_n \uparrow |f| \) where \( s_n \) is a nonnegative simple function. From\[ \text{[HOT]} \]

\[
\int s_n d(\mu \times \nu) = \int \int s_n d\mu d\nu.
\]

Letting \( n \to \infty \) and using the monotone convergence theorem, yields

\[
\int |f| d(\mu \times \nu) = \int \int |f| d\mu d\nu < \infty
\]

10.10 Alternative Treatment Of Product Measure

10.10.1 Monotone Classes And Algebras

Measures are defined on \( \sigma \) algebras which are closed under countable unions. It is for this reason that the theory of measure and integration is so useful in dealing with limits of sequences. However, there is a more basic notion which involves only finite unions and differences.
Definition 10.10.1 \( \mathcal{A} \) is said to be an algebra of subsets of a set, \( Z \) if \( Z \in \mathcal{A}, \emptyset \in \mathcal{A}, \) and when \( E, F \in \mathcal{A}, \ E \cup F \) and \( E \setminus F \) are both in \( \mathcal{A} \).

It is important to note that if \( \mathcal{A} \) is an algebra, then it is also closed under finite intersections. This is because \( E \cap F = (E^C \cup F^C)^C \in \mathcal{A} \) since \( E^C = Z \setminus E \in \mathcal{A} \) and \( F^C = Z \setminus F \in \mathcal{A} \). Note that every \( \sigma \) algebra is an algebra but not the other way around.

Something satisfying the above definition is called an algebra because union is like addition, the set difference is like subtraction and intersection is like multiplication. Furthermore, only finitely many operations are done at a time and so there is nothing like a limit involved.

How can you recognize an algebra when you see one? The answer to this question is the purpose of the following lemma.

Lemma 10.10.2 Suppose \( \mathcal{R} \) and \( \mathcal{E} \) are subsets of \( \mathcal{P}(Z) \) such that \( \mathcal{E} \) is defined as the set of all finite disjoint unions of sets of \( \mathcal{R} \). Suppose also

\[
\emptyset, Z \in \mathcal{R}
\]

\[
A \cap B \in \mathcal{R} \quad \text{whenever} \ A, B \in \mathcal{R},
\]

\[
A \setminus B \in \mathcal{E} \quad \text{whenever} \ A, B \in \mathcal{R}.
\]

Then \( \mathcal{E} \) is an algebra of sets of \( Z \).

Proof: Note first that if \( A \in \mathcal{R} \), then \( A^C \in \mathcal{E} \) because \( A^C = Z \setminus A \).

Now suppose that \( E_1 \) and \( E_2 \) are in \( \mathcal{E} \),

\[
E_1 = \bigcup_{i=1}^{m} R_i, \quad E_2 = \bigcup_{j=1}^{n} R_j
\]

where the \( R_i \) are disjoint sets in \( \mathcal{R} \) and the \( R_j \) are disjoint sets in \( \mathcal{R} \). Then

\[
E_1 \cap E_2 = \bigcup_{i=1}^{m} \bigcup_{j=1}^{n} R_i \cap R_j
\]

which is clearly an element of \( \mathcal{E} \) because no two of the sets in the union can intersect and by assumption they are all in \( \mathcal{R} \). Thus by induction, finite intersections of sets of \( \mathcal{E} \) are in \( \mathcal{E} \). Consider the difference of two elements of \( \mathcal{E} \) next.

If \( E = \bigcup_{i=1}^{n} R_i \in \mathcal{E} \),

\[
E^C = \bigcap_{i=1}^{n} R_i^C = \text{finite intersection of sets of } \mathcal{E}
\]

which was just shown to be in \( \mathcal{E} \). Now, if \( E_1, E_2 \in \mathcal{E} \),

\[
E_1 \setminus E_2 = E_1 \cap E_2^C \in \mathcal{E}
\]

from what was just shown about finite intersections.

\[\text{Set of all subsets of } Z\]
Finally consider finite unions of sets of $\mathcal{E}$. Let $E_1$ and $E_2$ be sets of $\mathcal{E}$. Then

$$E_1 \cup E_2 = (E_1 \setminus E_2) \cup E_2 \in \mathcal{E}$$

because $E_1 \setminus E_2$ consists of a finite disjoint union of sets of $\mathcal{R}$ and these sets must be disjoint from the sets of $\mathcal{R}$ whose union yields $E_2$ because $(E_1 \setminus E_2) \cap E_2 = \emptyset$. This proves the lemma.

The following corollary is particularly helpful in verifying the conditions of the above lemma.

**Corollary 10.10.3** Let $(Z_1, \mathcal{R}_1, \mathcal{E}_1)$ and $(Z_2, \mathcal{R}_2, \mathcal{E}_2)$ be as described in Lemma 12.1.2. Then $(Z_1 \times Z_2, \mathcal{R}, \mathcal{E})$ also satisfies the conditions of Lemma 12.1.2 if $\mathcal{R}$ is defined as

$$\mathcal{R} \equiv \{ R_1 \times R_2 : R_i \in \mathcal{R}_i \}$$

and

$$\mathcal{E} \equiv \{ \text{finite disjoint unions of sets of } \mathcal{R} \}.$$

Consequently, $\mathcal{E}$ is an algebra of sets.

**Proof:** It is clear $\emptyset, Z_1 \times Z_2 \in \mathcal{R}$. Let $A \times B$ and $C \times D$ be two elements of $\mathcal{R}$.

$$A \times B \cap C \times D = A \cap C \times B \cap D \in \mathcal{R}$$

by assumption.

$$A \times B \setminus (C \times D) =$$

$$\begin{align*}
    &\underset{\in \mathcal{E}_2}{\left( A \times (B \setminus D) \right) \cup \left( A \setminus C \right) \times \left( D \cap B \right)} \\
    &= (A \times Q) \cup (P \times R)
\end{align*}$$

where $Q \in \mathcal{E}_2$, $P \in \mathcal{E}_1$, and $R \in \mathcal{R}_2$.

Since $A \times Q$ and $P \times R$ do not intersect, it follows the above expression is in $\mathcal{E}$ because each of these terms are. This proves the corollary.

**Definition 10.10.4** $\mathcal{M} \subseteq \mathcal{P}(Z)$ is called a monotone class if

a.) $\cdots E_n \supseteq E_{n+1} \supseteq \cdots$, $E = \cap_{n=1}^{\infty} E_n$, and $E_n \in \mathcal{M}$, then $E \in \mathcal{M}$.

b.) $\cdots E_n \subseteq E_{n+1} \subseteq \cdots$, $E = \cup_{n=1}^{\infty} E_n$, and $E_n \in \mathcal{M}$, then $E \in \mathcal{M}$.

(In simpler notation, $E_n \downarrow E$ and $E_n \in \mathcal{M}$ implies $E \in \mathcal{M}$. $E_n \uparrow E$ and $E_n \in \mathcal{M}$ implies $E \in \mathcal{M}$.)
Theorem 10.10.5 (Monotone Class theorem) Let \( \mathcal{A} \) be an algebra of subsets of \( Z \) and let \( \mathcal{M} \) be a monotone class containing \( \mathcal{A} \). Then \( \mathcal{M} \supseteq \sigma(\mathcal{A}) \), the smallest \( \sigma \)-algebra containing \( \mathcal{A} \).

Proof: Consider all monotone classes which contain \( \mathcal{A} \), and take their intersection. The result is still a monotone class which contains \( \mathcal{A} \) and is therefore the smallest monotone class containing \( \mathcal{A} \). Therefore, assume without loss of generality that \( \mathcal{M} \) is the smallest monotone class containing \( \mathcal{A} \) because if it is shown the smallest monotone class containing \( \mathcal{A} \) contains \( \sigma(\mathcal{A}) \), then the given monotone class does also. To avoid more notation, let \( \mathcal{M} \) denote this smallest monotone class.

The plan is to show \( \mathcal{M} \) is a \( \sigma \)-algebra. It will then follow \( \mathcal{M} \supseteq \sigma(\mathcal{A}) \) because \( \sigma(\mathcal{A}) \) is defined as the intersection of all \( \sigma \) algebras which contain \( \mathcal{A} \). For \( A \in \mathcal{A} \), define

\[
\mathcal{M}_A \equiv \{ B \in \mathcal{M} \text{ such that } A \cup B \in \mathcal{M} \}.
\]

Clearly \( \mathcal{M}_A \) is a monotone class containing \( \mathcal{A} \). Hence \( \mathcal{M}_A \supseteq \mathcal{M} \) because \( \mathcal{M} \) is the smallest such monotone class. But by construction, \( \mathcal{M}_A \subseteq \mathcal{M} \). Therefore, \( \mathcal{M} = \mathcal{M}_A \). This shows that \( A \cup B \in \mathcal{M} \) whenever \( A \in \mathcal{A} \) and \( B \in \mathcal{M} \). Now pick \( B \in \mathcal{M} \) and define

\[
\mathcal{M}_B \equiv \{ D \in \mathcal{M} \text{ such that } D \cup B \in \mathcal{M} \}.
\]

It was just shown that \( \mathcal{A} \subseteq \mathcal{M}_B \). It is clear that \( \mathcal{M}_B \) is a monotone class. Thus by a similar argument, \( \mathcal{M}_B = \mathcal{M} \) and it follows that \( D \cup B \in \mathcal{M} \) whenever \( D \in \mathcal{M} \) and \( B \in \mathcal{M} \). This shows \( \mathcal{M} \) is closed under finite unions.

Next consider the difference of two sets. Let \( A \in \mathcal{A} \)

\[
\mathcal{M}_A \equiv \{ B \in \mathcal{M} \text{ such that } B \setminus A \text{ and } A \setminus B \in \mathcal{M} \}.
\]

Then \( \mathcal{M}_A \) is a monotone class containing \( \mathcal{A} \). As before, \( \mathcal{M} = \mathcal{M}_A \). Thus \( B \setminus A \) and \( A \setminus B \) are both in \( \mathcal{M} \) whenever \( A \in \mathcal{A} \) and \( B \in \mathcal{M} \). Now pick \( A \in \mathcal{M} \) and consider

\[
\mathcal{M}_A \equiv \{ B \in \mathcal{M} \text{ such that } B \setminus A \text{ and } A \setminus B \in \mathcal{M} \}.
\]

It was just shown \( \mathcal{M}_A \) contains \( \mathcal{A} \). Now \( \mathcal{M}_A \) is a monotone class and so \( \mathcal{M}_A = \mathcal{M} \) as before.

Thus \( \mathcal{M} \) is both a monotone class and an algebra. Hence, if \( E \in \mathcal{M} \) then \( Z \setminus E \in \mathcal{M} \). Next consider the question of whether \( \mathcal{M} \) is a \( \sigma \)-algebra. If \( E_i \in \mathcal{M} \) and \( F_n = \bigcup_{i=1}^{\infty} E_i \), then \( F_n \in \mathcal{M} \) and \( F_n \uparrow \bigcup_{i=1}^{\infty} E_i \). Since \( \mathcal{M} \) is a monotone class, \( \bigcup_{i=1}^{\infty} E_i \in \mathcal{M} \) and so \( \mathcal{M} \) is a \( \sigma \)-algebra. This proves the theorem.

10.10.2 Product Measure

Definition 10.10.6 Let \((X, S, \mu)\) and \((Y, F, \lambda)\) be two measure spaces. A measurable rectangle is a set \( A \times B \subseteq X \times Y \) where \( A \in S \) and \( B \in F \). An elementary set will be any subset of \( X \times Y \) which is a finite union of disjoint measurable rectangles. \( S \times F \) will denote the smallest \( \sigma \) algebra of sets in \( \mathcal{P}(X \times Y) \) containing all elementary sets.
Example 10.10.7 It follows from Lemma 12.1.2 or more easily from Corollary 12.1.3 that the elementary sets form an algebra.

Definition 10.10.8 Let $E \subseteq X \times Y$,

$$E_x = \{y \in Y : (x, y) \in E\},$$

$$E^y = \{x \in X : (x, y) \in E\}.$$  

These are called the $x$ and $y$ sections.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{sections.png}
\caption{Sections $E_x$ and $E^y$.}
\end{figure}

Theorem 10.10.9 If $E \in S \times F$, then $E_x \in F$ and $E^y \in S$ for all $x \in X$ and $y \in Y$.

Proof: Let

$$\mathcal{M} = \{E \subseteq S \times F \text{ such that for all } x \in X, \ E_x \in F,$$

and for all $y \in Y$, $E^y \in S\}.$$  

Then $\mathcal{M}$ contains all measurable rectangles. If $E_i \in \mathcal{M}$,

$$(\bigcup_{i=1}^{\infty} E_i)_x = \bigcup_{i=1}^{\infty} (E_i)_x \in \mathcal{F}.$$  

Similarly,

$$(\bigcup_{i=1}^{\infty} E_i)^y = \bigcup_{i=1}^{\infty} E_i^y \in \mathcal{S}.$$  

It follows $\mathcal{M}$ is closed under countable unions.

If $E \in \mathcal{M}$,

$$ (E^C)_x = (E_x)^C \in \mathcal{F}. $$

Similarly, $(E^C)^y \in \mathcal{S}$. Thus $\mathcal{M}$ is closed under complementation. Therefore $\mathcal{M}$ is a $\sigma$-algebra containing the elementary sets. Hence, $\mathcal{M} \supseteq S \times \mathcal{F}$ because $S \times \mathcal{F}$ is the smallest $\sigma$ algebra containing these elementary sets. But $\mathcal{M} \subseteq S \times \mathcal{F}$ by definition and so $\mathcal{M} = S \times \mathcal{F}$. This proves the theorem.

It follows from Lemma 12.1.2 that the elementary sets form an algebra because clearly the intersection of two measurable rectangles is a measurable rectangle and

$$ (A \times B) \setminus (A_0 \times B_0) = (A \setminus A_0) \times B \cup (A \cap A_0) \times (B \setminus B_0), $$

an elementary set.
**Theorem 10.10.10** If \((X, \mathcal{S}, \mu)\) and \((Y, \mathcal{F}, \lambda)\) are both finite measure spaces \((\mu(X), \lambda(Y)) < \infty\), then for every \(E \in \mathcal{S} \times \mathcal{F},\)

a.) \(x \to \lambda(E_x)\) is \(\mu\) measurable, \(y \to \mu(E^y)\) is \(\lambda\) measurable

b.) \(\int_X \lambda(E_x) d\mu = \int_Y \mu(E^y) d\lambda.

**Proof:** Let \(\mathcal{M} = \{E \in \mathcal{S} \times \mathcal{F} \text{ such that both a.) and b.) hold}\).

Since \(\mu\) and \(\lambda\) are both finite, the monotone convergence and dominated convergence theorems imply \(\mathcal{M}\) is a monotone class.

Next I will argue \(\mathcal{M}\) contains the elementary sets. Let
\[ E = \bigcup_{i=1}^n A_i \times B_i \]
where the measurable rectangles, \(A_i \times B_i\) are disjoint. Then
\[
\lambda(E_x) = \int_Y \chi_E(x, y) d\lambda = \sum_{i=1}^n \int_Y \chi_{A_i \times B_i}(x, y) d\lambda = \sum_{i=1}^n \chi_{A_i}(x) \lambda(B_i)
\]
which is clearly \(\mu\) measurable. Furthermore,
\[
\int_X \lambda(E_x) d\mu = \sum_{i=1}^n \int_X \chi_{A_i}(x) \lambda(B_i) d\mu = \sum_{i=1}^n \mu(A_i) \lambda(B_i).
\]
Similarly,
\[
\int_Y \mu(E^y) d\lambda = \sum_{i=1}^n \mu(A_i) \lambda(B_i)
\]
and \(y \to \mu(E^y)\) is \(\lambda\) measurable and this shows \(\mathcal{M}\) contains the algebra of elementary sets. By the monotone class theorem, \(\mathcal{M} = \mathcal{S} \times \mathcal{F}\). This proves the theorem.

One can easily extend this theorem to the case where the measure spaces are \(\sigma\) finite.

**Theorem 10.10.11** If \((X, \mathcal{S}, \mu)\) and \((Y, \mathcal{F}, \lambda)\) are both \(\sigma\) finite measure spaces, then for every \(E \in \mathcal{S} \times \mathcal{F},\)

a.) \(x \to \lambda(E_x)\) is \(\mu\) measurable, \(y \to \mu(E^y)\) is \(\lambda\) measurable.

b.) \(\int_X \lambda(E_x) d\mu = \int_Y \mu(E^y) d\lambda.

**Proof:** Let \(X = \bigcup_{n=1}^\infty X_n, Y = \bigcup_{n=1}^\infty Y_n\) where,
\[ X_n \subseteq X_{n+1}, Y_n \subseteq Y_{n+1}, \mu(X_n) < \infty, \lambda(Y_n) < \infty. \]
Let
\[ S_n = \{A \cap X_n : A \in \mathcal{S}\}, \quad F_n = \{B \cap Y_n : B \in \mathcal{F}\}. \]
10.10. ALTERNATIVE TREATMENT OF PRODUCT MEASURE

Thus \((X_n, S_n, \mu)\) and \((Y_n, F_n, \lambda)\) are both finite measure spaces.

**Claim:** If \(E \in S \times F\), then \(E \cap (X_n \times Y_n) \in S_n \times F_n\).

**Proof:** Let

\[
M_n = \{ E \in S \times F : E \cap (X_n \times Y_n) \in S_n \times F_n \}.
\]

Clearly \(M_n\) contains the algebra of elementary sets. It is also clear that \(M_n\) is a monotone class. Thus \(M_n = S \times F\).

Now let \(E \in S \times F\). By Theorem 10.10.11,

\[
\int_{X_n} \lambda((E \cap (X_n \times Y_n))_x) \, d\mu = \int_{Y_n} \mu((E \cap (X_n \times Y_n))^y) \, d\lambda \tag{10.10.49}
\]

where the integrands are measurable. Also

\[
(E \cap (X_n \times Y_n))_x = \emptyset
\]

if \(x \notin X_n\) and a similar observation holds for the second integrand in (10.10.49) if \(y \notin Y_n\). Therefore,

\[
\int_X \lambda((E \cap (X_n \times Y_n))_x) \, d\mu = \int_{X_n} \lambda((E \cap (X_n \times Y_n))_x) \, d\mu = \int_{Y_n} \mu((E \cap (X_n \times Y_n))^y) \, d\lambda = \int_Y \mu((E \cap (X_n \times Y_n))^y) \, d\lambda.
\]

Then letting \(n \to \infty\), the monotone convergence theorem implies b.) and the measurability assertions of a.) are valid because

\[
\lambda(E_x) = \lim_{n \to \infty} \lambda((E \cap (X_n \times Y_n))_x)
\]

\[
\mu(E^y) = \lim_{n \to \infty} \mu((E \cap (X_n \times Y_n))^y).
\]

This proves the theorem.

This theorem makes it possible to define product measure.

**Definition 10.10.12** For \(E \in S \times F\) and \((X, S, \mu), (Y, F, \lambda)\) finite, \((\mu \times \lambda)(E) \equiv \int_X \lambda(E_x) \, d\mu = \int_Y \mu(E^y) \, d\lambda\).

This definition is well defined because of Theorem 10.10.11.

**Theorem 10.10.13** If \(A \in S, B \in F\), then \((\mu \times \lambda)(A \times B) = \mu(A)\lambda(B)\), and \(\mu \times \lambda\) is a measure on \(S \times F\) called product measure.

**Proof:** The first assertion about the measure of a measurable rectangle was established above. Now suppose \(\{E_i\}_{i=1}^\infty\) is a disjoint collection of sets of \(S \times F\).
Then using the monotone convergence theorem along with the observation that 
\((E_i)_x \cap (E_j)_x = \emptyset\),

\[
(\mu \times \lambda)(\bigcup_{i=1}^{\infty} E_i) = \int_X \lambda((\bigcup_{i=1}^{\infty} E_i)_x) d\mu \\
= \int_X \lambda(\bigcup_{i=1}^{\infty} (E_i)_x) d\mu = \int_X \sum_{i=1}^{\infty} \lambda((E_i)_x) d\mu \\
= \sum_{i=1}^{\infty} \int_X \lambda((E_i)_x) d\mu \\
= \sum_{i=1}^{\infty} (\mu \times \lambda)(E_i)
\]

This proves the theorem.

The next theorem is one of several theorems due to Fubini and Tonelli. These
theorems all have to do with interchanging the order of integration in a multiple
integral.

**Theorem 10.10.14** Let \(f : X \times Y \to [0, \infty]\) be measurable with respect to \(S \times \mathcal{F}\) and suppose \(\mu\) and \(\lambda\) are \(\sigma\) finite. Then

\[
\int_{X \times Y} f d(\mu \times \lambda) = \int_X \int_Y f(x, y) d\lambda d\mu = \int_Y \int_X f(x, y) d\mu d\lambda \quad (10.10.50)
\]

and all integrals make sense.

**Proof:** For \(E \in S \times \mathcal{F}\),

\[
\int_Y \chi_E(x, y) d\lambda = \lambda(E_x), \quad \int_X \chi_E(x, y) d\mu = \mu(E^y).
\]

Thus from Definition \[10.10.42 \] and \[10.10.49 \] holds if \(f = \chi_E\). It follows that \[10.10.49 \] holds for every nonnegative simple function. By Theorem \[9.3.9 \] on Page \[227 \], there exists an increasing sequence, \(\{f_n\}\), of simple functions converging pointwise to \(f\). Then

\[
\int_Y f(x, y) d\lambda = \lim_{n \to \infty} \int_Y f_n(x, y) d\lambda,
\]

\[
\int_X f(x, y) d\mu = \lim_{n \to \infty} \int_X f_n(x, y) d\mu.
\]

This follows from the monotone convergence theorem. Since

\[
x \to \int_Y f_n(x, y) d\lambda
\]

is measurable with respect to \(S\), it follows that \(x \to \int_Y f(x, y) d\lambda\) is also measurable with respect to \(S\). A similar conclusion can be drawn about \(y \to \int_X f(x, y) d\mu\). Thus the two iterated integrals make sense. Since \[10.10.49 \] holds for \(f_n\), another application of the Monotone Convergence theorem shows \[10.10.49 \] holds for \(f\). This proves the theorem.
Corollary 10.10.15 Let \( f : X \times Y \to \mathbb{C} \) be \( \mathcal{S} \times \mathcal{F} \) measurable. Suppose either
\[
\int_X \int_Y |f| \, d\mu \, d\lambda < \infty
\]
\[\text{or}\]
\[
\int_Y \int_X |f| \, d\mu \, d\lambda < \infty.
\]
Then \( f \in L^1(X \times Y, \mu \times \lambda) \) and
\[
\int_{X \times Y} f \, d(\mu \times \lambda) = \int_X \int_Y f \, d\mu \, d\lambda = \int_Y \int_X f \, d\mu \, d\lambda
\]
with all integrals making sense.

**Proof:** Suppose first that \( f \) is real valued. Apply Theorem 10.10.14 to \( f^+ \) and \( f^- \). (10.10.51) follows from observing that \( f = f^+ - f^- \); and that all integrals are finite. If \( f \) is complex valued, consider real and imaginary parts. This proves the corollary.

Suppose \( f \) is product measurable. From the above discussion, and breaking \( f \) down into a sum of positive and negative parts of real and imaginary parts and then using Theorem 10.11.5 on Page 227 on approximation by simple functions, it follows that whenever \( f \) is \( \mathcal{S} \times \mathcal{F} \) measurable, \( x \to f(x,y) \) is \( \mu \) measurable, \( y \to f(x,y) \) is \( \lambda \) measurable.

### 10.11 Completion Of Measures

Suppose \( (\Omega, \mathcal{F}, \mu) \) is a measure space. Then it is always possible to enlarge the \( \sigma \) algebra and define a new measure \( \bar{\mu} \) on this larger \( \sigma \) algebra such that \( (\Omega, \mathcal{F}, \bar{\mu}) \) is a complete measure space. Recall this means that if \( N \subseteq N' \in \mathcal{F} \) and \( \bar{\mu}(N') = 0 \), then \( N \in \mathcal{F} \). The following theorem is the main result. The new measure space is called the completion of the measure space.

**Theorem 10.11.1** Let \( (\Omega, \mathcal{F}, \mu) \) be a \( \sigma \) finite measure space. Then there exists a unique measure space, \( (\Omega, \mathcal{F}, \bar{\mu}) \) satisfying

1. \( (\Omega, \mathcal{F}, \bar{\mu}) \) is a complete measure space.
2. \( \bar{\mu} = \mu \) on \( \mathcal{F} \)
3. \( \mathcal{F} \supseteq \mathcal{F} \)
4. For every \( E \subseteq \mathcal{F} \) there exists \( G \in \mathcal{F} \) such that \( G \supseteq E \) and \( \mu(G) = \bar{\mu}(E) \).
5. For every \( E \subseteq \mathcal{F} \) there exists \( F \in \mathcal{F} \) such that \( F \subseteq E \) and \( \mu(F) = \bar{\mu}(E) \).

Also for every \( E \in \mathcal{F} \) there exist sets \( G, F \in \mathcal{F} \) such that \( G \supseteq E \supseteq F \) and
\[
\mu(G \setminus F) = \bar{\mu}(G \setminus F) = 0
\]
(10.11.52)

**Proof:** First consider the claim about uniqueness. Suppose \( (\Omega, \mathcal{F}_1, \nu_1) \) and \( (\Omega, \mathcal{F}_2, \nu_2) \) both work and let \( E \in \mathcal{F}_1 \). Also let \( \mu(\Omega_n) < \infty \), \( \cdots \cap \Omega_n \subseteq \Omega_{n+1} \cdots \), and \( \cup_{n=1}^\infty \Omega_n = \Omega \). Define \( E_n = E \cap \Omega_n \). Then pick \( G_n \supseteq E_n \supseteq F_n \) such that \( \mu(G_n) = \).
\(\mu(F_n) = \nu_1(E_n)\). It follows \(\mu(G_n \setminus F_n) = 0\). Then letting \(G = \cup_n G_n, F = \cup_n F_n\), it follows \(G \supseteq E \supseteq F\) and
\[
\mu(G \setminus F) \leq \mu(\cup_n (G_n \setminus F_n)) \\
\leq \sum_n \mu(G_n \setminus F_n) = 0.
\]

It follows that \(\nu_2(G \setminus F) = 0\) also. Now \(E \setminus F \subseteq G \setminus F\) and since \((\Omega, \mathcal{F}, \nu_2)\) is complete, it follows \(E \setminus F \in \mathcal{F}_2\). Since \(F \in \mathcal{F}_2\), it follows \(E = (E \setminus F) \cup F \in \mathcal{F}_2\). Thus \(\mathcal{F}_1 \subseteq \mathcal{F}_2\). Similarly \(\mathcal{F}_2 \subseteq \mathcal{F}_1\). Now it only remains to verify \(\nu_1 = \nu_2\). Thus let \(E \in \mathcal{F}_1 = \mathcal{F}_2\) and let \(G\) and \(F\) be as just described. Since \(\nu_1 = \mu\) on \(\mathcal{F}\),
\[
\mu(F) = \nu_1(F) \\
= \nu_1(G \setminus F) + \nu_1(F) \\
\leq \nu_1(G \setminus F) + \nu_1(F) \\
= \nu_1(F) = \mu(F)
\]

Similarly \(\nu_2(E) = \mu(F)\). This proves uniqueness. The construction has also verified \(\mu\).

Next define an outer measure, \(\overline{\mu}\) on \(\mathcal{P}(\Omega)\) as follows. For \(S \subseteq \Omega\),
\[
\overline{\mu}(S) = \inf \{ \mu(E) : E \in \mathcal{F} \}.
\]

Then it is clear \(\overline{\mu}\) is increasing. It only remains to verify \(\overline{\mu}\) is subadditive. Then let \(S = \cup_{i=1}^\infty S_i\). If any \(\overline{\mu}(S_i) = \infty\), there is nothing to prove so suppose \(\overline{\mu}(S_i) < \infty\) for each \(i\). Then there exist \(E_i \in \mathcal{F}\) such that \(E_i \supseteq S_i\) and
\[
\overline{\mu}(S_i) + \varepsilon/2^i > \mu(E_i).
\]

Then
\[
\overline{\mu}(S) = \overline{\mu}(\cup_i S_i) \\
\leq \mu(\cup_i E_i) \leq \sum_i \mu(E_i) \\
\leq \sum_i (\overline{\mu}(S_i) + \varepsilon/2^i) = \sum_i \overline{\mu}(S_i) + \varepsilon.
\]

Since \(\varepsilon\) is arbitrary, this verifies \(\overline{\mu}\) is subadditive and is an outer measure as claimed.

Denote by \(\mathcal{F}\) the \(\sigma\) algebra of measurable sets in the sense of Caratheodory. Then it follows from the Carathéodory procedure, Theorem 10.1.4 on Page 250, that \((\Omega, \mathcal{F}, \overline{\mu})\) is a complete measure space. This verifies \(\mathbb{1}\).

Now let \(E \in \mathcal{F}\). Then from the definition of \(\overline{\mu}\), it follows
\[
\overline{\mu}(E) = \inf \{ \mu(F) : F \in \mathcal{F} \text{ and } F \supseteq E \} \leq \mu(E).
\]

If \(F \supseteq E\) and \(F \in \mathcal{F}\), then \(\mu(F) \geq \mu(E)\) and so \(\mu(E)\) is a lower bound for all such \(\mu(F)\) which shows that
\[
\overline{\mu}(E) = \inf \{ \mu(F) : F \in \mathcal{F} \text{ and } F \supseteq E \} \geq \mu(E).
\]
10.11. COMPLETION OF MEASURES

This verifies 2.

Next consider 3. Let $E \in \mathcal{F}$ and let $S$ be a set. I must show

$$\bar{\mu} (S) \geq \bar{\mu} (S \setminus E) + \bar{\mu} (S \cap E).$$

If $\bar{\mu} (S) = \infty$ there is nothing to show. Therefore, suppose $\bar{\mu} (S) < \infty$. Then from the definition of $\bar{\mu}$ there exists $G \supseteq S$ such that $G \in \mathcal{F}$ and $\mu (G) = \bar{\mu} (S)$. Then from the definition of $\bar{\mu}$,

$$\begin{align*}
\bar{\mu} (S) &\leq \bar{\mu} (S \setminus E) + \bar{\mu} (S \cap E) \\
&\leq \mu (G \setminus E) + \mu (G \cap E) \\
&= \mu (G) = \bar{\mu} (S)
\end{align*}$$

This verifies 3.

Claim 4 comes by the definition of $\bar{\mu}$ as used above. The only other case is when $\bar{\mu} (S) = \infty$. However, in this case, you can let $G = \Omega$.

It only remains to verify 5. Let the $\Omega_n$ be as described above and let $E \in \mathcal{F}$ such that $E \subseteq \Omega_n$. By 3 there exists $H \in \mathcal{F}$ such that $H \subseteq \Omega_n$, $H \supseteq \Omega_n \setminus E$, and

$$\mu (H) = \bar{\mu} (\Omega_n \setminus E). \quad (10.11.53)$$

Then let $F \equiv \Omega_n \cap H^c$. It follows $F \subseteq E$ and

$$E \setminus F = E \cap F^c = E \cap (H \cup \Omega_n^c) = E \cap H = H \setminus (\Omega_n \setminus E)$$

Hence from

$$\bar{\mu} (E \setminus F) = \bar{\mu} (H \setminus (\Omega_n \setminus E)) = 0.$$ 

It follows

$$\bar{\mu} (E) = \bar{\mu} (F) = \mu (F).$$

In the case where $E \in \mathcal{F}$ is arbitrary, not necessarily contained in some $\Omega_n$, it follows from what was just shown that there exists $F_n \in \mathcal{F}$ such that $F_n \subseteq E \cap \Omega_n$ and

$$\mu (F_n) = \bar{\mu} (E \cap \Omega_n).$$

Letting $F \equiv \cup_n F_n$

$$\bar{\mu} (E \setminus F) \leq \bar{\mu} (\cup_n (E \cap \Omega_n \setminus F_n)) \leq \sum_n \bar{\mu} (E \cap \Omega_n \setminus F_n) = 0.$$ 

Therefore, $\bar{\mu} (E) = \mu (F)$ and this proves 5. This proves the theorem.

Now here is an interesting theorem about complete measure spaces.
Theorem 10.11.2 Let $(\Omega, \mathcal{F}, \mu)$ be a complete measure space and let $f \leq g \leq h$ be functions having values in $[0, \infty]$. Suppose also that $f(\omega) = h(\omega)$ a.e. $\omega$ and that $f$ and $h$ are measurable. Then $g$ is also measurable. If $(\Omega, \mathcal{F}, \pi)$ is the completion of a $\sigma$ finite measure space $(\Omega, \mathcal{F}, \mu)$ as described above in Theorem 10.11.1 then if $f$ is measurable with respect to $\mathcal{F}$ having values in $[0, \infty]$, it follows there exists $g$ measurable with respect to $\mathcal{F}$, $g \leq f$, and a set $N \in \mathcal{F}$ with $\mu(N) = 0$ and $g = f$ on $N^c$. There also exists $h$ measurable with respect to $\mathcal{F}$ such that $h \geq f$, and a set of measure zero, $M \in \mathcal{F}$ such that $f = h$ on $M^c$.

Proof: Let $\alpha \in \mathbb{R}$.

$[f > \alpha] \subseteq [g > \alpha] \subseteq [h > \alpha]$

Thus

$[g > \alpha] = [f > \alpha] \cup ([g > \alpha] \setminus [f > \alpha])$

and $[g > \alpha] \setminus [f > \alpha]$ is a measurable set because it is a subset of the set of measure zero,

$[h > \alpha] \setminus [f > \alpha]$.

Now consider the last assertion. By Theorem 10.11.4 on Page 323 there exists an increasing sequence of nonnegative simple functions, $\{s_n\}$ measurable with respect to $\mathcal{F}$ which converges pointwise to $f$. Letting

$$s_n (\omega) = \sum_{k=1}^{m_n} c_n^k \chi_{E_k^n} (\omega)$$

be one of these simple functions, it follows from Theorem 10.11.1 there exist sets, $F_k^n \in \mathcal{F}$ such that $F_k^n \subseteq E_k^n$ and $\mu(F_k^n) = \overline{\pi}(E_k^n)$. Then let

$$t_n (\omega) = \sum_{k=1}^{m_n} c_n^k \chi_{F_k^n} (\omega).$$

Thus $t_n = s_n$ off a set of measure zero, $N_n \in \mathcal{F}, t_n \leq s_n$. Let $N' \equiv \cap_n N_n$. Then by Theorem 10.11.4 again, there exists $N \in \mathcal{F}$ such that $N \supseteq N'$ and $\mu(N) = 0$. Consider the simple functions,

$$s'_n (\omega) \equiv t_n (\omega) \chi_{N^c} (\omega).$$

It is an increasing sequence so let $g(\omega) = \lim_{n \to \infty} s'_n (\omega)$. It follows $g$ is measurable with respect to $\mathcal{F}$ and equals $f$ off $N$.

Finally, to obtain the function, $h \geq f$, in 10.11.5 use Theorem 10.11.2 to obtain the existence of $F_k^n \in \mathcal{F}$ such that $F_k^n \supseteq E_k^n$ and $\mu(F_k^n) = \overline{\pi}(E_k^n)$. Then let

$$t_n (\omega) = \sum_{k=1}^{m_n} c_n^k \chi_{F_k^n} (\omega).$$
10.12. ANOTHER VERSION OF PRODUCT MEASURES

Thus \( t_n = s_n \) off a set of measure zero, \( M_n \in \mathcal{F}, t_n \geq s_n \), and \( t_n \) is measurable with respect to \( \mathcal{F} \). Then define

\[
s'_n = \max_{k \leq n} t_n.
\]

It follows \( s'_n \) is an increasing sequence of \( \mathcal{F} \) measurable nonnegative simple functions. Since each \( s'_n \geq s_n \), it follows that if \( h(\omega) = \lim_{n \to \infty} s'_n(\omega) \), then \( h(\omega) \geq f(\omega) \). Also if \( h(\omega) > f(\omega) \), then \( \omega \in \cup_n M_n \equiv M' \), a set of \( \mathcal{F} \) having measure zero. By Theorem 10.11.1, there exists \( M \supseteq M' \) such that \( M \in \mathcal{F} \) and \( \mu(M) = 0 \). It follows \( h = f \) off \( M \). This proves the theorem.

10.12 Another Version Of Product Measures

10.12.1 General Theory

Given two finite measure spaces, \((X, \mathcal{F}, \mu)\) and \((Y, \mathcal{S}, \nu)\), there is a way to define a \( \sigma \) algebra of subsets of \( X \times Y \), denoted by \( \mathcal{F} \times \mathcal{S} \) and a measure, denoted by \( \mu \times \nu \) defined on this \( \sigma \) algebra such that

\[
\mu \times \nu (A \times B) = \mu(A) \nu(B)
\]

whenever \( A \in \mathcal{F} \) and \( B \in \mathcal{S} \). This is naturally related to the concept of iterated integrals similar to what is used in calculus to evaluate a multiple integral. The approach is based on something called a \( \pi \) system, \([34]\).

**Definition 10.12.1** Let \((X, \mathcal{F}, \mu)\) and \((Y, \mathcal{S}, \nu)\) be two measure spaces. A measurable rectangle is a set of the form \( A \times B \) where \( A \in \mathcal{F} \) and \( B \in \mathcal{S} \).

**Definition 10.12.2** Let \( \Omega \) be a set and let \( \mathcal{K} \) be a collection of subsets of \( \Omega \). Then \( \mathcal{K} \) is called a \( \pi \) system if \( \emptyset, \Omega \in \mathcal{K} \) and whenever \( A, B \in \mathcal{K} \), it follows \( A \cap B \in \mathcal{K} \).

Obviously an example of a \( \pi \) system is the set of measurable rectangles because

\[
A \times B \cap A' \times B' = (A \cap A') \times (B \cap B').
\]

The following is the fundamental lemma which shows these \( \pi \) systems are useful. This lemma is due to Dynkin.

**Lemma 10.12.3** Let \( \mathcal{K} \) be a \( \pi \) system of subsets of \( \Omega \), a set. Also let \( \mathcal{G} \) be a collection of subsets of \( \Omega \) which satisfies the following three properties.

1. \( \mathcal{K} \subseteq \mathcal{G} \)
2. If \( A \in \mathcal{G} \), then \( A^C \in \mathcal{G} \)
3. If \( \{A_i\}_{i=1}^{\infty} \) is a sequence of disjoint sets from \( \mathcal{G} \) then \( \bigcup_{i=1}^{\infty} A_i \in \mathcal{G} \).

Then \( \mathcal{G} \supseteq \sigma(\mathcal{K}) \), where \( \sigma(\mathcal{K}) \) is the smallest \( \sigma \) algebra which contains \( \mathcal{K} \).
**Proof:** First note that if
\[ H \equiv \{ G : \text{I - 3 all hold} \} \]
then \( \cap H \) yields a collection of sets which also satisfies I - 3. Therefore, I will assume in the argument that \( G \) is the smallest collection satisfying I - 3. Let \( A \in K \) and define
\[ G_A \equiv \{ B \in G : A \cap B \in G \} . \]
I want to show \( G_A \) satisfies I - 3 because then it must equal \( G \) since \( G \) is the smallest collection of subsets of \( \Omega \) which satisfies I - 3. This will give the conclusion that for \( A, B \in G \), \( A \cap B \in G \). This information will then be used to show that if \( A, B \in G \) then \( A \cup B \in G \). From this it will follow very easily that \( G \) is a \( \sigma \) algebra which will imply it contains \( \sigma(K) \). Now here are the details of the argument.

Since \( K \) is given to be a \( \pi \) system, \( K \subseteq G_A \). Property 3 is obvious because if \( f B_i \) is a sequence of disjoint sets in \( G_A \), then \( A \setminus \bigcup_{i=1}^{\infty} B_i = \bigcup_{i=1}^{\infty} A \setminus B_i \in G \) because \( A \setminus B_i \in G \) and the property 3 of \( G \).

It remains to verify Property 2, so let \( B \in G_A \). I need to verify that \( B \subseteq G \). In other words, I need to show that \( A \cap B \subseteq G \). However,
\[
A \cap B^C = (A^C \cup (A \cap B))^C \in G
\]
Here is why. Since \( B \in G_A \), \( A \cap B \subseteq G \) and since \( A \in K \subseteq G \) it follows \( A^C \subseteq G \) by assumption 3. It follows from assumption 3 the union of the disjoint sets, \( A^C \) and \( (A \cap B) \) is in \( G \) and then from 3 the complement of their union is in \( G \). Thus \( G_A \) satisfies I - 3 and this implies since \( G \) is the smallest such, that \( G_A \supseteq G \). However, \( G_A \) is constructed as a subset of \( G \). This proves that for every \( B \in G \) and \( A \in \mathcal{K} \), \( A \cap B \in G \). Now pick \( B \in G \) and consider
\[ G_B \equiv \{ A \in G : A \cap B \in G \} . \]
I just proved \( K \subseteq G_B \). The other arguments are identical to show \( G_B \) satisfies I - 3 and is therefore equal to \( G \). This shows that whenever \( A, B \in G \) it follows \( A \cap B \in G \).

This implies \( G \) is a \( \sigma \) algebra. To show this, all that is left is to verify \( G \) is closed under countable unions because then it follows \( G \) is a \( \sigma \) algebra. Let \( \{ A_i \} \subseteq G \).

Then let \( A'_1 = A_1 \) and
\[
A'_{n+1} = A_{n+1} \setminus \bigcup_{i=1}^{n} A_i = A_{n+1} \cap (\bigcap_{i=1}^{n} A_i^C) = \bigcap_{i=1}^{n} (A_{n+1} \cap A_i^C ) \in G
\]
because finite intersections of sets of \( G \) are in \( G \). Since the \( A'_i \) are disjoint, it follows
\[ \bigcup_{i=1}^{\infty} A_i = \bigcup_{i=1}^{\infty} A'_i \in G \]
Therefore, \( \mathcal{G} \supseteq \sigma (\mathcal{K}) \) and this proves the Lemma. □

With this lemma, it is easy to define product measure.

Let \((X, \mathcal{F}, \mu)\) and \((Y, \mathcal{S}, \nu)\) be two finite measure spaces. Define \(\mathcal{K}\) to be the set of measurable rectangles, \(A \times B, A \in \mathcal{F}\) and \(B \in \mathcal{S}\). Let

\[
\mathcal{G} \equiv \left\{ E \subseteq X \times Y : \int_Y \int_X \chi_E d\mu d\nu = \int_X \int_Y \chi_E d\nu d\mu \right\} \quad (10.12.55)
\]

where in the above, part of the requirement is for all integrals to make sense.

Then \(\mathcal{K} \subseteq \mathcal{G}\). This is obvious.

Next I want to show that if \(E \in \mathcal{G}\) then \(E^C \in \mathcal{G}\). Observe \(\chi_{E^C} = 1 - \chi_E\) and so

\[
\int_Y \int_X \chi_{E^C} d\mu d\nu = \int_Y \int_X (1 - \chi_E) d\mu d\nu \\
= \int_X \int_Y (1 - \chi_E) d\nu d\mu \\
= \int_X \int_Y \chi_{E^C} d\nu d\mu
\]

which shows that if \(E \in \mathcal{G}\), then \(E^C \in \mathcal{G}\).

Next I want to show \(\mathcal{G}\) is closed under countable unions of disjoint sets of \(\mathcal{G}\). Let \(\{A_i\}\) be a sequence of disjoint sets from \(\mathcal{G}\). Then

\[
\int_Y \int_X \chi_{\bigcup_{i=1}^{\infty} A_i} d\mu d\nu = \int_Y \int_X \sum_{i=1}^{\infty} \chi_{A_i} d\mu d\nu \\
= \int_Y \sum_{i=1}^{\infty} \int_X \chi_{A_i} d\mu d\nu \\
= \sum_{i=1}^{\infty} \int_Y \int_X \chi_{A_i} d\mu d\nu \\
= \sum_{i=1}^{\infty} \int_X \int_Y \chi_{A_i} d\nu d\mu \\
= \int_X \sum_{i=1}^{\infty} \int_Y \chi_{A_i} d\nu d\mu \\
= \int_X \int_Y \sum_{i=1}^{\infty} \chi_{A_i} d\nu d\mu, \quad (10.12.56)
\]

the interchanges between the summation and the integral depending on the monotone convergence theorem. Thus \(\mathcal{G}\) is closed with respect to countable disjoint unions.
From Lemma 10.12.3, \( G \supseteq \sigma(K) \). Also the computation in 10.12.56 implies that on \( \sigma(K) \) one can define a measure, denoted by \( \mu \times \nu \) and that for every \( E \in \sigma(K) \),

\[
(\mu \times \nu)(E) = \int_Y \int_X \mathcal{X}_E d\mu d\nu = \int_X \mathcal{X}_E d\nu \int_Y d\mu. \tag{10.12.57}
\]

Now here is Fubini’s theorem.

**Theorem 10.12.4** Let \( f : X \times Y \to [0, \infty] \) be measurable with respect to the \( \sigma \) algebra, \( \sigma(K) \) just defined and let \( \mu \times \nu \) be the product measure of 10.12.57 where \( \mu \) and \( \nu \) are finite measures on \((X, F)\) and \((Y, S)\) respectively. Then

\[
\int_{X \times Y} f d(\mu \times \nu) = \int_Y \int_X f d\mu d\nu = \int_X \int_Y f d\nu d\mu.
\]

**Proof:** Let \( \{s_n\} \) be an increasing sequence of \( \sigma(K) \) measurable simple functions which converges pointwise to \( f \). The above equation holds for \( s_n \) in place of \( f \) from what was shown above. The final result follows from passing to the limit and using the monotone convergence theorem. ■

The symbol, \( F \times S \) denotes \( \sigma(K) \).

Of course one can generalize right away to measures which are only \( \sigma \) finite.

**Theorem 10.12.5** Let \( f : X \times Y \to [0, \infty] \) be measurable with respect to the \( \sigma \) algebra, \( \sigma(K) \) just defined and let \( \mu \times \nu \) be the product measure of 10.12.54 where \( \mu \) and \( \nu \) are \( \sigma \) finite measures on \((X, F)\) and \((Y, S)\) respectively. Then

\[
\int_{X \times Y} f d(\mu \times \nu) = \int_Y \int_X f d\mu d\nu = \int_X \int_Y f d\nu d\mu.
\]

**Proof:** Since the measures are \( \sigma \) finite, there exist increasing sequences of sets, \( \{X_n\} \) and \( \{Y_n\} \) such that \( \mu(X_n) < \infty \) and \( \nu(Y_n) < \infty \). Then \( \mu \) and \( \nu \) restricted to \( X_n \) and \( Y_n \) respectively are finite. Then from Theorem 10.12.54,

\[
\int_{Y_n} \int_{X_n} f d\mu d\nu = \int_{X_n} \int_{Y_n} f d\nu d\mu
\]

Passing to the limit yields

\[
\int_Y \int_X f d\mu d\nu = \int_X \int_Y f d\nu d\mu
\]

whenever \( f \) is as above. In particular, you could take \( f = \mathcal{X}_E \) where \( E \in F \times S \) and define

\[
(\mu \times \nu)(E) \equiv \int_Y \int_X \mathcal{X}_E d\mu d\nu = \int_X \mathcal{X}_E d\nu \int_Y d\mu.
\]

Then just as in the proof of Theorem 10.12.3, the conclusion of this theorem is obtained. This proves the theorem.

It is also useful to note that all the above holds for \( \prod_{i=1}^n X_i \) in place of \( X \times Y \). You would simply modify the definition of \( G \) in 10.12.53 including all permutations for the iterated integrals and for \( K \) you would use sets of the form \( \prod_{i=1}^n A_i \) where \( A_i \) is measurable. Everything goes through exactly as above. Thus the following is obtained.
Theorem 10.12.6
Let \( \{(X_i, F_i, \mu_i)\}_{i=1}^n \) be \( \sigma \) finite measure spaces and let \( \prod_{i=1}^n F_i \) denote the smallest \( \sigma \) algebra which contains the measurable boxes of the form \( \prod_{i=1}^n A_i \), where \( A_i \in F_i \). Then there exists a measure, \( \lambda \) defined on \( \prod_{i=1}^n F_i \) such that if \( f : \prod_{i=1}^n X_i \to [0, \infty) \) is \( \prod_{i=1}^n F_i \) measurable, and \( (i_1, \ldots, i_n) \) is any permutation of \( (1, \ldots, n) \), then
\[
\int f \, d\lambda = \int_{X_{i_1}} \cdots \int_{X_{i_n}} f \, d\mu_{i_1} \cdots d\mu_{i_n}
\]

10.12.2 Completion Of Product Measure Spaces

Using Theorem 10.11.2 it is easy to give a generalization to yield a theorem for the completion of product spaces.

Theorem 10.12.7
Let \( \{(X_i, F_i, \mu_i)\}_{i=1}^n \) be \( \sigma \) finite measure spaces and let \( \prod_{i=1}^n F_i \) denote the smallest \( \sigma \) algebra which contains the measurable boxes of the form \( \prod_{i=1}^n A_i \), where \( A_i \in F_i \). Then there exists a measure, \( \lambda \) defined on \( \prod_{i=1}^n F_i \) such that if \( f : \prod_{i=1}^n X_i \to [0, \infty) \) is \( \prod_{i=1}^n F_i \) measurable, and \( (i_1, \ldots, i_n) \) is any permutation of \( (1, \ldots, n) \), then
\[
\int f \, d\lambda = \int_{X_{i_1}} \cdots \int_{X_{i_n}} f \, d\mu_{i_1} \cdots d\mu_{i_n}
\]

Let \( (\prod_{i=1}^n X_i, \prod_{i=1}^n F_i, \lambda) \) denote the completion of this product measure space and let
\[
f : \prod_{i=1}^n X_i \to [0, \infty]
\]
be \( \prod_{i=1}^n F_i \) measurable. Then there exists \( N \in \prod_{i=1}^n F_i \) such that \( \lambda(N) = 0 \) and a nonnegative function, \( f_1 \) measurable with respect to \( \prod_{i=1}^n F_i \) such that \( f_1 = f \) off \( N \) and if \( (i_1, \ldots, i_n) \) is any permutation of \( (1, \ldots, n) \), then
\[
\int f \, d\lambda = \int_{X_{i_1}} \cdots \int_{X_{i_n}} f_1 \, d\mu_{i_1} \cdots d\mu_{i_n}.
\]
Furthermore, \( f_1 \) may be chosen to satisfy either \( f_1 \leq f \) or \( f_1 \geq f \).

Proof: This follows immediately from Theorem 10.11.4 and Theorem 10.11.6.

By the second theorem, there exists a function \( f_1 \geq f \) such that \( f_1 = f \) for all \( (x_1, \ldots, x_n) \notin N \), a set of \( \prod_{i=1}^n F_i \) having measure zero. Then by Theorem 10.11.4 and Theorem 10.11.6
\[
\int f \, d\lambda = \int f_1 \, d\lambda = \int_{X_{i_1}} \cdots \int_{X_{i_n}} f_1 \, d\mu_{i_1} \cdots d\mu_{i_n}.
\]
Since \( f_1 = f \) off a set of measure zero, I will dispense with the subscript. Also it is customary to write
\[
\lambda = \mu_1 \times \cdots \times \mu_n
\]
and
\[ \mathcal{X} = \mu_1 \times \cdots \times \mu_n. \]

Thus in more standard notation, one writes
\[ \int f d(\mu_1 \times \cdots \times \mu_n) = \int_{\mathcal{X}_n} \cdots \int_{\mathcal{X}_1} f d\mu_1 \cdots d\mu_n. \]

This theorem is often referred to as Fubini’s theorem. The next theorem is also called this.

**Corollary 10.12.8** Suppose \( f \in L^1 \left( \prod_{i=1}^n X_i, \prod_{i=1}^n F_i, \mu_1 \times \cdots \times \mu_n \right) \) where each \( X_i \) is a \( \sigma \)-finite measure space. Then if \((i_1, \cdots, i_n)\) is any permutation of \((1, \cdots, n)\), it follows
\[ \int f d(\mu_1 \times \cdots \times \mu_n) = \int_{\mathcal{X}_n} \cdots \int_{\mathcal{X}_1} f d\mu_{i_1} \cdots d\mu_{i_n}. \]

**Proof:** Just apply Theorem 10.12.7 to the positive and negative parts of the real and imaginary parts of \( f \). This proves the theorem.

Here is another easy corollary.

**Corollary 10.12.9** Suppose in the situation of Corollary 10.12.8, \( f = f_1 \) off \( N \), a set of \( \prod_{i=1}^n F_i \) having \( \mu_1 \times \cdots \times \mu_n \) measure zero and that \( f_1 \) is a complex valued function measurable with respect to \( \prod_{i=1}^n F_i \). Suppose also that for some permutation of \((1, 2, \cdots, n), (j_1, \cdots, j_n)\)
\[ \int_{\mathcal{X}_{j_n}} \cdots \int_{\mathcal{X}_{j_1}} |f_1| d\mu_{j_1} \cdots d\mu_{j_n} < \infty. \]

Then
\[ f \in L^1 \left( \prod_{i=1}^n X_i, \prod_{i=1}^n F_i, \mu_1 \times \cdots \times \mu_n \right) \]
and the conclusion of Corollary 10.12.8 holds.

**Proof:** Since \(|f_1|\) is \( \prod_{i=1}^n F_i \) measurable, it follows from Theorem 10.12.7 that
\[ \infty > \int_{\mathcal{X}_{j_n}} \cdots \int_{\mathcal{X}_{j_1}} |f_1| d\mu_{j_1} \cdots d\mu_{j_n} \]
\[ = \int |f_1| d(\mu_1 \times \cdots \times \mu_n) \]
\[ = \int |f_1| d(\mu_1 \times \cdots \times \mu_n) \]
\[ = \int |f| d(\mu_1 \times \cdots \times \mu_n). \]

Thus \( f \in L^1 \left( \prod_{i=1}^n X_i, \prod_{i=1}^n F_i, \mu_1 \times \cdots \times \mu_n \right) \) as claimed and the rest follows from Corollary 10.12.8. This proves the corollary.

The following lemma is also useful.
Lemma 10.12.10 Let $(X, \mathcal{F}, \mu)$ and $(Y, \mathcal{S}, \nu)$ be \( \sigma \) finite complete measure spaces and suppose \( f \geq 0 \) is \( \mathcal{F} \times \mathcal{S} \) measurable. Then for a.e. \( x \),

\[
y \to f(x, y)
\]

is \( \mathcal{S} \) measurable. Similarly for a.e. \( y \),

\[
x \to f(x, y)
\]

is \( \mathcal{F} \) measurable.

**Proof:** By Theorem [10.11.2], there exist \( \mathcal{F} \times \mathcal{S} \) measurable functions, \( g \) and \( h \) and a set, \( N \in \mathcal{F} \times \mathcal{S} \) of \( \mu \times \lambda \) measure zero such that \( g \leq f \leq h \) and for \((x, y) \notin N\), it follows that \( g(x, y) = h(x, y) \). Then

\[
\int_X \int_Y g \, d\nu \, d\mu = \int_X \int_Y h \, d\nu \, d\mu
\]

and so for a.e. \( x \),

\[
\int_Y g \, d\nu = \int_Y h \, d\nu.
\]

Then it follows that for these values of \( x, g(x, y) = h(x, y) \) and so by Theorem [10.11.2] again and the assumption that \((Y, \mathcal{S}, \nu)\) is complete, \( y \to f(x, y) \) is \( \mathcal{S} \) measurable. The other claim is similar. This proves the lemma.

### 10.13 Disturbing Examples

There are examples which help to define what can be expected of product measures and Fubini type theorems. Three such examples are given in Rudin [102]. Some of the theorems given above are more general than those in this reference but the same examples are still useful for showing that the hypotheses of the above theorems are all necessary.

**Example 10.13.1** Let \( \{a_n\} \) be an increasing sequence of numbers in \((0, 1)\) which converges to 1. Let \( g_n \in C_c(a_n, a_{n+1}) \) such that \( \int g_n \, dx = 1 \). Now for \((x, y) \in [0, 1) \times [0, 1) \) define

\[
f(x, y) = \sum_{k=1}^{\infty} g_n(y) (g_n(x) - g_{n+1}(x)).
\]

Note this is actually a finite sum for each such \((x, y)\). Therefore, this is a continuous function on \([0, 1) \times [0, 1)\). Now for a fixed \( y \),

\[
\int_0^1 f(x, y) \, dx = \sum_{k=1}^{\infty} g_n(y) \int_0^1 (g_n(x) - g_{n+1}(x)) \, dx = 0
\]
showing that \( \int_0^1 \int_0^1 f(x, y) \, dx \, dy = \int_0^1 0 \, dy = 0 \). Next fix \( x \).

\[
\int_0^1 f(x, y) \, dy = \sum_{k=1}^{\infty} (g_n(x) - g_{n+1}(x)) \int_0^1 g_n(y) \, dy = g_1(x).
\]

Hence \( \int_0^1 \int_0^1 f(x, y) \, dy \, dx = \int_0^1 g_1(x) \, dx = 1 \). The iterated integrals are not equal. Note the function, \( g \) is not nonnegative even though it is measurable. In addition, neither \( \int_0^1 \int_0^1 |f(x, y)| \, dx \, dy \) nor \( \int_0^1 \int_0^1 |f(x, y)| \, dy \, dx \) is finite and so you can’t apply Corollary 10.10.13. The problem here is the function is not nonnegative and is not absolutely integrable.

**Example 10.13.2** This time let \( \mu = m \), Lebesgue measure on \([0, 1]\), and let \( \nu \) be counting measure on \([0, 1]\), in this case, the \( \sigma \) algebra is \( \mathcal{P}([0, 1]) \). Let \( l \) denote the line segment in \([0, 1] \times [0, 1] \) which goes from \((0, 0)\) to \((1, 1)\). Thus \( l = (x, x) \) where \( x \in [0, 1] \). Consider the outer measure of \( l \) in \( m \times \nu \). Let \( l \subseteq \bigcup_k A_k \times B_k \) where \( A_k \) is Lebesgue measurable and \( B_k \) is a subset of \([0, 1]\). Let \( \mathcal{B} = \{ k \in \mathbb{N} : \nu(B_k) = \infty \} \).

If \( m(\bigcup_{k \in \mathcal{B}} A_k) \) has measure zero, then there are uncountably many points of \([0, 1]\) outside of \( \bigcup_{k \in \mathcal{B}} A_k \). For \( p \) one of these points, \((p, p) \in A_i \times B_i \) and \( i \notin \mathcal{B} \). Thus each of these points is in \( \bigcup_{i \notin \mathcal{B}} B_i \), a countable set because these \( B_i \) are each finite. But this is a contradiction because there need to be uncountably many of these points as just indicated. Thus \( m(A_k) > 0 \) for some \( k \in \mathcal{B} \) and so \( m \times \nu(A_k \times B_k) = \infty \). It follows \( m \times \nu(l) = \infty \) and so \( l \) is \( m \times \nu \) measurable. Thus \( \int X_i(x, y) \, dm \times \nu = \infty \) and so you cannot apply Fubini’s theorem, Theorem 10.10.2. Since \( \nu \) is not \( \sigma \) finite, you cannot apply the corollary to this theorem either. Thus there is no contradiction to the above theorems in the following observation.

\[
\int \int X_i(x, y) \, d\nu \, dm = \int 1 \, dm = 1, \int \int X_i(x, y) \, dm \, d\nu = \int 0 \, d\nu = 0.
\]

The problem here is that you have neither \( \int f \, d m \times \nu < \infty \) not \( \sigma \) finite measure spaces.

The next example is far more exotic. It concerns the case where both iterated integrals make perfect sense but are unequal. In 1877 Cantor conjectured that the cardinality of the real numbers is the next size of infinity after countable infinity. This hypothesis is called the continuum hypothesis and it has never been proved or disproved. Assuming this continuum hypothesis will provide the basis for the following example. It is due to Sierpinski.

**Example 10.13.3** Let \( X \) be an uncountable set. It follows from the well ordering theorem which says every set can be well ordered which is presented in the appendix that \( X \) can be well ordered. Let \( \omega \in X \) be the first element of \( X \) which is

\[\text{In 1940 it was shown by Godel that the continuum hypothesis cannot be disproved. In 1963 it was shown by Cohen that the continuum hypothesis cannot be proved. These assertions are based on the axiom of choice and the Zermelo Franke axioms of set theory. This topic is far outside the scope of this book and this is only a hopefully interesting historical observation.}\]
preceded by uncountably many points of \(X\). Let \(\Omega\) denote \(\{x \in X : x < \omega\}\). Then \(\Omega\) is uncountable but there is no smaller uncountable set. Thus by the continuum hypothesis, there exists a one to one and onto mapping, \(j\) which maps \([0,1]\) onto \(\Omega\). Thus, for \(x \in [0,1], j(x)\) is preceded by countably many points. Let

\[Q \equiv \{(x,y) \in [0,1]^2 : j(x) < j(y)\}\]

and let \(f(x,y) = \chi_Q(x,y)\). Then

\[\int_0^1 f(x,y) \, dy = 1, \quad \int_0^1 f(x,y) \, dx = 0\]

In each case, the integrals make sense. In the first, for fixed \(x\), \(f(x,y) = 1\) for all but countably many \(y\) so the function of \(y\) is Borel measurable. In the second where \(y\) is fixed, \(f(x,y) = 0\) for all but countably many \(x\). Thus

\[\int_0^1 \int_0^1 f(x,y) \, dydx = 1, \quad \int_0^1 \int_0^1 f(x,y) \, dxdy = 0.\]

The problem here must be that \(f\) is not \(m \times m\) measurable.

### 10.14 Exercises

1. Let \(\Omega = \mathbb{N}\), the natural numbers and let \(d(p,q) = |p - q|\), the usual distance in \(\mathbb{R}\). Show that \((\Omega,d)\) the closures of the balls are compact. Now let

\[\Lambda f = \sum_{k=1}^{\infty} f(k)\]

whenever \(f \in C_c(\Omega)\). Show this is a well defined positive linear functional on the space \(C_c(\Omega)\). Describe the measure of the Riesz representation theorem which results from this positive linear functional. What if \((\Lambda f) = \int f(1)\)? What measure would result from this functional? Which functions are measurable?

2. Verify that \(\mu\) defined in Lemma [10.13] is an outer measure.

3. Let \(F : \mathbb{R} \to \mathbb{R}\) be increasing and right continuous. Let \(\Lambda f = \int f \, dF\) where the integral is the Riemann Stieltjes integral of \(f\). Show the measure \(\mu\) from the Riesz representation theorem satisfies

\[\mu([a,b]) = F(b) - F(a-), \quad \mu((a,b]) = F(b) - F(a),\]

\[\mu([a,a]) = F(a) - F(a-).\]

4. Let \(\Omega\) be a metric space with the closed balls compact and suppose \(\mu\) is a measure defined on the Borel sets of \(\Omega\) which is finite on compact sets. Show there exists a unique Radon measure, \(\mu\) which equals \(\mu\) on the Borel sets.

5. Random vectors are measurable functions, \(X\), mapping a probability space, \((\Omega, P, \mathcal{F})\) to \(\mathbb{R}^n\). Thus \(X(\omega) \in \mathbb{R}^n\) for each \(\omega \in \Omega\) and \(P\) is a probability measure defined on the sets of \(\mathcal{F}\), a \(\sigma\) algebra of subsets of \(\Omega\). For \(E\) a Borel set in \(\mathbb{R}^n\), define

\[\mu(E) = P(X^{-1}(E)) = \text{probability that } X \in E.\]
Show this is a well defined measure on the Borel sets of $\mathbb{R}^n$ and use Problem 4 to obtain a Radon measure, $\lambda_X$ defined on a $\sigma$ algebra of sets of $\mathbb{R}^n$ including the Borel sets such that for $E$ a Borel set, $\lambda_X (E) =$ Probability that $(X \in E)$.

6. Suppose $X$ and $Y$ are metric spaces having compact closed balls. Show $(X \times Y, d_{X\times Y})$ is also a metric space which has the closures of balls compact. Here

$$d_{X\times Y} ((x_1, y_1), (x_2, y_2)) \equiv \max (d(x_1, x_2), d(y_1, y_2)).$$

Let

$$A \equiv \{ E \times F : E \text{ is a Borel set in } X, F \text{ is a Borel set in } Y \}.$$

Show $\sigma(A)$, the smallest $\sigma$ algebra containing $A$ contains the Borel sets. **Hint:** Show every open set in a metric space which has closed balls compact can be obtained as a countable union of compact sets. Next show this implies every open set can be obtained as a countable union of open sets of the form $U \times V$ where $U$ is open in $X$ and $V$ is open in $Y$.

7. Suppose $(\Omega, \mathcal{S}, \mu)$ is a measure space which may not be complete. Could you obtain a complete measure space, $(\Omega, \mathcal{S}, \mu_1)$ by simply letting $\mathcal{S}$ consist of all sets of the form $E$ where there exists $F \in \mathcal{S}$ such that $(F \setminus E) \cup (E \setminus F) \subseteq N$ for some $N \in \mathcal{S}$ which has measure zero and then let $\mu (E) = \mu_1 (F)$?

8. If $\mu$ and $\nu$ are Radon measures defined on $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively, show $\mu \times \nu$ is also a radon measure on $\mathbb{R}^{n+m}$. **Hint:** Show the $\mu \times \nu$ measurable sets include the open sets using the observation that every open set in $\mathbb{R}^{n+m}$ is the countable union of sets of the form $U \times V$ where $U$ and $V$ are open in $\mathbb{R}^n$ and $\mathbb{R}^m$ respectively. Next verify outer regularity by considering $A \times B$ for $A, B$ measurable. Argue sets of $\mathcal{R}$ defined above have the property that they can be approximated in measure from above by open sets. Then verify the same is true of sets of $\mathcal{R}_1$. Finally conclude using an appropriate lemma that $\mu \times \nu$ is inner regular as well.

9. Let $(\Omega, \mathcal{S}, \mu)$ be a $\sigma$ finite measure space and let $f : \Omega \to [0, \infty)$ be measurable. Define

$$A \equiv \{ (x, y) : y < f(x) \}$$

Verify that $A$ is $\mu \times m$ measurable. Show that

$$\int f \, d\mu = \int \int 1_A (x, y) \, d\mu \, dm = \int 1_A \, d\mu \times m.$$
Chapter 11

Lebesgue Measure

11.1 Basic Properties

Definition 11.1.1 Define the following positive linear functional for $f \in C_c(\mathbb{R}^n)$.

$$
\Lambda f \equiv \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} f(x) \, dx_1 \cdots dx_n.
$$

Then the measure representing this functional is Lebesgue measure.

The following lemma will help in understanding Lebesgue measure.

Lemma 11.1.2 Every open set in $\mathbb{R}^n$ is the countable disjoint union of half open boxes of the form

$$
\prod_{i=1}^{n}(a_i, a_i + 2^{-k}]
$$

where $a_i = l2^{-k}$ for some integers, $l, k$. The sides of these boxes are of equal length. One could also have half open boxes of the form

$$
\prod_{i=1}^{n}[a_i, a_i + 2^{-k})
$$

and the conclusion would be unchanged.

Proof: Let

$$
C_k = \{ \text{All half open boxes } \prod_{i=1}^{n}(a_i, a_i + 2^{-k}] \text{ where } a_i = l2^{-k} \text{ for some integer } l \}.
$$

Thus $C_k$ consists of a countable disjoint collection of boxes whose union is $\mathbb{R}^n$. This is sometimes called a tiling of $\mathbb{R}^n$. Think of tiles on the floor of a bathroom and
you will get the idea. Note that each box has diameter no larger than $2^{-k}\sqrt{n}$. This is because if

$$x, y \in \prod_{i=1}^{n} (a_i, a_i + 2^{-k}],$$

then $|x - y| \leq 2^{-k}$. Therefore,

$$|x - y| \leq \left( \sum_{i=1}^{n} (2^{-k})^2 \right)^{1/2} = 2^{-k}\sqrt{n}.$$

Let $U$ be open and let $B_1 \equiv \{\text{all sets of } C_1 \text{ which are contained in } U\}$. If $B_1, \cdots, B_k$ have been chosen, $B_{k+1} \equiv \{\text{all sets of } C_{k+1} \text{ contained in } U \setminus \bigcup_{i=1}^{k} B_i \}$. Let $B_\infty = \bigcup_{i=1}^{\infty} B_i$. In fact $\cup B_\infty = U$. Clearly $\cup B_\infty \subseteq U$ because every box of every $B_i$ is contained in $U$. If $p \in U$, let $k$ be the smallest integer such that $p$ is contained in a box from $C_k$ which is also a subset of $U$. Thus

$$p \in \cup B_k \subseteq \cup B_\infty.$$

Hence $B_\infty$ is the desired countable disjoint collection of half open boxes whose union is $U$. The last assertion about the other type of half open rectangle is obvious. This proves the lemma.

Now what does Lebesgue measure do to a rectangle, $\prod_{i=1}^{n} (a_i, b_i]$?

**Lemma 11.1.3** Let $R = \prod_{i=1}^{n} [a_i, b_i]$, $R_0 = \prod_{i=1}^{n} (a_i, b_i)$. Then

$$m_n (R_0) = m_n (R) = \prod_{i=1}^{n} (b_i - a_i).$$

**Proof:** Let $k$ be large enough that

$$a_i + 1/k < b_i - 1/k$$

for $i = 1, \cdots, n$ and consider functions $g_i^k$ and $f_i^k$ having the following graphs.

Let

$$g^k(x) = \prod_{i=1}^{n} g_i^k(x_i), \quad f^k(x) = \prod_{i=1}^{n} f_i^k(x_i).$$
Then by elementary calculus along with the definition of $\Lambda$,

$$\prod_{i=1}^{n}(b_i - a_i + 2/k) \geq \Lambda g^k = \int g^k dm_n \geq m_n(R) \geq m_n(R_0)$$

$$\geq \int f^k dm_n = \Lambda f^k \geq \prod_{i=1}^{n}(b_i - a_i - 2/k).$$

Letting $k \to \infty$, it follows that

$$m_n(R) = m_n(R_0) = \prod_{i=1}^{n}(b_i - a_i).$$

This proves the lemma.

**Lemma 11.1.4** Let $U$ be an open or closed set. Then $m_n(U) = m_n(x + U)$.

**Proof:** By Lemma 11.1.2 there is a sequence of disjoint half open rectangles, $\{R_i\}$ such that $\bigcup_i R_i = U$. Therefore, $x + U = \bigcup_i (x + R_i)$ and the $x + R_i$ are also disjoint rectangles which are identical to the $R_i$ but translated. From Lemma 11.1.3, $m_n(U) = \sum_i m_n(R_i) = \sum_i m_n(x + R_i) = m_n(x + U)$.

It remains to verify the lemma for a closed set. Let $H$ be a closed bounded set first. Then $H \subseteq B(0, R)$ for some $R$ large enough. First note that $x + H$ is a closed set. Thus

$$m_n(B(x, R)) = m_n(x + H) + m_n((B(0, R) + x) \setminus (x + H))$$

$$= m_n(x + H) + m_n((B(0, R) \setminus H) + x)$$

$$= m_n(x + H) + m_n((B(0, R) \setminus H))$$

$$= m_n(B(0, R)) - m_n(H) + m_n(x + H)$$

$$= m_n(B(x, R)) - m_n(H) + m_n(x + H)$$

the last equality because of the first part of the lemma which implies $m_n(B(x, R)) = m_n(B(0, R))$. Therefore, $m_n(x + H) = m_n(H)$ as claimed. If $H$ is not bounded, consider $H_m \equiv B(0, m) \cap H$. Then $m_n(x + H_m) = m_n(H_m)$. Passing to the limit as $m \to \infty$ yields the result in general.

**Theorem 11.1.5** Lebesgue measure is translation invariant. That is

$$m_n(E) = m_n(x + E)$$

for all $E$ Lebesgue measurable.

**Proof:** Suppose $m_n(E) < \infty$. By regularity of the measure, there exist sets $G, H$ such that $G$ is a countable intersection of open sets, $H$ a countable union of compact sets, $m_n(G \setminus H) = 0$, and $G \supseteq E \supseteq H$. Now $m_n(G) = m_n(G + x)$ and
Chapter 11. Lebesgue Measure

\[ m_n(H) = m_n(H + x) \] which follows from Lemma applied to the sets which are either intersected to form \( G \) or unioned to form \( H \). Now

\[ x + H \subseteq x + E \subseteq x + G \]

and both \( x + H \) and \( x + G \) are measurable because they are either countable unions or countable intersections of measurable sets. Furthermore,

\[ m_n(x + G \setminus x + H) = m_n(x + G) - m_n(x + H) = m_n(G) - m_n(H) = 0 \]

and so by completeness of the measure, \( x + E \) is measurable. It follows

\[ m_n(E) = m_n(H) = m_n(x + H) \leq m_n(x + E) \leq m_n(x + G) = m_n(G) = m_n(E). \]

If \( m_n(E) \) is not necessarily less than \( \infty \), consider \( E_m = B(0, m) \cap E \). Then \( m_n(E_m) = m_n(E_m + x) \) by the above. Letting \( m \to \infty \) it follows \( m_n(E) = m_n(E + x) \). This proves the theorem.

**Corollary 11.1.6** Let \( D \) be an \( n \times n \) diagonal matrix and let \( U \) be an open set. Then

\[ m_n(DU) = |\det(D)| m_n(U). \]

**Proof:** If any of the diagonal entries of \( D \) equals 0 there is nothing to prove because then both sides equal zero. Therefore, it can be assumed none are equal to zero. Suppose these diagonal entries are \( k_1, \ldots, k_n \). From Lemma there exist half open boxes, \( \{R_i\} \) having all sides equal such that \( U = \bigcup_i R_i \). Suppose one of these is \( R_i = \prod_{j=1}^n (a_j, b_j) \), where \( b_j - a_j = l_j \). Then \( DR_i = \prod_{j=1}^n I_j \) where \( I_j = (k_j a_j, k_j b_j) \) if \( k_j > 0 \) and \( I_j = [k_j b_j, k_j a_j] \) if \( k_j < 0 \). Then the rectangles, \( DR_i \) are disjoint because \( D \) is one to one and their union is \( DU \). Also,

\[ m_n(DR_i) = \prod_{j=1}^n |k_j| l_j = |\det D| m_n(R_i). \]

Therefore,

\[ m_n(DU) = \sum_{i=1}^{\infty} m_n(DR_i) = |\det(D)| \sum_{i=1}^{\infty} m_n(R_i) = |\det(D)| m_n(U). \]

and this proves the corollary.

From this the following corollary is obtained.

**Corollary 11.1.7** Let \( M > 0 \). Then \( m_n(B(a, Mr)) = M^nm_n(B(0, r)). \)

**Proof:** By Lemma there is no loss of generality in taking \( a = 0 \). Let \( D \) be the diagonal matrix which has \( M \) in every entry of the main diagonal so \( |\det(D)| = M^n \). Note that \( DB(0, r) = B(0, Mr) \). By Corollary \( m_n(B(0, Mr)) = m_n(DB(0, r)) = M^nm_n(B(0, r)). \)
11.2. THE VITALI COVERING THEOREM

There are many norms on $\mathbb{R}^n$. Other common examples are

$$\|x\|_\infty \equiv \max \{|x_k| : x = (x_1, \ldots, x_n)\}$$

or

$$\|x\|_p \equiv \left(\sum_{i=1}^n |x_i|^p\right)^{1/p}.$$

With $\|\cdot\|$ any norm for $\mathbb{R}^n$ you can define a corresponding ball in terms of this norm.

$$B(a, r) \equiv \{x \in \mathbb{R}^n \text{ such that } \|x - a\| < r\}$$

It follows from general considerations involving metric spaces presented earlier that these balls are open sets. Therefore, Corollary 11.1.7 has an obvious generalization.

**Corollary 11.1.8** Let $\|\cdot\|$ be a norm on $\mathbb{R}^n$. Then for $M > 0$, $m_n(B(a, Mr)) = M^n m_n(B(0, r))$ where these balls are defined in terms of the norm $\|\cdot\|$.

11.2 The Vitali Covering Theorem

The Vitali covering theorem is concerned with the situation in which a set is contained in the union of balls. You can imagine that it might be very hard to get disjoint balls from this collection of balls which would cover the given set. However, it is possible to get disjoint balls from this collection of balls which have the property that if each ball is enlarged appropriately, the resulting enlarged balls do cover the set. When this result is established, it is used to prove another form of this theorem in which the disjoint balls do not cover the set but they only miss a set of measure zero.

Recall the Hausdorff maximal principle, Theorem 1.4.2 on Page 32 which is proved to be equivalent to the axiom of choice in the appendix. For convenience, here it is:

**Theorem 11.2.1 (Hausdorff Maximal Principle)** Let $F$ be a nonempty partially ordered set. Then there exists a maximal chain.

I will use this Hausdorff maximal principle to give a very short and elegant proof of the Vitali covering theorem. This follows the treatment in Evans and Gariepy [44] which they got from another book. I am not sure who first did it this way but it is very nice because it is so short. In the following lemma and theorem, the balls will be either open or closed and determined by some norm on $\mathbb{R}^n$. When pictures are drawn, I shall draw them as though the norm is the usual norm but the results are unchanged for any norm. Also, I will write (in this section only) $B(a, r)$ to indicate a set which satisfies

$$\{x \in \mathbb{R}^n : \|x - a\| < r\} \subseteq B(a, r) \subseteq \{x \in \mathbb{R}^n : \|x - a\| \leq r\}$$

and $\hat{B}(a, r)$ to indicate the usual ball but with radius 5 times as large,

$$\{x \in \mathbb{R}^n : \|x - a\| < 5r\}.$$
Lemma 11.2.2 Let \( \| \cdot \| \) be a norm on \( \mathbb{R}^n \) and let \( F \) be a collection of balls determined by this norm. Suppose 
\[
\infty > M \equiv \sup \{ r : B(p, r) \in \mathcal{F} \} > 0
\]
and \( k \in (0, \infty) \). Then there exists \( G \subseteq F \) such that
\[
\text{if } B(p, r) \in G \text{ then } r > k, \tag{11.2.1}
\]
\[
\text{if } B_1, B_2 \in G \text{ then } B_1 \cap B_2 = \emptyset, \tag{11.2.2}
\]
\( G \) is maximal with respect to \( \text{11.2.1} \) and \( \text{11.2.2} \).

Note that if there is no ball of \( F \) which has radius larger than \( k \) then \( G = \emptyset \).

**Proof:** Let \( \mathcal{H} = \{ B \subseteq \mathcal{F} \text{ such that } \text{11.2.1} \text{ and } \text{11.2.2} \text{ hold} \} \). If there are no balls with radius larger than \( k \) then \( \mathcal{H} = \emptyset \) and you let \( G = \emptyset \). In the other case, \( \mathcal{H} \neq \emptyset \) because there exists \( B(p, r) \in \mathcal{F} \) with \( r > k \). In this case, partially order \( \mathcal{H} \) by set inclusion and use the Hausdorff maximal principle (see the appendix on set theory) to let \( \mathcal{C} \) be a maximal chain in \( \mathcal{H} \). Clearly \( \cup \mathcal{C} \) satisfies \( \text{11.2.1} \) and \( \text{11.2.2} \) because if \( B_1 \) and \( B_2 \) are two balls from \( \cup \mathcal{C} \) then since \( \mathcal{C} \) is a chain, it follows there is some element of \( \mathcal{C}, \mathcal{B} \) such that both \( B_1 \) and \( B_2 \) are elements of \( \mathcal{B} \) and \( \mathcal{B} \) satisfies \( \text{11.2.1} \) and \( \text{11.2.2} \). If \( \cup \mathcal{C} \) is not maximal with respect to these two properties, then \( \mathcal{C} \) was not a maximal chain because then there would exist \( \mathcal{B} \supseteq \cup \mathcal{C} \), that is, \( \mathcal{B} \) contains \( \mathcal{C} \) as a proper subset and \( \{ \mathcal{C}, \mathcal{B} \} \) would be a strictly larger chain in \( \mathcal{H} \). Let \( G = \cup \mathcal{C} \).

Theorem 11.2.3 (Vitali) Let \( F \) be a collection of balls and let
\[
A \equiv \cup \{ B : B \in F \}.
\]
Suppose
\[
\infty > M \equiv \sup \{ r : B(p, r) \in \mathcal{F} \} > 0.
\]
Then there exists \( G \subseteq \mathcal{F} \) such that \( G \) consists of disjoint balls and
\[
A \subseteq \cup \{ \hat{B} : B \in G \}.
\]

**Proof:** Using Lemma 11.2.2 there exists \( G_1 \subseteq \mathcal{F} \equiv \mathcal{F}_0 \) which satisfies
\[
B(p, r) \in G_1 \text{ implies } r > \frac{M}{2}, \tag{11.2.3}
\]
\[
B_1, B_2 \in G_1 \text{ implies } B_1 \cap B_2 = \emptyset, \tag{11.2.4}
\]
\( G_1 \) is maximal with respect to \( \text{11.2.1} \) and \( \text{11.2.2} \).

Suppose \( G_1, \ldots, G_m \) have been chosen, \( m \geq 1 \). Let
\[
\mathcal{F}_m \equiv \{ B \in \mathcal{F} : B \subseteq \mathbb{R}^n \setminus \cup \{ G_1 \cup \cdots \cup G_m \} \}.
\]
11.3. THE VITALI COVERING THEOREM (ELEMENTARY VERSION)

Using Lemma 11.2.2, there exists \( G_{m+1} \subseteq F_m \) such that

\[
B(p, r) \in G_{m+1} \text{ implies } r > \frac{M}{2^{m+1}},
\]

(11.2.5)

\[
B_1, B_2 \in G_{m+1} \text{ implies } B_1 \cap B_2 = \emptyset,
\]

(11.2.6)

\( G_{m+1} \) is a maximal subset of \( F_m \) with respect to (11.2.5) and (11.2.6).

Note it might be the case that \( G_{m+1} = \emptyset \) which happens if \( F_m = \emptyset \). Define

\[
\mathcal{G} = \cup_{k=1}^{\infty} G_k.
\]

Thus \( \mathcal{G} \) is a collection of disjoint balls in \( F \). I must show \( \{ \hat{B} : B \in \mathcal{G} \} \) covers \( A \).

Let \( x \in B(p, r) \in F \) and let

\[
\frac{M}{2^m} < r \leq \frac{M}{2^{m-1}}.
\]

Then \( B(p, r) \) must intersect some set, \( B(p_0, r_0) \in G_1 \cup \cdots \cup G_m \) since otherwise, \( G_m \) would fail to be maximal. Then \( r_0 > \frac{M}{2^m} \) because all balls in \( G_1 \cup \cdots \cup G_m \) satisfy this inequality.

Then for \( x \in B(p, r) \), the following chain of inequalities holds because \( r \leq \frac{M}{2^{m-1}} \) and \( r_0 > \frac{M}{2^m} \)

\[
|x - p_0| \leq |x - p| + |p - p_0| \leq r + r_0 + r \\
\leq \frac{2M}{2^{m-1}} + r_0 = \frac{4M}{2^m} + r_0 < 5r_0.
\]

Thus \( B(p, r) \subseteq \hat{B}(p_0, r_0) \) and this proves the theorem.

11.3 The Vitali Covering Theorem (Elementary Version)

The proof given here is from Basic Analysis [75]. It first considers the case of open balls and then generalizes to balls which may be neither open nor closed or closed.
Lemma 11.3.1 Let $\mathcal{F}$ be a countable collection of balls satisfying

$$\infty > M \equiv \sup \{ r : B(p, r) \in \mathcal{F} \} > 0$$

and let $k \in (0, \infty)$. Then there exists $\mathcal{G} \subseteq \mathcal{F}$ such that

- If $B(p, r) \in \mathcal{G}$ then $r > k$, \hspace{1cm} (11.3.7)
- If $B_1, B_2 \in \mathcal{G}$ then $B_1 \cap B_2 = \emptyset$, \hspace{1cm} (11.3.8)
- $\mathcal{G}$ is maximal with respect to 11.3.7 and 11.3.8. \hspace{1cm} (11.3.9)

**Proof:** If no ball of $\mathcal{F}$ has radius larger than $k$, let $\mathcal{G} = \emptyset$. Assume therefore, that some balls have radius larger than $k$. Let $\mathcal{F} \equiv \{ B_i \}_{i=1}^{\infty}$. Now let $B_{n_1}$ be the first ball in the list which has radius greater than $k$. If every ball having radius larger than $k$ intersects this one, then stop. The maximal set is just $B_{n_1}$. Otherwise, let $B_{n_2}$ be the next ball having radius larger than $k$ which is disjoint from $B_{n_1}$. Continue this way obtaining $\{ B_{n_i} \}_{i=1}^{\infty}$, a finite or infinite sequence of disjoint balls having radius larger than $k$. Then let $\mathcal{G} \equiv \{ B_{n_i} \}$. To see that $\mathcal{G}$ is maximal with respect to 11.3.7 and 11.3.8, suppose $B \in \mathcal{F}$, $B$ has radius larger than $k$, and $\mathcal{G} \cup \{ B \}$ satisfies 11.3.7 and 11.3.8. Then at some point in the process, $B$ would have been chosen because it would be the ball of radius larger than $k$ which has the smallest index. Therefore, $B \in \mathcal{G}$ and this shows $\mathcal{G}$ is maximal with respect to 11.3.7 and 11.3.8.

For the next lemma, for an open ball, $B = B(x, r)$, denote by $\bar{B}$ the open ball, $B(x, 4r)$.

**Lemma 11.3.2** Let $\mathcal{F}$ be a collection of open balls, and let

$$A \equiv \cup \{ B : B \in \mathcal{F} \}.$$  

Suppose

$$\infty > M \equiv \sup \{ r : B(p, r) \in \mathcal{F} \} > 0.$$  

Then there exists $\mathcal{G} \subseteq \mathcal{F}$ such that $\mathcal{G}$ consists of disjoint balls and

$$A \subseteq \cup \{ \bar{B} : B \in \mathcal{G} \}.$$  

**Proof:** Without loss of generality assume $\mathcal{F}$ is countable. This is because there is a countable subset of $\mathcal{F}$, $\mathcal{F}'$ such that $\cup \mathcal{F}' = A$. To see this, consider the set of balls having rational radii and centers having all components rational. This is a countable set of balls and you should verify that every open set is the union of balls of this form. Therefore, you can consider the subset of this set of balls consisting of those which are contained in some open set of $\mathcal{F}$, $G$ so $\cup G = A$ and use the axiom of choice to define a subset of $\mathcal{F}$ consisting of a single set from $\mathcal{F}$ containing each set of $G$. Then this is $\mathcal{F}'$. The union of these sets equals $A$. Then consider $\mathcal{F}'$ instead of $\mathcal{F}$. Therefore, assume at the outset $\mathcal{F}$ is countable. By Lemma 11.5.1, there exists $\mathcal{G}_1 \subseteq \mathcal{F}$ which satisfies 11.5.8, 11.5.9 and 11.5.10 with $k = \frac{2M}{3}$. 

11.3. THE VITALI COVERING THEOREM (ELEMENTARY VERSION) 329

Suppose $\mathcal{G}_1, \cdots, \mathcal{G}_{m-1}$ have been chosen for $m \geq 2$. Let

$$\mathcal{F}_m = \{ B \in \mathcal{F} : B \subseteq \mathbb{R}^n \setminus \bigcup_{i=1}^{m} \mathcal{G}_i \}$$

and using Lemma 11.3.1, let $\mathcal{G}_m$ be a maximal collection of disjoint balls from $\mathcal{F}_m$ with the property that each ball has radius larger than $\left( \frac{2}{3} \right)^m M$. Let $\mathcal{G} \equiv \cup_{k=1}^{\infty} \mathcal{G}_k$. Let $x \in B(p, r) \in \mathcal{F}$. Choose $m$ such that

$$\left( \frac{2}{3} \right)^m M < r \leq \left( \frac{2}{3} \right)^{m-1} M$$

Then $B(p, r)$ must have nonempty intersection with some ball from $\mathcal{G}_1 \cup \cdots \cup \mathcal{G}_m$ because if it didn’t, then $\mathcal{G}_m$ would fail to be maximal. Denote by $B(p_0, r_0)$ a ball in $\mathcal{G}_1 \cup \cdots \cup \mathcal{G}_m$ which has nonempty intersection with $B(p, r)$. Thus

$$r_0 > \left( \frac{2}{3} \right)^m M.$$ 

Consider the picture, in which $w \in B(p_0, r_0) \cap B(p, r)$.

Then

$$|x - p_0| \leq |x - p| + |p - w| + |w - p_0| < \frac{2}{3} r_0 \leq r + r_0 \leq 2 \left( \frac{2}{3} \right)^{m-1} M + r_0 < 2 \left( \frac{3}{2} \right) r_0 + r_0 = 4r_0.$$ 

This proves the lemma since it shows $B(p, r) \subseteq B(p_0, 4r_0)$.

With this Lemma consider a version of the Vitali covering theorem in which the balls do not have to be open. A ball centered at $x$ of radius $r$ will denote something which contains the open ball, $B(x, r)$ and is contained in the closed ball, $\overline{B}(x, r)$. Thus the balls could be open or they could contain some but not all of their boundary points.

Definition 11.3.3 Let $B$ be a ball centered at $x$ having radius $r$. Denote by $\hat{B}$ the open ball, $B(x, 5r)$. 
Theorem 11.3.4 (Vitali) Let $\mathcal{F}$ be a collection of balls, and let

$$ A = \bigcup \{ B : B \in \mathcal{F} \}.$$ 

Suppose

$$ \infty > M \equiv \sup \{ r : B(p, r) \in \mathcal{F} \} > 0.$$ 

Then there exists $\mathcal{G} \subseteq \mathcal{F}$ such that $\mathcal{G}$ consists of disjoint balls and

$$ A \subseteq \bigcup \{ \widehat{B} : B \in \mathcal{G} \}.$$ 

Proof: For $B$ one of these balls, say $\overline{B}(x, r) \supseteq B \supseteq B(x, r)$, denote by $B_1$, the ball $B(x, \frac{5r}{4})$. Let $\mathcal{F}_1 \equiv \{ B_1 : B \in \mathcal{F} \}$ and let $A_1$ denote the union of the balls in $\mathcal{F}_1$. Apply Lemma 11.3.2 to $\mathcal{F}_1$ to obtain

$$ A_1 \subseteq \bigcup \{ \widetilde{B}_1 : B_1 \in \mathcal{G}_1 \},$$

where $\mathcal{G}_1$ consists of disjoint balls from $\mathcal{F}_1$. Now let $\mathcal{G} \equiv \{ B \in \mathcal{F} : B_1 \in \mathcal{G}_1 \}$. Thus $\mathcal{G}$ consists of disjoint balls from $\mathcal{F}$ because they are contained in the disjoint open balls, $\mathcal{G}_1$. Then

$$ A \subseteq A_1 \subseteq \bigcup \{ \widetilde{B}_1 : B_1 \in \mathcal{G}_1 \} = \bigcup \{ \widehat{B} : B \in \mathcal{G} \}$$

because for $B_1 = B(x, \frac{5r}{4})$, it follows $\widetilde{B}_1 = B(x, 5r) = \widehat{B}$. This proves the theorem.

11.4 Vitali Coverings

There is another version of the Vitali covering theorem which is also of great importance. In this one, balls from the original set of balls almost cover the set, leaving out only a set of measure zero. It is like packing a truck with stuff. You keep trying to fill in the holes with smaller and smaller things so as to not waste space. It is remarkable that you can avoid wasting any space at all when you are dealing with balls of any sort provided you can use arbitrarily small balls.

Definition 11.4.1 Let $\mathcal{F}$ be a collection of balls that cover a set, $E$, which have the property that if $x \in E$ and $\varepsilon > 0$, then there exists $B \in \mathcal{F}$, diameter of $B < \varepsilon$ and $x \in B$. Such a collection covers $E$ in the sense of Vitali.

In the following covering theorem, $\overline{\mu}_n$ denotes the outer measure determined by $n$ dimensional Lebesgue measure.

Theorem 11.4.2 Let $E \subseteq \mathbb{R}^n$ and suppose $0 < \overline{\mu}_n(E) < \infty$ where $\overline{\mu}_n$ is the outer measure determined by $m_n$, $n$ dimensional Lebesgue measure, and let $\mathcal{F}$ be a collection of closed balls of bounded radii such that $\mathcal{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{ B_j \}_{j=1}^{\infty}$, such that $\overline{\mu}_n(E \setminus \bigcup_{j=1}^{\infty} B_j) = 0$. 
**Proof:** From the definition of outer measure there exists a Lebesgue measurable set, \( E_1 \supseteq E \) such that \( m_n(E_1) = \overline{m_n}(E) \). Now by outer regularity of Lebesgue measure, there exists \( U \), an open set which satisfies
\[
m_n(E_1) > (1 - 10^{-n})m_n(U), \quad U \supseteq E_1.
\]

Each point of \( E \) is contained in balls of \( \mathcal{F} \) of arbitrarily small radii and so there exists a covering of \( E \) with balls of \( \mathcal{F} \) which are themselves contained in \( U \). Therefore, by the Vitali covering theorem, there exist disjoint balls, \( \{B_i\}_{i=1}^{\infty} \subseteq \mathcal{F} \) such that
\[
E \subseteq \bigcup_{j=1}^{\infty} \widehat{B}_j, \quad B_j \subseteq U.
\]

Therefore,
\[
m_n(E_1) = \overline{m_n}(E) \leq m_n\left( \bigcup_{j=1}^{\infty} \widehat{B}_j \right) \leq \sum_j m_n(\widehat{B}_j) = 5^n \sum_j m_n(B_j) = 5^n m_n\left( \bigcup_{j=1}^{\infty} B_j \right)
\]

Then \( E_1 \) and \( \bigcup_{j=1}^{\infty} B_j \) are contained in \( U \) and so
\[
m_n(E_1) > (1 - 10^{-n})m_n(U) \\
\geq (1 - 10^{-n})[m_n(E_1 \setminus \bigcup_{j=1}^{\infty} B_j) + m_n(\bigcup_{j=1}^{\infty} B_j)] \\
= m_n(E_1) \\
\geq (1 - 10^{-n})[m_n(E_1 \setminus \bigcup_{j=1}^{\infty} B_j) + 5^{-n} \overline{m_n}(E)].
\]

and so
\[
(1 - (1 - 10^{-n}) 5^{-n}) m_n(E_1) \geq (1 - 10^{-n})m_n(E_1 \setminus \bigcup_{j=1}^{\infty} B_j)
\]

which implies
\[
m_n(E_1 \setminus \bigcup_{j=1}^{\infty} B_j) \leq \frac{(1 - (1 - 10^{-n}) 5^{-n})}{(1 - 10^{-n})} m_n(E_1)
\]
Now a short computation shows

\[ 0 < \frac{(1 - (1 - 10^{-n})5^{-n})}{(1 - 10^{-n})} < 1 \]

Hence, denoting by \( \theta_n \) a number such that

\[ \frac{(1 - (1 - 10^{-n})5^{-n})}{(1 - 10^{-n})} < \theta_n < 1, \]

\[ \overline{m}_n(E \setminus \bigcup_{j=1}^{\infty} B_j) \leq m_n(E_1 \setminus \bigcup_{j=1}^{\infty} B_j) < \theta_n m_n(E_1) = \theta_n \overline{m}_n(E) \]

Now using Theorem 9.1.5 on Page 208 there exists \( N_1 \) large enough that

\[ \theta_n \overline{m}_n(E) \geq m_n(E_1 \setminus \bigcup_{j=1}^{N_1} B_j) \geq \overline{m}_n(E \setminus \bigcup_{j=1}^{N_1} B_j) \]  \hspace{1cm} (11.4.10)

Let \( \mathcal{F}_1 = \{B \in \mathcal{F} : B_j \cap B = \emptyset, \ j = 1, \cdots, N_1\} \). If \( E \setminus \bigcup_{j=1}^{N_1} B_j = \emptyset \), then \( \mathcal{F}_1 = \emptyset \) and

\[ \overline{m}_n \left( E \setminus \bigcup_{j=1}^{N_1} B_j \right) = 0 \]

Therefore, in this case let \( B_k = \emptyset \) for all \( k > N_1 \). Consider the case where

\[ E \setminus \bigcup_{j=1}^{N_1} B_j \neq \emptyset. \]

In this case, since the balls are closed and \( \mathcal{F} \) is a Vitali cover, \( \mathcal{F}_1 \neq \emptyset \) and covers \( E \setminus \bigcup_{j=1}^{N_1} B_j \) in the sense of Vitali. Repeat the same argument, letting \( E \setminus \bigcup_{j=1}^{N_1} B_j \) play the role of \( E \). (You pick a different \( E_1 \) whose measure equals the outer measure of \( E \setminus \bigcup_{j=1}^{N_1} B_j \) and proceed as before.) Then choosing \( B_j \) for \( j = N_1 + 1, \cdots, N_2 \) as in the above argument,

\[ \theta_n \overline{m}_n(E \setminus \bigcup_{j=1}^{N_1} B_j) \geq \overline{m}_n(E \setminus \bigcup_{j=1}^{N_2} B_j) \]

and so from (11.4.10),

\[ \theta^2_n \overline{m}_n(E) \geq \overline{m}_n \left( E \setminus \bigcup_{j=1}^{N_2} B_j \right). \]

Continuing this way

\[ \theta^k_n \overline{m}_n(E) \geq \overline{m}_n \left( E \setminus \bigcup_{j=1}^{N_k} B_j \right). \]

If it is ever the case that \( E \setminus \bigcup_{j=1}^{N_k} B_j = \emptyset \), then as in the above argument,

\[ \overline{m}_n \left( E \setminus \bigcup_{j=1}^{N_k} B_j \right) = 0. \]

Otherwise, the process continues and

\[ \overline{m}_n \left( E \setminus \bigcup_{j=1}^{\infty} B_j \right) \leq \overline{m}_n \left( E \setminus \bigcup_{j=1}^{N_k} B_j \right) \leq \theta^k_n \overline{m}_n(E) \]

for every \( k \in \mathbb{N} \). Therefore, the conclusion holds in this case also. This proves the Theorem.

There is an obvious corollary which removes the assumption that \( 0 < \overline{m}_n(E) \).
11.4. VITALI COVERINGS

Corollary 11.4.3 Let $E \subseteq \mathbb{R}^n$ and suppose $\overline{m_n}(E) < \infty$ where $\overline{m_n}$ is the outer measure determined by $m_n$, n dimensional Lebesgue measure, and let $\mathcal{F}$, be a collection of closed balls of bounded radii such that $\mathcal{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{B_j\}_{j=1}^{\infty}$, such that $\overline{m_n}(E \setminus \bigcup_{j=1}^{\infty} B_j) = 0$.

Proof: If $0 = \overline{m_n}(E)$ you simply pick any ball from $\mathcal{F}$ for your collection of disjoint balls.

It is also not hard to remove the assumption that $\overline{m_n}(E) < \infty$.

Corollary 11.4.4 Let $E \subseteq \mathbb{R}^n$ and let $\mathcal{F}$, be a collection of closed balls of bounded radii such that $\mathcal{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{B_j\}_{j=1}^{\infty}$, such that $\overline{m_n}(E \setminus \bigcup_{j=1}^{\infty} B_j) = 0$.

Proof: Let $R_{m} \equiv (-m, m)^n$ be the open rectangle having sides of length $2m$ which is centered at 0 and let $R_0 = \emptyset$. Let $H_m \equiv \overline{R_m} \setminus R_m$. Since both $\overline{R_m}$ and $R_m$ have the same measure, $(2m)^n$, it follows $m_n (H_m) = 0$. Now for all $k \in \mathbb{N}$, $R_k \subseteq \overline{R_k} \subseteq R_{k+1}$. Consider the disjoint open sets, $U_k \equiv \overline{R_k} \setminus \overline{R_k}$. Thus $\mathbb{R}^n = \bigcup_{k=0}^{\infty} U_k \cup N$ where $N$ is a set of measure zero equal to the union of the $H_k$.

Let $\mathcal{F}_k$ denote those balls of $\mathcal{F}$ which are contained in $U_k$ and let $E_k \equiv U_k \cap E$. Then from Theorem 11.4.3 there exists a sequence of disjoint balls, $D_k \equiv \{B^k_j\}_{j=1}^{\infty}$ of $\mathcal{F}_k$ such that $\overline{m_n}(E_k \setminus \bigcup_{j=1}^{\infty} B^k_j) = 0$. Letting $\{B_j\}_{j=1}^{\infty}$ be an enumeration of all the balls of $\bigcup_k D_k$, it follows that

$$\overline{m_n}(E \setminus \bigcup_{j=1}^{\infty} B_j) \leq m_n (N) + \sum_{k=1}^{\infty} \overline{m_n}(E_k \setminus \bigcup_{j=1}^{\infty} B^k_j) = 0.$$ 

Also, you don’t have to assume the balls are closed.

Corollary 11.4.5 Let $E \subseteq \mathbb{R}^n$ and let $\mathcal{F}$, be a collection of open balls of bounded radii such that $\mathcal{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{B_j\}_{j=1}^{\infty}$, such that $\overline{m_n}(E \setminus \bigcup_{j=1}^{\infty} B_j) = 0$.

Proof: Let $\overline{\mathcal{F}}$ be the collection of closures of balls in $\mathcal{F}$. Then $\overline{\mathcal{F}}$ covers $E$ in the sense of Vitali and so from Corollary 11.4.3 there exists a sequence of disjoint closed balls from $\overline{\mathcal{F}}$ satisfying $\overline{m_n}(E \setminus \bigcup_{i=1}^{\infty} \overline{B_i}) = 0$. Now boundaries of the balls, $B_i$ have measure zero and so $\{B_i\}$ is a sequence of disjoint open balls satisfying $\overline{m_n}(E \setminus \bigcup_{i=1}^{\infty} B_i) = 0$. The reason for this is that

$$(E \setminus \bigcup_{i=1}^{\infty} B_i) \setminus (E \setminus \bigcup_{i=1}^{\infty} \overline{B_i}) \subseteq \bigcup_{i=1}^{\infty} \overline{B_i} \setminus \bigcup_{i=1}^{\infty} B_i \subseteq \bigcup_{i=1}^{\infty} \overline{B_i} \setminus B_i,$$

a set of measure zero. Therefore,

$$E \setminus \bigcup_{i=1}^{\infty} B_i \subseteq (E \setminus \bigcup_{i=1}^{\infty} \overline{B_i}) \cup (\bigcup_{i=1}^{\infty} \overline{B_i} \setminus B_i)$$

and so

$$\overline{m_n}(E \setminus \bigcup_{i=1}^{\infty} B_i) \leq \overline{m_n}(E \setminus \bigcup_{i=1}^{\infty} \overline{B_i}) + m_n (\bigcup_{i=1}^{\infty} \overline{B_i} \setminus B_i) = \overline{m_n}(E \setminus \bigcup_{i=1}^{\infty} \overline{B_i}) = 0.$$
This implies you can fill up an open set with balls which cover the open set in the sense of Vitali.

**Corollary 11.4.6** Let $U \subseteq \mathbb{R}^n$ be an open set and let $\mathcal{F}$ be a collection of closed or even open balls of bounded radii contained in $U$ such that $\mathcal{F}$ covers $U$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{B_j\}_{j=1}^{\infty}$, such that $m_n(U \setminus \bigcup_{j=1}^{\infty} B_j) = 0$.

### 11.5 Change Of Variables For Linear Maps

To begin with certain kinds of functions map measurable sets to measurable sets. It will be assumed that $U$ is an open set in $\mathbb{R}^n$ and that $h : U \to \mathbb{R}^n$ satisfies

$$Dh(x) \text{ exists for all } x \in U, \quad (11.5.11)$$

**Lemma 11.5.1** Let $h$ satisfy $(11.5.11)$. If $T \subseteq U$ and $m_n(T) = 0$, then $m_n(h(T)) = 0$.

**Proof:** Let

$$T_k \equiv \{x \in T : ||Dh(x)|| < k\}$$

and let $\varepsilon > 0$ be given. Now by outer regularity, there exists an open set, $V$, containing $T_k$ which is contained in $U$ such that $m_n(V) < \varepsilon$. Let $x \in T_k$. Then by differentiability,

$$h(x + v) = h(x) + Dh(x)v + o(v)$$

and so there exist arbitrarily small $r_x < 1$ such that $B(x, 5r_x) \subseteq V$ and whenever $|v| \leq r_x$, $|o(v)| < k|v|$. Thus

$$h(B(x, r_x)) \subseteq B(h(x), 2kr_x).$$

From the Vitali covering theorem there exists a countable disjoint sequence of these sets, $\{B(x_i, r_i)\}_{i=1}^{\infty}$ such that $\{B(x_i, 5r_i)\}_{i=1}^{\infty} = \bigcup_{i=1}^{\infty} B_i$ covers $T_k$ Then letting $\bar{m_n}$ denote the outer measure determined by $m_n$,

$$\bar{m_n}(h(T_k)) \leq \bar{m_n}\left(h\left(\bigcup_{i=1}^{\infty} B_i\right)\right)$$

$$\leq \sum_{i=1}^{\infty} \bar{m_n}\left(h\left(B_i\right)\right) \leq \sum_{i=1}^{\infty} m_n(B(h(x_i), 2kr_{x_i}))$$

$$= \sum_{i=1}^{\infty} m_n(B(x_i, 2kr_{x_i})) = (2k)^n \sum_{i=1}^{\infty} m_n(B(x_i, r_{x_i}))$$

$$\leq (2k)^n m_n(V) \leq (2k)^n \varepsilon$$

Since $\varepsilon > 0$ is arbitrary, this shows $m_n(h(T_k)) = 0$. Now

$$m_n(h(T)) = \lim_{k \to \infty} m_n(h(T_k)) = 0.$$  

This proves the lemma.
Lemma 11.5.2 Let \( h \) satisfy \( \text{(11.5.1)} \). If \( S \) is a Lebesgue measurable subset of \( U \), then \( h(S) \) is Lebesgue measurable.

Proof: Let \( S_k = S \cap B(0,k), \) \( k \in \mathbb{N} \). By inner regularity of Lebesgue measure, there exists a set, \( F \), which is the countable union of compact sets and a set \( T \) with \( m_n(T) = 0 \) such that

\[
F \cup T = S_k.
\]

Then \( h(F) \subseteq h(S_k) \subseteq h(F) \cup h(T) \). By continuity of \( h \), \( h(F) \) is a countable union of compact sets and so it is Borel. By Lemma \( \text{(11.5.1)} \), \( m_n(h(T)) = 0 \) and so \( h(S_k) \) is Lebesgue measurable because of completeness of Lebesgue measure. Now \( h(S) = \bigcup_{k=1}^{\infty} h(S_k) \) and so it is also true that \( h(S) \) is Lebesgue measurable. This proves the lemma.

In particular, this proves the following corollary.

Corollary 11.5.3 Suppose \( A \) is an \( n \times n \) matrix. Then if \( S \) is a Lebesgue measurable set, it follows \( AS \) is also a Lebesgue measurable set.

Lemma 11.5.4 Let \( R \) be unitary \( (R^*R = RR^* = I) \) and let \( V \) be a an open or closed set. Then \( m_n(RV) = m_n(V) \).

Proof: First assume \( V \) is a bounded open set. By Corollary \( \text{(11.5.1)} \) there is a disjoint sequence of closed balls, \( \{B_i\} \) such that \( V = \bigcup_{i=1}^{\infty} B_i \cup N \) where \( m_n(N) = 0 \). Denote by \( x_i \) the center of \( B_i \) and let \( r_i \) be the radius of \( B_i \). Then by Lemma \( \text{(11.5.1)} \)

\[
m_n(RV) = \sum_{i=1}^{\infty} m_n(RB_i) = \sum_{i=1}^{\infty} m_n(RB(0,r_i)).
\]

Now by invariance of translation of Lebesgue measure, this equals \( \sum_{i=1}^{\infty} m_n(RB(0,r_i) - Rx_i) = \sum_{i=1}^{\infty} m_n(RB(0,0)) \). Since \( R \) is unitary, it preserves all distances and so \( RB(0,0) = B(0,0) \) and therefore,

\[
m_n(RV) = \sum_{i=1}^{\infty} m_n(B(0,r_i)) = \sum_{i=1}^{\infty} m_n(B_i) = m_n(V).
\]

This proves the lemma in the case that \( V \) is bounded. Suppose now that \( V \) is just an open set. Let \( V_k = V \cap B(0,k) \). Then \( m_n(RV_k) = m_n(V_k) \). Letting \( k \to \infty \), this yields the desired conclusion. This proves the lemma in the case that \( V \) is open.

Suppose now that \( H \) is a closed and bounded set. Let \( B(0,R) \supseteq H \). Then letting \( B = B(0,R) \) for short,

\[
m_n(RH) = m_n(RB) - m_n(R(B \setminus H)) = m_n(B) - m_n(B \setminus H) = m_n(H).
\]

In general, let \( H_m = H \cap \overline{B(0,m)} \). Then from what was just shown, \( m_n(RH_m) = m_n(H_m) \). Now let \( m \to \infty \) to get the conclusion of the lemma in general. This proves the lemma.

Lemma 11.5.5 Let \( E \) be Lebesgue measurable set in \( \mathbb{R}^n \) and let \( R \) be unitary. Then \( m_n(RE) = m_n(E) \).
**Proof:** First suppose $E$ is bounded. Then there exist sets, $G$ and $H$ such that $H \subseteq E \subseteq G$ and $H$ is the countable union of closed sets while $G$ is the countable intersection of open sets such that $m_n(G \setminus H) = 0$. By Lemma 11.5.4 applied to these sets whose union or intersection equals $H$ or $G$ respectively, it follows

$$m_n(RG) = m_n(G) = m_n(H) = m_n(RH).$$

Therefore,

$$m_n(H) = m_n(RH) \leq m_n(RE) \leq m_n(RG) = m_n(G) = m_n(E) = m_n(H).$$

In the general case, let $E_m = E \cap B(0,m)$ and apply what was just shown and let $m \to \infty$.

**Lemma 11.5.6** Let $V$ be an open or closed set in $\mathbb{R}^n$ and let $A$ be an $n \times n$ matrix. Then $m_n(AV) = |\det(A)| m_n(V)$.

**Proof:** Let $RU$ be the right polar decomposition (Theorem 11.5.6 on Page 324) of $A$ and let $V$ be an open set. Then from Lemma 11.5.4,

$$m_n(AV) = m_n(RUV) = m_n(UV).$$

Now $U = Q^*DQ$ where $D$ is a diagonal matrix such that $|\det(D)| = |\det(A)|$ and $Q$ is unitary. Therefore,

$$m_n(AV) = m_n(Q^*DQV) = m_n(DQV).$$

Now $QV$ is an open set and so by Corollary 11.1.6 on Page 324 and Lemma 11.5.4,

$$m_n(AV) = |\det(D)| m_n(QV) = |\det(D)| m_n(V) = |\det(A)| m_n(V).$$

This proves the lemma in case $V$ is open.

Now let $H$ be a closed set which is also bounded. First suppose $\det(A) = 0$. Then letting $V$ be an open set containing $H$,

$$m_n(AH) \leq m_n(AV) = |\det(A)| m_n(V) = 0$$

which shows the desired equation is obvious in the case where $\det(A) = 0$. Therefore, assume $A$ is one to one. Since $H$ is bounded, $H \subseteq B(0,R)$ for some $R > 0$. Then letting $B = B(0,R)$ for short,

$$m_n(AH) = m_n(AB) - m_n(A(B \setminus H)) = |\det(A)| m_n(B) - |\det(A)| m_n(B \setminus H) = |\det(A)| m_n(H).$$

If $H$ is not bounded, apply the result just obtained to $H_m = H \cap \overline{B}(0,m)$ and then let $m \to \infty$.

With this preparation, the main result is the following theorem.
Theorem 11.5.7 Let $E$ be Lebesgue measurable set in $\mathbb{R}^n$ and let $A$ be an $n \times n$ matrix. Then $m_n(AE) = |\det (A)| m_n(E)$.

Proof: First suppose $E$ is bounded. Then there exist sets, $G$ and $H$ such that $H \subseteq E \subseteq G$ and $H$ is the countable union of closed sets while $G$ is the countable intersection of open sets such that $m_n(G \setminus H) = 0$. By Lemma 11.5.6 applied to these sets whose union or intersection equals $H$ or $G$ respectively, it follows

$$m_n(AG) = |\det (A)| m_n(G) = |\det (A)| m_n(H) = m_n(AH).$$

Therefore,

$$|\det (A)| m_n(E) = |\det (A)| m_n(H) = m_n(AH) \leq m_n(AE).$$

In the general case, let $E_m = E \cap B(0, m)$ and apply what was just shown and let $m \to \infty$.

11.6 Change Of Variables For $C^1$ Functions

In this section theorems are proved which generalize the above to $C^1$ functions. More general versions can be seen in Kuttler [75], Kuttler [76], and Rudin [102]. There is also a very different approach to this theorem given in [75]. The more general version in [75] follows [102] and both are based on the Brouwer fixed point theorem and a very clever lemma presented in Rudin [102]. The proof will be based on a sequence of easy lemmas.

Lemma 11.6.1 Let $U$ and $V$ be bounded open sets in $\mathbb{R}^n$ and let $h, h^{-1}$ be $C^1$ functions such that $h(U) = V$. Also let $f \in C_c(V)$. Then

$$\int_V f(y) \, dm_n = \int_U f(h(x)) |\det (Dh(x))| \, dm_n$$

Proof: First note $h^{-1}(\text{spt}(f))$ is a closed subset of the bounded set, $U$ and so it is compact. Thus $x \to f(h(x)) |\det (Dh(x))|$ is bounded and continuous.

Let $x \in U$. By the assumption that $h$ and $h^{-1}$ are $C^1$,

$$h(x+v) - h(x) = Dh(x)v + o(v)$$

$$= Dh(x)(v + Dh^{-1}(h(x)) o(v))$$

$$= Dh(x)(v + o(v))$$

and so if $r > 0$ is small enough then $B(x, r)$ is contained in $U$ and

$$h(B(x, r)) - h(x) =$$

$$h(x + B(0, r)) - h(x) \subseteq Dh(x)(B(0, (1 + \varepsilon) r)).$$

(11.6.12)
Making \( r \) still smaller if necessary, one can also obtain

\[
|f(y) - f(h(x))| < \varepsilon
\]  

(11.6.13)

for any \( y \in h(B(x,r)) \) and also

\[
|f(h(x_1))| |det(Dh(x_1))| - f(h(x))|det(Dh(x))| < \varepsilon
\]  

(11.6.14)

whenever \( x_1 \in B(x,r) \). The collection of such balls is a Vitali cover of \( U \). By Corollary 11.6.4 there is a sequence of disjoint closed balls \( \{B_i\} \) such that \( U = \bigcup_{i=1}^{\infty} B_i \cup N \) where \( m_n(N) = 0 \). Denote by \( x_i \) the center of \( B_i \) and \( r_i \) the radius. Then by Lemma 11.6.3, the monotone convergence theorem, and 11.6.14,

\[
\int_V f(y) \, dm_n = \sum_{i=1}^{\infty} \int_{h(B_i)} f(y) \, dm_n
\]

\[
\leq \varepsilon m_n(V) + \sum_{i=1}^{\infty} \int_{h(B_i)} f(h(x_i)) \, dm_n
\]

\[
\leq \varepsilon m_n(V) + \sum_{i=1}^{\infty} f(h(x_i)) m_n(h(B_i))
\]

\[
\leq \varepsilon m_n(V) + \sum_{i=1}^{\infty} f(h(x_i)) m_n(Dh(x_i)(B(0, (1 + \varepsilon) r_i)))
\]

\[
= \varepsilon m_n(V) + (1 + \varepsilon)^n \sum_{i=1}^{\infty} \int_{B_i} f(h(x_i)) |det(Dh(x_i))| \, dm_n
\]

\[
\leq \varepsilon m_n(V) + (1 + \varepsilon)^n \sum_{i=1}^{\infty} \int_{B_i} f(h(x_i)) |det(Dh(x_i))| \, dm_n + \varepsilon m_n(B_i)
\]

\[
\leq \varepsilon m_n(V) + (1 + \varepsilon)^n \sum_{i=1}^{\infty} \int_{B_i} f(h(x)) |det(Dh(x))| \, dm_n + (1 + \varepsilon)^n \varepsilon m_n(U)
\]

\[
= \varepsilon m_n(V) + (1 + \varepsilon)^n \int_V f(h(x)) |det(Dh(x))| \, dm_n + (1 + \varepsilon)^n \varepsilon m_n(U)
\]

Since \( \varepsilon > 0 \) is arbitrary, this shows

\[
\int_V f(y) \, dm_n \leq \int_U f(h(x)) |det(Dh(x))| \, dm_n
\]  

(11.6.15)

whenever \( f \in C_c(V) \). Now \( x \to f(h(x)) |det(Dh(x))| \) is in \( C_c(U) \) and so using the same argument with \( U \) and \( V \) switching roles and replacing \( h \) with \( h^{-1} \),

\[
\int_U f(h(x)) |det(Dh(x))| \, dm_n
\]

\[
\leq \int_V f(h(h^{-1}(y))) |det(Dh(h^{-1}(y)))| |det(Dh^{-1}(y))| \, dm_n
\]

\[
= \int_V f(y) \, dm_n
\]

by the chain rule. This with 11.6.14 proves the lemma.

The next task is to relax the assumption that \( f \) is continuous.

**Corollary 11.6.2** Let \( U \) and \( V \) be bounded open sets in \( \mathbb{R}^n \) and let \( h, h^{-1} \) be \( C^1 \) functions such that \( h(U) = V \) and \( |det(Dh(x))| \) is bounded. Also let \( E \subseteq V \) be measurable. Then

\[
\int_V \chi_E(y) \, dm_n = \int_U \chi_E(h(x)) |det(Dh(x))| \, dm_n.
\]
Proof: By regularity, there exist compact sets, $K_k$ and open sets $G_k$ such that

$$K_k \subseteq E \subseteq G_k$$

and $m_n (G_k \setminus K_k) < 2^{-k}$. By Theorem 10.2.7, there exist $f_k$ such that $K_k \prec f_k \prec G_k$. Then $f_k (y) \to \chi_E (y)$ a.e. because if $y$ is such that convergence fails, it must be the case that $y$ is in $G_k \setminus K_k$ for infinitely many $k$ and $\sum_k m_n (G_k \setminus K_k) < \infty$.

This set equals

$$N = \cap_{m=1}^{\infty} \cup_{k=m}^{\infty} G_k \setminus K_k$$

and so for each $m \in \mathbb{N}$

$$m_n (N) \leq m_n (\cup_{k=m}^{\infty} G_k \setminus K_k) \leq \sum_{k=m}^{\infty} m_n (G_k \setminus K_k) < \sum_{k=m}^{\infty} 2^{-k} = 2^{-(m-1)}$$

showing $m_n (N) = 0$.

Then $f_k (h(x))$ must converge to $\chi_E (h(x))$ for all $x \notin h^{-1} (N)$, a set of measure zero by Lemma 11.5.1. Thus

$$\int_V f_k (y) \, dm_n = \int_U f_k (h(x)) \, |det (Dh(x))| \, dm_n.$$

By the dominated convergence theorem using a dominating function, $\chi_V$ in the integral on the left and $\chi_U |det (Dh)|$ on the right, it follows

$$\int_V \chi_E (y) \, dm_n = \int_U \chi_E (h(x)) \, |det (Dh(x))| \, dm_n.$$

This proves the corollary.

You don’t need to assume the open sets are bounded.

Corollary 11.6.3 Let $U$ and $V$ be open sets in $\mathbb{R}^n$ and let $h, h^{-1}$ be $C^1$ functions such that $h(U) = V$. Also let $E \subseteq V$ be measurable. Then

$$\int_V \chi_E (y) \, dm_n = \int_U \chi_E (h(x)) \, |det (Dh(x))| \, dm_n.$$

Proof: For each $x \in U$, there exists $r_x$ such that $B(x, r_x) \subseteq U$ and $r_x < 1$. Then by the mean value inequality Theorem 11.6.3, it follows $h (B(x, r_x))$ is also bounded. This is a Vitali cover of $U$ and so by Corollary 11.6.4 there is a sequence of these balls, $\{B_i\}$ such that they are disjoint, $h (B_i)$ is also bounded and

$$m_n (U \setminus \cup_i B_i) = 0.$$
It follows from Lemma 11.5.1 that $h(U \setminus \bigcup B_i)$ also has measure zero. Then from Corollary 11.6.2

$$
\int_V \chi_E(y) \, dm_n = \sum_i \int_{h(B_i)} \chi_{E \cap h(B_i)}(y) \, dm_n \\
= \sum_i \int_{B_i} \chi_E(h(x)) |\det (Dh(x))| \, dm_n \\
= \int_U \chi_E(h(x)) |\det (Dh(x))| \, dm_n.
$$

This proves the corollary.

With this corollary, the main theorem follows.

**Theorem 11.6.4** Let $U$ and $V$ be open sets in $\mathbb{R}^n$ and let $h, h^{-1}$ be $C^1$ functions such that $h(U) = V$. Then if $g$ is a nonnegative Lebesgue measurable function,

$$
\int_V g(y) \, dy = \int_U g(h(x)) |\det (Dh(x))| \, dx.
$$

**Proof:** From Corollary 11.6.3 holds for any nonnegative simple function in place of $g$. In general, let $\{s_k\}$ be an increasing sequence of simple functions which converges to $g$ pointwise. Then from the monotone convergence theorem

$$
\int_V g(y) \, dy = \lim_{k \to \infty} \int_V s_k(y) \, dy = \lim_{k \to \infty} \int_U s_k(h(x)) |\det (Dh(x))| \, dx \\
= \int_U g(h(x)) |\det (Dh(x))| \, dx.
$$

This proves the theorem.

This is a pretty good theorem but it isn’t too hard to generalize it. In particular, it is not necessary to assume $h^{-1}$ is $C^1$.

**Lemma 11.6.5** (Sard) Let $U$ be an open set in $\mathbb{R}^n$ and let $h : U \to \mathbb{R}^n$ be $C^1$. Let

$$
Z \equiv \{x \in U : \det Dh(x) = 0\}.
$$

Then $m_n(h(Z)) = 0$.

**Proof:** Let $Z_k$ denote those points $x$ of $Z$ such that $||Dh(x)|| \leq k$ and such that $|x| < k$. Let $\varepsilon > 0$ be given. For $x \in Z_k$,

$$
h(x + v) = h(x) + Dh(x)v + o(v)
$$

and so whenever $r$ is small enough,

$$
h(x + B(0,r)) = h(B(x,r)) \subseteq h(x) + Dh(x)B(0,r) + B(0,r\varepsilon)$$

CHAPTER 11. LEBESGUE MEASURE

340
11.6. CHANGE OF VARIABLES FOR $C^1$ FUNCTIONS

Note $Dh(x) B(0, r)$ is contained in an $n - 1$ dimensional subspace of $\mathbb{R}^n$ due to the fact $Dh(x)$ has rank less than $n$. Now let $Q$ denote an orthogonal transformation preserving all distances,

$$QQ^* = Q^*Q = I,$$

such that

$$QDh(x) B(0, r) \subseteq \mathbb{R}^{n-1}.$$

Then

$$Qh(B(x, r)) \subseteq Qh(x) + QDh(x) B(0, r) + B(0, r\varepsilon)$$

and by translation invariance of Lebesgue measure,

$$m_n(Qh(B(x, r))) \leq m_n(QDh(x) B(0, r) + B(0, r\varepsilon))$$

$$\leq (||QDh(x)||)(2r + 2r\varepsilon)^{n-1} 2r\varepsilon = C(1 + \varepsilon)^{n-1} m_n(B(0, r)) \varepsilon$$

These balls give a Vitali cover of $Z_k$ and so there exists a disjoint sequence of them $\{B_i\}$, each contained in $B(0, k)$ which covers $Z_k$ except for a set of measure zero which is mapped by $h$ to a set of measure zero. Therefore using Theorem 11.5.7,

$$m_n(h(Z_k)) = m_n(h(\bigcup_{i=1}^{\infty} B_i)) \leq \sum_{i=1}^{\infty} m_n(h(B_i))$$

$$= \sum_{i=1}^{\infty} m_n(Qh(B_i)) \leq C(1 + \varepsilon)^{n-1} \varepsilon \sum_{i=1}^{\infty} m_n(B_i) \leq C(1 + \varepsilon)^{n-1} \varepsilon m_n(B(0, k))$$

and since $\varepsilon$ is arbitrary, this shows $m_n(h(Z_k)) = 0$. Now

$$m_n(h(Z)) = \lim_{k \to \infty} m_n(h(Z_k)) = 0.$$

This proves the lemma.

With this important lemma, here is a generalization of Theorem 11.6.4.

**Theorem 11.6.6** Let $U$ be an open set and let $h$ be a $1-1, C^1$ function with values in $\mathbb{R}^n$. Then if $g$ is a nonnegative Lebesgue measurable function,

$$\int_{h(U)} g(y) dy = \int_{U} g(h(x)) |\det(Dh(x))| dx. \quad (11.6.17)$$

**Proof:** Let $Z = \{x : \det(Dh(x)) = 0\}$. Then by the inverse function theorem, $h^{-1}$ is $C^1$ on $h(U \setminus Z)$ and $h(U \setminus Z)$ is an open set. Therefore, from Lemma 11.6.5 and Theorem 11.6.4,

$$\int_{h(U)} g(y) dy = \int_{h(U \setminus Z)} g(y) dy = \int_{U \setminus Z} g(h(x)) |\det(Dh(x))| dx$$

$$= \int_{U} g(h(x)) |\det(Dh(x))| dx.$$

This proves the theorem.

Of course the next generalization considers the case when $h$ is not even one to one.
11.7 Mappings Which Are Not One To One

Now suppose \( h \) is only \( C^1 \), not necessarily one to one. For \( U_+ \equiv \{ x \in U : |\det Dh(x)| > 0 \} \) and \( Z \) the set where \( |\det Dh(x)| = 0 \), Lemma 11.6.5 implies \( m_n(h(Z)) = 0 \). For \( x \in U_+ \), the inverse function theorem implies there exists an open set \( B_x \) such that \( x \in B_x \subseteq U_+ \), \( h \) is one to one on \( B_x \).

Let \( \{ B_i \} \) be a countable subset of \( \{ B_x \}_{x \in U_+} \) such that \( U_+ = \bigcup_{i=1}^{\infty} B_i \). Let \( E_1 = B_1 \). If \( E_1, \ldots, E_k \) have been chosen, \( E_{k+1} = B_{k+1} \setminus \bigcup_{i=1}^{k} E_i \). Thus
\[
\bigcup_{i=1}^{\infty} E_i = U_+, \quad h \text{ is one to one on } E_i, \quad E_i \cap E_j = \emptyset,
\]
and each \( E_i \) is a Borel set contained in the open set \( B_i \). Now define
\[
n(y) = \sum_{i=1}^{\infty} \alpha_h(E_i)(y) + \alpha_h(Z)(y).
\]
The set, \( h(E_i), h(Z) \) are measurable by Lemma 11.5.2. Thus \( n(\cdot) \) is measurable.

Lemma 11.7.1 Let \( F \subseteq h(U) \) be measurable. Then
\[
\int_{h(U)} n(y)\mathcal{X}_F(y)dy = \int_U \mathcal{X}_F(h(x))|\det Dh(x)|dx.
\]

Proof: Using Lemma 11.6.1 and the Monotone Convergence Theorem or Fubini’s Theorem,
\[
\int_{h(U)} n(y)\mathcal{X}_F(y)dy = \int_{h(U)} \left( \sum_{i=1}^{\infty} \alpha_h(E_i)(y) + \alpha_h(Z)(y) \right) \mathcal{X}_F(y)dy
\]
\[
= \sum_{i=1}^{\infty} \int_{h(U)} \alpha_h(E_i)(y)\mathcal{X}_F(y)dy
\]
\[
= \sum_{i=1}^{\infty} \int_{h(U) \cap h(E_i)} \mathcal{X}_F(y)dy
\]
\[
= \sum_{i=1}^{\infty} \int_{h(B_i) \cap h(E_i)} \mathcal{X}_F(y)dy
\]
11.8. LEBESGUE MEASURE AND ITERATED INTEGRALS

\[ \sum_{i=1}^{\infty} \int_{B_i} x_{E_i}(y) x_{F}(y) dy = \] 
\[ = \sum_{i=1}^{\infty} \int_{B_i} x_{E_i}(x) x_{F}(x) |det D_h(x)| dx.\]

This proves the lemma.

**Definition 11.7.2** For \( y \in \mathbf{h}(U) \), define a function, \( \# \), according to the formula

\[ \#(y) \equiv \text{number of elements in } \mathbf{h}^{-1}(y). \]

Observe that

\[ \#(y) = n(y) \quad \text{a.e.} \quad (11.7.18) \]

because \( n(y) = \#(y) \) if \( y \notin \mathbf{h}(Z) \), a set of measure 0. Therefore, \( \# \) is a measurable function.

**Theorem 11.7.3** Let \( g \geq 0 \), \( g \) measurable, and let \( \mathbf{h} \) be \( C^1(U) \). Then

\[ \int_{\mathbf{h}(U)} \#(y) g(y) dy = \int_{U} g(\mathbf{h}(x)) |det D_h(x)| dx. \quad (11.7.19) \]

**Proof:** From [11.7.13] and Lemma [11.7.1], [11.7.14] holds for all \( g \), a nonnegative simple function. Approximating an arbitrary measurable nonnegative function, \( g \), with an increasing pointwise convergent sequence of simple functions and using the monotone convergence theorem, yields [11.7.14] for an arbitrary nonnegative measurable function, \( g \). This proves the theorem.

11.8 Lebesgue Measure And Iterated Integrals

The following is the main result.

**Theorem 11.8.1** Let \( f \geq 0 \) and suppose \( f \) is a Lebesgue measurable function defined on \( \mathbb{R}^n \) and \( \int_{\mathbb{R}^n} f dm_n < \infty \). Then

\[ \int_{\mathbb{R}^n} f dm_n = \int_{\mathbb{R}^k} \int_{\mathbb{R}^{n-k}} f dm_{n-k} dm_k. \]
This will be accomplished by Fubini’s theorem, Theorem 10.9.11 and the following lemma.

**Lemma 11.8.2** \( m_k \times m_{n-k} = m_n \) on the \( m_n \) measurable sets.

**Proof:** First of all, let \( R = \prod_{i=1}^n (a_i, b_i) \) be a measurable rectangle and let \( R_k = \prod_{i=1}^k (a_i, b_i), R_{n-k} = \prod_{i=k+1}^n (a_i, b_i) \). Then by Fubini’s theorem,

\[
\int X_R d(m_k \times m_{n-k}) = \int_{R_k} \int_{R_{n-k}} X_R d_m dm_{n-k} = \int \int X_R d m_k \int X_R d m_{n-k} = \int X_R d m_n
\]

and so \( m_k \times m_{n-k} \) and \( m_n \) agree on every half open rectangle. By Lemma 11.1.2 these two measures agree on every open set. Now if \( K \) is a compact set, then \( K = \bigcap_{k=1}^\infty U_k \) where \( U_k \) is the open set, \( K + B (0, \frac{1}{k}) \). Another way of saying this is \( U_k \equiv \{ x : \text{dist} (x,K) < \frac{1}{k} \} \) which is obviously open because \( x \to \text{dist} (x,K) \) is a continuous function. Since \( K \) is the countable intersection of these decreasing open sets, each of which has finite measure with respect to either of the two measures, it follows that \( m_k \times m_{n-k} \) and \( m_n \) agree on all the compact sets. Now let \( E \) be a bounded Lebesgue measurable set. Then there are sets, \( H \) and \( G \) such that \( H \) is a countable union of compact sets, \( G \) a countable intersection of open sets, \( H \subseteq E \subseteq G \), and \( m_n (G \setminus H) = 0 \). Then from what was just shown about compact and open sets, the two measures agree on \( G \) and on \( H \). Therefore,

\[
m_n (H) = m_k \times m_{n-k} (H) \leq m_k \times m_{n-k} (E) \leq m_k \times m_{n-k} (G) = m_n (E) = m_n (H)
\]

By completeness of the measure space for \( m_k \times m_{n-k} \), it follows \( E \) is \( m_k \times m_{n-k} \) measurable and \( m_k \times m_{n-k} (E) = m_n (E) \).

This proves the lemma.

You could also show that the two \( \sigma \) algebras are the same. However, this is not needed for the lemma or the theorem.

**Proof of Theorem 11.8.1** By the lemma and Fubini’s theorem, Theorem 10.9.11,

\[
\int_{\mathbb{R}^n} f dm_n = \int_{\mathbb{R}^n} f d (m_k \times m_{n-k}) = \int_{\mathbb{R}^k} \int_{\mathbb{R}^n-k} f dm_{n-k} dm_k.
\]

**Corollary 11.8.3** Let \( f \) be a nonnegative real valued measurable function. Then

\[
\int_{\mathbb{R}^n} f dm_n = \int_{\mathbb{R}^k} \int_{\mathbb{R}^n-k} f dm_{n-k} dm_k.
\]
11.9. SPHERICAL COORDINATES IN P DIMENSIONS

Proof: Let $S_p \equiv \{x \in \mathbb{R}^n : 0 \leq f(x) \leq p\} \cap B(0, p)$. Then $\int_{\mathbb{R}^n} f \mathcal{X}_{s_p} dm_n < \infty$. Therefore, from Theorem \[11.8.1\],

$$\int_{\mathbb{R}^n} f \mathcal{X}_{s_p} dm_n = \int_{\mathbb{R}^k} \int_{\mathbb{R}^n-k} \mathcal{X}_{s_p} f dm_{n-k} dm_k.$$  

Now let $p \to \infty$ and use the Monotone convergence theorem and the Fubini Theorem \[10.9.11\] on Page \[297\].

Not surprisingly, the following corollary follows from this.

Corollary 11.8.4 Let $f \in L^1(\mathbb{R}^n)$ where the measure is $m_n$. Then

$$\int_{\mathbb{R}^n} f dm_n = \int_{\mathbb{R}^k} \int_{\mathbb{R}^n-k} f dm_{n-k} dm_k.$$  

Proof: Apply Corollary \[11.8.3\] to the positive and negative parts of the real and imaginary parts of $f$.

11.9 Spherical Coordinates In $p$ Dimensions

Sometimes there is a need to deal with spherical coordinates in more than three dimensions. In this section, this concept is defined and formulas are derived for these coordinate systems. Recall polar coordinates are of the form

$$y_1 = \rho \cos \theta$$  

$$y_2 = \rho \sin \theta$$  

where $\rho > 0$ and $\theta \in \mathbb{R}$. Thus these transformation equations are not one to one but they are one to one on $(0, \infty) \times [0, 2\pi)$. Here I am writing $\rho$ in place of $r$ to emphasize a pattern which is about to emerge. I will consider polar coordinates as spherical coordinates in two dimensions. I will also simply refer to such coordinate systems as polar coordinates regardless of the dimension. This is also the reason I am writing $y_1$ and $y_2$ instead of the more usual $x$ and $y$. Now consider what happens when you go to three dimensions. The situation is depicted in the following picture.

From this picture, you see that $y_3 = \rho \cos \phi_1$. Also the distance between $(y_1, y_2)$ and $(0, 0)$ is $\rho \sin (\phi_1)$. Therefore, using polar coordinates to write $(y_1, y_2)$ in terms of $\theta$ and this distance,

$$y_1 = \rho \sin \phi_1 \cos \theta,$$  

$$y_2 = \rho \sin \phi_1 \sin \theta,$$  

$$y_3 = \rho \cos \phi_1.$$
where \( \phi_1 \in \mathbb{R} \) and the transformations are one to one if \( \phi_1 \) is restricted to be in \([0, \pi]\). What was done is to replace \( \rho \) with \( \rho \sin \phi_1 \) and then to add in \( y_3 = \rho \cos \phi_1 \). Having done this, there is no reason to stop with three dimensions. Consider the following picture:

\[
\begin{array}{c}
\mathbb{R}^3 \\
\phi_2 \\
\rho \\
(y_1, y_2, y_3, y_4)
\end{array}
\]

From this picture, you see that \( y_4 = \rho \cos \phi_2 \). Also the distance between \((y_1, y_2, y_3)\) and \((0, 0, 0)\) is \( \rho \sin (\phi_2) \). Therefore, using polar coordinates to write \((y_1, y_2, y_3)\) in terms of \( \theta, \phi_1 \), and this distance,

\[
y_1 = \rho \sin \phi_2 \sin \phi_1 \cos \theta, \\
y_2 = \rho \sin \phi_2 \sin \phi_1 \sin \theta, \\
y_3 = \rho \sin \phi_2 \cos \phi_1, \\
y_4 = \rho \cos \phi_2
\]

where \( \phi_2 \in \mathbb{R} \) and the transformations will be one to one if

\[
\phi_2, \phi_1 \in (0, \pi), \theta \in (0, 2\pi), \rho \in (0, \infty).
\]

Continuing this way, given spherical coordinates in \( \mathbb{R}^p \), to get the spherical coordinates in \( \mathbb{R}^{p+1} \), you let \( y_{p+1} = \rho \cos \phi_{p-1} \) and then replace every occurrence of \( \rho \) with \( \rho \sin \phi_{p-1} \) to obtain \( y_1 \cdots y_p \) in terms of \( \phi_1, \phi_2, \ldots, \phi_{p-1}, \theta \), and \( \rho \).

It is always the case that \( \rho \) measures the distance from the point in \( \mathbb{R}^p \) to the origin in \( \mathbb{R}^p \), \( \mathbf{0} \). Each \( \phi_i \in \mathbb{R} \) and the transformations will be one to one if each \( \phi_i \in (0, \pi) \), and \( \theta \in (0, 2\pi) \). Denote by \( h_p \left( \rho, \phi_1, \theta \right) \) the above transformation.

It can be shown using math induction and geometric reasoning that these coordinates map \( \prod_{i=1}^{p-1} (0, \pi) \times (0, 2\pi) \times (0, \infty) \) one to one onto an open subset of \( \mathbb{R}^p \) which is everything except for the set of measure zero \( \Psi_p (N) \) where \( N \) results from having some \( \phi_i \) equal to 0 or \( \pi \) or for \( \rho = 0 \) or for \( \theta \) equal to either \( 2\pi \) or 0. Each of these are sets of Lebesgue measure zero and so their union is also a set of measure zero. You can see that \( h_p \left( \prod_{i=1}^{p-2} (0, \pi) \times (0, 2\pi) \times (0, \infty) \right) \) omits the union of the coordinate axes except for maybe one of them. This is not important to the integral because it is just a set of measure zero.

**Theorem 11.9.1** Let \( y = h_p \left( \phi, \theta, \rho \right) \) be the spherical coordinate transformations in \( \mathbb{R}^p \). Then letting \( A = \prod_{i=1}^{p-2} (0, \pi) \times (0, 2\pi) \), it follows \( h \) maps \( A \times (0, \infty) \) one to one onto all of \( \mathbb{R}^p \) except a set of measure zero given by \( h_p (N) \) where \( N \) is the set of measure zero

\[
(\bar{A} \times [0, \infty)) \setminus (A \times (0, \infty))
\]
Also \(|\det D h_p (\vec{\phi}, \theta, \rho)|\) will always be of the form
\[
|\det D h_p (\vec{\phi}, \theta, \rho)| = \rho^{p-1} \Phi (\vec{\phi}, \theta),
\]
(11.9.20)
where \(\Phi\) is a continuous function of \(\vec{\phi}\) and \(\theta\). Then if \(f\) is nonnegative and Lebesgue measurable,
\[
\int_{\mathbb{R}^p} f (y) \, dm_p = \int_{h_p (A)} f (y) \, dm_p = \int_A f \left( h_p (\vec{\phi}, \theta, \rho) \right) \rho^{p-1} \Phi (\vec{\phi}, \theta) \, dm_p
\]
(11.9.21)
Furthermore whenever \(f\) is Borel measurable and nonnegative, one can apply Fubini’s theorem and write
\[
\int_{\mathbb{R}^p} f (y) \, dy = \int_0^\infty \int_A f \left( h_p (\vec{\phi}, \theta, \rho) \right) \Phi (\vec{\phi}, \theta) \, d\vec{\phi} d\theta d\rho
\]
(11.9.22)
where here \(d\vec{\phi} d\theta\) denotes \(dm_{p-1}\) on \(A\). The same formulas hold if \(f \in L^1 (\mathbb{R}^p)\).

\textbf{Proof:} Formula (11.9.20) is obvious from the definition of the spherical coordinates because in the matrix of the derivative, there will be a \(1\) in \(p - 1\) columns. The first claim is also clear from the definition and math induction or from the geometry of the above description. It remains to verify (11.9.21) and (11.9.22). It is clear \(h_p\) maps \(A \times (0, \infty)\) onto \(\mathbb{R}^p\). Since \(h_p\) is differentiable, it maps sets of measure zero to sets of measure zero. Then
\[
\mathbb{R}^p = h_p (N \cup A \times (0, \infty)) = h_p (N) \cup h_p (A \times (0, \infty)),
\]
the union of a set of measure zero with \(h_p (A \times (0, \infty))\). Therefore, from the change of variables formula,
\[
\int_{\mathbb{R}^p} f (y) \, dm_p = \int_{h_p (A \times (0, \infty))} f (y) \, dm_p = \int_{A \times (0, \infty)} f \left( h_p (\vec{\phi}, \theta, \rho) \right) \rho^{p-1} \Phi (\vec{\phi}, \theta) \, dm_p
\]
which proves (11.9.21). This formula continues to hold if \(f\) is in \(L^1 (\mathbb{R}^p)\). Finally, if \(f \geq 0\) or in \(L^1 (\mathbb{R}^n)\) and is Borel measurable, then it is \(\mathcal{F}_p\) measurable as well. Recall that \(\mathcal{F}_p\) includes the smallest \(\sigma\) algebra which contains products of open intervals. Hence \(\mathcal{F}_p\) includes the Borel sets \(\mathcal{B} (\mathbb{R}^p)\). Thus from the definition of \(m_p\)
\[
\int_{A \times (0, \infty)} f \left( h_p (\vec{\phi}, \theta, \rho) \right) \rho^{p-1} \Phi (\vec{\phi}, \theta) \, dm_p
\]
\[
= \int_{(0, \infty)} \int_A f \left( h_p (\vec{\phi}, \theta, \rho) \right) \rho^{p-1} \Phi (\vec{\phi}, \theta) \, dm_{p-1} \, dm
\]
\[
= \int_{(0, \infty)} \rho^{p-1} \int_A f \left( h_p (\vec{\phi}, \theta, \rho) \right) \Phi (\vec{\phi}, \theta) \, dm_{p-1} \, dm
\]
\(^1\)Actually it is only a function of the first but this is not important in what follows.
Now the claim about \( f \in L^1 \) follows routinely from considering the positive and negative parts of the real and imaginary parts of \( f \) in the usual way.  

Note that the above equals  
\[
\int_{A \times [0, \infty)} f \left( h_p (\vec{\phi}, \theta, \rho) \right) \rho^{p-1} \Phi (\vec{\phi}, \theta) \, dm_p \n\]
and the iterated integral is also equal to  
\[
\int_{[0, \infty)} \rho^{p-1} \int_{A} f \left( h_p (\vec{\phi}, \theta, \rho) \right) \Phi (\vec{\phi}, \theta) \, dm_{p-1} \, dm
\]
because the difference is just a set of measure zero.

**Notation 11.9.2** Often this is written differently. Note that from the spherical coordinate formulas,  
\[ f \left( h (\vec{\phi}, \theta, \rho) \right) = f (\rho w) \quad \text{where} \quad |w| = 1. \]
Letting \( S^{p-1} \) denote the unit sphere, \( \{ \omega \in \mathbb{R}^p : |\omega| = 1 \} \), the inside integral in the above formula is sometimes written as  
\[ \int_{S^{p-1}} f (\rho w) \, d\sigma \]
where \( \sigma \) is a measure on \( S^{p-1} \). See [75] for another description of this measure. It isn’t an important issue here. Either \( \int_{A} \Phi (\vec{\phi}, \theta) \, dm_{p-1} \) or the formula  
\[ \int_0^\infty \rho^{p-1} \left( \int_{S^{p-1}} f (\rho w) \, d\sigma \right) \, d\rho \]
will be referred to as polar coordinates and is very useful in establishing estimates. Here \( \sigma (S^{p-1}) = \int_A \Phi (\vec{\phi}, \theta) \, dm_{p-1}. \)

**Example 11.9.3** For what values of \( s \) is the integral  
\[ \int_{B(0,R)} \left( 1 + |x|^2 \right)^s \, dy \]
bounded independent of \( R \)? Here \( B(0,R) \) is the ball, \( \{ x \in \mathbb{R}^p : |x| \leq R \} \).

I think you can see immediately that \( s \) must be negative but exactly how negative? It turns out it depends on \( p \) and using polar coordinates, you can find just exactly what is needed. From the polar coordinates formula above,  
\[
\int_{B(0,R)} \left( 1 + |x|^2 \right)^s \, dy \quad = \quad \int_0^R \int_{S^{p-1}} (1 + \rho^2)^s \rho^{p-1} \, d\sigma \, d\rho \\
= \quad C_p \int_0^R (1 + \rho^2)^s \rho^{p-1} \, d\rho
\]
Now the very hard problem has been reduced to considering an easy one variable problem of finding when  
\[
\int_0^R \rho^{p-1} (1 + \rho^2)^s \, d\rho
\]
is bounded independent of \( R \). You need \( 2s + (p-1) < -1 \) so you need \( s < -p/2. \)
11.10 The Brouwer Fixed Point Theorem

This seems to be a good place to present a short proof of one of the most important of all fixed point theorems. There are many approaches to this but one of the easiest and shortest I have ever seen is the one in Dunford and Schwartz [42]. This is what is presented here. In Evans [45] there is a different proof which depends on integration theory. A good reference for an introduction to various kinds of fixed point theorems is the book by Smart [107]. This book also gives an entirely different approach to the Brouwer fixed point theorem.

The proof given here is based on the following lemma. Recall that the mixed partial derivatives of a $C^2$ function are equal. In the following lemma, and elsewhere, a comma followed by an index indicates the partial derivative with respect to the indicated variable. Thus, $f_{i,j}$ will mean $\frac{\partial f}{\partial x_j}$. Also, write $Dg$ for the Jacobian matrix which is the matrix of $Dg$ taken with respect to the usual basis vectors in $\mathbb{R}^n$. Recall that for $A$ an $n \times n$ matrix, $\text{cof}(A)_{ij}$ is the determinant of the matrix which results from deleting the $i^{th}$ row and the $j^{th}$ column and multiplying by $(-1)^{i+j}$. The following lemma is proved earlier. See Lemma 14.3.1.

**Lemma 11.10.1** Let $g : U \to \mathbb{R}^n$ be $C^2$ where $U$ is an open subset of $\mathbb{R}^n$. Then

$$\sum_{j=1}^{n} \text{cof}(Dg)_{i,j} = 0,$$

where here $(Dg)_{i,j} \equiv g_{i,j} \equiv \frac{\partial g_i}{\partial x_j}$. Also, $\text{cof}(Dg)_{i,j} = \frac{\partial \det(Dg)}{\partial g_{i,j}}$.

To prove the Brouwer fixed point theorem, first consider a version of it valid for $C^2$ mappings. This is the following lemma.

**Lemma 11.10.2** Let $B_r = B(0,r)$ and suppose $g$ is a $C^2$ function defined on $\mathbb{R}^n$ which maps $B_r$ to $B_r$. Then $g(x) = x$ for some $x \in B_r$.

**Proof:** Suppose not. Then $|g(x) - x|$ must be bounded away from zero on $B_r$. Let $a(x)$ be the larger of the two roots of the equation,

$$|x + a(x)(x - g(x))|^2 = r^2. \quad (11.10.23)$$

Thus

$$a(x) = \frac{- (x, (x - g(x)) + \sqrt{(x, (x - g(x)))^2 + (r^2 - |x|^2) |x - g(x)|^2}}{|x - g(x)|^2} \quad (11.10.24)$$

The expression under the square root sign is always nonnegative and it follows from the formula that $a(x) \geq 0$. Therefore, $(x, (x - g(x))) \geq 0$ for all $x \in B_r$. The reason for this is that $a(x)$ is the larger zero of a polynomial of the form $p(z) = |x|^2 + z^2 |x - g(x)|^2 - 2z(x, x - g(x))$ and from the formula above, it is
nonnegative. \(-2(x, x - g(x))\) is the slope of the tangent line to \(p(z)\) at \(z = 0\). If \(x \neq 0\), then \(|x|^2 > 0\) and so this slope needs to be negative for the larger of the two zeros to be positive. If \(x = 0\), then \((x, x - g(x)) = 0\).

Now define for \(t \in [0, 1]\),

\[
f(t, x) = x + ta(x)(x - g(x)).
\]

The important properties of \(f(t, x)\) and \(a(x)\) are that

\[
a(x) = 0 \text{ if } |x| = r \tag{11.10.25}
\]

and

\[
|f(t, x)| = r \text{ for all } |x| = r \tag{11.10.26}
\]

These properties follow immediately from (11.10.24) and the above observation that for \(x \in B_r\), it follows \((x, (x - g(x))) \geq 0\).

Also from (11.10.24), \(a\) is a \(C^2\) function near \(B_r\). This is obvious from (11.10.24) as long as \(|x| < r\). However, even if \(|x| = r\) it is still true. To show this, it suffices to verify the expression under the square root sign is positive. If this expression were not positive for some \(|x| = r\), then \((x, (x - g(x))) = 0\). Then also, since \(g(x) \neq x\),

\[
\frac{|g(x) + x|}{2} < r
\]

and so

\[
r^2 > \left(x, \frac{g(x) + x}{2}\right) = \frac{1}{2}(x, g(x)) + \frac{r^2}{2} = \frac{|x|^2}{2} + \frac{r^2}{2} = r^2,
\]

a contradiction. Therefore, the expression under the square root in (11.10.24) is always positive near \(B_r\) and so \(a\) is a \(C^2\) function near \(B_r\) as claimed because the square root function is \(C^2\) away from zero.

Now define

\[
I(t) = \int_{B_r} \det(D^2 f(t, x)) \, dx.
\]

Then

\[
I(0) = \int_{B_r} dx = m_n(B_r) > 0. \tag{11.10.27}
\]

Using the dominated convergence theorem one can differentiate \(I(t)\) as follows.

\[
I'(t) = \int_{B_r} \sum_{ij} \frac{\partial \det(D^2 f(t, x))}{\partial f_{ij}} \frac{\partial f_{ij}}{\partial t} \, dx
\]

\[
= \int_{B_r} \sum_{ij} \text{cof}(D^2 f)_{ij} \frac{\partial (a(x)(x_i - g_i(x)))}{\partial x_j} \, dx.
\]
11.10. THE BROUWER FIXED POINT THEOREM

Now from \( a(x) = 0 \) when \( |x| = r \) and so integration by parts and Lemma 11.10.25 yields

\[
I'(t) = \int_{B_{r}} \sum_{ij} \text{cof} \left( D_{2}f \right)_{ij} \frac{\partial (a(x) (x_i - g_i(x)))}{\partial x_j} \, dx
\]

\[
= - \int_{B_{r}} \sum_{ij} \text{cof} \left( D_{2}f \right)_{ij,j} a(x) (x_i - g_i(x)) \, dx = 0.
\]

Therefore, \( I(1) = I(0) \). However, from 11.10.23 it follows that for \( t = 1 \),

\[
\sum_{i} f_i f_i = r^2
\]

and so, \( \sum_{i} f_i g_i f_i = 0 \) which implies since \( |f(1,x)| = r \) by 11.10.23 that \( \det(f_{i,j}) = \det(D_{2}F(1,x)) = 0 \) and so \( I(1) = 0 \), a contradiction to 11.10.27 since \( I(1) = I(0) \).

The following theorem is the Brouwer fixed point theorem for a ball.

**Theorem 11.10.3** Let \( B_r \) be the above closed ball and let \( f : B_r \rightarrow B_r \) be continuous. Then there exists \( x \in B_r \) such that \( f(x) = x \).

**Proof:** Let \( f_k(x) \equiv \frac{f(x)}{1+k} \). Thus \( ||f_k - f|| < \frac{r}{1+k} \) where

\[
||h|| \equiv \max \{ |h(x)| : x \in B_r \}.
\]

Using the Weierstrass approximation theorem, there exists a polynomial \( g_k \) such that \( ||g_k - f_k|| < \frac{r}{1+k} \). Then if \( x \in B_r \), it follows

\[
|g_k(x)| \leq |g_k(x) - f_k(x)| + |f_k(x)| < \frac{r}{1+k} + \frac{kr}{1+k} = r
\]

and so \( g_k \) maps \( B_r \) to \( B_r \). By Lemma 11.10.2 each of these \( g_k \) has a fixed point, \( x_k \) such that \( g_k(x_k) = x_k \). The sequence of points, \( \{x_k\} \) is contained in the compact set, \( B_r \) and so there exists a convergent subsequence still denoted by \( \{x_k\} \) which converges to a point, \( x \in B_r \). Then

\[
|f(x) - x| \leq |f(x) - f_k(x)| + |f_k(x) - x_k| + |f_k(x_k) - g_k(x_k)| + |x_k - x| \leq \frac{r}{1+k} + |f(x) - f(x_k)| + \frac{r}{1+k} + |x_k - x|.
\]

Now let \( k \rightarrow \infty \) in the right side to conclude \( f(x) = x \). 

It is not surprising that the ball does not need to be centered at \( 0 \).

**Corollary 11.10.4** Let \( f : \overline{B(a,r)} \rightarrow \overline{B(a,r)} \) be continuous. Then there exists \( x \in \overline{B(a,r)} \) such that \( f(x) = x \).
CHAPTER 11. LEBESGUE MEASURE

Proof: Let \( g : B_r \to B_r \) be defined by \( g(y) = f(y + a) - a \). Then \( g \) is a continuous map from \( B_r \) to \( B_r \). Therefore, there exists \( y \in B_r \) such that \( g(y) = y \). Therefore, \( f(y + a) - a = y \) and so letting \( x = y + a \), \( f \) also has a fixed point as claimed.

11.11 The Brouwer Fixed Point Theorem Another Proof

This proof is also based on Lemma 11.3. I found this proof of the Brouwer fixed point theorem or one close to it in Evans [45]. It is even shorter than the proof just presented. I think it might be easier to remember also. It is also based on Lemma 11.3 which is stated next for convenience.

Lemma 11.11.1 Let \( g : U \to \mathbb{R}^n \) be \( C^2 \) where \( U \) is an open subset of \( \mathbb{R}^n \). Then

\[
\sum_{j=1}^n \text{cof} (Dg)_{ij,j} = 0,
\]

where here \( (Dg)_{ij} \equiv g_{i,j} \equiv \frac{\partial g_i}{\partial x_j} \). Also, \( \text{cof} (Dg)_{ij} = \frac{\partial \det(Dg)}{\partial g_{i,j}} \).

Definition 11.11.2 Let \( h \) be a function defined on an open set, \( U \subseteq \mathbb{R}^n \). Then \( h \in C^k(U) \) if there exists a function \( g \) defined on an open set, \( W \) containing \( U \) such that \( g = h \) on \( U \) and \( g \) is \( C^k(W) \).

Lemma 11.11.3 There does not exist \( h \in C^2\left(B(0,R)\right) \) such that \( h : B(0,R) \to \partial B(0,R) \) which also has the property that \( h(x) = x \) for all \( x \in \partial B(0,R) \). Such a function is called a retraction.

Proof: Suppose such an \( h \) exists. Let \( \lambda \in [0,1] \) and let \( p_\lambda(x) \equiv x + \lambda(h(x) - x) \). This function, \( p_\lambda \), is a homotopy of the identity map and the retraction, \( h \). Let

\[
I(\lambda) \equiv \int_{B(0,R)} \det(Dp_\lambda(x)) \, dx.
\]

Then using the dominated convergence theorem,

\[
I'(\lambda) = \int_{B(0,R)} \sum_{i,j} \frac{\partial \det(Dp_\lambda(x))}{\partial p_{\lambda ij}} \frac{\partial p_{\lambda ij}}{\partial x_i} \, dx
\]

\[
= \int_{B(0,R)} \sum_i \sum_j \frac{\partial \det(Dp_\lambda(x))}{\partial p_{\lambda ij}} (h_j(x) - x_j) \, dx
\]

\[
= \int_{B(0,R)} \sum_i \sum_j \text{cof}(Dp_\lambda(x))_{ij} (h_j(x) - x_j) \, dx
\]
Now by assumption, \( h_i(x) = x_i \) on \( \partial B(0, R) \) and so one can integrate by parts and write
\[
I'(\lambda) = - \sum_i \int_{B(0,R)} \sum_j \text{cof} (Dp_\lambda(x))_{ij,j} (h_i(x) - x_i) \, dx = 0.
\]
Therefore, \( I(\lambda) \) equals a constant. However,
\[
I(0) = \text{max} (B(0,R)) > 0
\]
but
\[
I(1) = \int_{B(0,1)} \det (Dh(x)) \, dm_n = \int_{B(0,1)} \#(y) \, dm_n = 0
\]
because from polar coordinates or other elementary reasoning, \( \text{max} (\partial B(0,1)) = 0 \).

The following is the Brouwer fixed point theorem for \( C^2 \) maps.

**Lemma 11.11.4** If \( h \in C^2 \left( \overline{B(0,R)} \right) \) and \( h : \overline{B(0,R)} \rightarrow \overline{B(0,R)} \), then \( h \) has a fixed point, \( x \) such that \( h(x) = x \).

**Proof:** Suppose the lemma is not true. Then for all \( x, |x - h(x)| \neq 0 \). Then define
\[
g(x) = h(x) + \frac{x - h(x)}{|x - h(x)|} t(x)
\]
where \( t(x) \) is nonnegative and is chosen such that \( g(x) \in \partial B(0,R) \).

This mapping is illustrated in the following picture.

![Diagram](image)

If \( x \rightarrow t(x) \) is \( C^2 \) near \( \overline{B(0,R)} \), it will follow \( g \) is a \( C^2 \) retraction onto \( \partial B(0,R) \) contrary to Lemma 11.11.3. Thus \( t(x) \) is the nonnegative solution to
\[
H(x,t) = |h(x)|^2 + 2 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right) t + t^2 = R^2 \quad (11.11.28)
\]
Then
\[
H_t(x,t) = 2 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right) + 2t.
\]
CHAPTER 11. LEBESGUE MEASURE

If this is nonzero for all $x$ near $B(0; R)$, it follows from the implicit function theorem that $t$ is a $C^2$ function of $x$. Then from (11.11.28)

$$2t = -2 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right)$$

$$\pm \sqrt{4 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right)^2 - 4 \left( |h(x)|^2 - R^2 \right)}$$

and so

$$H_t(x, t) = 2t + 2 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right)$$

$$= \pm \sqrt{4 \left( R^2 - |h(x)|^2 \right) + 4 \left( h(x), \frac{x - h(x)}{|x - h(x)|} \right)^2}$$

If $|h(x)| < R$, this is nonzero. If $|h(x)| = R$, then it is still nonzero unless

$$(h(x), x - h(x)) = 0.$$ But this cannot happen because the angle between $h(x)$ and $x - h(x)$ cannot be $\pi/2$. Alternatively, if the above equals zero, you would need

$$(h(x), x) = |h(x)|^2 = R^2$$

which cannot happen unless $x = h(x)$ which is assumed not to happen. Therefore, $x \to t(x)$ is $C^2$ near $B(0; R)$ and so $g(x)$ given above contradicts Lemma (11.11.3).

Now it is easy to prove the Brouwer fixed point theorem.

**Theorem 11.11.5** Let $f : B(0; R) \to B(0; R)$ be continuous. Then $f$ has a fixed point.

**Proof:** For $f$ continuous, define $\|f\| = \max \left\{ |f(x)| : x \in B(0; R) \right\}$. Let

$$f_k(x) = \frac{1}{1 + (1/k)} f(x)$$

Then by Weierstrass approximation theorem, there exists $g_k$ a function in $C^2 \left( B(0; R) \right)$ such that

$$\|f_k - g_k\| < R / (k + 1)$$

Then

$$\|g_k\| \leq \|f_k\| + \frac{R}{k + 1} \leq \frac{R}{1 + (1/k)} + \frac{R}{k + 1} = R$$

Then $g_k$ has a fixed point $x_k$ and so

$$|f(x_k) - x_k| \leq |f(x_k) - g_k(x_k)| + |g_k(x_k) - x_k|$$

$$= |f(x_k) - g_k(x_k)| < \frac{R}{1 + k}$$
There is a subsequence, still called \( \{x_k\} \) which converges to \( x \in \overline{B(0,R)} \) and so, passing to a limit, one gets that

\[
|f(x) - x| \leq 0
\]

so \( f \) has a fixed point.

11.12 Invariance Of Domain

This principal says that if \( f : U \subseteq \mathbb{R}^n \to f(U) \subseteq \mathbb{R}^n \) where \( U \) is open and \( f \) is one to one and continuous, then \( f(U) \) is also open. To do this, we first prove the following lemma. I found something like this on the web. I liked it a lot because it shows how the Brouwer fixed point theorem implies the invariance of domain. The other ways I know about involve degree theory or some sort of algebraic topology. I will give two proofs of the following lemma, the first being somewhat more informal than the second.

**Lemma 11.12.1** Let \( B \) be a closed ball in \( \mathbb{R}^n \) centered at \( a \) which has radius \( r \). Let \( f : B \to \mathbb{R}^n \). Then \( f(a) \) is an interior point of \( f(B) \).

**Proof:** Since \( f(B) \) is compact and \( f \) is one to one, \( f^{-1} \) is continuous on \( f(B) \). Use Tietze extension theorem on components of \( f^{-1} \) or some such thing to obtain \( g : \mathbb{R}^n \to \mathbb{R}^n \) such that \( g \) is continuous and equals \( f^{-1} \) on \( f(B) \). Then multiply by a suitable truncation function to get \( g \) uniformly continuous on \( \mathbb{R}^n \).

Suppose \( f(a) \) is not an interior point of \( f(B) \). Then there exists \( c_k \to f(a) \) but \( c_k \notin f(B) \). In the picture, let \( C_k \) be a sphere whose radius is

\[
2|c_k - f(a)|
\]

Let \( \hat{g}_k \) be \( C^1 \) and let it satisfy

\[
\|\hat{g}_k - g\|_{f(B) \cup D} = \max_{y \in f(B) \cup D} |\hat{g}_k(y) - g(y)| < \varepsilon_k
\]

\( \varepsilon_k \) is very small, \( \varepsilon_k \to 0 \). How small will be considered later. Here \( D \) is a large closed disk which contains all of the spheres \( C_k \) considered above. The idea is to have a large compact set which includes everything of interest below.
To get $\tilde{g}_k$, you could use the Weierstrass approximation theorem, Theorem 7.2.9. An easier way involving convolution will be presented in the next chapter. Also let $a \notin \tilde{g}_k (C_k)$. This is no problem. $C_k$ has measure zero and so $\tilde{g} (C_k)$ also has measure zero thanks to the assumption that $\tilde{g}$ is $C^1$ and Lemma 11.5.1. Therefore, you could simply add a small enough nonzero vector to $\tilde{g}$ to preserve the above inequality of $g$ and $f$ so that $\tilde{g} (C_k)$ no longer contains $a$. That is, replace $\tilde{g}$ with $\tilde{g} + a - b$ where $|a - b|$ is very small but $b \notin \tilde{g} (C_k)$.

There is a set $\Sigma_k$ consisting of that part of $f (B)$ which is outside of the sphere $C_k$ in the picture along with the sphere $C_k$ itself. By construction, $\tilde{g}_k$ misses $a$ on $C_k$. As to the other part of $\Sigma_k$, $g$ misses $a$ on this part, because $f$ is one to one and so $f^{-1}$ is also. Now we will squash the part of $f (B)$ inside $C_k$ onto $C_k$ while leaving the rest of $f (B)$ unchanged.

Let $\Phi_k$ be defined on $f (B)$

$$\Phi_k (y) \equiv \max \left( \frac{2 |c_k - f (a)|}{|y - c_k|}, 1 \right) (y - c_k) + c_k$$

This $\Phi_k$ squashes the part of $f (B)$ inside $C_k$ to $C_k$ and leaves the rest of $f (B)$ unchanged. Thus

$$\Phi_k : f (B) \rightarrow f (B) \cap [y : |y - c_k| \geq 2 |c_k - f (a)|] \cup C_k$$

a compact set. Now $\|\tilde{g}_k \circ \Phi_k - f\|_{f (B)} \rightarrow 0$ and $g$ misses $a$ on the part of $f (B)$ outside of $C_k$. In the above, we chose $\tilde{g}_k$ so close to $g$ that it also misses $a$ on the part of $f (B)$ which is outside of $C_k$. Then by construction, $\tilde{g}_k$ misses $a$ on $C_k$ and so in fact $\tilde{g}_k \circ \Phi_k$ misses $a$ on $f (B)$. Now consider $a + x - \tilde{g}_k (\Phi_k (f (x)))$ for $x \in B$.

$$|a + x - \tilde{g}_k (\Phi_k (f (x)))| = |x - \tilde{g}_k (\Phi_k (f (x)))|$$

For $f (x)$ outside of $C_k$, we could have chosen $\tilde{g}_k$ such that $\|g - \tilde{g}_k\|_{f (B)} < \frac{r}{2}$ and this was indeed done. When $f (x)$ is inside $C_k$, then eventually, for large $k$, both $g (f (x))$, $\tilde{g}_k (\Phi_k (f (x)))$ are close to $g (f (a))$. To see this,

$$|\tilde{g}_k (\Phi_k (f (x))) - g (\Phi_k (f (x)))| + |g (\Phi_k (f (x))) - g (f (x))|$$

the last term being small for large $k$, and so for large $k$, $x \rightarrow a + x - \tilde{g}_k (\Phi_k (f (x)))$ maps $B$ to $B$ and so by Brouwer fixed point theorem, it has a fixed point and hence $\tilde{g}_k (\Phi_k (f (x))) = a$ contrary to what was argued above. Hence, $f (a)$ must be an interior point after all.

Now here is the same lemma with the details.

**Lemma 11.12.2** Let $B$ be a closed ball in $\mathbb{R}^n$ centered at $a$ which has radius $r$. Let $f : B \rightarrow \mathbb{R}^n$. Then $f (a)$ is an interior point of $f (B)$. 
**Proof:** Since $f(B)$ is compact and $f$ is one to one, $f^{-1}$ is continuous on $f(B)$. Use Tietze extension theorem on components of $f^{-1}$ or some such thing to obtain $g : \mathbb{R}^n \to \mathbb{R}^n$ such that $g$ is continuous and equals $f^{-1}$ on $f(B)$.

Suppose $f(a)$ is not an interior point of $f(B)$. Then for every $\varepsilon > 0$ there exists $c_\varepsilon \in B(f(a), \varepsilon) \setminus f(B)$. So fix $\varepsilon$ small and refer to $c_\varepsilon$ as $c$. $\varepsilon$ will be so small that

$$|g(y) - g(f(a))| < \frac{r}{10} \text{ for } y \in B(f(a), 4\varepsilon)$$

There is $\delta > 0$ such that if $|x - \tilde{x}| < \delta$, then

$$|f(x) - f(\tilde{x})| < \varepsilon$$  \hspace{1cm} (11.12.29)

Let $\tilde{g}$ be $C^1$ and on $f(B)$, let it satisfy

$$\|\tilde{g} - g\|_{f(B)} = \max_{y \in f(B)} |\tilde{g}(y) - g(y)| < \min\left(\frac{r}{10}, \frac{\delta}{2}\right)$$

To get $\tilde{g}_k$, you could use the Weierstrass approximation theorem, Theorem 7.2.4. An easier way involving convolution will be presented in the next chapter. Also let $a \notin \tilde{g}(\partial B(c, 2\varepsilon))$. This is no problem. $\partial B(a, 2\varepsilon)$ has measure zero and so $\tilde{g}(\partial B(c, \varepsilon))$ also has measure zero thanks to the assumption that $\tilde{g}$ is $C^1$ and Lemma 11.5.1. Therefore, you could simply add a small enough nonzero vector to $\tilde{g}$ to preserve the above inequality of $\tilde{g}$ and $g$ so that $\tilde{g}(\partial B(c, 2\varepsilon))$ no longer contains $a$. That is, replace $\tilde{g}$ with $\tilde{g} + a - b$ where $|a - b|$ is very small but $b \notin \tilde{g}(\partial B(c, 2\varepsilon))$. A summary of the rest of the argument is contained in the following picture in which the sphere has radius $2\varepsilon$.

![Picture of a sphere and a mapping (f(B), g, g ≠ a, g close to g)](image)

There is a set $\Sigma$ consisting of that part of $f(B)$ which is outside of the sphere $C$ in the picture along with the sphere $C$ itself. By construction, $\tilde{g}$ misses $a$ on $C$. As to the other part of $\Sigma$, that $g$ misses $a$ on this part, follows from the assumption that $f$ is one to one and so $f^{-1}$ is also. Then $\tilde{g}$ missing $a$ follows from $\tilde{g}$ being close enough to $g$. We define a continuous mapping $\Phi$ which maps $f(B)$ to this set $\Sigma$. This map squishes that part of $f(B)$ which is inside $C$ onto $C$ and does nothing to the part of $f(B)$ which is outside of $C$. This is where $c$ not in $f(B)$ but close to $f(B)$ is used. Then we argue that $\tilde{g} \circ \Phi$ is continuous and close to $g$ and misses $a$. It will be close to $g$ and $\tilde{g}$ because of the above assumption that everything inside
CHAPTER 11. LEBESGUE MEASURE

C is close to \( f(a) \) and \( g \) and \( \tilde{g} \) are continuous. This will yield an easy contradiction from a use of the Brouwer fixed point theorem.

Now let \( \Phi \) be defined on \( f(B) \)

\[
\Phi(y) = \max \left( \frac{2\varepsilon}{|y - c|}, 1 \right) (y - c) + c
\]

If \( |y - c| \geq 2\varepsilon \), then \( \Phi(y) = y \). If \( |y - c| < 2\varepsilon \), then \( \Phi(y) = \frac{2\varepsilon}{|y - c|} (y - c) + c \) and so

\[
|\Phi(y) - c| = 2\varepsilon \frac{|y - c|}{|y - c|} = 2\varepsilon
\]

Note that this function is well defined because \( c \notin f(B) \). Thus

\[
\Phi : f(B) \to f(B) \cap [y : |y - c| \geq 2\varepsilon] \cup \partial B(c, 2\varepsilon) \equiv \Sigma
\]
a compact set. Now the interesting thing about this set \( \Sigma \) is this. For \( y \in \Sigma \), \( \tilde{g}(y) \neq a \). Why is this? It is because by construction, \( a \notin \tilde{g}(\partial B(c, 2\varepsilon)) \). What if \( y \in f(B) \cap [y : |y - c| \geq 2\varepsilon] \), the other set in \( \Sigma \)? Could \( \tilde{g}(y) = a \)? If so, then

\[
|g(y) - a| \leq |g(y) - \tilde{g}(y)| + |\tilde{g}(y) - a| \leq \frac{\delta}{2}
\]

and so by \( \delta \equiv 2\varepsilon \),

\[
|y - f(a)| < \varepsilon
\]

But \( |y - c| \geq 2\varepsilon \) and so

\[
|y - f(a)| \geq |y - c| - |c - f(a)| \geq 2\varepsilon - |c - f(a)| \geq 2\varepsilon - \varepsilon = \varepsilon
\]

which contradicts the above inequality.

Therefore, \( \tilde{g}(y) \neq a \) for any \( y \in \Sigma \). So consider \( \tilde{g}(\Phi(y)) \) for \( y \in f(B) \).

\[
|\tilde{g}(\Phi(y)) - g(y)| \leq |\tilde{g}(\Phi(y)) - g(\Phi(y))| + |g(\Phi(y)) - g(y)|
\]

\[
\leq \frac{r}{10} + |g(\Phi(y)) - g(f(a)) - (g(y) - g(f(a)))| \quad (11.12.30)
\]

This last equals 0 if \( |y - c| \geq 2\varepsilon \). On the other hand, if \( |y - c| < 2\varepsilon \),

\[
y \in B(f(a), 2\varepsilon), \Phi(y) \in \partial B(c, 2\varepsilon)
\]

so both \( y, \Phi(y) \) are in \( B(f(a), 4\varepsilon) \) and so this last term in \( (11.12.30) \) is no larger than \( |g(\Phi(y) - g(f(a)))| + |g(y) - g(f(a))| < \frac{r}{10} + \frac{r}{10} \) and so for all \( y \in f(B) \),

\[
|\tilde{g}(\Phi(y)) - g(y)| \leq \frac{3r}{10}
\]

Now note that for \( x \in B \), from what was just shown,

\[
|\tilde{g}(\Phi(f(x))) - x| = |\tilde{g}(\Phi(f(x))) - g(f(x))| \leq \frac{3r}{10}
\]
It follows that for every $x \in B, a + x - \tilde{g}(\Phi(f(x))) \in B$ and so by the Brouwer fixed point theorem, there is a fixed point $x$ and hence

$$a + x - \tilde{g}(\Phi(f(x))) = x$$

so $\tilde{g}(\Phi(f(x))) = a$ contrary to what was just shown that there is no solution to $\tilde{g}(y) = a$ for $y \in \Sigma$. ■

With the lemma, it is easy to prove the invariance of domain theorem which is as follows.

**Theorem 11.12.3** Let $U$ be an open set in $\mathbb{R}^n$ and let $f : U \to f(U) \subseteq \mathbb{R}^n$. Then $f(U)$ is also an open set in $\mathbb{R}^n$.

**Proof:** For $a \in U$, let $a \in B_a \subseteq U$, where $B_a$ is a closed ball centered at $a$. Then from Lemma 11.12.2, $f(a) \in V_{f(a)}$ an open subset of $f(B_a)$. Hence $f(U) = \bigcup_{a \in U} V_{f(a)}$ which is open. ■
Chapter 12

Some Extension Theorems

12.1 Algebras

First of all, here is the definition of an algebra and theorems which tell how to recognize one when you see it. An algebra is like a $\sigma$ algebra except it is only closed with respect to finite unions.

**Definition 12.1.1** $A$ is said to be an algebra of subsets of a set, $Z$ if $Z \in A$, $\emptyset \in A$, and when $E, F \in A$, $E \cup F$ and $E \setminus F$ are both in $A$.

It is important to note that if $A$ is an algebra, then it is also closed under finite intersections. This is because $E \cap F = (E^C \cup F^C)^C \in A$ since $E^C = Z \setminus E \in A$ and $F^C = Z \setminus F \in A$. Note that every $\sigma$ algebra is an algebra but not the other way around.

Something satisfying the above definition is called an algebra because union is like addition, the set difference is like subtraction and intersection is like multiplication. Furthermore, only finitely many operations are done at a time and so there is nothing like a limit involved.

How can you recognize an algebra when you see one? The answer to this question is the purpose of the following lemma.

**Lemma 12.1.2** Suppose $R$ and $E$ are subsets of $\mathcal{P}(Z)$ such that $E$ is defined as the set of all finite disjoint unions of sets of $R$. Suppose also

$$\emptyset, Z \in R$$

$$A \cap B \in R \quad \text{whenever} \ A, B \in R,$$

$$A \setminus B \in E \quad \text{whenever} \ A, B \in R.$$  

Then $E$ is an algebra of sets of $Z$.

---

(Set of all subsets of $Z$)

361
CHAPTER 12. SOME EXTENSION THEOREMS

Proof: Note first that if $A \in \mathcal{R}$, then $A^C \in \mathcal{E}$ because $A^C = Z \setminus A$.

Now suppose that $E_1$ and $E_2$ are in $\mathcal{E}$,

$$E_1 = \bigcup_{i=1}^m R_i, \quad E_2 = \bigcup_{j=1}^n R_j$$

where the $R_i$ are disjoint sets in $\mathcal{R}$ and the $R_j$ are disjoint sets in $\mathcal{R}$. Then

$$E_1 \cap E_2 = \bigcup_{i=1}^m \bigcup_{j=1}^n R_i \cap R_j$$

which is clearly an element of $\mathcal{E}$ because no two of the sets in the union can intersect and by assumption they are all in $\mathcal{R}$. Thus by induction, finite intersections of sets of $\mathcal{E}$ are in $\mathcal{E}$. Consider the difference of two elements of $\mathcal{E}$ next.

If $E = \bigcup_{i=1}^n R_i \in \mathcal{E}$,

$$E^C = \cap_{i=1}^n R_i^C = \text{finite intersection of sets of } \mathcal{E}$$

which was just shown to be in $\mathcal{E}$. Now, if $E_1, E_2 \in \mathcal{E}$,

$$E_1 \setminus E_2 = E_1 \cap E_2^C \in \mathcal{E}$$

from what was just shown about finite intersections.

Finally consider finite unions of sets of $\mathcal{E}$. Let $E_1$ and $E_2$ be sets of $\mathcal{E}$. Then

$$E_1 \cup E_2 = (E_1 \setminus E_2) \cup E_2 \in \mathcal{E}$$

because $E_1 \setminus E_2$ consists of a finite disjoint union of sets of $\mathcal{R}$ and these sets must be disjoint from the sets of $\mathcal{R}$ whose union yields $E_2$ because $(E_1 \setminus E_2) \cap E_2 = \emptyset$. This proves the lemma.

The following corollary is particularly helpful in verifying the conditions of the above lemma.

Corollary 12.1.3 Let $(Z_1, \mathcal{R}_1, \mathcal{E}_1)$ and $(Z_2, \mathcal{R}_2, \mathcal{E}_2)$ be as described in Lemma 12.1.2. Then $(Z_1 \times Z_2, \mathcal{R}, \mathcal{E})$ also satisfies the conditions of Lemma 12.1.2 if $\mathcal{R}$ is defined as

$$\mathcal{R} \equiv \{ R_1 \times R_2 : R_i \in \mathcal{R}_i \}$$

and

$$\mathcal{E} \equiv \{ \text{finite disjoint unions of sets of } \mathcal{R} \}.$$  

Consequently, $\mathcal{E}$ is an algebra of sets.

Proof: It is clear $\emptyset, Z_1 \times Z_2 \in \mathcal{R}$. Let $A \times B$ and $C \times D$ be two elements of $\mathcal{R}$.

$$A \times B \cap C \times D = A \cap C \times B \cap D \in \mathcal{R}$$

by assumption.

$$A \times B \setminus (C \times D) =$$

$$A \times (B \setminus D) \cup \left( A \setminus \underbrace{C \times D} \right)$$

and

$$A \setminus \underbrace{(B \setminus D)} \cap \underbrace{(C \times D)} \cap \underbrace{(D \cap B)}$$
where \( Q \in \mathcal{E}_2, P \in \mathcal{E}_1, \) and \( R \in \mathcal{R}_2. \)

Since \( A \times Q \) and \( P \times R \) do not intersect, it follows the above expression is in \( \mathcal{E} \) because each of these terms are. This proves the corollary.

### 12.2 Caratheodory Extension Theorem

The Caratheodory extension theorem is a fundamental result which makes possible the consideration of measures on infinite products among other things. The idea is that if a finite measure defined only on an algebra is trying to be a measure, then in fact it can be extended to a measure.

**Definition 12.2.1** Let \( \mathcal{E} \) be an algebra of sets of \( \Omega \) and let \( \mu_0 \) be a finite measure on \( \mathcal{E} \). This means \( \mu_0 \) is finitely additive and if \( E_i, E \) are sets of \( \mathcal{E} \) with the \( E_i \) disjoint and

\[
E = \bigcup_{i=1}^{\infty} E_i,
\]

then

\[
\mu_0 (E) = \sum_{i=1}^{\infty} \mu_0 (E_i)
\]

while \( \mu_0 (\Omega) < \infty. \)

In this definition, \( \mu_0 \) is trying to be a measure and acts like one whenever possible. Under these conditions, \( \mu_0 \) can be extended uniquely to a complete measure, \( \mu \), defined on a \( \sigma \) algebra of sets containing \( \mathcal{E} \) such that \( \mu \) agrees with \( \mu_0 \) on \( \mathcal{E} \). The following is the main result.

**Theorem 12.2.2** Let \( \mu_0 \) be a measure on an algebra of sets, \( \mathcal{E} \), which satisfies \( \mu_0 (\Omega) < \infty. \) Then there exists a complete measure space \( (\Omega, \mathcal{S}, \mu) \) such that

\[
\mu (E) = \mu_0 (E)
\]

for all \( E \in \mathcal{E}. \) Also if \( \nu \) is any such measure which agrees with \( \mu_0 \) on \( \mathcal{E} \), then \( \nu = \mu \) on \( \sigma (\mathcal{E}) \), the \( \sigma \) algebra generated by \( \mathcal{E}. \)
CHAPTER 12. SOME EXTENSION THEOREMS

Proof: Define an outer measure as follows.

\[ \mu(S) \equiv \inf \left\{ \sum_{i=1}^{\infty} \mu_0(E_i) : S \subseteq \bigcup_{i=1}^{\infty} E_i, E_i \in \mathcal{E} \right\} \]

Claim 1: \( \mu \) is an outer measure.

Proof of Claim 1: Let \( S \subseteq \bigcup_{i=1}^{\infty} S_i \) and let \( S_i \subseteq \bigcup_{j=1}^{\infty} E_{ij} \), where

\[ \mu(S_i) + \frac{\varepsilon}{2^i} \geq \sum_{j=1}^{\infty} \mu(E_{ij}) \]

Then

\[ \mu(S) \leq \sum_i \sum_j \mu(E_{ij}) = \sum_i \left( \mu(S_i) + \frac{\varepsilon}{2^i} \right) = \sum_i \mu(S_i) + \varepsilon. \]

Since \( \varepsilon \) is arbitrary, this shows \( \mu \) is an outer measure as claimed.

By the Caratheodory procedure, there exists a unique \( \sigma \)-algebra, \( \mathcal{S} \), consisting of the \( \mu \) measurable sets such that

\( (\Omega, \mathcal{S}, \mu) \)

is a complete measure space. It remains to show \( \mu \) extends \( \mu_0 \).

Claim 2: If \( \mathcal{S} \) is the \( \sigma \)-algebra of \( \mu \) measurable sets, \( \mathcal{S} \supseteq \mathcal{E} \) and \( \mu = \mu_0 \) on \( \mathcal{E} \).

Proof of Claim 2: First observe that if \( A \in \mathcal{E} \), then \( \mu(A) \leq \mu_0(A) \) by definition. Letting

\[ \mu(A) + \varepsilon > \sum_{i=1}^{\infty} \mu_0(E_i) \cup \bigcup_{i=1}^{\infty} E_i \supseteq A, E_i \in \mathcal{E}, \]

it follows

\[ \mu(A) + \varepsilon \geq \sum_{i=1}^{\infty} \mu_0(E_i \cap A) \geq \mu_0(A) \]

since \( A = \bigcup_{i=1}^{\infty} E_i \cap A \). Therefore, \( \mu = \mu_0 \) on \( \mathcal{E} \).

Consider the assertion that \( \mathcal{E} \subseteq \mathcal{S} \). Let \( A \in \mathcal{E} \) and let \( S \subseteq \Omega \) be any set. There exist sets \( \{E_i\} \subseteq \mathcal{E} \) such that \( \bigcup_{i=1}^{\infty} E_i \supseteq S \) but \( \mu(S) + \varepsilon > \sum_{i=1}^{\infty} \mu(E_i) \).

Then

\[ \mu(S) \leq \mu(S \cap A) + \mu(S \setminus A) \]
\[ \leq \mu(\bigcup_{i=1}^{\infty} E_i \setminus A) + \mu(\bigcup_{i=1}^{\infty} (E_i \cap A)) \]
\[ \leq \sum_{i=1}^{\infty} \mu(E_i \setminus A) + \sum_{i=1}^{\infty} \mu(E_i \cap A) = \sum_{i=1}^{\infty} \mu(E_i) < \mu(S) + \varepsilon. \]
Since $\varepsilon$ is arbitrary, this shows $A \in \mathcal{S}$.

This has proved the existence part of the theorem. To verify uniqueness, let

$$\mathcal{G} \equiv \{ E \in \sigma (\mathcal{E}) : \mu (E) = \nu (E) \} .$$

Then $\mathcal{G}$ is given to contain $\mathcal{E}$ and is obviously closed with respect to countable disjoint unions and complements. Therefore by Lemma 10.12.3, $\mathcal{G} \supseteq \sigma (\mathcal{E})$ and this proves the lemma.

The following lemma is also very significant.

**Lemma 12.2.3** Let $M$ be a metric space with the closed balls compact and suppose $\mu$ is a measure defined on the Borel sets of $M$ which is finite on compact sets. Then there exists a unique Radon measure, $\overline{\mu}$ which equals $\mu$ on the Borel sets. In particular $\mu$ must be both inner and outer regular on all Borel sets.

**Proof:** Define a positive linear functional, $\Lambda (f) = \int fd\mu$. Let $\overline{\mu}$ be the Radon measure which comes from the Riesz representation theorem for positive linear functionals. Thus for all $f \in C_0 (M)$,

$$\int fd\mu = \int f d\overline{\mu} .$$

If $V$ is an open set, let $\{ f_n \}$ be a sequence of continuous functions in $C_0 (M)$ which is increasing and converges to $\chi_V$ pointwise. Then applying the monotone convergence theorem,

$$\int \chi_V d\mu = \mu (V) = \int \chi_V d\overline{\mu} = \overline{\mu} (V)$$

and so the two measures coincide on all open sets. Every compact set is a countable intersection of open sets and so the two measures coincide on all compact sets. Now let $B(a, n)$ be a ball of radius $n$ and let $E$ be a Borel set contained in this ball. Then by regularity of $\overline{\mu}$ there exist sets $F, G$ such that $G$ is a countable intersection of open sets and $F$ is a countable union of compact sets such that $F \subseteq E \subseteq G$ and $\overline{\mu} (G \setminus F) = 0$. Now $\mu (G) = \overline{\mu} (G)$ and $\mu (F) = \overline{\mu} (F)$. Thus

$$\overline{\mu} (G \setminus F) + \overline{\mu} (F) = \overline{\mu} (G)$$

and so $\mu (G \setminus F) = \overline{\mu} (G \setminus F)$. It follows

$$\mu (E) = \mu (F) = \overline{\mu} (F) = \overline{\mu} (G) = \overline{\mu} (E) .$$

If $E$ is an arbitrary Borel set, then

$$\mu (E \cap B(a, n)) = \overline{\mu} (E \cap B(a, n))$$

and letting $n \to \infty$, this yields $\mu (E) = \overline{\mu} (E)$. 

12.3 The Tychonoff Theorem

Sometimes it is necessary to consider infinite Cartesian products of topological spaces. When you have finitely many topological spaces in the product and each is compact, it can be shown that the Cartesian product is compact with the product topology. It turns out that the same thing holds for infinite products but you have to be careful how you define the topology. The first thing likely to come to mind by analogy with finite products is not the right way to do it.

First recall the Hausdorff maximal principle.

**Theorem 12.3.1 (Hausdorff maximal principle)** Let $F$ be a nonempty partially ordered set. Then there exists a maximal chain.

The main tool in the study of products of compact topological spaces is the Alexander subbasis theorem which is presented next. Recall a set is compact if every basic open cover admits a finite subcover. This was pretty easy to prove. However, there is a much smaller set of open sets called a subbasis which has this property. The proof of this result is much harder.

**Definition 12.3.2** $S \subseteq \tau$ is called a subbasis for the topology $\tau$ if the set $B$ of finite intersections of sets of $S$ is a basis for the topology, $\tau$.

**Theorem 12.3.3** Let $(X, \tau)$ be a topological space and let $S \subseteq \tau$ be a subbasis for $\tau$. Then if $H \subseteq X$, $H$ is compact if and only if every open cover of $H$ consisting entirely of sets of $S$ admits a finite subcover.

**Proof:** The only if part is obvious because the subbasic sets are themselves open.

If every basic open cover admits a finite subcover then the set in question is compact. Suppose then that $H$ is a subset of $X$ having the property that subbasic open covers admit finite subcovers. Is $H$ compact? Assume this is not so. Then what was just observed about basic covers implies there exists a basic open cover of $H$, $O$, which admits no finite subcover. Let $F$ be defined as

$$\{O : O \text{ is a basic open cover of } H \text{ which admits no finite subcover}\}.$$  

The assumption is that $F$ is nonempty. Partially order $F$ by set inclusion and use the Hausdorff maximal principle to obtain a maximal chain, $C$, of such open covers and let

$$D = \cup C.$$  

If $D$ admits a finite subcover, then since $C$ is a chain and the finite subcover has only finitely many sets, some element of $C$ would also admit a finite subcover, contrary to the definition of $F$. Therefore, $D$ admits no finite subcover. If $D'$ properly contains $D$ and $D'$ is a basic open cover of $H$, then $D'$ has a finite subcover of $H$ since otherwise, $C$ would fail to be a maximal chain, being properly contained in $C \cup \{D'\}$. Every set of $D$ is of the form

$$U = \cap_{i=1}^{m} B_i, \ B_i \in S$$
because they are all basic open sets. If it is the case that for all \( U \in \mathcal{D} \) one of the \( B_i \) is found in \( \mathcal{D} \), then replace each such \( U \) with the subbasic set from \( \mathcal{D} \) containing it. But then this would be a subbasic open cover of \( \mathcal{H} \) which by assumption would admit a finite subcover contrary to the properties of \( \mathcal{D} \). Therefore, one of the sets of \( \mathcal{D} \), denoted by \( U \), has the property that

\[
U = \bigcap_{i=1}^{m} B_i, \quad B_i \in \mathcal{S}
\]

and no \( B_i \) is in \( \mathcal{D} \). Thus \( \mathcal{D} \cup \{B_i\} \) admits a finite subcover, for each of the above \( B_i \) because it is strictly larger than \( \mathcal{D} \). Let this finite subcover corresponding to \( B_i \) be denoted by

\[
V_i^1, \ldots, V_i^m, B_i
\]

Consider

\[
\{U, V_j^1, j = 1, \ldots, m_i, i = 1, \ldots, m\}.
\]

If \( p \in H \setminus \bigcup \{V_j^1\} \), then \( p \in B_i \) for each \( i \) and so \( p \in U \). This is therefore a finite subcover of \( \mathcal{D} \) contradicting the properties of \( \mathcal{D} \). Therefore, \( \mathcal{F} \) must be empty and this proves the theorem.

**Definition 12.3.4** Let \( I \) be a set and suppose for each \( i \in I \), \( (X_i, \tau_i) \) is a nonempty topological space. The Cartesian product of the \( X_i \), denoted by \( \prod_{i \in I} X_i \), consists of the set of all choice functions defined on \( I \) which select a single element of each \( X_i \). Thus \( f \in \prod_{i \in I} X_i \) means for every \( i \in I \), \( f(i) \in X_i \). The axiom of choice says \( \prod_{i \in I} X_i \) is nonempty. Let

\[
P_j(A) = \prod_{i \in I} B_i
\]

where \( B_i = X_i \) if \( i \neq j \) and \( B_j = A \). A subbasis for a topology on the product space consists of all sets \( P_j(A) \) where \( A \in \tau_j \). (These sets have an open set from the topology of \( X_j \) in the \( j^{th} \) slot and the whole space in the other slots.) Thus a basis consists of finite intersections of these sets. Note that the intersection of two of these basic sets is another basic set and their union yields \( \prod_{i \in I} X_i \). Therefore, they satisfy the condition needed for a collection of sets to serve as a basis for a topology. This topology is called the product topology and is denoted by \( \prod \tau_i \).

**Proposition 12.3.5** The product topology is the smallest topology \( \tau \) for \( X = \prod_{i \in I} X_i \) such that each \( \pi_i \) is continuous. Here \( \pi_i \) is defined in the following manner. For \( x \in X \), \( \pi_i(x) \equiv x_i \). Thus \( \pi_i \) delivers the \( i^{th} \) entry of \( x \).

**Proof:** If each \( \pi_i \) is continuous, then for \( A \in \tau_i \), \( \pi_i^{-1}(A) \) must be in \( \tau \). However, \( \pi_i^{-1}(A) = P_j(A) \) having \( A \) in the \( i^{th} \) slot and \( X_j \) in every other. Therefore, \( \tau \) must contain the sets \( P_j(A) \). Since it must be a topology, it must also contain all finite intersections of these sets. Thus the topology \( \tau \) must contain the product topology described in the above definition. Is it any larger? No, because if it were, it would not be the smallest topology making the coordinate maps continuous, due to the observation that these coordinate maps are indeed continuous with respect to the product topology. \( \blacksquare \)
It is tempting to define a basis for a topology to be sets of the form $\prod_{i \in I} A_i$ where $A_i$ is open in $X_i$. This is not the same thing at all. Note that the basis just described has at most finitely many slots filled with an open set which is not the whole space. The thing just mentioned in which every slot may be filled by a proper open set is called the box topology and there exist people who are interested in it.

The Alexander subbasis theorem is used to prove the Tychonoff theorem which says that if each $X_i$ is a compact topological space, then in the product topology, $\prod_{i \in I} X_i$ is also compact.

**Theorem 12.3.6** If $(X_i, \tau_i)$ is compact, then so is $(\prod_{i \in I} X_i, \tau)$ where $\tau$ is the product topology.

**Proof:** By the Alexander subbasis theorem, the theorem will be proved if every subbasic open cover admits a finite subcover. Therefore, let $O$ be a subbasic open cover of $X \equiv \prod_{i \in I} X_i$. Let

$$O_j = \{Q \in O : \pi_i Q = X_i \text{ for } i \neq j\}$$
$$\pi_j O_j = \{\pi_j Q : Q \in O_j\}$$

Thus $O_j$ are those sets of $O$ which might have a proper open subset of $X_j$ in the $j^{th}$ position. If each $\pi_j O_j$ fails to cover $X_j$, then there exists

$$f \in \prod_{j \in I} X_j \setminus \cup_{j \in I} \pi_j O_j$$

Now $f$ is contained in some open set from $O$ which must be in some $O_j$. Hence $\pi_j f = f(j) \in \cup \pi_j O_j$ but this does not happen. Hence for some $j, \pi_j O_j$ must cover $X_j$.

$$X_j = \cup \pi_j O_j$$

and so by compactness of $X_j$, there exist $A_1, \cdots, A_m$, sets in $\tau_j$ such that $X_j \subseteq \cup_{k=1}^m A_k$ and letting $\pi_j U_k = A_k$ for $U_k \in O_j$, $\{U_k\}_{k=1}^m$ covers $\prod_{i \in I} X_i$. By the Alexander subbasis theorem this proves $\prod_{i \in I} X_i$ is compact. ■

### 12.4 Kolmogorov Extension Theorem

Let a subbasis for $[\infty, \infty]$ be sets of the form $[\infty, a)$ and $(a, \infty]$. Thus with this subbasis, $[\infty, \infty]$ is a compact Hausdorff space. Also let $M_t \equiv [\infty, \infty]^{n_t}$ where $n_t$ is a positive integer and endow this product with the product topology so that $M_t$ is also a compact Hausdorff space.

$I$ will denote a totally ordered index set, (Like $\mathbb{R}$) and the interest will be in building a measure on the product space, $\prod_{i \in I} M_t$. By the well ordering principle, you can always put an order on any index set so this order is no restriction, but we do not insist on a well order and in fact, index sets of great interest are $\mathbb{R}$ or $[0, \infty)$. Also for $X$ a topological space, $\mathcal{B}(X)$ will denote the Borel sets.
Notation 12.4.1 The symbol $J$ will denote a finite subset of $I$, $J = (t_1, \ldots, t_n)$, the $t_i$ taken in order. $E_J$ will denote a set which has a set $E_t$ of $B(M_t)$ in the $t^{th}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{th}$ position will be $M_t$. $K_J$ will denote a set which has a compact set in the $t^{th}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{th}$ position will be $M_t$. Thus $K_J$ is compact in the product topology of $\Omega = \prod_{t \in J} M_t$. Also denote by $R_J$ the sets $E_J$ and $R$ the union of the $R_J$. Let $E_J$ denote finite disjoint unions of sets of $R_J$ and let $E$ denote finite disjoint unions of sets of $R$. Thus if $F$ is a set of $E$, there exists $J$ such that $F$ is a finite disjoint union of sets of $R_J$. For $F \in \Omega$, denote by $\pi_J(F)$ the set $\prod_{t \in J} F_t$ where $F = \prod_{t \in I} F_t$.

Lemma 12.4.2 The sets, $E, E_J$ defined above form an algebra of sets of $\prod_{t \in I} M_t$.

Proof: First consider $R_J$. If $A, B \in R_J$, then $A \cap B \in R_J$ also. Is $A \setminus B$ a finite disjoint union of sets of $R_J$? It suffices to verify that $\pi_J(A \setminus B)$ is a finite disjoint union of $\pi_J(R_J)$. Let $|J|$ denote the number of indices in $J$. If $|J| = 1$, then it is obvious that $\pi_J(A \setminus B)$ is a finite disjoint union of sets of $\pi_J(R_J)$. In fact, letting $J = (t)$ and the $t^{th}$ entry of $A$ is $A$ and the $t^{th}$ entry of $B$ is $B$, then the $t^{th}$ entry of $A \setminus B$ is $A \setminus B$, a Borel set of $M_t$, a finite disjoint union of Borel sets of $M_t$.

Suppose then that for $A, B$ sets of $R_J$, $\pi_J(A \setminus B)$ is a finite disjoint union of sets of $\pi_J(R_J)$ for $|J| \leq n$, and consider $J = (t_1, \ldots, t_n, t_{n+1})$. Let the $t_i^{th}$ entry of $A$ and $B$ be respectively $A_i$ and $B_i$. It follows that $\pi_J(A \setminus B)$ has the following in the entries for $J$

\[
(A_1 \times A_2 \times \cdots \times A_n \times A_{n+1}) \setminus (B_1 \times B_2 \times \cdots \times B_n \times B_{n+1})
\]

Letting $A$ represent $A_1 \times A_2 \times \cdots \times A_n$ and $B$ represent $B_1 \times B_2 \times \cdots \times B_n$, this is of the form

\[
A \times (A_{n+1} \setminus B_{n+1}) \cup (A \setminus B) \times (A_{n+1} \cap B_{n+1})
\]

By induction, $(A \setminus B)$ is the finite disjoint union of sets of $\mathcal{R}(t_1, \ldots, t_n)$. Therefore, the above is the finite disjoint union of sets of $R_J$. It follows that $E_J$ is an algebra.

Now suppose $A, B \in \mathcal{R}$. Then for some finite set $J$, both are in $R_J$. Then from what was just shown,

\[
A \setminus B \in E_J \subseteq \mathcal{E}, A \cap B \in \mathcal{R}.
\]

By Lemma 10.10.2 on Page 380 this shows $\mathcal{E}$ is an algebra. ■

With this preparation, here is the Kolmogorov extension theorem. In the statement and proof of the theorem, $F_i, G_i,$ and $E_i$ will denote Borel sets. Any list of indices from $I$ will always be assumed to be taken in order. Thus, if $J \subseteq I$ and $J = (t_1, \ldots, t_n)$, it will always be assumed $t_1 < t_2 < \cdots < t_n$.

Theorem 12.4.3 For each finite set

\[
J = (t_1, \ldots, t_n) \subseteq I,
\]
suppose there exists a Borel probability measure, \( \nu_J = \nu_{t_1, \ldots, t_n} \) defined on the Borel sets of \( \prod_{t \in J} M_t \) such that the following consistency condition holds. If

\[
(t_1, \ldots, t_n) \subseteq (s_1, \ldots, s_p),
\]

then

\[
\nu_{t_1, \ldots, t_n}(F_{t_1} \times \cdots \times F_{t_n}) = \nu_{s_1, \ldots, s_p}(G_{s_1} \times \cdots \times G_{s_p})
\]  

(12.4.1)

where if \( s_i = t_j \), then \( G_{s_i} = F_{t_j} \) and if \( s_i \) is not equal to any of the indices, \( t_k \), then \( G_{s_i} = M_{s_i} \). Then for \( E \) defined in Definition 12.4.1, there exists a probability measure, \( P \) and a \( \sigma \) algebra \( \mathcal{F} = \sigma(E) \) such that

\[
\left( \prod_{t \in I} M_t, P, \mathcal{F} \right)
\]

is a probability space. Also there exist measurable functions, \( X_s : \prod_{t \in I} M_t \rightarrow M_s \) defined as

\[ X_s \equiv x_s \]

for each \( s \in I \) such that for each \( (t_1 \cdots t_n) \subseteq I \),

\[
\nu_{t_1, \ldots, t_n}(F_{t_1} \times \cdots \times F_{t_n}) = P\left( [X_{t_1} \in F_{t_1}] \cap \cdots \cap [X_{t_n} \in F_{t_n}] \right)
\]

\[
= P\left( X_{t_1}, \ldots, X_{t_n} \in \prod_{j=1}^n F_{t_j} \right) = P\left( \prod_{t \in I} F_t \right)
\]  

(12.4.2)

where \( F_t = M_t \) for every \( t \notin \{t_1, \ldots, t_n\} \) and \( F_{t_i} \) is a Borel set. Also if \( f \) is a nonnegative function of finitely many variables, \( x_{t_1}, \ldots, x_{t_n} \), measurable with respect to \( B \left( \prod_{j=1}^n M_{t_j} \right) \), then \( f \) is also measurable with respect to \( \mathcal{F} \) and

\[
\int_{M_{t_1} \times \cdots \times M_{t_n}} f(x_{t_1}, \ldots, x_{t_n}) \, d\nu_{t_1, \ldots, t_n}
\]

\[
= \int_{\prod_{t \in I} M_t} f(x_{t_1}, \ldots, x_{t_n}) \, dP
\]

(12.4.3)

**Proof:** Let \( \mathcal{E} \) be the algebra of sets defined in Definition 12.4.1. I want to define a measure on \( \mathcal{E} \). For \( F \in \mathcal{E} \), there exists \( J \) such that \( F \) is the finite disjoint unions of sets of \( \mathcal{R}_J \). Define

\[
P_0(F) \equiv \nu_J(\pi_J(F))
\]

Then \( P_0 \) is well defined because of the consistency condition on the measures \( \nu_J \). \( P_0 \) is clearly finitely additive because the \( \nu_J \) are measures and one can pick \( J \) as large as desired to include all \( t \) where there may be something other than \( M_t \). Also, from the definition,

\[
P_0(\Omega) = P_0\left( \prod_{t \in I} M_t \right) = \nu_{t_1}(M_{t_1}) = 1.
\]
Next I will show $P_0$ is a finite measure on $\mathcal{E}$. After this it is only a matter of using the Caratheodory extension theorem to get the existence of the desired probability measure $P$.

**Claim:** Suppose $E^n$ is in $\mathcal{E}$ and suppose $E^n \downarrow \emptyset$. Then $P_0 (E^n) \downarrow 0$.

**Proof of the claim:** If not, there exists a sequence such that although $E^n \downarrow \emptyset, P_0 (E^n) \downarrow \varepsilon > 0$. Let $E^n \in \mathcal{E}_{J_n}$. Thus it is a finite disjoint union of sets of $\mathcal{R}_{J_n}$.

By regularity of the measures $\nu_J$, there exists a compact set $K_{J_n} \subseteq E^n$ such that

$$\nu_{J_n} (\pi_{J_n} (K_{J_n})) + \frac{\varepsilon}{2n+2} > \nu_{J_n} (\pi_{J_n} (E^n))$$

Thus

$$P_0 (K_{J_n}) + \frac{\varepsilon}{2n+2} = \nu_{J_n} (\pi_{J_n} (K_{J_n})) + \frac{\varepsilon}{2n+2} > \nu_{J_n} (\pi_{J_n} (E^n)) \equiv P_0 (E^n)$$

The interesting thing about these $K_{J_n}$ is: they have the finite intersection property. Here is why.

$$\varepsilon \leq P_0 (\cap_{k=1}^m K_{J_k}) + P_0 (E^n \setminus \cap_{k=1}^m K_{J_k})$$

$$\leq P_0 (\cap_{k=1}^m K_{J_k}) + P_0 (\cup_{k=1}^m E^k \setminus K_{J_k})$$

$$< P_0 (\cap_{k=1}^m K_{J_k}) + \sum_{k=1}^\infty \frac{\varepsilon}{2^k+2} < P_0 (\cap_{k=1}^m K_{J_k}) + \varepsilon/2,$$

and so $P_0 (\cap_{k=1}^m K_{J_k}) > \varepsilon/2$. Now this yields a contradiction, because this finite intersection property implies the intersection of all the $K_{J_k}$ is nonempty, contradicting $E^n \downarrow \emptyset$ since each $K_{J_n}$ is contained in $E^n$.

With the claim, it follows $P_0$ is a measure on $\mathcal{E}$. Here is why: If $E = \cup_{k=1}^\infty E^k$ where $E, E^k \in \mathcal{E}$, then $(E \setminus \cup_{k=1}^m E^k) \downarrow \emptyset$ and so

$$P_0 (\cup_{k=1}^m E^k) \rightarrow P_0 (E).$$

Hence if the $E_k$ are disjoint, $P_0 (\cup_{k=1}^m E^k) = \sum_{k=1}^n P_0 (E^k) \rightarrow P_0 (E)$. Thus for disjoint $E_k$ having $\cup_k E_k = E \in \mathcal{E}$,

$$P_0 (\cup_{k=1}^\infty E^k) = \sum_{k=1}^\infty P_0 (E_k).$$

Now to conclude the proof, apply the Caratheodory extension theorem to obtain $P$ a probability measure which extends $P_0$ to a $\sigma$ algebra which contains $\sigma (\mathcal{E})$ the sigma algebra generated by $\mathcal{E}$ with $P = P_0$ on $\mathcal{E}$. Thus for $E_J \in \mathcal{E}$, $P (E_J) = P_0 (E_J) = \nu_J (P_J E_J)$.

Next, let $(\prod_{l \in I} M_l, \mathcal{F}, P)$ be the probability space and for $x \in \prod_{l \in I} M_l$ let $X_t (x) = x_t$, the $t^{th}$ entry of $x$. It follows $X_t$ is measurable (also continuous) because if $U$ is open in $M_t$, then $X_t^{-1} (U)$ has a $U$ in the $t^{th}$ slot and $M_s$ everywhere else for $s \neq t$. Thus inverse images of open sets are measurable. Also, letting $J$ be a finite
subset of \( I \) and for \( J = (t_1, \cdots , t_n) \), and \( F_{t_1}, \cdots , F_{t_n} \) Borel sets in \( M_{t_1} \cdots M_{t_n} \) respectively, it follows \( F_J \), where \( F_J \) has \( F_{t_i} \) in the \( t_i^{th} \) entry, is in \( E \) and therefore,

\[
P(\{X_{t_1} \in F_{t_1}\} \cap \{X_{t_2} \in F_{t_2}\} \cap \cdots \cap \{X_{t_n} \in F_{t_n}\}) = P(\{X_{t_1}, X_{t_2}, \cdots , X_{t_n}\} \in F_{t_1} \times \cdots \times F_{t_n}) = P(\{X_{t_1}, X_{t_2}, \cdots , X_{t_n}\} \in F_{t_1} \times \cdots \times F_{t_n})
\]

Finally consider the claim about the integrals. Suppose \( f(x_{t_1}, \cdots , x_{t_n}) = \mathcal{X}_F \) where \( F \) is a Borel set of \( \prod_{t \in J} M_t \) where \( J = (t_1, \cdots , t_n) \). To begin with suppose

\[
F = F_{t_1} \times \cdots \times F_{t_n}
\]

where each \( F_{t_i} \) is in \( B(M_{t_i}) \). Then

\[
\int_{M_{t_1} \times \cdots \times M_{t_n}} \mathcal{X}_F (x_{t_1}, \cdots , x_{t_n}) \, d\nu_{t_1 \cdots t_n} = \nu_{t_1 \cdots t_n} (F_{t_1} \times \cdots \times F_{t_n})
\]

\[
= P(\prod_{t \in I} F_t) = \int_{\Omega} \mathcal{X}_{\prod_{t \in I} F_t} (x) \, dP
\]

\[
= \int_{\Omega} \mathcal{X}_F (x_{t_1}, \cdots , x_{t_n}) \, dP
\]

where \( F_t = M_t \) if \( t \notin J \). Let \( K \) denote sets, \( F \) of the sort in \( \text{12.4.4} \). It is clearly a \( \pi \) system. Now let \( \mathcal{G} \) denote those sets \( F \) in \( B(\prod_{t \in J} M_t) \) such that \( \text{12.4.4} \) holds. Thus \( \mathcal{G} \supseteq K \). It is clear that \( \mathcal{G} \) is closed with respect to countable disjoint unions and complements. Hence \( \mathcal{G} \supseteq \sigma (K) \) but \( \sigma (K) = B(\prod_{t \in J} M_t) \) because every open set in \( \prod_{t \in J} M_t \) is the countable union of rectangles like \( \text{12.4.4} \) in which each \( F_t \) is open. Therefore, \( \text{12.4.4} \) holds for every \( F \in B(\prod_{t \in J} M_t) \).

Passing to simple functions and then using the monotone convergence theorem yields the final claim of the theorem. \( \blacksquare \)

The next task is to consider the case where \( M_t = (-\infty, \infty)^{m_t} \). To consider this case, here is a lemma which will allow this case to be deduced from the above theorem. In this lemma, \( M'_t \equiv [-\infty, \infty]^{m_t} \).

**Lemma 12.4.4** Let \( J \) be a finite subset of \( I \). Then \( U \) is a Borel set in \( \prod_{t \in J} M_t \) if and only if there exists a Borel set, \( U' \) in \( \prod_{t \in J} M'_t \) such that \( U = U' \cap \prod_{t \in J} M_t \).

**Proof:** A subbasis for the topology for \( [-\infty, \infty] \) is sets of the form \([-\infty, a)\) and \((a, \infty]\). Also a subbasis for the topology of \([\infty, \infty]^n \) is sets of the form \( \prod_{i=1}^n [-\infty, a_i] \) and \( \prod_{i=1}^n (a_i, \infty] \). Similarly, a subbasis for the topology of \((\infty, \infty)^n \) consists of sets of the form \( \prod_{i=1}^n (\infty, a_i] \) and \( \prod_{i=1}^n (a_i, \infty] \). Thus the basic open sets of \( \prod_{t \in J} M_t \) are of the form \( U' \cap \prod_{t \in J} M_t \) where \( U' \) is a basic open set in \( \prod_{t \in J} M'_t \). It follows the open sets of \( \prod_{t \in J} M_t \) are of the form \( U' \cap \prod_{t \in J} M_t \) where \( U' \) is open in \( \prod_{t \in J} M'_t \). Let \( F \) denote those Borel sets of \( \prod_{t \in J} M_t \) which are of the
form $U' \cap \prod_{t \in J} M_t$ for $U'$ a Borel set in $\prod_{t \in J} M'_t$. Then as just shown, $\mathcal{F}$ contains the $\pi$ system of open sets in $\prod_{t \in J} M_t$. Let $\mathcal{G}$ denote those Borel sets of $\prod_{t \in J} M_t$ which are of the desired form. It is clearly closed with respect to complements and countable disjoint unions. Hence $\mathcal{G}$ equals the Borel sets of $\prod_{t \in J} M_t$. ■

Maybe this diagram will help to keep the argument straight.

Now here is the Kolmogorov extension theorem in the desired form.

**Theorem 12.4.5** (Kolmogorov extension theorem) For each finite set $J = (t_1, \ldots, t_n) \subseteq I$,

suppose there exists a Borel probability measure, $\nu_J = \nu_{t_1, \ldots, t_n}$ defined on the Borel sets of $\prod_{t \in J} M_t$ for $M_t = \mathbb{R}^{n_t}$ for $n_t$ an integer, such that the following consistency condition holds. If

$$(t_1, \ldots, t_n) \subseteq (s_1, \ldots, s_p),$$

then

$$\nu_{t_1, \ldots, t_n} (F_{t_1} \times \cdots \times F_{t_n}) = \nu_{s_1, \ldots, s_p} (G_{s_1} \times \cdots \times G_{s_p})$$

(12.4.6)

where if $s_i = t_j$, then $G_{s_i} = F_{t_j}$ and if $s_i$ is not equal to any of the indices, $t_k$, then $G_{s_i} = M_{s_i}$. Then for $\mathcal{E}$ defined as in Definition 12.4.1, adjusted so that $\pm \infty$ never appears as any endpoint of any interval, there exists a probability measure, $P$ and a $\sigma$ algebra $\mathcal{F} = \sigma(\mathcal{E})$ such that

$$\left( \prod_{t \in I} M_t, P, \mathcal{F} \right)$$

is a probability space. Also there exist measurable functions, $X_s : \prod_{t \in I} M_t \to M_s$ defined as

$$X_s(x) = x_s$$

for each $s \in I$ such that for each $(t_1 \cdots t_n) \subseteq I$,

$$\nu_{t_1, \ldots, t_n} (F_{t_1} \times \cdots \times F_{t_n}) = P (\text{[}X_{t_1} \in F_{t_1}] \cap \cdots \cap [X_{t_n} \in F_{t_n}]\text{])$$

$$= P \left( \bigcap_{j=1}^{n} F_{t_j} \right) = P \left( \prod_{t \in I} F_t \right)$$

(12.4.7)

where $F_t = M_t$ for every $t \notin \{t_1, \ldots, t_n\}$ and $F_{t_i}$ is a Borel set. Also if $f$ is a nonnegative function of finitely many variables, $x_{t_1}, \ldots, x_{t_n}$, measurable with respect to
$B\left(\prod_{j=1}^{n} M_{t_j}\right)$, then $f$ is also measurable with respect to $\mathcal{F}$ and

$$\int_{M_{t_1} \times \cdots \times M_{t_n}} f(x_{t_1}, \cdots, x_{t_n}) \, d\nu_{t_1 \cdots t_n} = \int_{\prod_{j \in I} M_{t_j}} f(x_{t_1}, \cdots, x_{t_n}) \, dP$$

(12.4.8)

**Proof:** Using Lemma 12.4.4 extend each measure, $\nu_j$ to $M'_j$, defined by adding in the points $\pm \infty$ at the ends, by letting $\nu_j(E) = \nu_j(E \cap \prod_{i \in I} M_i)$ for all $E \in B\left(\prod_{i \in I} M'_j\right)$. Then apply Theorem 12.4.3 to these extended measures and use the definition of the extensions of each $\nu_j$ to replace each $M'_j$ with $M_j$ everywhere it occurs.

As a special case, you can obtain a version of product measure for possibly infinitely many factors. Suppose in the context of the above theorem that $\nu_t$ is a probability measure defined on the Borel sets of $M_t \equiv \mathbb{R}^{n_t}$ for $n_t$ a positive integer, and let the measures, $\nu_{t_1 \cdots t_n}$ be defined on the Borel sets of $\prod_{i=1}^{n} M_{t_i}$ by

$$\nu_{t_1 \cdots t_n}(E) \equiv (\nu_{t_1} \times \cdots \times \nu_{t_n})(E).$$

Then these measures satisfy the necessary consistency condition and so the Kolmogorov extension theorem given above can be applied to obtain a measure $P$ defined on a $(\prod_{i \in I} M_i, \mathcal{F})$ and measurable functions $X_s : \prod_{i \in I} M_i \to M_s$ such that for $F_{t_i}$ a Borel set in $M_{t_i}$,

$$P\left( (X_{t_1}, \cdots, X_{t_n}) \in \prod_{i=1}^{n} F_{t_i} \right) = \nu_{t_1 \cdots t_n}(F_{t_1} \times \cdots \times F_{t_n})$$

$$= \nu_{t_1}(F_{t_1}) \cdots \nu_{t_n}(F_{t_n}).$$

(12.4.9)

In particular, $P(X_t \in F_t) = \nu_t(F_t)$. Then $P$ in the resulting probability space,

$$\left( \prod_{i \in I} M_i, \mathcal{F}, P \right)$$

will be denoted as $\prod_{i \in I} \nu_t$. This proves the following theorem which describes an infinite product measure.

**Theorem 12.4.6** Let $M_t$ for $t \in I$ be given as in Theorem 12.4.3 and let $\nu_t$ be a Borel probability measure defined on the Borel sets of $M_t$. Then there exists a measure $P$ and a $\sigma$ algebra $\mathcal{F} = \sigma(\mathcal{E})$ where $\mathcal{E}$ is given in Definition 12.4.4 such that $(\prod_{i \in I} M_i, \mathcal{F}, P)$ is a probability space satisfying (12.4.3) whenever each $F_{t_i}$ is a Borel set of $M_{t_i}$. This probability measure is sometimes denoted as $\prod_{i \in I} \nu_t$. 
12.5 Exercises

1. Let \((X, \mathcal{S}, \mu)\) and \((Y, \mathcal{F}, \lambda)\) be two finite measure spaces. A subset of \(X \times Y\) is called a measurable rectangle if it is of the form \(A \times B\) where \(A \in \mathcal{S}\) and \(B \in \mathcal{F}\). A subset of \(X \times Y\) is called an elementary set if it is a finite disjoint union of measurable rectangles. Denote this set of functions by \(\mathcal{E}\). Show that \(\mathcal{E}\) is an algebra of sets.

2. For \(A \in \sigma(\mathcal{E})\), the smallest \(\sigma\) algebra containing \(\mathcal{E}\), show that \(x \to \chi_A(x, y)\) is \(\mu\) measurable and that
   \[
y \to \int \chi_A(x, y) \, d\mu \]
   is \(\lambda\) measurable. Show similar assertions hold for \(y \to \chi_A(x, y)\) and
   \[
x \to \int \chi_A(x, y) \, d\lambda \]
   and that
   \[
   \int \int \chi_A(x, y) \, d\mu \, d\lambda = \int \int \chi_A(x, y) \, d\lambda \, d\mu. \tag{12.5.10}
   \]
   **Hint:** Let \(\mathcal{M} \equiv \{A \in \sigma(\mathcal{E}) : [12.5.10] \text{ holds}\}\) along with all relevant measurability assertions. Show \(\mathcal{M}\) contains \(\mathcal{E}\) and is a monotone class. Then apply the Theorem [12.5.10].

3. For \(A \in \sigma(\mathcal{E})\) define \((\mu \times \lambda)(A) \equiv \int \int \chi_A(x, y) \, d\mu \, d\lambda\). Show that \((\mu \times \lambda)\) is a measure on \(\sigma(\mathcal{E})\) and that whenever \(f \geq 0\) is measurable with respect to \(\sigma(\mathcal{E})\),
   \[
   \int_{X \times Y} f \, d(\mu \times \lambda) = \int \int f(x, y) \, d\mu \, d\lambda = \int \int f(x, y) \, d\lambda \, d\mu.
   \]
   This is a common approach to Fubini’s theorem.

4. Generalize the above version of Fubini’s theorem to the case where the measure spaces are only \(\sigma\) finite.

5. Suppose now that \(\mu\) and \(\lambda\) are both complete \(\sigma\) finite measures. Let \(\overline{(\mu \times \lambda)}\) denote the completion of this measure. Let the larger measure space be \(\overline{(X \times Y)}\). Thus if \(E \in \sigma(\overline{\mathcal{E}})\), it follows there exists a set \(A \in \sigma(\mathcal{E})\) such that \(E \cup N = A\) where \(\overline{(\mu \times \lambda)}(N) = 0\). Now argue that for \(\lambda\) a.e. \(y, x \to \chi_N(x, y)\) is measurable because it is equal to zero \(\mu\) a.e. and \(\mu\) is complete. Therefore,
   \[
   \int \int \chi_N(x, y) \, d\mu \, d\lambda
   \]
makes sense and equals zero. Use to argue that for \( \lambda \) a.e. \( y, x \to \mathcal{X}_E(x, y) \) is \( \mu \) measurable and equals \( \int \mathcal{X}_A(x, y) \, d\mu \). Then by completeness of \( \lambda, y \to \int \mathcal{X}_E(x, y) \, d\mu \) is \( \lambda \) measurable and

\[
\int \int \mathcal{X}_A(x, y) \, d\mu d\lambda = \int \int \mathcal{X}_E(x, y) \, d\mu d\lambda = (\mu \times \lambda)(E).
\]

Similarly

\[
\int \int \mathcal{X}_E(x, y) \, d\lambda d\mu = (\mu \times \lambda)(E).
\]

Use this to give a generalization of the above Fubini theorem. Prove that if \( f \) is measurable with respect to the \( \sigma \) algebra, \( \sigma(E) \) and nonnegative, then

\[
\int_{X \times Y} f d(\mu \times \lambda) = \int \int f(x, y) \, d\mu d\lambda = \int \int f(x, y) \, d\lambda d\mu
\]

where the iterated integrals make sense.
Chapter 13

The $L^p$ Spaces

13.1 Basic Inequalities And Properties

One of the main applications of the Lebesgue integral is to the study of various sorts of functions space. These are vector spaces whose elements are functions of various types. One of the most important examples of a function space is the space of measurable functions whose absolute values are $p^{th}$ power integrable where $p \geq 1$. These spaces, referred to as $L^p$ spaces, are very useful in applications. In the chapter $(\Omega, S, \mu)$ will be a measure space.

**Definition 13.1.1** Let $1 \leq p < \infty$. Define

$$L^p(\Omega) = \{ f : f \text{ is measurable and } \int_{\Omega} |f(\omega)|^p d\mu < \infty \}$$

In terms of the distribution function,

$$L^p(\Omega) = \{ f : f \text{ is measurable and } \int_{1}^{\infty} pt^{p-1} \mu(|f| > t) dt < \infty \}$$

For each $p > 1$ define $q$ by

$$\frac{1}{p} + \frac{1}{q} = 1.$$

Often one uses $p'$ instead of $q$ in this context.

$L^p(\Omega)$ is a vector space and has a norm. This is similar to the situation for $\mathbb{R}^n$ but the proof requires the following fundamental inequality.

**Theorem 13.1.2** (Holder’s inequality) If $f$ and $g$ are measurable functions, then if $p > 1$,

$$\int |f| |g| \ d\mu \leq \left( \int |f|^p d\mu \right)^{\frac{1}{p}} \left( \int |g|^q d\mu \right)^{\frac{1}{q}}. \quad (13.1.1)$$

**Proof:** First here is a proof of Young’s inequality.
Lemma 13.1.3 If $p > 1$, and $0 \leq a, b$ then $ab \leq \frac{a^p}{p} + \frac{b^q}{q}$.

Proof: Consider the following picture:

![Graph](image)

From this picture, the sum of the area between the $x$ axis and the curve added to the area between the $t$ axis and the curve is at least as large as $ab$. Using beginning calculus, this is equivalent to the following inequality.

$$ab \leq \int_0^a t^{p-1} dt + \int_0^b x^{q-1} dx = \frac{a^p}{p} + \frac{b^q}{q}.$$  

The above picture represents the situation which occurs when $p > 2$ because the graph of the function is concave up. If $2 \geq p > 1$ the graph would be concave down or a straight line. You should verify that the same argument holds in these cases just as well. In fact, the only thing which matters in the above inequality is that the function $x = t^{p-1}$ be strictly increasing.

Note equality occurs when $a^p = b^q$.

Here is an alternate proof.

Lemma 13.1.4 For $a, b \geq 0$,

$$ab \leq \frac{a^p}{p} + \frac{b^q}{q}$$

and equality occurs when if and only if $a^p = b^q$.

Proof: If $b = 0$, the inequality is obvious. Fix $b > 0$ and consider

$$f(a) = \frac{a^p}{p} + \frac{b^q}{q} - ab.$$

Then $f'(a) = a^{p-1} - b$. This is negative when $a < b^{1/(p-1)}$ and is positive when $a > b^{1/(p-1)}$. Therefore, $f$ has a minimum when $a = b^{1/(p-1)}$. In other words, when $a^p = b^{p/(p-1)} = b^q$ since $1/p + 1/q = 1$. Thus the minimum value of $f$ is

$$\frac{b^q}{p} + \frac{b^q}{q} - b^{1/(p-1)}b = b^q - b^q = 0.$$

It follows $f \geq 0$ and this yields the desired inequality.
Proof of Holder’s inequality: If either \( \int |f|^p \, d\mu \) or \( \int |g|^p \, d\mu \) equals \( \infty \), the inequality \( 13.1.1 \) is obviously valid because \( \infty \geq \) anything. If either \( \int |f|^p \, d\mu \) or \( \int |g|^p \, d\mu \) equals 0, then \( f = 0 \) a.e. or that \( g = 0 \) a.e. and so in this case the left side of the inequality equals 0 and so the inequality is therefore true. Therefore assume both \( \int |f|^p \, d\mu \) and \( \int |g|^p \, d\mu \) are less than \( \infty \) and not equal to 0. Let 

\[
\left( \int |f|^p \, d\mu \right)^{1/p} = I(f)
\]

and let \( \left( \int |g|^p \, d\mu \right)^{1/q} = I(g) \). Then using the lemma,

\[
\int \frac{|f|}{I(f)} \frac{|g|}{I(g)} \, d\mu \leq \frac{1}{p} \int \frac{|f|^p}{I(f)^p} \, d\mu + \frac{1}{q} \int \frac{|g|^q}{I(g)^q} \, d\mu = 1.
\]

Hence,

\[
\int |f| |g| \, d\mu \leq I(f) I(g) = \left( \int |f|^p \, d\mu \right)^{1/p} \left( \int |g|^q \, d\mu \right)^{1/q}.
\]

This proves Holder’s inequality.

The following lemma will be needed.

**Lemma 13.1.5** Suppose \( x, y \in \mathbb{C} \). Then

\[
|x + y|^p \leq 2^{p-1} (|x|^p + |y|^p).
\]

**Proof:** The function \( f(t) = t^p \) is concave up for \( t \geq 0 \) because \( p > 1 \). Therefore, the secant line joining two points on the graph of this function must lie above the graph of the function. This is illustrated in the following picture.

```
(\( |x| + |y| \)/2 = m
```

Now as shown above,

\[
\left( \frac{|x| + |y|}{2} \right)^p \leq \frac{|x|^p + |y|^p}{2}
\]

which implies

\[
|x + y|^p \leq (|x| + |y|)^p \leq 2^{p-1} (|x|^p + |y|^p)
\]

and this proves the lemma.

Note that if \( y = \phi(x) \) is any function for which the graph of \( \phi \) is concave up, you could get a similar inequality by the same argument.
Corollary 13.1.6 (Minkowski inequality) Let $1 \leq p < \infty$. Then
\[
\left( \int |f + g|^p \, d\mu \right)^{1/p} \leq \left( \int |f|^p \, d\mu \right)^{1/p} + \left( \int |g|^p \, d\mu \right)^{1/p}. \tag{13.1.2}
\]

Proof: If $p = 1$, this is obvious because it is just the triangle inequality. Let $p > 1$. Without loss of generality, assume
\[
\left( \int |f|^p \, d\mu \right)^{1/p} + \left( \int |g|^p \, d\mu \right)^{1/p} < \infty
\]
and $(\int |f + g|^p \, d\mu)^{1/p} \neq 0$ or there is nothing to prove. Therefore, using the above lemma,
\[
\int |f + g|^p \, d\mu \leq 2^{p-1} \left( \int |f|^p + |g|^p \, d\mu \right) < \infty.
\]
Now $|f(\omega) + g(\omega)|^p \leq |f(\omega) + g(\omega)|^{p-1} (|f(\omega)| + |g(\omega)|)$. Also, it follows from the definition of $p$ and $q$ that $p - 1 = \frac{p}{q}$. Therefore, using this and Holder’s inequality,
\[
\int |f + g|^p \, d\mu \leq
\]
\[
\int |f + g|^{p-1} |f| \, d\mu + \int |f + g|^{p-1} |g| \, d\mu
\]
\[
= \int |f + g|^\frac{p}{q} |f| \, d\mu + \int |f + g|^\frac{p}{q} |g| \, d\mu
\]
\[
\leq \left( \int |f + g|^p \, d\mu \right)^\frac{1}{p} \left( \int |f|^p \, d\mu \right)^\frac{1}{q} + \left( \int |f + g|^p \, d\mu \right)^\frac{1}{p} \left( \int |g|^p \, d\mu \right)^\frac{1}{q}.
\]
Dividing both sides by $(\int |f + g|^p \, d\mu)^{1/p}$ yields \textcolor{red}{\textbf{3.3.1}}. This proves the corollary.

The following follows immediately from the above.

Corollary 13.1.7 Let $f_i \in L^p(\Omega)$ for $i = 1, 2, \cdots, n$. Then
\[
\left( \int \left| \sum_{i=1}^n f_i \right|^p \, d\mu \right)^{1/p} \leq \sum_{i=1}^n \left( \int |f_i|^p \, d\mu \right)^{1/p}.
\]

This shows that if $f, g \in L^p$, then $f + g \in L^p$. Also, it is clear that if $a$ is a constant and $f \in L^p$, then $af \in L^p$ because
\[
\int |af|^p \, d\mu = |a|^p \int |f|^p \, d\mu < \infty.
\]
Thus $L^p$ is a vector space and

a.) $(\int |f|^p \, d\mu)^{1/p} \geq 0$, $(\int |f|^p \, d\mu)^{1/p} = 0$ if and only if $f = 0$ a.e.
13.1. BASIC INEQUALITIES AND PROPERTIES

b.) \( (\int |af|^p \, d\mu)^{1/p} = |a| \left( \int |f|^p \, d\mu \right)^{1/p} \) if \( a \) is a scalar.

c.) \( (\int |f + g|^p \, d\mu)^{1/p} \leq (\int |f|^p \, d\mu)^{1/p} + (\int |g|^p \, d\mu)^{1/p} \).

\( f \to (\int |f|^p \, d\mu)^{1/p} \) would define a norm if \( (\int |f|^p \, d\mu)^{1/p} = 0 \) implied \( f = 0 \). Unfortunately, this is not so because if \( f = 0 \) a.e. but is nonzero on a set of measure zero, \( (\int |f|^p \, d\mu)^{1/p} = 0 \) and this is not allowed. However, all the other properties of a norm are available and so a little thing like a set of measure zero will not prevent the consideration of \( L^p \) as a normed vector space if two functions in \( L^p \) which differ only on a set of measure zero are considered the same. That is, an element of \( L^p \) is really an equivalence class of functions where two functions are equivalent if they are equal a.e. With this convention, here is a definition.

**Definition 13.1.8** Let \( f \in L^p(\Omega) \). Define

\[
||f||_p \equiv ||f||_{L^p} \equiv \left( \int |f|^p \, d\mu \right)^{1/p}.
\]

Then with this definition and using the convention that elements in \( L^p \) are considered to be the same if they differ only on a set of measure zero, \( || \cdot ||_p \) is a norm on \( L^p(\Omega) \) because if \( ||f||_p = 0 \) then \( f = 0 \) a.e. and so \( f \) is considered to be the zero function because it differs from 0 only on a set of measure zero.

The following is an important definition.

**Definition 13.1.9** A complete normed linear space is called a Banach space.

\( L^p \) is a Banach space. This is the next big theorem.

**Theorem 13.1.10** The following hold for \( L^p(\Omega) \)

a.) \( L^p(\Omega) \) is complete.

b.) If \( \{f_n\} \) is a Cauchy sequence in \( L^p(\Omega) \), then there exists \( f \in L^p(\Omega) \) and a subsequence which converges a.e. to \( f \in L^p(\Omega) \), and \( ||f_n - f||_p \to 0 \).

**Proof:** Let \( \{f_n\} \) be a Cauchy sequence in \( L^p(\Omega) \). This means that for every \( \varepsilon > 0 \) there exists \( N \) such that if \( n, m \geq N \), then \( ||f_n - f_m||_p < \varepsilon \). Now select a subsequence as follows. Let \( n_1 \) be such that \( ||f_n - f_m||_p < 2^{-1} \) whenever \( n, m \geq n_1 \).

---

These spaces are named after Stefan Banach, 1892-1945. Banach spaces are the basic item of study in the subject of functional analysis and will be considered later in this book.

There is a recent biography of Banach, R. Katuža, *The Life of Stefan Banach*, (A. Kostant and W. Woyczyński, translators and editors) Birkhauser, Boston (1996). More information on Banach can also be found in a recent short article written by Douglas Henderson who is in the department of chemistry and biochemistry at BYU.

Banach was born in Austria, worked in Poland and died in the Ukraine but never moved. This is because borders kept changing. There is a rumor that he died in a German concentration camp which is apparently not true. It seems he died after the war of lung cancer.

He was an interesting character. He hated taking examinations so much that he did not receive his undergraduate university degree. Nevertheless, he did become a professor of mathematics due to his important research. He and some friends would meet in a cafe called the Scottish cafe where they wrote on the marble table tops until Banach’s wife supplied them with a notebook which became the "Scottish notebook" and was eventually published.
Let \( n_2 \) be such that \( n_2 > n_1 \) and \( \| f_n - f_m \|_p < 2^{-2} \) whenever \( n, m \geq n_2 \). If \( n_1, \ldots, n_k \) have been chosen, let \( n_{k+1} > n_k \) and whenever \( n, m \geq n_{k+1}, \| f_n - f_m \|_p < 2^{-(k+1)} \). The subsequence just mentioned is \( \{ f_{n_k} \} \). Thus, \( \| f_{n_k} - f_{n_{k+1}} \|_p < 2^{-k} \). Let

\[
g_{k+1} = f_{n_{k+1}} - f_{n_k}.
\]

Then by the corollary to Minkowski’s inequality,

\[
\infty > \sum_{k=1}^{\infty} \| g_{k+1} \|_p \geq \sum_{k=1}^{m} \| g_{k+1} \|_p \geq \left\| \sum_{k=1}^{m} g_{k+1} \right\|_p
\]

for all \( m \). It follows that

\[
\int \left( \sum_{k=1}^{m} |g_{k+1}| \right)^p d\mu \leq \left( \sum_{k=1}^{\infty} \| g_{k+1} \|_p \right)^p < \infty
\]

for all \( m \) and so the monotone convergence theorem implies that the sum up to \( m \) in \( \{ g_{k+1} \} \) can be replaced by a sum up to \( \infty \). Thus,

\[
\int \left( \sum_{k=1}^{\infty} |g_{k+1}| \right)^p d\mu < \infty
\]

which requires

\[
\sum_{k=1}^{\infty} |g_{k+1}(x)| < \infty \text{ a.e. } x.
\]

Therefore, \( \sum_{k=1}^{\infty} g_{k+1}(x) \) converges for a.e. \( x \) because the functions have values in a complete space, \( C \), and this shows the partial sums form a Cauchy sequence. Now let \( x \) be such that this sum is finite. Then define

\[
f(x) \equiv f_{n_1}(x) + \sum_{k=1}^{\infty} g_{k+1}(x) = \lim_{m \to \infty} f_{n_m}(x)
\]

since \( \sum_{k=1}^{m} g_{k+1}(x) = f_{n_{m+1}}(x) - f_{n_1}(x) \). Therefore there exists a set, \( E \) having measure zero such that

\[
\lim_{k \to \infty} f_{n_k}(x) = f(x)
\]

for all \( x \notin E \). Redefine \( f_{n_k} \) to equal 0 on \( E \) and let \( f(x) = 0 \) for \( x \in E \). It then follows that \( \lim_{k \to \infty} f_{n_k}(x) = f(x) \) for all \( x \). By Fatou’s lemma, and the Minkowski inequality,

\[
\| f - f_{n_k} \|_p = \left( \int |f - f_{n_k}|^p d\mu \right)^{1/p} \leq \lim_{m \to \infty} \left( \int |f_m - f_{n_k}|^p d\mu \right)^{1/p} = \lim_{m \to \infty} \| f_m - f_{n_k} \|_p \leq
\]
13.1. BASIC INEQUALITIES AND PROPERTIES

\[
\lim \inf_{m \to \infty} \sum_{j=k}^{m-1} \left| f_{n_{j+1}} - f_{n_j} \right|_p \leq \sum_{i=k}^{\infty} \left| f_{n_{i+1}} - f_{n_i} \right|_p \leq 2^{-(k-1)}. \tag{13.1.4}
\]

Therefore, \( f \in L^p(\Omega) \) because

\[
\|f\|_p \leq \|f - f_{n_k}\|_p + \|f_{n_k}\|_p < \infty,
\]

and \( \lim_{k \to \infty} \|f_{n_k} - f\|_p = 0 \). This proves \( \text{b).} \)

This has shown \( f_{n_k} \) converges to \( f \) in \( L^p(\Omega) \). It follows the original Cauchy sequence also converges to \( f \) in \( L^p(\Omega) \). This is a general fact that if a subsequence of a Cauchy sequence converges, then so does the original Cauchy sequence. You should give a proof of this. This proves the theorem.

In working with the \( L^p \) spaces, the following inequality also known as Minkowski’s inequality is very useful. It is similar to the Minkowski inequality for sums. To see this, replace the integral, \( \int_X \) with a finite summation sign and you will see the usual Minkowski inequality or rather the version of it given in Corollary 7.1.7.

To prove this theorem first consider a special case of it in which technical considerations which shed no light on the proof are excluded.

**Lemma 13.1.11** Let \((X, \mathcal{S}, \mu)\) and \((Y, \mathcal{F}, \lambda)\) be finite complete measure spaces and let \( f \) be \( \mu \times \lambda \) measurable and uniformly bounded. Then the following inequality is valid for \( p \geq 1 \).

\[
\int_X \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu \geq \left( \int_Y \left( \int_X |f(x,y)|^p d\mu \right)^{\frac{1}{p}} d\lambda \right)^{\frac{1}{p}}. \tag{13.1.5}
\]

**Proof:** Since \( f \) is bounded and \( \mu(X), \lambda(Y) < \infty \),

\[
\left( \int_Y \left( \int_X |f(x,y)|^p d\mu \right)^{\frac{1}{p}} d\lambda \right)^{\frac{1}{p}} < \infty.
\]

Let

\[
J(y) = \int_X |f(x,y)| d\mu.
\]

Note there is no problem in writing this for a.e. \( y \) because \( f \) is product measurable. Then by Fubini’s theorem,

\[
\int_Y \left( \int_X |f(x,y)| d\mu \right)^p d\lambda = \int_Y J(y)^{p-1} \int_X |f(x,y)| d\mu d\lambda
= \int_X \int_Y J(y)^{p-1} |f(x,y)| d\lambda d\mu.
\]

Now apply Holder’s inequality in the last integral above and recall \( p - 1 = \frac{p}{q} \). This
yields
\[
\int_Y \left( \int_X |f(x,y)| d\mu \right)^p d\lambda \\
\leq \int_X \left( \int_Y J(y)^p d\lambda \right)^{\frac{1}{p}} \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu \\
= \left( \int_Y J(y)^p d\lambda \right)^{\frac{1}{p}} \int_X \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu \\
= \left( \int_Y \left( \int_X |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} \right)^{\frac{1}{p}} \int_X \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu. \tag{13.1.6}
\]
Therefore, dividing both sides by the first factor in the above expression,
\[
\left( \int_Y \left( \int_X |f(x,y)| d\mu \right)^p d\lambda \right)^{\frac{1}{p}} \leq \int_X \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu. \tag{13.1.7}
\]
Note that (13.1.7) holds even if the first factor of (13.1.6) equals zero. This proves the lemma.

Now consider the case where \( f \) is not assumed to be bounded and where the measure spaces are \( \sigma \)-finite.

**Theorem 13.1.12** Let \((X, S, \mu)\) and \((Y, F, \lambda)\) be \( \sigma \)-finite measure spaces and let \( f \) be product measurable. Then the following inequality is valid for \( p \geq 1 \).
\[
\int_X \left( \int_Y |f(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu \leq \left( \int_Y \left( \int_X |f(x,y)| d\mu \right)^p d\lambda \right)^{\frac{1}{p}}. \tag{13.1.8}
\]

**Proof:** Since the two measure spaces are \( \sigma \)-finite, there exist measurable sets, \( X_m \) and \( Y_k \) such that \( X_m \subseteq X_{m+1} \) for all \( m \), \( Y_k \subseteq Y_{k+1} \) for all \( k \), and \( \mu (X_m) \), \( \lambda (Y_k) \) < \( \infty \). Now define
\[
f_n (x,y) \equiv \begin{cases} f(x,y) & \text{if} \ |f(x,y)| \leq n \\ n & \text{if} \ |f(x,y)| > n. \end{cases}
\]
Thus \( f_n \) is uniformly bounded and product measurable. By the above lemma,
\[
\int_{X_m} \left( \int_{Y_k} |f_n(x,y)|^p d\lambda \right)^{\frac{1}{p}} d\mu \geq \left( \int_{Y_k} \left( \int_{X_m} |f_n(x,y)| d\mu \right)^p d\lambda \right)^{\frac{1}{p}}. \tag{13.1.9}
\]
Now observe that \( |f_n(x,y)| \) increases in \( n \) and the pointwise limit is \( |f(x,y)| \). Therefore, using the monotone convergence theorem in (13.1.9) yields the same inequality with \( f \) replacing \( f_n \). Next let \( k \to \infty \) and use the monotone convergence theorem again to replace \( Y_k \) with \( Y \). Finally let \( m \to \infty \) in what is left to obtain (13.1.8). This proves the theorem.
13.2. DENSITY CONSIDERATIONS

Note that the proof of this theorem depends on two manipulations, the interchange of the order of integration and Holder’s inequality. Note that there is nothing to check in the case of double sums. Thus if \( a_{ij} \geq 0 \), it is always the case that

\[
\left( \sum_j \left( \sum_i a_{ij} \right)^p \right)^{1/p} \leq \sum_i \left( \sum_j a_{ij}^p \right)^{1/p}
\]

because the integrals in this case are just sums and \((i,j) \rightarrow a_{ij}\) is measurable.

The \( L^p \) spaces have many important properties.

13.2 Density Considerations

**Theorem 13.2.1** Let \( p \geq 1 \) and let \((\Omega, \mathcal{S}, \mu)\) be a measure space. Then the simple functions are dense in \( L^p(\Omega) \).

**Proof:** Recall that a function, \( f \), having values in \( \mathbb{R} \) can be written in the form \( f = f^+ - f^- \) where

\[
f^+ = \max(0, f), \quad f^- = \max(0, -f).
\]

Therefore, an arbitrary complex valued function, \( f \) is of the form

\[
f = \text{Re } f^+ - \text{Re } f^- + i (\text{Im } f^+ - \text{Im } f^-).
\]

If each of these nonnegative functions is approximated by a simple function, it follows \( f \) is also approximated by a simple function. Therefore, there is no loss of generality in assuming at the outset that \( f \geq 0 \).

Since \( f \) is measurable, Theorem 9.3.9 implies there is an increasing sequence of simple functions, \( \{s_n\} \), converging pointwise to \( f(x) \). Now

\[
|f(x) - s_n(x)| \leq |f(x)|.
\]

By the Dominated Convergence theorem,

\[
0 = \lim_{n \to \infty} \int |f(x) - s_n(x)|^p d\mu.
\]

Thus simple functions are dense in \( L^p \).

Recall that for \( \Omega \) a topological space, \( C_c(\Omega) \) is the space of continuous functions with compact support in \( \Omega \). Also recall the following definition.

**Definition 13.2.2** Let \((\Omega, \mathcal{S}, \mu)\) be a measure space and suppose \((\Omega, \tau)\) is also a topological space. Then \((\Omega, \mathcal{S}, \mu)\) is called a regular measure space if the \( \sigma \) algebra of Borel sets is contained in \( \mathcal{S} \) and for all \( E \in \mathcal{S} \),

\[
\mu(E) = \inf\{ \mu(V) : V \supseteq E \text{ and } V \text{ open} \}.
\]
and if $\mu(E) < \infty$,

$$\mu(E) = \sup \{ \mu(K) : K \subseteq E \text{ and } K \text{ is compact} \}$$

and $\mu(K) < \infty$ for any compact set, $K$.

For example, Lebesgue measure is an example of such a measure. More generally, these measures are often referred to as Radon measures.

**Lemma 13.2.3** Let $\Omega$ be a metric space in which the closed balls are compact and let $K$ be a compact subset of $V$, an open set. Then there exists a continuous function $f : \Omega \to [0, 1]$ such that $f(x) = 1$ for all $x \in K$ and $\text{spt}(f)$ is a compact subset of $V$. That is, $K \prec f \prec V$.

**Proof:** Let $K \subseteq W \subseteq \overline{W} \subseteq V$ and $\overline{W}$ is compact. To obtain this list of inclusions consider a point in $K$, $x$, and take $B(x, r_x)$ a ball containing $x$ such that $\overline{B}(x, r_x)$ is a compact subset of $V$. Next use the fact that $K$ is compact to obtain the existence of a list, $\{ B(x_i, r_{x_i}/2) \}_{i=1}^m$ which covers $K$. Then let

$$W \equiv \bigcup_{i=1}^m B \left( x_i, \frac{r_{x_i}}{2} \right).$$

It follows since this is a finite union that

$$\overline{W} = \bigcup_{i=1}^m B \left( x_i, \frac{r_{x_i}}{2} \right)$$

and so $\overline{W}$, being a finite union of compact sets is itself a compact set. Also, from the construction

$$\overline{W} \subseteq \bigcup_{i=1}^m B \left( x_i, r_{x_i} \right).$$

Define $f$ by

$$f(x) = \frac{\text{dist}(x, \overline{W})}{\text{dist}(x, K) + \text{dist}(x, \overline{W})}.$$

It is clear that $f$ is continuous if the denominator is always nonzero. But this is clear because if $x \in \overline{W}$ there must be a ball $B(x, r)$ such that this ball does not intersect $K$. Otherwise, $x$ would be a limit point of $K$ and since $K$ is closed, $x \in K$. However, $x \notin K$ because $K \subseteq \overline{W}$.

It is not necessary to be in a metric space to do this. You can accomplish the same thing using Urysohn’s lemma.

**Theorem 13.2.4** Let $(\Omega, S, \mu)$ be a regular measure space as in Definition 13.2.2 where the conclusion of Lemma 13.2.3 holds. Then $C_c(\Omega)$ is dense in $L^p(\Omega)$.

**Proof:** First consider a measurable set, $E$ where $\mu(E) < \infty$. Let $K \subseteq E \subseteq V$ where $\mu(V \setminus K) < \varepsilon$. Now let $K \prec h \prec V$. Then

$$\int |h - \chi_E|^p \, d\mu \leq \int \chi_{V \setminus K}^p \, d\mu = \mu(V \setminus K) < \varepsilon.$$
13.3. SEPARABILITY

It follows that for each \( s \) a simple function in \( L^p(\Omega) \), there exists \( h \in C_c(\Omega) \) such that \( \|s - h\|_p < \varepsilon \). This is because if

\[
s(x) = \sum_{i=1}^{m} c_i \chi_{E_i}(x)
\]

is a simple function in \( L^p \) where the \( c_i \) are the distinct nonzero values of \( s \) each \( \mu(E_i) < \infty \) since otherwise \( s \notin L^p \) due to the inequality

\[
\int |s|^p \, d\mu \geq |c_i|^p \mu(E_i).
\]

By Theorem 13.3.1, simple functions are dense in \( L^p(\Omega) \), and so this proves the Theorem.

13.3 Separability

**Theorem 13.3.1** For \( p \geq 1 \) and \( \mu \) a Radon measure, \( L^p(\mathbb{R}^n, \mu) \) is separable. Recall this means there exists a countable set, \( D \), such that if \( f \in L^p(\mathbb{R}^n, \mu) \) and \( \varepsilon > 0 \), there exists \( g \in D \) such that \( \|f - g\|_p < \varepsilon \).

**Proof:** Let \( Q \) be all functions of the form \( c\chi_{[a,b)} \) where

\[
[a, b) \equiv [a_1, b_1) \times [a_2, b_2) \times \cdots \times [a_n, b_n),
\]

and both \( a_i, b_i \) are rational, while \( c \) has rational real and imaginary parts. Let \( D \) be the set of all finite sums of functions in \( Q \). Thus, \( D \) is countable. In fact \( D \) is dense in \( L^p(\mathbb{R}^n, \mu) \). To prove this it is necessary to show that for every \( f \in L^p(\mathbb{R}^n, \mu) \), there exists an element of \( D, s \) such that \( \|s - f\|_p < \varepsilon \). If it can be shown that for every \( g \in C_c(\mathbb{R}^n) \) there exists \( h \in D \) such that \( \|g - h\|_p < \varepsilon \), then this will suffice because if \( f \in L^p(\mathbb{R}^n) \) is arbitrary, Theorem 13.3.1 implies there exists \( g \in C_c(\mathbb{R}^n) \) such that \( \|f - g\|_p \leq \frac{\varepsilon}{2} \) and then there would exist \( h \in C_c(\mathbb{R}^n) \) such that \( \|h - g\|_p < \frac{\varepsilon}{2} \). By the triangle inequality,

\[
\|f - h\|_p \leq \|h - g\|_p + \|g - f\|_p < \varepsilon.
\]

Therefore, assume at the outset that \( f \in C_c(\mathbb{R}^n) \).

Let \( \mathcal{P}_m \) consist of all sets of the form \( [a, b) \equiv \prod_{i=1}^{n} [a_i, b_i) \) where \( a_i = j2^{-m} \) and \( b_i = (j + 1)2^{-m} \) for \( j \) an integer. Thus \( \mathcal{P}_m \) consists of a tiling of \( \mathbb{R}^n \) into half open rectangles having diameters \( 2^{-m}n \). There are countably many of these rectangles; so, let \( \mathcal{P}_m = \{[a_i, b_i]\}_{i=1}^{\infty} \) and \( \mathbb{R}^n = \bigcup_{i=1}^{\infty} [a_i, b_i) \). Let \( c_i^m \) be complex numbers with rational real and imaginary parts satisfying

\[
|f(a_i) - c_i^m| < 2^{-m},
\]

\[
|c_i^m| \leq |f(a_i)|.
\] (13.3.10)
Let
\[ s_m(x) = \sum_{i=1}^{\infty} c_i^m \chi_{[a_i, b_i]}(x). \]

Since \( f(a_i) = 0 \) except for finitely many values of \( i \), the above is a finite sum. Then \( \|s_m - f\|_p = 0 \) because \( |s_m| \leq |f| \) and so
\[
\|s_m - f\|_p = \left( \int |s_m - f|^p \, d\mu \right)^{1/p} = \left( \int_{\text{spt}(f)} |s_m - f|^p \, d\mu \right)^{1/p} \leq [\varepsilon m_n(\text{spt}(f))]^{1/p}
\]
whenever \( m \) is large enough.

Since \( f \in C_c(\mathbb{R}^n) \) it follows that \( f \) is uniformly continuous and so given \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that if \( |x - y| < \delta \), \( |f(x) - f(y)| < \varepsilon /2 \). Now let \( m \) be large enough that every box in \( P_m \) has diameter less than \( \delta \) and also that \( 2^{-m} < \varepsilon /2 \). Then if \( [a_i, b_i] \) is one of these boxes of \( P_m \), and \( x \in [a_i, b_i] \),
\[
|f(x) - f(a_i)| < \varepsilon /2
\]
and
\[
|f(a_i) - c_i^m| < 2^{-m} < \varepsilon /2.
\]

Therefore, using the triangle inequality, it follows that
\[
|f(x) - c_i^m| = |s_m(x) - f(x)| < \varepsilon
\]
and since \( x \) is arbitrary, this establishes uniform convergence. This proves the theorem.

Here is an easier proof if you know the Weierstrass approximation theorem.

**Theorem 13.3.2** For \( p \geq 1 \) and \( \mu \) a Radon measure, \( L^p(\mathbb{R}^n, \mu) \) is separable. Recall this means there exists a countable set, \( D \), such that if \( f \in L^p(\mathbb{R}^n, \mu) \) and \( \varepsilon > 0 \), there exists \( g \in D \) such that \( \|f - g\|_p < \varepsilon \).

**Proof:** Let \( P \) denote the set of all polynomials which have rational coefficients. Then \( P \) is countable. Let \( \tau_k \in C_c((-(k + 1), (k + 1))^n) \) such that \( [-k, k]^{\sigma} \prec \tau_k \prec ((-k + 1), (k + 1))^n \). Let \( D_k \) denote the functions which are of the form, \( pr_k \) where \( p \in P \). Thus \( D_k \) is also countable. Let \( D \equiv \bigcup_{k=1}^{\infty} D_k \). It follows each function in \( D \) is in \( C_c(\mathbb{R}^n) \) and so it in \( L^p(\mathbb{R}^n, \mu) \). Let \( f \in L^p(\mathbb{R}^n, \mu) \). By regularity of \( \mu \) there exists \( g \in C_c(\mathbb{R}^n) \) such that \( \|f - g\|_{L^p(\mathbb{R}^n, \mu)} < \frac{\varepsilon}{3} \). Let \( k \) be such that \( \text{spt}(g) \subseteq (-k, k)^n \). Now by the Weierstrass approximation theorem there exists a polynomial \( q \) such that
\[
\|g - q\|_{[-(k+1),k+1]^n} = \sup \{|g(x) - q(x)| : x \in [-k, k]^n\} < \frac{\varepsilon}{3k}.
\]
13.4. CONTINUITY OF TRANSLATION

It follows

\[ ||g - \tau_kq||_{[-(k+1),k+1]^n} = ||\tau_kg - \tau_kq||_{[-(k+1),k+1]^n} < \frac{\varepsilon}{3\mu((-k + 1), k + 1)^n}. \]

Without loss of generality, it can be assumed this polynomial has all rational coefficients. Therefore, \( \tau_kq \in D \).

\[ ||g - \tau_kq||_{L^p(\mathbb{R}^n)} = \int_{[-(k+1),k+1]^n} |g(x) - \tau_k(x) q(x)|^p \, d\mu \]
\[ \leq \left( \frac{\varepsilon}{3\mu((-k + 1), k + 1)^n} \right)^p \mu((-k + 1), k + 1)^n \]
\[ < \left( \frac{\varepsilon}{3} \right)^p. \]

It follows

\[ ||f - \tau_kq||_{L^p(\mathbb{R}^n, \mu)} \leq ||f - g||_{L^p(\mathbb{R}^n, \mu)} + ||g - \tau_kq||_{L^p(\mathbb{R}^n, \mu)} < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} < \varepsilon. \]

This proves the theorem.

**Corollary 13.3.3** Let \( \Omega \) be any \( \mu \) measurable subset of \( \mathbb{R}^n \) and let \( \mu \) be a Radon measure. Then \( L^p(\Omega, \mu) \) is separable. Here the \( \sigma \) algebra of measurable sets will consist of all intersections of measurable sets with \( \Omega \) and the measure will be \( \mu \) restricted to these sets.

**Proof:** Let \( \mathcal{D} \) be the restrictions of \( D \) to \( \Omega \). If \( f \in L^p(\Omega) \), let \( F \) be the zero extension of \( f \) to all of \( \mathbb{R}^n \). Let \( \varepsilon > 0 \) be given. By Theorem 13.3.1 or 13.3.2 there exists \( s \in D \) such that \( ||F - s||_{L^p} < \varepsilon \). Thus

\[ ||s - f||_{L^p(\Omega, \mu)} \leq ||s - F||_{L^p(\mathbb{R}^n, \mu)} < \varepsilon \]

and so the countable set \( \mathcal{D} \) is dense in \( L^p(\Omega) \).

### 13.4 Continuity Of Translation

**Definition 13.4.1** Let \( f \) be a function defined on \( U \subseteq \mathbb{R}^n \) and let \( w \in \mathbb{R}^n \). Then \( f_w \) will be the function defined on \( w + U \) by

\[ f_w(x) = f(x - w). \]

**Theorem 13.4.2** (Continuity of translation in \( L^p \)) Let \( f \in L^p(\mathbb{R}^n) \) with the measure being Lebesgue measure. Then

\[ \lim_{||w|| \to 0} ||f_w - f||_p = 0. \]
 CHAPTER 13. THE $L^p$ SPACES

**Proof**: Let $\varepsilon > 0$ be given and let $g \in C_c(\mathbb{R}^n)$ with $\|g - f\|_p < \frac{\varepsilon}{3}$. Since Lebesgue measure is translation invariant ($m_n(w + E) = m_n(E)$),

$$\|g_w - f_w\|_p = \|g - f\|_p < \frac{\varepsilon}{3}.$$ 

You can see this from looking at simple functions and passing to the limit or you could use the change of variables formula to verify it.

Therefore

$$\|f - f_w\|_p \leq \|f - g\|_p + \|g - g_w\|_p + \|g_w - f_w\|$$

$$< \frac{2\varepsilon}{3} + \|g - g_w\|_p.$$ 

(13.4.11) But $\lim_{w \to 0} g_w(x) = g(x)$ uniformly in $x$ because $g$ is uniformly continuous. Now let $B$ be a large ball containing $\text{spt}(g)$ and let $\delta_1$ be small enough that $B(x, \delta) \subseteq B$ whenever $x \in \text{spt}(g)$. If $\varepsilon > 0$ is given there exists $\delta < \delta_1$ such that if $|w| < \delta$, it follows that $|g(x - w) - g(x)| < \varepsilon/3 \left(1 + m_n(B)^{1/p}\right)$. Therefore,

$$\|g - g_w\|_p = \left(\int_B |g(x) - g(x - w)|^p dm_n\right)^{1/p}$$

$$\leq \varepsilon \frac{m_n(B)^{1/p}}{3 \left(1 + m_n(B)^{1/p}\right)} < \frac{\varepsilon}{3}.$$ 

Therefore, whenever $|w| < \delta$, it follows $\|g - g_w\|_p < \frac{\varepsilon}{3}$ and so from (13.4.11) $\|f - f_w\|_p < \varepsilon$. This proves the theorem.

### 13.5 Mollifiers And Density Of Smooth Functions

**Definition 13.5.1** Let $U$ be an open subset of $\mathbb{R}^n$. $C_\infty^c(U)$ is the vector space of all infinitely differentiable functions which equal zero for all $x$ outside of some compact set contained in $U$. Similarly, $C_m^c(U)$ is the vector space of all functions which are $m$ times continuously differentiable and whose support is a compact subset of $U$.

**Example 13.5.2** Let $U = B(z, 2r)$

$$\psi(x) = \begin{cases} 
\exp \left( \frac{1}{\left(\frac{|x - z|^2 - r^2}{r^2}\right)^{1}} \right) & \text{if } |x - z| < r, \\
0 & \text{if } |x - z| \geq r.
\end{cases}$$

Then a little work shows $\psi \in C_\infty^c(U)$. Note that if $z = 0$ then $\psi(x) = \psi(-x)$. The following also is easily obtained.

**Lemma 13.5.3** Let $U$ be any open set. Then $C_\infty^c(U) \neq \emptyset$. 
Proof: Pick \( z \in U \) and let \( r \) be small enough that \( B(z, 2r) \subseteq U \). Then let \( \psi \in C_c^\infty(B(z, 2r)) \subseteq C_c^\infty(U) \) be the function of the above example.

Definition 13.5.4 Let \( U = \{ x \in \mathbb{R}^n : |x| < 1 \} \). A sequence \( \{ \psi_m \} \subseteq C_c^\infty(U) \) is called a mollifier (This is sometimes called an approximate identity if the differentiability is not included.) if

\[
\psi_m(x) \geq 0, \psi_m(x) = 0, \text{ if } |x| \geq \frac{1}{m},
\]

and \( \int \psi_m(x) = 1 \). Sometimes it may be written as \( \{ \psi_\varepsilon \} \) where \( \psi_\varepsilon \) satisfies the above conditions except \( \psi_\varepsilon(x) = 0 \) if \( |x| \geq \varepsilon \). In other words, \( \varepsilon \) takes the place of \( 1/m \) and in everything that follows \( \varepsilon \to 0 \) instead of \( m \to \infty \).

As before, \( \int f(x, y)d\mu(y) \) will mean \( x \) is fixed and the function \( y \to f(x, y) \) is being integrated. To make the notation more familiar, \( dx \) is written instead of \( dm_n(x) \).

Example 13.5.5 Let

\[
\psi \in C_c^\infty(B(0, 1)) \quad (B(0, 1) = \{ x : |x| < 1 \})
\]

with \( \psi(x) \geq 0 \) and \( \int \psi dm = 1 \). Let \( \psi_m(x) = c_m \psi(mx) \) where \( c_m \) is chosen in such a way that \( \int \psi_m dm = 1 \). By the change of variables theorem \( c_m = m^n \).

Definition 13.5.6 A function, \( f \), is said to be in \( L^1_{\text{loc}}(\mathbb{R}^n; \mu) \) if \( f \) is \( \mu \) measurable and if \( |f|1_K \in L^1(\mathbb{R}^n, \mu) \) for every compact set, \( K \). Here \( \mu \) is a Radon measure on \( \mathbb{R}^n \). Usually \( \mu = m_n \), Lebesgue measure. When this is so, write \( L^1_{\text{loc}}(\mathbb{R}^n) \) or \( L^p(\mathbb{R}^n) \), etc. If \( f \in L^1_{\text{loc}}(\mathbb{R}^n, \mu) \), and \( g \in C_c(\mathbb{R}^n) \),

\[
f \ast g(x) \equiv \int f(y)g(x-y)d\mu.
\]

The following lemma will be useful in what follows. It says that one of these very unregular functions in \( L^1_{\text{loc}}(\mathbb{R}^n; \mu) \) is smoothed out by convolving with a mollifier.

Lemma 13.5.7 Let \( f \in L^1_{\text{loc}}(\mathbb{R}^n, \mu) \), and \( g \in C_c^\infty(\mathbb{R}^n) \). Then \( f \ast g \) is an infinitely differentiable function. Here \( \mu \) is a Radon measure on \( \mathbb{R}^n \).

Proof: Consider the difference quotient for calculating a partial derivative of \( f \ast g \).

\[
\frac{f \ast g(x + te_j) - f \ast g(x)}{t} = \int f(y)\frac{g(x + te_j - y) - g(x-y)}{t}d\mu(y).
\]

Using the fact that \( g \in C_c^\infty(\mathbb{R}^n) \), the quotient,

\[
\frac{g(x + te_j - y) - g(x-y)}{t},
\]
is uniformly bounded. To see this easily, use Theorem 5.13 on Page 128 to get the existence of a constant, $M$ depending on

$$\max \{||Dg(x)|| : x \in \mathbb{R}^n\}$$

such that

$$|g(x + te_j - y) - g(x - y)| \leq M |t|$$

for any choice of $x$ and $y$. Therefore, there exists a dominating function for the integrand of the above integral which is of the form $C |f(y)| \mathcal{X}_K$ where $K$ is a compact set depending on the support of $g$. It follows the limit of the difference quotient above passes inside the integral as $t \to 0$ and

$$\frac{\partial}{\partial x_j} (f * g)(x) = \int f(y) \frac{\partial}{\partial x_j} g(x - y) \, d\mu(y).$$

Now letting $\frac{\partial}{\partial x_j} g$ play the role of $g$ in the above argument, partial derivatives of all orders exist. A similar use of the dominated convergence theorem shows all these partial derivatives are also continuous. This proves the lemma.

**Theorem 13.5.8** Let $K$ be a compact subset of an open set, $U$. Then there exists a function, $h \in C^\infty_c(U)$, such that $h(x) = 1$ for all $x \in K$ and $h(x) \in [0, 1]$ for all $x$.

**Proof:** Let $r > 0$ be small enough that $K + B(0, 3r) \subseteq U$. The symbol, $K + B(0, 3r)$ means

$$\{k + x : k \in K \text{ and } x \in B(0, 3r)\}.$$

Thus this is simply a way to write

$$\cup \{B(k, 3r) : k \in K\}.$$

Think of it as fattening up the set, $K$. Let $K_r = K + B(0, r)$. A picture of what is happening follows.

Consider $\mathcal{X}_{K_r} \ast \psi_m$ where $\psi_m$ is a mollifier. Let $m$ be so large that $\frac{1}{m} < r$. Then from the definition of what is meant by a convolution, and using that $\psi_m$ has support in $B(0, \frac{1}{m})$, $\mathcal{X}_{K_r} \ast \psi_m = 1$ on $K$ and that its support is in $K + B(0, 3r)$. Now using Lemma 13.3.1, $\mathcal{X}_{K_r} \ast \psi_m$ is also infinitely differentiable. Therefore, let $h = \mathcal{X}_{K_r} \ast \psi_m$.

The following corollary will be used later.
Corollary 13.5.9 Let $K$ be a compact set in $\mathbb{R}^n$ and let $\{U_i\}_{i=1}^\infty$ be an open cover of $K$. Then there exist functions, $\psi_k \in C_c^\infty(U_i)$ such that $\psi_i \prec U_i$ and for all $x \in K$,

$$\sum_{i=1}^\infty \psi_i(x) = 1.$$ 

If $K_1$ is a compact subset of $U_1$ there exist such functions such that also $\psi_1(x) = 1$ for all $x \in K_1$.

Proof: This follows from a repeat of the proof of Theorem 10.2.11 on Page 268, replacing the lemma used in that proof with Theorem 13.5.8.

Note that in the last conclusion of above corollary, the set $U_1$ could be replaced with $U_i$ for any fixed $i$ by simply renumbering.

Theorem 13.5.10 For each $p \geq 1$, $C_c^\infty(\mathbb{R}^n)$ is dense in $L^p(\mathbb{R}^n)$. Here the measure is Lebesgue measure.

Proof: Let $f \in L^p(\mathbb{R}^n)$ and let $\varepsilon > 0$ be given. Choose $g \in C_c(\mathbb{R}^n)$ such that $\|f - g\|_p < \frac{\varepsilon}{2}$. This can be done by using Theorem 13.2.4. Now let

$$g_m(x) = g * \psi_m(x) = \int g(x-y) \psi_m(y) \, dm_n(y) = \int g(y) \psi_m(x-y) \, dm_n(y)$$

where $\{\psi_m\}$ is a mollifier. It follows from Lemma 13.5.7 $g_m \in C_c^\infty(\mathbb{R}^n)$. It vanishes if $x \notin \text{spt}(g) + B(0, \frac{1}{m})$.

$$\|g - g_m\|_p = \left( \int |g(x) - \int g(x-y) \psi_m(y) \, dm_n(y)|^p \, dm_n(x) \right)^{\frac{1}{p}}$$

$$\leq \left( \int (\int |g(x) - g(x-y)| \psi_m(y) \, dm_n(y))^p \, dm_n(x) \right)^{\frac{1}{p}}$$

$$\leq \int (\int |g(x) - g(x-y)|^p \, dm_n(x))^{\frac{1}{p}} \psi_m(y) \, dm_n(y)$$

$$= \int_{B(0, \frac{1}{m})} \|g - g_m\|_p \psi_m(y) \, dm_n(y) < \frac{\varepsilon}{2}$$

whenever $m$ is large enough thanks to the uniform continuity of $g$. Theorem 13.1.12 was used to obtain the third inequality. There is no measurability problem because the function

$$(x, y) \rightarrow |g(x) - g(x-y)| \psi_m(y)$$

is continuous. Thus when $m$ is large enough,

$$\|f - g_m\|_p \leq \|f - g\|_p + \|g - g_m\|_p < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$ 

This proves the theorem.
This is a very remarkable result. Functions in $L^p(\mathbb{R}^n)$ don’t need to be continuous anywhere and yet every such function is very close in the $L^p$ norm to one which is infinitely differentiable having compact support. The same result holds for $L^p(U)$ for $U$ an open set. This is the next corollary.

**Corollary 13.5.11** Let $U$ be an open set. For each $p \geq 1$, $C_c^\infty(U)$ is dense in $L^p(U)$. Here the measure is Lebesgue measure.

**Proof:** Let $f \in L^p(U)$ and let $\varepsilon > 0$ be given. Choose $g \in C_c(U)$ such that $\|f - g\|_p < \frac{\varepsilon}{2}$. This is possible because Lebesgue measure restricted to the open set, $U$ is regular. Thus the existence of such a $g$ follows from Theorem 13.2.4. Now let

$$g_m(x) = g \ast \psi_m(x) = \int g(x-y)\psi_m(y)\,dm_n(y) = \int g(y)\psi_m(x-y)\,dm_n(y)$$

where $\{\psi_m\}$ is a mollifier. It follows from Lemma 13.5.7, $g_m \in C_c^\infty(U)$ for all $m$ sufficiently large. It vanishes if $x \notin \text{spt}(g) + B(0, \frac{1}{m})$. Then

$$\|g - g_m\|_p = \left( \int |g(x) - \int g(x-y)\psi_m(y)\,dm_n(y)|^p \,dm_n(x) \right)^{\frac{1}{p}}$$

$$\leq \left( \int \left( \int |g(x-y)|\psi_m(y)\,dm_n(y) \right)^p \,dm_n(x) \right)^{\frac{1}{p}}$$

$$\leq \int \left( \int |g(x-y)|\,dm_n(x) \right)^{\frac{1}{p}} \psi_m(y)\,dm_n(y)$$

$$= \int_{B(0, \frac{1}{m})} \|g - g_y\|_p \psi_m(y)\,dm_n(y) < \frac{\varepsilon}{2}$$

whenever $m$ is large enough thanks to uniform continuity of $g$. Theorem 13.1.12 was used to obtain the third inequality. There is no measurability problem because the function

$$(x, y) \rightarrow |g(x) - g(x-y)|\psi_m(y)$$

is continuous. Thus when $m$ is large enough,

$$\|f - g_m\|_p \leq \|f - g\|_p + \|g - g_m\|_p \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$

This proves the corollary.

Another thing should probably be mentioned. If you have had a course in complex analysis, you may be wondering whether these infinitely differentiable functions having compact support have anything to do with analytic functions which also have infinitely many derivatives. The answer is no! Recall that if an analytic function has a limit point in the set of zeros then it is identically equal to zero. Thus these functions in $C_c^\infty(\mathbb{R}^n)$ are not analytic. This is a strictly real analysis phenomenon and has absolutely nothing to do with the theory of functions of a complex variable.
13.6 Exercises

1. Let $E$ be a Lebesgue measurable set in $\mathbb{R}$. Suppose $m(E) > 0$. Consider the set

$$E - E = \{x - y : x \in E, y \in E\}.$$ 

Show that $E - E$ contains an interval. **Hint:** Let

$$f(x) = \int \chi_E(t) \chi_E(x + t) dt.$$ 

Note $f$ is continuous at 0 and $f(0) > 0$ and use continuity of translation in $L^p$.

2. Establish the inequality $\|fg\|_r \leq \|f\|_p \|g\|_q$ whenever $\frac{1}{r} = \frac{1}{p} + \frac{1}{q}$.

3. Let $(\Omega, \mathcal{S}, \mu)$ be counting measure on $\mathbb{N}$. Thus $\Omega = \mathbb{N}$ and $\mathcal{S} = \mathcal{P}(\mathbb{N})$ with $\mu(S) =$ number of things in $S$. Let $1 \leq p \leq q$. Show that in this case,

$$L^1(\mathbb{N}) \subseteq L^p(\mathbb{N}) \subseteq L^q(\mathbb{N}).$$ 

**Hint:** This is real easy if you consider what $\int_\Omega f \, d\mu$ equals. How are the norms related?

4. Consider the function, $f(x, y) = \frac{x^{p-1}}{py} + \frac{y^{q-1}}{qx}$ for $x, y > 0$ and $\frac{1}{p} + \frac{1}{q} = 1$. Show directly that $f(x, y) \geq 1$ for all such $x, y$ and show this implies $xy \leq \frac{x^p}{p} + \frac{y^q}{q}$.

5. Give an example of a sequence of functions in $L^p(\mathbb{R})$ which converges to zero in $L^p$ but does not converge pointwise to 0. Does this contradict the proof of the theorem that $L^p$ is complete?

6. Let $K$ be a bounded subset of $L^p(\mathbb{R}^n)$ and suppose that there exists $G$ such that $\overline{G}$ is compact with

$$\int_{\mathbb{R}^n \setminus \overline{G}} |u(x)|^p \, dx < \varepsilon^p$$ 

and for all $\varepsilon > 0$, there exist a $\delta > 0$ and such that if $|h| < \delta$, then

$$\int |u(x + h) - u(x)|^p \, dx < \varepsilon^p$$ 

for all $u \in K$. Show that $K$ is precompact in $L^p(\mathbb{R}^n)$. **Hint:** Let $\phi_k$ be a mollifier and consider $K_k \equiv \{u * \phi_k : u \in K\}$.

Verify the conditions of the Ascoli Arzela theorem for these functions defined on $\overline{G}$ and show there is an $\varepsilon$ net for each $\varepsilon > 0$. Can you modify this to let an arbitrary open set take the place of $\mathbb{R}^n$?
7. Let \((\Omega, d)\) be a metric space and suppose also that \((\Omega, \mathcal{S}, \mu)\) is a regular measure space such that \(\mu(\Omega) < \infty\) and let \(f \in L^1(\Omega)\) where \(f\) has complex values. Show that for every \(\varepsilon > 0\), there exists an open set of measure less than \(\varepsilon\), denoted here by \(V\) and a continuous function, \(g\) defined on \(\Omega\) such that \(f = g\) on \(V^C\). Thus, aside from a set of small measure, \(f\) is continuous. If \(|f(\omega)| \leq M\), show that it can be assumed that \(|g(\omega)| \leq M\). This is called Lusin’s theorem. \textbf{Hint:} Use Theorems 13.2.4 and 13.1.10 to obtain a sequence of functions in \(C_c(\Omega), \{g_n\}\) which converges pointwise a.e. to \(f\) and then use Egoroff’s theorem to obtain a small set, \(W\) of measure less than \(\varepsilon/2\) such that convergence is uniform on \(W^C\). Now let \(F\) be a closed subset of \(W^C\) such that \(\mu(W^C \setminus F) < \varepsilon/2\). Let \(V = F^C\). Thus \(\mu(V) < \varepsilon\) and on \(F = V^C\), the convergence of \(\{g_n\}\) is uniform showing that the restriction of \(f\) to \(V^C\) is continuous. Now use the Tietze extension theorem.

8. Let \(\phi_m \in C^\infty(\mathbb{R}^n), \phi_m(x) \geq 0\), and \(\int_{\mathbb{R}^n} \phi_m(y)dy = 1\) with
\[
\lim_{m \to \infty} \sup \{|x| : x \in \text{spt}(\phi_m)| = 0.
\]
Show if \(f \in L^p(\mathbb{R}^n)\), \(\lim_{m \to \infty} f * \phi_m = f\) in \(L^p(\mathbb{R}^n)\).

9. Let \(\phi : \mathbb{R} \to \mathbb{R}\) be convex. This means
\[
\phi(\lambda x + (1-\lambda)y) \leq \lambda \phi(x) + (1-\lambda)\phi(y)
\]
whenever \(\lambda \in [0,1]\). Verify that if \(x < y < z\), then \(\frac{\phi(y)-\phi(x)}{y-x} \leq \frac{\phi(z)-\phi(y)}{z-y}\) and that \(\frac{\phi(z)-\phi(x)}{z-x} \leq \frac{\phi(z)-\phi(y)}{z-y}\). Show if \(s \in \mathbb{R}\) there exists \(\lambda\) such that \(\phi(s) \leq \phi(t) + \lambda(s-t)\) for all \(t\). Show that if \(\phi\) is convex, then \(\phi\) is continuous.

10. \(\dagger\) Prove Jensen’s inequality. If \(\phi : \mathbb{R} \to \mathbb{R}\) is convex, \(\mu(\Omega) = 1\), and \(f : \Omega \to \mathbb{R}\) is in \(L^1(\Omega)\), then \(\phi(\int_{\Omega} fdu) \leq \int_{\Omega} \phi(f)du\). \textbf{Hint:} Let \(s = \int_{\Omega} fdu\) and use Problem 3.

11. Let \(\frac{1}{p} + \frac{1}{p'} = 1\), \(p > 1\), let \(f \in L^p(\mathbb{R})\), \(g \in L^{p'}(\mathbb{R})\). Show \(f * g\) is uniformly continuous on \(\mathbb{R}\) and \(|(f * g)(x)| \leq \|f\|_{L^p}\|g\|_{L^{p'}}\). \textbf{Hint:} You need to consider why \(f * g\) exists and then this follows from the definition of convolution and continuity of translation in \(L^p\).

12. \(B(p,q) = \int_0^1 x^{p-1}(1-x)^{q-1}dx\), \(\Gamma(p) = \int_0^\infty e^{-t} t^{p-1}dt\) for \(p,q > 0\). The first of these is called the beta function, while the second is the gamma function. Show a.) \(\Gamma(p + 1) = p\Gamma(p)\); b.) \(\Gamma(p)\Gamma(q) = B(p,q)\Gamma(p+q)\).

13. Let \(f \in C_c(0,\infty)\) and define \(F(x) = \frac{1}{x} \int_x^\infty f(t)dt\). Show
\[
\|F\|_{L^p(0,\infty)} \leq \frac{p}{p-1}\|f\|_{L^p(0,\infty)} \quad \text{whenever } p > 1.
\]
Hint: Argue there is no loss of generality in assuming \( f \geq 0 \) and then assume this is so. Integrate \( \int_0^\infty |F(x)|^p dx \) by parts as follows:

\[
\int_0^\infty F^p dx = \left[ xF^p \right]_0^\infty - p \int_0^\infty xF^{p-1}F' dx.
\]

Now show \( xF' = f - F \) and use this in the last integral. Complete the argument by using Holder’s inequality and \( p = q \).

14. Now suppose \( f \in L^p(0, \infty), p > 1 \), and \( f \) not necessarily in \( C_c(0, \infty) \). Show that \( F(x) = \frac{1}{x} \int_0^x f(t) dt \) still makes sense for each \( x > 0 \). Show the inequality of Problem 13 is still valid. This inequality is called Hardy’s inequality. \textbf{Hint:}
To show this, use the above inequality along with the density of \( C_c(0, \infty) \) in \( L^p(0, \infty) \).

15. Suppose \( f, g \geq 0 \). When does equality hold in Holder’s inequality?

16. Prove Vitali’s Convergence theorem: Let \( \{f_n\} \) be uniformly integrable and complex valued, \( \mu(\Omega) < \infty, f_n(x) \rightarrow f(x) \) a.e. where \( f \) is measurable. Then \( f \in L^1 \) and \( \lim_{n \rightarrow \infty} \int_\Omega |f_n - f| d\mu = 0 \). \textbf{Hint:} Use Egoroff’s theorem to show \( \{f_n\} \) is a Cauchy sequence in \( L^1(\Omega) \). This yields a different and easier proof than what was done earlier. See Theorem 9.5.3 on Page 244.

17. Show the Vitali Convergence theorem implies the Dominated Convergence theorem for finite measure spaces but there exist examples where the Vitali convergence theorem works and the dominated convergence theorem does not.

18. Suppose \( \mu(\Omega) < \infty, \{f_n\} \subseteq L^1(\Omega), \) and

\[
\int_\Omega h(|f_n|) d\mu < C
\]

for all \( n \) where \( h \) is a continuous, nonnegative function satisfying

\[
\lim_{t \rightarrow \infty} \frac{h(t)}{t} = \infty.
\]

Show \( \{f_n\} \) is uniformly integrable. In applications, this often occurs in the form of a bound on \(|f_n|_p\).

19. Sometimes, especially in books on probability, a different definition of uniform integrability is used than that presented here. A set of functions, \( \mathcal{S} \), defined on a finite measure space, \((\Omega, \mathcal{S}, \mu)\) is said to be uniformly integrable if for all \( \varepsilon > 0 \) there exists \( \alpha > 0 \) such that for all \( f \in \mathcal{S} \),

\[
\int_{|f| \geq \alpha} |f| d\mu \leq \varepsilon.
\]
Show that this definition is equivalent to the definition of uniform integrability given earlier in Definition 9.5.1 on Page 243 with the addition of the condition that there is a constant, \( C < \infty \) such that
\[
\int |f| \, d\mu \leq C
\]
for all \( f \in \mathcal{G} \).

20. \( f \in L^\infty(\Omega, \mu) \) if there exists a set of measure zero, \( E \), and a constant \( C < \infty \) such that \( |f(x)| \leq C \) for all \( x \notin E \).

Show \( \|f\|_\infty \equiv \inf \{C : |f(x)| \leq C \text{ a.e.}\} \).

Show \( \| \| \) is a norm on \( L^\infty(\Omega, \mu) \) provided \( f \) and \( g \) are identified if \( f(x) = g(x) \) a.e. Show \( L^\infty(\Omega, \mu) \) is complete. \textbf{Hint}: You might want to show that \( \|f\|_\infty \) has measure zero so \( \|f\|_\infty \) is the smallest number at least as large as \( |f(x)| \) for a.e. \( x \). Thus \( \|f\|_\infty \) is one of the constants, \( C \) in the above.

21. Suppose \( f \in L^\infty \cap L^1 \). Show \( \lim_{p \to \infty} \|f\|_{L^p} = \|f\|_\infty \). \textbf{Hint}:
\[
(||f||_\infty - \varepsilon)^p \mu (|f| > ||f||_\infty - \varepsilon) \leq \int_{|f| > ||f||_\infty - \varepsilon} |f|^p \, d\mu \leq \int |f|^p \, d\mu = \int |f|^{p-1} |f| \, d\mu \leq ||f||_\infty^{p-1} \int |f| \, d\mu.
\]
Now raise both ends to the \( 1/p \) power and take \( \lim inf \) and \( \lim sup \) as \( p \to \infty \). You should get \( ||f||_\infty - \varepsilon \leq \lim inf \|f\|_p \leq \lim sup \|f\|_p \leq ||f||_\infty \).

22. Suppose \( \mu(\Omega) < \infty \). Show that if \( 1 \leq p < q \), then \( L^q(\Omega) \subseteq L^p(\Omega) \). \textbf{Hint} Use Holder’s inequality.

23. Show \( L^1(\mathbb{R}) \nsubseteq L^2(\mathbb{R}) \) and \( L^2(\mathbb{R}) \nsubseteq L^1(\mathbb{R}) \) if Lebesgue measure is used. \textbf{Hint}: Consider \( 1/\sqrt{x} \) and \( 1/x \).

24. Suppose that \( \theta \in [0, 1] \) and \( r, s, q > 0 \) with
\[
\frac{1}{q} = \frac{\theta}{r} + \frac{1-\theta}{s}.
\]
show that
\[
\left( \int |f|^q d\mu \right)^{1/q} \leq \left( \int |f|^r d\mu \right)^{1/r} \left( \int |f|^s d\mu \right)^{1/s} \left( \int |f|^{q(1-q)} d\mu \right)^{1-q}.
\]
If \( q, r, s \geq 1 \) this says that
\[
\|f\|_q \leq \|f\|_r \|f\|_s^{1-\theta}.
\]
Using this, show that
\[ \ln \left( \|f\|_q \right) \leq \theta \ln (\|f\|_r) + (1 - \theta) \ln (\|f\|_s) . \]

**Hint:**
\[ \int |f|^q \, d\mu = \int |f|^\theta |f|^{q(1-\theta)} \, d\mu . \]

Now note that 1 = \( \frac{\theta q}{r} + \frac{q(1-\theta)}{s} \) and use Holder’s inequality.

25. Suppose \( f \) is a function in \( L^1(\mathbb{R}) \) and \( f \) is infinitely differentiable. Is \( f' \in L^1(\mathbb{R}) \)? **Hint:** What if \( \phi \in C_0^\infty (0,1) \) and \( f(x) = \phi(2^n (x - n)) \) for \( x \in (n, n+1) \), \( f(x) = 0 \) if \( x < 0 \)?
CHAPTER 13. THE $L^p$ SPACES
Chapter 14

Stone’s Theorem And Partitions Of Unity

This section is devoted to Stone’s theorem which says that a metric space is paracompact, defined below. See [89] for this which is where I read it. First is the definition of what is meant by a refinement.

Definition 14.0.1 Let $S$ be a topological space. We say that a collection of sets $\mathcal{D}$ is a refinement of an open cover $\mathcal{G}$, if every set of $\mathcal{D}$ is contained in some set of $\mathcal{G}$. An open refinement would be one in which all sets are open, with a similar convention holding for the term “closed refinement”.

Definition 14.0.2 We say that a collection of sets $\mathcal{D}$, is locally finite if for all $p \in S$, there exists $V$ an open set containing $p$ such that $V$ has nonempty intersection with only finitely many sets of $\mathcal{D}$.

Definition 14.0.3 We say $S$ is paracompact if it is Hausdorff and for every open cover $\mathcal{G}$, there exists an open refinement $\mathcal{D}$ such that $\mathcal{D}$ is locally finite and $\mathcal{D}$ covers $S$.

Theorem 14.0.4 If $\mathcal{D}$ is locally finite then
\[ \bigcup\{D : D \in \mathcal{D}\} = \overline{\bigcup\{D : D \in \mathcal{D}\}}. \]

Proof: It is clear the left side is a subset of the right. Let $p$ be a limit point of $\bigcup\{D : D \in \mathcal{D}\}$ and let $p \in V$, an open set intersecting only finitely many sets of $\mathcal{D}$, $D_1, \ldots, D_n$. If $p$ is not in any of $D_i$ then $p \in W$ where $W$ is some open set which contains no points of $\bigcup_{i=1}^n D_i$. Then $V \cap W$ contains no points of any set of $\mathcal{D}$ and this contradicts the assumption that $p$ is a limit point of $\bigcup\{D : D \in \mathcal{D}\}$.

401
Thus \( p \in D_i \) for some \( i \). ■

We say \( \mathcal{S} \subseteq \mathcal{P}(S) \) is countably locally finite if

\[
\mathcal{S} = \bigcup_{n=1}^{\infty} \mathcal{S}_n
\]

and each \( \mathcal{S}_n \) is locally finite. The following theorem appeared in the 1950’s. It will be used to prove Stone’s theorem.

**Theorem 14.0.5** Let \( S \) be a regular topological space. (If \( p \in U \) open, then there exists an open set \( V \) such that \( p \in V \subseteq U \).) The following are equivalent

1.) Every open covering of \( S \) has a refinement that is open, covers \( S \) and is **countably locally finite**.

2.) Every open covering of \( S \) has a refinement that is locally finite and covers \( S \). (The sets in refinement maybe not open.)

3.) Every open covering of \( S \) has a refinement that is closed, locally finite, and covers \( S \). (Sets in refinement are closed.)

4.) Every open covering of \( S \) has a refinement that is open, locally finite, and covers \( S \). (Sets in refinement are open.)

**Proof:**

1.) \( \Rightarrow \) 2.)

Let \( \mathcal{S} \) be an open cover of \( S \) and let \( \mathcal{B} \) be an open countably locally finite refinement

\[
\mathcal{B} = \bigcup_{n=1}^{\infty} \mathcal{B}_n
\]

where \( \mathcal{B}_n \) is an open refinement of \( \mathcal{S} \) and \( \mathcal{B}_n \) is locally finite. For \( B \in \mathcal{B}_n \), let

\[
E_n(B) = B \setminus \bigcup_{k<n} \left( \cup \{ B : B \in \mathcal{B}_k \} \right).
\]

Thus, in words, \( E_n(B) \) consists of points in \( B \) which are not in any set from any \( \mathcal{B}_k \) for \( k < n \).

**Claim:** \( \{ E_n(B) : n \in \mathbb{N}, B \in \mathcal{B}_n \} \) is locally finite.

**Proof of the claim:** Let \( p \in S \). Then \( p \in B_0 \in \mathcal{B}_n \) for some \( n \). Let \( V \) be open, \( p \in V \), and \( V \) intersects only finitely many sets of \( \mathcal{B}_1 \cup \ldots \cup \mathcal{B}_n \). Then consider \( B_0 \cap V \). If \( m > n \),

\[
(B_0 \cap V) \cap E_m(B) \subseteq \left[ \bigcup_{k<m} (\cup \{ B : B \in \mathcal{B}_k \} \right]^C \subseteq B_0^C.
\]

In words, \( E_m(B) \) has nothing in it from any of the \( \mathcal{B}_k \) for \( k < m \). In particular, it has nothing in it from \( B_0 \). Thus \( (B_0 \cap V) \cap E_m(B) = \emptyset \) for \( m > n \). Thus \( p \in B_0 \cap V \) which intersects only finitely many sets of \( \mathcal{S} \), no more than those intersected by \( V \). This establishes the claim.

**Claim:** \( \{ E_n(B) : n \in \mathbb{N}, B \in \mathcal{B}_n \} \) covers \( S \).

**Proof:** Let \( p \in S \) and let \( n = \min \{ k \in \mathbb{N} : p \in B \text{ for some } B \in \mathcal{B}_k \} \). Let \( p \in B \in \mathcal{B}_n \). Then \( p \in E_n(B) \).
The two claims show that 1.\implies 2.

2.\implies 3.

Let $\mathcal{G}$ be an open cover and let

$$
\mathcal{G} \equiv \{U : U \text{ is open and } U \subseteq V \in \mathcal{G} \text{ for some } V \in \mathcal{G}\}.
$$

Then since $S$ is regular, $\mathcal{G}$ covers $S$. (If $p \in S$, then $p \in U \subseteq \tilde{U} \subseteq V \in \mathcal{G}$.) By 2.), $\mathcal{G}$ has a locally finite refinement $\mathcal{C}$, covering $S$. Consider

$$
\{E : E \in \mathcal{C}\}.
$$

This collection of closed sets covers $S$ and is locally finite because if $p \in S$, there exists $V$, $p \in V$, and $V$ has nonempty intersections with only finitely many elements of $\mathcal{C}$, say $E_1, \ldots, E_n$. If $E \cap V \neq \emptyset$, then $E \cap V \neq \emptyset$ and so $V$ intersects only $E_1, \ldots, E_n$. This shows 2.\implies 3.).

3.\implies 4.) Here is a table of symbols with a short summary of their meaning.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$S$</td>
<td>original covering</td>
</tr>
<tr>
<td>$\mathcal{G}$</td>
<td>open covering</td>
</tr>
<tr>
<td>$\mathcal{B}$</td>
<td>by 3. can be closed refinement</td>
</tr>
<tr>
<td>$\mathcal{F}$</td>
<td>open interectors</td>
</tr>
<tr>
<td>$\mathcal{C}$</td>
<td>closed refinement</td>
</tr>
</tbody>
</table>

Let $\mathcal{G}$ be an open cover and let $\mathcal{B}$ be a locally finite refinement which covers $S$. By 3.) we can take $\mathcal{B}$ to be a closed refinement but this is not important here. Let

$$
\mathcal{F} \equiv \{U : U \text{ is open and } U \text{ intersects only finitely many sets of } \mathcal{B}\}.
$$

Then $\mathcal{F}$ covers $S$ because $\mathcal{B}$ is locally finite. If $p \in S$, then there exists an open set $U$ containing $p$ which intersects only finitely many sets of $\mathcal{B}$. Thus $p \in U \in \mathcal{F}$. By 3., $\mathcal{F}$ has a locally finite closed refinement $\mathcal{C}$, which covers $S$. Define for $B \in \mathcal{B}$

$$
\mathcal{C}(B) \equiv \{C \in \mathcal{C} : C \cap B = \emptyset\}
$$

Thus these closed sets $C$ do not intersect $B$ and so $B$ is in their complement. We use $\mathcal{C}(B)$ to fatten up $B$. Let

$$
E(B) \equiv (\cup\{C : C \in \mathcal{C}(B)\})^C.
$$

In words, $E(B)$ is the complement of the union of all closed sets of $\mathcal{C}$ which do not intersect $B$. Thus $E(B) \supseteq B$, and has fattened up $B$. Then since $\mathcal{C}(B)$ is locally finite, $E(B)$ is an open set by Theorem 14.0.4. Now let $F(B)$ be defined such that for $B \in \mathcal{B}$,

$$
B \subseteq F(B) \in \mathcal{G}
$$

(by definition $B$ is in some set of $\mathcal{G}$), and let

$$
\mathcal{L} = \{E(B) \cap F(B) : B \in \mathcal{B}\}
$$

The intersection with $F(B)$ is to ensure that $\mathcal{L}$ is a refinement of $\mathcal{G}$. The important thing to notice is that if $C \in \mathcal{C}$ intersects $E(B)$, then it must also intersect...
If not, you could include it in the list of closed sets which do not intersect \( B \) and whose complement is \( E(B) \). Thus \( E(B) \) would be too large.

**Claim:** \( \mathcal{L} \) covers \( S \).

This claim is obvious because if \( p \in S \) then \( p \in B \) for some \( B \in \mathcal{B} \). Hence

\[ p \in E(B) \cap F(B) \in \mathcal{L}. \]

**Claim:** \( \mathcal{L} \) is locally finite and a refinement of \( \mathcal{G} \).

**Proof:** It is clear \( \mathcal{L} \) is a refinement of \( \mathcal{G} \) because every set of \( \mathcal{L} \) is a subset of a set of \( \mathcal{G} \), \( F(B) \). Let \( p \in S \). There exists an open set \( W \), such that \( p \in W \) and \( W \) intersects only \( C_1, \ldots, C_n \), elements of \( \mathcal{C} \). Hence \( W \subseteq \cup_{i=1}^{n} C_i \) since \( \mathcal{C} \) covers \( S \).

But \( C_i \) is contained in a set \( U_i \in \mathcal{B} \) which intersects only finitely many sets of \( \mathcal{B} \). Thus each \( C_i \) intersects only finitely many \( B \in \mathcal{B} \) and so each \( C_i \) intersects only finitely many of the sets, \( E(B) \). (If it intersects \( E(B) \), then it intersects \( B \).) Thus \( W \) intersects only finitely many of the \( E(B) \), hence finitely many of the \( E(B) \cap F(B) \). It follows that \( \mathcal{L} \) is locally finite.

It is obvious that 4.) \( \Rightarrow \) 1.). ■

The following theorem is Stone’s theorem.

**Theorem 14.0.6** If \( S \) is a metric space then \( S \) is paracompact (Every open cover has a locally finite open refinement also an open cover.)

**Proof:** Let \( \mathcal{G} \) be an open cover. Well order \( \mathcal{G} \). For \( B \in \mathcal{G} \),

\[ B_n = \{ x \in B : \text{dist}(x, B^c) < \frac{1}{2^n} \}, n = 1, 2, \ldots. \]

Thus \( B_n \) is contained in \( B \) but approximates it up to \( 2^{-n} \). Let

\[ E_n(B) = B_n \setminus \cup \{ D : D \prec B \text{ and } D \neq B \} \]

where \( \prec \) denotes the well order. If \( B, D \in \mathcal{G} \), then one is first in the well order. Let \( D \prec B \). Then from the construction, \( E_n(B) \subseteq D^c \) and \( E_n(D) \) is further than \( 1/2^n \) from \( D^c \). Hence, assuming neither set is empty,

\[ \text{dist}(E_n(B), E_n(D)) \geq 2^{-n} \]
for all $B, D \in \mathcal{S}$. Fatten up $E_n(B)$ as follows.

$$
\widehat{E_n(B)} \equiv \bigcup \{ B \left( x, 8^{-n} \right) : x \in E_n(B) \}.
$$

Thus $\widehat{E_n(B)} \subseteq B$ and

$$
\text{dist} \left( \widehat{E_n(B)}, \widehat{E_n(D)} \right) \geq \frac{1}{2^n} - 2 \left( \frac{1}{8} \right)^n \equiv \delta_n > 0.
$$

It follows that the collection of open sets

$$
\{ \widehat{E_n(B)} : B \in \mathcal{S} \} = \mathcal{F}_n
$$

is locally finite. In fact, $B \left( p, \frac{\delta_n}{2} \right)$ cannot intersect more than one of them. In addition to this,

$$
S \subseteq \bigcup \{ \widehat{E_n(B)} : n \in \mathbb{N}, B \in \mathcal{S} \}
$$

because if $p \in S$, let $B$ be the first set in $\mathcal{S}$ to contain $p$. Then $p \in E_n(B)$ for $n$ large enough because it will not be in anything deleted. Thus this is an open countably locally finite refinement. Thus 1.) in the above theorem is satisfied.

### 14.1 Partitions Of Unity And Stone’s Theorem

First observe that if $S$ is a nonempty set, then $\text{dist} \left( x, S \right)$ satisfies $|\text{dist} \left( x, S \right) - \text{dist} \left( y, S \right)| \leq d(x, y)$. To see this,

$$
|\text{dist} \left( x, S \right) - \text{dist} \left( y, S \right)| \leq d(x, y)
$$

To see this, say $\text{dist} \left( x, S \right)$ is the larger of the two. Then there exists $z \in S$ such that

$$
\text{dist} \left( y, S \right) \geq d(y, z) - \varepsilon
$$

It follows that

$$
|\text{dist} \left( x, S \right) - \text{dist} \left( y, S \right)| = \text{dist} \left( x, S \right) - \text{dist} \left( y, S \right)
$$

$$
\leq \text{dist} \left( x, S \right) - (d(y, z) - \varepsilon)
$$

$$
\leq d(x, z) - d(y, z) + \varepsilon
$$

where

$$
\leq d(x, y) + d(y, z) - d(y, z) + \varepsilon = d(x, y) + \varepsilon
$$

Since $\varepsilon > 0$ is arbitrary, this shows the desired conclusion.

**Theorem 14.1.1** Let $S$ be a metric space and let $\mathcal{S}$ be any open cover of $S$. Then there exists a set $\mathcal{F}$, an open refinement of $\mathcal{S}$, and functions $\{ \phi_F : F \in \mathcal{F} \}$ such that

$$
\phi_F : S \rightarrow [0, 1]
$$
\( \phi_F \) is continuous
\( \phi_F (x) \) equals 0 for all but finitely many \( F \in \mathcal{F} \)
\[ \sum (\phi_F (x) : F \in \mathcal{F}) = 1 \text{ for all } x \in S. \]

Each \( \phi_F \) is locally Lipschitz continuous which means that for each \( z \) there is an open set \( W \) containing \( z \) for which, if \( x, y \in W \), then there is a constant \( K \) such that
\[ |\phi_F (x) - \phi_F (y)| \leq K d(x, y) \]

**Proof:** By Stone’s theorem, there exists a locally finite refinement \( \mathcal{F} \) covering \( S \). For \( F \in \mathcal{F} \)
\[ g_F (x) \equiv \text{dist}(x, F^C) \]

Let
\[ \phi_F (x) \equiv \left( \sum (g_F (x) : F \in \mathcal{F}) \right)^{-1} g_F (x). \]

Now
\[ \sum (g_F (x) : F \in \mathcal{F}) \]
is a continuous function because if \( x \in S \), then there exists an open set \( W \) with \( x \in W \) and \( W \) has nonempty intersection with only finitely many sets of \( F \in \mathcal{F} \). Then for \( y \in W \),
\[ \sum (g_F (y) : F \in \mathcal{F}) = \sum_{i=1}^{n} g_{F_i} (y). \]

Since \( \mathcal{F} \) is a cover of \( S \),
\[ \sum (g_F (x) : F \in \mathcal{F}) \neq 0 \]
for any \( x \in S \). Hence \( \phi_F \) is continuous. This also shows \( \phi_F (x) = 0 \) for all but finitely many \( F \in \mathcal{F} \). It is obvious that
\[ \sum (\phi_F (x) : F \in \mathcal{F}) = 1 \]
from the definition.

Let \( z \in S \). Then there is an open set \( W \) containing \( z \) such that \( W \) has nonempty intersection with only finitely many \( F \in \mathcal{F} \). Thus for \( y, x \in W \),
\[ \left| \phi_{F_j} (x) - \phi_{F_j} (y) \right| \leq \frac{g_{F_j} (x) \sum_{i=1}^{n} g_{F_i} (y) - g_{F_j} (y) \sum_{i=1}^{n} g_{F_i} (x)}{\sum_{i=1}^{n} g_{F_i} (x) \sum_{i=1}^{n} g_{F_i} (y)} \]

If \( F \) is not one of these \( F_i \), then \( g_F (x) = \phi_F (x) = \phi_F (y) = g_F (y) = 0 \). Thus there is nothing to show for these. It suffices to consider the ones above. Restricting \( W \) if necessary, we can assume that for \( x \in W \),
\[ \sum_{F} g_F (x) = \sum_{i=1}^{n} g_{F_i} (x) > \delta > 0, \ g_{F_j} (x) < \Delta < \infty, \ j \leq n \]
Then, simplifying the above, and letting $x, y \in W$, for each $j \leq n$,

\[ \left| \phi_{F_j} (x) - \phi_{F_j} (y) \right| \leq \frac{1}{\delta^2} \left| g_{F_j} (x) \sum_F g_F (y) - g_{F_j} (y) \sum_F g_F (y) \right| + g_{F_j} (y) \sum_F g_F (y) - g_{F_j} (y) \sum_F g_F (x) \]

\[ \leq \frac{1}{\delta^2} \Delta \left| g_{F_j} (x) - g_{F_j} (y) \right| + \frac{1}{\delta^2} \sum_{i=1}^n \left| g_{F_i} (y) - g_{F_i} (x) \right| \]

\[ \leq \frac{\Delta}{\delta^2} d(x, y) + \frac{\Delta}{\delta^2} n d(x, y) = (n + 1) \frac{\Delta}{\delta^2} d(x, y). \]

Thus on this set $W$ containing $z$, all $\phi_F$ are Lipschitz continuous with Lipschitz constant $(n + 1) \frac{\Delta}{\delta^2}$. ■

The functions described above are called a partition of unity subordinate to the open cover $\mathcal{G}$. A useful observation is contained in the following corollary.

Corollary 14.1.2 Let $S$ be a metric space and let $\mathcal{G}$ be any open cover of $S$. Then there exists a set $\mathcal{F}$, an open refinement of $\mathcal{G}$, and functions $\{ \phi_F : F \in \mathcal{F} \}$ such that

\[ \phi_F : S \to [0, 1] \]

$\phi_F$ is continuous

$\phi_F (x)$ equals 0 for all but finitely many $F \in \mathcal{F}$

\[ \sum \{ \phi_F (x) : F \in \mathcal{F} \} = 1 \text{ for all } x \in S. \]

Each $\phi_F$ is Lipschitz continuous. If $U \in \mathcal{G}$ and $H$ is a closed subset of $U$, the partition of unity can be chosen such that each $\phi_F = 0$ on $H$ except for one which equals 1 on $H$.

Proof: Just change your open cover to consist of $U$ and $V \setminus H$ for each $V \in \mathcal{G}$. Then every function but one equals 0 on $H$ and so exactly one of them equals 1 on $H$. ■

14.2 An Extension Theorem, Retracts

Lemma 14.2.1 Let $A$ be a closed set in a metric space and let $x_n \notin A, x_n \to a_0 \in A$ and $a_n \in A$ such that $d(a_n, x_n) < 6 \text{ dist } (x_n, A).$ Then $a_n \to a_0.$

Proof: By assumption,

\[ d(a_n, a_0) \leq d(a_n, x_n) + d(x_n, a_0) < 6 \text{ dist } (x_n, A) + d(x_n, a_0) \leq 6d(x_n, a_0) + d(x_n, a_0) = 7d(x_n, a_0) \]

and this converges to 0. ■
Note that there was nothing magic about 6 in the above. Another number would work as well.

In the proof of the following theorem, you get a covering of $A^C$ with open balls $B$ such that for each of these balls, there exists $a \in A$ such that for all $x \in B, \|x - a\| \leq 6 \text{dist}(x, A)$. The 6 is not important. Any other constant with this property would work. Then you use Stone’s theorem.

A Banach space is a normed vector space which is also a complete metric space where the metric comes from the norm.

Thus you can add things in a Banach space. Much more will be considered about Banach spaces a little later.

**Definition 14.2.2** A Banach space is a complete normed linear space. If you have a subset $B$ of a Banach space, then $\text{conv}(B)$ denotes the smallest closed convex set which contains $B$. It can be obtained by taking the intersection of all closed convex sets containing $B$. Recall that a set $C$ is convex if whenever $x, y \in C$, then so is $\lambda x + (1 - \lambda) y$ for all $\lambda \in [0, 1]$. Note how this makes sense in a vector space but maybe not in a general metric space.

In the following theorem, we have in mind both $X$ and $Y$ are Banach spaces, but this is not needed in the proof. All that is needed is that $X$ is a metric space and $Y$ a normed linear space or possibly something more general in which it makes sense to do addition and scalar multiplication.

**Theorem 14.2.3** Let $A$ be a closed subset of a metric space $X$ and let $F : A \to Y$, $Y$ a normed linear space. Then there exists an extension of $F$ denoted as $\hat{F}$ such that $\hat{F}$ is defined on all of $X$ and agrees with $F$ on $A$. It has values in $\text{conv}(F(A))$, the convex hull of $F(A)$.

**Proof:** For each $c \notin A$, let $B_c$ be a ball contained in $A^C$ centered at $c$ where distance of $c$ to $A$ is at least $\text{diam}(B_c)$.
So for \( x \in B_c \) what about \( \text{dist} (x, A) \)? How does it compare with \( \text{dist} (c, A) \)?

\[
\text{dist} (c, A) \leq d (c, x) + \text{dist} (x, A)
\]

\[
\leq \frac{1}{2} \text{diam} (B_c) + \text{dist} (x, A)
\]

\[
\leq \frac{1}{2} \text{dist} (c, A) + \text{dist} (x, A)
\]

so

\[
\text{dist} (c, A) \leq 2 \text{dist} (x, A)
\]

Now the following is also valid. Letting \( x \in B_c \) be arbitrary, it follows from the assumption on the diameter that there exists \( a_0 \in A \) such that \( d (c, a_0) < 2 \text{dist} (c, A) \).

Then

\[
d (x, a_0) \leq \sup_{y \in B_c} d (y, a_0) \leq \sup_{y \in B_c} (d (y, c) + d (c, a_0)) \leq \frac{\text{diam} (B_c)}{2} + 2 \text{dist} (c, A)
\]

\[
\leq \frac{\text{dist} (c, A)}{2} + 2 \text{dist} (c, A) < 3 \text{dist} (c, A)
\]

(14.2.1)

It follows from (14.2.1)

\[
d (x, a_0) \leq 3 \text{dist} (c, A) \leq 6 \text{dist} (x, A)
\]

Thus for any \( x \in B_c \), there is an \( a_0 \in A \) such that \( d (x, a_0) \) is bounded by a fixed multiple of the distance from \( x \) to \( A \).

By Stone’s theorem, there is a locally finite open refinement \( \mathcal{R} \). These are open sets each of which is contained in one of the balls just mentioned such that each of these balls is the union of sets of \( \mathcal{R} \). Thus \( \mathcal{R} \) is a locally finite cover of \( A^C \). Since \( x \in A^C \) is in one of those balls, it was just shown that there exists \( a_R \in A \) such that for all \( x \in R \in \mathcal{R} \) we have \( d (x, a_R) \leq 6 \text{dist} (x, A) \). Of course there may be more than one because \( R \) might be contained in more than one of those special balls.

One \( a_R \) is chosen for each \( R \in \mathcal{R} \).

Now let \( \phi_R (x) \equiv \text{dist} (x, R^C) \). Then let

\[
\hat{F} (x) \equiv \begin{cases} F (x) & \text{for } x \in A \\ \sum_{R \in \mathcal{R}} F (a_R) \frac{\phi_R (x)}{\sum_{R \in \mathcal{R}} \phi_R (x)} & \text{for } x \notin A \end{cases}
\]

The sum in the bottom is always finite because the covering is locally finite. Also, this sum is never 0 because \( \mathcal{R} \) is a covering. Also \( \hat{F} \) has values in \( \text{conv} (F (K)) \).

It only remains to verify that \( \hat{F} \) is continuous. It is clearly so on the interior of \( A \) thanks to continuity of \( F \). It is also clearly continuous on \( A^C \) because the functions \( \phi_R \) are continuous. So it suffices to consider \( x_n \to a \in \partial A \subseteq A \) where \( x_n \notin A \) and see whether \( F (a) = \lim_{n \to \infty} \hat{F} (x_n) \).

Suppose this does not happen. Then there is a sequence converging to some \( a \in \partial A \) and \( \varepsilon > 0 \) such that

\[
\varepsilon \leq \left\| \hat{F} (a) - \hat{F} (x_n) \right\| \text{ all } n
\]
For $x_n \in R$, it was shown above that $d(x_n, a_{R_n}) \leq 6 \text{dist}(x_n, A)$. By the above Lemma 14.2.1, it follows that $a_{R_n} \to a$ and so $F(a_{R_n}) \to F(a)$.

$$\varepsilon \leq \left\| \hat{F}(a) - \hat{F}(x_n) \right\| \leq \sum_{R \in R} \| F(a_{R_n}) - F(a) \| \frac{\phi_R(x_{R_n})}{\sum_{R \in R} \phi_R(x_{R_n})}$$

By local finiteness of the cover, each $x_n$ involves only finitely many $R$. Thus, in this limit process, there are countably many $R$ involved. Thus one can apply Fatou’s lemma.

$$\varepsilon \leq \lim_{n \to \infty} \inf \left\| \hat{F}(a) - \hat{F}(x_n) \right\| \leq \sum_{j=1}^\infty \lim_{n \to \infty} \inf \left\| F(a_{R_j,n}) - F(a) \right\| \frac{\phi_{R_j}(x_{R_j,n})}{\sum_{j=1}^\infty \phi_{R_j}(x_{R_j,n})} \leq \sum_{j=1}^\infty \lim_{n \to \infty} \inf \left\| F(a_{R_j,n}) - F(a) \right\| = 0 \blacksquare$$

The last step is needed because you lose local finiteness as you approach $\partial A$. Note that the only thing needed was that $X$ is a metric space. The addition takes place in $Y$ so it needs to be a vector space. Did it need to be complete? No, this was not used. Nor was completeness of $X$ used. The main interest here is in Banach spaces, but the result is more general than that.

It also appears that $\hat{F}$ is locally Lipschitz on $A^C$.

**Definition 14.2.4** Let $S$ be a subset of $X$, a Banach space. Then it is a retract if there exists a continuous function $R : X \to S$ such that $Rs = s$ for all $s \in S$. This $R$ is a retraction. More generally, $S \subseteq T$ is called a retract of $T$ if there is a continuous $R : T \to S$ such that $Rs = s$ for all $s \in S$.

**Theorem 14.2.5** Let $K$ be closed and convex subset of $X$ a Banach space. Then $K$ is a retract.

**Proof:** By Theorem 14.2.3, there is a continuous function $\hat{I}$ extending $I$ to all of $X$. Then also $\hat{I}$ has values in $\text{conv}(IK) = \text{conv}(K) = K$. Hence $\hat{I}$ is a continuous function which does what is needed. It maps everything into $K$ and keeps the points of $K$ unchanged. \( \blacksquare \)

Sometimes people call the set a retraction also or the function which does the job a retraction. This seems like strange thing to call it because a retraction is the act of repudiating something you said earlier. Nevertheless, I will call it that. Note that if $S$ is a retract of the whole metric space $X$, then it must be a retract of every set which contains $S$.

### 14.3 Something Which Is Not A Retract

The next lemma is a fundamental result which will be used to develop the Brouwer degree. It will also be used to give a short proof of the Brouwer fixed point theorem.
14.3. SOMETHING WHICH IS NOT A RETRACT

in the exercises. This major fixed point theorem is probably the most fundamental theorem in nonlinear analysis. The proof outlined in the exercises is from [15].

Lemma 14.3.1 Let $g : U \rightarrow \mathbb{R}^n$ be $C^2$ where $U$ is an open subset of $\mathbb{R}^n$. Then

$$\sum_{j=1}^{n} \text{cof} ((Dg)_{i,j}) = 0,$$

where here $(Dg)_{i,j} = \frac{\partial g_i}{\partial x_j}$. Also, $\text{cof} ((Dg)_{i,j}) = \frac{\partial \det (Dg)}{\partial g_{i,j}}$.

Proof: From the cofactor expansion theorem,

$$\det (Dg) = \sum_{i=1}^{n} g_{i,j} \text{cof} ((Dg)_{i,j})$$

and so

$$\frac{\partial \det (Dg)}{\partial g_{i,j}} = \text{cof} ((Dg)_{i,j})$$

which shows the last claim of the lemma. Also

$$\delta_{kj} \det (Dg) = \sum_{i} g_{i,k} \text{cof} ((Dg)_{i,j})$$

because if $k \neq j$ this is just the cofactor expansion of the determinant of a matrix in which the $k^{th}$ and $j^{th}$ columns are equal. Differentiate with respect to $x_j$ and sum on $j$. This yields

$$\sum_{r,s,j} \delta_{kj} \frac{\partial (\det Dg)}{\partial g_{r,s}} g_{r,x_j} = \sum_{i} g_{i,kj} \text{cof} ((Dg)_{i,j}) + \sum_{ij} g_{i,k} \text{cof} ((Dg)_{i,j,j}).$$

Hence, using $\delta_{kj} = 0$ if $j \neq k$ and

$$\sum_{rs} \text{cof} (Dg)_{rs} g_{r,sk} = \sum_{rs} g_{r,ks} \text{cof} (Dg)_{r,s} + \sum_{ij} g_{i,k} \text{cof} (Dg)_{i,j,j}.$$

Subtracting the first sum on the right from both sides and using the equality of mixed partials,

$$\sum_{ij} g_{i,k} \left( \sum_{j} \text{cof} (Dg)_{i,j,j} \right) = 0.$$ 

If $\det (g_{i,k}) \neq 0$ so that $(g_{i,k})$ is invertible, this shows $\sum_{j} \text{cof} (Dg)_{i,j,j} = 0$. If $\det (Dg) = 0$, let

$$g_k = g + \varepsilon_k I$$

where $\varepsilon_k \rightarrow 0$ and $\det (Dg + \varepsilon_k I) \equiv \det (Dg_k) \neq 0$. Then

$$\sum_{j} \text{cof} (Dg)_{i,j,j} = \lim_{k \rightarrow \infty} \sum_{j} \text{cof} (Dg_k)_{i,j,j} = 0 \blacksquare$$
Definition 14.3.2 Let \( h \) be a function defined on an open set, \( U \subseteq \mathbb{R}^n \). Then \( h \in C^k(U) \) if there exists a function \( g \) defined on an open set, \( W \) containing \( U \) such that \( g = h \) on \( U \) and \( g \) is \( C^k(W) \).

Lemma 14.3.3 There does not exist \( h \in C^2\left(\overline{B(0,R)}\right) \) such that \( h : \overline{B(0,R)} \to \partial B(0,R) \) which also has the property that \( h(x) = x \) for all \( x \in \partial B(0,R) \). That is, there is no retraction of \( \overline{B(0,R)} \) to \( \partial B(0,R) \).

Proof: Suppose such an \( h \) exists. Let \( \lambda \in [0,1] \) and let \( p_\lambda(x) = x + \lambda(h(x) - x) \). This function, \( p_\lambda \) is a homotopy of the identity map and the retraction, \( h \). Let

\[
I(\lambda) = \int_{B(0,R)} \det(Dp_\lambda(x)) \, dx.
\]

Then using the dominated convergence theorem,

\[
I'(\lambda) = \int_{B(0,R)} \sum_{i,j} \frac{\partial \det(Dp_\lambda(x))}{\partial p_{\lambda,i,j}} \frac{\partial p_{\lambda,i,j}}{\partial \lambda} \, dx
\]

\[
= \int_{B(0,R)} \sum_{i,j} \frac{\partial \det(Dp_\lambda(x))}{\partial p_{\lambda,i,j}} (h_i(x) - x_i)_j \, dx
\]

\[
= \int_{B(0,R)} \sum_{i,j} \cof(Dp_\lambda(x))_{ij} (h_i(x) - x_i)_j \, dx
\]

Now by assumption, \( h_i(x) = x_i \) on \( \partial B(0,R) \) and so one can integrate by parts and write

\[
I'(\lambda) = -\sum_i \int_{\partial B(0,R)} \sum_j \cof(Dp_\lambda(x))_{ij} (h_i(x) - x_i)_j \, dx = 0.
\]

Therefore, \( I(\lambda) \) equals a constant. However,

\[
I(0) = m_n\left(\overline{B(0,R)}\right) > 0
\]

but

\[
I(1) = \int_{B(0,R)} \det(Dh(x)) \, dm_n = \int_{\partial B(0,R)} \#(y) \, dm_n = 0
\]

because from polar coordinates or other elementary reasoning, \( m_n(\partial B(0,1)) = 0 \).

The last formula uses the change of variables formula for functions which are not one to one. In this formula, \( \#(y) \) equals the number of \( x \) such that \( h(x) = y \). To see this is so in case you have not seen this, note that \( h \) is \( C^1 \) and so the inverse function theorem from advanced calculus applies. Thus

\[
\int_{B(0,R)} \det(Dh(x)) \, dm_n = \int_{\det(Dh(x)) > 0} \det(Dh(x)) \, dm_n
\]

\[
+ \int_{\det(Dh(x)) < 0} \det(Dh(x)) \, dm_n
\]

\[
= \int_{\det(Dh(x)) > 0} \det(Dh(x)) \, dm_n
\]

\[
+ \int_{\det(Dh(x)) < 0} \det(Dh(x)) \, dm_n
\]

\[
= 0
\]
Thus \( h \) is locally one to one on the two open sets \([\det(Dh(x)) > 0]\), \([\det(Dh(x)) < 0]\). Now use inverse function theorem and change of variables for one to one \( h \) to verify that both of these integrals equal 0. You cover \([\det(Dh(x)) > 0]\) with countably many balls on which \( h \) is one to one and then use change of variables for each of these integrals over \([\det(Dh(x)) > 0]\) intersected with this ball.

The following is the Brouwer fixed point theorem for \( C^2 \) maps.

**Lemma 14.3.4** If \( h \in C^2 \left( \overline{B(0,R)} \right) \) and \( h : \overline{B(0,R)} \to \overline{B(0,R)} \), then \( h \) has a fixed point, \( x \) such that \( h(x) = x \).

**Proof:** Suppose the lemma is not true. Then for all \( x, |x - h(x)| \neq 0 \). Then define
\[
g(x) = h(x) + \frac{x - h(x)}{|x - h(x)|} t(x)
\]
where \( t(x) \) is nonnegative and is chosen such that \( g(x) \in \partial B(0,R) \). This mapping is illustrated in the following picture.

\[
\begin{align*}
H(x,t) &\equiv |h(x)|^2 + 2 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right) t + t^2 = R^2 \\
H_t(x,t) &= 2 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right) + 2t.
\end{align*}
\]

If this is nonzero for all \( x \) near \( \overline{B(0,R)} \), it follows from the implicit function theorem that \( t \) is a \( C^2 \) function of \( x \). Then from (14.3.4)

\[
2t = -2 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right) \\
\pm \sqrt{4 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right)^2 - 4 \left( |h(x)|^2 - R^2 \right)}
\]

and so

\[
H_t(x,t) = 2t + 2 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right) \\
= \pm \sqrt{4 \left( R^2 - |h(x)|^2 \right) + 4 \left( h(x) \cdot \frac{x - h(x)}{|x - h(x)|} \right)^2}
\]
Suppose you have a Banach space $X$ and a set $A \subseteq X$. Suppose $A$ is a retract of $B$ where $B$ has the fixed point property. By this is meant that $A \subseteq B$ and there is a continuous function $f : B \rightarrow A$ such that $f$ equals the identity on $A$. Show that it follows that then $A$ also has the fixed point property.

**Definition 14.3.6** A nonempty topological space $A$ is said to have the fixed point property if every continuous mapping $f : A \rightarrow A$ has a fixed point.

### 14.4 Exercises

1. Suppose you have a Banach space $X$ and a set $A \subseteq X$. Suppose $A$ is a retract of $B$ where $B$ has the fixed point property. By this is meant that $A \subseteq B$ and there is a continuous function $f : B \rightarrow A$ such that $f$ equals the identity on $A$. Show that it follows that then $A$ also has the fixed point property.
2. Show that the fixed point property is a topological property. That is, if you have \( A, B \) two topological spaces and there is a continuous one to one onto mapping \( f : A \to B \) which has continuous inverse, then the two topological spaces either both have the fixed point property or neither one does.

3. The Brouwer fixed point theorem says that every closed ball in \( \mathbb{R}^n \) centered at 0 has the fixed point property. Show that it follows that every bounded convex closed set in \( \mathbb{R}^n \) has the fixed point property. **Hint:** You know that the closed convex set is a retract of \( \mathbb{R}^n \). Now if it is also a bounded set, then you could enclose it in \( B(0,r) \) for some large enough \( r \).

4. Convex closed sets in \( \mathbb{R}^n \) are retracts. Are there other examples of retracts not considered by Theorem 14.2.3?

5. In \( \mathbb{R}^2 \), consider an annulus, \( \{ x : 1 \leq |x| \leq 2 \} \). Show that this set does not have the fixed point property. Could it be a retract of \( \mathbb{R}^2 \)?

6. Does \( \{ x \in \mathbb{R}^n : |x| = 1 \} \) have the fixed point property?

7. Suppose you have a closed subset \( H \) of \( X \) a metric space and suppose also that \( C \) is an open cover of \( H \). Show there is another open cover \( \mathring{C} \) such that the closure of each open set in \( \mathring{C} \) is contained in some set of \( C \). **Hint:** You might want to use the fact that metric space is normal.

8. If \( H \) is a closed nonempty subset of \( \mathbb{R}^n \) and \( C \) is an open cover of \( H \), show that there is a refined open cover such that each of the new open sets are bounded. In the partition of unity result obtained above, applied to \( H \) show that the functions in the partition of unity can be assumed to be infinitely differentiable with compact support.

9. Check that the conclusion of Theorem 14.2.3 applies for \( X \) just a metric space. Then apply it to give another proof of the Tietze extension theorem.

10. Suppose you have that \( h_k : B \to B \) for \( B \) a compact set and each \( h_k \) has a fixed point. Suppose also that \( h_k \) converges to \( h \) uniformly on \( B \). Then \( h \) also has a fixed point. Verify this.

11. The Brouwer fixed point theorem is a finite dimensional creature. Consider a separable Hilbert space \( H \) with a complete orthonormal basis \( \{ e_k \}_{k=1}^{\infty} \). Then define the following map. For \( x = \sum_{i=1}^{\infty} x_i e_i \), define \( L(\sum_{i=1}^{\infty} x_i e_i) = \sum_{i=1}^{\infty} x_i e_{i+1} \). Now let \( f(x) = \frac{1}{2} (1 - \|x\|_H) e_1 + Lx \). Verify that \( f : B(0,1) \to B(0,1) \) is continuous and yet it has no fixed point. This example is in [52].
Chapter 15

Banach Spaces

15.1 Theorems Based On Baire Category

15.1.1 Baire Category Theorem

Some examples of Banach spaces that have been discussed up to now are $\mathbb{R}^n$, $\mathbb{C}^n$, and $L^p(\Omega)$. Theorems about general Banach spaces are proved in this chapter. The main theorems to be presented here are the uniform boundedness theorem, the open mapping theorem, the closed graph theorem, and the Hahn Banach theorem. The first three of these theorems come from the Baire category theorem which is about to be presented. They are topological in nature. The Hahn Banach theorem has nothing to do with topology. Banach spaces are all normed linear spaces and as such, they are all metric spaces because a normed linear space may be considered as a metric space with $d(x, y) = \|x - y\|$. You can check that this satisfies all the axioms of a metric. As usual, if every Cauchy sequence converges, the metric space is called complete.

Definition 15.1.1 A complete normed linear space is called a Banach space.

The following remarkable result is called the Baire category theorem. To get an idea of its meaning, imagine you draw a line in the plane. The complement of this line is an open set and is dense because every point, even those on the line, are limit points of this open set. Now draw another line. The complement of the two lines is still open and dense. Keep drawing lines and looking at the complements of the union of these lines. You always have an open set which is dense. Now what if there were countably many lines? The Baire category theorem implies the complement of the union of these lines is dense. In particular it is nonempty. Thus you cannot write the plane as a countable union of lines. This is a rather rough description of this very important theorem. The precise statement and proof follow.

Theorem 15.1.2 Let $(X, d)$ be a complete metric space and let $\{U_n\}_{n=1}^\infty$ be a sequence of open subsets of $X$ satisfying $\overline{U_n} = X$ ($U_n$ is dense). Then $D \equiv \cap_{n=1}^\infty U_n$ is a dense subset of $X$.
Proof: Let \( p \in X \) and let \( r_0 > 0 \). I need to show \( D \cap B(p, r_0) \neq \emptyset \). Since \( U_1 \) is dense, there exists \( p_1 \in U_1 \cap B(p, r_0) \), an open set. Let \( p_1 \in B(p_1, r_1) \subseteq U_1 \cap B(p, r_0) \) and \( r_1 < 2^{-1} \). This is possible because \( U_1 \cap B(p, r_0) \) is an open set and so there exists \( r_1 \) such that \( B(p_1, r_1) \subseteq U_1 \cap B(p, r_0) \). But

\[
B(p_1, r_1) \subseteq B(p_1, r_1) \subseteq B(p_1, 2r_1)
\]

because \( B(p_1, r_1) = \{ x \in X : d(x, p) \leq r_1 \} \). (Why?)

There exists \( p_2 \in U_2 \cap B(p_1, r_1) \) because \( U_2 \) is dense. Let

\[
p_2 \in B(p_2, r_2) \subseteq B(p_2, r_2) \subseteq U_2 \cap B(p_1, r_1) \subseteq U_1 \cap U_2 \cap B(p, r_0).
\]

and let \( r_2 < 2^{-2} \). Continue in this way. Thus

\[
r_n < 2^{-n},
\]

\[
B(p_n, r_n) \subseteq U_1 \cap U_2 \cap \ldots \cap U_n \cap B(p, r_0),
\]

\[
\overline{B(p_n, r_n)} \subseteq B(p_{n-1}, r_{n-1}).
\]

The sequence, \( \{ p_n \} \) is a Cauchy sequence because all terms of \( \{ p_k \} \) for \( k \geq n \) are contained in \( B(p_n, r_n) \), a set whose diameter is no larger than \( 2^{-n} \). Since \( X \) is complete, there exists \( p_\infty \) such that

\[
\lim_{n \to \infty} p_n = p_\infty.
\]

Since all but finitely many terms of \( \{ p_n \} \) are in \( \overline{B(p_m, r_m)} \), it follows that \( p_\infty \in \overline{B(p_m, r_m)} \) for each \( m \). Therefore,

\[
p_\infty \in \cap_{m=1}^{\infty} \overline{B(p_m, r_m)} \subseteq \cap_{i=1}^{\infty} U_i \cap B(p, r_0).
\]

This proves the theorem.

The following corollary is also called the Baire category theorem.

Corollary 15.1.3 Let \( X \) be a complete metric space and suppose \( X = \cup_{i=1}^{\infty} F_i \) where each \( F_i \) is a closed set. Then for some \( i \), interior \( F_i \neq \emptyset \).

Proof: If all \( F_i \) has empty interior, then \( F_i^C \) would be a dense open set. Therefore, from Theorem 15.1.2, it would follow that

\[
\emptyset = (\cup_{i=1}^{\infty} F_i)^C = \cap_{i=1}^{\infty} F_i^C \neq \emptyset.
\]
The set $D$ of Theorem 15.1.2 is called a $G_\delta$ set because it is the countable intersection of open sets. Thus $D$ is a dense $G_\delta$ set.

Recall that a norm satisfies:

a.) $||x|| \geq 0$, $||x|| = 0$ if and only if $x = 0$.

b.) $||x + y|| \leq ||x|| + ||y||$.

c.) $||cx|| = |c|||x||$ if $c$ is a scalar and $x \in X$.

From the definition of continuity, it follows easily that a function is continuous if

$$\lim_{n \to \infty} x_n = x$$

implies

$$\lim_{n \to \infty} f(x_n) = f(x).$$

**Theorem 15.1.4** Let $X$ and $Y$ be two normed linear spaces and let $L : X \to Y$ be linear ($L(ax + by) = aL(x) + bL(y)$ for $a, b$ scalars and $x, y \in X$). The following are equivalent

a.) $L$ is continuous at 0

b.) $L$ is continuous

c.) There exists $K > 0$ such that $||Lx||_Y \leq K ||x||_X$ for all $x \in X$ ($L$ is bounded).

**Proof:** a.)$\Rightarrow$b.) Let $x_n \to x$. It is necessary to show that $Lx_n \to Lx$. But $(x_n - x) \to 0$ and so from continuity at 0, it follows

$$L(x_n - x) = Lx_n - Lx \to 0$$

so $Lx_n \to Lx$. This shows a.) implies b.).

b.)$\Rightarrow$c.) Since $L$ is continuous, $L$ is continuous at 0. Hence $||Lx||_Y < 1$ whenever $||x||_X \leq \delta$ for some $\delta$. Therefore, suppressing the subscript on the $|| ||$,

$$||L \left( \frac{\delta x}{||x||} \right)|| \leq 1.$$ 

Hence

$$||Lx|| \leq \frac{1}{\delta} ||x||.$$

c.)$\Rightarrow$a.) follows from the inequality given in c.).

**Definition 15.1.5** Let $L : X \to Y$ be linear and continuous where $X$ and $Y$ are normed linear spaces. Denote the set of all such continuous linear maps by $\mathcal{L}(X,Y)$ and define

$$||L|| = \sup\{||Lx|| : ||x|| \leq 1\}. \quad (15.1.1)$$

This is called the operator norm.
CHAPTER 15. BANACH SPACES

Note that from Theorem 15.1.4 \( \|L\| \) is well defined because of part c.) of that Theorem.

The next lemma follows immediately from the definition of the norm and the assumption that \( L \) is linear.

Lemma 15.1.6 With \( \|L\| \) defined in 15.1.1, \( \mathcal{L}(X, Y) \) is a normed linear space. Also \( \|Lx\| \leq \|L\| \|x\| \).

Proof: Let \( x \neq 0 \) then \( x/\|x\| \) has norm equal to 1 and so

\[
\left\| L \left( \frac{x}{\|x\|} \right) \right\| \leq \|L\|.
\]

Therefore, multiplying both sides by \( \|x\| \), \( \|Lx\| \leq \|L\| \|x\| \). This is obviously a linear space. It remains to verify the operator norm really is a norm. First of all, if \( \|L\| = 0 \), then \( Lx = 0 \) for all \( \|x\| \leq 1 \). It follows that for any \( x \neq 0 \), \( 0 = L \left( \frac{x}{\|x\|} \right) \) and so \( Lx = 0 \). Therefore, \( L = 0 \). Also, if \( c \) is a scalar,

\[
\|cL\| = \sup_{\|x\| \leq 1} \|cL(x)\| = |c| \sup_{\|x\| \leq 1} \|Lx\| = |c| \|L\|.
\]

It remains to verify the triangle inequality. Let \( L, M \in \mathcal{L}(X, Y) \).

\[
\|L + M\| = \sup_{\|x\| \leq 1} \|(L + M)(x)\| \leq \sup_{\|x\| \leq 1} (\|Lx\| + \|Mx\|) \\
\leq \sup_{\|x\| \leq 1} \|Lx\| + \sup_{\|x\| \leq 1} \|Mx\| = \|L\| + \|M\|.
\]

This shows the operator norm is really a norm as hoped. This proves the lemma.

For example, consider the space of linear transformations defined on \( \mathbb{R}^n \) having values in \( \mathbb{R}^m \). The fact the transformation is linear automatically imparts continuity to it. You should give a proof of this fact. Recall that every such linear transformation can be realized in terms of matrix multiplication.

Thus, in finite dimensions the algebraic condition that an operator is linear is sufficient to imply the topological condition that the operator is continuous. The situation is not so simple in infinite dimensional spaces such as \( C(X; \mathbb{R}^n) \). This explains the imposition of the topological condition of continuity as a criterion for membership in \( \mathcal{L}(X, Y) \) in addition to the algebraic condition of linearity.

Theorem 15.1.7 If \( Y \) is a Banach space, then \( \mathcal{L}(X, Y) \) is also a Banach space.

Proof: Let \( \{L_n\} \) be a Cauchy sequence in \( \mathcal{L}(X, Y) \) and let \( x \in X \).

\[
\|L_n x - L_m x\| \leq \|x\| \|L_n - L_m\|.
\]

Thus \( \{L_n x\} \) is a Cauchy sequence. Let

\[
Lx = \lim_{n \to \infty} L_n x.
\]
Then, clearly, \( L \) is linear because if \( x_1, x_2 \) are in \( X \), and \( a, b \) are scalars, then
\[
L(ax_1 + bx_2) = \lim_{n \to \infty} L_n(ax_1 + bx_2) \\
= \lim_{n \to \infty} (aL_n x_1 + bL_n x_2) \\
= aLx_1 + bLx_2.
\]

Also \( L \) is continuous. To see this, note that \( \{ \|L_n\| \} \) is a Cauchy sequence of real numbers because \( \|L_n\| - \|L_m\| \leq \|L_n - L_m\| \). Hence there exists \( K > \sup \{ \|L_n\| : n \in \mathbb{N} \} \). Thus, if \( x \in X \),
\[
\|Lx\| = \lim_{n \to \infty} \|L_n x\| \leq K\|x\|.
\]

This proves the theorem.

15.1.2 Uniform Boundedness Theorem

The next big result is sometimes called the Uniform Boundedness theorem, or the Banach-Steinhaus theorem. This is a very surprising theorem which implies that for a collection of bounded linear operators, if they are bounded pointwise, then they are also bounded uniformly. As an example of a situation in which pointwise bounded does not imply uniformly bounded, consider the functions \( f_\alpha (x) = x^{-\alpha} \) for \( \alpha \in (0, 1) \). Clearly each function is bounded and the collection of functions is bounded at each point of \((0, 1)\), but there is no bound for all these functions taken together. One problem is that \((0, 1)\) is not a Banach space. Therefore, the functions cannot be linear.

**Theorem 15.1.8** Let \( X \) be a Banach space and let \( Y \) be a normed linear space. Let \( \{ L_\alpha \}_{\alpha \in \Lambda} \) be a collection of elements of \( \mathcal{L}(X,Y) \). Then one of the following happens.

a.) \( \sup \{ \|L_\alpha\| : \alpha \in \Lambda \} < \infty \)

b.) There exists a dense \( G_\delta \) set, \( D \), such that for all \( x \in D \),
\[
\sup \{ \|L_\alpha x\| : \alpha \in \Lambda \} = \infty.
\]

**Proof:** For each \( n \in \mathbb{N} \), define
\[
U_n = \{ x \in X : \sup \{ \|L_\alpha x\| : \alpha \in \Lambda \} > n \}.
\]

Then \( U_n \) is an open set because if \( x \in U_n \), then there exists \( \alpha \in \Lambda \) such that
\[
\|L_\alpha x\| > n
\]

But then, since \( L_\alpha \) is continuous, this situation persists for all \( y \) sufficiently close to \( x \), say for all \( y \in B(x, \delta) \). Then \( B(x, \delta) \subseteq U_n \) which shows \( U_n \) is open.

Case b.) is obtained from Theorem 15.1.2 if each \( U_n \) is dense.

The other case is that for some \( n \), \( U_n \) is not dense. If this occurs, there exists \( x_0 \) and \( r > 0 \) such that for all \( x \in B(x_0, r) \), \( \|L_\alpha x\| \leq n \) for all \( \alpha \). Now if \( y \in \)
\(B(0, r), \quad x_0 + y \in B(x_0, r)\). Consequently, for all such \(y\), \(\|L_\alpha(x_0 + y)\| \leq n\). This implies that for all \(\alpha \in \Lambda\) and \(\|y\| < r\),
\[
\|L_\alpha y\| \leq n + \|L_\alpha(x_0)\| \leq 2n.
\]
Therefore, if \(\|y\| \leq 1\), \(\left\| \frac{r}{2}y \right\| < r\) and so for all \(\alpha\),
\[
\|L_\alpha \left( \frac{r}{2}y \right) \| \leq 2n.
\]
Now multiplying by \(r/2\) it follows that whenever \(\|y\| \leq 1\), \(\|L_\alpha(y)\| \leq 4n/r\). Hence case a.) holds.

15.1.3 Open Mapping Theorem

Another remarkable theorem which depends on the Baire category theorem is the open mapping theorem. Unlike Theorem 15.1.8 it requires both \(X\) and \(Y\) to be Banach spaces.

**Theorem 15.1.9** Let \(X\) and \(Y\) be Banach spaces, let \(L \in \mathcal{L}(X, Y)\), and suppose \(L\) is onto. Then \(L\) maps open sets onto open sets.

To aid in the proof, here is a lemma.

**Lemma 15.1.10** Let \(a\) and \(b\) be positive constants and suppose
\[
B(0, a) \subseteq L(B(0, b)).
\]
Then
\[
L(B(0, b)) \subseteq L(B(0, 2b)).
\]

**Proof of Lemma 15.1.10** Let \(y \in L(B(0, b))\). There exists \(x_1 \in B(0, b)\) such that \(\|y - Lx_1\| < \frac{a}{2}\). Now this implies
\[
2y - 2Lx_1 \in B(0, a) \subseteq L(B(0, b)).
\]
Thus \(2y - 2Lx_1 \in L(B(0, b))\), just like \(y\) was. Therefore, there exists \(x_2 \in B(0, b)\) such that \(\|2y - 2Lx_1 - Lx_2\| < a/2\). Hence \(\|4y - 4Lx_1 - 2Lx_2\| < a\), and there exists \(x_3 \in B(0, b)\) such that \(\|4y - 4Lx_1 - 2Lx_2 - Lx_3\| < a/2\). Continuing in this way, there exist \(x_1, x_2, x_3, x_4, \ldots\) in \(B(0, b)\) such that
\[
\|2^n y - \sum_{i=1}^{n} 2^{n-(i-1)} L(x_i)\| < a
\]
which implies
\[
\|y - \sum_{i=1}^{n} 2^{-(i-1)} L(x_i)\| = \|y - L \left( \sum_{i=1}^{n} 2^{-(i-1)} (x_i) \right)\| < 2^{-n} a \quad (15.1.2)
\]
15.1. THEOREMS BASED ON BANACH CATEGORY

Now consider the partial sums of the series, \( \sum_{i=1}^{\infty} 2^{-(i-1)}x_i \).

\[
\sum_{i=m}^{n} 2^{-(i-1)}x_i \leq b \sum_{i=m}^{\infty} 2^{-(i-1)} = b \cdot 2^{m-2}.
\]

Therefore, these partial sums form a Cauchy sequence and so since \( X \) is complete, there exists \( x = \sum_{i=1}^{\infty} 2^{-(i-1)}x_i \). Letting \( n \to \infty \) in (15.1.2) yields \( \|y - Lx\| = 0 \). Now

\[
\|x\| = \lim_{n \to \infty} \| \sum_{i=1}^{n} 2^{-(i-1)}x_i \|
\]

\[
\leq \lim_{n \to \infty} \sum_{i=1}^{n} 2^{-(i-1)}\|x_i\| < \lim_{n \to \infty} \sum_{i=1}^{n} 2^{-(i-1)}b = 2b.
\]

This proves the lemma.

**Proof of Theorem** (15.1.4): \( Y = \cup_{n=1}^{\infty} L(B(0,n)) \). By Corollary (15.1.3), the set, \( L(B(0,n)) \) has nonempty interior for some \( n_0 \). Thus \( B(y,r) \subseteq L(B(0,n_0)) \) for some \( y \) and some \( r > 0 \). Since \( L \) is linear \( B(-y,r) \subseteq L(B(0,n_0)) \) also. Here is why. If \( z \in B(-y,r) \), then \( -z \in B(y,r) \) and so there exists \( x_n \in B(0,n_0) \) such that \( Lx_n \to z \). Therefore, \( L(-x_n) \to z \) and \( -x_n \in B(0,n_0) \). Therefore \( z \in L(B(0,n_0)) \). Then it follows that

\[
B(0,r) \subseteq B(y,r) + B(-y,r)
\]

\[
= \{y_1 + y_2 : y_1 \in B(y,r) \text{ and } y_2 \in B(-y,r)\}
\]

\[
\subseteq L(B(0,2n_0))
\]

The reason for the last inclusion is that from the above, if \( y_1 \in B(y,r) \) and \( y_2 \in B(-y,r) \), there exists \( x_n, z_n \in B(0,n_0) \) such that

\[
Lx_n \to y_1, \quad Lz_n \to y_2.
\]

Therefore,

\[
\|x_n + z_n\| \leq 2n_0
\]

and so \( (y_1 + y_2) \in L(B(0,2n_0)) \).

By Lemma (15.1.4), \( L(B(0,2n_0)) \subseteq L(B(0,4n_0)) \) which shows

\[
B(0,r) \subseteq L(B(0,4n_0)).
\]

Letting \( a = r(4n_0)^{-1} \), it follows, since \( L \) is linear, that \( B(0,a) \subseteq L(B(0,1)) \). It follows since \( L \) is linear,

\[
L(B(0,r)) \supseteq B(0,ar).
\]  

(15.1.3)

Now let \( U \) be open in \( X \) and let \( x + B(0,r) = B(x,r) \subseteq U \). Using (15.1.5),

\[
L(U) \supseteq L(x + B(0,r))
\]

\[
= Lx + L(B(0,r)) \supseteq Lx + B(0,ar) = B(Lx, ar).
\]
Hence
\[ Lx \in B(Lx, ar) \subseteq L(U). \]
which shows that every point, \( Lx \in LU \), is an interior point of \( LU \) and so \( LU \) is open. This proves the theorem.

This theorem is surprising because it implies that if \(|\cdot|\) and \(||\cdot||\) are two norms with respect to which a vector space \( X \) is a Banach space such that \(|\cdot| \leq K ||\cdot||\), then there exists a constant \( k \), such that \(||\cdot|| \leq k |\cdot|\). This can be useful because sometimes it is not clear how to compute \( k \) when all that is needed is its existence.

To see the open mapping theorem implies this, consider the identity map \( \text{id} : x = x \).

Then \( \text{id} : (X, ||\cdot||) \to (X, |\cdot|) \) is continuous and onto. Hence \( \text{id} \) is an open map which implies \( \text{id}^{-1} \) is continuous. Theorem \( 15.1.4 \) gives the existence of the constant \( k \).

### 15.1.4 Closed Graph Theorem

**Definition 15.1.11** Let \( f : D \to E \). The set of all ordered pairs of the form \( \{(x, f(x)) : x \in D\} \) is called the graph of \( f \).

**Definition 15.1.12** If \( X \) and \( Y \) are normed linear spaces, make \( X \times Y \) into a normed linear space by using the norm \( ||(x, y)|| = \max(||x||, ||y||) \) along with component-wise addition and scalar multiplication. Thus \( a(x, y) + b(z, w) \equiv (ax + bz, ay + bw) \).

There are other ways to give a norm for \( X \times Y \). For example, you could define \( ||(x, y)|| = ||x|| + ||y|| \)

**Lemma 15.1.13** The norm defined in Definition \( 15.1.12 \) on \( X \times Y \) along with the definition of addition and scalar multiplication given there make \( X \times Y \) into a normed linear space.

**Proof:** The only axiom for a norm which is not obvious is the triangle inequality. Therefore, consider
\[
||(x_1, y_1) + (x_2, y_2)|| = ||(x_1 + x_2, y_1 + y_2)|| \\
= \max(||x_1 + x_2||, ||y_1 + y_2||) \\
\leq \max(||x_1|| + ||x_2||, ||y_1|| + ||y_2||) \\
\leq \max(||x_1||, ||y_1||) + \max(||x_2||, ||y_2||) \\
= ||(x_1, y_1)|| + ||(x_2, y_2)||.
\]
It is obvious \( X \times Y \) is a vector space from the above definition. This proves the lemma.

**Lemma 15.1.14** If \( X \) and \( Y \) are Banach spaces, then \( X \times Y \) with the norm and vector space operations defined in Definition \( 15.1.12 \) is also a Banach space.
Proof: The only thing left to check is that the space is complete. But this follows from the simple observation that \( \{(x_n, y_n)\} \) is a Cauchy sequence in \( X \times Y \) if and only if \( \{x_n\} \) and \( \{y_n\} \) are Cauchy sequences in \( X \) and \( Y \) respectively. Thus if \( \{(x_n, y_n)\} \) is a Cauchy sequence in \( X \times Y \), it follows there exist \( x \) and \( y \) such that \( x_n \to x \) and \( y_n \to y \). But then from the definition of the norm, \( (x_n, y_n) \to (x, y) \).

Lemma 15.1.15 Every closed subspace of a Banach space is a Banach space.

Proof: If \( F \subseteq X \) where \( X \) is a Banach space and \( \{x_n\} \) is a Cauchy sequence in \( F \), then since \( X \) is complete, there exists a unique \( x \in X \) such that \( x_n \to x \). However this means \( x \in \overline{F} = F \) since \( F \) is closed.

Definition 15.1.16 Let \( X \) and \( Y \) be Banach spaces and let \( D \subseteq X \) be a subspace. A linear map \( L : D \to Y \) is said to be closed if its graph is a closed subspace of \( X \times Y \). Equivalently, \( L \) is closed if \( x_n \to x \) and \( Lx_n \to y \) implies \( x \in D \) and \( y = Lx \).

Note the distinction between closed and continuous. If the operator is closed the assertion that \( y = Lx \) only follows if it is known that the sequence \( \{Lx_n\} \) converges. In the case of a continuous operator, the convergence of \( \{Lx_n\} \) follows from the assumption that \( x_n \to x \). It is not always the case that a mapping which is closed is necessarily continuous. Consider the function \( f(x) = \tan(x) \) if \( x \) is not an odd multiple of \( \frac{\pi}{2} \) and \( f(x) \equiv 0 \) at every odd multiple of \( \frac{\pi}{2} \). Then the graph is closed and the function is defined on \( \mathbb{R} \) but it clearly fails to be continuous. Of course this function is not linear. You could also consider the map,

\[
\frac{d}{dx} : \{ y \in C^1([0,1]) : y(0) = 0 \} = D \to C([0,1]).
\]

where the norm is the uniform norm on \( C([0,1]) \), \( ||y||_\infty \). If \( y \in D \), then

\[
y(x) = \int_0^x y'(t) \, dt.
\]

Therefore, if \( \frac{dy_n}{dx} \to f \in C([0,1]) \) and if \( y_n \to y \) in \( C([0,1]) \) it follows that

\[
\begin{align*}
y_n(x) &= \int_0^x \frac{dy_n(t)}{dx} \, dt \\
y(x) &= \int_0^x f(t) \, dt
\end{align*}
\]

and so by the fundamental theorem of calculus \( f(x) = y'(x) \) and so the mapping is closed. It is obviously not continuous because it takes \( y(x) \) and \( y(x) + \frac{1}{n} \sin(nx) \) to two functions which are far from each other even though these two functions are very close in \( C([0,1]) \). Furthermore, it is not defined on the whole space, \( C([0,1]) \).

The next theorem, the closed graph theorem, gives conditions under which closed implies continuous.
**Theorem 15.1.17** Let $X$ and $Y$ be Banach spaces and suppose $L : X \to Y$ is closed and linear. Then $L$ is continuous.

**Proof:** Let $G$ be the graph of $L$. $G = \{(x, Lx) : x \in X\}$. By Lemma 15.1.15 it follows that $G$ is a Banach space. Define $P : G \to X$ by $P(x, Lx) = x$. $P$ maps the Banach space $G$ onto the Banach space $X$ and is continuous and linear. By the open mapping theorem, $P$ maps open sets onto open sets. Since $P$ is also one to one, this says that $P^{-1}$ is continuous. Thus $||P^{-1}x|| \leq K||x||$. Hence

$$||Lx|| \leq \max(||x||, ||Lx||) \leq K||x||$$

By Theorem 15.1.4 on Page 419, this shows $L$ is continuous and proves the theorem.

The following corollary is quite useful. It shows how to obtain a new norm on the domain of a closed operator such that the domain with this new norm becomes a Banach space.

**Corollary 15.1.18** Let $L : D \subseteq X \to Y$ where $X, Y$ are a Banach spaces, and $L$ is a closed operator. Then define a new norm on $D$ by

$$||x||_D \equiv ||x||_X + ||Lx||_Y.$$ 

Then $D$ with this new norm is a Banach space.

**Proof:** If $\{x_n\}$ is a Cauchy sequence in $D$ with this new norm, it follows both $\{x_n\}$ and $\{Lx_n\}$ are Cauchy sequences and therefore, they converge. Since $L$ is closed, $x_n \to x$ and $Lx_n \to Lx$ for some $x \in D$. Thus $||x_n - x||_D \to 0$.

### 15.2 Hahn Banach Theorem

The closed graph, open mapping, and uniform boundedness theorems are the three major topological theorems in functional analysis. The other major theorem is the Hahn-Banach theorem which has nothing to do with topology. Before presenting this theorem, here are some preliminaries about partially ordered sets.

#### 15.2.1 Partially Ordered Sets

**Definition 15.2.1** Let $\mathcal{F}$ be a nonempty set. $\mathcal{F}$ is called a partially ordered set if there is a relation, denoted here by $\leq$, such that

- $x \leq x$ for all $x \in \mathcal{F}$.
- If $x \leq y$ and $y \leq z$ then $x \leq z$.

$\mathcal{C} \subseteq \mathcal{F}$ is said to be a chain if every two elements of $\mathcal{C}$ are related. This means that if $x, y \in \mathcal{C}$, then either $x \leq y$ or $y \leq x$. Sometimes a chain is called a totally ordered set. $\mathcal{C}$ is said to be a maximal chain if whenever $D$ is a chain containing $\mathcal{C}$, $D = \mathcal{C}$.
The most common example of a partially ordered set is the power set of a given set with \( \subseteq \) being the relation. It is also helpful to visualize partially ordered sets as trees. Two points on the tree are related if they are on the same branch of the tree and one is higher than the other. Thus two points on different branches would not be related although they might both be larger than some point on the trunk. You might think of many other things which are best considered as partially ordered sets. Think of food for example. You might find it difficult to determine which of two favorite pies you like better although you may be able to say very easily that you would prefer either pie to a dish of lard topped with whipped cream and mustard. The following theorem is equivalent to the axiom of choice. For a discussion of this, see the appendix on the subject.

**Theorem 15.2.2 (Hausdorff Maximal Principle)** Let \( F \) be a nonempty partially ordered set. Then there exists a maximal chain.

**15.2.2 Gauge Functions And Hahn Banach Theorem**

**Definition 15.2.3** Let \( X \) be a real vector space \( \rho : X \to \mathbb{R} \) is called a gauge function if

\[
\rho(x + y) \leq \rho(x) + \rho(y),
\]

\[
\rho(az) = a\rho(x) \text{ if } a \geq 0.
\]

(15.2.4)

Suppose \( M \) is a subspace of \( X \) and \( z \notin M \). Suppose also that \( f \) is a linear real-valued function having the property that \( f(x) \leq \rho(x) \) for all \( x \in M \). Consider the problem of extending \( f \) to \( M \oplus \mathbb{R}z \) such that if \( F \) is the extended function, \( F(y) \leq \rho(y) \) for all \( y \in M \oplus \mathbb{R}z \) and \( F \) is linear. Since \( F \) is to be linear, it suffices to determine how to define \( F(z) \). Letting \( a > 0 \), it is required to define \( F(z) \) such that the following hold for all \( x, y \in M \).

\[
\frac{f(x)}{F(x) + aF(z) = F(x + az) \leq \rho(x + az)},
\]

\[
\frac{f(y)}{F(y) - aF(z) = F(y - az) \leq \rho(y - az)}.
\]

(15.2.5)

Now if these inequalities hold for all \( y/a \), they hold for all \( y \) because \( M \) is given to be a subspace. Therefore, multiplying by \( a^{-1} \) implies that what is needed is to choose \( F(z) \) such that for all \( x, y \in M \),

\[
f(x) + F(z) \leq \rho(x + z), \quad f(y) - \rho(y - z) \leq F(z)
\]

and that if \( F(z) \) can be chosen in this way, this will satisfy \( 15.2.4 \) for all \( x, y \) and the problem of extending \( f \) will be solved. Hence it is necessary to choose \( F(z) \) such that for all \( x, y \in M \)

\[
f(y) - \rho(y - z) \leq F(z) \leq \rho(x + z) - f(x).
\]

(15.2.6)
Is there any such number between \( f(y) - \rho(y - z) \) and \( \rho(x + z) - f(x) \) for every pair \( x, y \in M \)? This is where \( f(x) \leq \rho(x) \) on \( M \) and that \( f \) is linear is used. For \( x, y \in M \),
\[
\rho(x + z) - f(x) - [f(y) - \rho(y - z)] \\
= \rho(x + z) + \rho(y - z) - (f(x) + f(y)) \\
\geq \rho(x + y) - f(x + y) \geq 0.
\]
Therefore there exists a number between
\[
\sup \{ f(y) - \rho(y - z) : y \in M \}
\]
and
\[
\inf \{ \rho(x + z) - f(x) : x \in M \}
\]
Choose \( F(z) \) to satisfy \[15.2.4\]. This has proved the following lemma.

**Lemma 15.2.4** Let \( M \) be a subspace of \( X \), a real linear space, and let \( \rho \) be a gauge function on \( X \). Suppose \( f : M \to \mathbb{R} \) is linear, \( z \notin M \), and \( f(x) \leq \rho(x) \) for all \( x \in M \). Then \( f \) can be extended to \( M \oplus \mathbb{R}z \) such that, if \( F \) is the extended function, \( F \) is linear and \( F(x) \leq \rho(x) \) for all \( x \in M \oplus \mathbb{R}z \).

With this lemma, the Hahn Banach theorem can be proved.

**Theorem 15.2.5** \( \text{(Hahn Banach theorem)} \) Let \( X \) be a real vector space, let \( M \) be a subspace of \( X \), let \( f : M \to \mathbb{R} \) be linear, let \( \rho \) be a gauge function on \( X \), and suppose \( f(x) \leq \rho(x) \) for all \( x \in M \). Then there exists a linear function, \( F : X \to \mathbb{R} \), such that
a.) \( F(x) = f(x) \) for all \( x \in M \)
b.) \( F(x) \leq \rho(x) \) for all \( x \in X \).

**Proof:** Let \( \mathcal{F} = \{ (V,g) : V \supseteq M, \ V \text{ is a subspace of } X, \ g : V \to \mathbb{R} \text{ is linear, } \ g(x) = f(x) \text{ for all } x \in M, \text{ and } g(x) \leq \rho(x) \text{ for } x \in V \} \). Then \((M,f) \in \mathcal{F}\) so \( \mathcal{F} \neq \emptyset \).

Define a partial order by the following rule.
\[
(V, g) \leq (W, h)
\]
means
\[
V \subseteq W \text{ and } h(x) = g(x) \text{ if } x \in V.
\]
By Theorem \[15.2.4\], there exists a maximal chain, \( \mathcal{C} \subseteq \mathcal{F} \). Let \( Y = \cup \{ V : (V, g) \in \mathcal{C} \} \) and let \( h : Y \to \mathbb{R} \) be defined by \( h(x) = g(x) \) where \( x \in V \) and \((V, g) \in \mathcal{C}\). This is well defined because if \( x \in V_1 \) and \( V_2 \) where \( (V_1, g_1) \) and \( (V_2, g_2) \) are both in the chain, then since \( \mathcal{C} \) is a chain, the two element related. Therefore, \( g_1(x) = g_2(x) \).

Also \( h \) is linear because if \( ax + by \in Y \), then \( x \in V_1 \) and \( y \in V_2 \) where \((V_1, g_1)\) and \((V_2, g_2)\) are elements of \( \mathcal{C} \). Therefore, letting \( V \) denote the larger of the two \( V_1 \),...
and \( g \) be the function that goes with \( V \), it follows \( ax + by \in V \) where \((V,g) \in C\). Therefore,

\[
    h(ax + by) = g(ax + by) \\
    = ag(x) + bg(y) \\
    = ah(x) + bh(y).
\]

Also, \( h(x) = g(x) \leq \rho(x) \) for any \( x \in Y \) because for such \( x \), \( x \in V \) where \((V,g) \in C\).

Is \( Y = X \)? If not, there exists \( z \in X \setminus Y \) and there exists an extension of \( h \) to \( Y \oplus \mathbb{R}z \) using Lemma 15.2.4. Letting \( \overline{h} \) denote this extended function, contradicts the maximality of \( C \). Indeed, \( C \cup \{(Y \oplus \mathbb{R}z, \overline{h})\} \) would be a longer chain. This proves the Hahn Banach theorem.

This is the original version of the theorem. There is also a version of this theorem for complex vector spaces which is based on a trick.

**15.2.3 The Complex Version Of The Hahn Banach Theorem**

**Corollary 15.2.6 (Hahn Banach)** Let \( M \) be a subspace of a complex normed linear space, \( X \), and suppose \( f : M \to \mathbb{C} \) is linear and satisfies \(|f(x)| \leq K\|x\| \) for all \( x \in M \). Then there exists a linear function, \( F \), defined on all of \( X \) such that \( F(x) = f(x) \) for all \( x \in M \) and \(|F(x)| \leq K\|x\| \) for all \( x \).

**Proof:** First note \( f(x) = \text{Re}f(x) + i\text{Im}f(x) \) and so

\[
    \text{Re}f(ix) + i\text{Im}f(ix) = f(ix) = if(x) = i\text{Re}f(x) = -\text{Im}f(x).
\]

Therefore, \( \text{Im}f(x) = -\text{Re}f(ix) \), and

\[
    f(x) = \text{Re}f(x) - i\text{Re}f(ix).
\]

This is important because it shows it is only necessary to consider \( \text{Re}f \) in understanding \( f \). Now it happens that \( \text{Re}f \) is linear with respect to real scalars so the above version of the Hahn Banach theorem applies. This is shown next.

If \( c \) is a real scalar

\[
    \text{Re}f(cx) - i\text{Re}f(icx) = cf(x) = c\text{Re}f(x) - ic\text{Re}f(ix).
\]

Thus \( \text{Re}f(cx) = c\text{Re}f(x) \). Also,

\[
    \text{Re}f(x + y) - i\text{Re}f(i(x + y)) = f(x + y) \\
    = f(x) + f(y)
\]

\[
    = \text{Re}f(x) - i\text{Re}f(ix) + \text{Re}f(y) - i\text{Re}f(iy).
\]

Equating real parts, \( \text{Re}f(x + y) = \text{Re}f(x) + \text{Re}f(y) \). Thus \( \text{Re}f \) is linear with respect to real scalars as hoped.
Consider $X$ as a real vector space and let $\rho(x) \equiv K||x||$. Then for all $x \in M$,

$$|\Re f(x)| \leq |f(x)| \leq K||x|| = \rho(x).$$

From Theorem 15.2.5, $\Re f$ may be extended to a function, $h$ which satisfies

$$h(ax + by) = ah(x) + bh(y) \text{ if } a, b \in \mathbb{R}$$

$$h(x) \leq K||x|| \text{ for all } x \in X.$$

Actually, $|h(x)| \leq K||x||$. The reason for this is that $h(-x) = -h(x) \leq K||-x|| = K||x||$ and therefore, $h(x) \geq -K||x||$. Let

$$F(x) \equiv h(x) - ih(ix).$$

By arguments similar to the above, $F$ is linear.

$$F(ix) = h(ix) - ih(-x)$$

$$= ih(x) + h(ix)$$

$$= i(h(x) - ih(ix)) = iF(x).$$

If $c$ is a real scalar,

$$F(cx) = h(cx) - ih(icx)$$

$$= ch(x) - cih(ix) = cF(x)$$

Now

$$F(x + y) = h(x + y) - ih(i(x + y))$$

$$= h(x) + h(y) - ih(ix) - ih(iy)$$

$$= F(x) + F(y).$$

Thus

$$F((a + ib)x) = F(ax + F(ibx)$$

$$= aF(x) + ibF(x)$$

$$= (a + ib)F(x).$$

This shows $F$ is linear as claimed.

Now $wF(x) = |F(x)|$ for some $|w| = 1$. Therefore

$$|F(x)| = wF(x) = h(wx) - ih(iwx) = h(wx)$$

$$= |h(wx)| \leq K||wx|| = K||x||.$$
15.2.4 The Dual Space And Adjoint Operators

**Definition 15.2.7** Let $X$ be a Banach space. Denote by $X'$ the space of continuous linear functions which map $X$ to the field of scalars. Thus $X' = \mathcal{L}(X, \mathbb{F})$. By Theorem 15.1.7 on Page 420, $X'$ is a Banach space. Remember with the norm defined on $\mathcal{L}(X, \mathbb{F})$,

$$\|f\| = \sup\{|f(x)| : \|x\| \leq 1\}$$

$X'$ is called the dual space.

**Definition 15.2.8** Let $X$ and $Y$ be Banach spaces and suppose $L \in \mathcal{L}(X, Y)$. Then define the adjoint map in $\mathcal{L}(Y', X')$, denoted by $L^*$, by

$$L^* y^*(x) \equiv y^*(Lx)$$

for all $y^* \in Y'$.

The following diagram is a good one to help remember this definition.

```
    L^*
   /
X'  ←  Y'
   /
   X  →  Y
```

This is a generalization of the adjoint of a linear transformation on an inner product space. Recall

$$(Ax, y) = (x, A^*y)$$

What is being done here is to generalize this algebraic concept to arbitrary Banach spaces. There are some issues which need to be discussed relative to the above definition. First of all, it must be shown that $L^* y^* \in X'$. Also, it will be useful to have the following lemma which is a useful application of the Hahn Banach theorem.

**Lemma 15.2.9** Let $X$ be a normed linear space and let $x \in X \setminus V$ where $V$ is a closed subspace of $X$. Then there exists $x^* \in X'$ such that $x^*(x) = \|x\|$, $x^*(V) = \{0\}$, and

$$\|x^*\| \leq \frac{1}{\text{dist}(x, V)}$$

In the case that $V = \{0\}$, $\|x^*\| = 1$.

**Proof:** Let $f : \mathbb{F}x + V \to \mathbb{F}$ be defined by $f(\alpha x + v) = \alpha \|x\|$. First it is necessary to show $f$ is well defined and continuous. If $\alpha_1 x + v_1 = \alpha_2 x + v_2$ then if $\alpha_1 \neq \alpha_2$, then $x \in V$ which is assumed not to happen so $f$ is well defined. It remains to show $f$ is continuous. Suppose then that $\alpha_n x + v_n \to 0$. It is necessary to show $\alpha_n \to 0$. If this does not happen, then there exists a subsequence, still denoted by $\alpha_n$ such that $|\alpha_n| \geq \delta > 0$. Then $x + (1/\alpha_n) v_n \to 0$ contradicting the assumption...
that \( x \notin V \) and \( V \) is a closed subspace. Hence \( f \) is continuous on \( F + V \). Being a little more careful,

\[
\|f\| = \sup_{\|\alpha x + v\| \leq 1} |f(\alpha x + v)| = \sup_{|\alpha| \leq \text{dist}(x, V)} |\alpha| \|x\| = \frac{1}{\text{dist}(x, V)} \|x\|
\]

By the Hahn Banach theorem, there exists \( x^* \in X' \) such that \( x^* = f \) on \( F + V \).
Thus \( x^*(x) = \|x\| \) and also

\[
\|x^*\| \leq \|f\| = \frac{1}{\text{dist}(x, V)}
\]

In case \( V = \{0\} \), the result follows from the above or alternatively,

\[
\|f\| = \sup_{|\alpha x| \leq 1} |f(\alpha x)| = \sup_{|\alpha| \leq 1} |\alpha| \|x\| = 1
\]

and so, in this case, \( \|x^*\| \leq \|f\| = 1 \). Since \( x^*(x) = \|x\| \) it follows

\[
\|x^*\| \geq x^* \left( \frac{x}{\|x\|} \right) = \frac{\|x\|}{\|x\|} = 1.
\]

Thus \( \|x^*\| = 1 \) and this proves the lemma.

**Theorem 15.2.10** Let \( L \in \mathcal{L}(X, Y) \) where \( X \) and \( Y \) are Banach spaces. Then

a.) \( L^* \in \mathcal{L}(Y', X') \) as claimed and \( \|L^*\| = \|L\| \).

b.) If \( L \) maps one to one onto a closed subspace of \( Y \), then \( L^* \) is onto.

c.) If \( L \) maps onto a dense subset of \( Y \), then \( L^* \) is one to one.

**Proof:** It is routine to verify \( L^*y^* \) and \( L^* \) are both linear. This follows immediately from the definition. As usual, the interesting thing concerns continuity.

\[
\|L^*y^*\| = \sup_{\|x\| \leq 1} |L^*y^*(x)| = \sup_{\|x\| \leq 1} |y^*(Lx)| \leq \|y^*\| \|L\|.
\]

Thus \( L^* \) is continuous as claimed and \( \|L^*\| \leq \|L\| \).

By Lemma 15.2.9, there exists \( y^*_z \in Y' \) such that \( \|y^*_z\| = 1 \) and \( y^*_z(Lx) = \|Lx\| \). Therefore,

\[
\|L^*\| = \sup_{\|y^*\| \leq 1} \|L^*y^*\| = \sup_{\|y^*\| \leq 1} \|L^*y^*(x)\| = \sup_{\|y^*\| \leq 1} \|L^*y^*(Lx)\| = \sup_{\|y^*\| \leq 1} \|y^*_z(Lx)\| = \|y^*_z\| \|L\| \leq \|L\| \|L\|
\]

showing that \( \|L^*\| \geq \|L\| \) and this shows part a.).

If \( L \) is one to one and onto a closed subset of \( Y \), then \( L(X) \) being a closed subspace of a Banach space, is itself a Banach space and so the open mapping theorem implies \( L^{-1} : L(X) \to X \) is continuous. Hence

\[
\|L^{-1}\| \|Lx\| \leq \|L^{-1}\| \|Lx\|
\]
Now let $x^* \in X'$ be given. Define $f \in \mathcal{L}(L(X), \mathbb{C})$ by $f(Lx) = x^*(x)$. The function, $f$ is well defined because if $Lx_1 = Lx_2$, then since $L$ is one to one, it follows $x_1 = x_2$ and so $f(L(x_1)) = x^*(x_1) = x^*(x_2) = f(L(x_2))$. Also, $f$ is linear because

$$
  f(aL(x_1) + bL(x_2)) = f(L(ax_1 + bx_2)) = x^*(ax_1 + bx_2) = ax^*(x_1) + bx^*(x_2) = af(L(x_1)) + bf(L(x_2)).
$$

In addition to this,

$$
  |f(Lx)| = |x^*(x)| \leq ||x^*|| \cdot ||x|| \leq ||x^*|| \cdot ||L^{-1}|| \cdot ||Lx||
$$

and so the norm of $f$ on $L(X)$ is no larger than $||x^*|| \cdot ||L^{-1}||$. By the Hahn Banach theorem, there exists an extension of $f$ to an element $y^* \in Y'$ such that $||y^*|| \leq ||x^*|| \cdot ||L^{-1}||$. Then

$$
  L^*y^*(x) = y^*(Lx) = f(Lx) = x^*(x)
$$

so $L^*y^* = x^*$ because this holds for all $x$. Since $x^*$ was arbitrary, this shows $L^*$ is onto and proves b).

Consider the last assertion. Suppose $L^*y^* = 0$. Is $y^* = 0$? In other words is $y^*(y) = 0$ for all $y \in Y$? Pick $y \in Y$. Since $L(X)$ is dense in $Y$, there exists a sequence, $\{Lx_n\}$ such that $Lx_n \to y$. But then by continuity of $y^*$, $y^*(y) = \lim_{n \to \infty} y^*(Lx_n) = \lim_{n \to \infty} L^*y^*(x_n) = 0$. Since $y^*(y) = 0$ for all $y$, this implies $y^* = 0$ and so $L^*$ is one to one.

**Corollary 15.2.11** Suppose $X$ and $Y$ are Banach spaces, $L \in \mathcal{L}(X,Y)$, and $L$ is one to one and onto. Then $L^*$ is also one to one and onto.

There exists a natural mapping, called the James map from a normed linear space, $X$, to the dual of the dual space which is described in the following definition.

**Definition 15.2.12** Define $J : X \to X''$ by $J(x)(x^*) = x^*(x)$.

**Theorem 15.2.13** The map, $J$, has the following properties.

a.) $J$ is one to one and linear.

b.) $||Jx|| = ||x||$ and $||J|| = 1$.

c.) $J(X)$ is a closed subspace of $X''$ if $X$ is complete.

Also if $x^* \in X'$,

$$
  ||x^*|| = \sup \{ ||x^{**}(x^*)|| : ||x^{**}|| \leq 1, x^{**} \in X'' \}.
$$

**Proof:**

$$
  J(ax + by)(x^*) = x^*(ax + by) = ax^*(x) + bx^*(y) = (aJ(x) + bJ(y))(x^*).
$$
Since this holds for all \( x^* \in X' \), it follows that
\[
J(ax + by) = aJ(x) + bJ(y)
\]
and so \( J \) is linear. If \( Jx = 0 \), then by Lemma 15.2.9 there exists \( x^* \) such that \( x^*(x) = ||x|| \) and \( ||x^*|| = 1 \). Then
\[
0 = J(x)(x^*) = x^*(x) = ||x||.
\]
This shows a).

To show b.), let \( x \in X \) and use Lemma 15.2.9 to obtain \( x^* \in X' \) such that \( x^*(x) = ||x|| \) with \( ||x^*|| = 1 \). Then
\[
||x|| \geq \sup\{|y^*(x)| : ||y^*|| \leq 1\} = \sup\{|J(x)(y^*)| : ||y^*|| \leq 1\} = ||Jx||
\]
Therefore, \( ||Jx|| = ||x|| \) as claimed. Therefore,
\[
||J|| = \sup\{|||Jx|| : ||x|| \leq 1\} = \sup\{|||x|| : ||x|| \leq 1\} = 1.
\]
This shows b).

To verify c.), use b.). If \( Jx_n \to y^{**} \in X'' \) then by b.), \( x_n \) is a Cauchy sequence converging to some \( x \in X \) because
\[
||x_n - x_m|| = ||Jx_n - Jx_m||
\]
and \( \{Jx_n\} \) is a Cauchy sequence. Then \( Jx = \lim_{n \to \infty} Jx_n = y^{**} \).

Finally, to show the assertion about the norm of \( x^* \), use what was just shown applied to the James map from \( X' \) to \( X'' \) still referred to as \( J \).
\[
||x^*|| = \sup\{|x^* (x)| : ||x|| \leq 1\} = \sup\{|J (x^*)| : ||Jx|| \leq 1\}
\]
\[
\leq \sup\{|x^{**} (x^*)| : ||x^{**}|| \leq 1\} = \sup\{|J (x^*) (x^{**})| : ||x^{**}|| \leq 1\}
\]
\[
\equiv ||Jx^*|| = ||x^*||.
\]
This proves the theorem.

**Definition 15.2.14** When \( J \) maps \( X \) onto \( X'' \), \( X \) is called reflexive.

It happens the \( L^p \) spaces are reflexive whenever \( p > 1 \). This is shown later.

### 15.3 Uniform Convexity Of \( L^p \)

These terms refer roughly to how round the unit ball is. Here is the definition.

**Definition 15.3.1** A Banach space is uniformly convex if whenever \( ||x_n||, ||y_n|| \leq 1 \) and \( ||x_n + y_n|| \to 2 \), it follows that \( ||x_n - y_n|| \to 0 \).
15.3. UNIFORM CONVEXITY OF $L^p$

You can show that uniform convexity implies strict convexity. There are various other things which can also be shown. See the exercises for some of these. In this section, it will be shown that the $L^p$ spaces are examples of uniformly convex spaces. This involves some inequalities known as Clarkson’s inequalities. Before presenting these, here are the backwards Hölder inequality and the backwards Minkowski inequality.

**Lemma 15.3.2** Let $0 < p < 1$ and let $f, g$ be measurable functions. Also

$$
\int_\Omega |g|^{p/(p-1)} \, d\mu < \infty, \quad \int_\Omega |f|^p \, d\mu < \infty
$$

Then the following backwards Hölder inequality holds.

$$
\int_\Omega |fg| \, d\mu \geq \left( \int_\Omega |f|^p \, d\mu \right)^{1/p} \left( \int_\Omega |g|^{p/(p-1)} \, d\mu \right)^{(p-1)/p}
$$

**Proof:** If $\int |fg| \, d\mu = \infty$, there is nothing to prove. Hence assume this is finite. Then

$$
\int |f|^p \, d\mu = \int |g|^{-p} |fg|^p \, d\mu
$$

This makes sense because, due to the hypothesis on $g$ it must be the case that $g$ equals 0 only on a set of measure zero, since $p/ (p - 1) < 0$. Then

$$
\int |f|^p \, d\mu \leq \left( \int |fg| \, d\mu \right)^p \left( \int \left( \frac{1}{|g|^p} \right)^{1/(1-p)} \, d\mu \right)^{1-p} = \left( \int |fg| \, d\mu \right)^p \left( \int |g|^{p/(p-1)} \, d\mu \right)^{1-p}
$$

Now divide and then take the $p^{th}$ root. ■

Here is the backwards Minkowski inequality.

**Corollary 15.3.3** Let $0 < p < 1$ and suppose $\int |h|^p \, d\mu < \infty$ for $h = f, g$. Then

$$
\left( \int (|f| + |g|)^p \, d\mu \right)^{1/p} \geq \left( \int |f|^p \, d\mu \right)^{1/p} + \left( \int |g|^p \, d\mu \right)^{1/p}
$$

**Proof:** If $\int (|f| + |g|)^p \, d\mu = 0$ then there is nothing to prove so assume this is not zero.

$$
\int (|f| + |g|)^p \, d\mu = \int (|f| + |g|)^{p-1} (|f| + |g|) \, d\mu
$$

$(|f| + |g|)^p \leq |f|^p + |g|^p$ and so

$$
\int \left( (|f| + |g|)^{p-1} \right)^{p/p-1} \, d\mu < \infty.
$$
Hence the backward Holder inequality applies and it follows that
\[
\int (|f| + |g|)^p \, d\mu = \int (|f| + |g|)^{p-1} |f| \, d\mu + \int (|f| + |g|)^{p-1} |g| \, d\mu
\]
\[
\geq \left( \int (|f| + |g|)^{(p-1)/p} \right)^{p/p-1} \left[ \left( \int |f|^p \, d\mu \right)^{1/p} + \left( \int |g|^p \, d\mu \right)^{1/p} \right]^{(p-1)/p}
\]
\[
= \left( \int (|f| + |g|)^{p/p-1} \right)^{p/p-1} \left[ \left( \int |f|^p \, d\mu \right)^{1/p} + \left( \int |g|^p \, d\mu \right)^{1/p} \right]^{p/p-1}
\]
and so, dividing gives the desired inequality. ■

Consider the easy Clarkson inequalities.

**Lemma 15.3.4** For any \( p \geq 2 \) the following inequality holds for any \( t \in [0, 1] \),

\[
\left| \frac{1 + t^p}{2} \right| + \left| \frac{1 - t^p}{2} \right| \leq \frac{1}{2} (|t|^p + 1)
\]

**Proof:** It is clear that, since \( p \geq 2 \), the inequality holds for \( t = 0 \) and \( t = 1 \). Thus it suffices to consider only \( t \in (0, 1) \). Let \( x = 1/t \). Then, dividing by \( 1/t^p \), the inequality holds if and only if

\[
\left( \frac{x + 1}{2} \right)^p + \left( \frac{x - 1}{2} \right)^p \leq \frac{1}{2} (1 + x^p)
\]

for all \( x \geq 1 \). Let

\[
f(x) = \frac{1}{2} (1 + x^p) - \left( \left( \frac{x + 1}{2} \right)^p + \left( \frac{x - 1}{2} \right)^p \right)
\]

Then \( f(1) = 0 \) and

\[
f'(x) = \frac{p}{2} x^{p-1} - \left( \frac{p}{2} \left( \frac{x + 1}{2} \right)^{p-1} + \frac{p}{2} \left( \frac{x - 1}{2} \right)^{p-1} \right)
\]

Since \( p - 1 \geq 1 \), by convexity of \( f(x) = x^{p-1} \),

\[
f'(x) \geq \frac{p}{2} x^{p-1} - p \left( \frac{x + 1 + x - 1}{2} \right)^{p-1} = \frac{p}{2} x^{p-1} - p \left( \frac{x}{2} \right)^{p-1} \geq 0
\]

Hence \( f(x) \geq 0 \) for all \( x \geq 1 \). ■

**Corollary 15.3.5** If \( z, w \in \mathbb{C} \) and \( p \geq 2 \), then

\[
\left| \frac{z + w}{2} \right|^p + \left| \frac{z - w}{2} \right|^p \leq \frac{1}{2} (|z|^p + |w|^p)
\]

(15.3.7)
15.3. UNIFORM CONVEXITY OF $L^p$

Proof: One of $|w|, |z|$ is larger. Say $|z| \geq |w|$. Then dividing both sides of the proposed inequality by $|z|^p$ it suffices to verify that for all complex $t$ having $|t| \leq 1$,

$$\frac{|1 + t|^p}{2} + \frac{|1 - t|^p}{2} \leq \frac{1}{2} (|t|^p + 1)$$

Say $t = re^{i\theta}$ where $r \leq 1$. Then consider the expression

$$\frac{|1 + re^{i\theta}|^p}{2} + \frac{|1 - re^{i\theta}|^p}{2}$$

It is $2^{-p}$ times

$$\left( (1 + r \cos \theta)^2 + r^2 \sin^2 (\theta) \right)^{p/2} + \left( (1 - r \cos \theta)^2 + r^2 \sin^2 (\theta) \right)^{p/2}
= (1 + r^2 + 2r \cos \theta)^{p/2} + (1 + r^2 - 2r \cos \theta)^{p/2},$$

a continuous periodic function for $\theta \in \mathbb{R}$ which achieves its maximum value when $\theta = 0$. This follows from the first derivative test from calculus. Therefore, for $|t| \leq 1$,

$$\frac{|1 + t|^p}{2} + \frac{|1 - t|^p}{2} \leq \frac{|1 + |t||^p}{2} + \frac{|1 - |t||^p}{2} \leq \frac{1}{2} (1 + |t|^p)$$

by the above lemma.

With this corollary, here is the easy Clarkson inequality.

**Theorem 15.3.6** Let $p \geq 2$. Then

$$\left\| \frac{f + g}{2} \right\|_{L^p}^p + \left\| \frac{f - g}{2} \right\|_{L^p}^p \leq \frac{1}{2} \left( \|f\|_{L^p}^p + \|g\|_{L^p}^p \right)$$

Proof: This follows right away from the above corollary.

$$\int_{\Omega} \left| \frac{f + g}{2} \right|^p d\mu + \int_{\Omega} \left| \frac{f - g}{2} \right|^p d\mu \leq \frac{1}{2} \int_{\Omega} (|f|^p + |g|^p) d\mu$$

Now it remains to consider the hard Clarkson inequalities. These pertain to $p < 2$. First is the following elementary inequality.

**Lemma 15.3.7** For $1 < p < 2$, the following inequality holds for all $t \in [0, 1]$.

$$\left| \frac{1 + t}{2} \right|^q + \left| \frac{1 - t}{2} \right|^q \leq \left( \frac{1}{2} + \frac{1}{2} |t|^p \right)^{q/p}$$

where here $1/p + 1/q = 1$ so $q > 2$. 
**Proof:** First note that if \( t = 0 \) or \( 1 \), the inequality holds. Next observe that the map \( s \mapsto \frac{1-t}{1+s} \) maps \((0, 1)\) onto \((0, 1)\). Replace \( t \) with \((1+s)^{-1} = 1 + s\). Then you get

\[
\left| \frac{1}{s + 1} \right|^q + \left| \frac{s}{s + 1} \right|^q \leq \left( \frac{1}{2} + \frac{1}{2} \left| \frac{1-s}{s + 1} \right| \right)^{q/p}
\]

Multiplying both sides by \((1+s)^q\), this is equivalent to showing that for all \( s \in (0, 1)\),

\[
1 + s^q \leq \left( (1 + s)^p \right)^{q/p} \left( \frac{1}{2} + \frac{1}{2} \left| \frac{1-s}{s + 1} \right| \right)^{q/p}
\]

This is the same as establishing

\[
\frac{1}{2} ((1 + s)^p + (1-s)^p) - (1 + s^q)^{p-1} \geq 0
\]

where \( p - 1 = p/q \) due to the definition of \( q \) above.

\[
\binom{p}{l} = \frac{p(p-1) \cdots (p-k+1)}{l!}, \quad l \geq 1
\]

and \( \binom{p}{0} = 1 \). What is the sign of \( \binom{p}{l} \)? Recall that \( 1 < p < 2 \) so the sign is positive if \( l = 0, l = 1, l = 2 \). What about \( l = 3 \)? \( \binom{p}{3} = \frac{p(p-1)(p-2)}{3!} \) so this is negative. Then \( \binom{p}{4} \) is positive. Thus these alternate between positive and negative with \( \binom{p}{2k} > 0 \) for all \( k \). What about \( \binom{p-1}{k} \)? When \( k = 0 \) it is positive. When \( k = 1 \) it is also positive. When \( k = 2 \) it equals \( \frac{(p-1)(p-2)}{2!} < 0 \). Then when \( k = 3 \), \( \binom{p-1}{3} > 0 \). Thus \( \binom{p-1}{k} \) is positive when \( k \) is odd and is negative when \( k \) is even.

Now return to 15.3.8. The left side equals

\[
\frac{1}{2} \left( \sum_{k=0}^{\infty} \binom{p}{k} s^k + \sum_{k=0}^{\infty} \binom{p}{k} (-s)^k \right) - \sum_{k=0}^{\infty} \binom{p-1}{k} s^q k.
\]

The first term equals 0. Then this reduces to

\[
\sum_{k=1}^{\infty} \binom{p}{2k} s^{2k} - \binom{p-1}{2k} s^{2qk} - \binom{p-1}{2k-1} s^{q(2k-1)}
\]
From the above observation about the binomial coefficients, the above is larger than

$$\sum_{k=1}^{\infty} \binom{p}{2k} s^{2k} - \binom{p-1}{2k-1} s^{q(2k-1)}$$

It remains to show the $k^{th}$ term in the above sum is nonnegative. Now $q(2k-1) > 2k$ for all $k \geq 1$ because $q > 2$. Then since $0 < s < 1$

$$\binom{p}{2k} s^{2k} - \binom{p-1}{2k-1} s^{q(2k-1)} \geq s^{2k} \left( \binom{p}{2k} - \binom{p-1}{2k-1} \right)$$

However, this is nonnegative because it equals

$$s^{2k} \left( \frac{p(p-1) \cdots (p-2k+1)}{(2k)!} - \frac{(p-1)(p-2) \cdots (p-2k+1)}{(2k-1)!} \right) \geq 0$$

As before, this leads to the following corollary.

**Corollary 15.3.8** Let $z, w \in \mathbb{C}$. Then for $p \in (1, 2)$,

$$\left| \frac{z+w}{2} \right|^q + \left| \frac{z-w}{2} \right|^q \leq \left( \frac{1}{2} |z|^p + \frac{1}{2} |w|^p \right)^{q/p}$$

**Proof:** One of $|w|, |z|$ is larger. Say $|w| \geq |z|$. Then dividing by $|w|^q$, for $t = z/w$, showing the above inequality is equivalent to showing that for all $t \in \mathbb{C}$, $|t| \leq 1$,

$$\left| \frac{t+1}{2} \right|^q + \left| \frac{1-t}{2} \right|^q \leq \left( \frac{1}{2} |t|^p + \frac{1}{2} \right)^{q/p}$$

Now $q > 2$ and so by the same argument given in proving Corollary [15.3.5] for $t = re^{i\theta}$, the left side of the above inequality is maximized when $\theta = 0$. Hence, from Lemma [15.3.7],

$$\left| \frac{t+1}{2} \right|^q + \left| \frac{1-t}{2} \right|^q \leq \left| \frac{|t|+1}{2} \right|^q + \left| \frac{1-|t|}{2} \right|^q$$

$$\leq \left( \frac{1}{2} |t|^p + \frac{1}{2} \right)^{q/p}$$

From this the hard Clarkson inequality follows. The two Clarkson inequalities are summarized in the following theorem.
CHAPTER 15. BANACH SPACES

Theorem 15.3.9 Let \( 2 \leq p \). Then
\[
\left\| \frac{f+g}{2} \right\|_{L^p}^p + \left\| \frac{f-g}{2} \right\|_{L^p}^p \leq \frac{1}{2} \left( \|f\|_{L^p}^p + \|g\|_{L^p}^p \right)
\]

Let \( 1 < p < 2 \) then for \( \frac{1}{p} + \frac{1}{q} = 1 \),
\[
\left\| \frac{f+g}{2} \right\|_{L^p}^q + \left\| \frac{f-g}{2} \right\|_{L^p}^q \leq \left( \frac{1}{2} \|f\|_{L^p}^p + \frac{1}{2} \|g\|_{L^p}^p \right)^{q/p}
\]

Proof: The first was established above.
\[
\left\| \frac{f+g}{2} \right\|_{L^p}^q + \left\| \frac{f-g}{2} \right\|_{L^p}^q \leq \left( \frac{1}{2} \|f\|_{L^p}^p + \frac{1}{2} \|g\|_{L^p}^p \right)^{q/p}
\]

Now \( p/q < 1 \) and so the backwards Minkowski inequality applies. Thus
\[
\leq \left( \int_{\Omega} \left( \left| \frac{f+g}{2} \right|^q + \left| \frac{f-g}{2} \right|^q \right) \right)^{q/p} d\mu
\]
From Corollary 15.3.8,
\[
\leq \left( \int_{\Omega} \left( \left( \frac{1}{2} \|f\|_{L^p}^p + \frac{1}{2} \|g\|_{L^p}^p \right)^{q/p} \right)^{p/q} d\mu \right)^{q/p}
\]
\[
= \left( \int_{\Omega} \left( \frac{1}{2} \|f\|_{L^p}^p + \frac{1}{2} \|g\|_{L^p}^p \right)^{q/p} d\mu \right) = \left( \frac{1}{2} \|f\|_{L^p}^p + \frac{1}{2} \|g\|_{L^p}^p \right)^{q/p}
\]

Now with these Clarkson inequalities, it is not hard to show that all the \( L^p \) spaces are uniformly convex.

Theorem 15.3.10 The \( L^p \) spaces are uniformly convex.

Proof: First suppose \( p \geq 2 \). Suppose \( \|f_n\|_{L^p}, \|g_n\|_{L^p} \leq 1 \) and \( \left\| \frac{f_n + g_n}{2} \right\|_{L^p} \to 1 \). Then from the first Clarkson inequality,
\[
\left\| \frac{f_n + g_n}{2} \right\|_{L^p}^p + \left\| \frac{f_n - g_n}{2} \right\|_{L^p}^p \leq \frac{1}{2} \left( \|f_n\|_{L^p}^p + \|g_n\|_{L^p}^p \right) \leq 1
\]
and so \( \|f_n - g_n\|_{L^p} \to 0 \).
Next suppose $1 < p < 2$ and $\left\| \frac{f_n + g_n}{2} \right\|_{L_p} \to 1$. Then from the second Clarkson inequality
\[
\left\| \frac{f_n + g_n}{2} \right\|_{L_p}^q + \left\| \frac{f_n - g_n}{2} \right\|_{L_p}^q \leq \left( \frac{1}{2} \left\| f_n \right\|_{L_p}^p + \frac{1}{2} \left\| g_n \right\|_{L_p}^p \right)^{q/p} \leq 1
\]
which shows that $\left\| f_n - g_n \right\|_{L_p} \to 0$. ■

15.4 Closed Subspaces

**Theorem 15.4.1** Let $X$ be a Banach space and let $V = \text{span} \{x_1, \ldots, x_n\}$. Then $V$ is a closed subspace of $X$.

**Proof:** Without loss of generality, it can be assumed $\{x_1, \ldots, x_n\}$ is linearly independent. Otherwise, delete those vectors which are in the span of the others till a linearly independent set is obtained. Let

\[
x = \lim_{p \to \infty} \sum_{k=1}^{n} c_k^p x_k \in V.
\]

First suppose $c^p \equiv (c_1^p, \ldots, c_n^p)$ is not bounded in $F^n$. Then $d^p \equiv c^p / \|c^p\|_{F^n}$ is a unit vector in $F^n$ and so there exists a subsequence, still denoted by $d^p$ which converges to $d$ where $\|d\| = 1$. Then

\[
0 = \lim_{p \to \infty} \frac{x}{\|c^p\|} = \lim_{p \to \infty} \sum_{k=1}^{n} d_k^p x_k = \sum_{k=1}^{n} d_k x_k
\]

where $\sum_k |d_k|^2 = 1$ in contradiction to the linear independence of the $\{x_1, \ldots, x_n\}$. Hence it must be the case that $c^p$ is bounded in $F^n$. Then taking a subsequence, still denoted as $p$, it can be assumed $c^p \to c$ and then in (15.4.1) it follows

\[
x = \sum_{k=1}^{n} c_k x_k \in \text{span} \{x_1, \ldots, x_n\}. ■
\]

**Proposition 15.4.2** Let $E$ be a separable Banach space. Then there exists an increasing sequence of subspaces, $\{F_n\}$ such that $\dim (F_{n+1}) - \dim (F_n) \leq 1$ and equals 1 for all $n$ if the dimension of $E$ is infinite. Also $\bigcup_{n=1}^{\infty} F_n$ is dense in $E$. In the case where $E$ is infinite dimensional, $F_n = \text{span} \{e_1, \ldots, e_n\}$ where for each $n$

\[
\text{dist} (e_{n+1}, F_n) \geq \frac{1}{2}
\]

and defining,

\[
G_k \equiv \text{span} \{e_j : j \neq k\}
\]

\[
\text{dist} (e_k, G_k) \geq \frac{1}{4}.
\]

15.4. CLOSED SUBSPACES
Proof: Since $E$ is separable, so is $\partial B(0,1)$, the boundary of the unit ball. Let $\{w_k\}_{k=1}^\infty$ be a countable dense subset of $\partial B(0,1)$.

Let $e_1 = w_1$. Let $F_1 = \mathbb{F}e_1$. Suppose $F_n$ has been obtained and equals span ($e_1, \ldots, e_n$) where $\{e_1, \ldots, e_n\}$ is independent, $||e_k|| = 1$, and
\[
\text{dist}(e_n, \text{span}(e_1, \ldots, e_{n-1})) \geq \frac{1}{2}.
\]

For each $n$, $F_n$ is closed by Theorem 15.4.1. If $F_n$ contains $\{w_k\}_{k=1}^\infty$, let $F_{m} = F_n$ for all $m > n$. Otherwise, pick $w \in \{w_k\}_{k=1}^\infty$ to be the point of $\{w_k\}_{k=1}^\infty$ having the smallest subscript which is not contained in $F_n$. Then $w$ is at a positive distance, $\lambda$ from $F_n$ because $F_n$ is closed. Therefore, there exists $y \in F_n$ such that $\lambda \leq ||y - w|| \leq 2\lambda$. Let $e_{n+1} = \frac{w-y}{||w-y||}$. It follows
\[
w = ||w - y|| e_{n+1} + y \in \text{span}(e_1, \ldots, e_{n+1}) \equiv F_{n+1}
\]
Then if $x \in \text{span}(e_1, \ldots, e_n)$,
\[
||e_{n+1} - x|| = \left|\left| \frac{w-y}{||w-y||} - x \right|\right| = \left|\left| \frac{w-y}{||w-y||} - \frac{||w-y||}{||w-y||} x \right|\right| \\
\geq \frac{1}{2\lambda} ||w - y|| ||w - y|| x || \\
\geq \frac{\lambda}{2\lambda} = \frac{1}{2}.
\]
This has shown the existence of an increasing sequence of subspaces, $\{F_n\}$ as described above. It remains to show the union of these subspaces is dense. First note that the union of these subspaces must contain the $\{w_k\}_{k=1}^\infty$ because if $w_m$ is missing, then it would contradict the construction at the $m^{th}$ step. That one should have been chosen. However, $\{w_k\}_{k=1}^\infty$ is dense in $\partial B(0,1)$. If $x \in E$ and $x \neq 0$, then $\frac{x}{||x||} \in \partial B(0,1)$ then there exists
\[
w_m \in \{w_k\}_{k=1}^\infty \subseteq \bigcup_{n=1}^\infty F_n
\]
such that $\left|\left| w_m - \frac{x}{||x||} \right|\right| < \frac{\varepsilon}{||x||}$. But then
\[
\left|\left| x ||w_m - x|| \right|\right| < \varepsilon
\]
and so $||x|| w_m$ is a point of $\bigcup_{n=1}^\infty F_n$ which is within $\varepsilon$ of $x$. This proves $\bigcup_{n=1}^\infty F_n$ is dense as desired. 15.4.11 follows from the construction. It remains to verify 15.4.11.

Let $y \in G_k$. Thus for some $n$,
\[
y = \sum_{j=1}^{k-1} c_j e_j \sum_{j=k+1}^{n} c_j e_j
\]
15.5. WEAK AND WEAK * TOPOLOGIES

and I need to show $\|y - e_k\| \geq 1/4$. Without loss of generality, $e_n \neq 0$ and $n > k$. Suppose (15.4.11) does not hold for some such $y$ so that

$$\left\| e_k - \left( \sum_{j=1}^{k-1} c_j e_j + \sum_{j=k+1}^{n} c_j e_j \right) \right\| < \frac{1}{4}.$$  (15.4.12)

Then from the construction,

$$\frac{1}{4} > |c_n| \left\| e_k - \left( \sum_{j=1}^{k-1} (c_j/c_n) e_j + \sum_{j=k+1}^{n-1} (c_j/c_n) e_j + e_n \right) \right\|$$

$$\geq |c_n| \frac{1}{2}$$

and so $|c_n| < 1/2$. Consider the left side of (15.4.12). By the construction

$$\left\| c_n (e_k - e_n) + (1 - e_n) e_k - \left( \sum_{j=1}^{k-1} c_j e_j + \sum_{j=k+1}^{n-1} c_j e_j \right) \right\|$$

$$\geq |1 - c_n| - |c_n| \left\| (e_k - e_n) - \left( \sum_{j=1}^{k-1} (c_j/c_n) e_j + \sum_{j=k+1}^{n-1} (c_j/c_n) e_j \right) \right\|$$

$$\geq |1 - c_n| - |c_n| \frac{1}{2} \geq 1 - \frac{3}{2} |c_n| > 1 - \frac{3}{2} \frac{1}{2} = \frac{1}{4},$$

a contradiction. This proves the desired estimate.

15.5 Weak And Weak * Topologies

15.5.1 Basic Definitions

Let $X$ be a Banach space and let $X'$ be its dual space. For $A'$ a finite subset of $X'$, denote by $\rho_{A'}$ the function defined on $X$

$$\rho_{A'}(x) \equiv \max_{x^* \in A'} |x^*(x)|$$  (15.5.13)

and also let $B_{A'}(x, r)$ be defined by

$$B_{A'}(x, r) \equiv \{ y \in X : \rho_{A'}(y - x) < r \}$$  (15.5.14)

Then certain things are obvious. First of all, if $a \in \mathbb{F}$ and $x, y \in X$,

$$\rho_{A'}(x + y) \leq \rho_{A'}(x) + \rho_{A'}(y),$$

$$\rho_{A'}(ax) = |a| \rho_{A'}(x).$$

\footnote{Actually, all this works in much more general settings than this.}
Similarly, letting $A$ be a finite subset of $X$, denote by $\rho_A$ the function defined on $X'$

$$\rho_A (x^*) \equiv \max_{x \in A} |x^*(x)|$$  \hspace{1cm} (15.5.15)

and let $B_A (x^*, r)$ be defined by

$$B_A (x^*, r) \equiv \{ y^* \in X' : \rho_A (y^* - x^*) < r \}. \hspace{1cm} (15.5.16)$$

It is also clear that

$$\rho_A (x^* + y^*) \leq \rho (x^*) + \rho_A (y^*),$$

$$\rho_A (ax^*) = \rho (a) \rho_A (x^*).$$

**Lemma 15.5.1** The sets, $B_{A'} (x, r)$ where $A'$ is a finite subset of $X'$ and $x \in X$ form a basis for a topology on $X$ known as the weak topology. The sets $B_A (x^*, r)$ where $A$ is a finite subset of $X$ and $x^* \in X'$ form a basis for a topology on $X'$ known as the weak $*$ topology.

**Proof:** The two assertions are very similar. I will verify the one for the weak topology. The union of these sets, $B_{A'} (x, r)$ for $x \in X$ and $r > 0$ is all of $X$:

Now suppose $z$ is contained in the intersection of two of these sets. Say

$$z \in B_{A'} (x, r) \cap B_{A'} (x_1, r_1)$$

Then let $C' = A' \cup A'_1$ and let

$$0 < \delta \leq \min \left( r - \rho_{A'} (z - x), r_1 - \rho_{A'_1} (z - x_1) \right).$$

Consider $y \in B_{C'} (z, \delta)$. Then

$$r - \rho_{A'} (z - x) \geq \delta > \rho_{C'} (y - z) \geq \rho_{A'} (y - z)$$

and so

$$r > \rho_{A'} (y - z) + \rho_{A'} (z - x) \geq \rho_{A'} (y - x)$$

which shows $y \in B_{A'} (x, r)$. Similar reasoning shows $y \in B_{A'_1} (x_1, r_1)$ and so

$$B_{C'} (z, \delta) \subseteq B_{A'} (x, r) \cap B_{A'_1} (x_1, r_1).$$

Therefore, the weak topology consists of the union of all sets of the form $B_A (x, r)$.

**15.5.2 Banach Alaoglu Theorem**

Why does anyone care about these topologies? The short answer is that in the weak $*$ topology, closed unit ball in $X'$ is compact. This is not true in the normal topology. This wonderful result is the Banach Alaoglu theorem. First recall the notion of the product topology, and the Tychonoff theorem, Theorem [PART on Page 605](#) which are stated here for convenience.
Definition 15.5.2 Let $I$ be a set and suppose for each $i \in I$, $(X_i, \tau_i)$ is a nonempty topological space. The Cartesian product of the $X_i$, denoted by $\prod_{i \in I} X_i$, consists of the set of all choice functions defined on $I$ which select a single element of each $X_i$. Thus $f \in \prod_{i \in I} X_i$ means for every $i \in I$, $f(i) \in X_i$. The axiom of choice says $\prod_{i \in I} X_i$ is nonempty. Let

$$P_j(A) = \prod_{i \in I} B_i$$

where $B_i = X_i$ if $i \neq j$ and $B_j = A$. A subbasis for a topology on the product space consists of all sets $P_j(A)$ where $A \in \tau_j$. (These sets have an open set from the topology of $X_j$ in the $j$th slot and the whole space in the other slots.) Thus a basis consists of finite intersections of these sets. Note that the intersection of two of these basic sets is another basic set and their union yields $\prod_{i \in I} X_i$. Therefore, they satisfy the condition needed for a collection of sets to serve as a basis for a topology. This topology is called the product topology and is denoted by $\prod \tau_i$.

Theorem 15.5.3 If $(X_i, \tau_i)$ is compact, then so is $(\prod_{i \in I} X_i, \prod \tau_i)$.

The Banach Alaoglu theorem is as follows.

Theorem 15.5.4 Let $B'$ be the closed unit ball in $X'$. Then $B'$ is compact in the weak * topology.

Proof: By the Tychonoff theorem, Theorem 15.5.3

$$P = \prod_{x \in X} B(0, ||x||)$$

is compact in the product topology where the topology on $B(0, ||x||)$ is the usual topology of $F$. Recall $P$ is the set of functions which map a point, $x \in X$ to a point in $B(0, ||x||)$. Therefore, $B' \subseteq P$. Also the basic open sets in the weak * topology on $B'$ are obtained as the intersection of basic open sets in the product topology of $P$ to $B'$ and so it suffices to show $B'$ is a closed subset of $P$. Suppose then that $f \in P \setminus B'$. Since $|f(x)| \leq ||x||$ for each $x$, it follows $f$ cannot be linear. There are two ways this can happen. One way is that for some $x, y$

$$f(x + y) \neq f(x) + f(y)$$

for some $x, y \in X$. However, if $g$ is close enough to $f$ at the three points, $x + y, x$, and $y$, the above inequality will hold for $g$ in place of $f$. In other words there is a basic open set containing $f$, such that for all $g$ in this basic open set, $g \notin B'$. A similar consideration applies in case $f(\lambda x) \neq \lambda f(x)$ for some scalar $\lambda$ and $x$. Since $P \setminus B'$ is open, it follows $B'$ is a closed subset of $P$ and is therefore, compact.

Sometimes one can consider the weak * topology in terms of a metric space.

Theorem 15.5.5 If $K \subseteq X'$ is compact in the weak * topology and $X$ is separable in the weak topology then there exists a metric, $d$, on $K$ such that if $\tau_d$ is the topology on $K$ induced by $d$ and if $\tau$ is the topology on $K$ induced by the weak * topology of $X'$, then $\tau = \tau_d$. Thus one can consider $K$ with the weak * topology as a metric space.
Proof: Let \( D = \{x_n\} \) be the dense countable subset in \( X \). The metric is

\[
d(f, g) = \sum_{n=1}^{\infty} 2^{-n} \frac{\rho_{x_n} (f - g)}{1 + \rho_{x_n} (f - g)}
\]

where \( \rho_{x_n} (f) = |f(x_n)| \). Clearly \( d(f, g) = d(g, f) \geq 0 \). If \( d(f, g) = 0 \), then this requires \( f(x_n) = g(x_n) \) for all \( x_n \in D \). Is it the case that \( f = g? \)

Let \( B_{\{f, g\}}(x, r) \) contains some \( x_n \in D \). Hence

\[
\max \{|f(x_n) - f(x)|, |g(x_n) - g(x)|\} < r
\]

and \( f(x_n) = g(x_n) \). It follows that \( |f(x) - g(x)| < 2r \). Since \( r \) is arbitrary, this implies \( f(x) = g(x) \). It is routine to verify the triangle inequality from the easy to establish inequality,

\[
\frac{x}{1+x} + \frac{y}{1+y} \geq \frac{x+y}{1+x+y},
\]

valid whenever \( x, y \geq 0 \). Therefore this is a metric.

Thus there are two topological spaces, \( (K, \tau) \) and \( (K, d) \), the first being \( K \) with the weak * topology and the second being \( K \) with this metric. It is clear that if \( i \) is the identity map, \( i : (K, \tau) \rightarrow (K, d) \), then \( i \) is continuous. Therefore, sets which are open in \( (K, d) \) are open in \( (K, \tau) \). Letting \( \tau_d \) denote those sets which are open with respect to the metric, \( \tau_d \subseteq \tau \).

Now suppose \( U \in \tau \). Is \( U \in \tau_d? \) Since \( K \) is compact with respect to \( \tau \), it follows from the above that \( K \) is compact with respect to \( \tau_d \subseteq \tau \). Hence \( K \setminus U \) is compact with respect to \( \tau_d \) and so it is closed with respect to \( \tau_d \). Thus \( U \) is open with respect to \( \tau_d \).

The fact that this set with the weak * topology can be considered a metric space is very significant because if a point is a limit point in a metric space, one can extract a convergent sequence.

Note that if a Banach space is separable, then it is weakly separable.

Corollary 15.5.6 If \( X \) is weakly separable and \( K \subseteq X' \) is compact in the weak * topology, then \( K \) is sequentially compact. That is, if \( \{f_n\}_{n=1}^{\infty} \subseteq K \), then there exists a subsequence \( f_{n_k} \) and \( f \in K \) such that for all \( x \in X \),

\[
\lim_{k \to \infty} f_{n_k} (x) = f (x).
\]

Proof: By Theorem 15.5.5, \( K \) is a metric space for the metric described there and it is compact. Therefore by the characterization of compact metric spaces, Proposition 6.2.5 on Page 146, \( K \) is sequentially compact. This proves the corollary.

15.5.3 Eberlein Smulian Theorem

Next consider the weak topology. The most interesting results have to do with a reflexive Banach space. The following lemma ties together the weak and weak * topologies in the case of a reflexive Banach space.
Lemma 15.5.7 Let $J : X \to X''$ be the James map

$$ Jx(f) \equiv f(x) $$

and let $X$ be reflexive so that $J$ is onto. Then $J$ is a homeomorphism of $(X, \text{weak topology})$ and $(X'', \text{weak * topology}).$ This means $J$ is one to one, onto, and both $J$ and $J^{-1}$ are continuous.

Proof: Let $f \in X'$ and let

$$ B_f(x,r) \equiv \{ y : |f(x) - f(y)| < r \}.$$ 

Thus $B_f(x,r)$ is a subbasic set for the weak topology on $X$. I claim that

$$ JB_f(x,r) = B_f(Jx,r) $$

where $B_f(Jx,r)$ is a subbasic set for the weak * topology. If $y \in B_f(x,r)$, then $\|Jy - Jx\| = \|x - y\| < r$ and so $JB_f(x,r) \subseteq B_f(Jx,r)$. Now if $x^{**} \in B_f(Jx,r)$, then since $J$ is reflexive, there exists $y \in X$ such that $Jy = x^{**}$ and so

$$ \|y - x\| = \|Jy - Jx\| < r $$

showing that $JB_f(x,r) = B_f(Jx,r).$ A typical subbasic set in the weak * topology is of the form $B_f(Jx,r).$ Thus $J$ maps the subbasic sets of the weak topology to the subbasic sets of the weak * topology. Therefore, $J$ is a homeomorphism as claimed. 

The following is an easy corollary.

**Corollary 15.5.8** If $X$ is a reflexive Banach space, then the closed unit ball is weakly compact.

Proof: Let $B$ be the closed unit ball. Then $B = J^{-1}(B^{**})$ where $B^{**}$ is the unit ball in $X''$ which is compact in the weak * topology. Therefore $B$ is weakly compact because $J^{-1}$ is continuous.

**Corollary 15.5.9** Let $X$ be a reflexive Banach space. If $K \subseteq X$ is compact in the weak topology and $X'$ is separable in the weak * topology, then there exists a metric $d$, on $K$ such that if $\tau_d$ is the weak topology on $K$ induced by $d$ and if $\tau$ is the topology on $K$ induced by the weak topology of $X$, then $\tau = \tau_d$. Thus one can consider $K$ with the weak topology as a metric space.

Proof: This follows from Theorem 15.5.3 and Lemma 15.5.4. Lemma 15.5.7 implies $J(K)$ is compact in $X''$. Then since $X'$ is separable in the weak * topology, $X$ is separable in the weak topology and so there is a metric, $d''$ on $J(K)$ which delivers the weak * topology on $J(K)$. Let $d(x,y) \equiv d''(Jx,Jy)$. Then

$$ (K, \tau_d) \xrightarrow{J} (J(K), \tau_{d''}) \xrightarrow{id} (J(K), \tau_{weak *}) \xrightarrow{J^{-1}} (K, \tau_{weak}) $$

and all the maps are homeomorphisms. 

Here is a useful lemma.
Lemma 15.5.10 Let $Y$ be a closed subspace of a Banach space $X$ and let $y \in X \setminus Y$. Then there exists $x^* \in X'$ such that $x^*(Y) = 0$ but $x^*(y) \neq 0$.

**Proof:** Define $f(x + \alpha y) \equiv \|y\| \alpha$. Thus $f$ is linear on $Y \oplus \mathbb{F}y$. I claim that $f$ is also continuous on this subspace of $X$. If not, then there exists $x_n + \alpha_n y \to 0$ but $|f(x_n + \alpha_n y)| \geq \varepsilon > 0$ for all $n$. First suppose $|\alpha_n|$ is bounded. Then, taking a further subsequence, we can assume $\alpha_n \to \alpha$. It follows then that $\{x_n\}$ must also converge to some $x \in Y$ since $Y$ is closed. Therefore, in this case, $x + \alpha y = 0$ and so $x = 0$ since otherwise, $y \in Y$. In the other case when $\alpha_n$ is unbounded, you have $(x_n/\alpha_n + y) \to 0$ and so it would require that $y \in \overline{Y}$ which cannot happen because $Y$ is closed. Hence $f$ is continuous as claimed. It follows that for some $k$,

$$|f(x + \alpha y)| \leq k \|x + \alpha y\|$$

Now apply the Hahn Banach theorem to extend $f$ to $x^* \in X'$.

Next is the Eberlein Smulian theorem which states that a Banach space is reflexive if and only if the closed unit ball is weakly sequentially compact. Actually, only half the theorem is proved here, the more useful only if part. The book by Yoshida [113] has the complete theorem discussed. First here is an interesting lemma for its own sake.

Lemma 15.5.11 A closed subspace of a reflexive Banach space is reflexive.

**Proof:** Let $Y$ be the closed subspace of the reflexive space, $X$. Consider the following diagram

$$
\begin{array}{ccc}
Y'' & \overset{i^{**}}{\longrightarrow} & X'' \\
Y' & \overset{i}{\twoheadrightarrow} & X' \\
Y & \overset{i}{\rightarrow} & X
\end{array}
$$

This diagram follows from Theorem 15.5.10 on Page 448, the theorem on adjoints. Now let $y^{**} \in Y''$. Then $i^{**}y^{**} = J_X(y)$ because $X$ is reflexive. I want to show that $y \in Y$. If it is not in $Y$ then $Y$ is closed, there exists $x^* \in X'$ such that $x^*(y) \neq 0$ but $x^*(Y) = 0$. Then $i^*x^* = 0$. Hence

$$0 = y^{**}(i^*x^*) = i^{**}y^{**}(x^*) = J_X(y)(x^*) = x^*(y) \neq 0,$$

a contradiction. Hence $y \in Y$. Letting $J_Y$ denote the James map from $Y$ to $Y''$ and $x^* \in X'$,

$$
\begin{align*}
y^{**}(i^*x^*) &= i^{**}y^{**}(x^*) = J_X(y)(x^*) \\
&= x^*(y) = x^*(iy) = i^*x^*(y) = J_Y(y)(i^*x^*)
\end{align*}
$$

Since $i^*$ is onto, this shows $y^{**} = J_Y(y)$.

**Theorem 15.5.12** (Eberlein Smulian) The closed unit ball in a reflexive Banach space $X$, is weakly sequentially compact. By this is meant that if $\{x_n\}$ is contained in the closed unit ball, there exists a subsequence, $\{x_{n_k}\}$ and $x \in X$ such that for all $x^* \in X'$,

$$x^*(x_{n_k}) \to x^*(x).$$
15.5. WEAK AND WEAK * TOPOLOGIES

Proof: Let \( \{x_n\} \subseteq B \equiv B(0,1) \). Let \( Y \) be the closure of the linear span of \( \{x_n\} \). Thus \( Y \) is a separable. It is reflexive because it is a closed subspace of a reflexive space so the above lemma applies. By the Banach Alaoglu theorem, the closed unit ball \( B^* \) in \( Y' \) is weak * compact. Also by Theorem 15.5.5, \( B^* \) is a metric space with a suitable metric.

\[
B^{**} \xrightarrow{i^{**}} Y'' \xrightarrow{i^{**} 1-1 \to} X''
\]
weakly separable \( B^* \) \( Y' \xleftarrow{i} X' \)
separable \( B \xrightarrow{i} Y \xrightarrow{i} X)

Thus \( B^* \) is complete and totally bounded with respect to this metric and it follows that \( B^* \) with the weak * topology is separable. This implies \( Y' \) is also separable in the weak * topology. To see this, let \( \{y_n^*\} \equiv D \) be a weak * dense set in \( B^* \) and let \( y_n^* \in Y' \). Let \( p \) be a large enough positive rational number that \( y_n^* / p \in B^* \). Then if \( A \) is any finite set from \( Y' \), there exists \( y_n^* \in D \) such that \( \rho_A (y_n^* / p - y_n^*) < \frac{1}{p} \). It follows \( py_n^* \in B_A (y_n^*, \varepsilon) \) showing that rational multiples of \( D \) are weak * dense in \( Y' \). Since \( Y \) is reflexive, the weak and weak * topologies on \( Y' \) coincide and so \( Y' \) is weakly separable. Since \( Y' \) is weakly separable, Corollary 15.5.13 implies \( B^{**} \), the closed unit ball in \( Y'' \) is weak * sequentially compact. Then by Lemma 15.5.7 \( B \), the unit ball in \( Y \), is weakly sequentially compact. It follows there exists a subsequence \( x_{n_k} \), of the sequence \( \{x_n\} \) and a point \( x \in Y' \), such that for all \( f \in Y' \),

\[
\lim_{k \to \infty} f(x_{n_k}) = f(x)
\]

Now if \( x^* \in X' \), and \( i \) is the inclusion map of \( Y \) into \( X \),

\[
x^* (x_{n_k}) = i^* x^* (x_{n_k}) \to i^* x^* (x) = x^* (x)
\]

which shows \( x_{n_k} \) converges weakly and this shows the unit ball in \( X \) is weakly sequentially compact. ■

Corollary 15.5.13 Let \( \{x_n\} \) be any bounded sequence in a reflexive Banach space \( X \). Then there exists \( x \in X \) and a subsequence, \( \{x_{n_k}\} \) such that for all \( x^* \in X' \),

\[
\lim_{k \to \infty} x^* (x_{n_k}) = x^* (x)
\]

Proof: If a subsequence, \( x_{n_k} \) has \( \|x_{n_k}\| \to 0 \), then the conclusion follows. Simply let \( x = 0 \). Suppose then that \( \|x_n\| \) is bounded away from 0. That is, \( \|x_n\| \in [\delta, C] \). Take a subsequence such that \( \|x_{n_k}\| \to a \). Then consider \( x_{n_k} / \|x_{n_k}\| \). By the Eberlein Smulian theorem, this subsequence has a further subsequence, \( x_{n_k_j} / \|x_{n_k_j}\| \) which converges weakly to \( x \in B \) where \( B \) is the closed unit ball. It follows from routine considerations that \( x_{n_k_j} \to ax \) weakly. This proves the corollary.
15.6 Operators With Closed Range

When is \( T(X) \) a closed subset of \( Y \) for \( T \in \mathcal{L}(X,Y) \)? One way this happens is when \( T = I - C \) for \( C \) compact.

Definition 15.6.1 Let \( C \in \mathcal{L}(X,Y) \) where \( X,Y \) are two Banach spaces. Then \( C \) is called a compact operator if \( C \) (bounded set) = (precompact set).

Lemma 15.6.2 Suppose \( C \in \mathcal{L}(X,X) \) is compact. Then \( (I-C)(X) \) is closed.

Proof: Let \((I-C)x_n \to y \). Let \( z_n \in \ker (I-C) \) such that

\[
\text{dist} (x_n, \ker (I-C)) \leq \|x_n - z_n\| \leq \left(1 + \frac{1}{n}\right) \text{dist} (x_n, \ker (I-C))
\]

Case 1: \( \|x_n - z_n\| \to \infty \).

In this case, you get \((I-C)(x_n - z_n) \to y \) and so there is a subsequence such that \( C \left( \frac{x_n - z_n}{\|x_n - z_n\|} \right) \) converges. Also \( \frac{x_n - z_n}{\|x_n - z_n\|} \) converges to the same thing. Let it be called \( w \). Thus

\[
C \left( \frac{x_n - z_n}{\|x_n - z_n\|} \right) \to w \text{ so } Cw = w, \ w \in \ker (I-C)
\]

\[
\left\| \frac{x_n - z_n}{\|x_n - z_n\|} - w \right\| = \frac{1}{\|x_n - z_n\|} \left\| (x_n - z_n) - w \|x_n - z_n\| \right\| \in \ker (I-C)
\]

\[
\geq \frac{1}{\|x_n - z_n\|} \text{dist} (x_n, \ker (I-C))
\]

\[
\geq \left( \left(1 + \frac{1}{n}\right) \text{dist} (x_n, \ker (I-C)) \right) \text{dist} (x_n, \ker (I-C))
\]

Now passing to a limit,

\[
0 \geq \lim_{n \to \infty} \frac{1}{1 + 1/n} = 1
\]

so Case 1 cannot occur.

Case 2: A subsequence of \( \|x_n - z_n\| \) is bounded.

Let \( n \) denote the subscript for the subsequence. Then there is a further subsequence still denoted with \( n \) such that \( C(x_n - z_n) \) converges. Then also \( (x_n - z_n) \) converges because \((I-C)(x_n) = (I-C)(x_n - z_n) \) is given to converge. Let \( (x_n - z_n) \to x \). Then

\[
y = \lim_{n \to \infty} (I-C)x_n = \lim_{n \to \infty} (I-C)(x_n - z_n) = (I-C)x
\]
15.6. OPERATORS WITH CLOSED RANGE

and so \( y \in (I - C)(X) \) showing that \((I - C)(X)\) is closed. ■

Here is a useful lemma.

**Lemma 15.6.3** Suppose \( W \) and \( V \) are closed subspaces of a Banach space \( X \) and \( V \not\subseteq W \) (\( V \) is a proper subset of \( W \)) while \((\lambda I - L)(W) \subseteq V, \lambda \neq 0 \). Then there exists \( w \in W \setminus V \) such that \( \|w\| = 1 \) and

\[
\text{dist} (Lw, LV) \geq 1/2
\]

**Proof:** Let \( w_0 \in W \setminus V \). Then let \( v \in V \) be such that \( \|\lambda w_0 - v\| \leq 2 \text{ dist} (\lambda w_0, V) \).

Then let

\[
w = \frac{\lambda w_0 - v}{\|\lambda w_0 - v\|}
\]

It follows that \( \|w\| = 1 \) and is in \( W \setminus V \). Now let \( x \in V \).

Then

\[
Lx - Lw = \lambda (x - w) + (L - \lambda I)(x - w)
\]

\[
= \frac{1}{\|\lambda w_0 - v\|} (\lambda x \|\lambda w_0 - v\| + (L - \lambda I)(x - w) \|\lambda w_0 - v\| - \lambda \|\lambda w_0 - v\| w)
\]

\[
= \frac{1}{\|\lambda w_0 - v\|} (\lambda x \|\lambda w_0 - v\| + (L - \lambda I)(x - w) \|\lambda w_0 - v\| - \lambda (\lambda w_0 - v))
\]

Thus

\[
\|Lx - Lw\| \geq \frac{1}{\|\lambda w_0 - v\|} \|\lambda x \|\lambda w_0 - v\| + (L - \lambda I)(x - w) \|\lambda w_0 - v\| + \lambda v - \lambda w_0
\]

\[
\geq \frac{1}{2 \text{ dist} (\lambda w_0, V)} \text{ dist} (\lambda w_0, V) = \frac{1}{2}
\]

Here is another fairly elementary lemma a little like the above.

**Lemma 15.6.4** Let \( Y \) be an infinite dimensional Banach space. Then there exists a sequence \( \{x_n\} \) in the unit sphere \( S, \|x_n\| = 1 \), such that \( \|x_n - x_m\| \geq \frac{1}{2} \) whenever \( n \neq m \).

**Proof:** Pick \( x_1 \in S \). Now the span of \( x_1 \) is not everything and so there exists \( u_2 \notin \text{span} (x_1) \). Let \( u_2 \) be a point of \( \text{span} (x_1) \) such that \( \|u_2 - w_2\| \leq 2 \text{ dist} (u_2, \text{span} (x_1)) \).

Then \( x_2 = \frac{u_2 - w_2}{\|u_2 - w_2\|} \). Then

\[
\|x_1 - x_2\| = \left\| \frac{u_2 - w_2}{\|u_2 - w_2\|} x_1 - (u_2 - w_2) \right\| \geq \frac{\text{dist} (u_2, \text{span} (x_1))}{2 \text{ dist} (u_2, \text{span} (x_1))} = \frac{1}{2}
\]

Now repeat the argument with \( \text{span} (x_1, x_2) \) in place of \( \text{span} (x_1) \) and continue to get the desired sequence. ■
Lemma 15.6.5 Let \( L \) be a compact linear map. Then the eigenspace of \( L \) is finite dimensional for each eigenvalue \( \lambda \neq 0 \).

**Proof:** Consider \((L - \lambda I)^{-1}(0) \cap S\) where \( S \) is the unit sphere. The eigenspace is just \((L - \lambda I)^{-1}(0)\). Let \( Y \) be this inverse image. If \( Y \) is infinite dimensional, then the above Lemma 15.6.3 applies. There exists \( \{x_n\} \subseteq (L - \lambda I)^{-1}(0) \cap S \) where \( \|x_n - x_m\| \geq 1/2 \) for all \( n \neq m \). Then there is a subsequence, still denoted with subscript \( n \) such that \( \{Lx_n\} \) is a Cauchy sequence. Thus \( Lx_n = \lambda x_n \) and so, since \( \lambda \neq 0 \), it follows that \( \{x_n\} \) is also a Cauchy sequence and converges to some \( x \). But this is impossible because of the construction of the \( \{x_n\} \) which prevents there being any Cauchy sequence. Thus \( Y \) must be finite dimensional. \( \blacksquare \)

This lemma is useful in proving the following major spectral theorem about the eigenvalues of a compact operator. I found this theorem in Deimling [65].

Theorem 15.6.6 Let \( L \in \mathcal{L}(X, X) \) with \( L \) compact. Let \( \Lambda \) be the eigenvalues of \( L \). That is \( \lambda \in \Lambda \) means there exists \( x \neq 0 \) such that \( Lx = \lambda x \). It is assumed the field of scalars is \( \mathbb{R} \) or \( \mathbb{C} \). Let \( R_\lambda \equiv L - \lambda I \). Then the following hold.

1. If \( \mu \in \Lambda \) then \( |\mu| \leq \|L\| \), \( \Lambda \) is at most countable and has no limit points other than possibly \( 0 \).

2. \( R_\lambda \) is a homeomorphism onto \( X \) whenever \( \lambda \notin \Lambda \cup \{0\} \).

3. For all \( \lambda \in \Lambda \setminus \{0\} \), there exists a smallest \( k = k(\lambda) \),

   (a) \( R^k_\lambda X \oplus N(R^k_\lambda) = X \) where \( N(R^k_\lambda) \) is the vectors \( x \) such that \( R^k_\lambda x = 0 \). \( R^k_\lambda X \) is closed, \( \dim(N(R^k_\lambda)) \) is finite.

   (b) \( R^k_\lambda X \) and \( N(R^k_\lambda) \) are invariant under \( L \) and \( R_\lambda R^k_\lambda X \) is a homeomorphism onto \( R^k_\lambda X \).

   (c) \( N(R^k_\lambda) \subseteq R^k_\lambda X \) for all \( \lambda, \mu \in \Lambda \setminus \{0\} \) where \( \lambda \neq \mu \).

**Proof:** Consider \( \lambda \neq 0 \). The \( N(R^k_\lambda) \) are increasing in \( k \) and \( R_\lambda (N(R^{k+1}_\lambda)) \subseteq N(R^k_\lambda) \). This follows from the definition. (It isn’t necessary to assume in most of this that \( \lambda \in \Lambda \), just a nonzero number will do.) Now

\[
R_\lambda = -\lambda \left( I - \frac{1}{\lambda}L \right)
\]

If these things are strictly increasing for infinitely many \( k \), then by Lemma 15.6.2, there is an infinite sequence \( x_k \subseteq N(R^{k+1}_\lambda) \setminus N(R^k_\lambda) \), dist \( (Lx_k, LN(R^k_\lambda)) \geq 1/2 \). Hence \( \|Lx_k - Lx_{k-1}\| \geq 1/2 \) and this can’t happen because \( L \) is compact so \( \{Lx_k\} \) has a Cauchy subsequence. Therefore there exists a smallest \( k \) such that

\[
N(R^k_\lambda) = N(R^m_\lambda), \ m \geq k
\]

On the other hand, \( \{R^k_\lambda X\} \) are decreasing in \( k \). By similar reasoning using Lemma 15.6.2 and the observation that \( R_\lambda (R^k_\lambda X) \supseteq R^{k+1}_\lambda X \) (in fact they are equal) it follows that the \( \{R^k_\lambda X\} \) are also eventually constant, say for \( m \geq l \).
Now if you have \( y \in N \left( R^k_\lambda \right) \cap R^k_\lambda X \), then \( y = R^k_\lambda w \) and also \( R^k_\lambda y = 0 \). Hence \( R^{2k}_\lambda w = 0 \) and so, \( w \in N \left( R^{2k}_\lambda \right) = N \left( R^k_\lambda \right) \) which implies \( R^k_\lambda w = 0 \) and so \( y = 0 \). It follows that \( N \left( R^k_\lambda \right) \cap R^k_\lambda X = \{0\} \).

Now suppose \( l > k \). Then there exists \( y \in R^{l-1}_\lambda \setminus R^l_\lambda X \) and so \( R^l_\lambda y \in R^l_\lambda X = R^{l+1}_\lambda X = R^l_\lambda R^k_\lambda X \). So \( R^l_\lambda y = R^l_\lambda z \) for some \( z \in R^l_\lambda X \). Thus \( y - z \neq 0 \) because \( y \notin R^l_\lambda X \) but \( z \) is. However, \( R^l_\lambda (y - z) = 0 \) and so

\[
(y - z) \in N \left( R^l_\lambda \right) \cap R^k_\lambda X \subseteq N \left( R^k_\lambda \right) \cap R^k_\lambda X
\]

which cannot happen from the above which showed that \( N \left( R^k_\lambda \right) \cap R^k_\lambda X = \{0\} \). Thus \( l \leq k \).

Next suppose \( l < k \). Then you would have \( R^l_\lambda X = R^k_\lambda X \) and \( N \left( R^k_\lambda \right) \supseteq N \left( R^l_\lambda \right) \). Thus there exists \( y \in N \left( R^l_\lambda \right) \) but not in \( N \left( R^k_\lambda \right) \). Hence \( R^k_\lambda y = 0 \) but \( R^l_\lambda y \neq 0 \). However, \( R^l_\lambda y \) is in \( R^k_\lambda X \) from the definition of \( l \) and so there is \( u \) such that \( R^l_\lambda y = R^k_\lambda u \). Thus

\[
0 = R^k_\lambda y = R^{k-l}_\lambda \left( R^l_\lambda y \right) = R^{k-l}_\lambda R^k_\lambda u = R^{2k-l}_\lambda u
\]

Now it follows that \( u \in N \left( R^{2k-l}_\lambda \right) = N \left( R^k_\lambda \right) \). This is a contradiction because it says that \( R^k_\lambda u = 0 \) but right above the displayed equation, we had \( R^k_\lambda y = R^k_\lambda u \) and \( R^l_\lambda y \neq 0 \). Thus, with the above paragraph, \( k = l \).

What about the claim that \( R^k_\lambda \) restricted to \( R^k_\lambda X \) is a homeomorphism? It maps \( R^k_\lambda X \) to \( R^{k+1}_\lambda X = R^k_\lambda X \). Also, if \( R^k_\lambda \left( y \right) = 0 \) for \( y \in R^k_\lambda X \), then \( R^k_\lambda y = 0 \) also and so \( y \in R^k_\lambda X \cap N \left( R^k_\lambda \right) \). It was shown above that this implies \( y = 0 \). Thus \( R^k_\lambda \) appears to be one to one. By assumption, it is continuous. Also from Lemma 15.6.2.

\[ R^k_\lambda X \text{ is closed.} \]

This follows from the observation that

\[
R^k_\lambda = \left( L - \lambda I \right)^k = \sum_{j=0}^{k} \binom{k}{j} L^j (-\lambda I)^{k-j} = (-\lambda)^k I + \sum_{j=1}^{k} \binom{k}{j} L^j (-\lambda I)^{k-j}
\]

(15.6.17)

which is a multiple of \( I - C \) where \( C \) is a compact map. Then by the open mapping theorem, it follows that \( R^k_\lambda \) is a homeomorphism onto \( R^{k+1}_\lambda X = R^k_\lambda X \).

What about \( R^k_\lambda X \oplus N \left( R^k_\lambda \right) = X \)? It only remains to verify that \( R^k_\lambda X + N \left( R^k_\lambda \right) = X \) because the only vector in the intersection was shown to be 0. Thus if you have \( x + y = 0 \) where \( x \) is in one of these and \( y \) in the other, then \( x = -y \) so each is in both and hence both are 0. Pick \( x \in X \). Then \( R^k_\lambda x \in R^k_\lambda \left( R^k_\lambda X \right) = R^k_\lambda X \). Therefore, \( R^k_\lambda x = R^k_\lambda \left( R^k_\lambda y \right) \) for some \( y \) and so \( R^k_\lambda \left( x - R^k_\lambda y \right) = 0 \). Hence

\[
x - R^k_\lambda y \in N \left( R^k_\lambda \right)
\]

showing that \( x \in R^k_\lambda X + N \left( R^k_\lambda \right) \).

It is obvious that \( R^k_\lambda X \) and \( N \left( R^k_\lambda \right) \) are invariant under \( L \). If \( \lambda_0 \notin \Lambda \setminus \{0\} \), then \( L - \lambda_0 I \) is one to one and so the compactness of \( L \) and Lemma 15.6.2 implies that
Thus \( Y \) is a homeomorphism onto \((L - \lambda I)X\). Is this last all of \( X\)? There is nothing in the above argument which involved an essential assumption that \( \lambda \in \Lambda \). Hence, repeating this argument, you see that \((L - \lambda I)X \oplus N (L - \lambda I) = X\) but \( N (L - \lambda I) = 0\). Hence \((L - \lambda I)X = X\) and so indeed \((L - \lambda I)\) is a homeomorphism.

For \( \mu \in \Lambda, Lx = \mu x\) and so \(|\mu|\|x\| \leq \|L\|\|x\|\) so \(|\mu| \leq \|L\|\). Why is \( \Lambda \) at most countable and has only one possible limit point at 0? It was shown that \( R_\Lambda \) is a homeomorphism when restricted to \( R_\Lambda^k X\). It follows that for \( x \in R_\Lambda^k X, \|R_\Lambda x\| > \delta \|x\|\) for some \( \delta > 0\), this for every such \( x \in R_\Lambda^k X\). Now consider \( \mu \) close to \( \lambda \) and consider \( R_\mu \). Then for \( x \in R_\Lambda^k X, \|R_\mu x\| = \|(\lambda + (\lambda - \mu)) x\| \geq \delta \|x\| - |\lambda - \mu| \|x\| > \frac{\delta}{2} \|x\|\) provided \( |\lambda - \mu| < \delta/2\). Thus for \( \mu \) close enough to \( \lambda, R_\mu \) is one to one on \( R_\Lambda^k X\). But also \( R_\mu \) is one to one on \( N (R_\Lambda^k)\). Let’s see why this is so.

Suppose \((L - \mu I) x = 0\) for \( x \in N (R_\Lambda^k)\). Then

\[
0 = (L - \mu I + (\mu - \lambda) I)^k x \\
= (\mu - \lambda)^k x + \sum_{j=1}^{k} \binom{k}{j} (L - \mu I)^j (\mu - \lambda)^{k-j} x
\]

and the second term involving the sum yields 0. Since \( R_\Lambda^k X \oplus N (R_\Lambda^k) = X\), this shows that \((L - \mu I)\) is one to one for \( \mu \) near \( \lambda \). It follows that for \( \mu \) near \( \lambda, \mu \notin \Lambda\). Thus the only possible limit point is 0. Note that there is no restriction on the size of \( \mu \) for \((L - \mu I)\) to be one to one on \( N (R_\Lambda^k)\).

Why is \( \dim (N (R_\Lambda^k)) < \infty\) for each \( \lambda \neq 0\)? This follows from Lemma \( 15.6.10\). \( R_\Lambda^k \) is a multiple of \( I - C \) for \( C \) a compact operator. Hence this is finite dimensional by Lemma \( 15.6.9\).

What about \( N (R_\mu^k) \subseteq R_\Lambda^k X\) for \( \mu \) an eigenvalue different than \( \lambda\)? Say \( R_\mu^k x = 0\). Then, does it follow that \( x \in R_\Lambda^k X\)? From what was just shown

\[
x = y + z, \ y \in R_\Lambda^k X, \ z \in N (R_\Lambda^k)
\]

Then

\[
0 = R_\mu^k x = R_\mu^k y + R_\mu^k z
\]

Here \( p = k(\mu)\). This is where it is important that \( \mu \in \Lambda\). However, \( N (R_\Lambda^k)\) and \( R_\Lambda^k X\) are invariant under \( R_\mu^k\) since it is clear that \( R_\Lambda \) and \( R_\mu \) commute. Thus \( R_\mu^k y = -R_\mu^k z\) and \( R_\mu^k y \in R_\Lambda^k X\), \(-R_\mu^k z \in N (R_\Lambda^k)\) and these are equal. Hence they are both 0. Now it was just shown that \( R_\mu \) is one to one on \( N (R_\Lambda^k)\) and so \( z = 0\). Hence \( x = y \in R_\Lambda^k X\).

Note that in the last step, we can’t conclude that \( y = 0\) because we only know that \( R_\mu \) is one to one on \( R_\Lambda^k X\) if \( \mu \) is sufficiently close to \( \lambda\). The above is about compact mappings from a single space to itself. However, there are also mappings which have closed range which map from one space to another. The Fredholm operators have this property that their image is closed. These are discussed next.

Suppose \( T \in \mathcal{L}(X, Y)\). Then \( TX \) is a subspace of \( Y\) and so it has a Hamel basis \( \mathcal{B}\). Extending \( \mathcal{B}\) to a Hamel basis for \( Y\) yields \( \mathcal{C}\). Then \( Y = \text{span}(\mathcal{B}) \oplus \text{span}(\mathcal{C} \setminus \mathcal{B})\). Thus \( Y = TX \oplus E\). For more on this, see \( [22]\).
15.6. OPERATORS WITH CLOSED RANGE

Definition 15.6.7 Let $T \in \mathcal{L}(X,Y)$. Then this is a Fredholm operator means

1. $\dim(\ker(T)) < \infty$
2. $\dim(E) < \infty$ where $Y = TX \oplus E$

Proposition 15.6.8 Let $T \in \mathcal{L}(X,Y)$. Then $TX$ is closed if and only if there exists $\delta > 0$ such that

$$\|Tx\| \geq \delta \text{dist}(x, \ker(T)).$$

Proof: First suppose $TX$ is closed. Let $\hat{T} : X/\ker(T) \to Y$ be defined as $\hat{T}([x]) := Tx$. Then by Theorem 15.6.4, $\hat{T}$ is one to one and continuous and $X/\ker(T)$ is a Banach space, $\|\hat{T}\| \leq \|T\|$. Also $\hat{T}$ has the same range as $T$. Thus $TX$ is the same as $\hat{T}(X/\ker(T))$ and $\hat{T} \in \mathcal{L}(X/\ker(T), Y)$. By the open mapping theorem, $\hat{T}$ is continuous and has continuous inverse. Recall

$$||(x)|| = \inf \{\|x + z\| : z \in \ker T\} = \text{dist}(x, \ker(T))$$

Then

$$\text{dist}(x, \ker(T)) = ||[x]|| = \left\|\hat{T}^{-1} \hat{T}[x]\right\| \leq \left\|\hat{T}^{-1}\right\| \left\|\hat{T}[x]\right\| = \left\|\hat{T}^{-1}\right\| \|Tx\|$$

and so,

$$\|Tx\| \geq \delta \text{dist}(x, \ker(T))$$

where $\delta = 1/\left\|\hat{T}^{-1}\right\|$

Next suppose the inequality holds. Why will $TX$ be closed? Say $\{Tx_n\}$ is a sequence in $TX$ converging to $y$. Then by the inequality,

$$\|Tx_n - Tx_m\| \geq \delta \text{dist}(x_n - x_m, \ker(T)) = \delta \|[x_n] - [x_m]\|_{X/\ker(T)}$$

showing that $\{[x_n]\}$ is a Cauchy sequence in $X/\ker(T)$. Therefore, since this is a Banach space, there exists $[x]$ such that $[x_n] \to [x]$ in $X/\ker(T)$ and so $\hat{T}([x_n]) \to \hat{T}([x])$ in $Y$. But this is the same as saying that $T(x_n) \to T(x)$. It follows that $y = Tx$ and so $TX$ is indeed closed. ■

Theorem 15.6.9 If $T$ is a Fredholm operator, then $TX$ is closed in $Y$.

Proof: Recall that $Y = TX \oplus E$ where $E$ is a closed subspace of $Y$. In fact, $E$ is finite dimensional, but it is only needed that $E$ is closed. Let $T_0 \in \mathcal{L}(X \times E, TX \oplus E)$ be given by

$$T_0(x,e) = Tx + e$$

Let the norm on $X \times E$ be

$$\|(x,e)\|_{X \times E} = \max\{\|x\|_X, \|e\|_E\}$$
Thus \( T_0(x, e) = 0 \) implies both \( Tx = 0 \) and \( e = 0 \). Thus \( \ker(T_0) = \ker(T) \times \{0\} \).

Also, \( T_0(X \times E) \) is closed in \( Y \) because in fact it is all of \( Y \), \( TX \oplus E \). By Proposition 15.6.8, there exists \( \delta > 0 \) such that

\[
\|T_0(x, e)\|_Y \geq \delta \text{ dist}((x, e), \ker(T_0)) = \delta \text{ dist}((x, e), \ker(T) \times \{0\}) \geq \delta \text{ dist} (x, \ker(T))
\]

Then

\[
\|Tx\|_Y = \|T_0(x, 0)\|_Y \geq \delta \text{ dist} (x, \ker(T))
\]

and by Proposition 15.6.8, \( TX \) is closed.

Actually, the above proves the following corollary.

**Corollary 15.6.10** If \( TX \oplus E \) is closed in \( Y \) and \( E \) is a closed subspace of \( Y \), then \( TX \) is closed. Here \( T \in \mathcal{L}(X, Y) \).

Note that it appears that \( \dim(\ker(T)) \leq \infty \) was not really needed.

Let \( B \) be a Hamel basis for \( TX \) and consider \( A \equiv \{ x : Tx \in B \} \). Then this is a linearly independent set of vectors in \( X \). Suppose now that \( \ker(T) = \text{span}(z_1, \ldots, z_n) \) where \( \{z_1, \ldots, z_n\} \) is linearly independent so here the assumption that \( \ker(T) \) has finite dimensions is being used. Then if \( x \in X, Tx \in TX \) and so there are finitely many vectors \( x_i \in A \) such that

\[
Tx = \sum_i c_i Tx_i.
\]

Hence

\[
T \left( x - \sum_i c_i x_i \right) = 0
\]

so

\[
x - \sum_i c_i x_i = \sum_{j=1}^n a_j z_j
\]

Hence \( X = \text{span}(A) + \ker(T) \). In fact, \( \{A, \{z_1, \cdots, z_n\}\} \) is linearly independent as is easily seen and so this is a basis for \( X \). Hence

\[
X = \text{span}(A) \oplus \ker(T) \equiv X_1 \oplus \ker(T)
\]

Is \( X_1 \) closed? Define \( S : TX \to X_1 \) as follows: \( Sy = x \in X_1 \) such that \( Tx = y \). Since \( T \) is one to one on \( X_1 \), there is only one such \( x \). Is \( S \) continuous? Yes, this is so by the open mapping theorem. It is just the inverse of a continuous one to one linear onto map. Now this reduces to the situation discussed above in Corollary 15.6.10. You have \( S \in \mathcal{L}(TX, X_1) \) and \( S(TX) \oplus \ker(T) \) is all of \( X \) and so it is closed in \( X \). Therefore, \( S(TX) = X_1 \) is closed. This, along with the above proves the following.

**Theorem 15.6.11** Let \( T \in \mathcal{L}(X, Y) \) be a Fredholm operator and suppose \( \ker(T) \) is finite dimensional and that \( Y = TX \oplus E \) where \( E \) is a finite dimensional subspace or more generally closed. Then \( TX \) is closed and also for \( X = X_1 \oplus \ker(T) \), it follows that \( X_1 \) is closed.
15.7 Exercises

1. Is \( \mathbb{N} \) a \( G_\delta \) set? What about \( \mathbb{Q} \)? What about a countable dense subset of a complete metric space?

2. \( \uparrow \) Let \( f : \mathbb{R} \to \mathbb{C} \) be a function. Define the oscillation of a function in \( B(x, r) \) by \( \omega_r f(x) = \sup \{ |f(z) - f(y)| : y, z \in B(x, r) \} \). Define the oscillation of the function at the point, \( x \) by \( \omega f(x) = \lim_{r \to 0} \omega_r f(x) \). Show \( f \) is continuous at \( x \) if and only if \( \omega f(x) = 0 \). Then show the set of points where \( f \) is continuous is a \( G_\delta \) set (try \( U_n = \{ x : \omega f(x) < \frac{1}{n} \} \)). Does there exist a function continuous at only the rational numbers? Does there exist a function continuous at every irrational and discontinuous elsewhere? \textbf{Hint:} Suppose \( D \) is any countable set, \( D = \{ d_i \}_{i=1}^\infty \), and define the function, \( f_n(x) \) to equal zero for every \( x \not\in \{ d_1, \cdots, d_n \} \) and \( 2^{-n} \) for \( x \) in this finite set. Then consider \( g(x) = \sum_{n=1}^\infty f_n(x) \). Show that this series converges uniformly.

3. Let \( f \in C([0, 1]) \) and suppose \( f'(x) \) exists. Show there exists a constant, \( K \), such that \( |f(x) - f(y)| \leq K|x - y| \) for all \( y \in [0, 1] \). Let \( U_n = \{ f \in C([0, 1]) \} \) such that for each \( x \in [0, 1] \) there exists \( y \in [0, 1] \) such that \( |f(x) - f(y)| > n|x - y| \). Show that \( U_n \) is open and dense in \( C([0, 1]) \) where for \( f \in C([0, 1]) \),

\[ ||f|| = \sup \{ |f(x)| : x \in [0, 1] \}. \]

Show that \( \cap_n U_n \) is a dense \( G_\delta \) set of nowhere differentiable continuous functions. Thus every continuous function is uniformly close to one which is nowhere differentiable.

4. \( \uparrow \) Suppose \( f(x) = \sum_{k=1}^\infty u_k(x) \) where the convergence is uniform and each \( u_k \) is a polynomial. Is it reasonable to conclude that \( f'(x) = \sum_{k=1}^\infty u'_k(x) \)? The answer is no. Use Problem 9 and the Weierstrass approximation theorem do show this.

5. Let \( X \) be a normed linear space. We say \( A \subseteq X \) is “weakly bounded” if for each \( x^* \in X' \), \( \sup \{ |x^*(x)| : x \in A \} < \infty \), while \( A \) is bounded if \( \sup \{ ||x|| : x \in A \} < \infty \). Show \( A \) is weakly bounded if and only if it is bounded.

6. Let \( X \) and \( Y \) be two Banach spaces. Define the norm

\[ ||(x, y)|| = ||x||_X + ||y||_Y. \]

Show this is a norm on \( X \times Y \) which is equivalent to the norm given in the chapter for \( X \times Y \). Can you do the same for the norm defined for \( p > 1 \) by

\[ ||(x, y)|| = (||x||_X^p + ||y||_Y^p)^{1/p}. \]

7. Let \( f \) be a \( 2\pi \) periodic locally integrable function on \( \mathbb{R} \). The Fourier series for \( f \) is given by

\[ \sum_{k = -\infty}^{\infty} a_k e^{ikx} = \lim_{n \to \infty} \sum_{k = -n}^{n} a_k e^{ikx} = \lim_{n \to \infty} S_n f(x) \]
where
\[ a_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{-ikx} f(x) \, dx. \]

Show
\[ S_n f(x) = \int_{-\pi}^{\pi} D_n(x-y) f(y) \, dy \]
where
\[ D_n(t) = \frac{\sin((n+\frac{1}{2})t)}{2\pi \sin(\frac{t}{2})}. \]

Verify that \( \int_{-\pi}^{\pi} D_n(t) \, dt = 1 \). Also show that if \( g \in L^1(\mathbb{R}) \), then
\[ \lim_{a \to \infty} \int_{\mathbb{R}} g(x) \sin(ax) \, dx = 0. \]
This last is called the Riemann Lebesgue lemma. \textbf{Hint:} For the last part, assume first that \( g \in C_c^{\infty}(\mathbb{R}) \) and integrate by parts. Then exploit density of the set of functions in \( L^1(\mathbb{R}) \).

8. \( \dagger \) It turns out that the Fourier series sometimes converges to the function pointwise. Suppose \( f \) is \( 2\pi \) periodic and Holder continuous. That is \( |f(x) - f(y)| \leq K|x-y|^\theta \) where \( \theta \in (0,1] \). Show that if \( f \) is like this, then the Fourier series converges to \( f \) at every point. Next modify your argument to show that if at every point, \( x, |f(x+)-f(y)| \leq K|x-y|^\theta \) for \( y \) close enough to \( x \) and larger than \( x \) and \( |f(x-)-f(y)| \leq K|x-y|^\theta \) for every \( y \) close enough to \( x \) and smaller than \( x \), then \( S_n f(x) \to f(x)+f(x-) \), the midpoint of the jump of the function. \textbf{Hint:} Use Problem 7.

9. \( \dagger \) Let \( Y = \{ f \text{ such that } f \text{ is continuous, defined on } \mathbb{R}, \text{ and } 2\pi \text{ periodic} \} \). Define \( ||f||_Y = \sup \{|f(x)| : x \in [-\pi, \pi] \} \). Show that \( (Y, ||.||_Y) \) is a Banach space. Let \( x \in \mathbb{R} \) and define \( L_x(f) = S_n f(x) \). Show \( L_x \in Y' \) but \( \lim_{n \to \infty} ||L_n|| = \infty \). Show that for each \( x \in \mathbb{R} \), there exists a dense \( G_\delta \) subset of \( Y \) such that for \( f \) in this set, \( |S_n f(x)| \) is unbounded. Finally, show there is a dense \( G_\delta \) subset of \( Y \) having the property that \( |S_n f(x)| \) is unbounded on the rational numbers. \textbf{Hint:} To do the first part, let \( f(y) \) approximate \( \text{sgn}(D_n(x-y)) \). Here \( \text{sgn} r = 1 \) if \( r > 0, -1 \) if \( r < 0 \) and \( 0 \) if \( r = 0 \). This rules out one possibility of the uniform boundedness principle. After this, show the countable intersection of dense \( G_\delta \) sets must also be a dense \( G_\delta \) set.

10. Let \( \alpha \in (0,1] \). Define, for \( X \) a compact subset of \( \mathbb{R}^p \),
\[ C^\alpha(X;\mathbb{R}^n) = \{ f \in C(X;\mathbb{R}^n) : \rho_\alpha(f) + ||f||_\alpha < \infty \} \]
where
\[ ||f||_\alpha = \sup \{|f(x)| : x \in X \} \]
and

\[ \rho_\alpha(f) \equiv \sup \{ \frac{|f(x) - f(y)|}{|x - y|^\alpha} : x, y \in X, x \neq y \}. \]

Show that \( (C^\alpha(X; \mathbb{R}^n), \|\cdot\|_\alpha) \) is a complete normed linear space. This is called a Holder space. What would this space consist of if \( \alpha > 1 \)?

11. Now recall Problem 10 about the Holder spaces. Let \( X \) be the Holder functions which are periodic of period \( 2\pi \). Define \( L_n f(x) = S_n f(x) \) where \( L_n : X \to Y \) for \( Y \) given in Problem 9. Show \( \|L_n\| \) is bounded independent of \( n \). Conclude that \( L_n f \to f \) in \( Y \) for all \( f \in X \). In other words, for the Holder continuous and \( 2\pi \) periodic functions, the Fourier series converges to the function uniformly. \textbf{Hint:} \( L_n f(x) \) is given by

\[ L_n f(x) = \int_{-\pi}^{\pi} D_n(y) f(x + y) \, dy \]

where \( f(x + y) = f(x) + g(x, y) \) where \( |g(x, y)| \leq C |y|^\alpha \). Use the fact the Dirichlet kernel integrates to one to write

\[ \left| \int_{-\pi}^{\pi} D_n(y) f(x + y) \, dy \right| \leq \left[ \int_{-\pi}^{\pi} D_n(y) f(x) \, dy \right] = |f(x)| + C \left| \int_{-\pi}^{\pi} \sin \left( \left( n + \frac{1}{2} \right)y \right) \frac{g(x, y)}{\sin(y/2)} \right| \]

Show the functions, \( y \mapsto g(x, y) / \sin(y/2) \) are bounded in \( L^1 \) independent of \( x \) and get a uniform bound on \( \|L_n\| \). Now use a similar argument to show \( \{L_n f\} \) is equicontinuous in addition to being uniformly bounded. If \( L_n f \) fails to converge to \( f \) uniformly, then there exists \( \varepsilon > 0 \) and a subsequence, \( n_k \) such that \( \|L_n f - f\|_{\infty} \geq \varepsilon \) where this is the norm in \( Y \) or equivalently the sup norm on \( [-\pi, \pi] \). By the Arzela Ascoli theorem, there is a further subsequence, \( L_{n_k} f \) which converges uniformly on \( [-\pi, \pi] \). But by Problem 9 \( L_n f(x) \to f(x) \).

12. Let \( X \) be a normed linear space and let \( M \) be a convex open set containing 0. Define

\[ \rho(x) = \inf \{ t > 0 : \frac{x}{t} \in M \}. \]

Show \( \rho \) is a gauge function defined on \( X \). This particular example is called a Minkowski functional. It is of fundamental importance in the study of locally convex topological vector spaces. A set, \( M \), is convex if \( \lambda x + (1 - \lambda)y \in M \) whenever \( \lambda \in [0, 1] \) and \( x, y \in M \).

13. The Hahn Banach theorem can be used to establish separation theorems. Let \( M \) be an open convex set containing 0. Let \( x \notin M \). Show there exists \( x^* \in X' \) such that \( \text{Re } x^*(x) \geq 1 > \text{Re } x^*(y) \) for all \( y \in M \). \textbf{Hint:} If \( y \in M, \rho(y) < 1 \).
Show this. If \( x \notin M, \rho(x) \geq 1 \). Try \( f(\alpha x) = \alpha \rho(x) \) for \( \alpha \in \mathbb{R} \). Then extend \( f \) to the whole space using the Hahn Banach theorem and call the result \( F \), show \( F \) is continuous, then fix it so \( F \) is the real part of \( x^* \in X' \).

14. A Banach space is said to be strictly convex if whenever \( ||x|| = ||y|| \) and \( x \neq y \), then
\[
\left\| \frac{x + y}{2} \right\| < ||x||.
\]
\( F : X \rightarrow X' \) is said to be a duality map if it satisfies the following:

a.) \( ||F(x)|| = ||x|| \).

b.) \( F(x)(x) = ||x||^2 \). Show that if \( X' \) is strictly convex, then such a duality map exists. The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space. **Hint:** For an arbitrary Banach space, let
\[
F(x) = \left\{ x^* : ||x^*|| \leq ||x|| \text{ and } x^*(x) = ||x||^2 \right\}
\]
Show \( F(x) \neq \emptyset \) by using the Hahn Banach theorem on \( f(\alpha x) = \alpha ||x||^2 \). Next show \( F(x) \) is closed and convex. Finally show that you can replace the inequality in the definition of \( F(x) \) with an equal sign. Now use strict convexity to show there is only one element in \( F(x) \).

15. Prove the following theorem which is an improved version of the open mapping theorem. **Hint:** Let \( X \) and \( Y \) be Banach spaces and let \( A \in \mathcal{L}(X, Y) \). Then the following are equivalent.

\( AX = Y \),

\( A \) is an open map.

There exists a constant \( M \) such that for every \( y \in Y \), there exists \( x \in X \) with \( y = Ax \) and
\[
||x|| \leq M ||y||.
\]
Note this gives the equivalence between \( A \) being onto and \( A \) being an open map. The open mapping theorem says that if \( A \) is onto then it is open.

16. Suppose \( D \subseteq X \) and \( D \) is dense in \( X \). Suppose \( L : D \rightarrow Y \) is linear and \( ||Lx|| \leq K||x|| \) for all \( x \in D \). Show there is a unique extension of \( L \), \( \tilde{L} \), defined on all of \( X \) with \( ||\tilde{L}x|| \leq K||x|| \) and \( \tilde{L} \) is linear. You do not get uniqueness when you use the Hahn Banach theorem. Therefore, in the situation of this problem, it is better to use this result.

17. A Banach space is uniformly convex if whenever \( ||x_n||, ||y_n|| \leq 1 \) and \( ||x_n + y_n|| \rightarrow 2 \), it follows that \( ||x_n - y_n|| \rightarrow 0 \). Show uniform convexity implies strict convexity (See Problem 14). **Hint:** Suppose it is not strictly convex. Then there exist \( ||x|| \) and \( ||y|| \) both equal to 1 and \( ||\frac{x_n + y_n}{2}|| = 1 \) consider \( x_n \equiv x \) and \( y_n \equiv y \), and use the conditions for uniform convexity to get a contradiction. It can be shown that \( L^p \) is uniformly convex whenever \( \infty > p > 1 \). See Hewitt and Stromberg or Ray.
18. Show that a closed subspace of a reflexive Banach space is reflexive. **Hint:**
The proof of this is an exercise in the use of the Hahn Banach theorem. Let 
$Y$ be the closed subspace of the reflexive space $X$ and let $y^{**} \in Y''$. Then 
$i^{**}y^{**} \in X''$ and so $i^{**}y^{**} = Jx$ for some $x \in X$ because $X$ is reflexive.
Now argue that $x \in Y$ as follows. If $x \notin Y$, then there exists $x^*$ such that 
$x^*(Y) = 0$ but $x^*(x) \neq 0$. Thus, $i^*x^* = 0$. Use this to get a contradiction.
When you know that $x = y \in Y$, the Hahn Banach theorem implies $i^*$ is onto 
$Y'$ and for all $x^* \in X'$,

$$ y^{**}(i^*x^*) = i^{**}y^{**}(x^*) = Jx(x^*) = x^*(ix) = i^*x^*(y). $$

19. We say that $x_n$ converges weakly to $x$ if for every $x^* \in X'$, $x^*(x_n) \to x^*(x)$.
$x_n \rightharpoonup x$ denotes weak convergence. Show that if $\|x_n - x\| \to 0$, then $x_n \rightharpoonup x$.

20. Show that if $X$ is uniformly convex, then if $x_n \rightharpoonup x$ and $\|x_n\| \to \|x\|$, it 
follows $\|x_n - x\| \to 0$. **Hint:** Use Lemma 15.7.4 to obtain $f \in X'$ with $\|f\| = 1$ and 
f$(x) = \|x\|$. See Problem 17 for the definition of uniform convexity.
Now by the weak convergence, you can argue that if $x \neq 0$, $f (x_n/\|x_n\|) \to f (x/\|x\|)$. You also might try to show this in the special case where $\|x_n\| = \|x\| = 1$.

21. Suppose $L \in \mathcal{L}(X,Y)$ and $M \in \mathcal{L}(Y,Z)$. Show $ML \in \mathcal{L}(X,Z)$ and that 
$(ML)^* = L^*M^*$.

22. Let $X$ and $Y$ be Banach spaces and suppose $f \in \mathcal{L}(X,Y)$ is compact. Recall 
this means that if $B$ is a bounded set in $X$, then $f(B)$ has compact closure 
in $Y$. Show that $f^*$ is also a compact map. **Hint:** Take a bounded subset of 
$Y', S$. You need to show $f^*(S)$ is totally bounded. You might consider using 
the Ascoli Arzela theorem on the functions of $S$ applied to $f(B)$ where $B$ is 
the closed unit ball in $X$. 

15.7. EXERCISES
Chapter 16

Locally Convex Topological Vector Spaces

16.1 Fundamental Considerations

The right context to consider certain topics like separation theorems is in locally convex topological vector spaces, a generalization of normed linear spaces. Let $X$ be a vector space and let $\Psi$ be a collection of functions defined on $X$ such that if $\rho \in \Psi$,

$$\rho(x + y) \leq \rho(x) + \rho(y),$$
$$\rho(ax) = |a| \rho(x) \text{ if } a \in \mathbb{F},$$
$$\rho(x) \geq 0,$$

where $\mathbb{F}$ denotes the field of scalars, either $\mathbb{R}$ or $\mathbb{C}$, assumed to be $\mathbb{C}$ unless otherwise specified. These functions are called seminorms because it is not necessarily true that $x = 0$ when $\rho(x) = 0$. A basis for a topology, $B$, is defined as follows.

**Definition 16.1.1** For $A$ a finite subset of $\Psi$ and $r > 0$,

$$B_A(x, r) \equiv \{ y \in X : \rho(x - y) < r \text{ for all } \rho \in A \}.$$

Then

$$B \equiv \{ B_A(x, r) : x \in X, r > 0, \text{ and } A \subseteq \Psi, A \text{ finite} \}.$$

That this really is a basis is the content of the next theorem.

**Theorem 16.1.2** $B$ is the basis for a topology.

**Proof:** I need to show that if $B_A(x, r_1)$ and $B_B(y, r_2)$ are two elements of $B$ and if $z \in B_A(x, r_1) \cap B_B(y, r_2)$, then there exists $U \in B$ such that $z \in U \subseteq B_A(x, r_1) \cap B_B(y, r_2)$. 

463
Let
\[ r = \min \{ \min \{ r_1 - \rho(z - x) \colon \rho \in A \}, \min \{ r_2 - \rho(z - y) \colon \rho \in B \} \} \]
and consider \( B_{A \cup B}(z, r) \). If \( w \) belongs to this set, then for \( \rho \in A \),
\[ \rho(w - z) < r_1 - \rho(z - x). \]
Hence
\[ \rho(w - x) \leq \rho(w - z) + \rho(z - x) < r_1 \]
for each \( \rho \in A \) and so \( B_{A \cup B}(z, r) \subseteq B_A(x, r_1) \). Similarly, \( B_{A \cup B}(z, r) \subseteq B_B(y, r_2) \).
This proves the theorem.

Let \( \tau \) be the topology consisting of unions of all subsets of \( \mathcal{B} \). Then \( (X, \tau) \) is a
locally convex topological vector space.

**Theorem 16.1.3** The vector space operations of addition and scalar multiplication
are continuous. More precisely,
\[ + : X \times X \to X, \cdot : F \times X \to X \]
are continuous.

**Proof:** It suffices to show \( +^{-1}(B) \) is open in \( X \times X \) and \( \cdot^{-1}(B) \) is open in \( F \times X \)
if \( B \) is of the form
\[ B = \{ y \in X : \rho(y - x) < r \} \]
because finite intersections of such sets form the basis \( \mathcal{B} \). (This collection of sets is
a subbasis.) Suppose \( u + v \in B \) where \( B \) is described above. Then
\[ \rho(u + v - x) < \lambda r \]
for some \( \lambda < 1 \). Consider
\[ B_{\rho}(u, \delta) \times B_{\rho}(v, \delta). \]
If \( (u_1, v_1) \) is in this set, then
\[ \rho(u_1 + v_1 - x) \leq \rho(u + v - x) + \rho(u_1 - u) + \rho(v_1 - v) < \lambda r + 2\delta. \]
Let \( \delta \) be positive but small enough that
\[ 2\delta + \lambda r < r. \]
Thus this choice of \( \delta \) shows that \( +^{-1}(B) \) is open and this shows + is continuous.

Now suppose \( \alpha z \in B \). Then
\[ \rho(\alpha z - x) < \lambda r < r \]
for some \( \lambda \in (0, 1) \). Let \( \delta > 0 \) be small enough that \( \delta < 1 \) and also
\[
\lambda r + \delta (\rho(z) + 1) + \delta |\alpha| < r.
\]
Then consider \( (\beta, w) \in B(\alpha, \delta) \times B_\rho(z, \delta) \).

\[
\rho(\beta w - x) - \rho(\alpha z - x) \leq \rho(\beta w - \alpha z)
\]
\[
\leq |\beta - \alpha| \rho(w) + \rho(w - z) |\alpha|
\]
\[
\leq |\beta - \alpha| (\rho(z) + 1) + \rho(w - z) |\alpha|
\]
\[
< \delta (\rho(z) + 1) + \delta |\alpha|.
\]

Hence
\[
\rho(\beta w - x) < \lambda r + \delta (\rho(z) + 1) + \delta |\alpha| < r
\]
and so
\[
B(\alpha, \delta) \times B_\rho(z, \delta) \subseteq \cdot^{-1}(B).
\]

This proves the theorem.

**Theorem 16.1.4** Let \( x \) be given and let \( f_x(y) = x + y \). Then \( f_x \) is \( 1-1 \), onto, and continuous. If \( \alpha \neq 0 \) and \( g_\alpha(x) = \alpha x \), then \( g_\alpha \) is also \( 1-1 \) onto and continuous.

**Proof:** The assertions about \( 1-1 \) and onto are obvious. It remains to show \( f_x \) and \( g_\alpha \) are continuous. Let \( B = B_\rho(z, r) \) and consider \( f_x^{-1}(B) \). Then it is easy to see that
\[
f_x^{-1}(B) = B_\rho(z - x, r)
\]
and so \( f_x \) is continuous. To see that \( g_\alpha \) is continuous, note that
\[
g_\alpha^{-1}(B) = B_\rho \left( \frac{z}{\alpha}, \frac{r}{|\alpha|} \right).
\]

This proves the theorem.

As in the case of a normed linear space, the vector space of continuous linear functionals, is denoted by \( X' \).

**Definition 16.1.5** Define, for \( A \) a finite subset of \( \Psi \),
\[
\rho_A(x) = \max \{ \rho(x) : \rho \in A \}.
\]

The following theorem is the equivalent to the earlier theorems concerning continuous linear functionals on normed linear spaces.

**Theorem 16.1.6** The following are equivalent for \( f \), a linear function mapping \( X \) to \( \mathbb{F} \).

\[
f \text{ is continuous at } 0. \quad (16.1.1)
\]

For some \( A \subseteq \Psi \), \( A \) finite,
\[
|f(x)| \leq C \rho_A(x) \quad (16.1.2)
\]
for all \( x \in X \) where the constant may depend on \( A \) but is independent of \( x \).

\[
f \text{ is continuous at } x \quad (16.1.3)
\]
for all \( x \).
**Proof:** Clearly (16.1.3) implies (16.1.1). Suppose (16.1.1). Then

\[ 0 = f(0) \in B(0, 1) \subseteq \mathbb{F}. \]

Since \( f \) is continuous at \( 0 \), \( 0 \in f^{-1}(B(0, 1)) \) and there exists an open set \( V \in \tau \) such that

\[ 0 \in V \subseteq f^{-1}(B(0, 1)). \]

Then \( 0 \in B_A(0, r) \subseteq V \) for some \( r \) and some \( A \subseteq \Psi \), \( A \) finite. Hence

\[ |f(y)| < 1 \text{ if } \rho_A(y) < r. \]

Since \( f \) is linear

\[ |f(x)| \leq \frac{2}{r} \rho_A(x). \]

To see this, note that if \( x \neq 0 \), then

\[ \frac{rx}{2\rho_A(x)} \in B_A(0, r) \]

and so

\[ \frac{|f(rx)|}{2\rho_A(x)} \leq 1 \]

which shows that (16.1.1) implies (16.1.2).

Now suppose (16.1.2) and suppose \( f(x) \in V \), an open set in \( \mathbb{F} \). Then

\[ f(x) \in B(f(x), r) \subseteq V \]

for some \( r > 0 \). Suppose \( \rho_A(x - y) < r(C_A + 1)^{-1} \). Then

\[ |f(x) - f(y)| = |f(x - y)| \leq C_A \rho_A(y - x) < r. \]

Hence

\[ f \left( B_A(\ x, r(C_A + 1)^{-1}) \right) \subseteq B(f(x), r) \subseteq V. \]

Thus \( f \) is continuous at \( x \). This proves the theorem.

What are some examples of locally convex topological vector spaces? It is obvious that any normed linear space is such an example. More generally, here is a theorem which shows how to make any vector space into a locally convex topological vector space.

**Theorem 16.1.7** Let \( X \) be a vector space and let \( Y \) be a vector space of linear functionals defined on \( X \). For each \( y \in Y \), define

\[ \rho_y(x) = |y(x)|. \]

Then the collection of seminorms \( \{\rho_y\}_{y \in Y} \) defined on \( X \) makes \( X \) into a locally convex topological vector space and \( Y = X' \).
16.2. SEPARATION THEOREMS

Proof: Clearly \( \{\rho_y\}_{y \in Y} \) is a collection of seminorms defined on \( X \); so, \( X \) supplied with the topology induced by this collection of seminorms is a locally convex topological vector space. Is \( Y = X' \)?

Let \( y \in Y \), let \( U \subseteq F \) be open and let \( x \in y^{-1}(U) \). Then \( B(y(x), r) \subseteq U \) for some \( r > 0 \). Letting \( A = \{y\} \), it is easy to see from the definition that \( B_A(x, r) \subseteq y^{-1}(U) \) and so \( y^{-1}(U) \) is an open set as desired. Thus, \( Y \subseteq X' \).

Now suppose \( z \in X' \). Then by 16.1.2, there exists a finite subset of \( Y \), \( A \equiv \{y_1, \ldots, y_n\} \), such that

\[
|z(x)| \leq C \rho_A(x).
\]

Let

\[
\pi(x) \equiv (y_1(x), \ldots, y_n(x))
\]

and let \( f \) be a linear map from \( \pi(X) \) to \( F \) defined by

\[
f(\pi x) \equiv z(x).
\]

(This is well defined because if \( \pi(x) = \pi(x_1) \), then \( y_i(x) = y_i(x_1) \) for \( i = 1, \ldots, n \) and so

\[
\rho_A(x - x_1) = 0.
\]

Thus,

\[
|z(x) - z(x)| = |z(x_1 - x)| \leq C \rho_A(x - x_1) = 0.
\]

Extend \( f \) to all of \( F^n \) and denote the resulting linear map by \( F \). Then there exists a vector

\[
\alpha = (\alpha_1, \ldots, \alpha_n) \in F^n
\]

with \( \alpha_i = F(e_i) \) such that

\[
F(\beta) = \alpha \cdot \beta.
\]

Hence for each \( x \in X \),

\[
z(x) = f(\pi x) = F(\pi x) = \sum_{i=1}^{n} \alpha_i y_i(x)
\]

and so

\[
z = \sum_{i=1}^{n} \alpha_i y_i \in Y.
\]

This proves the theorem.

16.2 Separation Theorems

It will always be assumed that \( X \) is a locally convex topological vector space. A set, \( K \), is said to be convex if whenever \( x, y \in K \),

\[
\lambda x + (1 - \lambda) y \in K
\]

for all \( \lambda \in [0, 1] \).
Definition 16.2.1 Let $U$ be an open convex set containing $0$ and define

$$m(x) = \inf \{ t > 0 : x/t \in U \}.$$ 

This is called a Minkowski functional.

Proposition 16.2.2 Let $X$ be a locally convex topological vector space. Then $m$ is defined on $X$ and satisfies

$$m(x + y) \leq m(x) + m(y) \quad (16.2.4)$$

$$m(\lambda x) = \lambda m(x) \quad \text{if } \lambda > 0. \quad (16.2.5)$$

Thus, $m$ is a gauge function on $X$.

**Proof:** Let $x \in X$ be arbitrary. There exists $A \subseteq \Psi$ such that

$$0 \in B_A(0,r) \subseteq U.$$ 

Then

$$\frac{rx}{2\rho_A(x)} \in B_A(0,r) \subseteq U$$

which implies

$$\frac{2\rho_A(x)}{r} \geq m(x). \quad (16.2.6)$$

Thus $m(x)$ is defined on $X$.

Let $x/t \in U$, $y/s \in U$. Then since $U$ is convex,

$$\frac{x + y}{t + s} = \left( \frac{t}{t+s} \right) \left( \frac{x}{t} \right) + \left( \frac{s}{t+s} \right) \left( \frac{y}{s} \right) \in U.$$ 

It follows that

$$m(x + y) \leq t + s.$$ 

Choosing $s, t$ such that $t - \varepsilon < m(x)$ and $s - \varepsilon < m(y)$,

$$m(x + y) \leq m(x) + m(y) + 2\varepsilon.$$ 

Since $\varepsilon$ is arbitrary, this shows $m(x + y) \leq t + s$. Thus $m(x + y) \leq m(x) + m(y) + 2\varepsilon$.

It remains to show $16.2.5$. Let $x/t \in U$. Then if $\lambda > 0$,

$$\frac{\lambda x}{\lambda t} \in U$$

and so $m(\lambda x) \leq \lambda t$. Thus $m(\lambda x) \leq \lambda m(x)$ for all $\lambda > 0$. Hence

$$m(x) = m(\lambda^{-1} \lambda x) \leq \lambda^{-1} m(\lambda x) \leq \lambda^{-1} \lambda m(x) = m(x)$$

and so

$$\lambda m(x) = m(\lambda x).$$

This proves the proposition.
Lemma 16.2.3  Let $U$ be an open convex set containing 0 and let $q \notin U$. Then there exists $f \in X'$ such that

$$\text{Re } f (q) > \text{Re } f (x)$$

for all $x \in U$.

Proof: Let $m$ be the Minkowski functional just defined and let

$$F (cq) = cm (q)$$

for $c \in \mathbb{R}$. If $c > 0$ then

$$F (cq) = m (cq)$$

while if $c \leq 0$,

$$F (cq) = cm (q) \leq 0 \leq m (cq).$$

By the Hahn Banach theorem, $F$ has an extension, $g$, defined on all of $X$ satisfying

$$g (x + y) = g (x) + g (y), \ g (cx) = cg (x)$$

for all $c \in \mathbb{R}$, and

$$g (x) \leq m (x).$$

Thus, $g (-x) \leq m (-x)$ and so

$$-m (-x) \leq g (x) \leq m (x).$$

It follows as in 16.2.40 that for some $A \subseteq \Psi$, $A$ finite, and $r > 0$,

$$|g (x)| \leq m (x) + m (-x) \leq \frac{2}{r} \rho_A (x) + \frac{2}{r} \rho_A (-x) = \frac{4}{r} \rho_A (x)$$

because

$$\rho_A (-x) = -1 \rho_A (x) = \rho_A (x).$$

Hence $g$ is continuous by Theorem 16.1.3. Now define

$$f (x) \equiv g (x) - ig (ix).$$

Thus $f$ is linear and continuous so $f \in X'$ and $\text{Re } f (x) = g (x)$. But for $x \in U$, Theorem 16.1.3 implies that $x/t \in U$ for some $t < 1$ and so $m (x) < 1$. Since $U$ is convex and $0 \in U$, it follows $q/t \notin U$ if $t < 1$ because if it were,

$$q = t \left( \frac{q}{t} \right) + (1 - t) 0 \in U.$$ 

Therefore, $m (q) \geq 1$ and for $x \in U$,

$$\text{Re } f (x) = g (x) \leq m (x) < 1 \leq m (q) = g (q) = \text{Re } f (q)$$

and this proves the lemma.
Corollary 16.2.4 Let \( U \) be an open nonempty convex set and let \( q \not\in U \). Then there exists \( f \in X' \) such that
\[
f(q) > f(x)
\]
for all \( x \in U \).

**Proof:** Let \( u_0 \in U \) and consider \( \hat{U} \equiv U - u_0 \). Then \( 0 \in \hat{U} \) and \( q - u_0 \not\in \hat{U} \). By separation theorems, Lemma 16.2.3, there exists \( f \in X' \) such that
\[
f(q - u_0) > f(x - u_0)
\]
for all \( x \in U \). Thus \( f(q) > f(x) \) for all \( x \in U \). □

**Theorem 16.2.5** Let \( K \) be closed and convex in a locally convex topological vector space and let \( p \not\in K \). Then there exists a real number \( c \), and \( f \in X' \) such that
\[
\text{Re} f(p) > c > \text{Re} f(k)
\]
for all \( k \in K \).

**Proof:** Since \( K \) is closed, and \( p \not\in K \), there exists a finite subset of \( \Psi, A \), and a positive \( r > 0 \) such that
\[
K \cap B_A(p, 2r) = \emptyset.
\]
Pick \( k_0 \in K \) and let
\[
U = K + B_A(0, r) - k_0, \quad q = p - k_0.
\]
It follows that \( U \) is an open convex set containing \( 0 \) and \( q \not\in U \). Therefore, by Lemma 16.2.3, there exists \( f \in X' \) such that
\[
\text{Re} f(p - k_0) = \text{Re} f(q) > \text{Re} f(k + e - k_0)
\]
for all \( k \in K \) and \( e \in B_A(0, r) \). If \( \text{Re} f(e) = 0 \) for all \( e \in B_A(0, r) \), then \( \text{Re} f = 0 \) and 16.2.7 could not hold. Therefore, \( \text{Re} f(e) > 0 \) for some \( e \in B_A(0, r) \) and so,
\[
\text{Re} f(p) > \text{Re} f(k) + \text{Re} f(e)
\]
for all \( k \in K \). Let \( c_1 \equiv \sup \{ \text{Re} f(k) : k \in K \} \). Then for all \( k \in K \),
\[
\text{Re} f(p) \geq c_1 + \text{Re} f(e) > c_1 + \frac{\text{Re} f(e)}{2} > \text{Re} f(k).
\]
Let \( c = c_1 + \frac{\text{Re} f(e)}{2} \). □

\[\begin{tikzpicture}
    \node (K) at (0,0) [draw, circle] {K};
    \node (p) at (1,0) {p};
    \node (x) at (-1,0) \{x : \text{Re} f(x) = c\};
    \draw [-stealth] (K) -- (x);
    \end{tikzpicture}\]
Corollary 16.2.6 In the situation of the above theorem, there exist real numbers $c, d$ such that $\Re f(p) > d > c > \Re f(k)$ for all $k \in K$.

Proof: From the theorem, there exists $\hat{c}$ such that $\Re f(p) > \hat{c} > \Re f(k)$ for all $k \in K$. Thus $\Re f(p) > \hat{c} \geq \sup_{k \in K} \Re f(k)$. Now choose $d, c$ such that $f(p) > d > c > \hat{c} \geq \sup_{k \in K} \Re f(k)$. Note that if the field of scalars comes from $\mathbb{R}$ rather than $\mathbb{C}$ there is no essential change to the above conclusions. Just eliminate all references to the real part.

16.2.1 Convex Functionals

As an important application, this theorem gives the basis for proving something about lower semicontinuity of functionals.

Definition 16.2.7 Let $X$ be a Banach space and let $\phi : X \to (0, \infty]$ be convex and lower semicontinuous. This means whenever $x \in X$ and $\lim_{n \to \infty} x_n = x$,

$$
\phi(x) \leq \liminf_{n \to \infty} \phi(x_n).
$$

Also assume $\phi$ is not identically equal to $\infty$.

Lemma 16.2.8 Let $X, Y$ be two Banach spaces. Then letting

$$
\|(x, y)\| \equiv \max(||x||_X, ||y||_Y),
$$

it follows $X \times Y$ is a Banach space and $\phi \in (X \times Y)'$ if and only if there exist $x^* \in X'$ and $y^* \in Y'$ such that

$$
\phi((x, y)) = x^*(x) + y^*(y).
$$

The topology coming from this norm is called the strong topology.

Proof: Most of these conclusions are obvious. In particular it is clear $X \times Y$ is a Banach space with the given norm. Let $\phi \in (X \times Y)'$. Also let $\pi_X(x, y) \equiv (x, 0)$ and $\pi_Y(x, y) \equiv (0, y)$. Then each of $\pi_X$ and $\pi_Y$ is continuous and

$$
\phi((x, y)) = \phi(\pi_X + \pi_Y)((x, y)) \\
= \phi((x, 0)) + \phi((0, y)).
$$

Thus $\phi \circ \pi_X$ and $\phi \circ \pi_Y$ are both continuous and their sum equals $\phi$. Let $x^* (x) \equiv \phi \circ \pi_X (x, 0)$ and let $y^* \equiv \phi \circ \pi_Y (x, 0)$. Then it is clear both $x^*$ and $y^*$ are continuous and linear defined on $X$ and $Y$ respectively. Also, if $(x^*, y^*) \in X' \times Y'$, then if $\phi((x, y)) \equiv x^*(x) + y^*(y)$, it follows $\phi \in (X \times Y)'$. This proves the lemma.

Lemma 16.2.9 Let $\phi$ be a functional as described in Definition 16.2.7. Then $\phi$ is lower semicontinuous if and only if the epigraph of $\phi$ is closed in $X \times \mathbb{R}$ with the strong topology. Here the epigraph is defined as

$$
\text{epi}(\phi) \equiv \{(x, y) : y \geq \phi(x)\}.
$$

In this case the functional is called strongly lower semicontinuous.
Proof: First suppose epi \((\phi)\) is closed and suppose \(x_n \to x\). Let \(l < \phi(x)\). Then \((x, l) \notin \text{epi}(\phi)\) and so there exists \(\delta > 0\) such that if \(|x - y| < \delta\) and \(|\alpha - l| < \delta\), then \(\alpha < \phi(y)\). This implies that if \(|x - y| < \delta\) and \(\alpha < l + \delta\), then the above holds. Therefore, \((x_n, \phi(x_n))\), being in \(\text{epi}(\phi)\) cannot satisfy both conditions,

\[
|x_n - x| < \delta, \phi(x_n) < l + \delta.
\]

However, for all \(n\) large enough, the first condition is satisfied. Consequently, for all \(n\) large enough, \(\phi(x_n) \geq l + \delta \geq l\). Thus

\[
\liminf_{n \to \infty} \phi(x_n) \geq l
\]

and since \(l < \phi(x)\) is arbitrary, it follows

\[
\liminf_{n \to \infty} \phi(x_n) \geq \phi(x).
\]

Next suppose the condition about the \(\liminf\). If \(\text{epi}(\phi)\) is not closed, then there exists \((x, l) \notin \text{epi}(\phi)\) which is a limit point of points of \(\text{epi}(\phi)\). Thus there exists \((x_n, l_n) \in \text{epi}(\phi)\) such that \((x_n, l_n) \to (x, l)\) and so

\[
l = \liminf_{n \to \infty} l_n \geq \liminf_{n \to \infty} \phi(x_n) \geq \phi(x),
\]

contradicting \((x, l) \notin \text{epi}(\phi)\). This proves the lemma.

Definition 16.2.10 Let \(\phi\) be convex and defined on \(X\), a Banach space. Then \(\phi\) is said to be weakly lower semicontinuous if \(\text{epi}(\phi)\) is closed in \(X \times \mathbb{R}\) where a basis for the topology of \(X \times \mathbb{R}\) consists of sets of the form \(U \times (a, b)\) for \(U\) a weakly open set in \(X\).

Theorem 16.2.11 Let \(\phi\) be a lower semicontinuous convex functional as described in Definition 16.2.7 and let \(X\) be a real Banach space. Then \(\phi\) is also weakly lower semicontinuous.

Proof: By Lemma 16.2.9 \(\text{epi}(\phi)\) is closed in \(X \times \mathbb{R}\) with the strong topology as well as being convex. Letting \((z, l) \notin \text{epi}(\phi)\), it follows from Theorem 16.2.8 and Lemma 16.2.8 there exists \((x^*, \alpha) \in X' \times \mathbb{R}\) such that for some \(c\)

\[
x^*(z) + \alpha l > c > x^*(x) + \alpha \beta
\]

whenever \(\beta \geq \phi(x)\). Consider \(B_{\{(x^*, \alpha)\}}((z, l), r)\) where \(r\) is chosen so small that if \((y, \gamma) \in B_{\{(x^*, \alpha)\}}((z, l), r)\), then

\[
x^*(y) + \alpha \gamma > c.
\]

This shows that the complement of \(\text{epi}(\phi)\) is weakly open and this proves the theorem.
16.2. SEPARATION THEOREMS

Corollary 16.2.12 Let \( \phi \) be a lower semicontinuous convex functional as described in Definition 16.2.7 and let \( X \) be a real Banach space. Then if \( x_n \) converges weakly to \( x \), it follows that

\[
\phi(x) \leq \liminf_{n \to \infty} \phi(x_n).
\]

Proof: Let \( l < \phi(x) \) so that \( (x,l) \notin \text{epi}(\phi) \). Then by Theorem 16.2.11 there exists \( B \times (-\infty,l+\delta) \) such that \( B \) is a weakly open set in \( X \) containing \( x \) and

\[
B \times (-\infty,l+\delta) \subseteq \text{epi}(\phi)'.
\]

Thus \( (x_n, \phi(x_n)) \notin B \times (-\infty,l+\delta) \) for all \( n \). However, \( x_n \in B \) for all \( n \) large enough. Therefore, for those values of \( n \), it must be the case that \( \phi(x_n) \notin (-\infty,l+\delta) \) and so

\[
\liminf_{n \to \infty} \phi(x_n) \geq l + \delta \geq l
\]

which shows, since \( l < \phi(x) \) is arbitrary that

\[
\liminf_{n \to \infty} \phi(x_n) \geq \phi(x).
\]

This proves the corollary.

The following is a convenient fact which follows from the above.

Proposition 16.2.13 Let \( A \) be a linear operator which maps a real normed linear space \((X, \|\cdot\|_X)\) to a real normed linear space \((Y, \|\cdot\|_Y)\). Then \( x_n \to x \) strongly implies \( Ax_n \to Ax \) if and only if whenever \( x_n \to x \) weakly, it follows that \( Ax_n \to Ax \) weakly.

Proof: \( \Rightarrow \) Define \( \phi(x) \equiv f(Ax) \) where \( f \in Y' \). Then \( \phi \) is convex and continuous. Therefore, if \( x_n \to x \) weakly, then

\[
\phi(x) = f(Ax) \leq \liminf_{n \to \infty} f(Ax_n) = \liminf_{n \to \infty} \phi(x_n)
\]

Then substituting \(-A\) for \( A \),

\[
-f(Ax) \leq \liminf_{n \to \infty} f(-Ax_n), \quad f(Ax) \geq \limsup_{n \to \infty} f(Ax_n)
\]

which shows that for each \( f \in Y' \),

\[
\limsup_{n \to \infty} f(Ax_n) \leq f(Ax) \leq \liminf_{n \to \infty} f(Ax_n)
\]

and so the second condition holds.

\( \Leftarrow \) By the second condition, \( x \to f(Ax) \) satisfies the condition that if \( x_n \to x \) weakly, then

\[
f(Ax) = \lim_{n \to \infty} f(Ax_n)
\]

If \( A \) is not bounded, then there exists \( x_n, \|x_n\| \leq 1 \) but \( \|Ax_n\| \geq n \). It follows that \( x_n/\sqrt{n} \to 0 \) and so \( A \left( \frac{x_n}{\sqrt{n}} \right) \to 0 \) weakly. Therefore, \( A \left( \frac{x_n}{\sqrt{n}} \right) \) is bounded contrary to the construction which says that \( \left\| A \left( \frac{x_n}{\sqrt{n}} \right) \right\| \geq \sqrt{n} \). Since \( A \) is bounded, it must be continuous. \( \blacksquare \)
16.2.2 More Separation Theorems

There are other separation theorems which can be proved in a similar way. The next theorem considers the separation of an open convex set from a convex set.

**Theorem 16.2.14** Let $A$ and $B$ be disjoint, convex and nonempty sets with $B$ open. Then there exists $f \in X'$ such that
\[
\Re f(a) < \Re f(b)
\]
for all $a \in A$ and $b \in B$.

**Proof:** Let $b_0 \in B, a_0 \in A$. Then the set
\[
B - A + a_0 - b_0
\]
is open, convex, contains 0, and does not contain $a_0 - b_0$. By Lemma 16.2.3 there exists $f \in X'$ such that
\[
\Re f(a_0 - b_0) > \Re f(b - a + a_0 - b_0)
\]
for all $a \in A$ and $b \in B$. Therefore, for all $a \in A, b \in B$,
\[
\Re f(b) > \Re f(a).
\]

Before giving another separation theorem, here is a lemma.

**Lemma 16.2.15** If $B$ is convex, then $\text{int}(B) \equiv \text{union of all open sets contained in } B \text{ is convex. Also, if } \text{int}(B) \neq \emptyset \text{, then } B \subseteq \text{int}(B)$.

**Proof:** Suppose $x, y \in \text{int}(B)$. Then there exists $r > 0$ and a finite set $A \subseteq \Psi$ such that
\[
B_A(x, r), B_A(y, r) \subseteq B.
\]
Let
\[
V \equiv \cup_{\lambda \in [0, 1]} \lambda B_A(x, r) + (1 - \lambda) B_A(y, r).
\]
Then $V$ is open, $V \subseteq B$, and if $\lambda \in [0, 1]$, then
\[
\lambda x + (1 - \lambda) y \in V \subseteq B.
\]
Therefore, $\text{int}(B)$ is convex as claimed.

Now let $y \in B$ and $x \in \text{int}(B)$. Let
\[
x \in B_A(x, r) \subseteq \text{int}(B)
\]
and let $x_\lambda \equiv (1 - \lambda)x + \lambda y$. Define the open cone,
\[
C \equiv \cup_{\lambda \in [0, 1]} B_A(x_\lambda, (1 - \lambda)r).
\]
Thus $C$ is represented in the following picture.
I claim $C \subseteq B$ as suggested in the picture. To see this, let

$$z \in B_A(x, (1 - \lambda)r), \lambda \in (0, 1).$$

Then

$$\rho_A(z - x_\lambda) < (1 - \lambda)r$$

and so

$$\rho_A\left(\frac{z}{1 - \lambda} - x - \frac{\lambda y}{1 - \lambda}\right) < r.$$ 

Therefore,

$$\frac{z}{1 - \lambda} - \frac{\lambda y}{1 - \lambda} \in B_A(x, r) \subseteq B.$$ 

It follows

$$(1 - \lambda)\left(\frac{z}{1 - \lambda} - \frac{\lambda y}{1 - \lambda}\right) + \lambda y = z \in B$$

and so $C \subseteq B$ as claimed. Now this shows $x_\lambda \in \operatorname{int}(B)$ and $\lim_{\lambda \to 1} x_\lambda = y$. Thus, $y \in \overline{\operatorname{int}(B)}$ and this proves the lemma.

Note this also shows that $\overline{B} = \overline{\operatorname{int}(B)}$.

**Corollary 16.2.16** Let $A, B$ be convex, nonempty sets. Suppose $\operatorname{int}(B) \neq \emptyset$ and $A \cap \operatorname{int}(B) = \emptyset$. Then there exists $f \in X'$, $f \neq 0$, such that for all $a \in A$ and $b \in B$,

$$\Re f(b) \geq \Re f(a).$$

**Proof:** By Theorem 16.2.14, there exists $f \in X'$ such that for all $b \in \operatorname{int}(B)$, and $a \in A$,

$$\Re f(b) > \Re f(a).$$

Thus, in particular, $f \neq 0$. By Lemma 16.2.15, if $b \in B$ and $a \in A$,

$$\Re f(b) \geq \Re f(a).$$

This proves the theorem.

**Lemma 16.2.17** If $X$ is a topological Hausdorff space then compact implies closed.
Proof: Let $K$ be compact and suppose $K^C$ is not open. Then there exists $p \in K^C$ such that $V_p \cap K \neq \emptyset$ for all open sets $V_p$ containing $p$. Let $C = \{(V_p)^C : V_p$ is an open set containing $p\}$. Then $C$ is an open cover of $K$ because if $q \in K$, there exist disjoint open sets $V_p$ and $V_q$ containing $p$ and $q$ respectively. Thus $q \in (V_p)^C$. This is an example of an open cover of $K$ which has no finite subcover, contradicting the assumption that $K$ is compact. This proves the lemma.

Lemma 16.2.18 If $X$ is a locally convex topological vector space, and if every point is a closed set, then the seminorms and $X'$ separate the points. This means if $x \neq y$, then for some $\rho \in \Psi$, $\rho (x - y) \neq 0$ and for some $f \in X'$, $f (x) \neq f (y)$. In this case, $X$ is a Hausdorff space.

Proof: Let $x \neq y$. Then by Theorem 16.2.5 there exists $f \in X'$ such that $f (x) \neq f (y)$. Thus $X'$ separates the points. Since $f \in X'$, Theorem 16.1.6 implies $|f (z)| \leq C \rho_A (z)$ for some $A$ a finite subset of $\Psi$. Thus $0 < |f (x - y)| \leq C \rho_A (x - y)$ and so $\rho (x - y) \neq 0$ for some $\rho \in A \subseteq \Psi$. Now to show $X$ is Hausdorff, let $0 < r < \rho (x - y) 2^{-1}$. Then the two disjoint open sets containing $x$ and $y$ respectively are $B_\rho (x, r)$ and $B_\rho (y, r)$.

This proves the lemma.

16.3 The Weak And Weak* Topologies

The weak and weak * topologies are examples which make the underlying vector space into a topological vector space. This section gives a description of these topologies. Unless otherwise specified, $X$ is a locally convex topological vector space. For $G$ a finite subset of $X'$ define $\delta_G : X \to [0, \infty)$ by $\delta_G (x) = \max\{|f (x)| : f \in G\}$. 
16.3. THE WEAK AND WEAK* TOPOLOGIES

Lemma 16.3.1 The functions $\delta_G$ for $G$ a finite subset of $X'$ are seminorms and the sets

$$B_G(x,r) \equiv \{y \in X : \delta_G(x - y) < r\}$$

form a basis for a topology on $X$. Furthermore, $X$ with this topology is a locally convex topological vector space. If each point in $X$ is a closed set, then the same is true of $X$ with respect to this new topology.

Proof: It is obvious that the functions $\delta_G$ are seminorms and therefore the proof that the sets $B_G(x,r)$ form a basis for a topology is the same as in Theorem 16.1.2. To see every point is a closed set in this new topology, assuming this is true for $X$ with the original topology, use Lemma 16.2.18 to assert $X'$ separates the points.

Let $x \in X$ and let $y \neq x$. There exists $f \in X'$ such that $f(x) \neq f(y)$. Let $G = \{f\}$ and consider

$$B_G(y,|f(x-y)|/2).$$

Then this open set does not contain $x$. Thus $\{x\}^C$ is open and so $\{x\}$ is closed. This proves the Lemma.

This topology for $X$ is called the weak topology for $X$. For $F$ a finite subset of $X$, define $\gamma_F : X' \to [0, \infty)$ by

$$\gamma_F(f) = \max\{|f(x)| : x \in F\}.$$ 

Lemma 16.3.2 The functions $\gamma_F$ for $F$ a finite subset of $X$ are seminorms and the sets

$$B_F(f,r) \equiv \{g \in X' : \gamma_F(f - g) < r\}$$

form a basis for a topology on $X'$. Furthermore, $X'$ with this topology is a locally convex topological vector space having the property that every point is a closed set.

Proof: The proof is similar to that of Lemma 16.3.1 but there is a difference in the part where every point is shown to be a closed set. Let $f \in X'$ and let $g \neq f$. Thus there exists $x \in X$ such that $f(x) \neq g(x)$. Let $F = \{x\}$. Then

$$B_F(g,|f - g|(x)/2)$$

contains $g$ but not $f$. Thus $\{f\}^C$ is open and so $\{f\}$ is closed.

Note that it was not necessary to assume points in $X$ are closed sets to get this.

The topology for $X'$ just described is called the weak * topology. In terms of Theorem 16.1.3 the weak topology is obtained by letting $Y = X'$ in that theorem while the weak * topology is obtained by letting $Y = X$ with the understanding that $X$ is a vector space of linear functionals on $X'$ defined by

$$x(x^*) \equiv x^*(x).$$

By Theorem 16.2.18, there is a useful result which follows immediately.
CHAPTER 16. LOCALLY CONVEX TOPOLOGICAL VECTOR SPACES

Theorem 16.3.3 Let $K$ be closed and convex in a Banach space $X$. Then it is also weakly closed. Furthermore, if $p \notin K$, there exists $f \in X'$ such that

$$\text{Re } f(p) > c > \text{Re } f(k)$$

(16.3.8)

for all $k \in K$. If $K^*$ is closed and convex in the dual of a Banach space, $X'$, then it is also weak * closed.

**Proof:** By Theorem 16.2.5 there exists $f \in X'$ such that (16.3.8) holds. Therefore, letting $A = \{f\}$, it follows that for $r$ small enough, $B_A(p, r) \cap K = \emptyset$. Thus $K$ is weakly closed. This establishes the first part.

For the second part, the seminorms for the weak * topology are determined from $X$ and the continuous linear functionals are of the form $x^* \to x^*(x)$ where $x \in X$. Thus if $p^* \notin K^*$, it follows from Theorem 16.2.5 there exists $x \in X$ such that

$$\text{Re } p^*(x) > c > \text{Re } k^*(x)$$

for all $k^* \in K^*$. Therefore, letting $A = \{x\}, B_A(p^*, r) \cap K^* = \emptyset$ whenever $r$ is small enough and this shows $K^*$ is weak * closed. ■

16.4 Mean Ergodic Theorem

The following theorem is called the mean ergodic theorem.

**Theorem 16.4.1** Let $(\Omega, \mathcal{S}, \mu)$ be a finite measure space and let $T : \Omega \to \Omega$ satisfy $T^{-1}(E) \in \mathcal{S}, T(E) \in \mathcal{S}$ for all $E \in \mathcal{S}$. Also suppose for all positive integers, $n$, that

$$\mu(T^{-n}(E)) \leq K \mu(E).$$

For $f \in L^p(\Omega)$, and $p > 1$, let

$$T^* f \equiv f \circ T.$$  \hspace{1cm} (16.4.9)

Then $T^* \in \mathcal{L}(L^p(\Omega), L^p(\Omega))$, the continuous linear mappings form $L^p(\Omega)$ to itself with

$$\|T^*n\| \leq K^{1/p}.$$ \hspace{1cm} (16.4.10)

Defining $A_n \in \mathcal{L}(L^p(\Omega), L^p(\Omega))$ by

$$A_n \equiv \frac{1}{n} \sum_{k=0}^{n-1} T^* k,$$

there exists $A \in \mathcal{L}(L^p(\Omega), L^p(\Omega))$ such that for all $f \in L^p(\Omega)$,

$$A_n f \to Af \text{ weakly}$$ \hspace{1cm} (16.4.11)

and $A$ is a projection, $A^2 = A$, onto the space of all $f \in L^p(\Omega)$ such that $T^* f = f$. (The invariant functions.) The norm of $A$ satisfies

$$\|A\| \leq K^{1/p}.$$ \hspace{1cm} (16.4.12)
16.4. MEAN ERGODIC THEOREM

Proof: To begin with, it follows from simple considerations that
\[ \int |\mathcal{X}_A (T^n (\omega))|^p \, d\mu = \int |\mathcal{X}_{T^{-n} (A)} (\omega)|^p \, d\mu = \mu (T^{-n} (A)) \leq K \mu (A) \]
Hence
\[ \| T^n (\mathcal{X}_A) \| \leq K^{1/p} \mu (A)^{1/p} = K^{1/p} \| \mathcal{X}_A \|_{L^p} \]
Next suppose you have a simple function \( s (\omega) = \sum_{k=1}^{n} \mathcal{X}_{A_i} (\omega) c_i \) where we assume the \( A_i \) are disjoint. From the above,
\[ \int |\sum_{k=1}^{n} \mathcal{X}_{A_i} (T^n (\omega)) c_i|^p \, d\mu = \int |\sum_{k=1}^{n} \mathcal{X}_{A_i} (T^n (\omega))|^p c_i^p \, d\mu \leq \sum_{k=1}^{n} K \mu (A_i) |c_i|^p = K \int |s|^p \, d\mu \]
and so
\[ \| T^n s \| \leq K^{1/p} \| s \| \]
and so the density of the simple functions implies that \( \| T^n s \| \leq K^{1/p} \).

Next let \( M \equiv \{ g \in L^p (\Omega) : \| A_n g \|_p \to 0 \} \)
It follows from 16.4.10 that \( M \) is a closed subspace of \( L^p (\Omega) \) containing \( (I - T^*) (L^p (\Omega)) \).
This is shown next.

Claim 1: \( M \) is a closed subspace which contains \( (I - T^m) (L^p (\Omega)) \).

First it is shown that this is true if \( m = 1 \) and then it will be observed that the same argument would work for any positive integer \( m \).
\[ A_n (f - T^* f) = \frac{1}{n} \sum_{k=0}^{n-1} T^k f - T^{k+1} f = \frac{1}{n} \sum_{k=0}^{n-1} T^k f - \frac{1}{n} \sum_{k=1}^{n} T^k f = \frac{1}{n} (f - T^n f) \]
Hence
\[ \| A_n (f - T^* f) \|_p \leq \frac{1}{n} \left( \| f \|_p + \| T^n f \|_p \right) \leq \frac{1}{n} \left( \| f \|_p + K^{1/p} \| f \|_p \right) \]
and this clearly converges to 0. In fact, the same argument shows that \( M \) contains \( (I - T^m) (L^p (\Omega)) \) for any \( m \). Now suppose \( g_n \in M \) and \( g_n \to g \). Does it follow that \( g \in M \) also? Note that \( T^* m \) is clearly linear. Thus
\[ \| T^m g \| \leq \| T^m g - T^m g_n \| + \| T^m g_n \| \leq K^{1/p} \| g - g_n \| + \| T^m g_n \| \]
Now pick \( n \) large enough that \( \| g_n - g \| < \varepsilon / (2K^{1/p}) \) so that
\[ \| T^m g \| \leq \frac{\varepsilon}{2} + \| T^m g_n \| \]
CHAPTER 16. LOCALLY CONVEX TOPOLOGICAL VECTOR SPACES

Then for all \( m \) large enough, the right side of the above is less than \( \varepsilon \) and this shows that \( g \in M \). Note that \( M \) is also a subspace and so it is a closed subspace.

**Claim 2:** If \( A_{nk} f \to g \) weakly and \( A_{mk} f \to h \) weakly, then \( g = h \).

It is first shown that if \( \xi \in L^p' (\Omega) \) and \( \int \xi g d\mu = 0 \) for all \( g \in M \), then \( \int \xi (g - h) d\mu = 0 \).

If \( \xi \in L^p' (\Omega) \) is such that \( \int \xi g d\mu = 0 \) for all \( g \in M \), then since \( M \supseteq (1 - T^*n)(L^p (\Omega)) \), it follows that for all \( k \in L^p (\Omega) \),

\[
\int \xi k d\mu = \int (\xi T^*n k + \xi (1 - T^*n) k) d\mu = \int \xi T^*n k d\mu
\]

and so from the definition of \( A_n \) as an average, for such \( \xi \),

\[
\int \xi k d\mu = \int \xi A_n k d\mu. \tag{16.4.13}
\]

Since \( A_{nk} f \to g \) weakly and \( A_{mk} f \to h \) weakly. Then (16.4.13) shows that

\[
\int \xi g d\mu = \lim_{k \to \infty} \int \xi A_{nk} f d\mu = \int \xi f d\mu = \lim_{k \to \infty} \int \xi A_{mk} f d\mu = \int \xi h d\mu. \tag{16.4.14}
\]

Thus for these special \( \xi \), it follows that

\[
\int \xi (g - h) d\mu = 0. \tag{16.4.15}
\]

Next observe that for each fixed \( n \), if \( n_k \to \infty \),

\[
\lim_{k \to \infty} \|T^*n A_{nk} f - A_{nk} f\| = 0 \tag{16.4.16}
\]

this follows like the arguments given above in Claim 1. Note that if \( L \in \mathcal{L} (X, X) \) and \( x_n \to x \) weakly in \( X \), then for \( \phi \in X' \)

\[
\langle \phi, L x_n \rangle = \langle L^* \phi, x_n \rangle \to \langle L^* \phi, x \rangle = \langle \phi, L x \rangle
\]

and so \( L x_n \to L x \) weakly. Therefore, this simple observation along with the above strong convergence (16.4.16) implies

\[
T^*n g = \text{weak } \lim_{k \to \infty} T^*n A_{nk} f = \text{weak } \lim_{k \to \infty} A_{nk} f = g.
\]

Similarly \( T^*n h = h \) where \( A_{mk} f \to h \) weakly. It follows that \( A_n (g - h) = g - h \) so if \( g \neq h \), then \( g - h \notin M \) because

\[
A_n (g - h) \to g - h \neq 0.
\]

It follows that since \( M \) is a closed subspace, there exists \( \xi \in L^p' (\Omega) \) such that \( \int \xi (g - h) d\mu \neq 0 \) but \( \int \xi k d\mu = 0 \) for all \( k \in M \), contradicting (16.4.16). This verifies Claim 2.
16.5. THE TYCHONOFF AND SCHAUDER FIXED POINT THEOREMS

Now

\[ \|A_n f\|_p = \left( \int \frac{1}{n} \sum_{k=0}^{n-1} f(T^k \omega) \|_{L^p} d\mu \right)^{1/p} \leq \frac{1}{n} \sum_{k=0}^{n-1} \left( \int |f(T^k \omega)|^p d\mu \right)^{1/p} \]

\[ = \frac{1}{n} \sum_{k=0}^{n-1} \|T^k f\|_p \leq \frac{1}{n} \sum_{k=0}^{n-1} K^{1/p} \|f\|_p = K^{1/p} \|f\|_p \]

(16.4.17)

Hence, by the Eberlein Smulian theorem, Theorem 15.5.12, in case \( p > 1 \), there is a subsequence for which \( A_n f \) converges weakly in \( L^p(\Omega) \). From the above, it follows that the original sequence must converge. That is, \( A_n f \) converges weakly for each \( f \in L^p(\Omega) \). Let \( Af \) denote this weak limit. Then it is clear that \( A \) is linear because this is true for each \( A_n \). What of the claim about the estimate? From weak lower semicontinuity of the norm, Corollary 16.2.12,

\[ \|Af\|_p \leq \liminf_{n \to \infty} \|A_n f\| \leq K^{1/p} \|f\|_p \]

16.5 The Tychonoff And Schauder Fixed Point Theorems

First we give a proof of the Schauder fixed point theorem which is an infinite dimensional generalization of the Brouwer fixed point theorem. This is a theorem which lives in Banach space. After this, we give a generalization to locally convex topological vector spaces where the theorem is sometimes called Tychonoff’s theorem. First here is an interesting example.

Exercise 16.5.1 Let \( B \) be the closed unit ball in a separable Hilbert space \( H \) which is infinite dimensional. Then there exists continuous \( f : B \to B \) which has no fixed point.

Let \( \{e_k\}_{k=1}^{\infty} \) be a complete orthonormal set in \( H \). Let \( L \in L(H, H) \) be defined as follows. \( Le_k = e_{k+1} \) and then extend linearly. Then in particular,

\[ L \left( \sum_i x_i e_i \right) = \sum_i x_i e_{i+1} \]

Then it is clear that \( L \) preserves norms and so it is linear and continuous. Note how this would not work at all if the Hilbert space were finite dimensional. Then define \( f(x) = \frac{1}{2} (1 - \|x\|_H) e_1 + Lx \). Then if \( \|x\| \leq 1 \),

\[ \|f(x)\| = \frac{1}{2} (1 - \|x\|)^2 + \|Lx\|^2 = \frac{1}{2} (1 - \|x\|^2)^2 + \|x\|^2 = \frac{1}{2} \|x\|^2 + \frac{1}{2} \leq 1 \]

and so \( f : B \to B \) yet has no fixed point because if it did, you would need to have

\[ x = \frac{1}{2} (1 - \|x\|_H) e_1 + Lx \]
and so
\[\|x\|^2 = \frac{1}{4}(1 - \|x\|)^2 + \|Lx\|^2 = \frac{1}{4}(1 - \|x\|)^2 + \|Lx\|^2 = \frac{1}{4} + \frac{5}{4}\|x\|^2 - \frac{1}{2}\|x\|\]
\[\|x\|^2 = \frac{1}{4} + \frac{1}{4}\|x\|^2\]

this requires \(\|x\| = 1\). But then you would need to have \(x = Lx\) which is not so because if \(x\) is in the closure of the span of \(\{e_i\}_{i=m}^{\infty}\), such that the first nonzero Fourier coefficient is the \(m^{th}\), then \(Lx\) is in the closure of the span of \(\{e_i\}_{i=m+1}^{\infty}\).

This shows you need something other than continuity if you want to get a fixed point. This also shows that there is a retraction of \(B\) onto \(\partial B\) in any infinite dimensional separable Hilbert space. You get it the usual way. Take the line from \(x\) to \(f(x)\) and the retraction will be the function which gives the point on \(\partial B\) which is obtained by extending this line till it hits the boundary of \(B\). Thus for Hilbert spaces, those which have \(\partial B\) a retraction of \(B\) are exactly those which are infinite dimensional. The above reference claims this retraction property holds for any infinite dimensional normed linear space. I think it is fairly clear to see from the above example that this is not a surprising assertion. Recall that one of the proofs of the Brouwer fixed point theorem used the non existence of such a retraction, obtained using integration theory, to prove the theorem.

We let \(K\) be a closed convex subset of \(X\) a Banach space and let 
\[f\) be continuous, \(f: K \rightarrow K\), and \(\overline{f(K)}\) is compact.

**Lemma 16.5.2** For each \(r > 0\) there exists a finite set of points 
\[\{y_1, \cdots, y_n\} \subseteq \overline{f(K)}\]
and continuous functions \(\psi_i\) defined on \(\overline{f(K)}\) such that for \(x \in \overline{f(K)}\),
\[\sum_{i=1}^{n} \psi_i(x) = 1, \quad (16.5.18)\]
\[\psi_i(x) = 0 \text{ if } x \notin B(y_i, r), \quad \psi_i(x) > 0 \text{ if } x \in B(y_i, r).\]

If
\[f_r(x) = \sum_{i=1}^{n} y_i \psi_i(f(x)), \quad (16.5.19)\]
then whenever \(x \in K\),
\[\|f(x) - f_r(x)\| \leq r.\]

**Proof:** Using the compactness of \(\overline{f(K)}\), there exists 
\[\{y_1, \cdots, y_n\} \subseteq \overline{f(K)} \subseteq K\]
such that

\[ \{B(y_i, r)\}_{i=1}^n \]

covers \(\overline{f(K)}\). Let

\[ \phi_i(y) \equiv (r - \|y - y_i\|)^+ \]

Thus \(\phi_i(y) > 0\) if \(y \in B(y_i, r)\) and \(\phi_i(y) = 0\) if \(y \notin B(y_i, r)\). For \(x \in \overline{f(K)}\), let

\[ \psi_i(x) \equiv \phi_i(x) \left( \sum_{j=1}^n \phi_j(x) \right)^{-1}. \]

Then \([16.5.18]\) is satisfied. Indeed the denominator is not zero because \(x\) is in one of the \(B(y_i, r)\). Thus it is obvious that the sum of these equals 1 on \(K\). Now let \(f_r\) be given by \([16.5.18]\) for \(x \in K\). For such \(x\),

\[ f(x) - f_r(x) = \sum_{i=1}^n (f(x) - y_i) \psi_i(f(x)) \]

Thus

\[ f(x) - f_r(x) = \sum_{\{i : f(x) \in B(y_i, r)\}} (f(x) - y_i) \psi_i(f(x)) \]

\[ + \sum_{\{i : f(x) \notin B(y_i, r)\}} (f(x) - y_i) \psi_i(f(x)) \]

\[ = \sum_{\{i : f(x) - y_i \in B(0, r)\}} (f(x) - y_i) \psi_i(f(x)) + \sum_{\{i : f(x) \notin B(y_i, r)\}} 0 \psi_i(f(x)) \in B(0, r) \]

because \(0 \in B(0, r)\), \(B(0, r)\) is convex, and \([16.5.18]\). It is just a convex combination of things in \(B(0, r)\).

Note that we could have had the \(y_i\) in \(f(K)\) in addition to being in \(\overline{f(K)}\). This would make it possible to eliminate the assumption that \(K\) is closed later on. All you really need is that \(K\) is convex.

We think of \(f_r\) as an approximation to \(f\). In fact it is uniformly within \(r\) of \(f\) on \(K\). The next lemma shows that this \(f_r\) has a fixed point. This is the main result and comes from the Brouwer fixed point theorem in \(\mathbb{R}^n\). It is an approximate fixed point.

**Lemma 16.5.3** For each \(r > 0\), there exists \(x_r \in \text{convex hull of } \overline{f(K)} \subseteq K\) such that

\[ f_r(x_r) = x_r, \quad \|f_r(x) - f(x)\| < r \text{ for all } x \]
Proof: If \( f_r(x_r) = x_r \) and 
\[
x_r = \sum_{i=1}^{n} a_i y_i
\]
for \( \sum_{i=1}^{n} a_i = 1 \) and the \( y_i \) described in the above lemma, we need 
\[
f_r(x_r) = \sum_{i=1}^{n} y_i \psi_i(f(x_r)) = \sum_{j=1}^{n} y_j \psi_j \left( f \left( \sum_{i=1}^{n} a_i y_i \right) \right) = \sum_{j=1}^{n} a_j y_j = x_r.
\]
Also, if this is satisfied, then we have the desired fixed point. This will be satisfied if for each \( j = 1, \cdots, n, \)
\[
a_j = \psi_j \left( f \left( \sum_{i=1}^{n} a_i y_i \right) \right);
\]
so, let
\[
\Sigma_{n-1} = \left\{ a \in \mathbb{R}^n : \sum_{i=1}^{n} a_i = 1, \ a_i \geq 0 \right\}
\]
and let \( h : \Sigma_{n-1} \to \Sigma_{n-1} \) be given by
\[
h(a)_j = \psi_j \left( f \left( \sum_{i=1}^{n} a_i y_i \right) \right).
\]
Since \( h \) is a continuous function of \( a \), the Brouwer fixed point theorem applies and there exists a fixed point for \( h \) which is a solution to \( 16.5.20 \).

The following is the Schauder fixed point theorem.

**Theorem 16.5.4** Let \( K \) be a closed and convex subset of \( X \), a normed linear space. Let \( f : K \to K \) be continuous and suppose \( \overline{f(K)} \) is compact. Then \( f \) has a fixed point.

**Proof:** Recall that \( f(x_r) - f_r(x_r) \in B(0, r) \) and \( f_r(x_r) = x_r \) with \( x_r \in \text{convex hull of } \overline{f(K)} \subseteq K \).

There is a subsequence, still denoted with subscript \( r \) such that \( f(x_r) \to x \in \overline{f(K)} \). Note that the fact that \( K \) is convex is what makes \( f \) defined at \( x_r, x_r \) is in the convex hull of \( \overline{f(K)} \subseteq K \). This is where we use \( K \) convex. Then since \( f_r \) is uniformly close to \( f \), it follows that \( f_r(x_r) = x_r \to x \) also. Thus \( x_r \) converges strongly to \( x \). Therefore,
\[
f(x) = \lim_{r \to 0} f(x_r) = \lim_{r \to 0} f_r(x_r) = \lim_{r \to 0} x_r = x.
\]

We usually have in mind the mapping defined on a Banach space. However, the completeness was never used. Thus the result holds in a normed linear space.

There is a nice corollary of this major theorem which is called the Schaefer fixed point theorem or the Leray Schauder alternative principle. \[\square\]
Theorem 16.5.5 Let $f : X \to X$ be a compact map. Then either

1. There is a fixed point for $tf$ for all $t \in [0, 1]$ or

2. For every $r > 0$, there exists a solution to $x = tf(x)$ for $t \in (0, 1)$ such that $\|x\| > r$.

Proof: Suppose there is $t_0 \in [0, 1]$ such that $t_0f$ has no fixed point. Then $t_0 \neq 0, t_0f$ obviously has a fixed point if $t_0 = 0$. Thus $t_0 \in (0, 1]$. Then let $r_M$ be the radial retraction onto $B(0, M)$. By Schauder’s theorem there exists $x \in B(0, M)$ such that $t_0r_Mf(x) = x$. Then if $\|f(x)\| \leq M$, $r_M$ has no effect and so $t_0f(x) = x$ which is assumed not to take place. Hence $\|f(x)\| > M$ and so $\|r_Mf(x)\| = M$ so $\|x\| = t_0M$. Also $t_0r_Mf(x) = t_0M \frac{f(x)}{\|f(x)\|} = x$ and so $x = tf(x), t = t_0M \frac{1}{\|f(x)\|} < 1$. Since $M$ is arbitrary, it follows that the solutions to $x = tf(x)$ for $t \in (0, 1)$ are unbounded. It was just shown that there is a solution to $x = tf(x), t < 1$ such that $\|x\| = t_0M$ where $M$ is arbitrary. Thus the second of the two alternatives holds.

Next this is considered in the more general setting of locally convex topological vector space. This is the Tychonoff fixed point theorem. In this theorem, $X$ will be a locally convex topological vector space in which every point is a closed set. Let $\mathcal{B}$ be the basis described earlier and let $\mathcal{B}_0$ consist of all sets of $\mathcal{B}$ which are of the form $B_A(0, r)$ where $A$ is a finite subset of $\Psi$ as described earlier. Note that for $U \in \mathcal{B}_0, U = -U$ and $U$ is convex. Also, if $U \in \mathcal{B}_0$, there exists $V \in \mathcal{B}_0$ such that $V + V \subseteq U$

where

$$V + V \equiv \{v_1 + v_2 : v_i \in V\}.$$

To see this, note

$$B_A(0, r/2) + B_A(0, r/2) \subseteq B_A(0, r).$$

We let $K$ be a closed convex subset of $X$ and let

$f$ be continuous, $f : K \to K$, and $\overline{f(K)}$ is compact.

Lemma 16.5.6 For each $U \in \mathcal{B}_0$, there exists a finite set of points

$$\{y_1, \ldots, y_n\} \subseteq \overline{f(K)}$$

and continuous functions $\psi_i$ defined on $\overline{f(K)}$ such that for $x \in \overline{f(K)}$,

$$\sum_{i=1}^{n} \psi_i(x) = 1, \quad (16.5.21)$$

$$\psi_i(x) = 0 \text{ if } x \notin y_i + U, \psi_i(x) > 0 \text{ if } x \in y_i + U.$$ 

If

$$f_U(x) \equiv \sum_{i=1}^{n} y_i \psi_i(f(x)), \quad (16.5.22)$$

then whenever $x \in K$,

$$f(x) - f_U(x) \in U.$$
Proof: Let $U = B_A(0, r)$. Using the compactness of $\overline{f(K)}$, there exists
$$\{y_1 \cdots y_n\} \subseteq \overline{f(K)}$$
such that
$$\{y_i + U\}_{i=1}^n$$
covers $\overline{f(K)}$. Let
$$\phi_i(y) \equiv (r - \rho_A(y - y_i))^+.$$ 
Thus $\phi_i(y) > 0$ if $y \in y_i + U$ and $\phi_i(y) = 0$ if $y \notin y_i + U$. For $x \in \overline{f(K)}$, let
$$\psi_i(x) \equiv \phi_i(x) \left( \sum_{j=1}^n \phi_j(x) \right)^{-1}.$$ 
Then $16.5.21$ is satisfied. Now let $f_U$ be given by $16.5.22$ for $x \in K$. For such $x$,
$$f(x) - f_U(x) = \sum_{\{i: f(x)-y_i \in U\}} (f(x) - y_i) \psi_i(f(x))$$
$$+ \sum_{\{i: f(x)-y_i \notin U\}} (f(x) - y_i) \psi_i(f(x))$$
$$= \sum_{\{i: f(x)-y_i \in U\}} (f(x) - y_i) \psi_i(f(x))$$
$$+ \sum_{\{i: f(x)-y_i \notin U\}} 0 \psi_i(f(x)) \in U$$
because $0 \in U$, $U$ is convex, and $16.5.21$. ■

We think of $f_U$ as an approximation to $f$.

Lemma 16.5.7 For each $U \in B_0$, there exists $x_U \in$ convex hull of $\overline{f(K)} \subseteq K$ such that
$$f_U(x_U) = x_U.$$ 

Proof: If $f_U(x_U) = x_U$ and
$$x_U = \sum_{i=1}^n a_i y_i$$
for $\sum_{i=1}^n a_i = 1$, we need
$$\sum_{j=1}^n y_j \psi_j \left( f \left( \sum_{i=1}^n a_i y_i \right) \right) = \sum_{j=1}^n a_i y_j.$$
Also, if this is satisfied, then we have the desired fixed point. This will be satisfied if for each $j = 1, \cdots, n$,

$$ a_j = \psi_j \left( f \left( \sum_{i=1}^{n} a_i y_i \right) \right) \quad (16.5.23) $$

so, let

$$ \Sigma_{n-1} \equiv \left\{ \mathbf{a} \in \mathbb{R}^n : \sum_{i=1}^{n} a_i = 1, a_i \geq 0 \right\} $$

and let $h : \Sigma_{n-1} \to \Sigma_{n-1}$ be given by

$$ h(\mathbf{a})_j = \psi_j \left( f \left( \sum_{i=1}^{n} a_i y_i \right) \right). $$

Since $h$ is continuous, the Brouwer fixed point theorem applies and we see there exists a fixed point for $h$ which is a solution to (16.5.23). \end{proof}

**Theorem 16.5.8** Let $K$ be a closed and convex subset of $X$, a locally convex topological vector space in which every point is closed. Let $f : K \to K$ be continuous and suppose $f(K)$ is compact. Then $f$ has a fixed point.

**Proof**: First consider the following claim which will yield a candidate for the fixed point. Recall that $f(x_U) - f_U(x_U) \in U$ and $f_U(x_U) = x_U$ with $x_U \in$ convex hull of $f(K) \subseteq K$.

**Claim**: There exists $x \in f(K)$ with the property that if $V \in \mathcal{B}_0$, there exists $U \subseteq V$, $U \in \mathcal{B}_0$, such that

$$ f(x_U) \in x + V. $$

**Proof of the claim**: If no such $x$ exists, then for each $x \in f(K)$, there exists $V_x \in \mathcal{B}_0$ such that whenever $U \subseteq V_x$, with $U \in \mathcal{B}_0$,

$$ f(x_U) \notin x + V_x. $$

Since $f(K)$ is compact, there exist $x_1, \cdots, x_n \in f(K)$ such that

$$ (x_i + V_{x_i})_{i=1}^{n} $$

cover $f(K)$. Let

$$ U \in \mathcal{B}_0, U \subseteq \cap_{i=1}^{n} V_{x_i} $$

and consider $x_U$.

$$ f(x_U) \in x_i + V_{x_i} $$

for some $i$ because these sets cover $f(K)$ and $f(x_U)$ is something in $f(K)$. But $U \subseteq V_{x_i}$, a contradiction. This shows the claim.

Now I show $x$ is the desired fixed point. Let $W \in \mathcal{B}_0$ and let $V \in \mathcal{B}_0$ with

$$ V + V + V \subseteq W. $$
Since $f$ is continuous at $x$, there exists $V_0 \in \mathcal{B}_0$ such that
\[ V_0 + V_0 \subseteq V \]
and if \( y - x \in V_0 + V_0 \),
then
\[ f(x) - f(y) \in V. \]
Using the claim, let $U \in \mathcal{B}_0$, $U \subseteq V_0$, such that
\[ f(x_U) \in x + V_0. \]
Then
\[ x - x_U = x - f(x_U) + f(x_U) - f_U(x_U) \in V_0 + U \]
and so
\[ f(x) - x = f(x) - f(x_U) + f(x_U) - f_U(x_U) + f_U(x_U) - x \]
\[ \subseteq V + U + V \subseteq W. \]
Since $W \in \mathcal{B}_0$ is arbitrary, it follows from Lemma 16.2.18 that $f(x) - x = 0$.

As an example of the usefulness of this fixed point theorem, consider the following application to the theory of ordinary differential equations. In the context of this theorem, $X = C([0,T]; \mathbb{R}^n)$, a Banach space with norm given by
\[ \|x\| = \max \{|x(t)| : t \in [0,T]\}. \]

**Theorem 16.5.9** Let $f : [0,T] \times \mathbb{R}^n \to \mathbb{R}^n$ be continuous and suppose there exists $L > 0$ such that for all $\lambda \in (0,1)$, if
\[ x' = \lambda f(t, x), \quad x(0) = x_0 \quad \text{(16.5.24)} \]
for all $t \in [0,T]$, then $|x| < L$. Then there exists a solution to
\[ x' = f(t, x), \quad x(0) = x_0 \quad \text{(16.5.25)} \]
for $t \in [0,T]$.

**Proof:** Let
\[ N(x) = \int_0^t f(s, x(s)) \, ds. \]
Thus a solution to the initial value problem exists if there exists a solution to
\[ x_0 + N(x) = x. \]
16.5. THE Tychonoff and Schauder Fixed Point Theorems

Let
\[ m = \max \left\{ |f(t, x)| : (t, x) \in [0, T] \times \overline{B(0, L)} \right\}, \quad M \equiv |x_0| + mT \]

and let
\[ K \equiv \{ x \in C(0, T; \mathbb{R}^n) : x(0) = x_0 \text{ and } ||x|| \leq M \} \]
Now define
\[ A x \equiv \begin{cases} x_0 + Nx & \text{if } ||Nx|| \leq M - |x_0|, \\ x_0 + \frac{(M - |x_0|)N x}{||Nx||} & \text{if } ||Nx|| > M - |x_0|. \end{cases} \]
Then \( A \) is continuous and maps \( X \) to \( K \) because
\[ ||Ax|| \leq |x_0| + ||Nx|| \leq M \text{ if } ||Nx|| \leq M - |x_0| \]
and otherwise,
\[ ||Ax|| \leq |x_0| + \left( \frac{M - |x_0|}{||Nx||} ||Nx|| \right) \leq |x_0| + M - |x_0| = M. \]
Also \( A(K) \) is equicontinuous because
\[ x_0 + Nx(t) - (x_0 + Nx(t_1)) = \int_{t_1}^t f(s, x(s)) \, ds \]
and the integrand is bounded. Thus \( A(K) \) is a compact set in \( X \) by the Ascoli Arzela theorem. By the Schauder fixed point theorem, \( A \) has a fixed point, \( x \in K \).

If \( ||N(x)|| > M - |x_0| \), then
\[ x_0 + \lambda N(x) = x \]
where
\[ \lambda = \frac{(M - |x_0|)}{||Nx||} < 1 \]
and so \( 16.5.24 \) holds. Therefore, by the assumed estimate on the solutions to \( 16.5.24 \), it follows that
\[ ||x|| < L \]
and so \( ||Nx|| \leq mT = M - |x_0| \), a contradiction. Therefore, it must be the case that
\[ ||N(x)|| \leq M - |x_0| \]
which implies that
\[ x_0 + N(x) = x. \]
Since this is equivalent to \( 16.5.24 \), this proves the theorem. □

Here is a neater proof which uses the Leray Schauder alternative, also called the Schaefer fixed point theorem presented above.
Theorem 16.5.10 Let $f : [0, T] \times \mathbb{R}^n \to \mathbb{R}^n$ be continuous and suppose there exists $L > 0$ such that for all $\lambda \in (0, 1)$, if
\[ x' = \lambda f(t, x), \quad x(0) = x_0 \quad (16.5.26) \]
for all $t \in [0, T]$, then $|x| < L$. Then there exists a solution to
\[ x' = f(t, x), \quad x(0) = x_0 \quad (16.5.27) \]
for $t \in [0, T]$.

Proof: Let $F : X \to X$ where $X$ described above.
\[ Fy(t) = \int_0^t f(s, y(s) + x_0) \, ds \]
Let $B$ be a bounded set in $X$. Then $|f(s, y(s) + x_0)|$ is bounded for $s \in [0, T]$ if $y \in B$. Say $|f(s, y(s) + x_0)| \leq C_B$. Hence $F(B)$ is bounded in $X$. Also, for $y \in B, s < t$,
\[ |Fy(t) - Fy(s)| \leq \left| \int_s^t f(s, y(s) + x_0) \, ds \right| \leq C_B |t - s| \]
and so $F(B)$ is pre-compact by the Ascoli Arzela theorem. By the Schaefer fixed point theorem, there are two alternatives. Either there are unbounded solutions $y$ to
\[ \lambda F(y) = y \]
for various $\lambda \in (0, 1)$ or for all $\lambda \in [0, 1]$, there is a fixed point for $\lambda F$. In the first case, there would be unbounded $y_\lambda$ solving
\[ y_\lambda(t) = \lambda \int_0^t f(s, y_\lambda(s) + x_0) \, ds \]
Then let $x_\lambda(s) = y_\lambda(s) + x_0$ and you get $\|x_\lambda\|$ also unbounded for various $\lambda \in (0, 1)$. The above implies
\[ x_\lambda(t) - x_0 = \lambda \int_0^t f(s, x_\lambda(s)) \, ds \]
so $x'_\lambda = \lambda f(t, x_\lambda), x_\lambda(0) = x_0$ and these would be unbounded for $\lambda \in (0, 1)$ contrary to the assumption that there exists an estimate for these valid for all $\lambda \in (0, 1)$. Hence the first alternative must hold and hence there is $y \in X$ such that
\[ Fy = y \]
Then letting $x(s) = y(s) + x_0$, it follows that
\[ x(t) - x_0 = \int_0^t f(s, x(s)) \, ds \]
and so $x$ is a solution to the differential equation on $[0, T]$.

Note that existence for solutions to $x' = f(t, x)$ is not assumed, only estimates of possible solutions. These estimates are called $a$-priori estimates. Also note this is a global existence theorem, not a local one for a solution defined on only a small interval.
16.6 A Variational Principle of Ekeland

**Definition 16.6.1** A function $\phi : X \to (-\infty, \infty]$ is called proper if it is not constantly equal to $\infty$. Here $X$ is assumed to be a complete metric space. The function $\phi$ is lower semicontinuous if $x_n \to x$ implies $\phi(x) \leq \liminf_{n \to \infty} \phi(x_n)$

It is bounded below if there is some constant $C$ such that $C \leq \phi(x)$ for all $x$.

The variational principle of Ekeland is the following theorem [52]. You start with an approximate minimizer $x_0$. It says there is $y_\lambda$ fairly close to $x_0$ such that if you subtract a “cone” from the value of $\phi$ at $y_\lambda$, then the resulting function is less than $\phi(x)$ for all $x \neq y_\lambda$. This cone is like a supporting plane for a convex function but pertains to functions which are certainly not convex.

**Theorem 16.6.2** Let $X$ be a complete metric space and let $\phi : X \to (-\infty, \infty]$ be proper, lower semicontinuous and bounded below. Let $x_0$ be such that

$$\phi(x_0) \leq \inf_{x \in X} \phi(x) + \varepsilon$$

Then for every $\lambda > 0$ there exists a $y_\lambda$ such that

1. $\phi(y_\lambda) \leq \phi(x_0)$
2. $d(y_\lambda, x_0) \leq \lambda$
3. $\phi(y_\lambda) - \frac{\varepsilon}{\lambda} d(x, y_\lambda) < \phi(x)$ for all $x \neq y_\lambda$

To motivate the proof, see the following picture which illustrates the first two steps. The $S_i$ will be sets in $X$ but are denoted symbolically by labeling them in $X \times (-\infty, \infty]$. 
Then the end result of this iteration would be a picture like the following.

Thus you would have \( \phi(y_\lambda) - \frac{\varepsilon}{\lambda}d(y_\lambda, x) \leq \phi(x) \) for all \( x \) which is seen to be what is wanted.

**Proof:** Let \( x_1 = x_0 \) and define

\[
S_1 \equiv \left\{ z \in X : \phi(z) \leq \phi(x_1) - \frac{\varepsilon}{\lambda}d(z, x_1) \right\}
\]

Then \( S_1 \) contains \( x_1 \) so it is nonempty. It is also clear that \( S_1 \) is a closed set. This follows from the lower semicontinuity of \( \phi \). Let \( x_2 \) be a point of \( S_1 \), possibly different than \( x_1 \) and let

\[
S_2 \equiv \left\{ z \in X : \phi(z) \leq \phi(x_2) - \frac{\varepsilon}{\lambda}d(z, x_2) \right\}
\]

Continue in this way. Now let there be a sequence of points \( \{x_k\} \) such that \( x_k \in S_{k-1} \) and define \( S_k \) by

\[
S_k \equiv \left\{ z \in X : \phi(z) \leq \phi(x_k) - \frac{\varepsilon}{\lambda}d(z, x_k) \right\}
\]

where \( x_k \) is some point of \( S_{k-1} \). Then \( x_k \) is a point of \( S_k \). Will this yield a nested sequence of nonempty closed sets? Yes, it appears that it would because if \( z \in S_k \) then

\[
\phi(z) \leq \phi(x_k) - \frac{\varepsilon}{\lambda}d(z, x_k) \leq \left( \phi(x_{k-1}) - \frac{\varepsilon}{\lambda}d(x_{k-1}, x_k) \right) - \frac{\varepsilon}{\lambda}d(z, x_k)
\]

\[
\leq \phi(x_{k-1}) - \frac{\varepsilon}{\lambda}d(z, x_{k-1})
\]

showing that \( z \) has what it takes to be in \( S_{k-1} \). Thus we would obtain a sequence of nested, nonempty, closed sets according to this scheme.

Now here is how to choose the \( x_k \in S_{k-1} \). Let

\[
\phi(x_k) < \inf_{x \in S_{k-1}} \phi(x) + \frac{1}{2k}
\]

Then for \( z \in S_{n+1} \subseteq S_n \),

\[
\phi(z) \leq \phi(x_{n+1}) - \frac{\varepsilon}{\lambda}d(z, x_{n+1})
\]
and so
\[
\frac{\varepsilon}{\lambda} d(z, x_{n+1}) \leq \phi(x_{n+1}) - \phi(z) \leq \inf_{x \in S_n} \phi(x) + \frac{1}{2^{n+1}} - \phi(z) \\
\leq \phi(z) + \frac{1}{2^{n+1}} - \phi(z) = \frac{1}{2^{n+1}}
\]

Thus every \( z \in S_{n+1} \) is within \( \frac{1}{2^{n+1}} \) of the single point \( x_{n+1} \) and so the diameter of \( S_n \) converges to 0 as \( n \to \infty \). By completeness of \( X \), there exists a unique \( y_{\lambda} \in \cap_n S_n \). Then it follows in particular that for \( x_0 = x_1 \) as above,
\[
\phi(y_{\lambda}) \leq \phi(x_0) - \frac{\varepsilon}{\lambda} d(y_{\lambda}, x_0) \leq \phi(x_0)
\]
which verifies the first of the above conclusions.

As to the second, \( \phi(x_0) \leq \inf_{x \in X} \phi(x) + \varepsilon \) and so, for any \( x \),
\[
\phi(y_{\lambda}) \leq \phi(x_0) - \frac{\varepsilon}{\lambda} d(y_{\lambda}, x_0) \leq \phi(x) + \varepsilon - \frac{\varepsilon}{\lambda} d(y_{\lambda}, x_0)
\]
this being true for \( x = y_{\lambda} \). Hence \( \frac{\varepsilon}{\lambda} d(y_{\lambda}, x_0) \leq \varepsilon \) and so \( d(y_{\lambda}, x_0) \leq \lambda \).

Finally consider the third condition. If it does not hold, then there exists \( z \neq y_{\lambda} \) such that
\[
\phi(y_{\lambda}) \geq \phi(z) + \frac{\varepsilon}{\lambda} d(z, y_{\lambda})
\]
so that
\[
\phi(z) \leq \phi(y_{\lambda}) - \frac{\varepsilon}{\lambda} d(z, y_{\lambda}).
\]
But then, by the definition of \( y_{\lambda} \) as being in all the \( S_n \),
\[
\phi(y_{\lambda}) \leq \phi(x_n) - \frac{\varepsilon}{\lambda} d(x_n, y_{\lambda})
\]
and so
\[
\phi(z) \leq \phi(x_n) - \frac{\varepsilon}{\lambda} (d(x_n, y_{\lambda}) + d(z, y_{\lambda})) \\
\leq \phi(x_n) - \frac{\varepsilon}{\lambda} d(x_n, z)
\]
Since \( n \) is arbitrary, this shows that \( z \in \cap_n S_n \) but there is only one element of this intersection and it is \( y_{\lambda} \), so \( z \) must equal \( y_{\lambda} \), a contradiction.

Note how if you make \( \lambda \) very small, you could pick \( \varepsilon \) very small such that the cone looks pretty flat.

### 16.6.1 Cariste Fixed Point Theorem

As mentioned in [52], the above result can be used to prove a fixed point theorem called the Cariste fixed point theorem.
Theorem 16.6.3 Let $\phi$ be lower semicontinuous, proper, and bounded below on a complete metric space $X$ and let $F : X \to \mathcal{P}(X)$ be set valued such that $F(x) \neq \emptyset$ for all $x$. Also suppose that for each $x \in X$, there exists $y \in F(x)$ such that

$$\phi(y) \leq \phi(x) - d(x, y)$$

Then there exists $x_0$ such that $x_0 \in F(x_0)$.

Proof: In the above Ekeland variational principle, let $\varepsilon = 1 = \lambda$. Then there exists $x_0$ such that for all $y \neq x_0$

$$\phi(x_0) - d(y, x_0) < \phi(y), \quad \text{so} \quad \phi(x_0) < \phi(y) + d(y, x_0) \quad (16.6.28)$$

for all $y \neq x_0$.

Suppose $x_0 \notin F(x_0)$. From the assumption, there is $y \in F(x_0)$ (so $y \neq x_0$) such that

$$\phi(y) \leq \phi(x_0) - d(x, y)$$

Since $y \neq x_0$, it follows

$$\phi(y) + d(x_0, y) \leq \phi(x_0) < \phi(y) + d(y, x_0)$$

a contradiction. Hence $x_0 \in F(x_0)$ after all. 

It is a funny theorem. It is easy to prove, but you look at it and wonder what it says. If $F$ is single valued, you would need to have a function $\phi$ such that for each $x$,

$$\phi(F(x)) \leq \phi(x) - d(x, y)$$

and if you have such a $\phi$ then you can assert there is a fixed point for $F$. Suppose $F$ is single valued and $d(Fx, Fy) \leq rd(x, y), 0 < r < 1$. Of course $F$ has a fixed point using easier techniques. However, this also follows from this result. Let

$$\phi(x) = \frac{1}{1 - r}d(x, F(x))$$

Then is it true that for each $x$, there exists $y \in F(x)$ such that the inequality holds for all $x$? Is

$$\frac{1}{1 - r}d(F(x), F(F(x))) \leq \frac{1}{1 - r}d(x, F(x)) - d(x, F(x))$$
Yes, this is certainly so because the right side reduces to \( \frac{1}{\lambda} d(x, F(x)) \). Thus this fixed point theorem implies the usual Banach fixed point theorem.

The Ekeland variational principle says that when \( \phi \) is lower semicontinuous proper and bounded below, there exists \( y \) such that

\[
\phi(y) - d(x, y) < \phi(x) \quad \text{for all } x \neq y
\]

In fact this can be proved from the Cariste fixed point theorem. Suppose the EVP does not hold. This would mean that for all \( y \) there exists \( x \neq y \) such that

\[
\phi(y) - d(x, y) \geq \phi(x)
\]

Thus, for all \( x \) there exists \( y \neq x \) such that

\[
\phi(x) - d(x, y) \geq \phi(y)
\]

The inequality is preserved if \( x = y \). Then let

\[
F(x) \equiv \{ y \neq x : \phi(x) - d(x, y) \geq \phi(y) \} \neq \emptyset
\]

by assumption. This is the hypothesis for the Cariste fixed point theorem. Hence there exists \( x_0 \in F(x_0) = \{ y \neq x_0 : \phi(x_0) - d(x_0, y) \geq \phi(y) \} \) but this cannot happen because you can’t have \( x_0 \neq x_0 \). Thus the Ekeland variational principle must hold after all.

### 16.6.2 A Density Result

There are several applications of the Ekeland variational principle. For more of them, see [25]. One of these is to show that there is a point where \( \phi' \) is small assuming \( \phi \) is bounded below, lower semicontinuous, and Gateaux differentiable. Here

\[
\langle \phi'(x), v \rangle \equiv \lim_{h \to 0} \frac{\phi(x + hv) - \phi(x)}{h}, \quad \phi'(x) \in X'
\]

It is sort of an approximate critical point at a point which causes \( \phi \) to be near the infimum.

**Theorem 16.6.4** Let \( X \) be a Banach space and \( \phi : X \to \mathbb{R} \) be Gateaux differentiable, bounded from below, and lower semicontinuous. Then for every \( \varepsilon > 0 \) there exists \( x \in X \) such that

\[
\phi(x_\varepsilon) \leq \inf_{x \in X} \phi(x) + \varepsilon \quad \text{and} \quad \| \phi'(x_\varepsilon) \|_{X'} \leq \varepsilon
\]

**Proof:** From the Ekeland variational principle with \( \lambda = 1 \), there exists \( x_\varepsilon \) such that

\[
\phi(x_\varepsilon) \leq \phi(x_0) \leq \inf_{x \in X} \phi(x) + \varepsilon
\]

and for all \( x \),

\[
\phi(x_\varepsilon) < \phi(x) + \varepsilon \| x - x_\varepsilon \|
\]
Then letting \( x = x_\varepsilon + hv \) where \( \|v\| = 1 \),
\[
\phi(x_\varepsilon + hv) - \phi(x_\varepsilon) > -\varepsilon |h|
\]
Let \( h < 0 \). Then divide by it
\[
\frac{\phi(x_\varepsilon + hv) - \phi(x_\varepsilon)}{h} < \varepsilon
\]
Passing to a limit as \( h \to 0 \) yields
\[
\left\langle \phi'(x_\varepsilon), v \right\rangle \leq \varepsilon
\]
Now \( v \) was arbitrary with norm 1 and so
\[
\sup_{\|v\|=1} \left\langle \phi'(x_\varepsilon), v \right\rangle = \|\phi'(x_\varepsilon)\| \leq \varepsilon \]

There is another very interesting application of the Ekeland variational principle.

**Theorem 16.6.5** Let \( X \) be a Banach space and \( \phi : X \to \mathbb{R} \) be Gateaux differentiable, bounded from below, and lower semicontinuous. Also suppose there exists \( a, c > 0 \) such that
\[
a \|x\| - c \leq \phi(x) \quad \text{for all } x \in X
\]
Then \( \{ \phi'(x) : x \in X \} \) is dense in the ball of \( X' \) centered at 0 with radius \( a \). Here \( \phi'(x) \in X' \) and is determined by
\[
\left\langle \phi'(x), v \right\rangle \equiv \lim_{h \to 0} \frac{\phi(x + hv) - \phi(x)}{h}
\]

**Proof:** Let \( x^* \in X', \|x^*\| \leq a \). Let
\[
\psi(x) = \phi(x) - \left\langle x^*, x \right\rangle
\]
This is lower semicontinuous. It is also bounded from below because
\[
\psi(x) \geq \phi(x) - a \|x\| \geq (a \|x\| - c) - a \|x\| = -c
\]
It is also clearly Gateaux differentiable and lower semicontinuous because the piece added in is actually continuous. It is clear that the Gateaux derivative is just \( \phi'(x) - x^* \). By Theorem 16.6.4, there exists \( x_\varepsilon \) such that
\[
\|\phi'(x_\varepsilon) - x^*\| \leq \varepsilon
\]
Thus this theorem says that if \( \phi(x) \geq a \|x\| - c \) where \( \phi \) has the nice properties of the theorem it follows that \( \phi'(x) \) is dense in \( B(0, a) \) in the dual space \( X' \). It follows that if for every \( a \), there exists \( c \) such that
\[
\phi(x) \geq a \|x\| - c \quad \text{for all } x \in X
\]
then \( \{ \phi'(x) : x \in X \} \) is dense in \( X' \). This proves the following lemma.
Lemma 16.6.6 Let $X$ be a Banach space and $\phi : X \to \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Suppose for all $a > 0$ there exists $c > 0$ such that
\[ \phi(x) \geq a \|x\| - c \text{ for all } x \]
Then $\{\phi'(x) : x \in X\}$ is dense in $X'$.

If the above holds, then
\[ \frac{\phi(x)}{\|x\|} \geq a - \frac{c}{\|x\|} \]
and so, since $a$ is arbitrary, it must be the case that
\[ \lim_{\|x\| \to \infty} \frac{\phi(x)}{\|x\|} = \infty. \tag{16.6.29} \]
In fact, this is sufficient. If not, there would exist $a > 0$ such that $\phi(x_n) < a \|x_n\| - n$. Let $-L$ be a lower bound for $\phi(x)$. Then
\[ -L + n \leq a \|x_n\| \]
and so $\|x_n\| \to \infty$. Now it follows that
\[ a \geq \frac{\phi(x_n)}{\|x_n\|} + \frac{n}{\|x_n\|} \geq \frac{\phi(x_n)}{\|x_n\|} \tag{16.6.30} \]
which is a contradiction to (16.6.29). This proves the following interesting density theorem.

Theorem 16.6.7 Let $X$ be a Banach space and $\phi : X \to \mathbb{R}$ be Gateaux differentiable, bounded from below, and lower semicontinuous. Also suppose the coercivity condition
\[ \lim_{\|x\| \to \infty} \frac{\phi(x)}{\|x\|} = \infty \]
Then $\{\phi'(x) : x \in X\}$ is dense in $X'$. Here $\phi'(x) \in X'$ and is determined by
\[ \langle \phi'(x), v \rangle \equiv \lim_{h \to 0} \frac{\phi(x + hv) - \phi(x)}{h} \]

16.7 Quotient Spaces

A useful idea is that of a quotient space. It is a way to create another Banach space from a given Banach space and a closed subspace. It generalizes similar concepts which are routine in linear algebra.

Definition 16.7.1 Let $X$ be a Banach space and let $V$ be a closed subspace of $X$. Then $X/V$ denotes the set of equivalence classes determined by the equivalence relation which says $x \sim y$ means $x - y \in V$. An individual equivalence class will be
denoted by any of the following symbols. \(x + V, [x], \) or \([x]_V\). Vector space operations are defined as follows:

\[(x + V) + y + V \equiv x + y + V\]

or in other symbols,

\[[x] + [y] \equiv [x + y]\]

and for \(\alpha \in \mathbb{F}\),

\[\alpha [x] \equiv [\alpha x].\]

Also a norm is defined by

\[\| [x] \| \equiv \inf \{ \| x + v \| : v \in V \}.\]

It is left as an exercise to verify the above algebraic operations are well defined. With the above definition, here is the major theorem about quotient spaces.

**Theorem 16.7.2** Let \(X\) be a Banach space and let \(V\) be a closed subspace of \(X\). Then with the above definitions of vector space operations, \(X/V\) is a Banach space. In the case where \(V = \ker (A)\) for \(A \in \mathcal{L}(X, Y)\) for \(Y\) another Banach space, define \(\hat{A} : X/V \to A(X) \subseteq Y\) by \(\hat{A}([x]) \equiv Ax\). Then \(\hat{A}\) is continuous and \(1 - 1\). In fact, \(\| \hat{A} \| \leq \| A \|\).

**Proof:** First of all, consider the claim that the given norm really is a norm. First note that \(\| x + V \| \geq 0\) and \(\| x + V \| = 0\) only if \(x \in V\) because \(V\) is closed. Therefore, \(x + V = 0 + V\). Next,

\[\| \alpha [x] \| = \| \alpha x \| \equiv \inf \{ \| \alpha x + v \| : v \in V \}\]

\[= \inf \{ \| \alpha x + \alpha v \| : v \in V \}\]

\[= |\alpha| \inf \{ \| x + v \| : v \in V \} = |\alpha| \| [x] \|.\]

Consider the triangle inequality.

\[\| [x + y] \| = \inf \{ \| x + y + v \| : v \in V \}\]

\[\leq \| x + v_1 \| + \| y + v_2 \|\]

for any choice of \(v_1\) and \(v_2\). Therefore, taking the infimum of both sides over \(v_2\) yields

\[\| [x + y] \| \leq \| x + v_1 \| + \| y \|\]

and then taking the infimum over all \(v_1\) yields

\[\| [x + y] \| \leq \| [x] \| + \| [y] \|.\]

Next consider the claim that \(X/V\) is a Banach space. Letting \([x_n]\) be a Cauchy sequence in \(X/V\), I will show a subsequence of this converges to a point in \(X/V\). This is done by defining a suitable sequence in \(X\) and then using completeness of \(X\). By
Let \( 16.7.31 \) first. I show this implies \( 16.7.33 \). Let \( z_1 \equiv x_1 \). Then choose \( v_2 \in V \) such that \( ||x_2 + v_2 - z_1|| < 2^{-1} \). Let \( z_2 = x_2 + v_2 \). Suppose \( \{z_1, \ldots, z_n\} \) have been chosen, each having the property that \( z_k = [x_k] \) and such that \( ||z_k - z_{k+1}|| < 2^{-k} \). Then let \( v_{n+1} \) be chosen such that \( ||x_{n+1} + v_{n+1} - z_n|| < 2^{-n} \) and let \( z_{n+1} \equiv x_{n+1} + v_{n+1} \). Thus \( \{z_n\} \) is a Cauchy sequence in \( X \) and so it converges to \( x \in X \). Then

\[
||x - [x_n]|| \leq ||x - (x_n + v_n)|| = ||x - z_n||
\]

and so \( \lim_{n \to \infty} [x_n] = [x] \).

Next consider the claim about \( \hat{A} \). This is well defined and linear because if \( [x] = [x_1] \), then \( x - x_1 \in \ker(A) \) and so \( Ax = Ax_1 \). Thus \( \hat{A}([x]) = \hat{A}([x_1]) \). It is linear because

\[
\hat{A}(\alpha [x] + \beta [y]) = \hat{A}((\alpha x + \beta y)) = A(\alpha x + \beta y) = \alpha Ax + \beta Ay = \alpha \hat{A}([x]) + \beta \hat{A}([y])
\]

Next consider the claim that \( \hat{A} \) is continuous. Letting \( v \in V \),

\[
||\hat{A}([x])|| \equiv ||Ax|| = ||A (x + v)|| \leq ||A|| ||x + v||
\]

and so, taking the infimum over all \( v \in V \),

\[
||\hat{A}([x])|| \leq ||A|| ||[x]||
\]

and this shows \( ||\hat{A}|| \leq ||A|| \). \( \square \)

Now with this theorem, here is an interesting application.

**Theorem 16.7.3** Let \( X_1 \) and \( X_2 \) be Banach spaces which are either reflexive or dual spaces for a separable Banach space and let \( A_i \in \mathcal{L}(X_i, Y) \) for \( Y \) a reflexive Banach space. The following are equivalent.

For some \( k > 0 \)

\[
A_1 \left( B(0,1) \right) \subseteq A_2 \left( B(0,k) \right) \tag{16.7.31}
\]

\[
||A_1^* y^*|| \leq k ||A_2^* y^*|| \tag{16.7.32}
\]

for all \( y \in Y^* \). If either of the above hold, then

\[
A_1 X_1 \subseteq A_2 X_2 \tag{16.7.33}
\]

**Proof:** Suppose \( 16.7.31 \) first. I show this implies \( 16.7.33 \). There are two cases. First suppose \( A_2 \) is one to one. Then in this case, \( A_2^{-1} A_1 \left( B(0,1) \right) \subseteq B(0,k) \). Therefore, if \( x \in X_1 \),

\[
A_2^{-1} A_1 (x/||x||) = y \in B(0,k)
\]

and so

\[
A_1 (x) = ||x|| A_2 (y) = A_2 (||x|| y) \in A_2 (X_2).
\]
Next suppose $A_2$ is not one to one. In this case, letting $\tilde{A}_2$ be the continuous linear map given by

$$\tilde{A}_2([x]) \equiv A_2x,$$

it follows $\tilde{A}_2$ is $1-1$ on $X_2/ \ker (A_2)$. Now note that if $||x|| \leq k$, then it is also the case that $||[x]|| \leq k$ and so

$$A_2\left(B(0,k)\right) \subseteq \tilde{A}_2\left(\tilde{B}_2(0,k)\right)$$

where in the second set, $\tilde{B}_2(0,k)$ is the unit ball in $X/ \ker (A_2)$. It follows from $16.7.31$

$$A_1\left(B(0,1)\right) \subseteq \tilde{A}_2\left(\tilde{B}_2(0,k)\right)$$

and so $\tilde{A}_2^{-1}A_1\left(B(0,1)\right) \subseteq \tilde{B}_2(0,k)$ which implies

$$A_1(x/||x||) = \tilde{A}_2[y] \in \tilde{A}_2\left(\tilde{B}_2(0,k)\right)$$

Therefore, letting $[y_1] = [y]$ be such that $||y_1|| < 2k$, it follows

$$A_1(x/||x||) = \tilde{A}_2[y_1] = A_2(y_1)$$

and so

$$A_1(x) = A_2(||x||y_1) \in A_2(X_2).$$

Next I show the equivalence of $16.7.32$ and $16.7.31$. First I want to show $A_1\left(B(0,r)\right)$ is closed. Suppose then that for $A = A_1$ or $A_2$, $A(x_n) \to y$ where $x_n \in B(0,r)$. In the case the $X_i$ are reflexive, it follows from the Eberlein Smulian theorem there exists a subsequence, still denoted as $\{x_n\}$ which converges weakly to $x \in B(0,r)$. Then $Ax_n \to y$ and $x_n \to x$ weakly. Thus $(x,y)$ is in the weak closure of the graph of $A,$

$$\{(x,Ax) : x \in X_1\}$$

This set is strongly closed and convex and hence it is weakly closed by Theorem $16.7.31$ so $y = Ax$ and this shows $A\left(B(0,r)\right)$ is closed. In the other case where $X_i$ is the dual space of a separable Banach space, it follows from Corollary $15.5.6$ there exists a subsequence still denoted as $\{x_n\}$ such that $x_n \to x$ weak * and similarly, $(x,y)$ is in the weak * closure of the graph of $A$ which shows again by Theorem $16.7.31$ that $(x,y)$ is in the graph of $A$, showing again that $A\left(B(0,r)\right)$ is closed.

Suppose $16.7.31$. Then letting $y^* \in Y^*$,

$$||A_1^*y^*|| = \sup_{||x_1||_{X_1} \leq 1} |y^*(A_1x_1)|$$

$$\leq \sup_{||x_2||_{X_2} \leq k} |y^*(A_2x_2)| = k ||A_2^*y^*||$$

which shows $16.7.32$. 

16.7. QUOTIENT SPACES

Now suppose (16.7.32). Then if (16.7.31) does not hold, it follows from the first part which gives \( A_i \left(B(0,r)\right) \) a closed set, there exists

\[ A_1 x_0 \in A_1 \left(B(0,1)\right) \setminus A_2 \left(B(0,k)\right) \]

Now \( A_2 \left(B(0,k)\right) \) is closed and convex, hence weakly closed, and so by Theorem (16.2.5) there exists \( y_0^* \in Y' \) such that

\[ \text{Re} \ y_0^* \left(A_2 \left(B(0,k)\right)\right) < c < \text{Re} \ y_0^* \left(A_1 x_0\right) \]

and so

\[ \|A_1^* y_0^*\| = \sup_{\|x_1\|_{X_1} \leq 1} |y_0^* (A x_1)| \geq \text{Re} \ y_0^* (A_1 x_0) \]

\[ > c > \text{Re} \ y_0^* (A_2 (x_2)) = \text{Re} \ A_2^* y_0^* (x_2) \]

whenever \( x_2 \in B(0,k) \) and so, taking the supremum of all such \( x_2 \),

\[ \|A_1^* y_0^*\| > c > k \|A_2^* y_0^*\|, \]

contradicting (16.7.32).
Chapter 17

Hilbert Spaces

In this chapter, Hilbert spaces, which have been alluded to earlier are given a complete discussion. These spaces, as noted earlier are just complete inner product spaces.

17.1 Basic Theory

Definition 17.1.1 Let $X$ be a vector space. An inner product is a mapping from $X \times X$ to $\mathbb{C}$ if $X$ is complex and from $X \times X$ to $\mathbb{R}$ if $X$ is real, denoted by $(x, y)$ which satisfies the following.

\begin{align}
(x, x) &\geq 0, \quad (x, x) = 0 \text{ if and only if } x = 0, \\
(x, y) &= \overline{(y, x)}. 
\end{align}

For $a, b \in \mathbb{C}$ and $x, y, z \in X$,

\[ (ax + by, z) = a(x, z) + b(y, z). \]

Note that 17.1.2 and 17.1.3 imply $(x, ay + bz) = \overline{a}(x, y) + \overline{b}(x, z)$. Such a vector space is called an inner product space.

The Cauchy Schwarz inequality is fundamental for the study of inner product spaces.

Theorem 17.1.2 (Cauchy Schwarz) In any inner product space

\[ |(x, y)| \leq ||x|| \cdot ||y||. \]

Proof: Let $\omega \in \mathbb{C}$, $|\omega| = 1$, and $\mathfrak{a}(x, y) = |(x, y)| = \text{Re}(x, y \omega)$. Let

\[ F(t) = (x + ty \omega, x + t \omega y). \]
CHAPTER 17. HILBERT SPACES

If \( y = 0 \) there is nothing to prove because

\[
(x, 0) = (x, 0 + 0) = (x, 0) + (x, 0)
\]

and so \( (x, 0) = 0 \). Thus, it can be assumed \( y \neq 0 \). Then from the axioms of the inner product,

\[
F(t) = ||x||^2 + 2t \Re(x, \omega y) + t^2||y||^2 \geq 0.
\]

This yields

\[
||x||^2 + 2||(x, y)|| + t^2||y||^2 \geq 0.
\]

Since this inequality holds for all \( t \in \mathbb{R} \), it follows from the quadratic formula that

\[
4 ||x,y||^2 - 4||x||^2||y||^2 \leq 0.
\]

This yields the conclusion and proves the theorem.

**Proposition 17.1.3** For an inner product space, \( ||x|| \equiv (x, x)^{1/2} \) does specify a norm.

**Proof:** All the axioms are obvious except the triangle inequality. To verify this,

\[
||x + y||^2 \equiv (x + y, x + y) \equiv ||x||^2 + ||y||^2 + 2 \Re(x, y) \\
\leq ||x||^2 + ||y||^2 + 2 ||(x, y)||, \\
\leq ||x||^2 + ||y||^2 + 2 ||x|| \cdot ||y|| = (||x|| + ||y||)^2.
\]

The following lemma is called the parallelogram identity.

**Lemma 17.1.4** In an inner product space,

\[
||x + y||^2 + ||x - y||^2 = 2||x||^2 + 2||y||^2.
\]

The proof, a straightforward application of the inner product axioms, is left to the reader.

**Lemma 17.1.5** For \( x \in H \), an inner product space,

\[
||x|| = \sup_{||y|| \leq 1} |(x, y)| \quad (17.1.4)
\]

**Proof:** By the Cauchy Schwarz inequality, if \( x \neq 0 \),

\[
||x|| \geq \sup_{||y|| \leq 1} |(x, y)| \geq \left( x, \frac{x}{||x||} \right) = ||x||.
\]

It is obvious that (17.1.4) holds in the case that \( x = 0 \).

**Definition 17.1.6** A Hilbert space is an inner product space which is complete. Thus a Hilbert space is a Banach space in which the norm comes from an inner product as described above.
In Hilbert space, one can define a projection map onto closed convex nonempty sets.

**Definition 17.1.7** A set, $K$, is convex if whenever $\lambda \in [0, 1]$ and $x, y \in K$, $\lambda x + (1 - \lambda) y \in K$.

**Theorem 17.1.8** Let $K$ be a closed convex nonempty subset of a Hilbert space, $H$, and let $x \in H$. Then there exists a unique point $Px \in K$ such that $\|Px - x\| \leq \|y - x\|$ for all $y \in K$.

**Proof:** Consider uniqueness. Suppose that $z_1$ and $z_2$ are two elements of $K$ such that for $i = 1, 2$,

\[ \|z_i - x\| \leq \|y - x\| \quad (17.1.5) \]

for all $y \in K$. Also, note that since $K$ is convex, $\frac{z_1 + z_2}{2} \in K$.

Therefore, by the parallelogram identity,

\[
\|z_1 - x\|^2 \leq \|\frac{z_1 + z_2}{2} - x\|^2 = \|\frac{z_1 - x}{2} + \frac{z_2 - x}{2}\|^2 = 2(\|\frac{z_1 - x}{2}\|^2 + \|\frac{z_2 - x}{2}\|^2) - \|\frac{z_1 - z_2}{2}\|^2 = \frac{1}{2}\|z_1 - x\|^2 + \frac{1}{2}\|z_2 - x\|^2 - \|\frac{z_1 - z_2}{2}\|^2 \\
\leq \|z_1 - x\|^2 - \|\frac{z_1 - z_2}{2}\|^2,
\]

where the last inequality holds because of (17.1.5) letting $z_1 = z_2$ and $y = z_1$. Hence $z_1 = z_2$ and this shows uniqueness.

Now let $\lambda = \inf \{\|x - y\| : y \in K\}$ and let $y_n$ be a minimizing sequence. This means $\{y_n\} \subseteq K$ satisfies $\lim_{n \to \infty} \|x - y_n\| = \lambda$. Now the following follows from properties of the norm.

\[
\|y_n - x + y_m - x\|^2 = 4(\|\frac{y_n + y_m}{2} - x\|^2)
\]

Then by the parallelogram identity, and convexity of $K$, $\frac{y_n + y_m}{2} \in K$, and so

\[
\| (y_n - x) - (y_m - x) \|^2 = 2(\|y_n - x\|^2 + \|y_m - x\|^2) - 4(\|\frac{y_n + y_m}{2} - x\|^2) \\
\leq 2(\|y_n - x\|^2 + \|y_m - x\|^2) - 4\lambda^2.
\]

Since $\|x - y_n\| \to \lambda$, this shows $\{y_n - x\}$ is a Cauchy sequence. Thus also $\{y_n\}$ is a Cauchy sequence. Since $H$ is complete, $y_n \to y$ for some $y \in H$ which must be in $K$ because $K$ is closed. Therefore

\[
\|x - y\| = \lim_{n \to \infty} \|x - y_n\| = \lambda.
\]

Let $Px = y$. 

Let $P$ be the projection map.
Corollary 17.1.9 Let $K$ be a closed, convex, nonempty subset of a Hilbert space, $H$, and let $x \in H$. Then for $z \in K$, $z = Px$ if and only if
\[ \text{Re}(x - z, y - z) \leq 0 \] (17.1.6)
for all $y \in K$.

Before proving this, consider what it says in the case where the Hilbert space is $\mathbb{R}^n$.

Condition (17.1.6) says the angle, $\theta$, shown in the diagram is always obtuse. Remember from calculus, the sign of $x \cdot y$ is the same as the sign of the cosine of the included angle between $x$ and $y$. Thus, in finite dimensions, the conclusion of this corollary says that $z = Px$ exactly when the angle of the indicated angle is obtuse. Surely the picture suggests this is reasonable.

The inequality (17.1.6) is an example of a variational inequality and this corollary characterizes the projection of $x$ onto $K$ as the solution of this variational inequality.

Proof of Corollary: Let $z \in K$ and let $y \in K$ also. Since $K$ is convex, it follows that if $t \in [0, 1]$,
\[ z + t(y - z) = (1 - t)z + ty \in K. \]
Furthermore, every point of $K$ can be written in this way. (Let $t = 1$ and $y \in K$.) Therefore, $z = Px$ if and only if for all $y \in K$ and $t \in [0, 1],$
\[ ||x - (z + t(y - z))||^2 = ||(x - z) - t(y - z)||^2 \geq ||x - z||^2 \]
for all $t \in [0, 1]$ and $y \in K$ if and only if for all $t \in [0, 1]$ and $y \in K$
\[ ||x - z||^2 + t^2 ||y - z||^2 - 2t \text{Re}(x - z, y - z) \geq ||x - z||^2 \]
If and only if for all $t \in [0, 1],$
\[ t^2 ||y - z||^2 - 2t \text{Re}(x - z, y - z) \geq 0 \] (17.1.7)
Now this is equivalent to (17.1.10) holding for all $t \in (0, 1)$. Therefore, dividing by $t \in (0, 1), \text{[17.1.7]}$ is equivalent to
\[ t ||y - z||^2 - 2 \text{Re}(x - z, y - z) \geq 0 \]
for all $t \in (0, 1)$ which is equivalent to (17.1.10). This proves the corollary.

Corollary 17.1.10 Let $K$ be a nonempty convex closed subset of a Hilbert space, $H$. Then the projection map, $P$ is continuous. In fact,
\[ |Px - Py| \leq |x - y|. \]
17.1. BASIC THEORY

Proof: Let \( x, x' \in H \). Then by Corollary 17.1.9,

\[
\text{Re} \left( x' - Px', Px - P{x'} \right) \leq 0, \quad \text{Re} \left( x - Px, Px' - P{x'} \right) \leq 0
\]

Hence

\[
0 \leq \text{Re} \left( x - Px, Px - P{x'} \right) - \text{Re} \left( x' - P{x}', Px - P{x'} \right) = \text{Re} \left( x - x',Px - P{x'} \right) - |Px - P{x'}|^2
\]

and so

\[
|Px - P{x'}|^2 \leq |x - x'| |Px - P{x'}|.
\]

This proves the corollary.

The next corollary is a more general form for the Brouwer fixed point theorem.

**Corollary 17.1.11** Let \( f : K \to K \) where \( K \) is a convex compact subset of \( \mathbb{R}^n \). Then \( f \) has a fixed point.

Proof: Let \( K \subseteq \overline{B(0, R)} \) and let \( P \) be the projection map onto \( K \). Then consider the map \( f \circ P \) which maps \( \overline{B(0, R)} \) to \( \overline{B(0, R)} \) and is continuous. By the Brouwer fixed point theorem for balls, this map has a fixed point. Thus there exists \( x \) such that

\[
f \circ P(x) = x.
\]

Now the equation also requires \( x \in K \) and so \( P(x) = x \). Hence \( f(x) = x \).

**Definition 17.1.12** Let \( H \) be a vector space and let \( U \) and \( V \) be subspaces. \( U \oplus V = H \) if every element of \( H \) can be written as a sum of an element of \( U \) and an element of \( V \) in a unique way.

The case where the closed convex set is a closed subspace is of special importance and in this case the above corollary implies the following.

**Corollary 17.1.13** Let \( K \) be a closed subspace of a Hilbert space, \( H \), and let \( x \in H \). Then for \( z \in K \), \( z = Px \) if and only if

\[
(x - z, y) = 0 \tag{17.1.8}
\]

for all \( y \in K \). Furthermore, \( H = K \oplus K^\perp \) where

\[
K^\perp = \{ x \in H : (x, k) = 0 \text{ for all } k \in K \}
\]

and

\[
||x||^2 = ||x - Px||^2 + ||Px||^2. \tag{17.1.9}
\]

Proof: Since \( K \) is a subspace, the condition (17.1.8) implies \( \text{Re}(x - z, y) \leq 0 \) for all \( y \in K \). Replacing \( y \) with \(-y\), it follows \( \text{Re}(x - z, -y) \leq 0 \) which implies \( \text{Re}(x - z, y) \geq 0 \) for all \( y \). Therefore, \( \text{Re}(x - z, y) = 0 \) for all \( y \in K \). Now let
|α| = 1 and α (x − z, y) = |(x − z, y)|. Since K is a subspace, it follows πy ∈ K for all y ∈ K. Therefore,

\[ 0 = \text{Re}((x - z, \pi y)) = (x - z, \pi y) = \alpha (x - z, y) = |(x - z, y)|. \]

This shows that z = Px, if and only if 17.1.10

For \( x \in H, x = x - Px + Px \) and from what was just shown, \( x - Px \in K^\perp \)
and \( Px \in K \). This shows that \( K^\perp + K = H \). Is there only one way to write
a given element of \( H \) as a sum of a vector in \( K \) with a vector in \( K^\perp \)? Suppose
\( y + z = y_1 + z_1 \) where \( z, z_1 \in K^\perp \) and \( y, y_1 \in K \). Then \( (y - y_1) = (z_1 - z) \)
and so from what was just shown, \( (y - y_1, y - y_1) = (y - y_1, z_1 - z) = 0 \) which shows
\( y_1 = y \) and consequently \( z_1 = z \). Finally, letting \( z = Px \),

\[
||x||^2 = (x - z + z, x - z + z) = ||x - z||^2 + (x - z, z) + (z, x - z) + ||z||^2
\]

This proves the corollary.

The following theorem is called the Riesz representation theorem for the dual of
a Hilbert space. If \( z \in H \) then define an element \( f \in H' \) by the rule \( (x, z) \equiv f (x) \). It
follows from the Cauchy Schwarz inequality and the properties of the inner product
that \( f \in H' \). The Riesz representation theorem says that all elements of \( H' \) are of
this form.

**Theorem 17.1.14** Let \( H \) be a Hilbert space and let \( f \in H' \). Then there exists a
unique \( z \in H \) such that

\[ f (x) = (x, z) \quad (17.1.10) \]

for all \( x \in H \).

**Proof:** Letting \( y, w \in H \) the assumption that \( f \) is linear implies

\[ f (yf(w) - f(y)w) = f (w) f (y) - f (y) f (w) = 0 \]

which shows that \( yf(w) - f(y)w \in f^{-1} (0) \), which is a closed subspace of \( H \) since
\( f \) is continuous. If \( f^{-1} (0) = H \), then \( f \) is the zero map and \( z = 0 \) is the unique
element of \( H \) which satisfies 17.1.11. If \( f^{-1} (0) \neq H \), pick \( u \notin f^{-1} (0) \) and let
\( w \equiv u - Pu \neq 0 \). Thus Corollary 17.1.12 implies \( (y, w) = 0 \) for all \( y \in f^{-1} (0) \). In
particular, let \( y = xf(w) - f(x)w \) where \( x \in H \) is arbitrary. Therefore,

\[ 0 = (f(w)x - f(x)w, w) = f(w)(x, w) - f(x)||w||^2. \]

Thus, solving for \( f (x) \) and using the properties of the inner product,

\[ f(x) = (x, \frac{f(w)w}{||w||^2}) \]

Let \( z = \frac{f(w)w}{||w||^2} \). This proves the existence of \( z \). If \( f(x) = (x, z_i) \) \( i = 1, 2 \),
for all \( x \in H \), then for all \( x \in H \), then \( (x, z_1 - z_2) = 0 \) which implies, upon taking
\( x = z_1 - z_2 \) that \( z_1 = z_2 \). This proves the theorem.

If \( R : H \rightarrow H' \) is defined by \( Rx (y) \equiv (y, x) \), the Riesz representation theorem
above states this map is onto. This map is called the Riesz map. It is routine to
show \( R \) is linear and \( ||Rx|| = |x| \).
17.2 The Hilbert Space $L(U)$

Let $L \in \mathcal{L}(U, H)$. Then one can consider the image of $L, L(U)$ as a Hilbert space. This is another interesting application of Theorem 17.1.8. First here is a definition which involves abominable and atrociously misleading notation which nevertheless seems to be well accepted.

**Definition 17.2.1** Let $L \in \mathcal{L}(U, H)$, the bounded linear maps from $U$ to $H$ for $U, H$ Hilbert spaces. For $y \in L(U)$, let $L^{-1}y$ denote the unique vector in $\{ x : Lx = y \}$ which is closest in $U$ to 0.

Note this is a good definition because $\{ x : Lx = y \}$ is closed thanks to the continuity of $L$ and it is obviously convex. Thus Theorem 17.1.8 applies. With this definition define an inner product on $L(U)$ as follows. For $y, z \in L(U)$, 

$$(y, z)_{L(U)} \equiv (L^{-1}y, L^{-1}z)_U$$

The notation is abominable because $L^{-1}(y)$ is the normal notation for $M_y$.

In terms of linear algebra, this $L^{-1}$ is the Moore Penrose inverse. There you obtain the least squares solution $x$ to $Lx = y$ which has smallest norm. Here there is an actual solution and among those solutions you get the one which has least norm. Of course a real honest solution is also a least squares solution so this is the Moore Penrose inverse restricted to $L(U)$.

First I want to understand $L^{-1}$ better. It is actually fairly easy to understand in terms of geometry. Here is a picture of $L^{-1}(y)$ for $y \in L(U)$. 

```
As indicated in the picture, here is a lemma which gives a description of the situation.

**Lemma 17.2.2** In the context of the above definition, \( L^{-1}(y) \) is characterized by

\[
(L^{-1}(y), x)_U = 0 \quad \text{for all} \quad x \in \ker(L)
\]

\[
L(L^{-1}(y)) = y, \quad (L^{-1}(y) \in M_y)
\]

In addition to this, \( L^{-1} \) is linear and the above definition does define an inner product.

**Proof:** The point \( L^{-1}(y) \) is well defined as noted above. I claim it is characterized by the following for \( y \in L(U) \)

\[
(L^{-1}(y), x)_U = 0 \quad \text{for all} \quad x \in \ker(L)
\]

\[
L(L^{-1}(y)) = y, \quad (L^{-1}(y) \in M_y)
\]

Let \( w \in M_y \) and suppose

\[
(v, x)_U = 0, L(v) = y
\]

Then from the above characterization,

\[
||w||^2 = \left\| \frac{w - v + v}{||v||^2} \right\|^2 = ||w - v||^2 + ||v||^2
\]

which shows that \( w = L^{-1}(y) \) if and only if \( w = v \) just described. From this characterization, it is clear that \( L^{-1} \) is linear. Then it is also obvious that

\[
(y, z)_{L(U)} = (L^{-1}y, L^{-1}z)_U
\]

also specifies an inner product. The algebraic axioms are all obvious because \( L^{-1} \) is linear. If \( (y, y)_{L(U)} = 0 \), then \( ||L^{-1}y||^2_U = 0 \) and so \( L^{-1}y = 0 \) which requires \( y = L(L^{-1}y) = 0 \). ■

With the above definition, here is the main result.

**Theorem 17.2.3** Let \( U, H \) be Hilbert spaces and let \( L \in \mathcal{L}(U, H) \). Then Definition [17.2.1] makes \( L(U) \) into a Hilbert space. Also \( L : U \to L(U) \) is continuous and \( L^{-1} : L(U) \to U \) is continuous. Also,

\[
||L||_{\mathcal{L}(U,H)} ||Lx||_{L(U)} \geq ||Lx||_H \quad \text{(17.2.11)}
\]

If \( U \) is separable, so is \( L(U) \). Also \( (L^{-1}(y), x) = 0 \) for all \( x \in \ker(L) \), and \( L^{-1} : L(U) \to U \) is linear. Also, in case that \( L \) is one to one, both \( L \) and \( \text{L}^{-1} \) preserve norms.
Proof: First consider the claim that \( L : U \to L(U) \) is continuous and \( L^{-1} : L(U) \to U \) is also continuous. Why is \( L \) continuous? Say \( u_n \to 0 \) in \( U \). Then
\[
\|Lu_n\|_{L(U)} = \|L^{-1}(L(u_n))\|_U.
\]
Now \( \|L^{-1}(L(u_n))\|_U \leq \|u_n\|_U \) and so it converges to 0. (Recall that \( L^{-1}(Lu_n) \) is the smallest vector in \( U \) which maps to \( Lu_n \). Since \( u_n \) is mapped by \( L \) to \( Lu_n \), it follows that \( \|L^{-1}(L(u_n))\|_U \leq \|u_n\|_U \). Hence \( L \) is continuous.

Next, why is \( L^{-1} \) continuous? Let \( \|y_n\|_{L(U)} \to 0 \). This requires \( \|L^{-1}(y_n)\|_U \to 0 \) by definition of the norm in \( L(U) \). Thus \( L^{-1} \) is continuous.

Why is \( L(U) \) a Hilbert space? Let \( \{y_n\} \) be a Cauchy sequence in \( L(U) \). Then from what was just observed, it follows that \( L^{-1}(y_n) \) is a Cauchy sequence in \( U \). Hence \( L^{-1}(y_n) \to x \in U \). It follows that \( y_n = L(L^{-1}(y_n)) \to Lx \) in \( L(U) \). This is in the norm of \( L(U) \). It was just shown that \( L \) is continuous as a map from \( U \) to \( L(U) \). This shows that \( L(U) \) is a Hilbert space. It was already shown that it is an inner product space and this has shown that it is complete.

If \( x \in U \), then \( \|Lx\|_H \leq \|L\|_{L(U,H)} \|x\|_U \). It follows that
\[
\|L(x)\|_H = \|L(L^{-1}(L(x)))\|_H \leq \|L\|_{L(U,H)} \|L^{-1}(L(x))\|_U = \|L\|_{L(U,H)} \|L(x)\|_{L(U)}.
\]
This verifies (7.2.11).

If \( U \) is separable, then letting \( D \) be a countable dense subset, it follows from the continuity of the operators \( L, L^{-1} \) discussed above that \( L(D) \) is separable in \( U \). To see this, note that
\[
\|L(x_n - x)\|_{L(U)} = \|L(L^{-1}(L(x_n - x)))\|_U \leq \|L\|_{L(U,H)} \|L^{-1}(L(x_n - x))\|_U \leq \|L\|_{L(U,H)} \|x_n - x\|_U
\]
As before, \( L^{-1}(L(x_n - x)) \) is the smallest vector which maps onto \( L(x_n - x) \) and so its norm is no larger than \( \|x_n - x\|_U \).

Consider the last claim. If \( L \) is one to one, then for \( y \in L(U) \), there is only one vector which maps to \( y \). Therefore,
\[
L^{-1}(L(x)) = x.
\]
Hence for \( y \in L(U) \),
\[
\|y\|_{L(U)} = \|L^{-1}(y)\|_U
\]
Also,
\[
\|Lu\|_{L(U)} = \|L^{-1}(L(u))\|_U = \|u\|_U
\]
Now here is another argument for various continuity claims.
\[
\|Lx\|_{L(U)} = \|L^{-1}(Lx)\|_U \leq \|x\|_U
\]
because \( L^{-1}(Lx) \) is the smallest thing in \( U \) which maps to \( Lx \) and \( x \) is something which maps to \( Lx \) so it follows that the inequality holds. Hence \( L \in L(U,L(U)) \) and in fact, \( \|L\|_{L(U,L(U))} = 1 \). Next, letting \( y \in L(U) \),
\[
\|L^{-1}y\|_U = \|y\|_{L(U)}
\]
and so $\|L^{-1}\|_{L(L(U),U)} = 1$ and this shows that $L \in \mathcal{L}(U, L(U))$ while $L^{-1} \in \mathcal{L}(L(U), U)$ and both have norm equal to 1.

Now

$$\|Lx\|_H = \|L(L^{-1}(Lx))\|_H \leq \|L\|_{L(U,H)} \|L^{-1}(Lx)\|_U = \|L\|_{L(U,H)} \|Lx\|_{L(U)}$$

Now here are some other very interesting results. I am following [98].

**Lemma 17.2.4** Let $L \in \mathcal{L}(U, H)$. Then $L \left( \overline{B(0,r)} \right)$ is closed and convex.

**Proof:** It is clear this is convex since $L$ is linear. Why is it closed? $\overline{B(0,r)}$ is compact in the weak topology by the Banach Alaoglu theorem, Theorem [15.3.4] on Page [179]. Furthermore, $L$ is continuous with respect to the weak topologies on $U$ and $H$. Here is why this is so. Suppose $u_n \rightarrow u$ weakly in $U$. Then if $h \in H$,

$$(Lu_n, h) = (u_n, L^*h) \rightarrow (u, L^*h) = (Lu, h)$$

which shows $Lu_n \rightarrow Lu$ weakly. Therefore, $L \left( \overline{B(0,r)} \right)$ is weakly compact because it is the continuous image of a compact set. Therefore, it must also be weakly closed because the weak topology is a Hausdorff space. (See Lemma [16.3.2] on Page [174], and so you can apply the separation theorem, Theorem [16.2.5] on Page [167] to obtain a separating functional. Thus if $x \neq y$, there exists $f \in H'$ such that $\Re f(y) > c > \Re f(x)$ and so taking

$$2r < \min (c - \Re f(x), \Re f(y) - c),$$

$$B_f(x,r) \cap B_f(y,r) = \emptyset$$

where

$$B_f(x,r) \equiv \{y \in H : |f(x-y)| < r\}$$

is an example of a basic open set in the weak topology.)

Now suppose $p \notin L \left( \overline{B(0,r)} \right)$. Since the set is weakly closed and convex, it follows by Theorem [16.2.4] and the Riesz representation theorem for Hilbert space that there exists $z \in H$ such that

$$\Re (p, z) > c > \Re (Lx, z)$$

for all $x \in \overline{B(0,r)}$. Therefore, $p$ cannot be a strong limit point because if it were, there would exist $x_n \in \overline{B(0,r)}$ such that $Lx_n \rightarrow p$ which would require $\Re (Lx_n, z) \rightarrow \Re (p, z)$ which is prevented by the above inequality. This proves the lemma.

Now here is a very interesting result about showing that $T_1(U_1) = T_2(U_2)$ where $U_i$ is a Hilbert space and $T_i \in \mathcal{L}(U_i, H)$. The situation is as indicated in the diagram.

$$\begin{array}{c}
H \\
\uparrow \\
U_1 \leftarrow T_1 \rightarrow \leftarrow T_2 \rightarrow U_2
\end{array}$$

The question is whether $T_1U_1 = T_2U_2$. 
Theorem 17.2.5 Let $U_i, i = 1, 2$ and $H$ be Hilbert spaces and let $T_i \in \mathcal{L}(U_i, H)$. If there exists $c \geq 0$ such that for all $x \in H$

$$||T_i^* x||_1 \leq c ||T_2 x||_2$$  \hspace{1cm} (17.2.12)

then

$$T_1 \left( B(0, 1) \right) \subseteq T_2 \left( B(0, c) \right)$$ \hspace{1cm} (17.2.13)

and so $T_1(U_1) \subseteq T_2(U_2)$. If $||T_i^* x||_1 = ||T^* x||_2$ for all $x \in H$, then $T_1(U_1) = T_2(U_2)$ and in addition to this,

$$||T_1^{-1} x||_1 = ||T_2^{-1} x||_2$$ \hspace{1cm} (17.2.14)

for all $x \in T_1(U_1) = T_2(U_2)$. In this theorem, $T_i^{-1}$ refers to Definition 17.2.7.

Proof: Consider the first claim. If it is not so, then there exists $u_0, ||u_0||_1 \leq 1$ but

$$T_1(u_0) \notin T_2 \left( B(0, c) \right)$$

the latter set being a closed convex nonempty set thanks to Lemma 17.2.4. Then by the separation theorem, Theorem 16.2.5 there exists $z \in H$ such that

$$\text{Re} \left( T_1(u_0), z \right)_H > 1 > \text{Re} \left( T_2(v), z \right)_H$$

for all $||v||_2 \leq c$. Therefore, replacing $v$ with $v\theta$ where $\theta$ is a suitable complex number having modulus 1, it follows

$$||T_1 z|| > 1 > |(v, T_2 z)|_{U_2}$$  \hspace{1cm} (17.2.15)

for all $||v||_2 \leq c$. If $c = 0$, (17.2.14) gives a contradiction immediately because of (17.2.13). Assume then that $c > 0$. From (17.2.13), if $||v||_2 \leq 1$, then

$$|(v, T_2 z)|_{U_2} < \frac{1}{c} < \frac{1}{c} ||T_i^* z||$$

Then from (17.2.13),

$$||T_2 z||_{U_2} = \sup_{||v|| \leq 1} |(v, T_2 z)|_{U_2} \leq \frac{1}{c} < \frac{1}{c} ||T_i^* z||$$

which contradicts (17.2.14). Therefore, it is clear that $T_1(U_1) \subseteq T_2(U_2)$.

Now consider the second claim. The first part shows $T_1(U_1) = T_2(U_2)$. Denote by $u_i \in U_i$, the point $T_i^{-1} x$. Without loss of generality, it can be assumed $x \neq 0$ because if $x = 0$, then the definition of $T_i^{-1}$ gives $T_i^{-1}(x) = 0$. Thus for $x \neq 0$ neither $u_i$ can equal 0. I need to verify that $||u_1||_1 = ||u_2||_2$. Suppose then that this is not so. Say $||u_1||_1 > ||u_2||_2 > 0$.

$$\frac{x}{||u_2||_2} = T_2 \left( \frac{u_2}{||u_2||_2} \right) \in T_2 \left( B(0, 1) \right)$$
But from the first part of the theorem this equals $T_1 \left( B(0,1) \right)$ and so there exists $u'_1 \in B(0,1)$ such that
\[
x \left\| u_2 \right\|_2 = T_1 u'_1.
\]
Hence
\[
T_1 \left( u'_1 - \frac{u_1}{\left\| u_2 \right\|_2} \right) = \frac{x}{\left\| u_2 \right\|_2} - \frac{x}{\left\| u_2 \right\|_2} = 0.
\]
From Theorem 17.2.3 this implies
\[
0 = \left( u_1, u'_1 - \frac{u_1}{\left\| u_2 \right\|_2} \right) \leq \left\| u_1 \right\|_1 \left\| u'_1 \right\|_1 - \left\| u_1 \right\|_1 \frac{\left\| u_1 \right\|_1}{\left\| u_2 \right\|_2} \left\| u_2 \right\|_2
\]
which is a contradiction because it was assumed $\frac{\left\| u_1 \right\|_1}{\left\| u_2 \right\|_2} > 1$. This proves the theorem.

17.3 Approximations In Hilbert Space

The Gram Schmidt process applies in any Hilbert space.

**Theorem 17.3.1** Let $\{x_1, \ldots, x_n\}$ be a basis for $M$ a subspace of $H$ a Hilbert space. Then there exists an orthonormal basis for $M$, $\{u_1, \ldots, u_n\}$ which has the property that for each $k \leq n$, $\text{span}(x_1, \ldots, x_k) = \text{span}(u_1, \ldots, u_k)$. Also if $\{x_1, \ldots, x_n\} \subseteq H$, then
\[
\text{span}(x_1, \ldots, x_n)
\]
is a closed subspace.

**Proof:** Let $\{x_1, \ldots, x_n\}$ be a basis for $M$. Let $u_1 \equiv x_1 / |x_1|$. Thus for $k = 1$, $\text{span}(u_1) = \text{span}(x_1)$ and $\{u_1\}$ is an orthonormal set. Now suppose for some $k < n$, $u_1, \ldots, u_k$ have been chosen such that $(u_j \cdot u_l) = \delta_{jl}$ and $\text{span}(x_1, \ldots, x_k) = \text{span}(u_1, \ldots, u_k)$. Then define
\[
u_{k+1} \equiv \frac{x_{k+1} - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) u_j}{\left| x_{k+1} - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) u_j \right|},
\]
where the denominator is not equal to zero because the $x_j$ form a basis and so
\[
x_{k+1} \notin \text{span}(x_1, \ldots, x_k) = \text{span}(u_1, \ldots, u_k)
\]
Thus by induction,
\[
u_{k+1} \in \text{span}(u_1, \ldots, u_k, x_{k+1}) = \text{span}(x_1, \ldots, x_k, x_{k+1})
\]
Also, \( x_{k+1} \in \text{span} \{u_1, \cdots, u_k, u_{k+1}\} \) which is seen easily by solving (17.3.16) for \( x_{k+1} \)
and it follows

\[
\text{span} \{x_1, \cdots, x_k, x_{k+1}\} = \text{span} \{u_1, \cdots, u_k, u_{k+1}\}.
\]

If \( l \leq k \),

\[
(u_{k+1} \cdot u_l) = C \left( (x_{k+1} \cdot u_l) - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) (u_j \cdot u_l) \right)
\]

\[
= C \left( (x_{k+1} \cdot u_l) - \sum_{j=1}^{k} (x_{k+1} \cdot u_j) \delta_{lj} \right)
\]

\[
= C \left( (x_{k+1} \cdot u_l) - (x_{k+1} \cdot u_l) \right) = 0.
\]

The vectors, \( \{u_j\}_{j=1}^{n} \), generated in this way are therefore an orthonormal basis because each vector has unit length.

Consider the second claim about finite dimensional subspaces. Without loss of generality, assume \( \{x_1, \cdots, x_n\} \) is linearly independent. If it is not, delete vectors until a linearly independent set is obtained. Then by the first part, \( \text{span} \{x_1, \cdots, x_n\} = \text{span} \{u_1, \cdots, u_n\} \equiv M \) where the \( u_i \) are an orthonormal set of vectors. Suppose \( \{y_k\} \subseteq M \) and \( y_k \to y \in H \). Is \( y \in M \)? Let

\[
y_k = \sum_{j=1}^{n} c_{kj} u_j \]

Then let \( c^k = (c_1^k, \cdots, c_n^k)^T \). Then

\[
|c^k - c'|^2 = \sum_{j=1}^{n} |c_j^k - c_j'|^2 = \left( \sum_{j=1}^{n} (c_j^k - c_j') u_j, \sum_{j=1}^{n} (c_j^k - c_j') u_j \right)
\]

\[
= ||y_k - y||^2
\]

which shows \( \{c^k\} \) is a Cauchy sequence in \( \mathbb{R}^n \) and so it converges to \( c \in \mathbb{R}^n \). Thus

\[
y = \lim_{k \to \infty} y_k = \lim_{k \to \infty} \sum_{j=1}^{n} c_j^k u_j = \sum_{j=1}^{n} c_j u_j \in M.
\]

This completes the proof.

**Theorem 17.3.2** Let \( M \) be the span of \( \{u_1, \cdots, u_n\} \) in a Hilbert space, \( H \) and let \( y \in H \). Then \( Py \) is given by

\[
Py = \sum_{k=1}^{n} (y, u_k) u_k \quad (17.3.17)
\]
and the distance is given by

\[ \sqrt{|y|^2 - \sum_{k=1}^{n} |(y, u_k)|^2}. \]  \hspace{1cm} (17.3.18)

**Proof:**

\[
\begin{pmatrix}
y - \sum_{k=1}^{n} (y, u_k) u_k, u_p \end{pmatrix} = (y, u_p) - \sum_{k=1}^{n} (y, u_k) (u_k, u_p) \\
= (y, u_p) - (y, u_p) = 0
\]

It follows that

\[
\begin{pmatrix}
y - \sum_{k=1}^{n} (y, u_k) u_k, u \end{pmatrix} = 0
\]

for all \( u \in M \) and so by Corollary 17.3.17 this verifies 17.3.17.

The square of the distance, \( d \) is given by

\[
d^2 = \left( y - \sum_{k=1}^{n} (y, u_k) u_k, y - \sum_{k=1}^{n} (y, u_k) u_k \right) \\
= |y|^2 - 2 \sum_{k=1}^{n} |(y, u_k)|^2 + \sum_{k=1}^{n} |(y, u_k)|^2
\]

and this shows 17.3.18.

What if the subspace is the span of vectors which are not orthonormal? There is a very interesting formula for the distance between a point of a Hilbert space and a finite dimensional subspace spanned by an arbitrary basis.

**Definition 17.3.3** Let \( \{x_1, \ldots, x_n\} \subseteq H \), a Hilbert space. Define

\[
G(x_1, \ldots, x_n) \equiv \begin{pmatrix}
(x_1, x_1) & \cdots & (x_1, x_n) \\
\vdots & \ddots & \vdots \\
(x_n, x_1) & \cdots & (x_n, x_n)
\end{pmatrix} \hspace{1cm} (17.3.19)
\]

Thus the \( ij \)th entry of this matrix is \( (x_i, x_j) \). This is sometimes called the Gram matrix. Also define \( G(x_1, \ldots, x_n) \) as the determinant of this matrix, also called the Gram determinant.

\[
G(x_1, \ldots, x_n) \equiv \begin{vmatrix}
(x_1, x_1) & \cdots & (x_1, x_n) \\
\vdots & \ddots & \vdots \\
(x_n, x_1) & \cdots & (x_n, x_n)
\end{vmatrix} \hspace{1cm} (17.3.20)
\]

The theorem is the following.
Theorem 17.3.4 Let \( M = \text{span}(x_1, \cdots, x_n) \subseteq H \), a Real Hilbert space where \( \{x_1, \cdots, x_n\} \) is a basis and let \( y \in H \). Then letting \( d \) be the distance from \( y \) to \( M \),

\[
d^2 = \frac{G(x_1, \cdots, x_n, y)}{G(x_1, \cdots, x_n)}. \tag{17.3.21}
\]

Proof: By Theorem 17.3.1 \( M \) is a closed subspace of \( H \). Let \( \sum_{k=1}^{n} \alpha_k x_k \) be the element of \( M \) which is closest to \( y \). Then by Corollary 17.1.13,

\[
\left( y - \sum_{k=1}^{n} \alpha_k x_k, x_p \right) = 0
\]

for each \( p = 1, 2, \cdots, n \). This yields the system of equations,

\[
(y, x_p) = \sum_{k=1}^{n} (x_p, x_k) \alpha_k, p = 1, 2, \cdots, n \tag{17.3.22}
\]

Also by Corollary 17.1.3:

\[
||y||^2 = \left( y - \sum_{k=1}^{n} \alpha_k x_k \right)^2 + \left( \sum_{k=1}^{n} \alpha_k x_k \right)^2
\]

and so, using 17.3.22,

\[
||y||^2 = d^2 + \sum_{j} \left( \sum_{k} \alpha_k (x_k, x_j) \right) \alpha_j = d^2 + \sum_{j} (y, x_j) \alpha_j \tag{17.3.23}
\]

\[
= d^2 + y_x^T \alpha \tag{17.3.24}
\]

in which

\[
y_x^T = ((y, x_1), \cdots, (y, x_n)), \quad \alpha^T = (\alpha_1, \cdots, \alpha_n).
\]

Then 17.3.22 and 17.3.23 imply the following system

\[
\begin{pmatrix}
G(x_1, \cdots, x_n) & 0 \\
y_x^T & 1
\end{pmatrix}
\begin{pmatrix}
\alpha \\
d^2
\end{pmatrix}
= \begin{pmatrix}
y_x \\
||y||^2
\end{pmatrix}
\]
By Cramer’s rule,
\[ d^2 = \frac{\det \begin{pmatrix} G(x_1, \ldots, x_n) & y_x \\ y_x^T & ||y||^2 \end{pmatrix}}{\det \begin{pmatrix} G(x_1, \ldots, x_n) & 0 \\ y_x^T & 1 \end{pmatrix}} \]
\[ = \frac{\det \begin{pmatrix} G(x_1, \ldots, x_n) & y_x \\ y_x^T & ||y||^2 \end{pmatrix}}{\det \left( G(x_1, \ldots, x_n, y) \right) \det \left( G(x_1, \ldots, x_n) \right)} \]
\[ = \frac{\det \left( G(x_1, \ldots, x_n) \right)}{\det \left( G(x_1, \ldots, x_n, y) \right)} \]
and this proves the theorem.

17.4 The Müntz Theorem

Recall the polynomials are dense in \( C([0,1]) \). This is a consequence of the Weierstrass approximation theorem. Now consider finite linear combinations of the functions, \( p^k \) where \( \{p_0, p_1, p_2, \ldots\} \) is a sequence of nonnegative real numbers, \( p_0 \equiv 0 \). The Müntz theorem says this set, \( S \) of finite linear combinations is dense in \( C([0,1]) \) exactly when \( \sum_{k=1}^{\infty} \frac{1}{p_k} = \infty \). There are two versions of this theorem, one for density of \( S \) in \( L^2(0,1) \) and one for \( C([0,1]) \). The presentation follows Cheney [32].

Recall the Cauchy identity presented earlier, Theorem 4.9.1 on Page 85 which is stated here for convenience.

Theorem 17.4.1 The following identity holds.
\[
\prod_{i,j} (a_i + b_j) \begin{vmatrix} 1 \frac{1}{a_1 + b_1} \cdots \frac{1}{a_1 + b_n} \\ \vdots \vdots \vdots \\ \frac{1}{a_n + b_1} \cdots \frac{1}{a_n + b_n} \end{vmatrix} = \prod_{j<i} (a_i - a_j)(b_i - b_j). \quad (17.4.25)
\]

Lemma 17.4.2 Let \( m, p_1, \ldots, p_n \) be distinct real numbers larger than \(-1/2\). Thus the functions, \( f_m(x) \equiv x^m, f_{p_j}(x) \equiv x^{p_j} \) are all in \( L^2(0,1) \). Let \( M = \text{span}(f_{p_1}, \ldots, f_{p_n}) \).

Then the \( L^2 \) distance, \( d \) between \( f_m \) and \( M \) is
\[
d = \frac{1}{\sqrt{2m+1}} \prod_{j=1}^{n} \frac{|m - p_j|}{m + p_j + 1}
\]

Proof: By Theorem 17.3.4
\[
d^2 = \frac{G(f_{p_1}, \ldots, f_{p_n}, f_m)}{G(f_{p_1}, \ldots, f_{p_n})^2}.
\]
\[ (f_{p_i}, f_{p_j}) = \int_0^1 x^{p_i} x^{p_j} \, dx = \frac{1}{1 + p_i + p_j} \]

Therefore,
\[
d^2 = \frac{1}{(1 + p_1 + p_1)(1 + p_1 + p_2) \ldots \frac{1}{1 + p_n + p_1)} \frac{1}{1 + p_n + p_2) \ldots (1 + p_n + p_n)} \]

Now from the Cauchy identity, letting \( a_i = p_i + \frac{1}{2} \) and \( b_j = \frac{1}{2} + p_j \) with \( p_{n+1} = m \), the numerator of the above equals
\[
\frac{\prod_{j<i \leq n+1} (p_i - p_j)(p_i - p_j)}{\prod_{i,j \leq n+1} (p_i + p_j + 1)}
\]

\[
= \frac{\prod_{k=1}^n (m-p_k)^2 \prod_{j<i \leq n} (p_i - p_j)^2}{\prod_{i=1}^n (m + p_i + 1)^2 \prod_{i,j \leq n} (p_i + p_j + 1)(2m+1)}
\]

while the denominator equals
\[
\frac{\prod_{j<i \leq n} (p_i - p_j)^2}{\prod_{i,j \leq n} (p_i + p_j + 1)}
\]

Therefore,
\[
d^2 = \frac{\left( \prod_{k=1}^n (m-p_k)^2 \prod_{j<i \leq n} (p_i - p_j)^2 \right)}{\left( \prod_{i,j \leq n}(p_i+p_j+1)(2m+1) \right)}
\]

\[
= \frac{\prod_{k=1}^n (m-p_k)^2}{\prod_{i=1}^n (m + p_i + 1)^2 (2m+1)}
\]

which shows
\[
d = \frac{1}{\sqrt{2m+1}} \prod_{k=1}^n \frac{|m-p_k|}{m+p_k+1}.
\]
and this proves the lemma.

The following lemma relates an infinite sum to a product. First consider the graph of \( \ln (1 - x) \) for \( x \in [0, \frac{1}{2}] \). Here is a rough sketch with two lines, \( y = -x \) which lies above the graph of \( \ln (1 - x) \) and \( y = -2x \) which lies below.

\[ \text{Lemma 17.4.3} \quad \text{Let } a_n \neq 1, a_n > 0, \text{ and } \lim_{n \to \infty} a_n = 0. \text{ Then} \]
\[ \prod_{k=1}^{\infty} (1 - a_n) \equiv \lim_{n \to \infty} \prod_{k=1}^{n} (1 - a_n) = 0 \]
\[ \text{if and only if} \]
\[ \sum_{n=1}^{\infty} a_n = +\infty. \]

\textbf{Proof:} Without loss of generality, you can assume \( a_n < 1/2 \) because the two conditions are determined by the values of \( a_n \) for \( n \) large. By the above sketch the following is obtained.
\[ \ln \prod_{k=1}^{n} (1 - a_k) = \sum_{k=1}^{n} \ln (1 - a_k) \in \left[ -2 \sum_{k=1}^{n} a_k, - \sum_{k=1}^{n} a_k \right] . \]
Therefore,
\[ e^{-2\sum_{k=1}^{n} a_k} \leq \prod_{k=1}^{n} (1 - a_k) \leq e^{-\sum_{k=1}^{n} a_k} \]
The conclusion follows.

The following is Müntz’s first theorem.

\textbf{Theorem 17.4.4} \ Let \( \{ p_n \} \) be a sequence of real numbers larger than \(-1/2\) such that \( \lim_{n \to \infty} p_n = \infty. \) Let \( S \) denote the set of finite linear combinations of the functions, \( \{ x^{p_1}, x^{p_2}, \ldots \} \). Then \( S \) is dense in \( L^2 (0,1) \) if and only if
\[ \sum_{i=1}^{\infty} \frac{1}{p_i} = \infty. \]
Proof: The polynomials are dense in $L^2(0,1)$ and so $S$ is dense in $L^2(0,1)$ if and only if for every $\varepsilon > 0$ there exists a function $f$ from $S$ such that for each integer $m \geq 0$, \( \left( \int_0^1 |f(x) - x^m|^2 \, dx \right)^{1/2} < \varepsilon \). This happens if and only if for all $n$ large enough, the distance in $L^2(0,1)$ between the function, $x \to x^m$ and span $\{x^{p_1}, x^{p_2}, \ldots, x^{p_n}\}$ is less than $\varepsilon$. However, from Lemma 17.4.2 this distance equals

\[
\frac{1}{\sqrt{2m+1}} \prod_{k=1}^n \frac{|m-p_k|}{m+p_k+1}
\]

Thus $S$ is dense if and only if

\[
\prod_{k=1}^{\infty} \left( 1 - \left( 1 - \frac{|m-p_k|}{m+p_k+1} \right) \right) = 0
\]

which, by Lemma 17.4.2, happens if and only if

\[
\sum_{k=1}^{\infty} \left( 1 - \frac{|m-p_k|}{m+p_k+1} \right) = +\infty
\]

But this sum equals

\[
\sum_{k=1}^{\infty} \left( \frac{m+p_k+1-|m-p_k|}{m+p_k+1} \right)
\]

which has the same convergence properties as $\sum \frac{1}{p_k}$ by the limit comparison test. This proves the theorem.

The following is Müntz’s second theorem.

**Theorem 17.4.5** Let $S$ be finite linear combinations of $\{1, x^{p_1}, x^{p_2}, \ldots\}$ where $p_j \geq 1$ and $\lim_{n \to \infty} p_n = \infty$. Then $S$ is dense in $C([0,1])$ if and only if $\sum_{k=1}^{\infty} \frac{1}{p_k} = \infty$.

Proof: If $S$ is dense in $C([0,1])$ then $S$ must also be dense in $L^2(0,1)$ and so by Theorem 17.4.2 $\sum_{k=1}^{\infty} \frac{1}{p_k} = \infty$.

Suppose then that $\sum_{k=1}^{\infty} \frac{1}{p_k} = \infty$ so that by Theorem 17.4.2, $S$ is dense in $L^2(0,1)$. The theorem will be proved if it is shown that for all $m$ a nonnegative integer,

\[
\max \{|x^m - f(x)| : x \in [0,1]\} < \varepsilon
\]

for some $f \in S$. This is true if $m = 0$ because $1 \in S$. Suppose then that $m > 0$. Let $S'$ denote finite linear combinations of the functions

\[
\{x^{p_1-1}, x^{p_2-1}, \ldots\}
\]
These functions are also dense in $L^2(0,1)$ because $\sum_{k=1}^{\infty} \frac{1}{p_k-1} = \infty$ by the limit comparison test. Then by Theorem 17.4.4, there exists $f \in S'$ such that
$$\left( \int_0^1 |f(x) - mx^{n-1}|^2 \, dx \right)^{1/2} < \varepsilon.$$ 
Thus $F(x) \equiv \int_0^x f(t) \, dt \in S$ and
$$|F(x) - x^n| = \left| \int_x^0 (f(t) - mt^{n-1}) \, dt \right| \leq \int_0^x |f(t) - mt^{n-1}| \, dt \leq \left( \int_0^1 |f(t) - mt^{n-1}|^2 \, dt \right)^{1/2} \left( \int_0^1 dx \right)^{1/2} \leq \varepsilon$$
and this proves the theorem.

### 17.5 Orthonormal Sets

The concept of an orthonormal set of vectors is a generalization of the notion of the standard basis vectors of $\mathbb{R}^n$ or $\mathbb{C}^n$.

**Definition 17.5.1** Let $H$ be a Hilbert space. $S \subseteq H$ is called an orthonormal set if $\|x\| = 1$ for all $x \in S$ and $(x,y) = 0$ if $x, y \in S$ and $x \neq y$. For any set, $D$,
$$D^\perp \equiv \{ x \in H : (x,d) = 0 \text{ for all } d \in D \}.$$
If $S$ is a set, span $(S)$ is the set of all finite linear combinations of vectors from $S$.

You should verify that $D^\perp$ is always a closed subspace of $H$.

**Theorem 17.5.2** In any separable Hilbert space, $H$, there exists a countable orthonormal set, $S = \{ x_i \}$ such that the span of these vectors is dense in $H$. Furthermore, if span $(S)$ is dense, then for $x \in H$,
$$x = \sum_{i=1}^{\infty} (x, x_i) x_i = \lim_{n \to \infty} \sum_{i=1}^{n} (x, x_i) x_i. \quad (17.5.26)$$

**Proof:** Let $\mathcal{F}$ denote the collection of all orthonormal subsets of $H$. $\mathcal{F}$ is nonempty because $\{ x \} \in \mathcal{F}$ where $\|x\| = 1$. The set, $\mathcal{F}$, is a partially ordered set with the order given by set inclusion. By the Hausdorff maximal theorem, there exists a maximal chain, $\mathcal{C}$, in $\mathcal{F}$. Then let $S \equiv \cup \mathcal{C}$. It follows $S$ must be a maximal orthonormal set of vectors. Why? It remains to verify that $S$ is countable span $(\mathcal{S})$.
17.5. ORTHONORMAL SETS

is dense, and the condition \(17.5.26\) holds. To see \(S\) is countable note that if \(x, y \in S\), then

\[ ||x - y||^2 = ||x||^2 + ||y||^2 - 2 \operatorname{Re}(x, y) = ||x||^2 + ||y||^2 = 2.\]

Therefore, the open sets, \(B \left( x, \frac{1}{2} \right)\) for \(x \in S\) are disjoint and cover \(S\). Since \(H\) is assumed to be separable, there exists a point from a countable dense set in each of these disjoint balls showing there can only be countably many of the balls and that consequently, \(S\) is countable as claimed.

It remains to verify \(17.5.26\) and that \(\operatorname{span}(S)\) is dense. If \(\operatorname{span}(S)\) is not dense, then \(\operatorname{span}(S)\) is a closed proper subspace of \(H\) and letting \(y \notin \operatorname{span}(S)\),

\[ z = \frac{y - P y}{||y - P y||} \in \operatorname{span}(S)^\perp. \]

But then \(S \cup \{z\}\) would be a larger orthonormal set of vectors contradicting the maximality of \(S\).

It remains to verify \(17.5.26\). Let \(S = \{x_i\}_{i=1}^\infty\) and consider the problem of choosing the constants, \(c_k\) in such a way as to minimize the expression

\[ \left\| x - \sum_{k=1}^n c_k x_k \right\|^2 = ||x||^2 + \sum_{k=1}^n |c_k|^2 - \sum_{k=1}^n c_k^* (x, x_k) - \sum_{k=1}^n c_k (x, x_k). \]

This equals

\[ ||x||^2 + \sum_{k=1}^n |c_k|^2 - \sum_{k=1}^n c_k^* (x, x_k) - \sum_{k=1}^n |(x, x_k)|^2 \]

and therefore, this minimum is achieved when \(c_k = (x, x_k)\) and equals

\[ ||x||^2 - \sum_{k=1}^n |(x, x_k)|^2 \]

Now since \(\operatorname{span}(S)\) is dense, there exists \(n\) large enough that for some choice of constants, \(c_k\),

\[ \left\| x - \sum_{k=1}^n c_k x_k \right\|^2 < \varepsilon. \]

However, from what was just shown,

\[ \left\| x - \sum_{i=1}^n (x, x_i) x_i \right\|^2 \leq \left\| x - \sum_{k=1}^n c_k x_k \right\|^2 < \varepsilon \]

showing that \(\lim_{n \to \infty} \sum_{i=1}^n (x, x_i) x_i = x\) as claimed. This proves the theorem.

The proof of this theorem contains the following corollary.
Corollary 17.5.3 Let $S$ be any orthonormal set of vectors and let

$$\{x_1, \ldots, x_n\} \subseteq S.$$ 

Then if $x \in H$

$$\left\| x - \sum_{k=1}^{n} c_k x_k \right\|^2 \geq \left\| x - \sum_{i=1}^{n} (x, x_i) x_i \right\|^2$$

for all choices of constants, $c_k$. In addition to this, Bessel’s inequality

$$\|x\|^2 \geq \sum_{k=1}^{n} |(x, x_k)|^2.$$ 

If $S$ is countable and span $(S)$ is dense, then letting $\{x_i\}_{i=1}^{\infty} = S$, Corollary 17.5.30 follows.

17.6 Fourier Series, An Example

In this section consider the Hilbert space, $L^2(0, 2\pi)$ with the inner product,

$$\langle f, g \rangle = \int_{0}^{2\pi} f \overline{g} dm.$$ 

This is a Hilbert space because of the theorem which states the $L^p$ spaces are complete, Theorem [3.1.10] on Page 381. An example of an orthonormal set of functions in $L^2(0, 2\pi)$ is

$$\phi_n(x) = \frac{1}{\sqrt{2\pi}} e^{inx}$$

for $n$ an integer. Is it true that the span of these functions is dense in $L^2(0, 2\pi)$?

Theorem 17.6.1 Let $S = \{\phi_n\}_{n \in \mathbb{Z}}$. Then span $(S)$ is dense in $L^2(0, 2\pi)$.

**Proof:** By regularity of Lebesgue measure, it follows from Theorem [3.1.10] that $C_c(0, 2\pi)$ is dense in $L^2(0, 2\pi)$. Therefore, it suffices to show that for $g \in C_c(0, 2\pi)$, then for every $\varepsilon > 0$ there exists $h \in \text{span} (S)$ such that $\|g - h\|_{L^2(0,2\pi)} < \varepsilon$.

Let $T$ denote the points of $\mathbb{C}$ which are of the form $e^{it}$ for $t \in \mathbb{R}$. Let $\mathcal{A}$ denote the algebra of functions consisting of polynomials in $z$ and $1/z$ for $z \in T$. Thus a typical such function would be one of the form

$$\sum_{k=-m}^{m} c_k z^k$$

for $m$ chosen large enough. This algebra separates the points of $T$ because it contains the function, $p(z) = z$. It annihilates no point of $t$ because it contains the constant function 1. Furthermore, it has the property that for $f \in \mathcal{A}$, $\overline{f} \in \mathcal{A}$. By the Stone Weierstrass approximation theorem, Theorem [7.2.10] on Page 189, $\mathcal{A}$ is dense in
Now for $g \in C_c(0, 2\pi)$, extend $g$ to all of $\mathbb{R}$ to be $2\pi$ periodic. Then letting $G(e^{it}) \equiv g(t)$, it follows $G$ is well defined and continuous on $T$. Therefore, there exists $H \in A$ such that for all $t \in \mathbb{R}$,

$$|H(e^{it}) - G(e^{it})| < \varepsilon^2 / 2\pi.$$ 

Thus $H(e^{it})$ is of the form

$$H(e^{it}) = \sum_{k=-m}^{m} c_k e^{ikt} \in \text{span } (S).$$

Let $h(t) = \sum_{k=-m}^{m} c_k e^{ikt}$. Then

$$\left(\int_0^{2\pi} |g - h|^2 \, dx\right)^{1/2} \leq \left(\int_0^{2\pi} \max \{|g(t) - h(t)| : t \in [0, 2\pi]\} \, dx\right)^{1/2} = \left(\int_0^{2\pi} \max \{|G(e^{it}) - H(e^{it})| : t \in [0, 2\pi]\} \, dx\right)^{1/2} < \left(\int_0^{2\pi} \frac{\varepsilon^2}{2\pi}\right)^{1/2} = \varepsilon.$$

This proves the theorem.

**Corollary 17.6.2** For $f \in L^2(0, 2\pi)$,

$$\lim_{m \to \infty} \left\| f - \sum_{k=-m}^{m} (f, \phi_k) \phi_k \right\|_{L^2(0, 2\pi)}$$

**Proof:** This follows from Theorem 17.5.2 on Page 522.

### 17.7 Compact Operators

#### 17.7.1 Compact Operators In Hilbert Space

**Definition 17.7.1** Let $A \in \mathcal{L}(H, H)$ where $H$ is a Hilbert space. Then $|(Ax, y)| \leq ||A|| ||x|| ||y||$ and so the map, $x \to (Ax, y)$ is continuous and linear. By the Riesz representation theorem, there exists a unique element of $H$, denoted by $A^* y$ such that

$$(Ax, y) = (x, A^* y).$$

It is clear $y \to A^* y$ is linear and continuous. $A^*$ is called the adjoint of $A$. $A$ is a self adjoint operator if $A = A^*$. Thus for a self adjoint operator, $(Ax, y) = (x, Ay)$ for all $x, y \in H$. $A$ is a compact operator if whenever $\{x_k\}$ is a bounded sequence, there exists a convergent subsequence of $\{Ax_k\}$. Equivalently, $A$ maps bounded sets to sets whose closures are compact.
The big result is called the Hilbert Schmidt theorem. It is a generalization to arbitrary Hilbert spaces of standard finite dimensional results having to do with diagonalizing a symmetric matrix. There is another statement and proof of this theorem around Page 647.

**Theorem 17.7.2** Let $A$ be a compact self adjoint operator defined on a Hilbert space, $H$. Then there exists a countable set of eigenvalues, $\{\lambda_i\}$ and an orthonormal set of eigenvectors, $u_i$ satisfying

$$\lambda_i \text{ is real, } |\lambda_n| \geq |\lambda_{n+1}|, \quad Au_i = \lambda_i u_i,$$

(17.7.27) and either

$$\lim_{n \to \infty} \lambda_n = 0,$$

(17.7.28)

or for some $n$,

$$\text{span } (u_1, \cdots, u_n) = H.$$  

(17.7.29)

In any case,

$$\text{span } \{u_i\}_{i=1}^\infty \text{ is dense in } A(H).$$

(17.7.30)

and for all $x \in H$,

$$Ax = \sum_{k=1}^\infty \lambda_k (x, u_k) u_k.$$  

(17.7.31)

This sequence of eigenvectors and eigenvalues also satisfies

$$|\lambda_n| = ||A_n||.$$  

(17.7.32)

and

$$A_n : H_n \to H_n.$$  

(17.7.33)

where $H \equiv H_1$ and $H_n \equiv \{u_1, \cdots, u_{n-1}\}^\perp$ and $A_n$ is the restriction of $A$ to $H_n$.

**Proof:** If $A = 0$ then pick $u \in H$ with $||u|| = 1$ and let $\lambda_1 = 0$. Since $A(H) = 0$ it follows the span of $u$ is dense in $A(H)$ and this proves the theorem in this uninteresting case.

Assume from now on $A \neq 0$. Let $\lambda_1$ be real and $\lambda_1^2 \equiv ||A||^2$. From the definition of $||A||$ there exists $x_n, ||x_n|| = 1$, and $||Ax_n|| \to ||A|| = |\lambda_1|$. Now it is clear that $A^2$ is also a compact self adjoint operator. Consider

$$((\lambda_1^2 - A^2) x_n, x_n) = \lambda_1^2 - ||Ax_n||^2 \to 0.$$  

Since $A$ is compact, there exists a subsequence of $\{x_n\}$ still denoted by $\{x_n\}$ such that $Ax_n$ converges to some element of $H$. Thus since $\lambda_1^2 - A^2$ satisfies

$$((\lambda_1^2 - A^2) y, y) \geq 0$$
in addition to being self adjoint, it follows $x, y \rightarrow ((\lambda_1^2 - A^2) x, y)$ satisfies all the axioms for an inner product except for the one which says that $(z, z) = 0$ only if $z = 0$. Therefore, the Cauchy Schwarz inequality may be used to write

$$\left| ((\lambda_1^2 - A^2) x_n, y) \right| \leq \left( (\lambda_1^2 - A^2) y, y \right)^{1/2} \left( (\lambda_1^2 - A^2) x_n, x_n \right)^{1/2}$$

where $e_n \to 0$ as $n \to \infty$. Therefore, taking the sup over all $\|y\| = 1$,

$$\lim_{n \to \infty} \left| (\lambda_1^2 - A^2) x_n \right| = 0.$$

Since $A^2 x_n$ converges, it follows since $\lambda_1 \neq 0$ that $\{x_n\}$ is a Cauchy sequence converging to $x$ with $\|x\| = 1$. Therefore, $A^2 x_n \to A^2 x$ and so

$$\left| (\lambda_1^2 - A^2) x \right| = 0.$$

Now

$$(\lambda_1 I - A)(\lambda_1 I + A) x = (\lambda_1 I + A)(\lambda_1 I - A) x = 0.$$

If $(\lambda_1 I - A) x = 0$, let $u_1 \equiv x$. If $(\lambda_1 I - A) x = y \neq 0$, let $u_1 \equiv \frac{y}{\|y\|}$.

Suppose $\{u_1, \cdots, u_n\}$ is such that $Au_k = \lambda_k u_k$ and $|\lambda_k| \geq |\lambda_{k+1}|$, $|\lambda_k| = |A_k|$ and $A_k : H_k \to H_k$ for $k \leq n$. If

$$\text{span}(u_1, \cdots, u_n) = H$$

this yields the conclusion of the theorem in the situation of \[17.7.29\]. Therefore, assume the span of these vectors is always a proper subspace of $H$. It is shown next that $A_{n+1} : H_{n+1} \to H_{n+1}$. Let

$$y \in H_{n+1} \equiv \{u_1, \cdots, u_n\}^\bot$$

Then for $k \leq n$

$$(Ay, u_k) = (y, Au_k) = \lambda_k (y, u_k) = 0,$$

showing $A_{n+1} : H_{n+1} \to H_{n+1}$ as claimed. There are two cases. Either $\lambda_n = 0$ or it is not. In the case where $\lambda_n = 0$ it follows $A_n = 0$. Every element of $H$ is the sum of one in span $(u_1, \cdots, u_n)$ and one in span $(u_1, \cdots, u_n)^\perp$. (note span $(u_1, \cdots, u_n)$ is a closed subspace.) Thus, if $x \in H$, $x = y + z$ where $y \in \text{span}(u_1, \cdots, u_n)$ and $z \in \text{span}(u_1, \cdots, u_n)^\perp$ and $Az = 0$. Say $y = \sum_{j=1}^{n} c_j u_j$. Then

$$Ax = Ay = \sum_{j=1}^{n} c_j Au_j$$

$$= \sum_{j=1}^{n} c_j \lambda_j u_j \in \text{span}(u_1, \cdots, u_n).$$

The conclusion of the theorem holds in this case because the above equation holds if with $c_i = (x, u_i)$. 

Now consider the case where \( \lambda_n \neq 0 \). In this case repeat the above argument used to find \( u_{n+1} \) and \( A_{n+1} \) for the operator, \( A_{n+1} \). This yields \( u_{n+1} \in H_{n+1} \equiv \{ u_1, \ldots, u_n \}^\perp \) such that

\[
\| u_{n+1} \| = 1, \quad \|Au_{n+1}\| = |\lambda_{n+1}| = \| A_{n+1} \| \leq \| A_n \| = |\lambda_n|
\]

and if it is ever the case that \( \lambda_n = 0 \), it follows from the above argument that the conclusion of the theorem is obtained.

I claim \( \lim_{n \to \infty} \lambda_n = 0 \). If this were not so, then for some \( \varepsilon > 0 \), \( 0 < \varepsilon = \lim_{n \to \infty} |\lambda_n| \) but then

\[
\|Au_n - Au_m\|^2 = \|\lambda_n u_n - \lambda_m u_m\|^2 = |\lambda_n|^2 + |\lambda_m|^2 \geq 2\varepsilon^2
\]

and so there would not exist a convergent subsequence of \( \{Au_k\}_{k=1}^\infty \) contrary to the assumption that \( A \) is compact. This verifies the claim that \( \lim_{n \to \infty} \lambda_n = 0 \).

It remains to verify that \( \text{span} \{\{u_i\} \} \) is dense in \( A(H) \). If \( w \in \text{span} \{\{u_i\} \}^\perp \) then \( w \in H_n \) for all \( n \) and so for all \( n \),

\[
\|Aw\| \leq \|A_n\| \|w\| \leq |\lambda_n| \|w\|.
\]

Therefore, \( Aw = 0 \). Now every vector from \( H \) can be written as a sum of one from

\[
\text{span} \{\{u_i\} \}^\perp = \text{span} \{\{u_i\} \}^\perp
\]

and one from \( \overline{\text{span}} \{\{u_i\} \} \). Therefore, if \( x \in H, x = y + w \) where \( y \in \overline{\text{span}} \{\{u_i\} \} \) and \( w \in \overline{\text{span}} \{\{u_i\} \} \) \( \perp \). It follows \( Aw = 0 \). Also, since \( y \in \overline{\text{span}} \{\{u_i\} \} \), there exist constants, \( c_k \) and \( n \) such that

\[
\left\| y - \sum_{k=1}^n c_k u_k \right\| < \varepsilon.
\]

Therefore, from Corollary 17.5.3,

\[
\left\| y - \sum_{k=1}^n (y, u_k) u_k \right\| = \left\| y - \sum_{k=1}^n (x, u_k) u_k \right\| < \varepsilon.
\]

Therefore,

\[
\|A\| \varepsilon > \left\| A \left( y - \sum_{k=1}^n (x, u_k) u_k \right) \right\| = \left\| Ax - \sum_{k=1}^n (x, u_k) \lambda_k u_k \right\|.
\]

Since \( \varepsilon \) is arbitrary, this shows \( \text{span} \{\{u_i\} \} \) is dense in \( A(H) \) and also implies 17.7.31. This proves the theorem.
17.7. COMPACT OPERATORS

Define \(v \otimes u \in \mathcal{L}(H, H)\) by
\[
v \otimes u (x) = (x, u) v,
\]
then (17.7.31) is of the form
\[
A = \sum_{k=1}^{\infty} \lambda_k u_k \otimes u_k
\]
This is the content of the following corollary.

**Corollary 17.7.3** The main conclusion of the above theorem can be written as
\[
A = \sum_{k=1}^{\infty} \lambda_k u_k \otimes u_k
\]
where the convergence of the partial sums takes place in the operator norm.

**Proof:** Using (17.7.31)
\[
\left| \left( A - \sum_{k=1}^{n} \lambda_k u_k \otimes u_k \right) x, y \right|
= \left| \left( A x - \sum_{k=1}^{n} \lambda_k \langle x, u_k \rangle u_k, y \right) \right|
= \left| \left( \sum_{k=n}^{\infty} \lambda_k \langle x, u_k \rangle u_k, y \right) \right|
= \left| \sum_{k=n}^{\infty} \lambda_k \langle x, u_k \rangle (u_k, y) \right|
\leq |\lambda_n| \left( \sum_{k=n}^{\infty} |\langle x, u_k \rangle|^2 \right)^{1/2} \left( \sum_{k=n}^{\infty} |\langle y, u_k \rangle|^2 \right)^{1/2}
\leq |\lambda_n| \|x\| \|y\|
\]
It follows
\[
\left| \left( A - \sum_{k=1}^{n} \lambda_k u_k \otimes u_k \right) x \right| \leq |\lambda_n| \|x\|
\]
and this proves the corollary.

**Corollary 17.7.4** Let \(A\) be a compact self adjoint operator defined on a separable Hilbert space, \(H\). Then there exists a countable set of eigenvalues, \(\{\lambda_i\}\) and an orthonormal set of eigenvectors, \(v_i\) satisfying
\[
Av_i = \lambda_i v_i, \|v_i\| = 1, \quad \text{(17.7.34)}
\]
\[
\text{span} \{\{v_i\}_{i=1}^{\infty}\} \text{ is dense in } H. \quad \text{(17.7.35)}
\]
Furthermore, if \(\lambda_i \neq 0\), the space, \(V_{\lambda_i} \equiv \{x \in H : Ax = \lambda_i x\}\) is finite dimensional.
Proof: In the proof of the above theorem, let \( W = \text{span} \left( \{ w_i \} \right) \). By Theorem 17.5.2, there is an orthonormal set of vectors, \( \{ w_i \} \) whose span is dense in \( W \). As shown in the proof of the above theorem, \( Aw = 0 \) for all \( w \in W \). Let \( \{ v_i \} \) be an orthonormal set of vectors whose span is dense in \( W \).

It remains to verify the space, \( V \), is finite dimensional. First observe that \( A : V \to V \). Since \( A \) is continuous, it follows that \( A : V \to V \). Thus \( A \) is a compact self-adjoint operator on \( V \), and by Theorem 17.7.2, holds because the only eigenvalue is \( \lambda_i \). This proves the corollary.

Note the last claim of this corollary holds independent of the separability of \( H \). This proves the corollary.

Suppose \( \lambda \notin \{ \lambda_n \} \) and \( \lambda \neq 0 \). Then the above formula for \( A \) yields an interesting formula for \( (A - \lambda I)^{-1} \). Note first that since \( \lim_{n \to \infty} \lambda_n = 0 \), it follows that \( \lambda^2_n / (\lambda_n - \lambda)^2 \) must be bounded, say by a positive constant, \( M \).

Corollary 17.7.5 Let \( A \) be a compact self adjoint operator and let \( \lambda \notin \{ \lambda_n \} \) and \( \lambda \neq 0 \) where the \( \lambda_n \) are the eigenvalues of \( A \). Then

\[
(A - \lambda I)^{-1} x = -\frac{1}{\lambda} x + \frac{1}{\lambda} \sum_{k=1}^{\infty} \frac{\lambda_k}{\lambda_k - \lambda} (x, u_k) u_k .
\] (17.7.36)

Proof: Let \( m < n \). Then since the \( \{ u_k \} \) form an orthonormal set,

\[
\left| \sum_{k=m}^{n} \frac{\lambda_k}{\lambda_k - \lambda} (x, u_k) u_k \right| = \left( \sum_{k=m}^{n} \frac{\lambda_k^2}{\lambda_k - \lambda} \right)^{1/2} \leq M \left( \sum_{k=m}^{n} |(x, u_k)|^2 \right)^{1/2} .
\] (17.7.37)

But from Bessel’s inequality,

\[
\sum_{k=1}^{\infty} |(x, u_k)|^2 \leq ||x||^2
\]

and so for \( m \) large enough, the first term in (17.7.37) is smaller than \( \varepsilon \). This shows the infinite series in (17.7.36) converges. It is now routine to verify that the formula in (17.7.36) is the inverse.

17.8 Sturm Liouville Problems

A Sturm Liouville problem involves the differential equation,

\[
(p(x) y')' + (\lambda q(x) + r(x)) y = 0 , \quad x \in [a, b] , \quad p(x) \geq 0
\] (17.8.38)

where we assume that \( q(x) \geq 0 \) for \( x \in [a, b] \) and is positive except for finitely many points. Also, assume it is continuous. Probably, you could generalize this to assume
less about $q$ if this is of interest. There will also be boundary conditions at $a, b$. These are typically of the form

$$\begin{align*}
C_1 y (a) + C_2 y' (a) &= 0 \\
C_3 y (b) + C_4 y' (b) &= 0
\end{align*}\quad (17.8.39)$$

where

$$C_1^2 + C_2^2 > 0, \quad C_3^2 + C_4^2 > 0. \quad (17.8.40)$$

Also we assume here that $a$ and $b$ are finite numbers. In the example, the constants $C_i$ are given and $\lambda$ is called the eigenvalue while a solution of the differential equation and given boundary conditions corresponding to $\lambda$ is called an eigenfunction.

There is a simple but important identity related to solutions of the above differential equation. Suppose $y_i$ and $y'_i$ for $i = 1, 2$ are two solutions of \(17.8.38\). Thus from the equation, we obtain the following two equations.

$$\begin{align*}
(p (x) y'_1) y_2 + (\lambda_1 q (x) + r (x)) y_1 y_2 &= 0, \\
(p (x) y'_2) y_1 + (\lambda_2 q (x) + r (x)) y_1 y_2 &= 0.
\end{align*}$$

Subtracting the second from the first yields

$$\begin{align*}
(p (x) y'_1) y_2 - (p (x) y'_2) y_1 + (\lambda_1 - \lambda_2) q (x) y_1 y_2 &= 0. \quad (17.8.41)
\end{align*}$$

Now we note that

$$\begin{align*}
(p (x) y'_1) y_2 - (p (x) y'_2) y_1 &= \frac{d}{dx} ((p (x) y'_1) y_2 - (p (x) y'_2) y_1)
\end{align*}$$

and so integrating \(17.8.41\) from $a$ to $b$, we obtain

$$\left( (p (x) y'_1) y_2 - (p (x) y'_2) y_1 \right) |^b_a + (\lambda_1 - \lambda_2) \int_a^b q (x) y_1 (x) y_2 (x) \, dx = 0 \quad (17.8.42)$$

We have been purposely vague about the nature of the boundary conditions because of a desire to not lose generality. However, we will always assume the boundary conditions are such that whenever $y_1$ and $y_2$ are two eigenfunctions, it follows that

$$\left( (p (x) y'_1) y_2 - (p (x) y'_2) y_1 \right) |^b_a = 0 \quad (17.8.43)$$

In the case where the boundary conditions are given by \(17.8.39\) and \(17.8.40\), we obtain \(17.8.43\). To see why this is so, consider the top limit. This yields

$$p (b) [y'_1 (b) y_2 (b) - y'_2 (b) y_1 (b)]$$

However we know from the boundary conditions that

$$\begin{align*}
C_3 y_1 (b) + C_4 y'_1 (b) &= 0 \\
C_3 y_2 (b) + C_4 y'_2 (b) &= 0
\end{align*}$$

and that from \[ 17.8.40 \] that not both \( C_3 \) and \( C_4 \) equal zero. Therefore the determinant of the matrix of coefficients must equal zero. But this implies

\[
[y_1'(b) y_2(b) - y_2'(b) y_1(b)] = 0
\]

which yields the top limit is equal to zero. A similar argument holds for the lower limit. **Note that** \( y_1, y_2 \) **satisfy different differential equations because of different eigenvalues.**

From now on the boundary condition will be conditions \( L, \check{L}; L_1, \check{L}_1(\gamma(a), y_1'(a)) = 0, \check{L}(\gamma(b), y_1'(b)) = 0 \) which imply that if \( y_i \) correspond to two different eigenvalues,

\[
((p(x)y_1'y_2 - p(x)y_2'y_1)|_a^b = 0 \quad (*)
\]

and if \( \alpha \) is a constant, if \( L(\alpha y(a), y'(a)) = 0, \check{L}(\alpha y(b), y'(b)) = 0 \), then also

\[
L(\alpha y(a), \alpha y'(a)) = 0, \check{L}(\alpha y(b), \alpha y'(b)) = 0
\]

For example, maybe one wants to say that \( y \) is bounded at \( a, b \).

With the identity \[ 17.8.41 \] here is a result on orthogonality of the eigenfunctions.

**Proposition 17.8.1** Suppose \( y_i \) solves the boundary conditions and the differential equation for \( \lambda = \lambda_i \), where \( \lambda_1 \neq \lambda_2 \). Then we have the orthogonality relation

\[
\int_a^b q(x) y_1(x) y_2(x) \, dx = 0. \tag{17.8.44}
\]

In addition to this, if \( u, v \) are two solutions to the differential equation corresponding to a single \( \lambda, \tag{17.8.38} \) not necessarily the boundary conditions, (same differential equation) then there exists a constant, \( C \) such that

\[
W(u,v)(x) p(x) = C \tag{17.8.45}
\]

for all \( x \in [a,b] \). In this formula, \( W(u,v) \) denotes the Wronskian given by

\[
\det \begin{pmatrix} u(x) & v(x) \\ u'(x) & v'(x) \end{pmatrix}. \tag{17.8.46}
\]

**Proof:** The orthogonality relation, \[ 17.8.44 \] follows from the fundamental assumption, \[ 17.8.34 \] and \[ 17.8.40 \].

It remains to verify \[ 17.8.41 \]. We have from \[ 17.8.41 \]

\[
0 = (\lambda - \lambda) q(x) uv + (p(x) u')' v - (p(x) v')' u
= \frac{d}{dx} (p(x) u' v - p(x) v' u) = \frac{d}{dx} (p(x) W(v, u)(x))
\]

and so \( p(x) W(u,v)(x) = -p(x) W(v, u)(x) = C \) as claimed.

Now consider the differential equation,

\[
(p(x)y')' + r(x)y = 0. \tag{17.8.47}
\]

This is obtained from the one of interest by letting \( \lambda = 0 \).
17.8. STURM LIOUVILLE PROBLEMS

Criterion 17.8.2 Suppose we are able to find functions, \( u \) and \( v \) such that they solve the differential equation, \( 17.8.47 \) and \( u \) solves the boundary condition at \( x = a \) while \( v \) solves the boundary condition at \( x = b \). Assume both are in \( L^2(a, b) \) and \( W(u, v) \neq 0 \). It follows that both are in \( L^2(a, b, q) \), the \( L^2 \) functions with respect to the measure \( q(x) \, dx \). Thus

\[
(f, g)_{L^2(a, b, q)} = \int_a^b f(x) g(x) q(x) \, dx
\]

If \( p(x) > 0 \) on \([a, b]\) it is typically clear from the fundamental existence and uniqueness theorems for ordinary differential equations that such functions \( u \) and \( v \) exist. (See any good differential equations book or Problem 10 on Page 724.)

However, such functions might exist even if \( p \) vanishes at the end points.

Lemma 17.8.3 Assume Criterion 17.8.2. A function \( y \) is a solution to the boundary conditions along with the equation,

\[
(p(x)y')' + r(x)y = g
\]

if

\[
y(x) = \int_a^b G(t, x) \, g(t) \, dt
\]

where

\[
G(t, x) = \begin{cases} \frac{1}{c} (v(x) \, u(t)) & \text{if } t < x \\ \frac{1}{c} (v(t) \, u(x)) & \text{if } t > x \\ \end{cases}
\]

and \( c \) is the constant of Proposition 17.8.1 which satisfies \( p(x)W(u, v)(x) = c \).

Proof: Why does \( y \) solve the equation 17.8.48 along with the boundary conditions?

\[
y(x) = \frac{1}{c} \int_a^x g(t) \, u(t) \, v(x) \, dt + \frac{1}{c} \int_x^b g(t) \, v(t) \, u(x) \, dt
\]

Differentiate

\[
y'(x) = \frac{1}{c} g(x) \, u(x) \, v(x) + \frac{1}{c} \int_a^x g(t) \, u(t) \, v'(x) \, dt
\]

\[
-\frac{1}{c} g(x) \, v(x) \, u(x) + \frac{1}{c} \int_x^b g(t) \, v(t) \, u'(x) \, dt
\]

\[
= \frac{1}{c} \int_a^x g(t) \, u(t) \, v'(x) \, dt + \frac{1}{c} \int_x^b g(t) \, v(t) \, u'(x) \, dt
\]

Then

\[
p(x)y'(x) = \frac{1}{c} \int_a^x g(t) \, u(t) \, p(x) \, v'(x) \, dt + \frac{1}{c} \int_x^b g(t) \, v(t) \, p(x) \, u'(x) \, dt
\]
Then \((p(x) y'(x))' = \frac{1}{c} g(x) p(x) u(x) v'(x) - \frac{1}{c} g(x) p(x) v(x) u'(x) + \frac{1}{c} \int_a^x g(t) u(t) (p(x) v'(x))' dt + \frac{1}{c} \int_x^b g(t) v(t) (p(x) u'(x))' dt\)

From the definition of \(c\), this equals

\[
g(x) + \frac{1}{c} \int_a^x g(t) u(t) (p(x) v'(x))' dt + \frac{1}{c} \int_x^b g(t) v(t) (p(x) u'(x))' dt
\]

\[
g(x) + \frac{1}{c} \int_a^x g(t) u(t) (-r(x) v(x)) dt + \frac{1}{c} \int_x^b g(t) v(t) (-r(x) u(x)) dt
\]

\[
g(x) - r(x) \left( \frac{1}{c} \int_a^x g(t) u(t) v(x) dt + \frac{1}{c} \int_x^b g(t) v(t) u(x) dt \right)
\]

Thus

\[
(p(x) y'(x))' + r(x) y(x) = g(x)
\]

so \(y\) satisfies the equation. As to the boundary conditions, by assumption,

\[
\hat{L}(y(b), y'(b)) = \hat{L} \left( v(b) \frac{1}{c} \int_a^b g(t) u(t) dt, v'(b) \frac{1}{c} \int_a^b g(t) u(t) dt \right) = 0
\]

because \(v\) satisfies the boundary condition at \(b\). The other boundary condition is exactly similar. □

Now in the case of Criterion 17.8.2, \(y\) is a solution to the Sturm Liouville eigenvalue problem, if and only if \(y\) solves the boundary conditions and the equation,

\[
(p(x) y')' + r(x) y(x) = -\lambda q(x) y(x).
\]

This happens if

\[
y(x) = -\frac{\lambda}{c} \int_a^x q(t) y(t) u(t) v(x) dt + \frac{\lambda}{c} \int_x^b q(t) y(t) v(t) u(x) dt,
\]

(17.8.51)

Letting \(\mu = \frac{1}{\lambda}\), this is of the form

\[
\mu y(x) = \int_a^b G(t, x) q(t) y(t) dt
\]

(17.8.52)

where

\[
G(t, x) = \begin{cases} 
-c^{-1} (v(x) u(t)) & \text{if } t < x \\
-c^{-1} (v(t) u(x)) & \text{if } t > x
\end{cases}
\]

(17.8.53)
17.8. STURM LIOUVEILLE PROBLEMS

Could \( \mu = 0 \)? If this happened, then from Lemma 17.8.3, we would have that \( y = 0 \) is a solution of \( (17.8.48) \) where the right side is \(-q(t)y(t)\) which would imply that \( q(t)y(t) = 0 \) (since the left side is 0) for all \( t \) which implies \( y(t) = 0 \) for all \( t \) thanks to assumptions on \( q(t) \). Thus we are not interested in this case. It follows from \( (17.8.53) \) that \( G : [a, b] \times [a, b] \rightarrow \mathbb{R} \) is continuous and symmetric, \( G(t, x) = G(x, t) \).

\[
G(x, t) = \begin{cases} 
-c^{-1}(v(t)u(x)) & \text{if } x < t \\
-c^{-1}(v(x)u(t)) & \text{if } x > t 
\end{cases}
= G(t, x)
\]

Also we see that for \( f \in C([a, b]), \) and

\[
w(x) = \int_{a}^{b} G(t, x) q(t) f(t) \, dt,
\]

Lemma 17.8.3 implies \( w \) is a solution to the boundary conditions and the equation

\[
(p(x)y')' + r(x)y = -q(x)f(x) \quad (17.8.54)
\]

**Theorem 17.8.4** Suppose \( u, v \) are given in Criterion 17.8.2. Then there exists a sequence of functions, \( \{y_n\}_{n=1}^{\infty} \) and real numbers, \( \lambda_n \) such that

\[
(p(x)y_n')' + (\lambda_n q(x) + r(x))y_n = 0, \quad x \in [a, b], \quad (17.8.55)
\]

\[
L(y(a), y'(a)) = 0,
\hat{L}(y(b), y'(b)) = 0. \quad (17.8.56)
\]

and

\[
\lim_{n \to \infty} |\lambda_n| = \infty \quad (17.8.57)
\]

such that for all \( f \in C([a, b]), \) whenever \( w \) satisfies \( (17.8.54) \) and the boundary conditions,

\[
w(x) = \sum_{n=1}^{\infty} \frac{1}{\lambda_n} (f, y_n) y_n. \quad (17.8.58)
\]

Also the functions, \( \{y_n\} \) form a dense set in \( L^2(a, b, q) \) which satisfy the orthogonality condition, \( (17.8.44) \).

**Proof:** Let \( Ay(x) = \int_{a}^{b} G(t, x) q(t) y(t) \, dt \) where \( G \) is defined above in \( (17.8.53) \). Then from symmetry and Fubini’s theorem,

\[
(Ay, z)_{L^2(a, b, q)} =
\]
Theorem

Of course, $H$ is not finite dimensional and so the second will not hold. Also from Theorem \ref{thm:compact},

\[
\text{span}\left\{ y_i \right\}_{i=1}^{\infty} \text{ is dense in } A(H). \tag{17.8.62}
\]
and so for all \( f \in C([a,b]) \),

\[
Af = \sum_{k=1}^{\infty} \mu_k (f, y_k) y_k. \tag{17.8.63}
\]

Thus for \( w \) a solution of (17.8.54) and suitable boundary conditions as above which cause *,

\[
w \equiv Af = \sum_{k=1}^{\infty} \frac{1}{\lambda_k} (f, y_k) y_k.
\]

The last claim follows from Corollary (17.7.4) and the observation above that \( \mu \) is never equal to zero. ■

Note that if \( q(x) \neq 0 \) we can say that for a given \( g \in C([a,b]) \), one can define \( f \) by \( g(x) = -q(x) f(x) \) and so if \( w \) is a solution to the boundary conditions and the equation

\[
(p(x) w'(x))' + r(x) w(x) = g(x) = -q(x) f(x),
\]

one obtains the formula

\[
w(x) = \sum_{k=1}^{\infty} \frac{1}{\lambda_k} (f, y_k) y_k
\]

More can be said about convergence of these series based on the eigenfunctions of a Sturm Liouville problem. In particular, it can be shown that for reasonable functions the pointwise convergence properties are like those of Fourier series and that the series converges to the midpoint of the jump. This is partly done for the Legendre polynomials in [27]. For more on these topics see the old book by Ince, written in Egypt in the 1920’s, [65], [66] or the 1955 book on differential equations by Coddington and Levinson [30].

As an example, consider the following eigenvalue problem

\[
x^2 y'' + xy' + (\lambda x^2 - n^2) y = 0, \ C_1 y(L) + C_2 y'(L) = 0, \ x \in [0, L] \quad (*)
\]

not both \( C_i \) equal zero. Then you can write the equation in “self adjoint” form as

\[
(xy')' + \left(\lambda x - \frac{n^2}{x}\right) y = 0
\]

Multiply by \( y \) and integrate from 0 to \( L \). Then the boundary terms cancel and you get

\[
\int_0^L \left(\lambda x - \frac{n^2}{x}\right) y^2 dx = 0
\]

and so you must have \( \lambda > 0 \).
Now it follows that corresponding to different values of $\lambda$ the eigenfunctions are orthogonal with respect to $x$. So what are the values of $\lambda$ and how can we describe the corresponding eigenfunctions?

Let $y$ be an eigenfunction. Let $z \left( \sqrt{\lambda x} \right) = y(x)$. Then
\[
0 = x^2 y'' + xy' + (\lambda x^2 - n^2) y
= \lambda x^2 z'' \left( \sqrt{\lambda x} \right) + \sqrt{\lambda x} z' \left( \sqrt{\lambda x} \right) + (\lambda x^2 - n^2) z \left( \sqrt{\lambda x} \right)
\]
Now replace $\sqrt{\lambda x}$ with $u$. Then
\[
u^2 z'' (u) + u z' (u) + (u^2 - n^2) z (u) = 0
\]
Then we need
\[z \left( \sqrt{\lambda L} \right) = 0\]
and $z$ is bounded near 0. This happens if and only if $z(u) = J_n(u)$ because the other solution to the Bessel equation is unbounded near 0. Then $J_n \left( \sqrt{\lambda L} \right) = 0$ and so for some $\alpha$ a zero of $J_n$,
\[
\sqrt{\lambda L} = \alpha, \quad \lambda = \frac{\alpha^2}{L^2}.
\]
Thus the eigenvalues are
\[
\frac{\alpha^2}{L^2}, \alpha \text{ a zero of } J_n(x)
\]
and the eigenfunctions are
\[
x \rightarrow J_n \left( \frac{\alpha}{L} x \right).
\]

Then Theorem 17.8.4 implies that if you have any $f \in L^2(a,b,x)$, you can obtain it as an expansion in terms of the functions $x \rightarrow J_n \left( \frac{\alpha_k}{L} x \right)$ where $\alpha_k$ are the zeros of the Bessel function. Note that this theorem and what was shown above also shows that there are countably many zeros of $J_n$ also.

### 17.8.1 Nuclear Operators

**Definition 17.8.5** A self adjoint operator $A \in \mathcal{L}(H,H)$ for $H$ a separable Hilbert space is called a nuclear operator if for some complete orthonormal set, $\{e_k\}$,
\[
\sum_{k=1}^{\infty} |(A e_k, e_k)| < \infty
\]

To begin with here is an interesting lemma.
Lemma 17.8.6 Suppose \( \{A_n\} \) is a sequence of compact operators in \( \mathcal{L}(X,Y) \) for two Banach spaces, \( X \) and \( Y \) and suppose \( A \in \mathcal{L}(X,Y) \) and

\[
\lim_{n \to \infty} \|A - A_n\| = 0.
\]

Then \( A \) is also compact.

**Proof:** Let \( B \) be a bounded set in \( X \) such that \( \|b\| \leq C \) for all \( b \in B \). I need to verify \( AB \) is totally bounded. Suppose then it is not. Then there exists \( \varepsilon > 0 \) and a sequence, \( \{Ab_i\} \) where \( b_i \in B \) and

\[
\|Ab_i - Ab_j\| \geq \varepsilon
\]

whenever \( i \neq j \). Then let \( n \) be large enough that

\[
\|A - A_n\| \leq \frac{\varepsilon}{4C}.
\]

Then

\[
\|A_n b_i - A_n b_j\| = \|Ab_i - Ab_j + (A_n - A) b_i - (A_n - A) b_j\| \\
\geq \|Ab_i - Ab_j\| - \|(A_n - A) b_i\| - \|(A_n - A) b_j\| \\
\geq \|Ab_i - Ab_j\| - \frac{\varepsilon}{4C} C - \frac{\varepsilon}{4C} C \geq \frac{\varepsilon}{2},
\]

a contradiction to \( A_n \) being compact. This proves the lemma.

Then one can prove the following lemma. In this lemma, \( A \geq 0 \) will mean \( (Ax, x) \geq 0 \).

Lemma 17.8.7 Let \( A \geq 0 \) be a nuclear operator defined on a separable Hilbert space, \( H \). Then \( A \) is compact and also, whenever \( \{e_k\} \) is a complete orthonormal set,

\[
A = \sum_{j=1}^{\infty} \sum_{i=1}^{\infty} (A e_i, e_j) e_i \otimes e_j.
\]

**Proof:** First consider the formula. Since \( A \) is given to be continuous,

\[
Ax = A \left( \sum_{j=1}^{\infty} (x, e_j) e_j \right) = \sum_{j=1}^{\infty} (x, e_j) Ae_j,
\]

the series converging because

\[
x = \sum_{j=1}^{\infty} (x, e_j) e_j
\]
Then also since $A$ is self adjoint,

\[
\sum_{j=1}^{\infty} \sum_{i=1}^{\infty} (Ae_i, e_j) e_i \otimes e_j (x) = \sum_{j=1}^{\infty} \sum_{i=1}^{\infty} (Ae_i, e_j) (x, e_j) e_i
\]

\[
= \sum_{j=1}^{\infty} (x, e_j) \sum_{i=1}^{\infty} (Ae_i, e_j) e_i
\]

\[
= \sum_{j=1}^{\infty} (x, e_j) \sum_{i=1}^{\infty} (Ae_j, e_i) e_i
\]

\[
= \sum_{j=1}^{\infty} (x, e_j) Ae_j
\]

Next consider the claim that $A$ is compact. Let $C_A \equiv \left( \sum_{j=1}^{\infty} |(Ae_j, e_j)| \right)^{1/2}$.

Let $A_n$ be defined by

\[
A_n \equiv \sum_{j=1}^{\infty} \sum_{i=1}^{n} (Ae_i, e_j) (e_i \otimes e_j).
\]

Then $A_n$ has values in span ($e_1, \ldots, e_n$) and so it must be a compact operator because bounded sets in a finite dimensional space must be precompact. Then

\[
|(Ax - A_n x, y)| = \left| \sum_{j=1}^{\infty} \sum_{i=n+1}^{\infty} (Ae_i, e_j) (y, e_j) (e_i, x) \right|
\]

\[
= \left| \sum_{j=1}^{\infty} (y, e_j) \sum_{i=n+1}^{\infty} (Ae_i, e_j) (e_i, x) \right|
\]

\[
\leq \left( \sum_{j=1}^{\infty} |(y, e_j)|^2 \right)^{1/2} \left( \sum_{j=1}^{\infty} |(Ae_j, e_j)| \right)^{1/2} \cdot \left( \sum_{i=n+1}^{\infty} |(x, e_i)|^2 \right)^{1/2} \left( \sum_{i=n+1}^{\infty} |(Ae_i, e_i)| \right)^{1/2}
\]

\[
\leq |y| |x| C_A \left( \sum_{i=n+1}^{\infty} |(Ae_i, e_i)| \right)^{1/2}
\]
and this shows that if \( n \) is sufficiently large,
\[
|\langle (A - A_n) x, y \rangle| \leq \varepsilon |x||y|
\]
Therefore,
\[
\lim_{n \to \infty} ||A - A_n|| = 0
\]
and so \( A \) is the limit in operator norm of finite rank bounded linear operators, each
of which is compact. Therefore, \( A \) is also compact.

**Definition 17.8.8** The trace of a nuclear operator \( A \in \mathcal{L}(H, H) \) such that \( A \geq 0 \)
is defined to equal
\[
\sum_{k=1}^{\infty} \langle Ae_k, e_k \rangle
\]
where \( \{e_k\} \) is an orthonormal basis for the Hilbert space, \( H \).

**Theorem 17.8.9** Definition [17.8.8] is well defined and equals \( \sum_{j=1}^{\infty} \lambda_j \) where the
\( \lambda_j \) are the eigenvalues of \( A \).

**Proof:** Suppose \( \{u_k\} \) is some other orthonormal basis. Then
\[
e_k = \sum_{j=1}^{\infty} u_j \langle e_k, u_j \rangle
\]
By Lemma [17.8.7] \( A \) is compact and so
\[
A = \sum_{k=1}^{\infty} \lambda_k u_k \otimes u_k
\]
where the \( u_k \) are the orthonormal eigenvectors of \( A \) which form a complete orthonormal set. Then
\[
\sum_{k=1}^{\infty} \langle Ae_k, e_k \rangle = \sum_{k=1}^{\infty} \left( \sum_{j=1}^{\infty} \langle u_j \langle e_k, u_j \rangle, \sum_{j=1}^{\infty} u_j \langle e_k, u_j \rangle \rangle \right)
\]
\[
= \sum_{k=1}^{\infty} \sum_{ij} (Au_j, u_i) \langle e_k, u_j \rangle \langle u_i, e_k \rangle
\]
\[
= \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} (Au_j, u_j) |\langle e_k, u_j \rangle|^2
\]
\[
= \sum_{j=1}^{\infty} (Au_j, u_j) \sum_{k=1}^{\infty} |\langle e_k, u_j \rangle|^2 = \sum_{j=1}^{\infty} (Au_j, u_j) |u_j|^2
\]
\[
= \sum_{j=1}^{\infty} (Au_j, u_j) = \sum_{j=1}^{\infty} \lambda_j
\]
and this proves the theorem.

This is just like it is for a matrix. Recall the trace of a matrix is the sum of the eigenvalues.

It is also easy to see that in any separable Hilbert space, there exist nuclear operators. Let \( \sum_{k=1}^{\infty} |\lambda_k| < \infty \). Then let \( \{e_k\} \) be a complete orthonormal set of vectors. Let

\[
A \equiv \sum_{k=1}^{\infty} \lambda_k e_k \otimes e_k.
\]

It is not too hard to verify this works.

Much more can be said about nuclear operators.

### 17.8.2 Hilbert Schmidt Operators

**Definition 17.8.10** Let \( H \) and \( G \) be two separable Hilbert spaces and let \( T \) map \( H \) to \( G \) be linear. Then \( T \) is called a Hilbert Schmidt operator if there exists some orthonormal basis for \( H \), \( \{e_j\} \) such that

\[
\sum_j ||Te_j||^2 < \infty.
\]

The collection of all such linear maps will be denoted by \( \mathcal{L}_2 (H,G) \).

**Theorem 17.8.11** \( \mathcal{L}_2 (H,G) \subseteq \mathcal{L} (H,G) \) and \( \mathcal{L}_2 (H,G) \) is a separable Hilbert space with norm given by

\[
||T||_{\mathcal{L}_2} \equiv \left( \sum_k ||Te_k||^2 \right)^{1/2}
\]

where \( \{e_k\} \) is some orthonormal basis for \( H \). Also \( \mathcal{L}_2 (H,G) \subseteq \mathcal{L} (H,G) \) and

\[
||T|| \leq ||T||_{\mathcal{L}_2} \quad (17.8.64)
\]

All Hilbert Schmidt operators are compact. Also for \( X \in H \) and \( Y \in G \), \( X \otimes Y \in \mathcal{L}_2 (H,G) \) and

\[
||X \otimes Y||_{\mathcal{L}_2} = ||X||_H ||Y||_G \quad (17.8.65)
\]

**Proof:** First I want to show \( \mathcal{L}_2 (H,G) \subseteq \mathcal{L} (H,G) \) and \( ||T|| \leq ||T||_{\mathcal{L}_2} \). Pick an orthonormal basis for \( H \), \( \{e_k\} \) and an orthonormal basis for \( G \), \( \{f_k\} \). Then letting

\[
x = \sum_{k=1}^{n} x_k e_k,
\]

\[
Tx = T \left( \sum_{k=1}^{n} x_k e_k \right) = \sum_{k=1}^{n} x_k T(e_k)
\]

This is just like it is for a matrix. Recall the trace of a matrix is the sum of the eigenvalues.
where \( x_k \equiv (x, e_k) \). Therefore using Minkowski’s inequality,

\[
||Tx|| = \left( \sum_{k=1}^{\infty} |(Tx, f_k)|^2 \right)^{1/2}
\]

\[
= \left( \sum_{k=1}^{\infty} \left( \sum_{j=1}^{n} x_j T e_j, f_k \right)^2 \right)^{1/2}
\]

\[
= \left( \sum_{k=1}^{\infty} \sum_{j=1}^{n} (x_j T e_j, e_k)^2 \right)^{1/2}
\]

\[
\leq \sum_{j=1}^{n} \left( \sum_{k=1}^{\infty} |(x_j T e_j, e_k)|^2 \right)^{1/2}
\]

\[
\leq \sum_{j=1}^{n} |x_j| \left( \sum_{k=1}^{\infty} |(T e_j, e_k)|^2 \right)^{1/2}
\]

\[
= \sum_{j=1}^{n} |x_j| ||T e_j|| \leq \left( \sum_{j=1}^{n} |x_j|^2 \right)^{1/2} ||T||_{L^2}
\]

\[
= ||x|| ||T||_{L^2}
\]

Therefore, since finite sums of the form \( \sum_{k=1}^{n} x_k e_k \) are dense in \( H \), it follows \( T \in L(H, G) \) and \( ||T|| \leq ||T||_{L^2} \).

Next consider the norm. I need to verify the norm does not depend on the choice of orthonormal basis. Let \( \{f_k\} \) be an orthonormal basis for \( G \). Then for \( \{e_k\} \) an orthonormal basis for \( H \),

\[
\sum_k ||Te_k||^2 = \sum_k \sum_j |(Te_k, f_j)|^2 = \sum_k \sum_j |(e_k, T^* f_j)|^2
\]

\[
= \sum_j \sum_k |(e_k, T^* f_j)|^2 = \sum_j ||T^* f_j||^2.
\]

The above computation makes sense because it was just shown that \( T \) is continuous. The same result would be obtained for any other orthonormal basis \( \{e'_k\} \) and this shows the norm is at least well defined. It is clear this does indeed satisfy the axioms of a norm, and this proves the above claims.

It only remains to verify \( L^2(H, G) \) is a separable Hilbert space. It is clear it is an inner product space because you only have to pick an orthonormal basis, \( \{e_k\} \) and define the inner product as

\[
(S, T) \equiv \sum_k (Se_k, Te_k).
\]
The only remaining issue is the completeness. Suppose then that \( \{T_n\} \) is a Cauchy sequence in \( L^2(H, G) \). Then from \( 17.8.64 \) \( \{T_n\} \) is a Cauchy sequence in \( L(H, G) \) and so there exists a unique \( T \) such that \( \lim_{n \to \infty} ||T_n - T|| = 0 \). Then it only remains to verify \( T \in L^2(H, G) \). But by Fatou’s lemma,

\[
\sum_k ||Te_k||^2 \leq \liminf_{n \to \infty} \sum_k ||T_n e_k||^2 = \liminf_{n \to \infty} ||T_n||_{L^2}^2 < \infty.
\]

All that remains is to verify \( L^2(H, G) \) is separable and these Hilbert Schmidt operators are compact. I will show an orthonormal basis for \( L^2(H, G) \) is \( \{f_j \otimes e_k\} \) where \( \{f_k\} \) is an orthonormal basis for \( G \) and \( \{e_k\} \) is an orthonormal basis for \( H \).

Here, for \( f \in G \) and \( e \in H \),

\[
f \otimes e (x) \equiv (x, e) f.
\]

I need to show \( f_j \otimes e_k \in L^2(H, G) \) and that it is an orthonormal basis for \( L^2(H, G) \) as claimed.

\[
\sum_k ||f_j \otimes e_i (e_k)||^2 = \sum_k ||f_j \delta_{ik}||^2 = ||f_j||^2 = 1 < \infty
\]

so each of these operators is in \( L^2(H, G) \). Next I show they are orthonormal.

\[
(f_j \otimes e_k, f_s \otimes e_r) = \sum_p (f_j \otimes e_k (e_p), f_s \otimes e_r (e_p))
\]

\[
= \sum_p \delta_{tp} \delta_{kp} (f_j, f_s) = \sum_p \delta_{tp} \delta_{kp} \delta_{js}
\]

If \( j = s \) and \( k = r \) this reduces to 1. Otherwise, this gives 0. Thus these operators are orthonormal. Now let \( T \in L^2(H, G) \). Consider

\[
T_n = \sum_{i=1}^{n} \sum_{j=1}^{n} (Te_i, f_j) f_j \otimes e_i
\]

Then

\[
T_n e_k = \sum_{i=1}^{n} \sum_{j=1}^{n} (Te_i, f_j) (e_k, e_i) f_j
\]

\[
= \sum_{j=1}^{n} (Te_k, f_j) f_j
\]

It follows

\[
||T_n e_k|| \leq ||Te_k||
\]
and
\[
\lim_{n \to \infty} T_n e_k = T e_k.
\]
Therefore, from the dominated convergence theorem,
\[
\lim_{n \to \infty} \|T - T_n\|_{L_2}^2 = \lim_{n \to \infty} \sum_k \|(T - T_n) e_k\|^2 = 0.
\]
Therefore, the linear combinations of the \(f_j \otimes e_i\) are dense in \(L_2(H,G)\) and this proves completeness of the orthonormal basis.

This also shows \(L_2(H,G)\) is separable. From (17.8.64) it also shows that every \(T \in L_2(H,G)\) is the limit in the operator norm of a sequence of compact operators. This follows because each of the \(f_j \otimes e_i\) is easily seen to be a compact operator because if \(x_m \to x\) weakly, then
\[
f_j \otimes e_i (x_m) = (x_m, e_i) f_j \to (x, e_i) f_j = f_j \otimes e_i (x)
\]
and since if \(\{x_m\}\) is any bounded sequence, there exists a subsequence, \(\{x_{n_k}\}\) which converges weakly and by the above, \(f_j \otimes e_i (x_{n_k}) \to f_j \otimes e_i (x)\) showing bounded sets are mapped to precompact sets. Therefore, each \(T \in L_2(H,G)\) must also be a compact operator. Here is why.

Let \(B\) be a bounded set in which \(\|x\| < M\) for all \(x \in B\) and consider \(TB\). I need to show \(TB\) is totally bounded. Let \(\varepsilon > 0\) be given. Then let \(\|T_m - T\| < \frac{\varepsilon}{3M}\) where \(T_m\) is a compact operator like those described above and let \(\{T_m x_j\}_{j=1}^N\) be an \(\varepsilon/3\) net for \(T_m (B)\). Then
\[
\|Tx_j - T_m x_j\| < \frac{\varepsilon}{3}
\]
and so letting \(x \in B\), pick \(x_j\) such that \(\|T_m x - T_m x_j\| < \varepsilon/3\). Then
\[
\|Tx - Tx_j\| \leq \|T x - T_m x\| + \|T_m x - T_m x_j\| + \|T_m x_j - Tx_j\|
\]
\[
< \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon
\]
showing \(\{Tx_j\}_{j=1}^N\) is an \(\varepsilon\) net for \(TB\).

Finally, consider (17.8.65). Let \(\{e_k\}\) be an orthonormal basis for \(H\) and consider the following computation which establishes this equation.
\[
\|Y \otimes X\|_{L_2}^2 = \sum_{k=1}^\infty \|Y \otimes X (e_k)\|^2
\]
\[
= \sum_{k=1}^\infty \|(e_k, X) Y\|^2
\]
\[
= \|Y\|_G^2 \sum_{k=1}^\infty |(e_k, X)|^2
\]
\[
= \|Y\|_G^2 \|X\|_H^2 < \infty. \quad (17.8.66)
\]
This proves the theorem.
17.9 Compact Operators In Banach Space

In general for \( A \in \mathcal{L}(X, Y) \) the following definition holds.

**Definition 17.9.1** Let \( A \in \mathcal{L}(X, Y) \). Then \( A \) is compact if whenever \( B \subseteq X \) is a bounded set, \( AB \) is precompact. Equivalently, if \( \{x_n\} \) is a bounded sequence in \( X \), then \( \{Ax_n\} \) has a subsequence which converges in \( Y \).

An important result is the following theorem about the adjoint of a compact operator.

**Theorem 17.9.2** Let \( A \in \mathcal{L}(X, Y) \) be compact. Then the adjoint operator, \( A^* \in \mathcal{L}(Y', X') \) is also compact.

**Proof:** Let \( \{y_n^*\} \) be a bounded sequence in \( Y' \). Let \( B \) be the closure of the unit ball in \( X \). Then \( AB \) is precompact. Then it is clear that the functions \( \{y_n^*\} \) are equicontinuous and uniformly bounded on the compact set, \( A(B) \). By the Ascoli Arzela theorem, there is a subsequence \( \{y_{n_k}^*\} \) which converges uniformly to a continuous function, \( f \) on \( A(B) \). Now define \( g \) on \( AX \) by

\[
g(Ax) = \|x\| f \left( A \left( \frac{x}{\|x\|} \right) \right), \quad g(A0) = 0.
\]

Thus for \( x_1, x_2 \neq 0 \), and \( a, b \) scalars,

\[
g(ax_1 + bx_2) = \|ax_1 + bx_2\| f \left( A \left( \frac{ax_1 + bx_2}{\|ax_1 + bx_2\|} \right) \right)
\]

\[
= \lim_{k \to \infty} \|ax_1 + bx_2\| y_{n_k}^* \left( A \left( \frac{ax_1 + bx_2}{\|ax_1 + bx_2\|} \right) \right)
\]

\[
= \lim_{k \to \infty} ay_{n_k}^* (Ax_1) + by_{n_k}^* (Ax_2)
\]

\[
= a \lim_{k \to \infty} \|x_1\| y_{n_k}^* \left( \frac{Ax_1}{\|x_1\|} \right) + b \lim_{k \to \infty} \|x_2\| y_{n_k}^* \left( \frac{Ax_2}{\|x_2\|} \right)
\]

\[
= a \|x_1\| f \left( \frac{Ax_1}{\|x_1\|} \right) + b \|x_2\| f \left( \frac{Ax_2}{\|x_2\|} \right)
\]

\[
= ag(Ax_1) + bg(Ax_2)
\]

showing that \( g \) is linear on \( AX \). Also

\[
|g(Ax)| = \lim_{k \to \infty} \|x\| y_{n_k}^* \left( A \left( \frac{x}{\|x\|} \right) \right) \leq C \|x\| \left\| A \left( \frac{x}{\|x\|} \right) \right\| = C \|Ax\|
\]

and so by the Hahn Banach theorem, there exists \( y^* \) extending \( g \) to all of \( Y \) having the same operator norm.

\[
y^* (Ax) = \lim_{k \to \infty} \|x\| y_{n_k}^* \left( A \left( \frac{x}{\|x\|} \right) \right) = \lim_{k \to \infty} y_{n_k}^* (Ax)
\]
Thus \( A^* y^*_{n_k}(x) \rightarrow A^* y^*(x) \) for every \( x \). In addition to this, for \( x \in B \),
\[
\| A^* y^*(x) - A^* y^*_{n_k}(x) \| &= \| y^*(Ax) - y^*_{n_k}(Ax) \| \\
&= \| g(Ax) - y^*_{n_k}(Ax) \| \\
&= \| ||x|| f \left( A \left( \frac{x}{||x||} \right) \right) - ||x|| y^*_{n_k} \left( \frac{Ax}{||x||} \right) \| \\
&\leq \| f \left( A \left( \frac{x}{||x||} \right) \right) - y^*_{n_k} \left( \frac{Ax}{||x||} \right) \|
\]
and this is uniformly small for large \( k \) due to the uniform convergence of \( y^*_{n_k} \) to \( f \) on \( A(B) \). Therefore, \( \| A^* y^* - A^* y^*_{n_k} \| \rightarrow 0 \).

### 17.10 The Fredholm Alternative

Recall that if \( A \) is an \( n \times n \) matrix and if the only solution to the system, \( Ax = 0 \) is \( x = 0 \) then for any \( y \in \mathbb{R}^n \) it follows that there exists a unique solution to the system \( Ax = y \). This holds because the first condition implies \( A \) is one to one and therefore, \( A^{-1} \) exists. Of course things are much harder in a general Banach space. Here is a simple example for a Hilbert space.

**Example 17.10.1** Let \( L^2(\mathbb{N}; \mu) = H \) where \( \mu \) is counting measure. Thus an element of \( H \) is a sequence, \( a = \{a_i\}_{i=1}^{\infty} \) having the property that
\[
||a||_H = \left( \sum_{k=1}^{\infty} |a_k|^2 \right)^{1/2} < \infty.
\]
Define \( A : H \rightarrow H \) by
\[
Aa = b \equiv \{0, a_1, a_2, \ldots \}.
\]
Thus \( A \) slides the sequence to the right and puts a zero in the first slot. Clearly \( A \) is one to one and linear but it cannot be onto because it fails to yield \( e_1 \equiv \{1, 0, 0, \ldots \} \).

Notwithstanding the above example, there are theorems which are like the linear algebra theorem mentioned above which hold in an arbitrary Banach spaces in the case where the operator is compact. To begin with here is an interesting lemma.

**Lemma 17.10.2** Suppose \( A \in \mathcal{L}(X, X) \) is compact for \( X \) a Banach space. Then \((I - A)(X)\) is a closed subspace of \( X \).

**Proof:** Suppose \((I - A)x_n \rightarrow y\). Let
\[
\alpha_n \equiv \text{dist} \,(x_n, \ker (I - A))
\]
and let \( z_n \in \ker (I - A) \) be such that
\[
\alpha_n \leq ||x_n - z_n|| \leq \left( 1 + \frac{1}{n} \right) \alpha_n.
\]
Thus \((I - A)(x_n - z_n) \to y\) because \((I - A)z_n = 0\).

**Case 1:** \(\{x_n - z_n\}\) has a bounded subsequence.

If this is so, the compactness of \(A\) implies there exists a subsequence, still denoted by \(n\) such that \(\{A(x_n - z_n)\}_{n=1}^{\infty}\) is a Cauchy sequence. Since \((I - A)(x_n - z_n) \to y\), this implies \(\{(x_n - z_n)\}\) is also a Cauchy sequence converging to a point, \(x \in X\). Then, taking the limit as \(n \to \infty\), \((I - A)x = y\) and so \(y \in (I - A)(X)\).

**Case 2:** \(\lim_{n \to \infty} ||x_n - z_n|| = \infty\). I will show this case cannot occur.

In this case, let \(w_n = \frac{x_n - z_n}{||x_n - z_n||}\). Thus \((I - A)w_n \to 0\) and \(w_n\) is bounded.

Therefore, there exists a subsequence, still denoted by \(n\) such that \(\{Aw_n\}\) is a Cauchy sequence. Now it follows

\[
Aw_n - Aw_m + e_n - e_m = w_n - w_m
\]

where \(e_k \to 0\) as \(k \to \infty\). This implies \(\{w_n\}\) is a Cauchy sequence which must converge to some \(w_\infty \in X\). Therefore, \((I - A)w_\infty = 0\) and so \(w_\infty \in \ker(I - A)\).

However, this is impossible because of the following argument. If \(z \in \ker(I - A)\),

\[
||w_n - z|| = \frac{1}{||x_n - z_n||} ||x_n - z_n|| = \frac{1}{||x_n - z_n||} \alpha_n \geq \frac{\alpha_n}{(1 + \frac{1}{n}) \alpha_n} = \frac{n}{n + 1}.
\]

Taking the limit, \(||w_\infty - z|| \geq 1\). Since \(z \in \ker(I - A)\) is arbitrary, this shows \(\text{dist}(w_\infty, \ker(I - A)) \geq 1\).

Since Case 2 does not occur, this proves the lemma.

**Theorem 17.10.3** Let \(A \in \mathcal{L}(X,X)\) be a compact operator and let \(f \in X\). Then there exists a solution, \(x\), to

\[
x - Ax = f
\]

if and only if

\[
x^*(f) = 0
\]

for all \(x^* \in \ker(I - A^*)\).

**Proof:** Suppose \(x\) is a solution to (17.10.67) and let \(x^* \in \ker(I - A^*)\). Then

\[
x^*(f) = x^* ((I - A)(x)) = ((I - A^*)x^*)(x) = 0.
\]

Next suppose \(x^*(f) = 0\) for all \(x^* \in \ker(I - A^*)\). I will show there exists \(x\) solving (17.10.67). By Lemma (17.10.2), \((I - A)(X)\) is a closed subspace of \(X\). If \(f \in (I - A)(X)\)? If not, then by the Hahn Banach theorem, there exists \(x^* \in X'\) such that \(x^*(f) \neq 0\) but \(x^* ((I - A)(x)) = 0\) for all \(x \in X\). However last statement says nothing more nor less than \((I - A^*)x^* = 0\). This is a contradiction because for such \(x^*\), it is given that \(x^*(f) = 0\). This proves the theorem.

The following corollary is called the Fredholm alternative.
Corollary 17.10.4  Let $A \in \mathcal{L}(X, X)$ be a compact operator. Then there exists a solution to the equation

$$x - Ax = f$$

for all $f \in X$ if and only if $(I - A^*)$ is one to one on $X'$.

Proof: Suppose $(I - A^*)$ is one to one first. Then if $x^* - A^*x^* = 0$ it follows $x^* = 0$ and so for any $f \in X$, $x^*(f) = 0$ for all $x^* \in \ker (I - A^*)$. By 17.10.3 there exists a solution to $(I - A)x = f$.

Now suppose there exists a solution, $x$, to $(I - A)x = f$ for every $f \in X$. If $(I - A^*)x^* = 0$, then for every $x \in X$,

$$(I - A^*)x^*(x) = x^*((I - A)(x)) = 0$$

Since $(I - A)$ is onto, this shows $x^* = 0$ and so $(I - A^*)$ is one to one as claimed. This proves the corollary.

The following is just an easier version of the above.

Corollary 17.10.5  In the case where $X$ is a Hilbert space, the conclusions of Corollary 17.10.4, Theorem 17.10.3, and Lemma 17.10.2 remain true if $H'$ is replaced by $H$ and the adjoint is understood in the usual manner for Hilbert space. That is

$$(Ax, y)_H = (x, A^*y)_H$$

## 17.11 Square Roots

In this section, $H$ will be a Hilbert space, real or complex, and $T$ will denote an operator which satisfies the following definition. A useful theorem about the existence of square roots of certain operators is presented. This proof is very elementary. I found it in [2].

**Definition 17.11.1** Let $T \in \mathcal{L}(H, H)$ satisfy $T = T^*$ (Hermitian) and for all $x \in H$,

$$(Tx, x) \geq 0$$

Such an operator is referred to as positive and self adjoint. It is probably better to refer to such an operator as “nonnegative” since the possibility that $Tx = 0$ for some $x \neq 0$ is not being excluded. Instead of “self adjoint” you can also use the term, Hermitian. To save on notation, write

$$T \geq 0$$

to mean $T$ is positive, satisfying 17.11.70.

With the above definition here is a fundamental result about positive self adjoint operators.
Proposition 17.11.2 Let $S, T$ be positive and self adjoint such that $ST = TS$. Then $ST$ is also positive and self adjoint.

Proof: It is obvious that $ST$ is self adjoint. The only problem is to show that $ST$ is positive. To show this, first suppose $S \leq I$. The idea is to write

$$S = S_{n+1} + \sum_{k=0}^{n} S_k^2$$

where $S_0 = S$ and the operators $S_k$ are self adjoint. This is a useful idea because it is then obvious that the sum is positive. If we want such a representation as above, then it follows that $S_0 \equiv S$ and

$$S_{n+1} \equiv S - S_n^2.$$ 

Thus it is obvious that the $S_k$ are all self adjoint. Also, the following claim holds.

Claim: $I \geq S_n \geq 0$.

Proof of the claim: This is true if $n = 0$. Assume true for $n$. Then from the definition,

$$S_{n+1} = S_n^2 (I - S_n) + (I - S_n)^2 S_n$$

and it is obvious from the definition that the sum of positive operators is positive. Therefore, it suffices to show the two terms in the above are both positive. It is clear from the definition that each $S_n$ is Hermitian (self adjoint) because they are just polynomials in $S$. Also each must commute with $T$ for the same reason. Therefore,

$$\langle S^2_n (I - S_n) x, x \rangle = \langle (I - S_n) S_n x, S_n x \rangle \geq 0$$

and also

$$\langle (I - S_n)^2 S_n x, x \rangle = \langle S_n (I - S_n) x, (I - S_n) x \rangle \geq 0$$

This proves the claim.

Now each $S_k$ commutes with $T$ because this is true of $S_0$ and succeeding $S_k$ are polynomials in terms of $S_0$. Therefore,

$$\langle ST x, x \rangle = \left( \left( S_{n+1} + \sum_{k=0}^{n} S_k^2 \right) T x, x \right)$$

$$= \langle S_{n+1} T x, x \rangle + \sum_{k=0}^{n} \langle S_k^2 T x, x \rangle$$

$$= \langle T x, S_{n+1} x \rangle + \sum_{k=0}^{n} \langle T S_k x, S_k x \rangle \quad (17.11.71)$$

Consider $S_{n+1} x$. From the claim,

$$\langle S x, x \rangle = \langle S_{n+1} x, x \rangle + \sum_{k=0}^{n} |S_k x|^2 \geq \sum_{k=0}^{n} |S_k x|^2$$
17.11. SQUARE ROOTS

and so \( \lim_{n \to \infty} S_n x = 0 \). Hence from (17.11.71)

\[
\lim \inf_{n \to \infty} (STx, x) = (STx, x) = \lim \inf_{n \to \infty} \sum_{k=0}^{n} (TS_k x, S_k x) \geq 0.
\]

All this was based on the assumption that \( S \leq I \). The next task is to remove this assumption. Let \( ST = TS \) where \( T \) and \( S \) are positive self adjoint operators. Then consider \( S/\|S\| \). This is still a positive self adjoint operator and it commutes with \( T \) just like \( S \) does. Therefore, from the first part,

\[
0 \leq \left( \frac{S}{\|S\|} T x, x \right) = \frac{1}{\|S\|} (STx, x) . \]

The proposition is like the familiar statement about real numbers which says that when you multiply two nonnegative real numbers the result is a nonnegative real number. The next lemma is a generalization of the familiar fact that if you have an increasing sequence of real numbers which is bounded above, then the sequence converges.

**Lemma 17.11.3** Let \( \{T_n\} \) be a sequence of self adjoint operators on a Hilbert space, \( H \) and let \( T_n \leq T_{n+1} \) for all \( n \). Also suppose there exists \( K \), a self adjoint operator such that for all \( n, T_n \leq K \). Suppose also that each operator commutes with all the others and that \( K \) commutes with all the \( T_n \). Then there exists a self adjoint continuous operator, \( T \) such that for all \( x \in H \),

\[
T_n x \to T x,
\]

\( T \leq K \), and \( T \) commutes with all the \( T_n \) and with \( K \).

**Proof:** Consider \( K - T_n \equiv S_n \). Then the \( \{S_n\} \) are decreasing, that is,

\[
\{(S_n x, x)\}
\]

is a decreasing sequence and from the hypotheses, \( S_n \geq 0 \) so the above sequence is bounded below by 0. Therefore, \( \lim_{n \to \infty} (S_n x, x) \) exists. By Proposition (17.11.2), if \( n \geq m \),

\[
S_m^2 - S_m S_n = S_m (S_m - S_n) \geq 0
\]

and similarly,

\[
S_n S_m - S_n^2 = S_n (S_m - S_n) \geq 0.
\]

Therefore, since \( S_n \) is self adjoint,

\[
|T_n x - T_m x|^2 = |S_n x - S_m x|^2 = \left( (S_n - S_m)^2 x, x \right)
\]

\[
= ((S_n^2 - 2S_n S_m + S_m^2) x, x) = ((S_n^2 - S_m S_n) x, x) + ((S_n^2 - S_n S_m) x, x)
\]

\[
\leq \left( (S_n^2 - S_m S_n) x, x \right) \leq \left( (S_n^2 - S_n^2) x, x \right)
\]
\[(S_m - S_n)(S_m + S_n)x, x) \leq 2((S_m - S_n)Kx, x) \]

\[\leq 2((S_m - S_n)Kx, Kx)^{1/2}((S_m - S_n)x, x)^{1/2}\]

The last step follows from an application of the Cauchy Schwarz inequality along with the fact \(S_m - S_n \geq 0\). The last expression converges to 0 because \(\lim_{n \to \infty} (S_n x, x)\) exists for each \(x\). It follows \(\{T_n x\}\) is a Cauchy sequence. Let \(T x\) be the thing to which it converges. \(T\) is obviously linear and

\[(Tx, x) = \lim_{n \to \infty} (T_n x, x) \leq (Kx, x).\]

Also

\[(KTx, y) = \lim_{n \to \infty} (KT_n x, y) = \lim_{n \to \infty} (T_n Kx, y) = (TKx, y)\]

and so \(TK = KT\). Similarly, \(T\) commutes with all \(T_n\).

In order to show \(T\) is continuous, apply the uniform boundedness principle, Theorem 15.1.8. The convergence of \(\{T_n x\}\) implies there exists a uniform bound on the norms, \(\|T_n\|\) and so

\[|(T_n x, y)| \leq C|x||y|\]

Now take the limit as \(n \to \infty\) to conclude

\[|(Tx, y)| \leq C|x||y|\]

which shows \(\|T\| \leq C\). This proves the lemma.

With this preparation, here is the theorem about square roots.

**Theorem 17.11.4** Let \(T \in \mathcal{L}(H, H)\) be a positive self adjoint linear operator. Then there exists a unique square root, \(A\) with the following properties. \(A^2 = T\), \(A\) is positive and self adjoint, \(A\) commutes with every operator which commutes with \(T\).

**Proof:** First suppose \(T \leq I\). Then define

\[A_0 \equiv 0, \quad A_{n+1} = A_n + \frac{1}{2}(T - A_n^2).\]

From this it follows that every \(A_n\) is a polynomial in \(T\). Therefore, \(A_n\) commutes with \(T\) and with every operator which commutes with \(T\).

**Claim 1:** \(A_n \leq I\).

**Proof of Claim 1:** This is true if \(n = 0\). Suppose it is true for \(n\). Then by the
17.11. SQUARE ROOTS

Assumption that $T \leq I$,

$$I - A_{n+1} = I - A_n + \frac{1}{2} (A_n^2 - T)$$

$$\geq I - A_n + \frac{1}{2} (A_n^2 - I)$$

$$= I - A_n - \frac{1}{2} (I - A_n) (I + A_n)$$

$$= (I - A_n) \left( I - \frac{1}{2} (I + A_n) \right)$$

$$= (I - A_n) (I - A_n) \frac{1}{2} \geq 0.$$

Claim 2: $A_n \leq A_{n+1}$
Proof of Claim 2: From the definition of $A_n$, this is true if $n = 0$ because

$$A_1 = T \geq 0 = A_0.$$

Suppose true for $n$. Then from Claim 1,

$$A_{n+2} - A_{n+1} = A_{n+1} + \frac{1}{2} (T - A_{n+1}^2) - \left[ A_n + \frac{1}{2} (T - A_n^2) \right]$$

$$= A_{n+1} - A_n + \frac{1}{2} (A_n^2 - A_{n+1}^2)$$

$$= (A_{n+1} - A_n) \left( I - \frac{1}{2} (A_n + A_{n+1}) \right)$$

$$\geq (A_{n+1} - A_n) \left( I - \frac{1}{2} (2I) \right) = 0.$$

Claim 3: $A_n \geq 0$
Proof of Claim 3: This is true if $n = 0$. Suppose it is true for $n$.

$$(A_{n+1} x, x) = (A_n x, x) + \frac{1}{2} (T x, x) - \frac{1}{2} (A_n^2 x, x)$$

$$\geq (A_n x, x) + \frac{1}{2} (T x, x) - \frac{1}{2} (A_n x, x) \geq 0$$

because $A_n - A_n^2 = A_n (I - A_n) \geq 0$ by Proposition 17.11.2.

Now $\{A_n\}$ is a sequence of positive self adjoint operators which are bounded above by $I$ such that each of these operators commutes with every operator which commutes with $T$. By Lemma 17.11.3, there exists a bounded linear operator, $A$ such that for all $x$,

$$A_n x \rightarrow Ax$$

Then $A$ commutes with every operator which commutes with $T$ because each $A_n$ has this property. Also $A$ is a positive operator because each $A_n$ is. From passing to the limit in the definition of $A_n$,

$$Ax = Ax + \frac{1}{2} (T x - A^2 x)$$
and so \(Tx = A^2x\). This proves the theorem in the case that \(T \leq I\).

In the general case, consider \(T/\|T\|\). Then
\[
\left( \frac{T}{\|T\|} x, x \right) = \frac{1}{\|T\|} (Tx, x) \leq |x|^2 = (Ix, x)
\]

and so \(T/\|T\| \leq I\). Therefore, it has a square root, \(B\). Let \(A = \sqrt{\|T\|}B\). Then \(A\) has all the right properties and \(A^2 = \|T\| B^2 = \|T\| (T/\|T\|) = T\). This proves the existence part of the theorem.

Next suppose both \(A\) and \(B\) are square roots of \(T\) having all the properties stated in the theorem. Then \(AB = BA\) because both \(A\) and \(B\) commute with every operator which commutes with \(T\).

\[
(A (A - B) x, (A - B) x), (B (A - B) x, (A - B) x) \geq 0 \quad (17.11.72)
\]

Therefore, on adding these,
\[
\left( (A^2 - AB + BA - B^2) x, (A - B) x \right) = (A^2 - B^2) x, (A - B) x
\]
\[
= (T - T) x, (A - B) x = 0.
\]

It follows both expressions in \(17.11.72\) equal 0 since both are nonnegative and when they are added the result is 0. Now applying the existence part of the theorem to \(A\), there exists a positive square root of \(A\) which is self adjoint. Thus
\[
\left( \sqrt{A} (A - B) x, \sqrt{A} (A - B) x \right) = 0
\]

so \(\sqrt{A} (A - B) x = 0\) which implies \(A (A - B) x = 0\). Similarly, \(B (A - B) x = 0\).

Subtracting these and taking the inner product with \(x\),
\[
0 = (A (A - B) - B (A - B)) x, x = (A - B)^2 x, x = |(A - B) x|^2
\]

and so \(Ax = Bx\) which shows \(A = B\) since \(x\) was arbitrary. This proves the theorem.

### 17.12 General Theory Of Continuous Semigroups

Much more on semigroups is available in Yosida [115]. This is just an introduction to the subject.

**Definition 17.12.1** A strongly continuous semigroup defined on \(H\), a Banach space is a function \(S : [0, \infty) \to H\) which satisfies the following for all \(x_0 \in H\).

\[
S(t) \in \mathcal{L}(H, H), S(t + s) = S(t) S(s),
\]

\[
t \to S(t) x_0 \text{ is continuous}, \lim_{t \to 0^+} S(t) x_0 = x_0
\]
Sometimes such a semigroup is said to be $C_0$. It is said to have the linear operator $A$ as its generator if

$$D(A) = \left\{ x : \lim_{h \to 0} \frac{S(h)x-x}{h} \text{ exists} \right\}$$

and for $x \in D(A)$, $A$ is defined by

$$\lim_{h \to 0} \frac{S(h)x-x}{h} \equiv Ax$$

The assertion that $t \to S(t)x_0$ is continuous and that $S(t) \in L(H,H)$ is not sufficient to say there is a bound on $\|S(t)\|$ for all $t$. Also the assertion that for each $x_0$,

$$\lim_{t \to 0^+} S(t)x_0 = x_0$$

is not the same as saying that $S(t) \to I$ in $L(H,H)$. It is a much weaker assertion. The next theorem gives information on the growth of $\|S(t)\|$. It turns out it has exponential growth.

**Lemma 17.12.2** Let $M \equiv \sup \{ ||S(t)|| : t \in [0,T] \}$. Then $M < \infty$.

**Proof:** If this is not true, then there exists $t_n \in [0,T]$ such that $||S(t_n)|| \geq n$. That is the operators $S(t_n)$ are not uniformly bounded. By the uniform boundedness principle, Theorem 15.1.8, there exists $x \in H$ such that $||S(t_n)x||$ is not bounded. However, this is impossible because it is given that $t \to S(t)x$ is continuous on $[0,T]$ and so $t \to ||S(t)x||$ must achieve its maximum on this compact set.

Now here is the main result for growth of $||S(t)||$.

**Theorem 17.12.3** For $M$ described in Lemma 17.12.2, there exists $\alpha$ such that

$$||S(t)|| \leq Me^{\alpha t}.$$ 

In fact, $\alpha$ can be chosen such that $M^{1/T} = e^\alpha$.

**Proof:** Let $t$ be arbitrary. Then $t = mT + r(t)$ where $0 \leq r(t) < T$. Then by the semigroup property

$$||S(t)|| = ||S(mT + r(t))||$$

$$= ||S(r(t))S(T)^m|| \leq M^{m+1}$$

Now $mT \leq t \leq mT + r(t) \leq (m+1)T$ and so

$$m \leq \frac{t}{T} \leq m + 1$$

Therefore,

$$||S(t)|| \leq M^{(t/T)+1} = M \left( M^{1/T} \right)^t.$$
Let \( M^{1/T} = e^\alpha \) and then
\[ \| S(t) \| \leq Me^{\alpha t} \]
This proves the theorem.

**Definition 17.12.4** Let \( S(t) \) be a continuous semigroup as described above. It is called a contraction semigroup if for all \( t \geq 0 \)
\[ \| S(t) \| \leq 1. \]
It is called a bounded semigroup if there exists \( M \) such that for all \( t \geq 0 \),
\[ \| S(t) \| \leq M. \]
Note that for \( S(t) \) an arbitrary continuous semigroup satisfying
\[ \| S(t) \| \leq Me^{\alpha t}, \]
It follows that the semigroup,
\[ T(t) = e^{-\alpha t}S(t) \]
is a bounded semigroup which satisfies
\[ \| T(t) \| \leq M. \]

**Proposition 17.12.5** Given a continuous semigroup \( S(t) \), its generator \( A \) exists and is a closed densely defined operator. Furthermore, for
\[ \| S(t) \| \leq Me^{\alpha t} \]
and \( \lambda > \alpha \), \( \lambda I - A \) is onto and \( (\lambda I - A)^{-1} \) maps \( H \) onto \( D(A) \) and is in \( \mathcal{L}(H;H) \).
Also for these values of \( \lambda \),
\[ (\lambda I - A)^{-1}x = \int_0^\infty e^{-\lambda t}S(t)x \, dt. \]
For \( \lambda \geq \alpha \), the following estimate holds.
\[ \| (\lambda I - A)^{-1} \| \leq \frac{M}{\lambda - \alpha}. \]

**Proof:** First note \( D(A) \neq 0 \). In fact \( 0 \in D(A) \). It follows from Theorem 17.12.2 that for all \( \lambda \) large enough, one can define a Laplace transform,
\[ R(\lambda) x = \int_0^\infty e^{-\lambda t}S(t)x \, dt \in H. \]
Here the integral is the ordinary improper Riemann integral. I claim each of these is in \( D(A) \).
\[ \frac{S(h)\int_0^\infty e^{-\lambda t}S(t)x \, dt - \int_0^\infty e^{-\lambda t}S(t)x \, dt}{h} \]

Using the semigroup property and changing the variables in the first of the above integrals, this equals
\[
\frac{1}{h} \left( e^{\lambda h} \int_0^\infty e^{-\lambda t} S(t) x dt - \int_0^\infty e^{-\lambda t} S(t) x dt \right) = \frac{1}{h} \left( (e^{\lambda h} - 1) \int_0^\infty e^{-\lambda t} S(t) x dt - e^{\lambda h} \int_0^h e^{-\lambda t} S(t) x dt \right)
\]
The limit as \( h \to 0 \) exists and equals
\[
\lambda R(\lambda) x - x
\]
Thus \( R(\lambda) x \in D(A) \) as claimed and
\[
AR(\lambda) x = \lambda R(\lambda) x - x
\]
Hence
\[
x = (\lambda I - A) R(\lambda) x. \tag{17.12.73}
\]
Since \( x \) is arbitrary, this shows that for \( \lambda \) large enough, \( \lambda I - A \) is onto.

Why is \( D(A) \) dense? It was shown above that \( R(\lambda) x \) and thererfore \( \lambda R(\lambda) x \in D(A) \). Then for \( \lambda > \alpha \) where \( \|S(t)\| \leq Me^{\alpha t} \),
\[
\|\lambda R(\lambda) x - x\| = \left\| \int_0^\infty \lambda e^{-\lambda t} S(t) x dt - \int_0^\infty \lambda e^{-\lambda t} x dt \right\| 
\leq \int_0^\infty \|\lambda e^{-\lambda t} (S(t) x - x)\| dt
\]
\[
= \int_0^h \|\lambda e^{-\lambda t} (S(t) x - x)\| dt + \int_h^\infty \|\lambda e^{-\lambda t} (S(t) x - x)\| dt
\]
\[
\leq \int_0^h \|\lambda e^{-\lambda t} (S(t) x - x)\| dt + \int_h^\infty \lambda e^{-(\lambda - \alpha) t} dt (M + 1) \|x\|
\]
Now since \( S(t) x - x \to 0 \), it follows that for \( h \) sufficiently small
\[
\leq \frac{\varepsilon}{2} \int_0^h \lambda e^{-\lambda t} dt + \frac{\lambda}{\lambda - \alpha} e^{-(\lambda - \alpha) h} (M + 1) \|x\|
\]
\[
\leq \frac{\varepsilon}{2} + \frac{\lambda}{\lambda - \alpha} e^{-(\lambda - \alpha) h} (M + 1) \|x\| < \varepsilon
\]
whenever \( \lambda \) is large enough. Thus \( D(A) \) is dense as claimed.

Let \( x \in D(A) \). Then for \( y^* \in H' \),
\[
y^* \left( \int_0^t S(s) A x ds \right) = \int_0^t y^* \left( S(s) \lim_{h \to 0^+} \frac{S(h)x - x}{h} \right) ds
\]
The difference quotient is given to have a limit and so the difference quotients are bounded. Therefore, one can use the dominated convergence theorem to take the limit outside the integral and write the above equals

\[
\lim_{h \to 0^+} \int_0^t y^* \left( S(s) \frac{S(h)x - x}{h} \right) ds
\]

\[
= \lim_{h \to 0^+} y^* \left( \frac{1}{h} \left( \int_{t-h}^{t+h} S(s)x ds - \int_0^t S(s)x ds \right) \right)
\]

\[
= \lim_{h \to 0^+} y^* \left( \int_{t-h}^{t+h} S(s)x ds - \int_0^h S(s)x \right)
\]

\[
= y^* (S(t)x - x).
\]

Thus since \( y^* \) is arbitrary, for \( x \in D(A) \)

\[
S(t)x = x + \int_0^t S(s)Ax ds
\]

Why is \( A \) closed? Suppose \( x_n \to x \) and \( x_n \in D(A) \) while \( Ax_n \to z \). From what was just shown

\[
S(t)x_n = x_n + \int_0^t S(s)Ax_n ds
\]

and so, passing to the limit this yields

\[
S(t)x = x + \int_0^t S(s)z ds
\]

which implies

\[
\lim_{t \to 0^+} \frac{S(t)x - x}{h} = \lim_{h \to 0^+} \frac{1}{h} \int_0^t S(s)z ds = z
\]

which shows \( Ax = z \) and \( x \in D(A) \). Thus \( A \) is closed.

Because of 17.12.73 it follows \( R(\lambda)x = (\lambda I - A)^{-1}x \). Also

\[
\|R(\lambda)x\| \leq \left\| \int_0^\infty e^{-\lambda t}S(t)x dt \right\|
\]

\[
\leq \int_0^\infty e^{-\lambda t}Me^{\alpha t} \|x\| \leq \frac{M}{|\lambda - \alpha|} \|x\|
\]

so \( R(\lambda) = (\lambda I - A)^{-1} \in \mathcal{L}(H, H) \) and this also proves the last estimate. Also from 17.12.73 \( R(\lambda) \) maps \( H \) onto \( D(A) \). This proves the proposition.

The linear mapping \( (\lambda I - A)^{-1} \) is called the resolvent.

The above proof contains an argument which implies the following corollary.
Corollary 17.12.6 Let $S(t)$ be a continuous semigroup and let $A$ be its generator. Then for $0 < a < b$ and $x \in D(A)$

$$S(b)x - S(a)x = \int_a^b S(t)Ax\,dt$$

and also for $t > 0$ you can take the derivative from the left,

$$\lim_{h \to 0^+} \frac{S(t)x - S(t-h)x}{h} = S(t)Ax$$

Proof: Letting $y^* \in H'$,

$$y^*\left(\int_a^b S(t)Ax\,dt\right) = \int_a^b y^*\left(S(t)\lim_{h \to 0^+} \frac{S(h)x-x}{h}\right)\,dt$$

The difference quotients are bounded because they converge to $Ax$. Therefore, from the dominated convergence theorem,

$$y^*\left(\int_a^b S(t)Ax\,dt\right) = \lim_{h \to 0^+} \int_a^b y^*\left(S(t)\frac{S(h)x-x}{h}\right)\,dt$$

$$= \lim_{h \to 0^+} y^*\left(\int_a^b S(t)\frac{S(h)x-x}{h}\,dt\right)$$

$$= \lim_{h \to 0^+} y^*\left(\frac{1}{h} \int_a^{a+h} S(t)x\,dt - \frac{1}{h} \int_a^b S(t)x\,dt\right)$$

$$= \lim_{h \to 0^+} y^*\left(\frac{1}{h} \int_a^{a+h} S(t)x\,dt - \frac{1}{h} \int_a^{a+h} S(t)x\,dt\right)$$

$$= y^*\left(S(b)x - S(a)x\right)$$

Since $y^*$ is arbitrary, this proves the first part. Now from what was just shown, if $t > 0$ and $h$ is small enough,

$$\frac{S(t)x - S(t-h)x}{h} = \frac{1}{h} \int_{t-h}^t S(s)Ax\,ds$$

which converges to $S(t)Ax$ as $h \to 0^+$. This proves the corollary.

Given a closed densely defined operator, when is it the generator of a bounded semigroup? This is answered in the following theorem which is called the Hille Yosida theorem.

Theorem 17.12.7 Suppose $A$ is a densely defined linear operator which has the property that for all $\lambda > 0$,

$$(\lambda I - A)^{-1} \in \mathcal{L}(H,H)$$
which means that $\lambda I - A : D(A) \to H$ is one to one and onto with continuous inverse. Suppose also that for all $n \in \mathbb{N}$,

$$\left\| \left( (\lambda I - A)^{-1} \right)^n \right\| \leq \frac{M}{\lambda^n}. \quad (17.12.74)$$

Then there exists a continuous semigroup, $S(t)$ which has $A$ as its generator and satisfies $\| S(t) \| \leq M$ and $A$ is closed. In fact letting

$$S_\lambda(t) \equiv \exp \left( -\lambda + \lambda^2 (\lambda I - A)^{-1} \right)$$

it follows $\lim_{\lambda \to \infty} S_\lambda(t) x = S(t) x$ uniformly on finite intervals. Conversely, if $A$ is the generator of $S(t)$, a bounded continuous semigroup having $\| S(t) \| \leq M$, then $(\lambda I - A)^{-1} \in \mathcal{L}(H, H)$ for all $\lambda > 0$ and $17.12.74$ holds.

**Proof:** Consider the operator

$$\lambda (\lambda I - A)^{-1} A$$

On $D(A)$, this equals

$$-\lambda + \lambda^2 (\lambda I - A)^{-1} \quad (17.12.75)$$

which makes sense on all of $H$, not just on $D(A)$. Also this last expression equals

$$\lambda A (\lambda I - A)^{-1}$$

on all of $H$ because $\lambda I - A$ is given to be onto. Denote this as $A_\lambda$ to save notation. Thus on $D(A)$,

$$\lambda A (\lambda I - A)^{-1} = \lambda (\lambda I - A)^{-1} A$$

For $x \in D(A)$,

$$\left\| \lambda (\lambda I - A)^{-1} x - x \right\| = \left\| (\lambda I - A)^{-1} (\lambda x - (\lambda I - A) x) \right\| = \left\| (\lambda I - A)^{-1} Ax \right\| \leq \frac{M}{\lambda} \| Ax \|$$

which converges to 0. Therefore, for $x \in D(A)$,

$$\| A_\lambda x - Ax \| = \left\| \lambda (\lambda I - A)^{-1} Ax - Ax \right\| \leq \frac{M \| Ax \|}{\lambda} \quad (17.12.76)$$

so it also converges to 0. Because of $17.12.74$, the operator $\lambda A (\lambda I - A)^{-1}$ is continuous. Now using $17.12.74$, define an approximate semigroup

$$S_\lambda(t) \equiv e^{-M} \sum_{k=0}^{\infty} t^k \frac{(\lambda^2 (\lambda I - A)^{-1})^k}{k!}$$
The sum converges in $\mathcal{L}(H,H)$ because it converges absolutely and $\mathcal{L}(H,H)$ is complete. Here is why it converges absolutely. It follows from the assumption in the lemma.

$$\sum_{k=0}^{\infty} \frac{t^k \left( (\lambda^2 (\lambda I - A))^{-1} \right)^k}{k!} \leq \sum_{k=0}^{\infty} \frac{t^k \left( (\lambda^2 (\lambda I - A))^{-1} \right)^k}{k!} \leq \sum_{k=0}^{\infty} \frac{t^k \lambda^k M}{k!} = Me^{t\lambda}$$

Thus

$$||S_\lambda (t)|| \leq e^{-\lambda t} Me^{t\lambda} = M$$

The series converges uniformly on any finite interval thanks to the Weierstrass $M$ test. Thus $t \to S_\lambda (t)$ is continuous and it is also routine to verify the semigroup identity. Clearly $\lim_{t \to 0} S_\lambda (t) x = x$. It is also the case that $S_\lambda (t)$ is generated by $-\lambda + \lambda^2 (\lambda I - A)^{-1} = A_\lambda$. This is easy to show from differentiating the power series which has a continuous derivative. Thus

$$(-\lambda) e^{-\lambda t} \sum_{k=0}^{\infty} \frac{t^k \left( (\lambda^2 (\lambda I - A))^{-1} \right)^k x}{k!} + e^{-\lambda t} \sum_{k=0}^{\infty} \frac{t^k \left( (\lambda^2 (\lambda I - A))^{-1} \right)^{k+1} x}{k!}$$

$$= \left( -\lambda + \lambda^2 (\lambda I - A)^{-1} \right) S_\lambda (t) x = S_\lambda (t) \left( -\lambda + \lambda^2 (\lambda I - A)^{-1} \right) x$$

Now let $t \to 0+$ to obtain $\left( -\lambda + \lambda^2 (\lambda I - A)^{-1} \right) x = A_\lambda x$.

Claim: For $\lambda, \mu > 0$, $(\lambda I - A)^{-1}$ and $(\mu I - A)^{-1}$ commute.

Proof of claim: Suppose

$$y = (\mu I - A)^{-1} (\lambda I - A)^{-1} x \quad (17.12.77)$$

$$z = (\lambda I - A)^{-1} (\mu I - A)^{-1} x \quad (17.12.78)$$

I need to show $y = z$. First note $z \in D(A)$ and

$$(\lambda I - A) z = (\mu I - A)^{-1} x \in D(A).$$

Hence

$$(\mu I - A) z = (\mu - \lambda) z + (\lambda I - A) z \in D(A).$$

Similarly

$$S_\lambda (t) y = (\mu I - A) y \in D(A).$$

From $17.12.78$

$$(\lambda I - A) (\mu I - A) y = x$$
and using \[17.12.78\],

\[
x = (\mu I - A) (\lambda I - A) z \\
= ((\mu - \lambda) I + (\lambda I - A)) (\lambda I - A) z \\
= (\mu - \lambda) (\lambda I - A) z + (\lambda I - A)^2 z \\
= (\lambda I - A) (\mu - \lambda) z + (\lambda I - A) (\lambda I - A) z
\]

Thus

\[
x = (\lambda I - A) (\mu I - A) z = (\lambda I - A) (\mu I - A) y
\]

and so \( z = y \). This proves the claim.

It follows from the description of \( S_{\lambda}(t) \) that \( S_{\lambda}(t) \) and \( S_{\mu}(s) \) commute and also \( A_{\lambda} \) commutes with \( S_{\mu}(t) \) for any \( t \).

I want to show that for each \( x \in D(A) \),

\[
\lim_{\lambda \to \infty} S_{\lambda}(t) x = S(t) x
\]

where \( S(t) \) is the desired semigroup. Let \( x \in D(A) \)

\[
||S_{\lambda}(t)x - S_{\mu}(t)x|| = \left|\int_0^t \frac{d}{dr} (S_{\lambda}(t - r) S_{\mu}(r)) x dr \right|
\]

Since \( A_{\lambda} \) commutes with \( S_{\mu}(r) \), the following formula follows from \[17.12.76\].

\[
\begin{align*}
&= \left|\int_0^t (S_{\lambda}(t - r) S_{\mu}(r) A_{\mu} x - S_{\lambda}(t - r) A_{\lambda} S_{\mu}(r) x) dr \right| \\
&\leq \int_0^t ||S_{\lambda}(t - r) S_{\mu}(r) (A_{\mu} x - A_{\lambda} x)|| dr \\
&\leq M^2 t ||A_{\mu} x - A_{\lambda} x|| \leq M^2 t (||A_{\mu} x - A x|| + ||A x - A_{\lambda} x||) \\
&\leq \left( \frac{||Ax||}{\mu} + \frac{||Ax||}{\lambda} \right) t M^2
\end{align*}
\]

Hence whenever \( \mu, \lambda \) large enough, \( ||S_{\lambda}(t) x - S_{\mu}(t) x|| \) is small. Thus \( S_{\lambda}(t) x \) converges uniformly on finite intervals to something denoted by \( S(t) x \). Therefore, \( t \to S(t) x \) is continuous for each \( x \in D(A) \) and also

\[
||S(t) x|| = \lim_{\lambda \to \infty} ||S_{\lambda}(t) x|| \leq M ||x||
\]
so that $S(t)$ can be extended to a continuous linear map, still called $S(t)$ defined on all of $H$ which also satisfies $\|S(t)\| \leq M$ since $D(A)$ is dense in $H$. If $x$ is arbitrary, let $y \in D(A)$ be close to $x$. Then
\[
\|S(t)x - S_\lambda(t)x\| \leq \|S(t)x - S(t)y\| + \|S(t)y - S_\lambda(t)y\| + \|S_\lambda(t)y - S_\lambda(t)x\|
\]
\[
\leq 2M \|x - y\| + \|S(t)y - S_\lambda(t)y\|
\]
and so $\lim_{\lambda \to \infty} S_\lambda(t)x = S(t)x$ for all $x$, uniformly on finite intervals. Thus $t \to S(t)x$ is continuous for any $x \in H$.

It remains to verify $A$ generates $S(t)$ and for all $x$, $S(t)x - x \to 0$. From the above,
\[
S_\lambda(t)x = x + \int_0^t S_\lambda(s) A_\lambda x ds
\]
and so
\[
\lim_{t \to 0^+} \|S_\lambda(t)x - x\| = 0
\]
By the uniform convergence just shown, there exists $\lambda$ large enough that for all $t \in [0, \delta]$,
\[
\|S(t)x - S_\lambda(t)x\| < \varepsilon.
\]
Then
\[
\limsup_{t \to 0^+} \|S(t)x - x\| \leq \limsup_{\lambda \to \infty} (\|S(t)x - S_\lambda(t)x\| + \|S_\lambda(t)x - x\|)
\]
\[
\leq \limsup_{t \to 0^+} (\varepsilon + \|S_\lambda(t)x - x\|) \leq \varepsilon
\]
It follows $\lim_{t \to 0^+} S(t)x = x$ because $\varepsilon$ is arbitrary.

Next, $\lim_{\lambda \to \infty} A_\lambda x = Ax$ for all $x \in D(A)$ by (17.12.76). Therefore, passing to the limit in (17.12.79) yields from the uniform convergence
\[
S(t)x = x + \int_0^t S(s)Ax ds
\]
and by continuity of $s \to S(s)Ax$, it follows
\[
\lim_{h \to 0^+} \frac{S(h)x - x}{h} = \lim_{h \to 0^+} \frac{1}{h} \int_0^h S(s)Ax ds = Ax
\]
Thus letting $B$ denote the generator of $S(t)$, $D(A) \subseteq D(B)$ and $A = B$ on $D(A)$.

It only remains to verify $D(A) = D(B)$.

To do this, let $\lambda > 0$ and consider the following where $y \in H$ is arbitrary.
\[
(\lambda I - B)^{-1} y = (\lambda I - B)^{-1} \left( (\lambda I - A) (\lambda I - A)^{-1} y \right)
\]
CHAPTER 17. HILBERT SPACES

Now \((\lambda I - A)^{-1} y \in D(A) \subseteq D(B)\) and \(A = B\) on \(D(A)\) and so
\[
(\lambda I - A)(\lambda I - A)^{-1} y = (\lambda I - B)(\lambda I - A)^{-1} y
\]
which implies,
\[
(\lambda I - B)^{-1} y =
(\lambda I - B)^{-1} \left( (\lambda I - B)(\lambda I - A)^{-1} y \right) = (\lambda I - A)^{-1} y
\]
Recall from Proposition 17.12.5 that an arbitrary element of \(D(B)\) is of the form \((\lambda I - B)^{-1} y\) and this has shown every such vector is in \(D(A)\), in fact it equals \((\lambda I - A)^{-1} y\). Hence \(D(B) \subseteq D(A)\) which shows \(A\) generates \(S(t)\) and this proves the first half of the theorem.

Next suppose \(A\) is the generator of a semigroup \(S(t)\) having \(\|S(t)\| \leq M\). Then by Proposition 17.12.5 for all \(\lambda > 0\), \((\lambda I - A)\) is onto and
\[
(\lambda I - A)^{-1} = \int_0^\infty e^{-\lambda t} S(t) \, dt
\]
thus
\[
\left\| \left( (\lambda I - A)^{-1} \right)^n \right\| = \left\| \int_0^\infty \cdots \int_0^\infty e^{-\lambda(t_1 + \cdots + t_n)} S(t_1 + \cdots + t_n) \, dt_1 \cdots dt_n \right\|
\leq \int_0^\infty \cdots \int_0^\infty e^{-\lambda(t_1 + \cdots + t_n)} M dt_1 \cdots dt_n = \frac{M}{\lambda^n}.
\]
This proves the theorem.

17.12.1 An Evolution Equation

When \(A\) generates a continuous semigroup, one can consider a very interesting theorem about evolution equations of the form
\[
y' - Ay = g(t)
\]
provided \(t \to g(t)\) is \(C^1\).

Theorem 17.12.8 Let \(A\) be the generator of \(S(t)\), a continuous semigroup on \(H\), a Banach space and let \(t \to g(t)\) be in \(C^1(0, \infty; H)\). Then there exists a unique solution to the initial value problem
\[
y' - Ay = g, \ y(0) = y_0 \in D(A)
\]
and it is given by
\[
y(t) = S(t) y_0 + \int_0^t S(t - s) g(s) \, ds. \quad (17.12.80)
\]
This solution is continuous having continuous derivative and has values in \(D(A)\).
\textbf{Proof:} First I show the following claim.

\textbf{Claim:} \( \int_0^t S(t-s)g(s)\, ds \in D(\Lambda) \) and

\[
\Lambda \left( \int_0^t S(t-s)g(s)\, ds \right) = S(t)g(0) - g(t) + \int_0^t S(t-s)g'(s)\, ds
\]

\textbf{Proof of the claim:}

\[
\frac{1}{h} \left( S(h) \int_0^t S(t-s)g(s)\, ds - \int_0^t S(t-s)g(s)\, ds \right)
\]

\[
= \frac{1}{h} \left( \int_0^t S(t-s+h)g(s)\, ds - \int_0^t S(t-s)g(s)\, ds \right)
\]

\[
= \frac{1}{h} \left( \int_{-h}^{t-h} S(t-s)g(s+h)\, ds - \int_0^t S(t-s)g(s)\, ds \right)
\]

\[
= \frac{1}{h} \int_{-h}^0 S(t-s)g(s+h)\, ds + \int_0^{t-h} S(t-s) \frac{g(s+h) - g(s)}{h} \, ds
\]

\[
- \frac{1}{h} \int_{t-h}^t S(t-s)g(s)\, ds
\]

Using the estimate in Theorem 17.12.3 on Page 565 and the dominated convergence theorem, the limit as \( h \to 0 \) of the above equals

\[
S(t)g(0) - g(t) + \int_0^t S(t-s)g'(s)\, ds
\]

which proves the claim.

Since \( y_0 \in D(\Lambda) \),

\[
S(t)y_0 = S(t) \lim_{h \to 0} \frac{S(h)y_0 - y_0}{h}
\]

\[
= \lim_{h \to 0} \frac{S(t+h) - S(t)}{h} \, y_0
\]

\[
= \lim_{h \to 0} \frac{S(h)S(t)\, y_0 - S(t)\, y_0}{h}
\]

(17.12.81)

Since this limit exists, the last limit in the above exists and equals

\[
\Lambda S(t)\, y_0
\]

(17.12.82)

and so \( S(t)y_0 \in D(\Lambda) \). Now consider 17.12.80,

\[
\frac{y(t+h) - y(t)}{h} = \frac{S(t+h) - S(t)}{h} \, y_0 +
\]
\[
\frac{1}{h} \left( \int_0^{t+h} S(t-s+h)g(s) \, ds - \int_0^t S(t-s)g(s) \, ds \right)
\]
\[
= \frac{S(t+h) - S(t)}{h} y_0 + \frac{1}{h} \int_t^{t+h} S(t-s+h)g(s) \, ds
\]
\[
+ \frac{1}{h} \left( S(h) \int_0^t S(t-s)g(s) \, ds - \int_0^t S(t-s)g(s) \, ds \right)
\]

From the claim and 17.12.81, 17.12.82, the limit of the right side is
\[
\Lambda S(t) y_0 + g(t) + \Lambda \left( \int_0^t S(t-s)g(s) \, ds \right)
\]
\[
= \Lambda \left( S(t) y_0 + \int_0^t S(t-s)g(s) \, ds \right) + g(t)
\]
Hence
\[
y'(t) = \Lambda y(t) + g(t)
\]
and from the formula, \(y'\) is continuous since by the claim and 17.12.82 it also equals
\[
S(t) \Lambda y_0 + g(t) + S(t) g(0) - g(t) + \int_0^t S(t-s) g'(s) \, ds
\]
which is continuous. The claim and 17.12.82 also shows \(y(t) \in D(\Lambda)\). This proves the existence part of the lemma.

It remains to prove the uniqueness part. It suffices to show that if
\[
y' - \Lambda y = 0, \ y(0) = 0
\]
and \(y\) is \(C^1\) having values in \(D(\Lambda)\), then \(y = 0\). Suppose then that \(y\) is this way. Letting \(0 < s < t\),
\[
\frac{d}{ds} (S(t-s) y(s))
\]
\[
= \lim_{h \to 0} S(t-s-h) \frac{y(s+h) - y(s)}{h} - \frac{S(t-s) y(s) - S(t-s-h) y(s)}{h}
\]
provided the limit exists. Since \(y'\) exists and \(y(s) \in D(\Lambda)\), this equals
\[
S(t-s) y'(s) - S(t-s) \Lambda y(s) = 0.
\]
Let \(y^* \in H^1\). This has shown that on the open interval \((0,t)\) the function \(s \to y^*(S(t-s) y(s))\) has a derivative equal to 0. Also from continuity of \(S\) and \(y\), this function is continuous on \([0,t]\). Therefore, it is constant on \([0,t]\) by the mean value theorem. At \(s = 0\), this function equals 0. Therefore, it equals 0 on \([0,t]\). Thus for fixed \(s > 0\) and letting \(t > s\), \(y^*(S(t-s) y(s)) = 0\). Now let \(t\) decrease toward \(s\). Then \(y^*(y(s)) = 0\) and since \(y^*\) was arbitrary, it follows \(y(s) = 0\). This proves uniqueness.
17.12.2 Adjoint, Hilbert Space

In Hilbert space, there are some special things which are true.

**Definition 17.12.9** Let $A$ be a densely defined closed operator on $H$ a real Hilbert space. Then $A^*$ is defined as follows.

$$D(A^*) = \{ y \in H : |(Ax, y)| \leq C|x| \}$$

Then since $D(A)$ is dense, there exists a unique element of $H$ denoted by $A^*y$ such that

$$(Ax, y) = (x, A^*y)$$

for all $x \in D(A)$.

**Lemma 17.12.10** Let $A$ be closed and densely defined on $D(H) \subseteq H$, a Hilbert space. Then $A^*$ is also closed and densely defined. Also $(A^*)^* = A$. In addition to this, if $(\lambda I - A)^{-1} \in \mathcal{L}(H, H)$, then $(\lambda I - A^*)^{-1} \in \mathcal{L}(H, H)$ and

$$\left( \left( (\lambda I - A)^{-1} \right)^n \right)^* = \left( (\lambda I - A^*)^{-1} \right)^n$$

**Proof:** Denote by $[x, y]$ an ordered pair in $H \times H$. Define $\tau : H \times H \to H \times H$ by

$$\tau [x, y] \equiv [-y, x]$$

Then the definition of adjoint implies that for $\mathcal{G}(B)$ equal to the graph of $B$,

$$\mathcal{G}(A^*) = (\tau \mathcal{G}(A))^\perp$$

(17.12.83)

In this notation the inner product on $H \times H$ with respect to which $\perp$ is defined is given by

$$([x, y], [a, b]) \equiv (x, a) + (y, b).$$

Here is why this is so. For $[x, A^*x] \in \mathcal{G}(A^*)$ it follows that for all $y \in D(A)$

$$([x, A^*x], [-Ay, y]) = -(Ay, x) + (y, A^*x) = 0$$

and so $[x, A^*x] \in (\tau \mathcal{G}(A))^\perp$ which shows

$$\mathcal{G}(A^*) \subseteq (\tau \mathcal{G}(A))^\perp$$

To obtain the other inclusion, let $[a, b] \in (\tau \mathcal{G}(A))^\perp$. This means that for all $x \in D(A)$,

$$([a, b], [-Ax, x]) = 0.$$ 

In other words, for all $x \in D(A)$,

$$(Ax, a) = (x, b)$$
and so $|(Ax, a)| \leq C |x|$ for all $x \in D(A)$ which shows $a \in D(A^*)$ and

$$(x, A^*a) = (x, b)$$

for all $x \in D(A)$. Therefore, since $D(A)$ is dense, it follows $b = A^*a$ and so $[a, b] \in G(A^*)$. This shows the other inclusion.

Note that if $V$ is any subspace of the Hilbert space $H \times H$,

$$(V^\perp)^\perp = V$$

and $S^\perp$ is always a closed subspace. Also $\tau$ and $\perp$ commute. The reason for this is that $[x, y] \in (\tau V)^\perp$ means that

$$(x, -b) + (y, a) = 0$$

for all $[a, b] \in V$ and $[x, y] \in \tau (V^\perp)$ means $[-y, x] \in V^\perp$ so for all $[a, b] \in V$,

$$(-y, a) + (x, b) = 0$$

which says the same thing. It is also clear that $\tau \circ \tau$ has the effect of multiplication by $-1$.

It follows from the above description of the graph of $A^*$ that even if $G(A)$ were not closed it would still be the case that $G(A^*)$ is closed.

Why is $D(A^*)$ dense? Suppose $z \in D(A^*)^\perp$. Then for all $y \in D(A^*)$ so that $[y, Ay] \in G(A^*)$, it follows $[z, 0] \in G(A^*)^\perp = \left( (\tau G(A))^\perp \right)^\perp = \tau G(A)$ but this implies

$$[0, z] \in -G(A)$$

and so $z = -A0 = 0$. Thus $D(A^*)$ must be dense since there is no nonzero vector in $D(A^*)^\perp$.

Since $A$ is a closed operator, meaning $G(A)$ is closed in $H \times H$, it follows from the above formula that

$$G((A^*)^*) = \left( \tau \left( (\tau G(A))^\perp \right) \right)^\perp = \left( (\tau G(A))^\perp \right)^\perp = \left( (\tau G(A))^\perp \right)^\perp = G(A)$$

and so $(A^*)^* = A$.

Now consider the final claim. First let $y \in D(A^*) = D(\lambda I - A^*)$. Then letting $x \in H$ be arbitrary,

$$(x, \left( (\lambda I - A) (\lambda I - A)^{-1} \right)^* y)$$

$$= \left( (\lambda I - A) (\lambda I - A)^{-1} x, y \right) = (x, \left( (\lambda I - A)^{-1} \right)^* (\lambda I - A^*) y)$$

Thus

$$\left( (\lambda I - A) (\lambda I - A)^{-1} \right)^* = I = \left( (\lambda I - A)^{-1} \right)^* (\lambda I - A^*) \quad (17.12.84)$$
on \( D(A^*) \). Next let \( x \in D(A) = D(\lambda I - A) \) and \( y \in H \) arbitrary.

\[
(x, y) = \left( (\lambda I - A)^{-1} (\lambda I - A) x, y \right) = \left( (\lambda I - A) x, (\lambda I - A)^{-1} y \right)
\]

Now it follows \(|(\lambda I - A) x, (\lambda I - A)^{-1} y)| \leq |y| |x|\) for any \( x \in D(A) \) and so

\[
\left( (\lambda I - A)^{-1} \right)^* y \in D(A^*)
\]

Hence

\[
(x, y) = \left( x, (\lambda I - A^*) \left( (\lambda I - A)^{-1} \right)^* y \right).
\]

Since \( x \in D(A) \) is arbitrary and \( D(A) \) is dense, it follows

\[
(\lambda I - A^*) \left( (\lambda I - A)^{-1} \right)^* = I
\]

From (17.12.84) and (17.12.85) it follows

\[
(\lambda I - A^*)^{-1} = \left( (\lambda I - A)^{-1} \right)^*
\]

and \((\lambda I - A^*)\) is one to one and onto with continuous inverse. Finally, from the above,

\[
\left( \left( (\lambda I - A^*)^{-1} \right) \right)^n = \left( \left( (\lambda I - A)^{-1} \right)^* \right)^n = \left( \left( (\lambda I - A)^{-1} \right)^* \right)^n.
\]

This proves the lemma.

With this preparation, here is an interesting result about the adjoint of the generator of a continuous bounded semigroup. I found this in Balakrishnan [4].

**Theorem 17.12.11** Suppose \( A \) is a densely defined closed operator which generates a continuous semigroup, \( S(t) \). Then \( A^* \) is also a closed densely defined operator which generates \( S^*(t) \) and \( S^*(t) \) is also a continuous semigroup.

**Proof:** First suppose \( S(t) \) is also a bounded semigroup, \(|S^*(t)| \leq M\). From Lemma (17.12.10) \( A^* \) is closed and densely defined. It follows from the Hille Yosida theorem, Theorem (17.12.4) that

\[
\left| \left( (\lambda I - A)^{-1} \right)^n \right| \leq \frac{M}{\lambda^n}
\]

From Lemma (17.12.10) and the fact the adjoint of a bounded linear operator preserves the norm,

\[
\frac{M}{\lambda^n} \geq \left| \left( \left( (\lambda I - A)^{-1} \right)^n \right)^* \right| = \left| \left( \left( (\lambda I - A)^{-1} \right)^* \right)^n \right|
\]

\[
= \left| \left( (\lambda I - A^*)^{-1} \right)^n \right|
\]
and so by Theorem 17.12.7 again it follows $A^*$ generates a continuous semigroup, $T(t)$ which satisfies $\|T(t)\| \leq M$. I need to identify $T(t)$ with $S^*(t)$. However, from the proof of Theorem 17.12.7 and Lemma 17.12.10, it follows that for $x \in D(A^*)$ and a suitable sequence $\{\lambda_n\}$,

$$(T(t)x, y) = \left( \lim_{n \to \infty} e^{-\lambda_n t} \sum_{k=0}^{\infty} t^k \frac{(\lambda_n^2 (\lambda_n I - A^*)^{-1})^k}{k!} x, y \right)$$

$$= \lim_{n \to \infty} \left( e^{-\lambda_n t} \sum_{k=0}^{\infty} t^k \frac{(\lambda_n^2 (\lambda_n I - A)^{-1})^k}{k!} x, y \right)$$

$$= \lim_{n \to \infty} \left( x, e^{-\lambda_n t} \sum_{k=0}^{\infty} t^k \frac{(\lambda_n^2 (\lambda_n I - A)^{-1})^k}{k!} y \right)$$

$$= (x, S(t)y) = (S^*(t)x, y).$$

Therefore, since $y$ is arbitrary, $S^*(t) = T(t)$ on $x \in D(A^*)$ a dense set and this shows the two are equal. This proves the proposition in the case where $S(t)$ is also bounded.

Next only assume $S(t)$ is a continuous semigroup. Then by Proposition 17.12.5 there exists $\alpha > 0$ such that

$$||S(t)|| \leq Me^{\alpha t}.$$  

Then consider the operator $-\alpha I + A$ and the bounded semigroup $e^{-\alpha t}S(t)$. For $x \in D(A)$

$$\lim_{h \to 0^+} \frac{e^{-\alpha h}S(h)x - x}{h} = \lim_{h \to 0^+} \left( e^{-\alpha h} \frac{S(h)x - x}{h} + \frac{e^{-\alpha h} - 1}{h} x \right)$$

$$= -\alpha x + Ax$$

Thus $-\alpha I + A$ generates $e^{-\alpha t}S(t)$ and it follows from the first part that $-\alpha I + A^*$ generates $e^{-\alpha t}S^*(t)$. Thus

$$-\alpha x + A^*x = \lim_{h \to 0^+} \frac{e^{-\alpha h}S^*(h)x - x}{h}$$

$$= \lim_{h \to 0^+} \left( e^{-\alpha h} \frac{S^*(h)x - x}{h} + \frac{e^{-\alpha h} - 1}{h} x \right)$$

$$= -\alpha x + \lim_{h \to 0^+} \frac{S^*(h)x - x}{h}$$

showing that $A^*$ generates $S^*(t)$ . It follows from Proposition 17.12.4 that $A^*$ is closed and densely defined. It is obvious $S^*(t)$ is a semigroup. Why is it continuous?
This also follows from the first part of the argument which establishes that
\[ e^{-\lambda t} S(t) \]
is continuous. This proves the theorem.

### 17.12.3 Adjoints, Reflexive Banach Space

Here the adjoint of a generator of a semigroup is considered. I will show that the
adjoint of the generator generates the adjoint of the semigroup in a reflexive Banach
space. This is about as far as you can go although a general but less satisfactory
result is given in Yosida [115].

**Definition 17.12.12** Let \( A \) be a densely defined closed operator on \( H \) a real Banach
space. Then \( A^* \) is defined as follows.

\[
D(A^*) \equiv \{ y^* \in H' : |y^*(Ax)| \leq C \|x\| \text{ for all } x \in D(A) \}
\]

Then since \( D(A) \) is dense, there exists a unique element of \( H' \) denoted by \( A^* y \) such
that

\[
A^*(y^*)(x) = y^*(Ax)
\]

for all \( x \in D(A) \).

**Lemma 17.12.13** Let \( A \) be closed and densely defined on \( D(A) \subseteq H \), a Banach
space. Then \( A^* \) is also closed and densely defined. Also \( (A^*)^* = A \). In addition to
this, if \( (\lambda I - A)^{-1} \in \mathcal{L}(H,H) \), then \( (\lambda I - A^*)^{-1} \in \mathcal{L}(H',H') \) and

\[
\left( \left( (\lambda I - A)^{-1} \right)^n \right)^* = \left( (\lambda I - A^*)^{-1} \right)^n
\]

**Proof:** Denote by \([x,y]\) an ordered pair in \( H \times H \). Define \( \tau : H \times H \rightarrow H \times H \)
by

\[
\tau [x,y] \equiv [-y,x]
\]

A similar notation will apply to \( H' \times H' \). Then the definition of adjoint implies
that for \( \mathcal{G}(B) \) equal to the graph of \( B \),

\[
\mathcal{G}(A^*) = (\tau \mathcal{G}(A))^\perp \quad (17.12.86)
\]

For \( S \subseteq H \times H \), define \( S^\perp \) by

\[
\{[a^*, b^*] \in H' \times H' : a^*(x) + b^*(y) = 0 \text{ for all } [x,y] \in S \}
\]

If \( S \subseteq H' \times H' \) a similar definition holds.

\[
\{[x,y] \in H \times H : a^*(x) + b^*(y) = 0 \text{ for all } [a^*, b^*] \in S \}
\]

Here is why (17.12.86) is so. For \([x^*, A^* x^*] \in \mathcal{G}(A^*) \) it follows that for all \( y \in D(A) \)

\[
x^*(Ay) = A^* x^*(y)
\]
and so for all \([y, Ay] \in \mathcal{G}(A)\),

\[-x^* (Ay) + A^* x^* (y) = 0\]

which is what it means to say \([x^*, A^* x^*] \in (\tau \mathcal{G}(A))^\perp\). This shows

\[\mathcal{G}(A^*) \subseteq (\tau \mathcal{G}(A))^\perp\]

To obtain the other inclusion, let \([a^*, b^*] \in (\tau \mathcal{G}(A))^\perp\). This means that for all \([x, Ax] \in \mathcal{G}(A)\),

\[-a^* (Ax) + b^* (x) = 0\]

In other words, for all \(x \in D(A)\),

\[|a^* (Ax)| \leq ||b^*|| ||x||\]

which means by definition, \(a^* \in D(A^*)\) and \(A^* a^* = b^*\). Thus \([a^*, b^*] \in \mathcal{G}(A^*)\). This shows the other inclusion.

Note that if \(V\) is any subspace of \(H \times H\),

\[(V^\perp)^\perp = V\]

and \(S^\perp\) is always a closed subspace. Also \(\tau\) and \(\perp\) commute. The reason for this is that \([x^*, y^*] \in (\tau V)^\perp\) means that

\[-x^* (b) + y^* (a) = 0\]

for all \([a, b] \in V\) and \([x^*, y^*] \in \tau (V^\perp)\) means \([-y^*, x^*] \in - (V^\perp) = V^\perp\) so for all \([a, b] \in V\),

\[-y^* (a) + x^* (b) = 0\]

which says the same thing. It is also clear that \(\tau \circ \tau\) has the effect of multiplication by \(-1\). If \(V \subseteq H' \times H'\), the argument for commuting \(\perp\) and \(\tau\) is similar.

It follows from the above description of the graph of \(A^*\) that even if \(\mathcal{G}(A)\) were not closed it would still be the case that \(\mathcal{G}(A^*)\) is closed.

Why is \(D(A^*)\) dense? If it is not dense, then by a typical application of the Hahn Banach theorem, there exists \(y^{**} \in H''\) such that \(y^{**} (D(A^*)) = 0\) but \(y^{**} \neq 0\). Since \(H\) is reflexive, there exists \(y \in H\) such that \(x^* (y) = 0\) for all \(x^* \in D(A^*)\). Thus

\[\begin{bmatrix} [y, 0] \end{bmatrix} \in \mathcal{G}(A^*)^\perp = (\tau \mathcal{G}(A))^\perp = \tau \mathcal{G}(A)\]

and so \([0, y] \in \mathcal{G}(A)\) which means \(y = A0 = 0\), a contradiction. Thus \(D(A^*)\) is indeed dense. Note this is where it was important to assume the space is reflexive. If you consider \(C([0, 1])\) it is not dense in \(L^\infty([0, 1])\) but if \(f \in L^1([0, 1])\) satisfies

\[\int_0^1 fg dm = 0\]

for all \(g \in C([0, 1])\), then \(f = 0\). Hence there is no nonzero \(f \in C([0, 1])^\perp\).
Since \( A \) is a closed operator, meaning \( \mathcal{G}(A) \) is closed in \( H \times H \), it follows from the above formula that
\[
\mathcal{G}((A^*)^*) = \left( \tau \left( \tau \mathcal{G}(A) \right)^\perp \right)^\perp = \left( \tau \mathcal{G}(A) \right)^\perp = \mathcal{G}(A)
\]
and so \((A^*)^* = A\).

Now consider the final claim. First let \( y^* \in D(A^*) = D(\lambda I - A^*) \). Then letting \( x \in H \) be arbitrary,
\[
y^*(x) = \left( (\lambda I - A)(\lambda I - A)^{-1} \right)^* y^*(x)
\]
\[
= y^* \left( (\lambda I - A)(\lambda I - A)^{-1} x \right)
\]
Since \( y^* \in D(A^*) \) and \( (\lambda I - A)^{-1} x \in D(A) \), this equals
\[
(\lambda I - A)^* y^* \left( (\lambda I - A)^{-1} x \right)
\]
Now by definition, this equals
\[
\left( (\lambda I - A)^{-1} \right)^* (\lambda I - A)^* y^* (x)
\]
It follows that for \( y^* \in D(A^*) \),
\[
\left( (\lambda I - A)^{-1} \right)^* (\lambda I - A)^* y^* = (\lambda I - A)^* y^* = y^*
\]
\[ (17.12.87) \]
Next let \( y^* \in H' \) be arbitrary and \( x \in D(A) \)
\[
y^*(x) = y^* \left( (\lambda I - A)^{-1} (\lambda I - A) x \right)
\]
\[
= \left( (\lambda I - A)^{-1} \right)^* y^* \left( (\lambda I - A) x \right)
\]
\[
= (\lambda I - A)^* \left( (\lambda I - A)^{-1} \right)^* y^* (x)
\]
In going from the second to the third line, the first line shows \( (\lambda I - A)^{-1} \) \( y^* \in D(A^*) \) and so the third line follows. Since \( D(A) \) is dense, it follows
\[
(\lambda I - A) \left( (\lambda I - A)^{-1} \right)^* = I
\]
\[ (17.12.88) \]
Then \[ (17.12.87) \] and \[ (17.12.88) \] show \( \lambda I - A^* \) is one to one and onto from \( D(A^*) \) to \( H' \) and
\[
(\lambda I - A^*)^{-1} = \left( (\lambda I - A)^{-1} \right)^* \]
Finally, from the above,
\[
\left( (\lambda I - A^*)^{-1} \right)^n = \left( \left( (\lambda I - A)^{-1} \right)^* \right)^n = \left( \left( (\lambda I - A)^{-1} \right)^n \right)^* .
\]

This proves the lemma.

With this preparation, here is an interesting result about the adjoint of the generator of a continuous bounded semigroup.

**Theorem 17.12.14** Suppose \( A \) is a densely defined closed operator which generates a continuous semigroup, \( S(t) \). Then \( A^* \) is also a closed densely defined operator which generates \( S^*(t) \) and \( S^*(t) \) is also a continuous semigroup.

**Proof:** First suppose \( S(t) \) is also a bounded semigroup, \( \|S(t)\| \leq M \). From Lemma 17.12.13 \( A^* \) is closed and densely defined. It follows from the Hille Yosida theorem, Theorem 17.12.7 that
\[
\left\| \left( (\lambda I - A)^{-1} \right)^n \right\| \leq \frac{M}{\lambda^n}
\]

From Lemma 17.12.13 and the fact the adjoint of a bounded linear operator preserves the norm,
\[
\frac{M}{\lambda^n} \geq \left\| \left( \left( (\lambda I - A)^{-1} \right)^n \right)^* \right\| = \left\| \left( \left( (\lambda I - A)^{-1} \right)^* \right)^n \right\| = \left\| \left( (\lambda I - A^*)^{-1} \right)^n \right\|
\]
and so by Theorem 17.12.7 again it follows \( A^* \) generates a continuous semigroup, \( T(t) \) which satisfies \( \|T(t)\| \leq M \). I need to identify \( T(t) \) with \( S^*(t) \). However, from the proof of Theorem 17.12.7 and Lemma 17.12.13 it follows that for \( x^* \in D(A^*) \) and a suitable sequence \( \{\lambda_n\} \),
\[
T(t) x^*(y) = \lim_{n \to \infty} e^{-\lambda_n t} \sum_{k=0}^{\infty} \frac{t^k \left( \lambda_n^2 (\lambda_n I - A)^{-1} \right)^k}{k!} x^*(y)
\]

\[
= \lim_{n \to \infty} e^{-\lambda_n t} \sum_{k=0}^{\infty} \frac{t^k \left( \lambda_n^2 (\lambda_n I - A)^{-1} \right)^k}{k!} x^*(y)
\]

\[
= \lim_{n \to \infty} x^* \left( e^{-\lambda_n t} \left( \sum_{k=0}^{\infty} \frac{t^k \left( \lambda_n^2 (\lambda_n I - A)^{-1} \right)^k}{k!} y \right) \right)
\]

\[
= x^*(S(t) y) = S^*(t)x^*(y).
\]
Therefore, since \( y \) is arbitrary, \( S^* (t) = T (t) \) on \( x \in D (A^*) \) a dense set and this shows the two are equal. In particular, \( S^* (t) \) is a semigroup because \( T (t) \) is. This proves the proposition in the case where \( S (t) \) is also bounded.

Next only assume \( S (t) \) is a continuous semigroup. Then by Proposition 17.12.5 there exists \( \alpha > 0 \) such that
\[
\| S (t) \| \leq M e^{\alpha t}.
\]
Then consider the operator \(-\alpha I + A\) and the bounded semigroup \( e^{-\alpha t} S (t) \). For \( x \in D (A) \)
\[
\lim_{h \to 0^+} \frac{e^{-\alpha h} S (h) x - x}{h} = \lim_{h \to 0^+} \left( \frac{e^{-\alpha h} S (h) x - x}{h} + \frac{e^{-\alpha h} - 1}{h} x \right) = -\alpha x + Ax
\]
Thus \(-\alpha I + A\) generates \( e^{-\alpha t} S (t) \) and it follows from the first part that \(-\alpha I + A^*\) generates the semigroup \( e^{-\alpha t} S^* (t) \). Thus
\[
-\alpha x + A^* x = \lim_{h \to 0^+} \frac{e^{-\alpha h} S^* (h) x - x}{h} = \lim_{h \to 0^+} \left( \frac{e^{-\alpha h} S^* (h) x - x}{h} + \frac{e^{-\alpha h} - 1}{h} x \right) = -\alpha x + \lim_{h \to 0^+} \frac{S^* (h) x - x}{h}
\]
showing that \( A^* \) generates \( S^* (t) \). It follows from Proposition 17.12.5 that \( A^* \) is closed and densely defined. It is obvious \( S^* (t) \) is a semigroup. Why is it continuous? This also follows from the first part of the argument which establishes that
\[
t \to e^{-\alpha t} S^* (t) x
\]
is continuous. This proves the theorem.
Chapter 18

Representation Theorems

18.1 Radon Nikodym Theorem

This chapter is on various representation theorems. The first theorem, the Radon Nikodym Theorem, is a representation theorem for one measure in terms of another. The approach given here is due to Von Neumann and depends on the Riesz representation theorem for Hilbert space, Theorem 17.1.1 on Page 503.

Definition 18.1.1 Let $\mu$ and $\lambda$ be two measures defined on a $\sigma$-algebra, $S$, of subsets of a set, $\Omega$. $\lambda$ is absolutely continuous with respect to $\mu$, written as $\lambda \ll \mu$, if $\lambda(E) = 0$ whenever $\mu(E) = 0$.

It is not hard to think of examples which should be like this. For example, suppose one measure is volume and the other is mass. If the volume of something is zero, it is reasonable to expect the mass of it should also be equal to zero. In this case, there is a function called the density which is integrated over volume to obtain mass. The Radon Nikodym theorem is an abstract version of this notion. Essentially, it gives the existence of the density function.

Theorem 18.1.2 (Radon Nikodym) Let $\lambda$ and $\mu$ be finite measures defined on a $\sigma$-algebra, $S$, of subsets of $\Omega$. Suppose $\lambda \ll \mu$. Then there exists a unique $f \in L^1(\Omega, \mu)$ such that $f(x) \geq 0$ and

$$\lambda(E) = \int_E f \, d\mu.$$ 

If it is not necessarily the case that $\lambda \ll \mu$, there are two measures, $\lambda_\perp$ and $\lambda_\parallel$, such that $\lambda = \lambda_\perp + \lambda_\parallel$, $\lambda_\parallel \ll \mu$ and there exists a set of $\mu$ measure zero, $N$ such that for all $E$ measurable, $\lambda_\perp(E) = \lambda(E \cap N) = \lambda_\perp(E \cap N)$. In this case the two measures, $\lambda_\perp$ and $\lambda_\parallel$, are unique and the representation of $\lambda = \lambda_\perp + \lambda_\parallel$ is called the Lebesgue decomposition of $\lambda$. The measure $\lambda_\parallel$ is the absolutely continuous part of $\lambda$ and $\lambda_\perp$ is called the singular part of $\lambda$. 

577
Proof: Let $\Lambda : L^2(\Omega, \mu + \lambda) \to \mathbb{C}$ be defined by

$$\Lambda g = \int_{\Omega} g \, d\lambda.$$ 

By Holder’s inequality,

$$|\Lambda g| \leq \left( \int_{\Omega} 1^2 d\lambda \right)^{1/2} \left( \int_{\Omega} |g|^2 (\lambda + \mu) \right)^{1/2} = \lambda(\Omega)^{1/2} ||g||_2$$

where $||g||_2$ is the $L^2$ norm of $g$ taken with respect to $\mu + \lambda$. Therefore, since $\Lambda$ is bounded, it follows from Theorem 15.1.4 on Page 419 that $\Lambda \in (L^2(\Omega, \mu + \lambda))'$, the dual space $L^2(\Omega, \mu + \lambda)$. By the Riesz representation theorem in Hilbert space, Theorem 17.1.14, there exists a unique $h \in L^2(\Omega, \mu + \lambda)$ with

$$\Lambda g = \int_{\Omega} g \, d\lambda = \int_{\Omega} h g d(\mu + \lambda). \quad (18.1.1)$$

The plan is to show $h$ is real and nonnegative at least a.e. Therefore, consider the set where $\text{Im} \, h$ is positive.

$$E = \{ x \in \Omega : \text{Im} \, h(x) > 0 \},$$

Now let $g = \chi_E$ and use (18.1.1) to get

$$\lambda(E) = \int_E (\text{Re} \, h + i \, \text{Im} \, h) d(\mu + \lambda). \quad (18.1.2)$$

Since the left side of (18.1.2) is real, this shows

$$0 = \int_E (\text{Im} \, h) \, d(\mu + \lambda) \geq \int_{E_n} (\text{Im} \, h) \, d(\mu + \lambda) \geq \frac{1}{n} (\mu + \lambda) (E_n)$$

where

$$E_n = \left\{ x : \text{Im} \, h(x) \geq \frac{1}{n} \right\}$$

Thus $(\mu + \lambda) (E_n) = 0$ and since $E = \bigcup_{n=1}^{\infty} E_n$, it follows $(\mu + \lambda) (E) = 0$. A similar argument shows that for

$$E = \{ x \in \Omega : \text{Im} \, h(x) < 0 \},$$

$(\mu + \lambda)(E) = 0$. Thus there is no loss of generality in assuming $h$ is real-valued.

The next task is to show $h$ is nonnegative. This is done in the same manner as above. Define the set where it is negative and then show this set has measure zero.
Let $E \equiv \{ x : h(x) < 0 \}$ and let $E_n \equiv \{ x : h(x) < -\frac{1}{n} \}$. Then let $g = \chi_{E_n}$. Since $E = \cup_n E_n$, it follows that if $(\mu + \lambda)(E) > 0$ then this is also true for $(\mu + \lambda)(E_n)$ for all $n$ large enough. Then from 18.1.2, 

$$\lambda(E_n) = \int_{E_n} h \, d(\mu + \lambda) \leq - (1/n) (\mu + \lambda)(E_n) < 0,$$

a contradiction. Thus it can be assumed $h \geq 0$.

At this point the argument splits into two cases.

**Case Where $\lambda \ll \mu$**. In this case, $h < 1$.

Let $E = [h \geq 1]$ and let $g = \chi_E$. Then 

$$\lambda(E) = \int_E h \, d(\mu + \lambda) \geq \mu(E) + \lambda(E).$$

Therefore $\mu(E) = 0$. Since $\lambda \ll \mu$, it follows that $\lambda(E) = 0$ also. Thus it can be assumed 

$$0 \leq h(x) < 1$$

for all $x$.

From 18.1.1, whenever $g \in L^2(\Omega, \mu + \lambda)$,

$$\int_{\Omega} g(1 - h) \, d\lambda = \int_{\Omega} h g \, d\mu. \tag{18.1.3}$$

Now let $E$ be a measurable set and define 

$$g(x) \equiv \sum_{i=0}^n h^i(x) \chi_E(x)$$

in 18.1.2. This yields 

$$\int_E (1 - h^{n+1}(x)) \, d\lambda = \int_E \sum_{i=1}^{n+1} h^i(x) \, d\mu. \tag{18.1.4}$$

Let $f(x) = \sum_{i=1}^{\infty} h^i(x)$ and use the Monotone Convergence theorem in 18.1.2 to let $n \to \infty$ and conclude 

$$\lambda(E) = \int_E f \, d\mu.$$ 

$f \in L^1(\Omega, \mu)$ because $\lambda$ is finite.

The function, $f$ is unique $\mu$ a.e. because, if $g$ is another function which also serves to represent $\lambda$, consider for each $n \in \mathbb{N}$ the set, 

$$E_n \equiv \left\{ f - g > \frac{1}{n} \right\}$$

and conclude that 

$$0 = \int_{E_n} (f - g) \, d\mu \geq \frac{1}{n} \mu(E_n).$$
Therefore, \( \mu(E_n) = 0 \). It follows that
\[
\mu([f - g > 0]) \leq \sum_{n=1}^{\infty} \mu(E_n) = 0
\]
Similarly, the set where \( g \) is larger than \( f \) has measure zero. This proves the theorem.

**Case where it is not necessarily true that \( \lambda \ll \mu \).**

In this case, let \( N = [h \geq 1] \) and let \( g = X_N \). Then
\[
\lambda(N) = \int_N h \, d(\mu + \lambda) \geq \mu(N) + \lambda(N)
\]
and so \( \mu(N) = 0 \). Now define a measure, \( \lambda_\perp \) by
\[
\lambda_\perp(E) \equiv \lambda(E \cap N)
\]
so \( \lambda_\perp(E \cap N) = \lambda(E \cap N \cap N) \equiv \lambda_\perp(E) \) and let \( \lambda_\parallel \equiv \lambda - \lambda_\perp \). Therefore,
\[
\mu(E) = \mu(E \cap N^C)
\]
Also,
\[
\lambda_\parallel(E) = \lambda(E) - \lambda_\perp(E) \equiv \lambda(E) - \lambda(E \cap N) = \lambda(E \cap N^C).
\]
Suppose \( \lambda_\parallel(E) > 0 \). Therefore, since \( h < 1 \) on \( N^C \)
\[
\lambda_\parallel(E) = \lambda(E \cap N^C) = \int_{E \cap N^C} h \, d(\mu + \lambda)
\]
\[
< \mu(E \cap N^C) + \lambda(E \cap N^C) = \mu(E) + \lambda_\parallel(E),
\]
which is a contradiction unless \( \mu(E) > 0 \). Therefore, \( \lambda_\parallel \ll \mu \) because if \( \mu(E) = 0 \), the above inequality cannot hold.

It only remains to verify the two measures \( \lambda_\perp \) and \( \lambda_\parallel \) are unique. Suppose then that \( \nu_1 \) and \( \nu_2 \) play the roles of \( \lambda_\perp \) and \( \lambda_\parallel \) respectively. Let \( N_1 \) play the role of \( N \) in the definition of \( \nu_1 \) and let \( f_1 \) play the role of \( f \) for \( \nu_2 \). I will show that \( f = f_1 \mu \) a.e. Let \( E_k = [f_1 - f > 1/k] \) for \( k \in \mathbb{N} \). Then on observing that \( \lambda_\perp - \nu_1 = \nu_2 - \lambda_\parallel \)
\[
0 = (\lambda_\perp - \nu_1) \left( E_k \cap (N_1 \cup N)^C \right) = \int_{E_k \cap (N_1 \cup N)^C} (g_1 - g) \, d\mu
\]
\[
\geq \frac{1}{k} \mu \left( E_k \cap (N_1 \cup N)^C \right) = \frac{1}{k} \mu(E_k).
\]
and so \( \mu(E_k) = 0 \). Therefore, \( \mu([f_1 - f > 0]) = 0 \) because \( [f_1 - f > 0] = \bigcup_{k=1}^{\infty} E_k \). It follows \( f_1 \leq f \mu \) a.e. Similarly, \( f_1 \geq f \mu \) a.e. Therefore, \( \nu_2 = \lambda_\parallel \) and so \( \lambda_\perp = \nu_1 \) also.

The \( f \) in the theorem for the absolutely continuous case is sometimes denoted by \( \frac{d\lambda}{d\mu} \) and is called the Radon Nikodym derivative.

The next corollary is a useful generalization to \( \sigma \) finite measure spaces.
Corollary 18.1.3 Suppose $\lambda \ll \mu$ and there exist sets $S_n \in \mathcal{S}$ with

$$S_n \cap S_m = \emptyset, \cup_{n=1}^{\infty} S_n = \Omega,$$

and $\lambda(S_n), \mu(S_n) < \infty$. Then there exists $f \geq 0$, where $f$ is $\mu$ measurable, and

$$\lambda(E) = \int_E f \, d\mu$$

for all $E \in \mathcal{S}$. The function $f$ is $\mu + \lambda$ a.e. unique.

Proof: Define the $\sigma$ algebra of subsets of $S_n$,

$$S_n = \{E \cap S_n : E \in \mathcal{S}\}.$$

Then both $\lambda$ and $\mu$ are finite measures on $S_n$, and $\lambda \ll \mu$. Thus, by Theorem 18.1.2, there exists a nonnegative $S_n$ measurable function $f_n$ with $\lambda(E) = \int_E f_n \, d\mu$ for all $E \in S_n$. Define $f(x) = f_n(x)$ for $x \in S_n$. Since the $S_n$ are disjoint and their union is all of $\Omega$, this defines $f$ on all of $\Omega$. The function, $f$ is measurable because

$$f^{-1}((a, \infty]) = \cup_{n=1}^{\infty} f_n^{-1}((a, \infty]) \in \mathcal{S}.$$

Also, for $E \in \mathcal{S}$,

$$\lambda(E) = \sum_{n=1}^{\infty} \lambda(E \cap S_n) = \sum_{n=1}^{\infty} \int_{E \cap S_n} \chi_{E \cap S_n}(x) f_n(x) \, d\mu$$

$$= \sum_{n=1}^{\infty} \int_{E \cap S_n} \chi_{E \cap S_n}(x) f(x) \, d\mu$$

By the monotone convergence theorem

$$\lim_{N \to \infty} \sum_{n=1}^{N} \int_{E \cap S_n} \chi_{E \cap S_n}(x) f(x) \, d\mu = \int_{\Omega} f \, d\mu.$$

This proves the existence part of the corollary.

To see $f$ is unique, suppose $f_1$ and $f_2$ both work and consider for $n \in \mathbb{N}$

$$E_k = \left[ f_1 - f_2 > \frac{1}{k} \right].$$

Then

$$0 = \lambda(E_k \cap S_n) - \lambda(E_k \cap S_n) = \int_{E_k \cap S_n} f_1(x) - f_2(x) \, d\mu.$$
Hence \( \mu(E_k \cap S_n) = 0 \) for all \( n \) so

\[
\mu(E_k) = \lim_{n \to \infty} \mu(E \cap S_n) = 0.
\]

Hence \( \mu([f_1 - f_2 > 0]) \leq \sum_{k=1}^{\infty} \mu(E_k) = 0 \). Therefore, \( \lambda([f_1 - f_2 > 0]) = 0 \) also. Similarly

\[
(\mu + \lambda) ([f_1 - f_2 < 0]) = 0.
\]

This version of the Radon Nikodym theorem will suffice for most applications, but more general versions are available. To see one of these, one can read the treatment in Hewitt and Stromberg [12]. This involves the notion of decomposable measure spaces, a generalization of \( \sigma \)-finite.

Not surprisingly, there is a simple generalization of the Lebesgue decomposition part of Theorem [3].

**Corollary 18.1.4** Let \( (\Omega, \mathcal{S}) \) be a set with a \( \sigma \)-algebra of sets. Suppose \( \lambda \) and \( \mu \) are two measures defined on the sets of \( \mathcal{S} \) and suppose there exists a sequence of disjoint sets of \( \mathcal{S} \), \( \{\Omega_i\}_{i=1}^{\infty} \) such that \( \lambda(\Omega_i), \mu(\Omega_i) < \infty \). Then there is a set of \( \mu \) measure zero, \( N \) and measures \( \lambda_\bot \) and \( \lambda_{\parallel} \) such that

\[
\lambda_\bot + \lambda_{\parallel} = \lambda, \lambda_{\parallel} \ll \mu, \lambda_{\parallel}(E) = \lambda(E \cap N) = \lambda_\bot(E \cap N).
\]

**Proof:** Let \( \mathcal{S}_i \equiv \{E \cap \Omega_i : E \in \mathcal{S}\} \) and for \( E \in \mathcal{S}_i \), let \( \lambda^i(E) = \lambda(E) \) and \( \mu^i(E) = \mu(E) \). Then by Theorem [3] there exist unique measures \( \lambda^i_\bot \) and \( \lambda^i_{\parallel} \) such that \( \lambda^i = \lambda^i_\bot + \lambda^i_{\parallel} \), a set of \( \mu^i \) measure zero, \( N_i \in \mathcal{S}_i \) such that for all \( E \in \mathcal{S}_i \),

\[
\lambda^i_\bot(E) = \lambda^i(E \cap \Omega_i), \lambda^i_{\parallel}(E) = \sum_i \lambda^i_{\parallel}(E \cap \Omega_i), N \equiv \bigcup_i N_i.
\]

First observe that \( \lambda_\bot \) and \( \lambda_{\parallel} \) are measures.

\[
\lambda_\bot(\bigcup_{j=1}^{\infty} E_j) = \lambda_\bot(\bigcup_{j=1}^{\infty} E_j \cap \Omega_i) = \sum_{i} \sum_{j} \lambda^i_\bot(E_j \cap \Omega_i)
\]

\[
= \sum_{j} \sum_{i} \lambda^i_\bot(E_j \cap \Omega_i) = \sum_{j} \sum_{i} \lambda(E_j \cap \Omega_i \cap N_i)
\]

\[
= \sum_{j} \lambda^i_\bot(E_j \cap \Omega_i) = \sum_{j} \lambda_\bot(E_j).
\]

The argument for \( \lambda_{\parallel} \) is similar. Now

\[
\mu(N) = \sum_i \mu(N \cap \Omega_i) = \sum_i \mu^i(N_i) = 0
\]

and

\[
\lambda_\bot(E) = \sum_i \lambda^i_\bot(E \cap \Omega_i) = \sum_i \lambda^i(E \cap \Omega_i \cap N_i)
\]

\[
= \sum_i \lambda(E \cap \Omega_i \cap N) = \lambda(E \cap N).
\]
Also if \( \mu(E) = 0 \), then \( \mu'(E \cap \Omega_i) = 0 \) and so \( \lambda_i' \( E \cap \Omega_i \) = 0 \). Therefore,

\[
\lambda_i(E) = \sum_i \lambda_i'(E \cap \Omega_i) = 0.
\]

The decomposition is unique because of the uniqueness of the \( \lambda_i' \) and \( \lambda_i \), and the observation that some other decomposition must coincide with the given one on the \( \Omega_i \).

## 18.2 Vector Measures

The next topic will use the Radon Nikodym theorem. It is the topic of vector and complex measures. The main interest is in complex measures although a vector measure can have values in any topological vector space. Whole books have been written on this subject. See for example the book by Diestal and Uhl [38] titled Vector measures.

**Definition 18.2.1** Let \((V, ||\cdot||)\) be a normed linear space and let \((\Omega, \mathcal{S})\) be a measure space. A function \( \mu : \mathcal{S} \to V \) is a vector measure if \( \mu \) is countably additive. That is, if \( \{E_i\}_{i=1}^\infty \) is a sequence of disjoint sets of \( \mathcal{S} \),

\[
\mu(\bigcup_{i=1}^\infty E_i) = \sum_{i=1}^\infty \mu(E_i).
\]

Note that it makes sense to take finite sums because it is given that \( \mu \) has values in a vector space in which vectors can be summed. In the above, \( \mu(E_i) \) is a vector. It might be a point in \( \mathbb{R}^n \) or in any other vector space. In many of the most important applications, it is a vector in some sort of function space which may be infinite dimensional. The infinite sum has the usual meaning. That is

\[
\sum_{i=1}^\infty \mu(E_i) = \lim_{n \to \infty} \sum_{i=1}^n \mu(E_i)
\]

where the limit takes place relative to the norm on \( V \).

**Definition 18.2.2** Let \((\Omega, \mathcal{S})\) be a measure space and let \( \mu \) be a vector measure defined on \( \mathcal{S} \). A subset, \( \pi(E) \), of \( \mathcal{S} \) is called a partition of \( E \) if \( \pi(E) \) consists of finitely many disjoint sets of \( \mathcal{S} \) and \( \bigcup \pi(E) = E \). Let

\[
|\mu|(E) = \sup \{ \sum_{F \in \pi(E)} ||\mu(F)|| : \pi(E) \text{ is a partition of } E \}.
\]

\( |\mu| \) is called the total variation of \( \mu \).

The next theorem may seem a little surprising. It states that, if finite, the total variation is a nonnegative measure.
Theorem 18.2.3 If $|\mu|(\Omega) < \infty$, then $|\mu|$ is a measure on $\mathcal{S}$. Even if $|\mu|(\Omega) = \infty$, $|\mu|(\cup_{i=1}^{\infty} E_i) \leq \sum_{i=1}^{\infty} |\mu|(E_i)$. That is $|\mu|$ is subadditive and $|\mu|(A) \leq |\mu|(B)$ whenever $A, B \in \mathcal{S}$ with $A \subseteq B$.

**Proof:** Consider the last claim. Let $a < |\mu|(A)$ and let $\pi(A)$ be a partition of $A$ such that

$$a < \sum_{F \in \pi(A)} ||\mu(F)||.$$ 

Then $\pi(A) \cup \{ B \setminus A \}$ is a partition of $B$ and

$$|\mu|(B) \geq \sum_{F \in \pi(A)} ||\mu(F)|| + ||\mu(B \setminus A)|| > a.$$ 

Since this is true for all such $a$, it follows $|\mu|(B) \geq |\mu|(A)$ as claimed.

Let $\{E_j\}_{j=1}^{\infty}$ be a sequence of disjoint sets of $\mathcal{S}$ and let $E_{\infty} = \cup_{j=1}^{\infty} E_j$. Then letting $a < |\mu|(E_{\infty})$, it follows from the definition of total variation there exists a partition of $E_{\infty}$, $\pi(E_{\infty}) = \{A_1, \ldots, A_n\}$ such that

$$a < \sum_{i=1}^{n} ||\mu(A_i)||.$$ 

Also,

$$A_i = \cup_{j=1}^{\infty} A_i \cap E_j$$

and so by the triangle inequality, $||\mu(A_i)|| \leq \sum_{j=1}^{\infty} ||\mu(A_i \cap E_j)||$. Therefore, by the above, and either Fubini’s theorem or Lemma 9.3.3 on Page 221

$$a < \sum_{i=1}^{n} \sum_{j=1}^{\infty} ||\mu(A_i \cap E_j)||$$

$$= \sum_{j=1}^{\infty} \sum_{i=1}^{n} ||\mu(A_i \cap E_j)||$$

$$\leq \sum_{j=1}^{\infty} |\mu|(E_j)$$

because $\{A_i \cap E_j\}_{i=1}^{n}$ is a partition of $E_j$.

Since $a$ is arbitrary, this shows

$$|\mu|(\cup_{j=1}^{\infty} E_j) \leq \sum_{j=1}^{\infty} |\mu|(E_j).$$

If the sets, $E_j$ are not disjoint, let $F_1 = E_1$ and if $F_n$ has been chosen, let $F_{n+1} \equiv E_{n+1} \setminus \cup_{i=1}^{n} E_i$. Thus the sets, $F_i$ are disjoint and $\cup_{i=1}^{\infty} F_i = \cup_{i=1}^{\infty} E_i$. Therefore,

$$|\mu|(\cup_{j=1}^{\infty} E_j) = |\mu|(\cup_{j=1}^{\infty} F_j) \leq \sum_{j=1}^{\infty} |\mu|(F_j) \leq \sum_{j=1}^{\infty} |\mu|(E_j).$$
and proves $|\mu|$ is always subadditive as claimed regardless of whether $|\mu|(\Omega) < \infty$.

Now suppose $|\mu|(\Omega) < \infty$ and let $E_1$ and $E_2$ be sets of $\mathcal{S}$ such that $E_1 \cap E_2 = \emptyset$ and let $\{A_1^i \cdots A_n^i\} = \pi(E_i)$, a partition of $E_i$ which is chosen such that

$$|\mu|(E_i) - \varepsilon < \sum_{j=1}^{n_i} ||\mu(A_j^i)|| \quad i = 1, 2.$$ \hfill (18.2.5)

Such a partition exists because of the definition of the total variation. Consider the sets which are contained in either of $\pi(E_1)$ or $\pi(E_2)$, it follows this collection of sets is a partition of $E_1 \cup E_2$ denoted by $\pi(E_1 \cup E_2)$. Then by the above inequality and the definition of total variation,

$$|\mu|(E_1 \cup E_2) \geq \sum_{F \in \pi(E_1 \cup E_2)} ||\mu(F)|| > |\mu|(E_1) + |\mu|(E_2) - 2\varepsilon,$$

which shows that since $\varepsilon > 0$ was arbitrary,

$$|\mu|(E_1 \cup E_2) \geq |\mu|(E_1) + |\mu|(E_2). \quad (18.2.5)$$

Then (18.2.5) implies that whenever the $E_i$ are disjoint, $|\mu|((\cup_{j=1}^{n} E_j)) \geq \sum_{j=1}^{n} |\mu|(E_j)$.

Therefore,

$$\sum_{j=1}^{\infty} |\mu|(E_j) \geq |\mu|((\cup_{j=1}^{\infty} E_j)) \geq |\mu|((\cup_{j=1}^{n} E_j)) \geq \sum_{j=1}^{n} |\mu|(E_j).$$

Since $n$ is arbitrary,

$$|\mu|((\cup_{j=1}^{\infty} E_j)) = \sum_{j=1}^{\infty} |\mu|(E_j)$$

which shows that $|\mu|$ is a measure as claimed. \qed

The following corollary is interesting. It concerns the case that $\mu$ is only finitely additive.

**Corollary 18.2.4** Suppose $(\Omega, \mathcal{F})$ is a set with a $\sigma$ algebra of subsets $\mathcal{F}$ and suppose $\mu : \mathcal{F} \to \mathbb{C}$ is only finitely additive. That is, $\mu(\cup_{i=1}^{n} E_i) = \sum_{i=1}^{n} \mu(E_i)$ whenever the $E_i$ are disjoint. Then $|\mu|$, defined in the same way as above, is also finitely additive provided $|\mu|$ is finite.

**Proof:** Say $E \cap F = \emptyset$ for $E, F \in \mathcal{F}$. Let $\pi(E), \pi(F)$ suitable partitions for which the following holds.

$$|\mu|(E \cup F) \geq \sum_{A \in \pi(E)} |\mu(A)| + \sum_{B \in \pi(F)} |\mu(B)| \geq |\mu|(E) + |\mu|(F) - 2\varepsilon.$$
Now let $E = \bigcup_{i=1}^{n} E_i$ where the $E_i$ are disjoint. Then letting $\pi (E)$ be a partition of $E$,

$$|\mu| (E) - \varepsilon \leq \sum_{F \in \pi (E)} |\mu (F)|,$$

it follows that

$$|\mu| (E) \leq \varepsilon + \sum_{F \in \pi (E)} |\mu (F)| = \varepsilon + \sum_{i=1}^{n} \sum_{F \in \pi (E)} |\mu (F \cap E_i)|$$

$$\leq \varepsilon + \sum_{i=1}^{n} \sum_{F \in \pi (E)} |\mu (F \cap E_i)| \leq \varepsilon + \sum_{i=1}^{n} |\mu| (E_i)$$

which shows $|\mu|$ is finitely additive.

In the case that $\mu$ is a complex measure, it is always the case that $|\mu| (\Omega) < \infty$.

**Theorem 18.2.5** Suppose $\mu$ is a complex measure on $(\Omega, S)$ where $S$ is a $\sigma$ algebra of subsets of $\Omega$. That is, whenever, $\{E_i\}$ is a sequence of disjoint sets of $S$,

$$\mu \left( \bigcup_{i=1}^{\infty} E_i \right) = \sum_{i=1}^{\infty} \mu (E_i).$$

Then $|\mu| (\Omega) < \infty$.

**Proof:** First here is a claim.

**Claim:** Suppose $|\mu| (E) = \infty$. Then there are disjoint subsets of $E$, $A$ and $B$ such that $E = A \cup B$, $|\mu (A)|, |\mu (B)| > 1$ and $|\mu| (B) = \infty$.

**Proof of the claim:** From the definition of $|\mu|$, there exists a partition of $E, \pi (E)$ such that

$$\sum_{F \in \pi (E)} |\mu (F)| > 20 \left( 1 + |\mu (E)| \right). \quad (18.2.6)$$

Here 20 is just a nice sized number. No effort is made to be delicate in this argument. Also note that $\mu (E) \in \mathbb{C}$ because it is given that $\mu$ is a complex measure. Consider the following picture consisting of two lines in the complex plane having slopes 1 and -1 which intersect at the origin, dividing the complex plane into four closed sets, $R_1, R_2, R_3$, and $R_4$ as shown.

```

\node at (0,0.5) {$R_1$};
\node at (-0.5,0) {$R_3$};
\node at (0,-0.5) {$R_4$};
\end{tikzpicture}
\end{center}
```
18.2. VECTOR MEASURES

Let \( \pi_i \) consist of those sets, \( A \) of \( \pi(E) \) for which \( \mu(A) \in R_i \). Thus, some sets, \( A \) of \( \pi(E) \) could be in two of the \( \pi_i \) if \( \mu(A) \) is on one of the intersecting lines. This is not important. The thing which is important is that if \( \mu(A) \in R_1 \) or \( R_3 \), then \( \frac{\sqrt{2}}{2} |\mu(A)| \leq |\text{Re}(\mu(A))| \) and if \( \mu(A) \in R_2 \) or \( R_4 \) then \( \frac{\sqrt{2}}{2} |\mu(A)| \leq |\text{Im}(\mu(A))| \) and \( \text{Re}(z) \) has the same sign for \( z \) in \( R_1 \) and \( R_3 \) while \( \text{Im}(z) \) has the same sign for \( z \) in \( R_2 \) or \( R_4 \). Then by (18.2.6), it follows that for some \( i \),

\[
\sum_{F \in \pi_i} |\mu(F)| > 5 (1 + |\mu(E)|). \tag{18.2.7}
\]

Suppose \( i \) equals 1 or 3. A similar argument using the imaginary part applies if \( i \) equals 2 or 4. Then,

\[
\left| \sum_{F \in \pi_i} \mu(F) \right| \geq \left| \sum_{F \in \pi_i} \text{Re}(\mu(F)) \right| = \sum_{F \in \pi_i} |\text{Re}(\mu(F))| \geq \frac{\sqrt{2}}{2} \sum_{F \in \pi_i} |\mu(F)| > 5 \frac{\sqrt{2}}{2} (1 + |\mu(E)|).
\]

Now letting \( C \) be the union of the sets in \( \pi_i \),

\[
|\mu(C)| = \left| \sum_{F \in \pi_i} \mu(F) \right| > \frac{5}{2} (1 + |\mu(E)|) > 1. \tag{18.2.8}
\]

Define \( D \equiv E \setminus C \).

Then \( \mu(C) + \mu(E \setminus C) = \mu(E) \) and so

\[
\frac{5}{2} (1 + |\mu(E)|) < |\mu(C)| = |\mu(E) - \mu(E \setminus C)| = |\mu(E) - \mu(D)| \leq |\mu(E)| + |\mu(D)|
\]

and so

\[
1 < \frac{5}{2} + \frac{3}{2} |\mu(E)| < |\mu(D)|.
\]
Now since $|\mu|(E) = \infty$, it follows from Theorem 18.2.4 that $\infty = |\mu|(E) \leq |\mu|(C) + |\mu|(D)$ and so either $|\mu|(C) = \infty$ or $|\mu|(D) = \infty$. If $|\mu|(C) = \infty$, let $B = C$ and $A = D$. Otherwise, let $B = D$ and $A = C$. This proves the claim.

Now suppose $|\mu|(\Omega) = \infty$. Then from the claim, there exist $A_1$ and $B_1$ such that $|\mu|(B_1) = \infty$, $|\mu(B_1)|, |\mu(A_1)| > 1$, and $A_1 \cup B_1 = \Omega$. Let $B_1 = \Omega \setminus A$ play the same role as $\Omega$ and obtain $A_2, B_2 \subseteq B_1$ such that $|\mu|(B_2) = \infty, |\mu(B_2)|, |\mu(A_2)| > 1$, and $A_2 \cup B_2 = B_1$. Continue in this way to obtain a sequence of disjoint sets, $\{A_i\}$ such that $|\mu(A_i)| > 1$. Then since $\mu$ is a measure,

$$
\mu(\bigcup_{i=1}^{\infty} A_i) = \sum_{i=1}^{\infty} \mu(A_i)
$$

but this is impossible because $\lim_{i \to \infty} \mu(A_i) \neq 0$. This proves the theorem.

**Theorem 18.2.6** Let $(\Omega, S)$ be a measure space and let $\lambda : S \to \mathbb{C}$ be a complex vector measure. Thus $|\lambda|(\Omega) < \infty$. Let $\mu : S \to [0, \mu(\Omega)]$ be a finite measure such that $\lambda \ll \mu$. Then there exists a unique $f \in L^1(\Omega)$ such that for all $E \in S$,

$$
\int_E f d\mu = \lambda(E).
$$

**Proof:** It is clear that $\text{Re}\lambda$ and $\text{Im}\lambda$ are real-valued vector measures on $S$. Since $|\lambda|(\Omega) < \infty$, it follows easily that $|\text{Re}\lambda|(\Omega)$ and $|\text{Im}\lambda|(\Omega) < \infty$. This is clear because

$$
|\lambda(E)| \geq |\text{Re}\lambda(E)|, |\text{Im}\lambda(E)|.
$$

Therefore, each of

$$
\frac{|\text{Re}\lambda| + \text{Re}\lambda}{2}, \quad \frac{|\text{Re}\lambda| - \text{Re}\lambda}{2}, \quad \frac{|\text{Im}\lambda| + \text{Im}\lambda}{2}, \quad \text{and} \quad \frac{|\text{Im}\lambda| - \text{Im}\lambda}{2}
$$

are finite measures on $S$. It is also clear that each of these finite measures are absolutely continuous with respect to $\mu$ and so there exist unique nonnegative functions in $L^1(\Omega)$, $f_1$, $f_2$, $g_1$, $g_2$ such that for all $E \in S$,

$$
\frac{1}{2}(|\text{Re}\lambda| + \text{Re}\lambda)(E) = \int_E f_1 d\mu,
$$

$$
\frac{1}{2}(|\text{Re}\lambda| - \text{Re}\lambda)(E) = \int_E f_2 d\mu,
$$

$$
\frac{1}{2}(|\text{Im}\lambda| + \text{Im}\lambda)(E) = \int_E g_1 d\mu,
$$

$$
\frac{1}{2}(|\text{Im}\lambda| - \text{Im}\lambda)(E) = \int_E g_2 d\mu.
$$

Now let $f = f_1 - f_2 + i(g_1 - g_2)$.

The following corollary is about representing a vector measure in terms of its total variation. It is like representing a complex number in the form $re^{i\theta}$. The proof requires the following lemma.
Lemma 18.2.7 Suppose \((\Omega, \mathcal{S}, \mu)\) is a measure space and \(f\) is a function in \(L^1(\Omega, \mu)\) with the property that
\[
|\int_E f \, d\mu| \leq \mu(E)
\]
for all \(E \in \mathcal{S}\). Then \(|f| \leq 1\) a.e.

**Proof of the lemma:** Consider the following picture.

\[ B(p,r) \]

\[ (0,0) \]

where \(B(p,r) \cap B(0,1) = \emptyset\). Let \(E = f^{-1}(B(p,r))\). In fact \(\mu(E) = 0\). If \(\mu(E) \neq 0\) then
\[
\left| \frac{1}{\mu(E)} \int_E f \, d\mu - p \right| = \left| \frac{1}{\mu(E)} \int_E (f - p) \, d\mu \right| \leq \frac{1}{\mu(E)} \int_E |f - p| \, d\mu < r
\]
because on \(E\), \(|f(x) - p| < r\). Hence
\[
\frac{1}{\mu(E)} \int_E f \, d\mu > 1
\]
because it is closer to \(p\) than \(r\). (Refer to the picture.) However, this contradicts the assumption of the lemma. It follows \(\mu(E) = 0\). Since the set of complex numbers, \(z\) such that \(|z| > 1\) is an open set, it equals the union of countably many balls, \(\{B_k\}_{k=1}^\infty\). Therefore,
\[
\mu(f^{-1}(\{z \in \mathbb{C} : |z| > 1\}) = \mu(\bigcup_{k=1}^\infty f^{-1}(B_k)) \leq \sum_{k=1}^\infty \mu(f^{-1}(B_k)) = 0.
\]
Thus \(|f(x)| \leq 1\) a.e. as claimed. This proves the lemma.

**Corollary 18.2.8** Let \(\lambda\) be a complex vector measure with \(|\lambda|(\Omega) < \infty\). Then there exists a unique \(f \in L^1(\Omega)\) such that \(\lambda(E) = \int_E f \, d|\lambda|\). Furthermore, \(|f| = 1\) for \(|\lambda|\) a.e. This is called the polar decomposition of \(\lambda\).

**Proof:** First note that \(\lambda \ll |\lambda|\) and so such an \(L^1\) function exists and is unique. It is required to show \(|f| = 1\) a.e. If \(|\lambda|(\Omega) \neq 0\),
\[
\frac{|\lambda(E)|}{|\lambda|(E)} = \left| \frac{1}{|\lambda|(E)} \int_E f \, d|\lambda| \right| \leq 1.
\]
\(^1\)As proved above, the assumption that \(|\lambda|(\Omega) < \infty\) is redundant.
Therefore by Lemma 18.2.7, $|f| \leq 1$, $|\lambda|$ a.e. Now let

$$E_n = \left[ |f| \leq 1 - \frac{1}{n} \right].$$

Let $\{F_1, \ldots, F_m\}$ be a partition of $E_n$. Then

$$\sum_{i=1}^{m} |\lambda(F_i)| = \sum_{i=1}^{m} \left| \int_{F_i} f |\lambda| \right| \leq \sum_{i=1}^{m} \int_{F_i} |f| |\lambda| \leq \sum_{i=1}^{m} \int_{F_i} \left( 1 - \frac{1}{n} \right) |\lambda| = \sum_{i=1}^{m} \left( 1 - \frac{1}{n} \right) |\lambda|(F_i)$$

$$= |\lambda|(E_n) \left( 1 - \frac{1}{n} \right).$$

Then taking the supremum over all partitions,

$$|\lambda|(E_n) \leq \left( 1 - \frac{1}{n} \right) |\lambda|(E_n)$$

which shows $|\lambda|(E_n) = 0$. Hence $|\lambda|([|f| < 1]) = 0$ because $|f| < 1 = \bigcup_{n=1}^{\infty} E_n$. This proves Corollary 18.2.8.

**Corollary 18.2.9** Let $\lambda$ be a complex vector measure such that $\lambda \ll \mu$ where $\mu$ is $\sigma$ finite. Then there exists a unique $g \in L^1(\Omega, \mu)$ such that $\lambda(E) = \int_E g \mu$.

**Proof:** By Corollary 18.2.7 and Theorem 18.2.5 which says that $|\lambda|$ is finite, there exists a unique $f$ such that $|f| = 1$ $|\lambda|$ a.e. and

$$\lambda(E) = \int_E f |\lambda|.$$

Now $|\lambda| \ll \mu$ and so it follows from Corollary 18.2.8 there exists a unique nonnegative measurable function $h$ such that for all $E$ measurable,

$$|\lambda|(E) = \int_E h \mu$$

where since $|\lambda|$ is finite, $h \in L^1(\Omega, \mu)$. It follows from approximating $f$ with simple functions and using the above formula that

$$\lambda(E) = \int_E f h \mu.$$

Then let $g = L^1(\Omega, \mu)$. This proves the corollary.

**Corollary 18.2.10** Suppose $(\Omega, S)$ is a measure space and $\mu$ is a finite nonnegative measure on $S$. Then for $h \in L^1(\mu)$, define a complex measure, $\lambda$ by

$$\lambda(E) \equiv \int_E h \mu.$$
18.3. REPRESENTATION THEOREMS FOR THE DUAL SPACE OF $L^p$

Then

$$|\lambda|(E) = \int_E |h| \, d\mu.$$  

Furthermore, $|h| = \overline{g}h$ where $gd|\lambda|$ is the polar decomposition of $\lambda$,

$$\lambda(E) = \int_E gd|\lambda|$$

Proof: From Corollary 18.2.8 there exists $g$ such that $|g| = 1, |\lambda|$ a.e. and for all $E \in S$

$$\lambda(E) = \int_E gd|\lambda| = \int_E hd\mu.$$  

Let $s_n$ be a sequence of simple functions converging pointwise to $\overline{g}$. Then from the above,

$$\int_E gs_n d|\lambda| = \int_E s_n hd\mu.$$  

Passing to the limit using the dominated convergence theorem,

$$\int_E d|\lambda| = \int_E \overline{g}hd\mu.$$  

It follows $\overline{g}h \geq 0$ a.e. and $|\overline{g}| = 1$. Therefore, $|h| = |\overline{g}h| = \overline{g}h$. It follows from the above, that

$$|\lambda|(E) = \int_E d|\lambda| = \int_E \overline{g}hd\mu = \int_E d|\lambda| = \int_E |h| d\mu$$

and this proves the corollary.

18.3 Representation Theorems For The Dual Space Of $L^p$

Recall the concept of the dual space of a Banach space in the Chapter on Banach space starting on Page 417. The next topic deals with the dual space of $L^p$ for $p \geq 1$ in the case where the measure space is $\sigma$ finite or finite. In what follows $q = \infty$ if $p = 1$ and otherwise, $\frac{1}{p} + \frac{1}{q} = 1$.

Theorem 18.3.1 (Riesz representation theorem) Let $p > 1$ and let $(\Omega, S, \mu)$ be a finite measure space. If $\Lambda \in (L^p(\Omega))'$, then there exists a unique $h \in L^q(\Omega)$ ($\frac{1}{p} + \frac{1}{q} = 1$) such that

$$\Lambda f = \int_{\Omega} hf d\mu.$$  

This function satisfies $||h||_q = ||\Lambda||$ where $||\Lambda||$ is the operator norm of $\Lambda$. 
Proof: (Uniqueness) If \( h_1 \) and \( h_2 \) both represent \( \Lambda \), consider

\[
f = |h_1 - h_2|^{q-2}(\overline{h_1} - \overline{h_2}),
\]

where \( \overline{h} \) denotes complex conjugation. By Holder’s inequality, it is easy to see that

\[
f \in L^p(\Omega).
\]

Thus

\[
0 = \Lambda f - \Lambda f = \int h_1|h_1 - h_2|^{q-2}(\overline{h_1} - \overline{h_2}) - h_2|h_1 - h_2|^{q-2}(\overline{h_1} - \overline{h_2}) d\mu
\]

\[
= \int |h_1 - h_2|^p d\mu.
\]

Therefore \( h_1 = h_2 \) and this proves uniqueness.

Now let \( \lambda(E) = \Lambda(\mathcal{X}_E) \). Since this is a finite measure space \( \mathcal{X}_E \) is an element of \( L^p(\Omega) \) and so it makes sense to write \( \Lambda(\mathcal{X}_E) \). In fact \( \lambda \) is a complex measure having finite total variation. Let \( A_1, \ldots, A_n \) be a partition of \( \Omega \).

\[
|\Lambda \mathcal{X}_{A_i}| = w_i(\Lambda \mathcal{X}_{A_i}) = \Lambda(w_i \mathcal{X}_{A_i})
\]

for some \( w_i \in \mathbb{C}, |w_i| = 1 \). Thus

\[
\sum_{i=1}^{n} |\Lambda(A_i)| = \sum_{i=1}^{n} |\Lambda(\mathcal{X}_{A_i})| = \Lambda(\sum_{i=1}^{n} w_i \mathcal{X}_{A_i})
\]

\[
\leq ||\lambda||(\int |\sum_{i=1}^{n} w_i \mathcal{X}_{A_i}|^p d\mu)^{\frac{1}{p}} = ||\lambda||(\int d\mu)^{\frac{1}{p}} = ||\lambda||\mu(\Omega)^{\frac{1}{p}}.
\]

This is because if \( x \in \Omega \), \( x \) is contained in exactly one of the \( A_i \) and so the absolute value of the sum in the first integral above is equal to 1. Therefore \( |\lambda|(\Omega) < \infty \) because this was an arbitrary partition. Also, if \( \{E_i\}_{i=1}^{\infty} \) is a sequence of disjoint sets of \( \mathcal{S} \), let

\[
F_n = \cup_{i=1}^{n} E_i, \quad F = \cup_{i=1}^{\infty} E_i.
\]

Then by the Dominated Convergence theorem,

\[
||\mathcal{X}_{F_n} - \mathcal{X}_F||_p \to 0.
\]

Therefore, by continuity of \( \Lambda \),

\[
\lambda(F) = \Lambda(\mathcal{X}_F) = \lim_{n \to \infty} \Lambda(\mathcal{X}_{F_n}) = \lim_{n \to \infty} \sum_{k=1}^{n} \Lambda(\mathcal{X}_{E_k}) = \sum_{k=1}^{\infty} \lambda(E_k).
\]

This shows \( \lambda \) is a complex measure with \( |\lambda| \) finite.

It is also clear from the definition of \( \lambda \) that \( \lambda \ll \mu \). Therefore, by the Radon Nikodym theorem, there exists \( h \in L^1(\Omega) \) with

\[
\lambda(E) = \int_E h d\mu = \Lambda(\mathcal{X}_E).
\]
18.3. REPRESENTATION THEOREMS FOR THE DUAL SPACE OF $L^p$

Actually $h \in L^q$ and satisfies the other conditions above. Let $s = \sum_{i=1}^{m} c_i \chi_{E_i}$ be a simple function. Then since $\Lambda$ is linear,

$$\Lambda(s) = \sum_{i=1}^{m} c_i \Lambda(\chi_{E_i}) = \sum_{i=1}^{m} c_i \int_{E_i} h \, d\mu = \int h \, s \, d\mu.$$  \hfill (18.3.9)

**Claim:** If $f$ is uniformly bounded and measurable, then

$$\Lambda(f) = \int h \, f \, d\mu.$$

**Proof of claim:** Since $f$ is bounded and measurable, there exists a sequence of simple functions, $\{s_n\}$ which converges to $f$ pointwise and in $L^p(\Omega)$. This follows from Theorem 9.3.9 on Page 227 upon breaking $f$ up into positive and negative parts of real and complex parts. In fact this theorem gives uniform convergence. Then

$$\Lambda(f) = \lim_{n \to \infty} \Lambda(s_n) = \lim_{n \to \infty} \int h \, s_n \, d\mu = \int h \, f \, d\mu,$$

the first equality holding because of continuity of $\Lambda$, the second following from 18.3.9 and the third holding by the dominated convergence theorem.

This is a very nice formula but it still has not been shown that $h \in L^q(\Omega)$. Let $E_n = \{ x : |h(x)| \leq n \}$. Thus $|hX_{E_n}| \leq n$. Then

$$|hX_{E_n}|^{q-2} (\overline{hX}_{E_n}) \in L^p(\Omega).$$

By the claim, it follows that

$$||hX_{E_n}||_q^q = \int |hX_{E_n}|^{q-2} (\overline{hX}_{E_n}) \, d\mu = \Lambda(\int |hX_{E_n}|^{q-2} (\overline{hX}_{E_n}))$$

$$\leq ||\Lambda|| \, ||hX_{E_n}|^{q-2} (\overline{hX}_{E_n})||_p = ||\Lambda|| \, ||hX_{E_n}||_q^p,$$

the last equality holding because $q - 1 = q/p$ and so

$$\left( \int |hX_{E_n}|^{q-2} (\overline{hX}_{E_n}) \, d\mu \right)^{1/p} = \left( \int \left( |hX_{E_n}|^{q/p} \right)^p \, d\mu \right)^{1/p} = ||hX_{E_n}||_q^\frac{q}{p}$$

Therefore, since $q - \frac{q}{p} = 1$, it follows that

$$||hX_{E_n}||_q \leq ||\Lambda||.$$

Letting $n \to \infty$, the Monotone Convergence theorem implies

$$||h||_q \leq ||\Lambda||.$$  \hfill (18.3.10)
Now that $h$ has been shown to be in $L^q(\Omega)$, it follows from Theorem 18.3.1 on Page 593 and the density of the simple functions, Theorem 18.3.4 on Page 594, that

$$\Lambda f = \int hf \, d\mu$$

for all $f \in L^p(\Omega)$.

It only remains to verify the last claim.

Proof of the claim: Let $x = c$. Therefore since $c$ is arbitrary, $\|f\|_\infty = \|c(1/c) f\|_\infty \leq \frac{1}{c} \|cf\|_\infty$ which implies $|c| \|f\|_\infty \leq |cf|_\infty$. Thus $\|f\|_\infty$ is a norm as claimed.

To verify completeness, let $\{f_n\}$ be a Cauchy sequence in $L^\infty(\Omega)$ and use the above claim to get the existence of a set of measure zero, $E_{nm}$ such that for all $x \notin E_{nm}$,

$$|f_n(x) - f_m(x)| \leq \|f_n - f_m\|_\infty$$

Let $E = \cup_{n,m} E_{nm}$. Thus $\mu(E) = 0$ and for each $x \notin E$, $\{f_n(x)\}_{n=1}^\infty$ is a Cauchy sequence in $\mathbb{C}$. Let

$$f(x) = \begin{cases} 0 & \text{if } x \in E \\ \lim_{n \to \infty} f_n(x) & \text{if } x \notin E \\ = \lim_{n \to \infty} X_{E^c}(x) f_n(x) 
\end{cases}$$
18.3. **REPRESENTATION THEOREMS FOR THE DUAL SPACE OF** \( L^p \)

Then \( f \) is clearly measurable because it is the limit of measurable functions. If

\[
F_n = \{ x : |f_n(x)| > \|f_n\|_\infty \}
\]

and \( F = \bigcup_{n=1}^\infty F_n \), it follows \( \mu(F) = 0 \) and that for \( x \notin F \cup E \),

\[
|f(x)| \leq \lim \inf_{n \to \infty} |f_n(x)| \leq \lim \inf_{n \to \infty} \|f_n\|_\infty < \infty
\]

because \( \{\|f_n\|_\infty\} \) is a Cauchy sequence. \( \{\|f_n\|_\infty - \|f_m\|_\infty\} \leq \|f_n - f_m\|_\infty \) by the triangle inequality.) Thus \( f \in L^\infty(\Omega) \). Let \( n \) be large enough that whenever \( m > n \),

\[
\|f_m - f_n\|_\infty < \varepsilon.
\]

Then, if \( x \notin E \),

\[
|f(x) - f_n(x)| = \lim_{m \to \infty} |f_m(x) - f_n(x)| \\
\leq \lim_{m \to \infty} \inf_{m \to \infty} \|f_m - f_n\|_\infty < \varepsilon.
\]

Hence \( \|f - f_n\|_\infty < \varepsilon \) for all \( n \) large enough. This proves the theorem.

The next theorem is the Riesz representation theorem for \( (L^1(\Omega))' \).

**Theorem 18.3.4 (Riesz representation theorem)** Let \( (\Omega, S, \mu) \) be a finite measure space. If \( \Lambda \in (L^1(\Omega))' \), then there exists a unique \( h \in L^\infty(\Omega) \) such that

\[
\Lambda(f) = \int_\Omega hf \, d\mu
\]

for all \( f \in L^1(\Omega) \). If \( h \) is the function in \( L^\infty(\Omega) \) representing \( \Lambda \in (L^1(\Omega))' \), then \( \|h\|_\infty = \|\Lambda\| \).

**Proof:** Just as in the proof of Theorem 18.3.1, there exists a unique \( h \in L^1(\Omega) \) such that for all simple functions, \( s \),

\[
\Lambda(s) = \int s h \, d\mu. \tag{18.3.11}
\]

To show \( h \in L^\infty(\Omega) \), let \( \varepsilon > 0 \) be given and let

\[
E = \{ x : |h(x)| \geq \|\Lambda\| + \varepsilon \}.
\]

Let \( |k| = 1 \) and \( hk = |h| \). Since the measure space is finite, \( k \in L^1(\Omega) \). As in Theorem 18.3.1 let \( \{s_n\} \) be a sequence of simple functions converging to \( k \) in \( L^1(\Omega) \), and pointwise. It follows from the construction in Theorem 9.3.9 on Page 222 that it can be assumed \( |s_n| \leq 1 \). Therefore

\[
\Lambda(kX_E) = \lim_{n \to \infty} \Lambda(s_nX_E) = \lim_{n \to \infty} \int_E hs_n \, d\mu = \int_E hk \, d\mu
\]
where the last equality holds by the Dominated Convergence theorem. Therefore,
\[ \|A\| \mu(E) \geq |A(kX_E)| = |\int_E hkX_E d\mu| = \int_E |h| d\mu \]
\[ \geq (\|A\| + \varepsilon) \mu(E). \]

It follows that \( \mu(E) = 0. \) Since \( \varepsilon > 0 \) was arbitrary, \( \|h\| \geq \|h\|_{\infty} \). It was shown that \( h \in L^\infty(\Omega) \), the density of the simple functions in \( L^1(\Omega) \) and \([18.3.11]\) imply
\[ \Lambda f = \int_\Omega hf d\mu, \quad \|A\| \geq \|h\|_{\infty}. \quad (18.3.12) \]

This proves the existence part of the theorem. To verify uniqueness, suppose \( h_1 \) and \( h_2 \) both represent \( \Lambda \) and let \( f \in L^1(\Omega) \) be such that \( |f| \leq 1 \) and \( f(h_1 - h_2) = |h_1 - h_2| \). Then
\[ 0 = \Lambda f - \Lambda f = \int (h_1 - h_2) f d\mu = \int |h_1 - h_2| d\mu. \]

Thus \( h_1 = h_2 \). Finally,
\[ \|A\| = \sup \{ \int h f d\mu : ||h||_1 \leq 1 \} \leq \|h\|_{\infty} \leq ||A|| \]

by \([18.3.12]\).

Next these results are extended to the \( \sigma \) finite case.

**Lemma 18.3.5** Let \( (\Omega, S, \mu) \) be a measure space and suppose there exists a measurable function, \( r \) such that \( r(x) > 0 \) for all \( x \), there exists \( M \) such that \( |r(x)| < M \) for all \( x \), and \( \int r d\mu < \infty. \) Then for
\[ \Lambda \in (L^p(\Omega, \mu))^\prime, \ p \geq 1, \]
there exists a unique \( h \in L^{p'}(\Omega, \mu), \ L^\infty(\Omega, \mu) \) if \( p = 1 \) such that
\[ \Lambda f = \int hf d\mu. \]

Also \( ||h|| = ||A||, \ (||h|| = ||h||_{p'} \ if \ p > 1, \ ||h||_\infty \ if \ p = 1). \) Here
\[ \frac{1}{p} + \frac{1}{p'} = 1. \]

**Proof:** Define a new measure \( \tilde{\mu} \), according to the rule
\[ \tilde{\mu}(E) \equiv \int_E r d\mu. \quad (18.3.13) \]

Thus \( \tilde{\mu} \) is a finite measure on \( S. \) Now define a mapping, \( \eta : L^p(\Omega, \mu) \to L^p(\Omega, \tilde{\mu}) \) by
\[ \eta f = r^{-\frac{1}{2}} f. \]
Then
\[ \|\eta f\|_{L^p(\mu)}^p = \int |r^{-\frac{1}{p}} f|^p d\mu = \|f\|_{L^p(\mu)}^p \]
and so \( \eta \) is one to one and in fact preserves norms. I claim that also \( \eta \) is onto. To see this, let \( g \in L^p(\Omega, \mu) \) and consider the function, \( r^{\frac{1}{p}} g \). Then
\[ \int |r^{\frac{1}{p}} g|^p d\mu = \int |g|^p d\mu = \int |g|^p d\bar{\mu} < \infty \]
Thus \( r^{\frac{1}{p}} g \in L^p(\Omega, \mu) \) and \( \eta \left( r^{\frac{1}{p}} g \right) = g \) showing that \( \eta \) is onto as claimed. Thus \( \eta \) is one to one, onto, and preserves norms. Consider the diagram below which is descriptive of the situation in which \( \eta^* \) must be one to one and onto.

Then for \( \Lambda \in L^p(\mu)^{\prime} \), there exists a unique \( \tilde{\Lambda} \in L^p(\bar{\mu})^{\prime} \) such that \( \eta^* \tilde{\Lambda} = \Lambda, \|\tilde{\Lambda}\| = ||\Lambda|| \). By the Riesz representation theorem for finite measure spaces, there exists a unique \( h \in L^{p^*}(\bar{\mu}) \) which represents \( \tilde{\Lambda} \) in the manner described in the Riesz representation theorem. Thus \( ||h||_{L^{p^*}(\bar{\mu})} = ||\tilde{\Lambda}|| = ||\Lambda|| \) and for all \( f \in L^p(\mu) \),
\[ \Lambda(f) = \eta^* \tilde{\Lambda}(f) = \tilde{\Lambda}(\eta f) = \int h(\eta f) d\bar{\mu} = \int r^\Lambda(f - \frac{1}{p} f) d\mu \]
Now
\[ \int |r^{\frac{1}{p}^*} h|^p d\mu = \int |h|^p d\mu = ||h||_{L^{p^*}(\bar{\mu})}^p < \infty. \]
Thus \( \|r^{\frac{1}{p}^*} h\|_{L^{p^*}(\mu)} = ||h||_{L^{p^*}(\bar{\mu})} = ||\tilde{\Lambda}|| = ||\Lambda|| \) and represents \( \Lambda \) in the appropriate way. If \( p = 1 \), then \( 1/p^* \equiv 0. \) This proves the Lemma.

A situation in which the conditions of the lemma are satisfied is the case where the measure space is \( \sigma \) finite. In fact, you should show this is the only case in which the conditions of the above lemma hold.

**Theorem 18.3.6** *(Riesz representation theorem)* Let \( (\Omega, \mathcal{S}, \mu) \) be \( \sigma \) finite and let
\[ \Lambda \in (L^p(\Omega, \mu))^\prime, \ p \geq 1. \]
Then there exists a unique \( h \in L^{p^*}(\Omega, \mu), \ L^{\infty}(\Omega, \mu) \) if \( p = 1 \) such that
\[ \Lambda f = \int h f d\mu. \]
Also \( ||h|| = ||\Lambda|| \). (\( ||h|| = ||h||_q \) if \( p > 1 \), \( ||h||_\infty \) if \( p = 1 \)). Here
\[
\frac{1}{p} + \frac{1}{q} = 1.
\]

**Proof:** Let \( \{\Omega_n\} \) be a sequence of disjoint elements of \( S \) having the property that
\[
0 < \mu(\Omega_n) < \infty, \bigcup_{n=1}^{\infty} \Omega_n = \Omega.
\]
Define
\[
r(x) = \sum_{n=1}^{\infty} \frac{1}{n^2} \chi_{\Omega_n}(x) \mu(\Omega_n)^{-1}, \quad \tilde{\mu}(E) = \int_E r d\mu.
\]
Thus
\[
\int_{\Omega} r d\mu = \tilde{\mu}(\Omega) = \sum_{n=1}^{\infty} \frac{1}{n^2} < \infty
\]
so \( \tilde{\mu} \) is a finite measure. The above lemma gives the existence part of the conclusion of the theorem. Uniqueness is done as before.

With the Riesz representation theorem, it is easy to show that
\( L^p(\Omega), \quad p > 1 \)
is a reflexive Banach space. Recall Definition [15.2.14] on Page 434 for the definition.

**Theorem 18.3.7** For \((\Omega, S, \mu)\) a \( \sigma \) finite measure space and \( p > 1 \), \( L^p(\Omega) \) is reflexive.

**Proof:** Let \( \delta_r : (L^r(\Omega))' \to L^{r'}(\Omega) \) be defined for \( \frac{1}{r} + \frac{1}{r'} = 1 \) by
\[
\int (\delta_r \Lambda) g d\mu = \Lambda g
\]
for all \( g \in L^{r'}(\Omega) \). From Theorem [15.2.14] \( \delta_r \) is one to one, onto, continuous and linear. By the open map theorem, \( \delta_r^{-1} \) is also one to one, onto, and continuous (\( \delta_r \Lambda \) equals the representor of \( \Lambda \)). Thus \( \delta_r^* \) is also one to one, onto, and continuous by Corollary [15.2.11]. Now observe that \( J = \delta_p^* \circ \delta_q^{-1} \). To see this, let \( z^* \in (L^q)' \), \( y^* \in (L^p)' \),
\[
\delta_p^* \circ \delta_q^{-1} (\delta_q z^*) (y^*) = (\delta_p^* z^*) (y^*) = z^* (\delta_p y^*) = \int (\delta_q z^*) (\delta_p y^*) d\mu,
\]
\[
J (\delta_q z^*) (y^*) = y^* (\delta_q z^*) = \int (\delta_p y^*) (\delta_q z^*) d\mu.
\]
Therefore \( \delta_p^* \circ \delta_q^{-1} = J \) on \( \delta_q (L^q)' = L^p \). But the two \( \delta \) maps are onto and so \( J \) is also onto.
18.4 The Dual Space Of $L^\infty (\Omega)$

What about the dual space of $L^1 (\Omega)$? This will involve the following Lemma. Also recall the notion of total variation defined in Definition 18.2.2.

Lemma 18.4.1 Let $(\Omega, \mathcal{F})$ be a measure space. Denote by $BV (\Omega)$ the space of \textit{finitely} additive complex measures $\nu$ such that $|\nu| (\Omega) < \infty$. Then defining $||\nu|| \equiv |\nu| (\Omega)$, it follows that $BV (\Omega)$ is a Banach space.

\textbf{Proof:} It is obvious that $BV (\Omega)$ is a vector space with the obvious conventions involving scalar multiplication. Why is $||\cdot||$ a norm? All the axioms are obvious except for the triangle inequality. However, this is not too hard either.

\[ ||\mu + \nu|| \equiv |\mu + \nu| (\Omega) = \sup_{\pi(\Omega)} \left\{ \sum_{A \in \pi(\Omega)} |\mu (A) + \nu (A)| \right\} \]

\[ \leq \sup_{\pi(\Omega)} \left\{ \sum_{A \in \pi(\Omega)} |\mu (A)| \right\} + \sup_{\pi(\Omega)} \left\{ \sum_{A \in \pi(\Omega)} |\nu (A)| \right\} \]

\[ \equiv |\mu| (\Omega) + |\nu| (\Omega) = ||\mu|| + ||\nu||. \]

Suppose now that $\{\nu_n\}$ is a Cauchy sequence. For each $E \in \mathcal{F}$,

\[ |\nu_n (E) - \nu_m (E)| \leq ||\nu_n - \nu_m|| \]

and so the sequence of complex numbers $\nu_n (E)$ converges. That to which it converges is called $\nu (E)$. Then it is obvious that $\nu (E)$ is finitely additive. Why is $|\nu|$ finite? Since $||\cdot||$ is a norm, it follows that there exists a constant $C$ such that for all $n$,

\[ |\nu_n| (\Omega) < C \]

Let $\pi (\Omega)$ be any partition. Then

\[ \sum_{A \in \pi(\Omega)} |\nu (A)| = \lim_{n \to \infty} \sum_{A \in \pi(\Omega)} |\nu_n (A)| \leq C. \]

Hence $\nu \in BV (\Omega)$. Let $\varepsilon > 0$ be given and let $N$ be such that if $n, m > N$, then

\[ ||\nu_n - \nu_m|| < \varepsilon / 2. \]

Pick any such $n$. Then choose $\pi (\Omega)$ such that

\[ |\nu - \nu_n| (\Omega) - \varepsilon / 2 < \sum_{A \in \pi(\Omega)} |\nu (A) - \nu_n (A)| \]

\[ = \lim_{m \to \infty} \sum_{A \in \pi(\Omega)} |\nu_m (A) - \nu_n (A)| < \lim_{m \to \infty} \inf |\nu_n - \nu_m| (\Omega) \leq \varepsilon / 2 \]

It follows that

\[ \lim_{n \to \infty} ||\nu - \nu_n|| = 0. \]
Corollary 18.4.2 Suppose \((\Omega, F)\) is a measure space as above and suppose \(\mu\) is a measure defined on \(F\). Denote by \(BV(\Omega; \mu)\) those finitely additive measures of \(BV(\Omega)\) \(\nu\) such that \(\nu \ll \mu\) in the usual sense that if \(\mu(E) = 0\), then \(\nu(E) = 0\). Then \(BV(\Omega; \mu)\) is a closed subspace of \(BV(\Omega)\).

Proof: It is clear that it is a subspace. Is it closed? Suppose \(\nu_n \rightarrow \nu\) and each \(\nu_n\) is in \(BV(\Omega; \mu)\). Then if \(\mu(E) = 0\), it follows that \(\nu_n(E) = 0\) and so \(\nu(E) = 0\) also, being the limit of 0. ■

Definition 18.4.3 For a simple function \(s(\omega) = \sum_{k=1}^n c_k \chi_{E_k}(\omega)\) and \(\nu \in BV(\Omega)\), define an “integral” with respect to \(\nu\) as follows.

\[ \int s d\nu \equiv \sum_{k=1}^n c_k \nu(E_k). \]

For a function which is in \(L^\infty(\Omega; \mu)\), define \(\int f d\nu\) as follows. Applying Theorem 9.3.9, to the positive and negative parts of real and imaginary parts of \(f\), there exists a sequence of simple functions \(\{s_n\}\) which converges uniformly to \(f\) off a set of \(\mu\) measure zero. Then

\[ \int f d\nu \equiv \lim_{n \to \infty} \int s_n d\nu \]

Lemma 18.4.4 The above definition of the integral with respect to a finitely additive measure in \(BV(\Omega; \mu)\) is well defined.

Proof: First consider the claim about the integral being well defined on the simple functions. This is clearly true if it is required that the \(c_k\) are disjoint and the \(E_k\) also disjoint having union equal to \(\Omega\). Thus define the integral of a simple function in this manner. First write the simple function as

\[ \sum_{k=1}^n c_k \chi_{E_k} \]

where the \(c_k\) are the values of the simple function. Then use the above formula to define the integral. Next suppose the \(E_k\) are disjoint but the \(c_k\) are not necessarily distinct. Let the distinct values of the \(c_k\) be \(a_1, \ldots, a_m\).

\[ \sum_k c_k \chi_{E_k} = \sum_j a_j \left( \sum_{i: c_i = a_j} \chi_{E_i} \right) = \sum_j a_j \nu \left( \bigcup_{i: c_i = a_j} E_i \right) \]

\[ = \sum_j a_j \sum_{i: c_i = a_j} \nu(E_i) = \sum_k c_k \nu(E_k) \]

and so the same formula for the integral of a simple function is obtained in this case also. Now consider two simple functions

\[ s = \sum_{k=1}^n a_k \chi_{E_k}, \quad t = \sum_{j=1}^m b_j \chi_{F_j} \]
where the $a_k$ and $b_j$ are the distinct values of the simple functions. Then from what was just shown,

$$\int (\alpha s + \beta t) \, d\nu = \int \left( \sum_{k=1}^{n} \sum_{j=1}^{m} \alpha a_k \chi_{E_k \cap F_j} + \sum_{j=1}^{m} \sum_{k=1}^{n} \beta b_j \chi_{E_k \cap F_j} \right) \, d\nu$$

$$= \int \left( \sum_{j,k} \alpha a_k \chi_{E_k \cap F_j} + \beta b_j \chi_{E_k \cap F_j} \right) \, d\nu$$

$$= \sum_{j,k} (\alpha a_k + \beta b_j) \nu (E_k \cap F_j)$$

Thus the integral is linear on simple functions so, in particular, the formula given in the above definition is well defined regardless.

So what about the definition for $f \in L^\infty (\Omega; \mu)$? Since $f \in L^\infty$, there is a set of $\mu$ measure zero $N$ such that on $N^\complement$ there exists a sequence of simple functions which converges uniformly to $f$ on $N^\complement$. Consider $s_n$ and $s_m$. As in the above, they can be written as

$$\sum_{k=1}^{p} c_k^n \chi_{E_k}, \quad \sum_{k=1}^{p} c_k^m \chi_{E_k}$$

respectively, where the $E_k$ are disjoint having union equal to $\Omega$. Then by uniform convergence, if $m, n$ are sufficiently large, $|c_k^n - c_k^m| < \varepsilon$ or else the corresponding $E_k$ is contained in $N^\complement$ a set of $\nu$ measure 0 thanks to $\nu \ll \mu$. Hence

$$\left| \int s_n d\nu - \int s_m d\nu \right| = \left| \sum_{k=1}^{p} (c_k^n - c_k^m) \nu (E_k) \right|$$

$$\leq \sum_{k=1}^{p} |c_k^n - c_k^m| \nu (E_k) \leq \varepsilon ||\nu||$$

and so the integrals of these simple functions converge. Similar reasoning shows that the definition is not dependent on the choice of approximating sequence. ■

Note also that for $s$ simple,

$$\left| \int s d\nu \right| \leq ||s||_{L^\infty} ||\nu|| (\Omega) = ||s||_{L^\infty} ||\nu||$$
Next the dual space of $L^\infty (\Omega; \mu)$ will be identified with $BV (\Omega; \mu)$. First here is a simple observation. Let $\nu \in BV (\Omega; \mu)$. Then define the following for $f \in L^\infty (\Omega; \mu)$:

$$T_\nu (f) \equiv \int f d\nu$$

**Lemma 18.4.5** For $T_\nu$ just defined,

$$|T_\nu f| \leq ||f||_{L^\infty} ||\nu||$$

**Proof:** As noted above, the conclusion true if $f$ is simple. Now if $f$ is in $L^\infty$, then it is the uniform limit of simple functions off a set of $\mu$ measure zero. Therefore, by the definition of the $T_\nu$,

$$|T_\nu f| = \lim_{n \to \infty} |T_\nu s_n| \leq \liminf_{n \to \infty} ||s_n||_{L^\infty} ||\nu|| = ||f||_{L^\infty} ||\nu||$$

Thus each $T_\nu$ is in $(L^\infty (\Omega; \mu))^\prime$. ■

Here is the representation theorem, due to Kantorovitch, for the dual of $L^\infty (\Omega; \mu)$.

**Theorem 18.4.6** Let $\theta : BV (\Omega; \mu) \to (L^\infty (\Omega; \mu))^\prime$ be given by $\theta (\nu) \equiv T_\nu$. Then $\theta$ is one to one, onto and preserves norms.

**Proof:** It was shown in the above lemma that $\theta$ maps into $(L^\infty (\Omega; \mu))^\prime$. It is obvious that $\theta$ is linear. Why does it preserve norms? From the above lemma,

$$||\theta \nu|| \equiv \sup_{||f||_{L^\infty} \leq 1} |T_\nu f| \leq ||\nu||$$

It remains to turn the inequality around. Let $\pi (\Omega)$ be a partition. Then

$$\sum_{A \in \pi (\Omega)} |\nu (A)| = \sum_{A \in \pi (\Omega)} \text{sgn} (\nu (A)) \nu (A) \equiv \int f d\nu$$

where $\text{sgn} (\nu (A))$ is defined to be a complex number of modulus 1 such that $\text{sgn} (\nu (A)) \nu (A) = |\nu (A)|$ and

$$f (\omega) = \sum_{A \in \pi (\Omega)} \text{sgn} (\nu (A)) \chi_A (\omega).$$

Therefore, choosing $\pi (\Omega)$ suitably, since $||f||_{L^\infty} \leq 1$,

$$||\nu|| - \varepsilon = |\nu| (\Omega) - \varepsilon \leq \sum_{A \in \pi (\Omega)} |\nu (A)| = T_\nu (f)$$

$$= |T_\nu (f)| = ||\theta (\nu) (f)|| \leq ||\theta (\nu)|| \leq ||\nu||$$

Thus $\theta$ preserves norms. Hence it is one to one also. Why is $\theta$ onto?

Let $\Lambda \in (L^\infty (\Omega; \mu))^\prime$. Then define

$$\nu (E) \equiv \Lambda (\chi_E) \quad (18.4.14)$$
18.5. Non $\sigma$ Finite Case

This is obviously finitely additive because $\Lambda$ is linear. Also, if $\mu(E) = 0$, then $\mathcal{X}_E = 0$ in $L^\infty$ and so $\Lambda(\mathcal{X}_E) = 0$. If $\pi(\Omega)$ is any partition of $\Omega$, then

$$\sum_{A \in \pi(\Omega)} |\nu(A)| = \sum_{A \in \pi(\Omega)} |\Lambda(\mathcal{X}_A)| = \sum_{A \in \pi(\Omega)} \operatorname{sgn}(\Lambda(\mathcal{X}_A)) \Lambda(\mathcal{X}_A)$$

$$= \Lambda \left( \sum_{A \in \pi(\Omega)} \operatorname{sgn}(\Lambda(\mathcal{X}_A)) \mathcal{X}_A \right) \leq ||\Lambda||$$

and so $||\nu|| \leq ||\Lambda||$ showing that $\nu \in BV(\Omega; \mu)$. Also from 18.4.14, if $s = \sum_{k=1}^n c_k \mathcal{X}_{E_k}$ is a simple function,

$$\int s d\nu = \sum_{k=1}^n c_k \nu(E_k) = \sum_{k=1}^n c_k \Lambda(\mathcal{X}_{E_k}) = \Lambda \left( \sum_{k=1}^n c_k \mathcal{X}_{E_k} \right) = \Lambda(s)$$

Then letting $f \in L^\infty(\Omega; \mu)$, there exists a sequence of simple functions converging to $f$ uniformly off a set of $\mu$ measure zero and so passing to a limit in the above with $s$ replaced with $s_n$ it follows that

$$\Lambda(f) = \int f d\nu$$

and so $\theta$ is onto. ■

18.5 Non $\sigma$ Finite Case

It is not necessary to assume $\mu$ is either finite or $\sigma$ finite to establish the Riesz representation theorem for $1 < p < \infty$. This involves the notion of uniform convexity. First we recall Clarkson’s inequalities.

**Lemma 18.5.1** Let $2 \leq p$. Then

$$\left| \frac{f + g}{2} \right|^p_{L^p} + \left| \frac{f - g}{2} \right|^p_{L^p} \leq \frac{1}{2} (||f||^p_{L^p} + ||g||^p_{L^p})$$

Let $1 < p < 2$, then for $1/p + 1/q = 1$,

$$\left| \frac{f + g}{2} \right|^q_{L^p} + \left| \frac{f - g}{2} \right|^q_{L^p} \leq \left( \frac{1}{2} ||f||^p_{L^p} + \frac{1}{2} ||g||^p_{L^p} \right)^{q/p}$$

Recall also the following definition of uniform convexity.

**Definition 18.5.2** A Banach space, $X$, is said to be uniformly convex if whenever $||x_n|| \leq 1$ and $||\frac{x_n + x_m}{2}|| \to 1$ as $n, m \to \infty$, then $\{x_n\}$ is a Cauchy sequence and $x_n \to x$ where $||x|| = 1$. 
Observe that Clarkson’s inequalities imply $L^p$ is uniformly convex for all $p > 1$. This was Theorem 15.3.10. Uniformly convex spaces have a very nice property which is described in the following lemma. Roughly, this property is that any element of the dual space achieves its norm at some point of the closed unit ball.

**Lemma 18.5.3** Let $X$ be uniformly convex and let $\phi \in X'$. Then there exists $x \in X$ such that $\|x\| = 1$, $\phi(x) = \|\phi\|$.

**Proof:** Let $\|x_n\| \leq 1$ and $|\phi(x_n)| \to \|\phi\|$. Let $x_n = w_n x_n$ where $|w_n| = 1$ and $w_n \phi x_n = |\phi x_n|$. Thus $\phi(x_n) = |\phi(x_n)| = |\phi(x_n)| \to |\phi|$. $\phi(x_n) \to \|\phi\|$, $\|x_n\| \leq 1$.

We can assume, without loss of generality, that

$$\phi(x_n) = |\phi(x_n)| \geq \frac{\|\phi\|}{2}$$

and $\phi \neq 0$.

**Claim** $\frac{x_n + x_m}{2} \to 1$ as $n, m \to \infty$.

**Proof of Claim:** Let $n, m$ be large enough that $\phi(x_n), \phi(x_m) \geq \|\phi\| - \frac{\varepsilon}{2}$ where $0 < \varepsilon$. Then $\|x_n + x_m\| \neq 0$ because if it equals 0, then $x_n = -x_m$ so $\phi(x_n) = \phi(x_m)$ and both $\phi(x_n)$ and $\phi(x_m)$ are positive. Therefore consider $\frac{x_n + x_m}{\|x_n + x_m\|}$, a vector of norm 1. Thus,

$$\|\phi\| \geq \phi \left( \frac{x_n + x_m}{\|x_n + x_m\|} \right) \geq \frac{2\|\phi\| - \varepsilon}{\|x_n + x_m\|}.$$

Hence

$$\|x_n + x_m\||\phi\| \geq 2\|\phi\| - \varepsilon.$$

Since $\varepsilon > 0$ is arbitrary, $\lim_{n,m \to \infty} \|x_n + x_m\| = 2$. This proves the claim.

By uniform convexity, $\{x_n\}$ is Cauchy and $x_n \to x$, $\|x\| = 1$. Thus $\phi(x) = \lim_{n \to \infty} \phi(x_n) = \|\phi\|$. $\blacksquare$

The proof of the Riesz representation theorem will be based on the following lemma which says that if you can show a directional derivative exists, then it can be used to represent a functional.

**Lemma 18.5.4** (McShane) Let $X$ be a complex normed linear space and let $\phi \in X'$. Suppose there exists $x \in X$, $\|x\| = 1$ with $\phi x = \|\phi\| \neq 0$. Let $y \in X$ and let $\psi_y(t) = \|x + ty\|$ for $t \in \mathbb{R}$. Suppose $\psi_y'(0)$ exists for each $y \in X$. Then for all $y \in X$,

$$\psi_y'(0) + i\psi_{-iy}'(0) = \|\phi\|^{-1}\phi(y).$$
**Proof:** Suppose first that \( ||\phi|| = 1 \). Then since \( \phi(x) = 1, \phi(y - \phi(y)x) = 0 \) and so
\[
\phi(x + t(y - \phi(y)x)) = \phi(x) = 1 = ||\phi||.
\]
Therefore, \( ||x + t(y - \phi(y)x)|| \geq 1 \) since otherwise \( ||x + t(y - \phi(y)x)|| = r < 1 \) and so
\[
\phi \left( x + t(y - \phi(y)x) \right) \left( \frac{1}{r} \right) = \frac{1}{r} \phi(x) = \frac{1}{r}
\]
which would imply that \( ||\phi|| > 1 \).

Also for small \( t, |\phi(y)t| < 1 \), and so
\[
1 \leq ||x + t(y - \phi(y)x)|| = ||(1 - \phi(y)t)x + ty||
\]
\[
\leq |1 - \phi(y)t| \left| x + \frac{t}{1 - \phi(y)t}y \right|.
\]
This implies
\[
|1 + t\phi(y) + o(t)| = \frac{1}{|1 - t\phi(y)|}
\]
\[
\leq \left| x + \frac{t}{1 - \phi(y)t}y \right| = ||x + ty + o(t)||
\]
(18.5.15)
where \( \lim_{t \to 0} o(t)(t^{-1}) = 0 \). Thus for \( t > 0 \),
\[
\text{Re} \phi(y) \leq |\text{Re} \phi(y)| \leq \frac{|1 + t\phi(y)| - 1}{t} \leq \frac{||x + ty|| - ||x||}{t} + \frac{o(t)}{t}
\]
and for \( t < 0 \),
\[
\text{Re} \phi(y) \geq \frac{|1 + t\phi(y)| - 1}{t} \geq \frac{||x + ty|| - ||x||}{t} + \frac{o(t)}{t}
\]
By assumption, letting \( t \to 0+ \) and \( t \to 0- \),
\[
\text{Re} \phi(y) = \lim_{t \to 0} \frac{||x + ty|| - ||x||}{t} = \psi'_y(0).
\]
Now
\[
\phi(y) = \text{Re} \phi(y) + i \text{Im} \phi(y)
\]
so
\[
\phi(-iy) = -i(\phi(y)) = -i \text{Re} \phi(y) + \text{Im} \phi(y)
\]
and
\[
\phi(-iy) = \text{Re} \phi(-iy) + i \text{Im} \phi(-iy).
\]
Hence
\[
\text{Re} \phi(-iy) = \text{Im} \phi(y).
\]
Consequently,
\[
\phi(y) = \text{Re} \phi(y) + i \text{Im} \phi(y) = \text{Re} \phi(y) + i \text{Re} \phi(-iy)
\]
$\psi_y' (0) + i \psi_{-iy}'(0)$.

This proves the lemma when $\|\phi\| = 1$. For arbitrary $\phi \neq 0$, let $\phi(x) = \|\phi\|, \|x\| = 1$. Then from above, if $\phi_1(y) \equiv \|\phi\|^{-1} \phi(y), \|\phi_1\| = 1$ and so from what was just shown,

$$\phi_1(y) = \frac{\phi(y)}{\|\phi\|} = \psi_y'(0) + i \psi_{-iy}(0) \quad \blacksquare$$

Now here are some short observations. For $t \ni R, p > 1$, and $x, y \in C, x \neq 0$

$$\lim_{t \to 0} \frac{|x + ty|^p - |x|^p}{t} = p |x|^{p-2} (\text{Re } x \text{ Re } y + \text{Im } x \text{ Im } y)$$

Also from convexity of $f(r) = r^p$, for $|t| < 1$,

$$|x + ty|^p - |x|^p \leq |x| + |t||y|^p - |x|^p$$

$$= \left[ (1 + |t|) \frac{|x| + |t||y|}{1 + |t|} \right]^p - |x|^p$$

$$\leq (1 + |t|)^p \frac{|x|^p}{1 + |t|} + |t||y|^p - |x|^p$$

$$\leq (1 + |t|)^{p-1} (|x|^p + |t||y|^p) - |x|^p$$

$$\leq \left( (1 + |t|)^{p-1} - 1 \right) |x|^p + 2^{p-1} |t||y|^p$$

Now for $f(t) \equiv (1 + t)^{p-1}, f'(t)$ is uniformly bounded, depending on $p$, for $t \in [0,1]$. Hence the above is dominated by an expression of the form

$$C_p (|x|^p + |y|^p)|t| \quad (18.5.17)$$

The above lemma and uniform convexity of $L^p$ can be used to prove a general version of the Riesz representation theorem next. This version makes no assumption that the measure space is $\sigma$ finite. Let $p > 1$ and let $\eta : L^p \to (L^p)'$ be defined by

$$\eta(g)(f) = \int_\Omega gf \, d\mu. \quad (18.5.18)$$

**Theorem 18.5.5 (Riesz representation theorem $p > 1$)** The map $\eta$ is 1-1, onto, continuous, and

$$\|\eta g\| = \|g\|, \|\eta\| = 1.$$

**Proof:** Obviously $\eta$ is linear. Suppose $\eta g = 0$. Then $0 = \int gf \, d\mu$ for all $f \in L^p$. Let $f = |g|^{q-2} \overline{g}$. Then $f \in L^q$ and so $0 = \int |g|^q d\mu$. Hence $g = 0$ and $\eta$ is 1-1. That $\eta g \in (L^p)'$ is obvious from the Holder inequality. In fact,

$$|\eta(g)(f)| \leq \|g\|_q \|f\|_p,$$
and so $||\eta(g)|| \leq ||g||_q$. To see that equality holds, let

$$f = |g|^{q-2}g ||g||^{1-q}_q.$$  

Then $||f||_p = 1$ and

$$\eta(g)(f) = \int \Omega |g|^q d\mu ||g||^{1-q}_q = ||g||_q.$$  

Thus $||\eta|| = 1$.

It remains to show $\eta$ is onto. Let $\phi \in (L^p)'$. Is $\phi = \eta g$ for some $g \in L^q$? Without loss of generality, assume $\phi \not= 0$. By uniform convexity of $L^p$, Lemma 18.5.16, there exists $g$ such that

$$\phi g = ||\phi||, \ g \in L^p, \ ||g|| = 1.$$  

For $f \in L^p$, define $\phi_f(t) = \int \Omega |g + tf|^p d\mu$. Thus

$$\psi_f(t) = ||g + tf||_p = \phi_f(t)^{\frac{1}{p}}.$$  

Does $\psi_f'(0)$ exist? Let $[g = 0]$ denote the set $\{x : g(x) = 0\}$.

$$\frac{\phi_f(t) - \phi_f(0)}{t} = \int \frac{(|g + tf|^p - |g|^p)}{t} d\mu$$

From Lemma 18.5.18, the integrand is bounded by $C_p (|f|^p + |g|^p)$. Therefore, using Lemma 18.5.10, the dominated convergence theorem applies and it follows $\phi_f'(0) =$

$$\lim_{t \to 0} \frac{\phi_f(t) - \phi_f(0)}{t} = \lim_{t \to 0} \left[ \int_{[g = 0]} |t|^{p-1} |f|^p d\mu + \int_{[g \not= 0]} \frac{(|g + tf|^p - |g|^p)}{t} d\mu \right]$$

$$= p \int_{[g \not= 0]} |g|^{p-2} \text{Re}(\overline{g} f) d\mu = p \int |g|^{p-2} \text{Re}(\overline{g} f) d\mu.$$  

Hence

$$\psi_f'(0) = ||g||^{-\frac{1}{p}} \int |g(x)|^{p-2} \text{Re}(\overline{g} f(x)) d\mu.$$  

Note $\frac{1}{p} - 1 = -\frac{1}{q}$. Therefore,

$$\psi_{-t} f(0) = ||g||^{-\frac{1}{p}} \int |g(x)|^{p-2} \text{Re}(ig(x)\overline{f}(x)) d\mu.$$  

But $\text{Re}(ig\overline{f}) = \text{Im}(-g\overline{f})$ and so by the McShane lemma,

$$\phi(f) = ||\phi|| ||g||^{-\frac{1}{p}} \int |g(x)|^{p-2} \text{Re}(g(x)\overline{f}(x)) + i \text{Re}(ig(x)\overline{f}(x)) d\mu$$

$$= ||\phi|| ||g||^{-\frac{1}{p}} \int |g(x)|^{p-2} \text{Re}(g(x)\overline{f}(x)) + i \text{Im}(-g(x)\overline{f}(x)) d\mu$$

$$= ||\phi|| ||g||^{-\frac{1}{p}} \int |g(x)|^{p-2} \overline{g}(x)f(x) d\mu.$$  

This shows that

$$\phi = \eta(||\phi|| ||g||^{-\frac{1}{p}} |g|^{p-2})$$

and verifies $\eta$ is onto. $\blacksquare$
18.6 The Dual Space Of \( C_0(X) \)

Consider the dual space of \( C_0(X) \) where \( X \) is a locally compact Hausdorff space. It will turn out to be a space of measures. To show this, the following lemma will be convenient. Recall this space is defined as follows.

**Definition 18.6.1** \( f \in C_0(X) \) means that for every \( \varepsilon > 0 \) there exists a compact set \( K \) such that \( |f(x)| < \varepsilon \) whenever \( x \notin K \). Recall the norm on this space is defined as follows.

\[
|f|_\infty \equiv \|f\| \equiv \sup \{|f(x)| : x \in X\}
\]

**Lemma 18.6.2** Suppose \( \lambda \) is a mapping which has nonnegative values which is defined on the nonnegative functions in \( C_0(X) \) such that

\[
\lambda(af + bg) = a\lambda(f) + b\lambda(g) \tag{18.6.19}
\]

whenever \( a, b \geq 0 \) and \( f, g \geq 0 \). Then there exists a unique extension of \( \lambda \) to all of \( C_0(X) \), \( \Lambda \) such that whenever \( f, g \in C_0(X) \) and \( a, b \in \mathbb{C} \), it follows

\[
\Lambda(af + bg) = a\Lambda(f) + b\Lambda(g).
\]

If

\[
|\lambda(f)| \leq C|f|_\infty
\]

then

\[
|\Lambda f| \leq C|f|_\infty
\]

**Proof:** Let \( C_0(X; \mathbb{R}) \) be the real-valued functions in \( C_0(X) \) and define

\[
\Lambda_R(f) = \lambda f^+ - \lambda f^-
\]

for \( f \in C_0(X; \mathbb{R}) \). Use the identity

\[
(f_1 + f_2)^+ + f_1^- + f_2^- = f_1^+ + f_2^+ + (f_1 + f_2)^-
\]

and \( \text{(18.6.19)} \) to write

\[
\lambda(f_1 + f_2)^+ - \lambda(f_1 + f_2)^- = \lambda f_1^+ - \lambda f_1^- + \lambda f_2^+ - \lambda f_2^- ,
\]

it follows that \( \Lambda_R(f_1 + f_2) = \Lambda_R(f_1) + \Lambda_R(f_2) \). To show that \( \Lambda_R \) is linear, it is necessary to verify that \( \Lambda_R(cf) = c\Lambda_R(f) \) for all \( c \in \mathbb{R} \). But

\[
(cf)^\pm = cf^\pm,
\]

if \( c \geq 0 \) while

\[
(cf)^+ = -c(f)^- ,
\]

if \( c < 0 \) and

\[
(cf)^- = (-c)f^+ ,
\]
if \( c < 0 \). Thus, if \( c < 0 \),
\[
\Lambda_R(cf) = \lambda(cf)^+ - \lambda(cf)^- = \lambda((-c)f^-) - \lambda((-c)f^+)
\]
\[
= -c\lambda(f^-) + c\lambda(f^+) = c(\lambda(f^+) - \lambda(f^-)) = c\Lambda_R(f).
\]
A similar formula holds more easily if \( c \geq 0 \).

Now let
\[
f = R(\text{Re} f) + i R(\text{Im} f)
\]
for arbitrary \( f \in C_0(X) \). This is linear as desired.

Here is why. It is obvious that \((f + g) = \Lambda(f) + \Lambda(g)\) from the fact that taking the real and imaginary parts are linear operations. The only thing to check is whether you can factor out a complex scalar.

\[
(af + ibf) = af + ibf = aR(\text{Re} f) + ibR(\text{Im} f)
\]
because \(ibf = ib\text{Re} f - b\text{Im} f\) and so \(\text{Re}(ibf) = -b\text{Im} f\) and \(\text{Im}(ibf) = b\text{Re} f\). Therefore, the above equals
\[
= (a+ib)\Lambda_R(\text{Re} f) + i(a+ib)\Lambda_R(\text{Im} f)
\]
\[
= (a+ib)(\Lambda_R(\text{Re} f) + i\Lambda_R(\text{Im} f)) = (a + ib)\Lambda f
\]
The extension is obviously unique because all the above is required in order for \( \Lambda \) to be linear.

It remains to verify the claim about continuity of \( \Lambda \). From the definition of \( \lambda \), if \( 0 \leq g \leq f \), then
\[
\lambda(f) = \lambda(f - g + g) = \lambda(f - g) + \lambda(g) \geq \lambda(g)
\]
\[
|\Lambda_R(f)| \equiv |\lambda f^+ - \lambda f^-| \leq \max(\lambda f^+, \lambda f^-) \leq \lambda(|f|) \leq C ||f||_{\infty}
\]
Then letting \( \omega \Lambda f = |\Lambda f|, |\omega| = 1 \), and using the above,
\[
|\Lambda f| = \omega \Lambda f = \Lambda(\omega f) = \Lambda_R(\text{Re}(\omega f)) = |\Lambda_R(\text{Re}(\omega f))|
\]
\[
\leq C ||\text{Re}(\omega f)|| \leq C ||f||_{\infty}
\]
This proves the lemma.

Let \( L \in C_0(X)' \). Also denote by \( C^+_0(X) \) the set of nonnegative continuous functions defined on \( X \). Define for \( f \in C^+_0(X) \)
\[
\lambda(f) = \sup \{|Lg| : |g| \leq f\}.
\]
Note that \( \lambda(f) < \infty \) because \( |Lg| \leq ||L||||g|| \leq ||L|| ||f|| \) for \( |g| \leq f \). Then the following lemma is important.
Lemma 18.6.3 If $c \geq 0$, $\lambda(cf) = c\lambda(f)$, $f_1 \leq f_2$ implies $\lambda f_1 \leq \lambda f_2$, and
\[ \lambda(f_1 + f_2) = \lambda(f_1) + \lambda(f_2). \]
Also
\[ 0 \leq \lambda(f) \leq ||L|| ||f||_\infty \]

Proof: The first two assertions are easy to see so consider the third. For $f_j \in C_0^+(X)$, there exists $g_i \in C_0(X)$ such that $|g_i| \leq f_i$ and
\[ \lambda(f_1) + \lambda(f_2) \leq |L(g_1)| + |L(g_2)| + 2\varepsilon \]
\[ = L(\omega_1 g_1) + L(\omega_2 g_2) + 2\varepsilon \]
\[ = L(\omega_1 g_1 + \omega_2 g_2) + 2\varepsilon \]
\[ = |L(\omega_1 g_1 + \omega_2 g_2)| + 2\varepsilon \]
where $|g_i| \leq f_i$ and $|\omega_i| = 1$ and $\omega_i L(g_i) = |L(g_i)|$. Now
\[ |\omega_1 g_1 + \omega_2 g_2| \leq |g_1| + |g_2| \leq f_1 + f_2 \]
and so the above shows
\[ \lambda(f_1) + \lambda(f_2) \leq \lambda(f_1 + f_2) + 2\varepsilon. \]
Since $\varepsilon$ is arbitrary, $\lambda(f_1) + \lambda(f_2) \leq \lambda(f_1 + f_2)$. It remains to verify the other inequality.

Now let $|g| \leq f_1 + f_2$, $|Lg| \geq \lambda(f_1 + f_2) - \varepsilon$. Let
\[ h_i(x) = \begin{cases} \frac{f_i(x)g(x)}{f_i(x) + f_2(x)} & \text{if } f_1(x) + f_2(x) > 0, \\ 0 & \text{if } f_1(x) + f_2(x) = 0. \end{cases} \]
Then $h_i$ is continuous and $h_1(x) + h_2(x) = g(x)$, $|h_i| \leq f_i$. The reason it is continuous at a point where $f_1(x) + f_2(x) = 0$ is that at every point $y$ where $f_1(y) + f_2(y) > 0$, the top description of the function gives
\[ \left| \frac{f_1(y)g(y)}{f_1(y) + f_2(y)} \right| \leq |g(y)| \]
Therefore,
\[ -\varepsilon + \lambda(f_1 + f_2) \leq |Lg| \leq |Lh_1 + Lh_2| \leq |Lh_1| + |Lh_2| \leq \lambda(f_1) + \lambda(f_2). \]
Since $\varepsilon > 0$ is arbitrary, this shows
\[ \lambda(f_1 + f_2) \leq \lambda(f_1) + \lambda(f_2) \leq \lambda(f_1 + f_2) \]
The last assertion follows from
\[ \lambda(f) = \sup\{|Lg| : |g| \leq f\} \leq \sup_{||g||_\infty \leq ||f||_\infty} ||L|| ||g||_\infty \leq ||L|| ||f||_\infty \]
18.6. THE DUAL SPACE OF $C_0(X)$

which proves the lemma.

Let $\Lambda$ be defined in Lemma 18.6.2. Then $\Lambda$ is linear by this lemma and also satisfies

$$|\Lambda f| \leq ||L|| \cdot ||f||_{\infty}. \quad (18.6.20)$$

Also, if $f \geq 0$,

$$\Lambda f = \Lambda_R f = \lambda(f) \geq 0.$$  

Therefore, $\Lambda$ is a positive linear functional on $C_0(X)$. In particular, it is a positive linear functional on $C_c(X)$. By Theorem 10.3.2 on Page 261, there exists a unique measure $\mu$ such that

$$\Lambda f = \int_X f d\mu$$

for all $f \in C_c(X)$. This measure is inner regular on all open sets and on all measurable sets having finite measure. In fact, it is actually a finite measure.

**Lemma 18.6.4** Let $L \in C_0(X)'$ as above. Then letting $\mu$ be the Radon measure just described, it follows $\mu$ is finite and

$$\mu(X) = ||\Lambda|| = ||L||$$

**Proof:** First of all, why is $||\Lambda|| = ||L||$? From 18.6.20 it follows $||\Lambda|| \leq ||L||$. But also

$$|Lg| \leq \lambda(|g|) = \Lambda(|g|) \leq ||\Lambda|| \cdot ||g||_{\infty}$$

and so by definition of the operator norm, $||L|| \leq ||\Lambda||$.

Now $X$ is an open set and so

$$\mu(X) = \sup \{\mu(K) : K \subseteq X\}$$

and so letting $K \prec f \prec X$ for one of these $K$, it also follows

$$\mu(X) = \sup \{\Lambda f : f \prec X\}$$

However, for such $f \prec X$,

$$0 \leq \Lambda f = \Lambda_R f \leq ||L|| \cdot ||f||_{\infty} = ||L||$$

and so

$$\mu(X) \leq ||L||.$$  

Now since $C_c(X)$ is dense in $C_0(X)$, there exists $f \in C_c(X)$ such that $||f|| \leq 1$ and

$$|\Lambda f| + \varepsilon > ||\Lambda|| = ||L||$$

Then also $f \prec X$ and so

$$||L|| - \varepsilon < |\Lambda f| = \Lambda f \leq \mu(X)$$

Since $\varepsilon$ is arbitrary, this shows $||L|| = \mu(X)$. This proves the lemma.

What follows is the Riesz representation theorem for $C_0(X)'$. 

**Theorem 18.6.5** Let \( L \in (C_0(X))' \) for \( X \) a locally compact Hausdorff space. Then there exists a finite Radon measure \( \mu \) and a function \( \sigma \in L^\infty(X,\mu) \) such that for all \( f \in C_0(X) \),
\[
L(f) = \int_X f \sigma \mu.
\]
Furthermore,
\[
\mu(X) = ||L||, \quad |\sigma| = 1 \text{ a.e.}
\]
and if
\[
\nu(E) = \int_E \sigma d\mu
\]
then \( \mu = |\nu| \).

**Proof:** From the above there exists a unique Radon measure \( \mu \) such that for all \( f \in C_c(X) \),
\[
\Lambda f = \int_X f d\mu
\]
Then for \( f \in C_c(X) \),
\[
|Lf| \leq \Lambda(|f|) = \int_X |f| d\mu = ||f||_{L^1(\mu)}.
\]
Since \( \mu \) is both inner and outer regular thanks to it being finite, \( C_c(X) \) is dense in \( L^1(X,\mu) \). (See Theorem 13.2.4 for more than is needed.) Therefore \( L \) extends uniquely to an element of \((L^1(X,\mu))'\), \( \tilde{L} \). By the Riesz representation theorem for \( L^1 \) for finite measure spaces, there exists a unique \( \sigma \in L^\infty(X,\mu) \) such that for all \( f \in L^1(X,\mu) \),
\[
\tilde{L} f = \int_X f \sigma d\mu
\]
In particular, for all \( f \in C_0(X) \),
\[
L f = \int_X f \sigma d\mu
\]
and it follows from Lemma 18.6.3, \( \mu(X) = ||L||. \)
It remains to verify \( |\sigma| = 1 \text{ a.e.} \). For any \( g \geq 0 \),
\[
\Lambda g = \int_X g d\mu \geq \int_X f d\mu = |Lf|
\]
Now if \( E \) is measurable, the regularity of \( \mu \) implies there exists a sequence of bounded functions \( f_n \in C_c(X) \) such that \( f_n(x) \to \chi_E(x) \) a.e. Then using the dominated convergence theorem in the above,
\[
\int_E d\mu = \lim_{n \to \infty} \int_X f_n d\mu \geq \lim_{n \to \infty} \int_X f_n \sigma d\mu = \int_E \sigma d\mu
\]
and so if $\mu(E) > 0$, 
\[ 1 \geq \left| \frac{1}{\mu(E)} \int_E \sigma d\mu \right| \]
which shows from Lemma 18.2.7 that $|\sigma| \leq 1$ a.e. But also, choosing $f_1$ appropriately, $||f_1||_\infty \leq 1$, and letting $\omega L f_1 = |Lf_1|$, 
\[
\mu(X) = ||L|| = \sup_{||f||_\infty \leq 1} |Lf| \leq |Lf_1| + \varepsilon \\
\leq \int_X f_1 \omega \sigma d\mu + \varepsilon = \int_X \text{Re}(f_1 \omega \sigma) d\mu + \varepsilon \\
\leq \int_X |\sigma| d\mu + \varepsilon 
\]
and since $\varepsilon$ is arbitrary, 
\[
\mu(X) \leq \int_X |\sigma| d\mu 
\]
which requires $|\sigma| = 1$ a.e. since it was shown to be no larger than 1 and if it is smaller than 1 on a set of positive measure, then the above could not hold.

It only remains to verify $\mu = |\nu|$. By Corollary 18.2.10, 
\[
|\nu| (E) = \int_E |\sigma| d\mu = \int_E 1 d\mu = \mu(E) 
\]
and so $\mu = |\nu|$. This proves the Theorem.

Sometimes people write 
\[
\int_X f d\nu \equiv \int_X f \sigma d|\nu| 
\]
where $\sigma d|\nu|$ is the polar decomposition of the complex measure $\nu$. Then with this convention, the above representation is 
\[
L(f) = \int_X f d\nu, \quad |\nu|(X) = ||L||. 
\]

18.7 The Dual Space Of $C_0(X)$, Another Approach

It is possible to obtain the above theorem by a slick trick after first proving it for the special case where $X$ is a compact Hausdorff space. For $X$ a locally compact Hausdorff space, $\bar{X}$ denotes the one point compactification of $X$. Thus, $\bar{X} = X \cup \{\infty\}$ and the topology of $\bar{X}$ consists of the usual topology of $X$ along with all complements of compact sets which are defined as the open sets containing $\infty$. Also $C_0(X)$ will denote the space of continuous functions, $f$, defined on $X$ such that in the topology of $\bar{X}$, $\lim_{x \to \infty} f(x) = 0$. For this space of functions, $||f||_0 = \sup \{|f(x)| : x \in X\}$ is a norm which makes this into a Banach space. Then the generalization is the following corollary.
Corollary 18.7.1 Let $L \in (C_0(X))'$ where $X$ is a locally compact Hausdorff space. Then there exists $\sigma \in L^\infty(X, \mu)$ for $\mu$ a finite Radon measure such that for all $f \in C_0(X)$,

$$L(f) = \int_X f\sigma d\mu.$$ 

Proof: Let

$$\tilde{D} \equiv \{ f \in C(\tilde{X}) : f(\infty) = 0 \}.$$ 

Thus $\tilde{D}$ is a closed subspace of the Banach space $C(\tilde{X})$. Let $\theta : C_0(X) \to \tilde{D}$ be defined by

$$\theta f(x) = \begin{cases} 
  f(x) & \text{if } x \in X, \\
  0 & \text{if } x = \infty.
\end{cases}$$

Then $\theta$ is an isometry of $C_0(X)$ and $\tilde{D}$. The following diagram is obtained.

$$C_0(X)' \xrightarrow{\theta^*} (\tilde{D})' \xleftarrow{i^*} C(\tilde{X})'$$

$$C_0(X) \xrightarrow{\theta} \tilde{D} \xleftarrow{i} C(\tilde{X})$$

By the Hahn Banach theorem, there exists $L_1 \in C(\tilde{X})'$ such that $\theta^* i^* L_1 = L$. Now apply Theorem 18.6.2 to get the existence of a finite Radon measure, $\mu_1$, on $\tilde{X}$ and a function $\sigma \in L^\infty(\tilde{X}, \mu_1)$, such that

$$L_1 g = \int_{\tilde{X}} g\sigma d\mu_1.$$ 

Letting the $\sigma$ algebra of $\mu_1$ measurable sets be denoted by $S_1$, define

$$S \equiv \{ E \setminus \{ \infty \} : E \in S_1 \}$$

and let $\mu$ be the restriction of $\mu_1$ to $S$. If $f \in C_0(X)$,

$$Lf = \theta^* i^* L_1 f \equiv L_1 i \theta f = L_1 \theta f = \int_{\tilde{X}} \theta f \sigma d\mu_1 = \int_X f \sigma d\mu.$$ 

This proves the corollary.

18.8 More Attractive Formulations

In this section, Corollary 18.7.1 will be refined and placed in an arguably more attractive form. The measures involved will always be complex Borel measures defined on a $\sigma$ algebra of subsets of $X$, a locally compact Hausdorff space.
Definition 18.8.1 Let $\lambda$ be a complex measure. Then $\int f d\lambda \equiv \int fh d|\lambda|$ where $hd|\lambda|$ is the polar decomposition of $\lambda$ described above. The complex measure, $\lambda$ is called regular if $|\lambda|$ is regular.

The following lemma says that the difference of regular complex measures is also regular.

Lemma 18.8.2 Suppose $\lambda_i, i = 1, 2$ is a complex Borel measure with total variation finite defined on $X$, a locally compact Hausdorff space. Then $\lambda_1 - \lambda_2$ is also a regular measure on the Borel sets.

Proof: Let $E$ be a Borel set. That way it is in the $\sigma$ algebras associated with both $\lambda_i$. Then by regularity of $\lambda_i$, there exist $K$ and $V$ compact and open respectively such that $K \subseteq E \subseteq V$ and $|\lambda_i|(V \setminus K) < \varepsilon/2$. Therefore,

$$\sum_{A \in \pi(V \setminus K)} |(\lambda_1 - \lambda_2)(A)| = \sum_{A \in \pi(V \setminus K)} |\lambda_1(A) - \lambda_2(A)| \leq \sum_{A \in \pi(V \setminus K)} |\lambda_1(A)| + |\lambda_2(A)| \leq |\lambda_1|(V \setminus K) + |\lambda_2|(V \setminus K) < \varepsilon.$$ 

Therefore, $|\lambda_1 - \lambda_2|(V \setminus K) \leq \varepsilon$ and this shows $\lambda_1 - \lambda_2$ is regular as claimed.

Theorem 18.8.3 Let $L \in C_0(X)'$ Then there exists a unique complex measure, $\lambda$ with $|\lambda|$ regular and Borel, such that for all $f \in C_0(X)$,

$$L(f) = \int_X fd\lambda.$$ 

Furthermore, $||L|| = |\lambda|(X)$.

Proof: By Corollary 18.7.1 there exists $\sigma \in L^\infty(X, \mu)$ where $\mu$ is a Radon measure such that for all $f \in C_0(X)$,

$$L(f) = \int_X f d\mu.$$ 

Let a complex Borel measure, $\lambda$ be given by

$$\lambda(E) = \int_E \sigma d\mu.$$ 

This is a well defined complex measure because $\mu$ is a finite measure. By Corollary 18.7.1,

$$|\lambda|(E) = \int_E |\sigma| d\mu$$ (18.8.21)

$^2$Recall this is automatic for a complex measure.
and \( \sigma = g|\sigma| \) where \( gd|\lambda| \) is the polar decomposition for \( \lambda \). Therefore, for \( f \in C_0(X) \),

\[
L(f) = \int_X f\sigma d\mu = \int_X fg|\sigma| d\mu = \int_X fgd|\lambda| \equiv \int_X f d\lambda.
\]

From [Lemma 18.9.1] and the regularity of \( \mu \), it follows that \( |\lambda| \) is also regular.

What of the claim about \( ||L||? \) By the regularity of \( |\lambda| \), it follows that \( C_0(X) \) (In fact, \( C_c(X) \)) is dense in \( L^1(X,|\lambda|) \). Since \( |\lambda| \) is finite, \( g \in L^1(X,|\lambda|) \). Therefore, there exists a sequence of functions in \( C_0(X) \), \( \{f_n\} \) such that \( f_n \rightarrow \overline{\sigma} \) in \( L^1(X,|\lambda|) \). Therefore, there exists a subsequence, still denoted by \( \{f_n\} \) such that \( f_n(x) \rightarrow \overline{\sigma}(x) \) \( |\lambda| \) a.e. also. But since \( \overline{\sigma}(x) \equiv 1 \) a.e. it follows that \( h_n(x) \equiv \frac{f_n(x)}{\overline{\sigma}(x)+\pi} \) also converges pointwise \( |\lambda| \) a.e. Then from the dominated convergence theorem and

\[
||L|| \geq \lim_{n \rightarrow \infty} \int_X h_n gd|\lambda| = |\lambda|(X).
\]

Also, if \( ||f||_{C_0(X)} \leq 1 \), then

\[
||L|| \leq \int_X |f|d|\lambda| \leq |\lambda|(X)||f||_{C_0(X)}
\]

and so \( ||L|| \leq |\lambda|(X) \). This proves everything but uniqueness.

Suppose \( \lambda \) and \( \lambda_1 \) both work. Then for all \( f \in C_0(X) \),

\[
0 = \int_X f d(\lambda - \lambda_1) = \int_X fhd|\lambda - \lambda_1|
\]

where \( hd|\lambda - \lambda_1| \) is the polar decomposition for \( \lambda - \lambda_1 \). By Lemma 18.9.1 \( \lambda - \lambda_1 \) is regular and so, as above, there exists \( \{f_n\} \) such that \( |f_n| \leq 1 \) and \( f_n \rightarrow h \) pointwise. Therefore, \( \int_X d|\lambda - \lambda_1| = 0 \) so \( \lambda = \lambda_1 \). This proves the theorem.

### 18.9 Sequential Compactness In \( L^1 \)

**Lemma 18.9.1** Let \( C \equiv \{E_i\}_{i=1}^\infty \) be a countable collection of sets and let \( \Omega_1 \equiv \cup_{i=1}^\infty E_i \). Then there exists an algebra of sets, \( A \), such that \( A \supseteq C \) and \( A \) is countable.

**Proof:** Let \( C_1 \) denote all finite unions of sets of \( C \) and also include \( \Omega_1 \) and \( \emptyset \). Thus \( C_1 \) is countable. Next let \( B_1 \) denote all sets of the form \( \Omega_1 \setminus A \) such that \( A \in C_1 \). Next let \( C_2 \) denote all finite unions of sets of \( B_1 \cup C_1 \). Then let \( B_2 \) denote all sets of the form \( \Omega_1 \setminus A \) such that \( A \in C_2 \) and let \( C_3 = B_2 \cup C_2 \). Continuing this way yields an increasing sequence, \( \{C_n\} \) each of which is countable. Let

\[
A \equiv \cup_{i=1}^\infty C_i.
\]

Then \( A \) is countable. Also \( A \) is an algebra. Here is why. Suppose \( A, B \in A \). Then there exists \( n \) such that both \( A, B \in C_{n-1} \). It follows \( A \cup B \in C_n \subseteq A \) from the
construction. It only remains to show that \( A \setminus B \in A \). Taking complements with respect to \( \Omega_1 \), it follows from the construction that \( A^C, B^C \) are both in \( B_1 \subseteq C_n \). Thus,
\[
A^C \cup B \in C_n
\]
and so
\[
A \setminus B = (A^C \cup B)^C \in B_n \subseteq C_{n+1} \subseteq A.
\]
This shows \( A \) is an algebra of sets of \( \Omega_1 \) which is also countable and contains \( C \).

**Lemma 18.9.2** Let \( \{f_n\} \) be a sequence of functions in \( L^1(\Omega, S, \mu) \). Then there exists a \( \sigma \) finite set of \( S, \Omega_1 \), and a \( \sigma \) algebra of subsets of \( \Omega_1, S_1 \), such that \( S_1 \subseteq S \), \( f_n = 0 \) off \( \Omega_1 \), \( f_n \in L^1(\Omega_1, S_1, \mu) \), and \( S_1 = \sigma (A) \), the \( \sigma \) algebra generated by \( A \), for some \( A \) a countable algebra.

**Proof:** Let \( \mathcal{E}_n \) denote the sets which are of the form
\[
\left\{ f_n^{-1} (B(z,r)) : z \in \mathbb{Q} + i\mathbb{Q}, r > 0, r \in \mathbb{Q}, \text{ and } 0 \notin \overline{B(z,r)} \right\}
\]
Since each \( \mathcal{E}_n \) is countable, so is
\[
\mathcal{E} \equiv \bigcup_{n=1}^{\infty} \mathcal{E}_n
\]
Now let \( \Omega_1 \equiv \cup \mathcal{E} \). I claim \( \Omega_1 \) is \( \sigma \) finite. To see this, let
\[
W_n = \left\{ \omega \in \Omega : |f_k(\omega)| > \frac{1}{n} \text{ for some } k = 1, 2, \ldots, n \right\}
\]
Thus if \( \omega \in W_n \), it follows that for some \( r \in \mathbb{Q} \), \( z \in \mathbb{Q} + i\mathbb{Q} \) sufficiently close to \( f_k(\omega) \)
\[
\omega \in f^{-1}_k(B(z,r)) \in \mathcal{E}_k
\]
and so \( \omega \in \bigcup_{k=1}^{n} \mathcal{E}_k \) and consequently, \( W_n \in \bigcup_{k=1}^{n} \mathcal{E}_k \). Also
\[
\mu(W_n) \frac{1}{n} \leq \int_{W_n} \sum_{k=1}^{n} |f_k(\omega)| \, d\mu < \infty.
\]
Now if \( \omega \in \Omega_1 \), then for some \( k, \omega \) is contained in a set of \( \mathcal{E}_k \). Therefore, for that \( k \),
\[
f_k(\omega) \in B(z,r)
\]
where \( r \) is a positive rational number and \( z \in \mathbb{Q} + i\mathbb{Q} \) and \( \overline{B(z,r)} \) does not contain 0. Therefore, \( f_k(\omega) \) is at a positive distance from 0 and so for large enough \( n, \omega \in W_n \). Take \( n \) so large that \( 1/n \) is less than the distance from \( \overline{B(z,r)} \) to 0 and also larger than \( k \).

By Lemma 18.9.1 there exists a countable algebra of sets \( \mathcal{A} \) which contains \( \mathcal{E} \). Let \( S_1 \equiv \sigma (A) \). It remains to show \( f_n(\omega) = 0 \) off \( \Omega_1 \) for all \( n \). Let \( \omega \notin \Omega_1 \). Then \( \omega \) is not contained in any set of \( \mathcal{E}_k \) and so \( f_k(\omega) \) cannot be nonzero. Hence \( f_k(\omega) = 0 \). This proves the lemma.

The following Theorem is the main result on sequential compactness in \( L^1(\Omega, S, \mu) \).
Theorem 18.9.3 Let \( K \subseteq L^1(\Omega, \mathcal{S}, \mu) \) be such that for some \( C > 0 \) and all \( f \in K \),
\[
\|f\|_{L^1} \leq C \tag{18.9.23}
\]
and \( K \) also satisfies the property that if \( \{E_n\} \) is a decreasing sequence of measurable sets such that \( \cap_{n=1}^{\infty} E_n = \emptyset \), then for all \( \varepsilon > 0 \) there exists \( n_\varepsilon \) such that if \( n \geq n_\varepsilon \), then
\[
\left| \int_{E_n} f \, d\mu \right| < \varepsilon \tag{18.9.24}
\]
for all \( f \in K \). Then every sequence of functions of \( K \) has an \( L^1(\Omega, \mu) \) weakly convergent subsequence.

**Proof:** Take \( \{f_n\} \) a sequence in \( K \) and let \( \mathcal{A}, \mathcal{S}_1, \Omega_1 \) be as in Lemma 18.9.2. Thus \( \mathcal{A} \) is a countable algebra and by assumption, for each \( E \in \mathcal{A} \),
\[
\left\{ \int_E f_n \, d\mu \right\}
\]
is a bounded sequence and so there exists a convergent subsequence. Therefore, from a Cantor diagonalization argument, there exists a subsequence, denoted by \( \{g_n\} \) such that
\[
\left\{ \int_E g_n \, d\mu \right\}
\]
converges for every \( E \in \mathcal{A} \).

Let
\[
\mathcal{M} \equiv \left\{ E \in \mathcal{S}_1 = \sigma(\mathcal{A}) \text{ such that } \lim_{n \to \infty} \int_E g_n \, d\mu \text{ exists} \right\}.
\]
Then it has been shown that \( \mathcal{A} \subseteq \mathcal{M} \). Suppose \( E_k \uparrow E \) where \( E_k \in \mathcal{M} \). Then letting \( \varepsilon > 0 \) be given, the assumption shows that for \( k \) large enough,
\[
\left| \int_{E \setminus E_k} g_n \, d\mu \right| < \varepsilon
\]
for all \( g_n \). Therefore, picking such a \( k \),
\[
\left| \int_E g_n \, d\mu - \int_{E_k} g_n \, d\mu \right| \leq 2\varepsilon + \left| \int_{E_k} g_n \, d\mu - \int_{E_k} g_m \, d\mu \right| < 3\varepsilon
\]
promised \( m, n \) are large enough. Therefore, \( \{\int_E g_n \, d\mu\} \) is a Cauchy sequence and so it converges.

In the case that \( E_k \downarrow E \) use the assumption to conclude there exists a \( k \) large enough that
\[
\left| \int_{E_k \setminus E} g_n \, d\mu \right| < \varepsilon
\]
for all \( g_n \). Then
\[
\left| \int_E g_n d\mu - \int_E g_m d\mu \right| = \left| \int_{E_k} g_n d\mu - \int_{E_k} g_m d\mu \right| \\
+ \left| \int_{E_k \setminus E} g_n d\mu \right| + \left| \int_{E \setminus E_k} g_m d\mu \right| \\
\leq \left| \int_{E_k} g_n d\mu - \int_{E_k} g_m d\mu \right| + 2\varepsilon < 3\varepsilon
\]
provided \( m, n \) large enough. Again \( \{ \int_E g_n d\mu \} \) is a Cauchy sequence. This shows \( \mathcal{M} \) is a monotone class and so by the monotone class theorem, Theorem 10.10.5 on Page 302 it follows \( \mathcal{M} = \mathcal{S}_1 \equiv \sigma (\mathcal{A}) \).

Therefore, picking \( E \in \mathcal{S}_1 \), you can define a complex measure,
\[
\lambda (E) \equiv \lim_{n \to \infty} \int_E g_n d\mu
\]
Then \( \lambda \ll \mu \) and so by Corollary 18.2.9 on Page 612 and the fact shown above that \( \Omega_1 \) is \( \sigma \) finite there exists a unique \( \mathcal{S}_1 \) measurable \( g \in L^1 (\Omega_1, \mu) \) such that
\[
\lambda (E) = \int_E g d\mu \equiv \lim_{n \to \infty} \int_E g_n d\mu.
\]
Extend \( g \) to equal 0 outside \( \Omega_1 \).

It remains to show \( \{ g_n \} \) converges weakly. It has just been shown that for every \( s \) a simple function measurable with respect to \( \mathcal{S}_1 \)
\[
\int_{\Omega} g_n s d\mu = \int_{\Omega_1} g_n s d\mu \to \int_{\Omega_1} gs d\mu = \int_{\Omega} gs d\mu
\]
Now let \( f \in L^\infty (\Omega_1, \mathcal{S}_1, \mu) \) and pick a uniformly bounded representative of this function. Then by Theorem 10.3.4 on Page 244 there exists a sequence of simple functions converging uniformly to \( f \) and so
\[
\left\{ \int_{\Omega} g_n f d\mu \right\}
\]
converges because
\[
\left| \int_{\Omega} g_n f d\mu - \int_{\Omega} g f d\mu \right| \leq \left| \int_{\Omega} g_n s d\mu - \int_{\Omega} gs d\mu \right| \\
+ \int_{\Omega} |g_n| \varepsilon d\mu + \int_{\Omega} |g| \varepsilon d\mu \\
\leq C \varepsilon + \|g\| \varepsilon + \int_{\Omega} g_n s d\mu - \int_{\Omega} gs d\mu
\]
for suitable simple \( s \) satisfying \( \sup_{\omega \in \Omega_1} |s(\omega) - f(\omega)| < \varepsilon \) and the last term converges to 0 as \( n \to \infty \).
(\(L^1(\Omega, S, \mu)\))' is a space I don’t know much about due to a possible lack of \(\sigma\) finiteness of \(\Omega\). However, it does follow that for \(i\) the inclusion map of \(L^1(\Omega_1, S_1, \mu)\) into \(L^1(\Omega, S, \mu)\) which merely extends the function as 0 off \(\Omega_1\) and \(f \in (L^1(\Omega, S, \mu))'\), there exists \(h \in L^\infty(\Omega_1)\) such that for all \(g \in L^1(\Omega_1, S_1, \mu)\)

\[ i^* f (g) = \int_{\Omega_1} h g d\mu. \]

This is because \(i^* f \in (L^1(\Omega_1, S_1, \mu))'\) and \(\Omega_1\) is \(\sigma\) finite and so the Riesz representation theorem applies to get a unique such \(h \in L^\infty(\Omega_1)\). Then since all the \(g_n\) equal 0 off \(\Omega_1\),

\[ f (g_n) = i^* f (g_n) = \int_{\Omega_1} h g_n d\mu \]

for a unique \(h \in L^\infty(\Omega_1, S_1, \mu)\) due to the Riesz representation theorem which holds here because \(\Omega_1\) was shown to be \(\sigma\) finite. Therefore,

\[ \lim_{n \to \infty} f (g_n) = \lim_{n \to \infty} \int_{\Omega_1} h g_n d\mu = \int_{\Omega_1} h g d\mu = i^* f (g) = f (g). \]

This proves the theorem.

For more on this theorem see [42]. I have only discussed the sufficiency of the conditions to give sequential compactness. They also discuss the necessity of these conditions.

There is another nice condition which implies the above results which is seen in books on probability. It is the concept of equi integrability.

**Definition 18.9.4** Let \((\Omega, S, \mu)\) be a measure space in which \(\mu(\Omega) < \infty\). Then \(K \subseteq L^1(\Omega, S, \mu)\) is said to be equi integrable if

\[ \lim_{\lambda \to \infty} \sup_{f \in K} \int_{[|f| \geq \lambda]} |f| d\mu = 0 \]

**Lemma 18.9.5** Let \(K\) be an equi integrable set. Then there exists \(C > 0\) such that for all \(f \in K\),

\[ ||f||_{L^1} \leq C \] (18.9.25)

and \(K\) also satisfies the property that if \(\{E_n\}\) is a decreasing sequence of measurable sets such that \(\cap_{n=1}^{\infty} E_n = \emptyset\), then for all \(\varepsilon > 0\) there exists \(n_\varepsilon\) such that if \(n \geq n_\varepsilon\),

\[ \left| \int_{E_n} f d\mu \right| < \varepsilon \] (18.9.26)

for all \(f \in K\).

**Proof:** Choose \(\lambda_0\) such that

\[ \sup_{f \in K} \int_{[|f| \geq \lambda_0]} |f| d\mu \leq 1. \]
Then for \( f \in K \),
\[
\int_\Omega |f| \, d\mu = \int_{||f|\geq \lambda_0} |f| \, d\mu + \int_{||f|<\lambda_0} |f| \, d\mu \\
\leq 1 + \lambda_0 \mu(\Omega) \equiv C
\]
and this proves \ref{eq:18.9.25}.

Next suppose \( \{E_n\} \) is a decreasing sequence which has empty intersection and let \( \varepsilon > 0 \) and choose \( \lambda_\varepsilon \) such that
\[
\sup_{f \in K} \int_{|f| \geq \lambda_\varepsilon} |f| \, d\mu \leq \varepsilon / 2.
\]
Then since \( \mu \) is finite, there exists \( n_\varepsilon \) such that if \( n \geq n_\varepsilon \), then \( \mu(E_n) \leq \varepsilon / 2 (1 + \lambda_\varepsilon) \). Then letting \( f \in K \),
\[
\int_{E_n} |f| \, d\mu = \int_{E_n \cap |f| \geq \lambda_\varepsilon} |f| \, d\mu + \int_{E_n \cap |f| < \lambda_\varepsilon} |f| \, d\mu \\
\leq \varepsilon / 2 + \int_{E_n} \lambda_\varepsilon d\mu < \varepsilon / 2 + \varepsilon / 2 = \varepsilon
\]
This proves \ref{eq:18.9.26} and proves the lemma.

**Corollary 18.9.6** Let \( (\Omega, S, \mu) \) be a measure space in which \( \mu(\Omega) < \infty \) and let \( K \subseteq L^1(\Omega, S, \mu) \) be equi integrable. Then every sequence from \( K \) has a weakly convergent subsequence.

**Proof:** From Lemma \ref{eq:18.9.25} the hypotheses of Theorem \ref{eq:18.9.3} are satisfied.

It is also convenient to consider the following proposition.

**Proposition 18.9.7** Let \( (\Omega, S, \mu) \) be a measure space in which \( \mu(\Omega) < \infty \). Then \( K \subseteq L^1(\Omega, S, \mu) \) is equi integrable if and only if \( K \) is uniformly integrable and there exists a constant, \( M \) such that for all \( f \in K \), \( ||f||_{L^1} \leq M \).

**Proof:** First suppose \( K \) is equi integrable. Then pick \( \lambda \) such that for all \( f \in K \),
\[
\int_{|f| \geq \lambda} |f| \, d\mu < 1.
\]
Then for \( f \in K \)
\[
\int_\Omega |f| \, d\mu = \int_{|f| \geq \lambda} |f| \, d\mu + \int_{|f|<\lambda} |f| \, d\mu \\
\leq 1 + \lambda \mu(\Omega) \equiv M.
\]
Also, if \( \varepsilon > 0 \), pick \( \lambda \) so large that for all \( f \in K \)
\[
\int_{|f| \geq \lambda} |f| \, d\mu < \varepsilon / 2.
\]
Then letting $A \in S$,
\[
\int_A |f| d\mu = \int_{A \cap \{|f| \geq \lambda\}} |f| d\mu + \int_{A \cap \{|f| < \lambda\}} |f| d\mu \\
< \frac{\varepsilon}{2} + \lambda P(A)
\]
and so if $P(A)$ is sufficiently small, this is less than $\varepsilon$. Thus $K$ is uniformly integrable.

Now suppose $||f||_1 \leq M$ for all $f \in K$ and $K$ is uniformly integrable. Then
\[
\int \{|f| \geq \lambda\} |f| d\mu \geq \lambda P(||f||_1 \geq \lambda)
\]
and so
\[
P(||f||_1 \geq \lambda) \leq \frac{1}{\lambda} \int \{|f| \geq \lambda\} |f| d\mu \leq \frac{1}{\lambda} \int_{\Omega} |f| d\mu \leq \frac{M}{\lambda}
\]
and so, by the assumption of uniform integrability,
\[
\int \{|f| \geq \lambda\} |f| d\mu \leq \varepsilon
\]
for all $f \in K$ provided $\lambda$ is large enough. This proves the proposition.

### 18.10 Exercises

1. Suppose $\mu$ is a vector measure having values in $\mathbb{R}^n$ or $\mathbb{C}^n$. Can you show that $|\mu|$ must be finite? **Hint:** You might define for each $e_i$, one of the standard basis vectors, the real or complex measure, $\mu_{e_i}$ given by $\mu_{e_i}(E) = e_i \cdot \mu(E)$. Why would this approach not yield anything for an infinite dimensional normed linear space in place of $\mathbb{R}^n$?

2. The Riesz representation theorem of the $L^p$ spaces can be used to prove a very interesting inequality. Let $r, p, q \in (1, \infty)$ satisfy
\[
\frac{1}{r} = \frac{1}{p} + \frac{1}{q} - 1.
\]
Then
\[
\frac{1}{q} = 1 + \frac{1}{r} - \frac{1}{p} > \frac{1}{r}
\]
and so $r > q$. Let $\theta \in (0, 1)$ be chosen so that $\theta r = q$. Then also we have
\[
\frac{1}{r} = \left( \frac{1/p + 1/p' = 1}{1 - \frac{1}{p'}} \right) + \frac{1}{q} - 1 = \frac{1}{q} - \frac{1}{p'}
\]
and so
\[ \frac{p}{q} = \frac{1}{q} - \frac{1}{p'} \]
which implies \( p' (1 - \theta) = q \). Now let \( f \in L^p (\mathbb{R}^n) \), \( g \in L^q (\mathbb{R}^n) \), \( f, g \geq 0 \). Justify the steps in the following argument using what was just shown that \( \theta r = q \) and \( p' (1 - \theta) = q \). Let

\[ h \in L^r' (\mathbb{R}^n), \left( \frac{1}{r} + \frac{1}{r'} = 1 \right) \]

\[
\int f * g (x) |h (x)| \, dx = \int \int f (y) g (x - y) |h (x)| \, dxdy.
\]

\[
\leq \int \int |f (y)||g (x - y)| \theta |g (x - y)|^{1 - \theta} |h (x)| \, dydx
\]

\[
\leq \int \left( \int \left( |g (x - y)|^{1 - \theta} |h (x)| \right)^{p/r'} \, dx \right)^{1/p'} \, dy
\]

\[
\int \left( \int |f (y)||g (x - y)| \theta \right)^{p/r} \, dy \right)^{1/p'} \, dx
\]

\[
\leq \left[ \int \left( \int \left( |g (x - y)|^{1 - \theta} |h (x)| \right)^{p/r'} \, dx \right)^{1/r'} \, dy \right]^{1/p}
\]

\[
\left[ \int \left( \int |f (y)||g (x - y)| \theta \right)^{p/r} \, dy \right]^{1/p'} \, dx
\]

\[
= \left[ \int |h (x)|^{p/r'} \left( \int |g (x - y)|^{1 - \theta} |y| \, dy \right)^{p/r} \, dx \right]^{1/p'}
\]

\[
= ||g||_q^{q/p} ||f||_p ||h||_r', ||g||_q ||f||_p ||h||_r'. \quad (18.10.27)
\]

Young’s inequality says that
\[
||f * g||_r \leq ||g||_q ||f||_p. \quad (18.10.28)
\]

Therefore \( ||f * g||_r \leq ||g||_q ||f||_p' \). How does this inequality follow from the above computation? Does (18.10.27) continue to hold if \( r, p, q \) are only assumed to be in \([1, \infty]\)? Explain. Does (18.10.28) hold even if \( r, p, q \) are only assumed to lie in \([1, \infty]\)?
3. Show that in a reflexive Banach space, weak and weak * convergence are the same.

4. Suppose $(\Omega, \mu, \mathcal{S})$ is a finite measure space and that $\{f_n\}$ is a sequence of functions which converge weakly to 0 in $L^p(\Omega)$. Suppose also that $f_n(x) \to 0$ a.e. Show that then $f_n \to 0$ in $L^{p-\varepsilon}(\Omega)$ for every $p > \varepsilon > 0$.

5. Give an example of a sequence of functions in $L^\infty(-\pi, \pi)$ which converges weak * to zero but which does not converge pointwise a.e. to zero.
Chapter 19

The Bochner Integral

19.1 Strong And Weak Measurability

In this chapter \((\Omega, \mathcal{S}, \mu)\) will be a \(\sigma\) finite measure space and \(X\) will be a Banach space which contains the values of either a function or a measure. The Banach space will be either a real or a complex Banach space but the field of scalars does not matter and so it is denoted by \(\mathbb{F}\) with the understanding that \(\mathbb{F} = \mathbb{C}\) unless otherwise stated. The theory presented here includes the case where \(X = \mathbb{R}^n\) or \(\mathbb{C}^n\) but it does not include the situation where \(f\) could have values in a space like \([0, \infty]\). To begin with here is a definition.

**Definition 19.1.1** A function, \(x : \Omega \to X\), for \(X\) a Banach space, is a simple function if it is of the form

\[
x(s) = \sum_{i=1}^{n} a_i \chi_{B_i}(s)
\]

where \(B_i \in \mathcal{S}\) and \(\mu(B_i) < \infty\) for each \(i\). A function \(x\) from \(\Omega\) to \(X\) is said to be strongly measurable if there exists a sequence of simple functions \(\{x_n\}\) converging pointwise to \(x\). The function \(x\) is said to be weakly measurable if, for each \(f \in X'\),

\[
f \circ x
\]

is a scalar valued measurable function.

Earlier, a function was measurable if inverse images of open sets were measurable. Something similar holds here. The difference is that another condition needs to hold.

**Theorem 19.1.2** \(x\) is strongly measurable if and only if \(x^{-1}(U)\) is measurable for all \(U\) open in \(X\) and \(x(\Omega)\) is separable.
Proof: Suppose first \( x^{-1}(U) \) is measurable for all \( U \) open in \( X \) and \( x(\Omega) \) is separable. Let \( \{a_n\}_{n=1}^{\infty} \) be the dense subset of \( x(\Omega) \). It follows \( x^{-1}(B) \) is measurable for all \( B \) Borel because

\[
\{ B : x^{-1}(B) \text{ is measurable} \}
\]

is a \( \sigma \) algebra containing the open sets. Let

\[
U^n_k \equiv \{ z \in X : \|z - a_k\| \leq \min \{\|z - a_l\| \} \}
\]

In words, \( U^n_k \) is the set of points of \( X \) which are as close to \( a_k \) as they are to any of the \( a_l \) for \( l \leq n \).

\[
B^n_k \equiv x^{-1}(U^n_k), \quad D^n_k \equiv B^n_k \setminus \bigcup_{i=1}^{k-1} B^n_i, \quad D^1_k \equiv B^1_1,
\]

and

\[
x_n(s) = \sum_{k=1}^{n} a_k \chi_{D^n_k}(s).
\]

Thus \( x_n(s) \) is a closest approximation to \( x(s) \) from \( \{a_k\}_{k=1}^{n} \) and so \( x_n(s) \to x(s) \) because \( \{a_n\}_{n=1}^{\infty} \) is dense in \( x(\Omega) \). Furthermore, \( x_n \) is measurable because each \( D^n_k \) is measurable.

Since \( (\Omega, \mathcal{S}, \mu) \) is \( \sigma \) finite, there exists \( \Omega_n \uparrow \Omega \) with \( \mu(\Omega_n) < \infty \). Let

\[
y_n(s) = \chi_{\Omega_n}(s) \chi_{\Omega_n}(s).
\]

Then \( y_n(s) \to x(s) \) for each \( s \) because for any \( s, s \in \Omega_n \) if \( n \) is large enough. Also \( y_n \) is a simple function because it equals 0 off a set of finite measure.

Now suppose that \( x \) is strongly measurable. Then some sequence of simple functions, \( \{x_n\} \), converges pointwise to \( x \). Then \( x^{-1}(W) \) is measurable for every open set \( W \) because it is just a finite union of measurable sets. Thus, \( x^{-1}_n(W) \) is measurable for every Borel set \( W \). This follows by considering

\[
\{ W : x^{-1}_n(W) \text{ is measurable} \}
\]

and observing this is a \( \sigma \) algebra which contains the open sets. Since \( X \) is a metric space, it follows that if \( U \) is an open set in \( X \), there exists a sequence of open sets, \( \{V_n\} \) which satisfies

\[
\bar{V}_n \subseteq U, \quad \forall n \subseteq V_{n+1}, \quad U = \cup_{n=1}^{\infty} V_n.
\]

Then

\[
x^{-1}(V_m) \subseteq \bigcup_{n<\infty} \bigcap_{k>n} x^{-1}_k(V_m) \subseteq x^{-1}(\bar{V}_m).
\]

This implies

\[
x^{-1}(U) = \bigcup_{m<\infty} x^{-1}(V_m)
\]
19.1. STRONG AND WEAK MEASURABILITY

\[ \cup_{m<\infty} \cap_{n<\infty} k \geq n x_k^{-1}(V_m) \subseteq \cup_{m<\infty} x^{-1}(V_m) \subseteq x^{-1}(U). \]

Since

\[ x^{-1}(U) = \cup_{m<\infty} \cap_{n<\infty} k \geq n x_k^{-1}(V_m), \]

it follows that \( x^{-1}(U) \) is measurable for every open \( U \). It remains to show \( x(\Omega) \) is separable. Let

\[ D \equiv \text{all values of the simple functions } x_n \]

which converge to \( x \) pointwise. Then \( D \) is clearly countable and dense in \( \overline{D} \), a set which contains \( x(\Omega) \).

**Claim:** \( x(\Omega) \) is separable.

**Proof of claim:** For \( n \in \mathbb{N} \), let \( B_n \equiv \{ B(d,r) : 0 < r < \frac{1}{n}, \ r \text{ rational}, d \in D \} \).

Thus \( B_n \) is countable. Let \( z \in \overline{D} \). Consider \( B(z, \frac{1}{2n}) \). Then there exists \( d \in D \cap B(z, \frac{1}{2n}) \).

Now pick \( r \in \mathbb{Q} \cap (\frac{1}{2n}, \frac{1}{n}) \) so that \( B(d,r) \in B_n \). Now \( z \in B(d,r) \) and so this shows that \( x(\Omega) \subseteq \overline{D} \subseteq \cup B_n \) for each \( n \).

Now let \( B'_n \) denote those sets of \( B_n \) which have nonempty intersection with \( x(\Omega) \). Say \( B'_n = \{ B_k \}_{n,k=1}^{\infty} \). By the axiom of choice, there exists \( x^n_k \in B_k \cap x(\Omega) \). Then if \( z \in x(\Omega) \), \( z \) is contained in some set of \( B'_n \) which also contains a point of \( \{ x^n_k \}_{n,k=1}^{\infty} \). Therefore, \( z \) is at least as close as \( 2/n \) to some point of \( \{ x^n_k \}_{n,k=1}^{\infty} \) which shows \( \{ x^n_k \}_{n,k=1}^{\infty} \) is a countable dense subset of \( x(\Omega) \). Therefore \( x(\Omega) \) is separable.

The last part also shows that a subset of a separable metric space is also separable. Therefore, the following simple corollary is obtained.

**Corollary 19.1.3** If \( X \) is a separable Banach space then \( x \) is strongly measurable if and only if \( x^{-1}(U) \) is measurable for all \( U \) open in \( X \).

The next lemma is interesting for its own sake. Roughly it says that if a Banach space is separable, then the unit ball in the dual space is weak \* separable. This will be used to prove Pettis’s theorem, one of the major theorems in this subject which relates weak measurability to strong measurability.

**Lemma 19.1.4** If \( X \) is a separable Banach space with \( B' \) the closed unit ball in \( X' \), then there exists a sequence \( \{ f_n \}_{n=1}^{\infty} \equiv D' \subseteq B' \) with the property that for every \( x \in X \),

\[ ||x|| = \sup_{f \in D'} |f(x)| \]

If \( H \) is a dense subset of \( X' \) then \( D' \) may be chosen to be contained in \( H \).

**Proof:** Let \( \{ a_k \} \) be a countable dense set in \( X \), and consider the mapping

\[ \phi_n : B' \to \mathbb{F}^n \]

given by

\[ \phi_n (f) \equiv (f(a_1), \cdots, f(a_n)). \]
Then $\phi_n (B')$ is contained in a compact subset of $\mathbb{F}^n$ because $|f(a_k)| \leq ||a_k||$. Therefore, there exists a countable dense subset of $\phi_n (B')$, $\{ \phi_n (f_k) \}_{k=1}^{\infty}$. Then pick $h_j^k \in H \cap B'$ such that $\lim_{j \to \infty} ||f_k - h_j^k|| = 0$. Then $\{ \phi_n (h_j^k), k, j \}$ must also be dense in $\phi_n (B')$. Let $D'_n = \{ h_j^k, k, j \}$. Define

$$D' = \bigcup_{k=1}^{\infty} D'_k.$$

Note that for each $x \in X$, there exists $f_x \in B'$ such that $f_x (x) = ||x||$. From the construction,

$$||a_m|| = \sup \{ ||f(a_m)|| : f \in D' \}$$

because $f_{a_m} (a_m)$ is the limit of numbers $f(a_m)$ for $f \in D'_m \subseteq D'$. Therefore, for $x$ arbitrary,

$$||x|| \leq ||x - a_m|| + ||a_m|| = \sup \{ ||f(a_m)|| : f \in D' \} + ||x - a_m||$$

$$\leq \sup \{ ||f(a_m - x) + f(x)|| : f \in D' \} + ||x - a_m||$$

$$\leq \sup \{ ||f(x)|| : f \in D' \} + 2||x - a_m|| \leq ||x|| + 2||x - a_m||.$$

Since $a_m$ is arbitrary and the $\{a_m\}_{m=1}^{\infty}$ are dense, this establishes the claim of the lemma. ■

The next theorem is one of the most important results in the subject. It is due to Pettis and appeared in 1938.

**Theorem 19.1.5** If $x$ has values in a separable Banach space $X$. Then $x$ is weakly measurable if and only if $x$ is strongly measurable.

**Proof:** It is necessary to show $x^{-1} (U)$ is measurable whenever $U$ is open. Since every open set is a countable union of balls, it suffices to show $x^{-1} (B(a,r))$ is measurable for any ball, $B(a,r)$. Since every open ball is the countable union of closed balls, it suffices to verify $x^{-1} \left( B(a,r) \right)$ is measurable. From Lemma [M3.10.3]

$$x^{-1} \left( B(a,r) \right) = \{ s : ||x(s) - a|| \leq r \}$$

$$= \left\{ s : \sup_{f \in D'} |f(x(s) - a)| \leq r \right\}$$

$$= \bigcap_{f \in D'} \{ s : |f(x(s) - a)| \leq r \}$$

$$= \bigcap_{f \in D'} \{ s : |f(x(s)) - f(a)| \leq r \}$$

$$= \bigcap_{f \in D'} (f \circ x)^{-1} B(f(a),r)$$

which equals a countable union of measurable sets because it is assumed that $f \circ x$ is measurable for all $f \in X'$.

Next suppose $x$ is strongly measurable. Then there exists a sequence of simple functions $x_n$ which converges to $x$ pointwise. Hence for all $f \in X'$, $f \circ x_n$ is measurable and $f \circ x_n \to f \circ x$ pointwise. Thus $x$ is weakly measurable. ■

The same method of proof yields the following interesting corollary.
Corollary 19.1.6 Let $X$ be a separable Banach space and let $\mathcal{B}(X)$ denote the $\sigma$ algebra of Borel sets. Let $H$ be a dense subset of $X'$. Then $\mathcal{B}(X) = \sigma(H) \equiv \mathcal{F}$, the smallest $\sigma$ algebra of subsets of $X$ which has the property that every function, $x^* \in H$ is measurable.

**Proof:** First I need to show $\mathcal{F}$ contains open balls because then $\mathcal{F}$ will contain the open sets and hence the Borel sets. As noted above, it suffices to show $\mathcal{F}$ contains closed balls. Let $D'$ be those functionals in $B'$ defined in Lemma 19.1.4. Then 

$$
\{x : \|x - a\| \leq r\} = \{x : \sup_{x^* \in D'} |x^*(x - a)| \leq r\} = \cap_{x^* \in D'} \{x : |x^*(x - a)| \leq r\} = \cap_{x^* \in D'} \{x : |x^*(x) - x^*(a)| \leq r\} = \cap_{x^* \in D'} x^{*-1}(B(x^*(a), r)) \in \sigma(H)
$$

which is measurable because this is a countable intersection of measurable sets. Thus $\mathcal{F}$ contains open sets so $\sigma(H) \equiv \mathcal{F} \supseteq \mathcal{B}(X)$.

To show the other direction for the inclusion, note that each $x^*$ is $\mathcal{B}(X)$ measurable because $x^{*-1}$ (open set) = open set. Therefore, $\mathcal{B}(X) \supseteq \sigma(H)$. ■

It is important to verify the limit of strongly measurable functions is itself strongly measurable. This happens under very general conditions. Suppose $X$ is any separable metric space and let $\tau$ denote the open sets of $X$. Then it is routine to see that

$$
\tau \text{ has a countable basis, } \mathcal{B}.
$$

(19.1.1)

Whenever $U \in \mathcal{B}$, there exists a sequence of open sets, $\{V_m\}_{m=1}^{\infty}$, such that

$$
\cdots V_m \subseteq V_m \subseteq V_{m+1} \subseteq \cdots , U = \bigcup_{m=1}^{\infty} V_m.
$$

(19.1.2)

Theorem 19.1.7 Let $f_n$ and $f$ be functions mapping $\Omega$ to $X$ where $\mathcal{F}$ is a $\sigma$ algebra of measurable sets of $\Omega$ and $(X, \tau)$ is a topological space satisfying (19.1.1). Then if $f_n$ is measurable, and $f(\omega) = \lim_{n \to \infty} f_n(\omega)$, it follows that $f$ is also measurable. (Pointwise limits of measurable functions are measurable.)

**Proof:** Let $\mathcal{B}$ be the countable basis of $\mathcal{B}$ and let $U \in \mathcal{B}$. Let $\{V_m\}$ be the sequence of $\mathcal{B}$. Since $f$ is the pointwise limit of $f_n$,

$$
f^{-1}(V_m) \subseteq \{\omega : f_k(\omega) \in V_m \text{ for all } k \text{ large enough}\} \subseteq f^{-1}(V_m).
$$

Therefore,

$$
f^{-1}(U) = \bigcup_{m=1}^{\infty} f^{-1}(V_m) \subseteq \bigcup_{m=1}^{\infty} \bigcap_{k=1}^{\infty} f_k^{-1}(V_m) \subseteq \bigcup_{m=1}^{\infty} f^{-1}(V_m) = f^{-1}(U).
$$
It follows $f^{-1}(U) \in \mathcal{F}$ because it equals the expression in the middle which is measurable. Now let $W \in \tau$. Since $\mathcal{B}$ is countable, $W = \bigcup_{n=1}^{\infty} U_n$ for some sets $U_n \in \mathcal{B}$. Hence

$$f^{-1}(W) = \bigcup_{n=1}^{\infty} f^{-1}(U_n) \in \mathcal{F}. \blacksquare$$

Note that the same conclusion would hold for any topological space with the property that for any open set $U$, it has such a sequence of $V_k$ attached to it as in 19.1.2.

Corollary 19.1.8 $x$ is strongly measurable if and only if $x(\Omega)$ is separable and $x$ is weakly measurable.

**Proof:** Strong measurability clearly implies weak measurability. If $x_n(s) \to x(s)$ where $x_n$ is simple, then $f(x_n(s)) \to f(x(s))$ for all $f \in X'$. Hence $f \circ x$ is measurable by Theorem [19.1.7] because it is the limit of a sequence of measurable functions. Let $D$ denote the set of all values of $x_n$. Then $\overline{D}$ is a separable set containing $x(\Omega)$. Thus $\overline{D}$ is a separable metric space. Therefore $x(\Omega)$ is separable also by the last part of the proof of Theorem [19.1.2].

Now suppose $D$ is a countable dense subset of $x(\Omega)$ and $x$ is weakly measurable. Let $Z$ be the subset consisting of all finite linear combinations of $D$ with the scalars coming from the set of rational points of $\mathbb{F}$. Thus, $Z$ is countable. Letting $Y = \mathbb{Z}$, $Y'$ is a separable Banach space containing $x(\Omega)$. If $f \in Y'$, $f$ can be extended to an element of $X'$ by the Hahn Banach theorem. Therefore, $x$ is a weakly measurable $Y'$ valued function. Now use Theorem [19.1.5] to conclude $x$ is strongly measurable. \blacksquare

Weakly measurable as defined above means $s \to x^*(x(s))$ is measurable for every $x^* \in X'$. The next lemma ties this weak measurability to the usual version of measurability in which a function is measurable when inverse images of open sets are measurable.

**Lemma 19.1.9** Let $X$ be a Banach space and let $x : (\Omega, \mathcal{F}) \to K \subseteq X$ where $K$ is weakly compact and $X'$ is separable. Then $x$ is weakly measurable if and only if $x^{-1}(U) \in \mathcal{F}$ whenever $U$ is a weakly open set.

**Proof:** By Corollary 15.5.9 on Page 447, there exists a metric $d$, such that the metric space topology with respect to $d$ coincides with the weak topology. Since $K$ is compact, it follows that $K$ is also separable. Hence it is completely separable and so there exists a countable basis of open sets $\mathcal{B}$ for the weak topology on $K$. It follows that if $U$ is any weakly open set, covered by basic sets of the form $B_A(x, r)$ where $A$ is a finite subset of $X'$, there exists a countable collection of these sets of the form $B_A(x, r)$ which covers $U$.

Suppose now that $x$ is weakly measurable. To show $x^{-1}(U) \in \mathcal{F}$ whenever $U$ is weakly open, it suffices to verify $x^{-1}(B_A(z, r)) \in \mathcal{F}$ for any set, $B_A(z, r)$.
19.1. STRONG AND WEAK MEASURABILITY

\[ A = \{x_1^*, \ldots, x_m^*\}. \]

Then

\[
x^{-1}(B_A(z,r)) = \{s \in \Omega : \rho_A(x(s) - z) < r\}
\]

\[
\subseteq \left\{ s \in \Omega : \max_{x^* \in A} |x^*(x(s) - z)| < r \right\}
\]

\[
= \bigcup_{i=1}^m \{s \in \Omega : |x_i^*(x(s) - z)| < r\}
\]

\[
= \bigcup_{i=1}^m \{s \in \Omega : |x_i^*(x(s)) - x_i^*(z)| < r\}
\]

which is measurable because each \(x_i^* \circ x\) is given to be measurable.

Next suppose \(x^{-1}(U) \in F\) whenever \(U\) is weakly open. Then in particular this holds when \(U = B_{x^*}(z,r)\) for arbitrary \(x^*\). Hence

\[
\{s \in \Omega : x(s) \in B_{x^*}(z,r)\} \in F.
\]

But this says the same as

\[
\{s \in \Omega : |x^*(x(s)) - x^*(z)| < r\} \in F
\]

Since \(x^*(z)\) can be a completely arbitrary element of \(F\), it follows \(x^* \circ x\) is an \(F\) valued measurable function. In other words, \(x\) is weakly measurable according to the former definition. ■

One can also define weak * measurability and prove a theorem just like the Pettis theorem above. The next lemma is the analogue of Lemma 19.1.4.

Lemma 19.1.10 Let \(B\) be the closed unit ball in \(X\). If \(X'\) is separable, there exists a sequence \(\{x_m\}_{m=1}^\infty \equiv D \subseteq B\) with the property that for all \(y^* \in X'\),

\[
||y^*|| = \sup_{x \in D} |y^*(x)|.
\]

Proof: Let

\[
\{x_k^*\}_{k=1}^\infty
\]

be the dense subspace of \(X'\). Define \(\phi_n : B \to \mathbb{F}^n\) by

\[
\phi_n(x) \equiv (x_1^*(x), \ldots, x_n^*(x)).
\]

Then \(|x_k^*(x)| \leq ||x_k^*||\) and so \(\phi_n(B)\) is contained in a compact subset of \(\mathbb{F}^n\). Therefore, there exists a countable set, \(D_n \subseteq B\) such that \(\phi_n(D_n)\) is dense in \(\phi_n(B)\). Let

\[
D \equiv \bigcup_{n=1}^\infty D_n.
\]

It remains to verify this works. Let \(y^* \in X'\). Then there exists \(y\) such that

\[
|y^*(y)| > ||y^*|| - \varepsilon.
\]

By density, there exists one of the \(x_k^*\) from the countable dense subset of \(X'\) such that also

\[
|x_k^*(y)| > ||y^*|| - \varepsilon, \quad ||x_k^* - y^*|| < \varepsilon.
\]
Now $x_k^w(y) \in \phi_k(B)$ and so there exists $x \in D_k \subseteq D$ such that

$$|x_k^w(x)| > ||y^*|| - \varepsilon.$$ 

Then since $||x^*_k - y^*|| < \varepsilon$, this implies

$$|y^*(x)| \geq ||y^*|| - 2\varepsilon.$$ 

Since $\varepsilon > 0$ is arbitrary,

$$||y^*|| \leq \sup_{x \in D} |y^*(x)| \leq ||y^*||$$

The next theorem is another version of the Pettis theorem. First here is a definition.

**Definition 19.1.11** A function $y$ having values in $X'$ is weak * measurable, when for each $x \in X$, $y(\cdot)(x)$ is a measurable scalar valued function.

**Theorem 19.1.12** If $X'$ is separable and $y : \Omega \rightarrow X'$ is weak * measurable, then $y$ is strongly measurable.

**Proof:** It is necessary to show $y^{-1}(B(a^*, r))$ is measurable. This will suffice because the separability of $X'$ implies every open set is the countable union of such balls of the form $B(a^*, r)$. It also suffices to verify inverse images of closed balls are measurable because every open ball is the countable union of closed balls. From Lemma 19.1.10

$$y^{-1}\left(\overline{B}(a^*, r)\right) = \{s : ||y(s) - a^*|| \leq r\}$$

$$= \left\{s : \sup_{x \in D} ||(y(s) - a^*)(x)|| \leq r\right\}$$

$$= \left\{s : \sup_{x \in D} |y(s)(x) - a^*(x)| \leq r\right\}$$

$$= \cap_{x \in D} y(\cdot)(x)^{-1}\left(\overline{B}(a^*(x), r)\right)$$

which is a countable intersection of measurable sets by hypothesis. 

The following are interesting consequences of the theory developed so far and are of interest independent of the theory of integration of vector valued functions.

**Theorem 19.1.13** If $X'$ is separable, then so is $X$.

**Proof:** Let $D = \{x_m\} \subseteq B$, the unit ball of $X$, be the sequence promised by Lemma 19.1.10. Let $V$ be all finite linear combinations of elements of $\{x_m\}$ with rational scalars. Thus $V$ is a separable subspace of $X$. The claim is that $V = X$. If not, there exists

$$x_0 \in X \setminus V.$$
But by the Hahn Banach theorem there exists \( x_0^* \in X' \) satisfying \( x_0^* (x_0) \neq 0 \), but \( x_0^* (v) = 0 \) for every \( v \in V \). Hence

\[
||x_0^*|| = \sup_{x \in D} |x_0^* (x)| = 0,
\]
a contradiction. ■

**Corollary 19.1.14** If \( X \) is reflexive, then \( X \) is separable if and only if \( X' \) is separable.

**Proof:** From the above theorem, if \( X' \) is separable, then so is \( X \). Now suppose \( X \) is separable with a dense subset equal to \( D \). Then since \( X \) is reflexive, \( J(D) \) is dense in \( X'' \) where \( J \) is the James map satisfying \( J x (x^*) = x^* (x) \). Then since \( X'' \) is separable, it follows from the above theorem that \( X' \) is also separable. ■

## 19.2 The Bochner Integral

### 19.2.1 Definition And Basic Properties

**Definition 19.2.1** Let \( a_k \in X \), a Banach space and let

\[
x (s) = \sum_{k=1}^{n} a_k X_{E_k} (s)
\]

(19.2.3)

where for each \( k \), \( E_k \) is measurable and \( \mu (E_k) < \infty \). Then define

\[
\int_{\Omega} x (s) d\mu = \sum_{k=1}^{n} a_k \mu (E_k).
\]

**Proposition 19.2.2** Definition 19.2.1 is well defined.

**Proof:** It suffices to verify that if

\[
\sum_{k=1}^{n} a_k X_{E_k} (s) = 0,
\]

then

\[
\sum_{k=1}^{n} a_k \mu (E_k) = 0.
\]

Let \( f \in X' \). Then

\[
f \left( \sum_{k=1}^{n} a_k X_{E_k} (s) \right) = \sum_{k=1}^{n} f (a_k) X_{E_k} (s) = 0
\]
and, therefore,
\[ 0 = \int_{\Omega} \left( \sum_{k=1}^{n} f(a_k) \mathcal{X}_{E_k}(s) \right) d\mu = \sum_{k=1}^{n} f(a_k) \mu(E_k) = f \left( \sum_{k=1}^{n} a_k \mu(E_k) \right). \]

Since \( f \in X' \) is arbitrary, and \( X' \) separates the points of \( X \), it follows that
\[ \sum_{k=1}^{n} a_k \mu(E_k) = 0 \]
as claimed. \( \blacksquare \)

It follows easily from this proposition that \( \int_{\Omega} d\mu \) is well defined and linear on simple functions.

**Definition 19.2.3** A strongly measurable function \( x \) is Bochner integrable if there exists a sequence of simple functions \( x_n \) converging to \( x \) pointwise and satisfying
\[ \int_{\Omega} ||x_n(s) - x_m(s)|| d\mu \to 0 \text{ as } m, n \to \infty. \] (19.2.4)

If \( x \) is Bochner integrable, define
\[ \int_{\Omega} x(s) d\mu \equiv \lim_{n \to \infty} \int_{\Omega} x_n(s) d\mu. \] (19.2.5)

**Theorem 19.2.4** The Bochner integral is well defined and if \( x \) is Bochner integrable and \( f \in X' \),
\[ f \left( \int_{\Omega} x(s) d\mu \right) = \int_{\Omega} f(x(s)) d\mu \] (19.2.6)

and
\[ \left\| \int_{\Omega} x(s) d\mu \right\| \leq \int_{\Omega} ||x(s)|| d\mu. \] (19.2.7)

Also, the Bochner integral is linear. That is, if \( a, b \) are scalars and \( x, y \) are two Bochner integrable functions, then
\[ \int_{\Omega} (ax(s) + by(s)) d\mu = a \int_{\Omega} x(s) d\mu + b \int_{\Omega} y(s) d\mu \] (19.2.8)

**Proof:** First it is shown that the triangle inequality holds on simple functions and that the limit in (19.2.4) exists. Thus, if \( x \) is given by (19.2.4) with the \( E_k \) disjoint,
\[
\left\| \int_{\Omega} x(s) d\mu \right\| \\
= \left\| \int_{\Omega} \sum_{k=1}^{n} a_k \mathcal{X}_{E_k}(s) d\mu \right\| = \left\| \sum_{k=1}^{n} a_k \mu(E_k) \right\| \\
\leq \sum_{k=1}^{n} ||a_k|| \mu(E_k) = \int_{\Omega} \sum_{k=1}^{n} ||a_k|| \mathcal{X}_{E_k}(s) d\mu = \int_{\Omega} ||x(s)|| d\mu
\]
which shows the triangle inequality holds on simple functions. This implies
\[ \left\| \int_{\Omega} x_n(s) \, d\mu - \int_{\Omega} x_m(s) \, d\mu \right\| = \left\| \int_{\Omega} (x_n(s) - x_m(s)) \, d\mu \right\| \leq \int_{\Omega} \|x_n(s) - x_m(s)\| \, d\mu \]
which verifies the existence of the limit in (19.2.5). This completes the first part of the argument.

Next it is shown the integral does not depend on the choice of the sequence satisfying (19.2.4) so that the integral is well defined. Suppose \( y_n, x_n \) both satisfy (19.2.4) and converge to \( x \) pointwise. By Fatou's lemma,
\[ \left\| \int_{\Omega} y_n d\mu - \int_{\Omega} x_n d\mu \right\| \leq \int_{\Omega} \|y_n - x\| \, d\mu + \int_{\Omega} \|x - x_n\| \, d\mu \leq \liminf_{k \to \infty} \int_{\Omega} \|y_n - y_k\| \, d\mu + \liminf_{k \to \infty} \int_{\Omega} \|x_k - x_m\| \leq \varepsilon/2 + \varepsilon/2 \]
if \( m \) and \( n \) are chosen large enough. Since \( \varepsilon \) is arbitrary, this shows the limit is the same for both sequences and demonstrates the Bochner integral is well defined.

It remains to verify the triangle inequality on Bochner integral functions and the claim about passing a continuous linear functional inside the integral. Let \( x \) be Bochner integrable and let \( x_n \) be a sequence which satisfies the conditions of the definition. Define
\[ y_n(s) = \begin{cases} x_n(s) & \text{if } \|x_n(s)\| \leq 2\|x(s)\|, \\ 0 & \text{if } \|x_n(s)\| > 2\|x(s)\|. \end{cases} \tag{19.2.9} \]
Thus
\[ y_n(s) = x_n(s) \chi_{\|x_n\| \leq 2\|x\|}(s). \]
If \( x(s) = 0 \) then \( y_n(s) = 0 \) for all \( n \). If \( \|x(s)\| > 0 \) then for all \( n \) large enough,
\[ y_n(s) = x_n(s). \]
Thus, \( y_n(s) \to x(s) \) and
\[ \|y_n(s)\| \leq 2\|x(s)\|. \tag{19.2.10} \]
By Fatou's lemma,
\[ \int_{\Omega} \|x\| \, d\mu \leq \liminf_{n \to \infty} \int_{\Omega} \|x_n\| \, d\mu. \tag{19.2.11} \]
Also from (19.2.4) and the triangle inequality on simple functions, \( \left\{ \int_{\Omega} \|x_n\| \, d\mu \right\}_{n=1}^{\infty} \) is a Cauchy sequence and so it must be bounded. Therefore, by (19.2.10), (19.2.11), and the dominated convergence theorem,
\[ 0 = \lim_{n,m \to \infty} \int_{\Omega} \|y_n - y_m\| \, d\mu \tag{19.2.12} \]
and it follows $x_n$ can be replaced with $y_n$ in Definition 19.2.3.

From Definition 19.2.1, 
\[ f \left( \int \Omega y_n \, d\mu \right) = \int \Omega f(y_n) \, d\mu. \]

Thus, 
\[ f \left( \int \Omega x \, d\mu \right) = \lim_{n \to \infty} f \left( \int \Omega y_n \, d\mu \right) = \lim_{n \to \infty} \int \Omega f(y_n) \, d\mu = \int \Omega f(x) \, d\mu, \]
the last equation holding from the dominated convergence theorem and 19.2.10 and 19.2.11. This shows 19.2.6. To verify 19.2.7, 
\[ \int \Omega x(s) \, d\mu = \lim_{n \to \infty} \int \Omega y_n(s) \, d\mu = \int \Omega \|x(s)\| \, d\mu \]
where the last equation follows from the dominated convergence theorem and 19.2.10, 19.2.11.

It remains to verify 19.2.8. Let $f \in X'$. Then from 19.2.10 
\[ f \left( \int \Omega (ax(s) + by(s)) \, d\mu \right) = \int \Omega (af(x(s)) + bf(y(s))) \, d\mu \]
\[ = a \int \Omega f(x(s)) \, d\mu + b \int \Omega f(y(s)) \, d\mu \]
\[ = f \left( a \int \Omega x(s) \, d\mu + b \int \Omega y(s) \, d\mu \right). \]

Since $X'$ separates the points of $X$, it follows 
\[ \int \Omega (ax(s) + by(s)) \, d\mu = a \int \Omega x(s) \, d\mu + b \int \Omega y(s) \, d\mu \]
and this proves 19.2.8. 

**Theorem 19.2.5** An $X$ valued function $x$, is Bochner integrable if and only if $x$ is strongly measurable and 
\[ \int \Omega \|x(s)\| \, d\mu < \infty. \] (19.2.13)

In this case there exists a sequence of simple functions \( \{y_n\} \) satisfying 19.2.22, $y_n(s)$ converging pointwise to $x(s)$, 
\[ \|y_n(s)\| \leq 2 \|x(s)\| \] (19.2.14)
and 
\[ \lim_{n \to \infty} \int \Omega \|x(s) - y_n(s)\| \, d\mu = 0. \] (19.2.15)
**Proof:** Suppose $x$ is strongly measurable and condition 19.2.13 holds. Since $x$ is strongly measurable, there exists a sequence of simple functions, $\{x_n\}$ converging pointwise to $x$. As before, let

$$y_n(s) = \begin{cases} x_n(s) & \text{if } ||x_n(s)|| \leq 2||x(s)||, \\ 0 & \text{if } ||x_n(s)|| > 2||x(s)||. \end{cases}$$

(19.2.16)

Then 19.2.14 holds for $y_n$ and $y_n(s) \to x(s)$. Then by the dominated convergence theorem,

$$\lim_{n \to \infty} \int_{\Omega} ||x(s) - y_n(s)|| \, d\mu = 0$$

and so

$$0 = \lim_{m,n \to \infty} \int_{\Omega} ||y_n(s) - y_m(s)|| \, d\mu.$$

Now suppose $x$ is Bochner integrable. Then it is strongly measurable and there exists a sequence of simple functions $\{x_n\}$ such that $x_n(s)$ converges pointwise to $x$ and

$$\lim_{m,n \to \infty} \int_{\Omega} ||x_n(s) - x_m(s)|| \, d\mu = 0.$$

Therefore, as before, since $\{\int_{\Omega} x_n \, d\mu\}_{n=1}^{\infty}$ is a Cauchy sequence, it follows

$$\left\{\int_{\Omega} ||x_n|| \, d\mu\right\}_{n=1}^{\infty}$$

is also a Cauchy sequence because

$$\left| \int_{\Omega} ||x_n|| \, d\mu - \int_{\Omega} ||x_m|| \, d\mu \right| \leq \int_{\Omega} ||||x_n|| - ||x_m|||| \, d\mu \\ \leq \int_{\Omega} ||x_n - x_m|| \, d\mu.$$

Thus

$$\int_{\Omega} ||x|| \, d\mu \leq \lim_{n \to \infty} \inf \int_{\Omega} ||x_n|| \, d\mu < \infty$$

Using 19.2.15 it follows $y_n$ satisfies 19.2.14, converges pointwise to $x$ and then from the dominated convergence theorem 19.2.15 holds. ■

Here is a simple corollary.

**Corollary 19.2.6** Let an $X$ valued function $x$ be Bochner integrable and let $L \in \mathcal{L}(X,Y)$ where $Y$ is another Banach space. Then $Lx$ is a $Y$ valued Bochner integrable function and

$$L\left(\int_{\Omega} x(s) \, d\mu\right) = \int_{\Omega} Lx(s) \, d\mu.$$
**Proof:** From Theorem 19.2.5 there is a sequence of simple functions \( \{y_n\} \) having the properties listed in that theorem. Then consider \( \{L y_n\} \) which converges pointwise to \( L x \). Since \( L \) is continuous and linear,

\[
\int_{\Omega} ||L y_n - Lx||_Y^d \mu \leq ||L|| \int_{\Omega} ||y_n - x||_X^d \mu
\]

which converges to 0. This implies

\[
\lim_{m,n \to \infty} \int_{\Omega} ||L y_n - L y_m||_Y^d \mu = 0
\]

and so by definition \( L x \) is Bochner integrable. Also

\[
\int_{\Omega} x(s) d \mu = \lim_{n \to \infty} \int_{\Omega} y_n(s) d \mu
\]
\[
\int_{\Omega} L x(s) d \mu = \lim_{n \to \infty} \int_{\Omega} L y_n(s) d \mu = \lim_{n \to \infty} L \int_{\Omega} y_n(s) d \mu
\]
\[
\left\| L \left( \int_{\Omega} x(s) d \mu \right) - \int_{\Omega} L x(s) d \mu \right\|_Y 
\leq \left\| L \left( \int_{\Omega} x(s) d \mu \right) - L \int_{\Omega} y_n(s) d \mu \right\|_Y + \left\| \int_{\Omega} L y_n(s) d \mu - \int_{\Omega} L x(s) d \mu \right\|_Y < \varepsilon/2 + \varepsilon/2 = \varepsilon
\]

whenever \( n \) large enough.

**19.2.2 Taking A Closed Operator Out Of The Integral**

Now let \( X \) and \( Y \) be separable Banach spaces and suppose \( A : D(A) \subseteq X \to Y \) be a closed operator. Recall this means that the graph of \( A \),

\[
G(A) \equiv \{(x, Ax) : x \in D(A)\}
\]

is a closed subset of \( X \times Y \) with respect to the product topology obtained from the norm

\[
||(x,y)|| = \max(||x||, ||y||).
\]

Thus also \( G(A) \) is a separable Banach space with the above norm. You can also consider \( D(A) \) as a separable Banach space having the graph norm

\[
||(x)||_{D(A)} \equiv \max(||x||, ||Ax||)
\]  
(19.2.17)

which is isometric to \( G(A) \) with the mapping, \( \theta x \equiv (x, Ax) \).
Lemma 19.2.7 A closed subspace of a reflexive Banach space is reflexive.

Proof: Consider the following diagram in which $Y$ is a closed subspace of the reflexive space, $X$.

$$
Y'' \xrightarrow{i^*} X'' \\
Y' \xrightarrow{i^*} X' \\
Y \xrightarrow{i} X
$$

This diagram follows from theorems on adjoints presented earlier.

Now let $y^{**} \in Y''$. Is $y^{**} = J(y)$ for some $y \in Y$? From the above, there exists $y \in X$ such that for all $x^*$, $i^*y^{**}(x^*) = x^*(y)$. Is $y \in Y$? If it is not in $Y$ then there exists $x^* \in X'$ such that $x^*(y) \neq 0$ but $x^*(Y) = 0$. Then $i^*x^* = 0$. Hence

$$0 = y^{**}(i^*x^*) = i^*y^{**}(x^*) = x^*(y) \neq 0,$$

a contradiction. Hence $y \in Y$. Thus

$$y^{**}(i^*x^*) = i^*y^{**}(x^*) = x^*(y) = x^*(iy) = i^*x^*(y), \ y \in Y$$

Now $i^*$ is onto. and so this says $y^{**}(y^*) = y^*(y)$ for all $y^* \in Y'$. In other words, $y^{**} = J(y)$. ■

Corollary 19.2.8 Suppose $Y$ is a reflexive Banach space and $X$ is a Banach space such that there exists a continuous one to one mapping, $g : X \to Y$ such that $g(X)$ is a closed subset of $Y$. Then $X$ is reflexive.

Proof: By the open mapping theorem, $g(X)$ and $X$ are homeomorphic since $g^{-1}$ must also be continuous. Therefore, since $g(X)$ is reflexive, it follows $X$ is also. ■

Lemma 19.2.9 Suppose $V$ and $W$ are reflexive Banach spaces and that $V$ is a dense subset of $W$ in the topology of $W$. Then $i^*W'$ is a dense subset of $V'$ where here $i$ is the inclusion map of $V$ into $W$.

Proof: First note that $i^*$ is one to one. If $i^*w^* = 0$ for $w^* \in W'$, then this means that for all $v \in V$,

$$i^*w(v) = w^*(v) = 0$$

and since $V$ is dense in $W$, this shows $w^* = 0$.

Consider the following diagram

$$
V'' \xrightarrow{i^*} W'' \\
V' \xrightarrow{i^*} W' \\
V \xrightarrow{i} W
$$

in which $i$ is the inclusion map. Next suppose $i^*W'$ is not dense in $V'$. Then there exists $v^* \in V''$ such that $v^{**} \neq 0$ but $v^{**}(i^*W') = 0$. It follows from $V$ being
reflexive, that $v^{**} = Jv_0$ where $J$ is the James map from $V$ to $V''$ for some $v_0 \in V$. Thus for every $w^* \in W'$, 

$$0 = v^{**} (i^* w^*) = i^{**} v^{**} (w^*)$$

$$= i^{**} Jv_0 (w^*) = Jv_0 (i^* w^*)$$

$$= i^* w^* (v_0) = w^* (v_0)$$

and since $W'$ separates the points of $W$, it follows $v_0 = 0$ which contradicts $v^{**} \neq 0$.

Note that in the proof, only $V$ reflexive was used.

This lemma implies an easy corollary.

**Corollary 19.2.10** Let $E$ and $F$ be reflexive Banach spaces and let $A$ be a closed operator, $A : D(A) \subseteq E \to F$. Suppose also that $D(A)$ is dense in $E$. Then making $D(A)$ into a Banach space by using the above graph norm given in [19.2.17], it follows that $D(A)$ is a Banach space and $i^* E'$ is a dense subspace of $D(A)'$.

**Proof:** First note that $E \times F$ is a reflexive Banach space and $G(A)$ is a closed subspace of $E \times F$ so it is also a reflexive Banach space. Now $D(A)$ is isometric to $G(A)$ and so it follows $D(A)$ is a dense subspace of $E$ which is reflexive. Therefore, from Lemma 19.2.9 the conclusion follows.

With this preparation, here is another interesting theorem. This one is about taking outside the integral a closed linear operator as opposed to a continuous linear operator.

**Theorem 19.2.11** Let $X, Y$ be separable Banach spaces and let $A : D(A) \subseteq X \to Y$ be a closed operator where $D(A)$ is a dense separable subset of $X$ with respect to the graph norm on $D(A)$ described above.\(^1\) Suppose also that $i^* X'$ is a dense subspace of $D(A)'$ where $D(A)$ is a Banach space having the graph norm described in [19.2.17]. Suppose that $(\Omega, \mathcal{F}, \mu)$ is a $\sigma$ finite measure space and $x : \Omega \to X$ is strongly measurable and it happens that $x(s) \in D(A)$ for all $s \in \Omega$. Then $x$ is strongly measurable as a mapping into $D(A)$. Also $Ax$ is strongly measurable as a map into $Y$ and if

$$\int_\Omega \|x(s)\| \, d\mu, \int_\Omega \|Ax(s)\| \, d\mu < \infty, \quad (19.2.18)$$

then

$$\int_\Omega x(s) \, d\mu \in D(A) \quad (19.2.19)$$

and

$$A \int_\Omega x(s) \, d\mu = \int_\Omega Ax(s) \, d\mu. \quad (19.2.20)$$

\(^1\)Note that this follows from the assumed separability of $X, Y$ because the graph is a subset of the separable space $X \times Y$.\(^2\)
Proof: First of all, consider the assertion that \( x \) is strongly measurable into \( D(A) \). Letting \( f \in D(A)' \) be given, there exists a sequence, \( \{g_n\} \subseteq i^*X' \) such that \( g_n \to f \) in \( D(A)' \). Therefore,

\[
s \to g_n(x(s))
\]

is measurable by assumption and

\[
g_n(x(s)) \to f(x(s))
\]

which shows that \( s \to f(x(s)) \) is measurable. By the Pettis theorem, it follows

\[
s \to x(s)
\]

is strongly measurable as a map into \( D(A) \).

It follows from Theorem 19.2.5 there exists a sequence of simple functions, \( \{x_n\} \) of the form

\[
x_n(s) = \sum_{k=1}^{m_n} a_k^n X_{E_k^n}(s), x_n(s) \in D(A),
\]

which converges strongly and pointwise to \( x(s) \) in \( D(A) \). Thus

\[
x_n(s) \to x(s), Ax_n(s) \to Ax(s),
\]

which shows \( s \to Ax(s) \) is strongly measurable in \( Y \) as claimed.

It remains to verify the assertions about the integral. 19.2.18 implies \( x \) is Bochner integrable as a function having values in \( D(A) \) with the norm on \( D(A) \) described above. Therefore, by Theorem 19.2.5 there exists a sequence of simple functions \( \{y_n\} \) having values in \( D(A) \),

\[
\lim_{m,n \to \infty} \int_{\Omega} \|y_n - y_m\|_{D(A)} d\mu = 0,
\]

\( y_n(s) \) converging pointwise to \( x(s) \),

\[
\|y_n(s)\|_{D(A)} \leq 2 \|x(s)\|_{D(A)}
\]

and

\[
\lim_{n \to \infty} \int_{\Omega} \|x(s) - y_n(s)\|_{D(A)} ds = 0.
\]

Therefore,

\[
\int_{\Omega} y_n(s) d\mu \in D(A), \int_{\Omega} y_n(s) d\mu \to \int_{\Omega} x(s) d\mu \text{ in } X,
\]

and since \( y_n \) is a simple function and \( A \) is linear,

\[
A \int_{\Omega} y_n(s) d\mu = \int_{\Omega} Ay_n(s) d\mu \to \int_{\Omega} Ax(s) d\mu \text{ in } Y.
\]
It follows, since $A$ is a closed operator, that

$$\int_{\Omega} x(s) \, d\mu \in D(A)$$

and

$$A \int_{\Omega} x(s) \, d\mu = \int_{\Omega} Ax(s) \, d\mu.$$  ■

Here is another version of this theorem which has different hypotheses.

**Theorem 19.2.12** Let $X$ and $Y$ be separable Banach spaces and let $A : D(A) \subseteq X \to Y$ be a closed operator. Also let $(\Omega, \mathcal{F}, \mu)$ be a a finite measure space and let $x : \Omega \to X$ be Bochner integrable such that $x(s) \in D(A)$ for all $s$. Also suppose $Ax$ is Bochner integrable. Then

$$\int Ax \, d\mu = A \int x \, d\mu$$

and $\int x \, d\mu \in D(A)$.

**Proof:** Consider the graph of $A$,

$$G(A) \equiv \{(x, Ax) : x \in D(A)\} \subseteq X \times Y.$$

Then since $A$ is closed, $G(A)$ is a closed separable Banach space with the norm $\|(x, y)\| \equiv \max(\|x\|, \|y\|)$. Therefore, for $g^* \in G(A)'$, one can apply the Hahn Banach theorem and obtain $(x^*, y^*) \in (X \times Y)'$ such that $g^*(x, Ax) = (x^*(x), y^*(Ax))$. Now it follows from the assumptions that $s \to (x^*(x(s)), y^*(Ax(s)))$ is measurable with values in $G(A)$. It is also separably valued because this is true of $G(A)$. By the Pettis theorem, $s \to (x(s), A(x(s)))$ must be strongly measurable. Also $\|x(s)\| + \|Ax(s)\| \, d\mu < \infty$ by assumption and so there exists a sequence of simple functions having values in $G(A), \{(x_n(s), Ax_n(s))\}$ which converges to $(x(s), A(s))$ pointwise such that $\int \| (x_n, Ax_n) - (x, Ax) \| \, d\mu \to 0$ in $G(A)$. Now for simple functions is it routine to verify that

$$\int (x_n, Ax_n) \, d\mu = \left( \int x_n \, d\mu, \int Ax_n \, d\mu \right)$$

$$= \left( \int x_n \, d\mu, A \int x_n \, d\mu \right)$$

Also

$$\left\| \int x_n \, d\mu - \int x \, d\mu \right\| \leq \int \| x_n - x \| \, d\mu$$

$$\leq \int \| (x_n, Ax_n) - (x, Ax) \| \, d\mu$$
19.3. OPERATOR VALUED FUNCTIONS

which converges to 0. Also
\[
\left\| \int A_n x \, d\mu - \int A x \, d\mu \right\| = \left\| A \int x_n \, d\mu - \int A x \, d\mu \right\|
\leq \int \left\| A_n x - A x \right\| \, d\mu
\leq \int \left\| (x_n, A x_n) - (x, A x) \right\| \, d\mu
\]
and this converges to 0. Therefore, \( \int x_n \, d\mu \to \int x \, d\mu \) and \( A \int x_n \, d\mu \to \int A x \, d\mu \).

Since each \( \int x_n \, d\mu \in D(A) \), and \( A \) is closed, this implies \( \int x \, d\mu \in D(A) \) and \( A \int x \, d\mu = \int A x \, d\mu \).

19.3 Operator Valued Functions

Consider the case where \( A(s) \in \mathcal{L}(X,Y) \) for \( X \) and \( Y \) separable Banach spaces. With the operator norm \( \mathcal{L}(X,Y) \) is a Banach space and so if \( A \) is strongly measurable, the Bochner integral can be defined as before. However, it is also possible to define the Bochner integral of such operator valued functions for more general situations. In this section, \( (\Omega, \mathcal{F}, \mu) \) will be a \( \sigma \) finite measure space as usual.

**Lemma 19.3.1** Let \( x \in X \) and suppose \( A \) is strongly measurable. Then
\[
s \to A(s) x
\]
is strongly measurable as a map into \( Y \).

**Proof:** Since \( A \) is assumed to be strongly measurable, it is the pointwise limit of simple functions of the form
\[
A_n(s) \equiv \sum_{k=1}^{m_n} A^k_n x_{m_n} (s)
\]
where \( A^k_n \) is in \( \mathcal{L}(X,Y) \). It follows \( A_n(s) x \to A(s) x \) for each \( s \) and so, since \( s \to A_n(s) x \) is a simple \( Y \) valued function, \( s \to A(s) x \) must be strongly measurable.

**Definition 19.3.2** Suppose \( A(s) \in \mathcal{L}(X,Y) \) for each \( s \in \Omega \) where \( X,Y \) are separable Banach spaces. Suppose also that for each \( x \in X \),
\[
s \to A(s) x \text{ is strongly measurable} \tag{19.3.21}
\]
and there exists \( C \) such that for each \( x \in X \),
\[
\int_{\Omega} \| A(s) x \| \, d\mu < C \| x \|
\tag{19.3.22}
\]
Then \( \int_{\Omega} A(s) \, d\mu \in \mathcal{L}(X,Y) \) is defined by the following formula.
\[
\left( \int_{\Omega} A(s) \, d\mu \right) (x) \equiv \int_{\Omega} A(s) x \, d\mu
\tag{19.3.23}
\]
Lemma 19.3.3 The above definition is well defined. Furthermore, if \( 19.3.21 \) holds then \( s \to \|A(s)\| \) is measurable and if \( 19.3.22 \) holds, then

\[
\left\| \int \Omega A(s) \, d\mu \right\| \leq \int \Omega \|A(s)\| \, d\mu.
\]

**Proof:** It is clear that in case \( s \to A(s) \, x \) is measurable for all \( x \in X \) there exists a unique \( \Psi \in L(X,Y) \) such that

\[
\Psi(x) = \int \Omega A(s) \, x \, d\mu.
\]

This is because \( x \to \int \Omega A(s) \, x \, d\mu \) is linear and continuous. Thus \( \Psi = \int \Omega A(s) \, d\mu \) and the definition is well defined.

Now consider the assertion about \( s \to \|A(s)\| \). Let \( D' \subseteq B' \) the closed unit ball in \( Y' \) be such that \( D' \) is countable and

\[
\|y\| = \sup_{y' \in D'} \|y'\| (y).
\]

Also let \( D \) be a countable dense subset of \( B \), the unit ball of \( X \). Then

\[
\{s : \|A(s)\| > \alpha\} = \{s : \sup_{x \in D} \|A(s) \, x\| > \alpha\} = \bigcup_{x \in D} \{s : \|A(s) \, x\| > \alpha\} = \bigcup_{x \in D, y' \in D'} \{\|y'\| (A(s) \, x) > \alpha\}
\]

and this is measurable because \( s \to A(s) \, x \) is strongly, hence weakly measurable.

Now suppose \( 19.3.22 \) holds. Then for all \( x \),

\[
\int \Omega \|A(s) \, x\| \, d\mu < C \|x\|.
\]

It follows that for \( \|x\| \leq 1 \),

\[
\left\| \left( \int \Omega A(s) \, d\mu \right) (x) \right\| = \left\| \int \Omega A(s) \, x \, d\mu \right\| \leq \int \Omega \|A(s) \, x\| \, d\mu \leq \int \Omega \|A(s)\| \, d\mu
\]

and so

\[
\left\| \int \Omega A(s) \, d\mu \right\| \leq \int \Omega \|A(s)\| \, d\mu.
\]

This proves the lemma.

Now it is interesting to consider the case where \( A(s) \in L(H,H) \) where \( s \to A(s) \, x \) is strongly measurable and \( A(s) \) is compact and self adjoint. Recall the Kuratowski measurable selection theorem, Theorem 9.1.11 on Page 212 listed here for convenience.
Theorem 19.3.4 Let $E$ be a compact metric space and let $(\Omega, \mathcal{F})$ be a measure space. Suppose $\psi : E \times \Omega \to \mathbb{R}$ has the property that $x \to \psi(x, \omega)$ is continuous and $\omega \to \psi(x, \omega)$ is measurable. Then there exists a measurable function, $f$ having values in $E$ such that

$$\psi(f(\omega), \omega) = \sup_{x \in E} \psi(x, \omega).$$

Furthermore, $\omega \to \psi(f(\omega), \omega)$ is measurable.

19.3.1 Review Of Hilbert Schmidt Theorem

Here I will give a proof of the Hilbert Schmidt theorem which will generalize to a result about measurable operators. Recall the following.

Definition 19.3.5 Define $v \otimes u \in \mathcal{L}(H, H)$ by

$$v \otimes u(x) = (x, u)v.$$

$A \in \mathcal{L}(H, H)$ is a compact operator if whenever $\{x_k\}$ is a bounded sequence, there exists a convergent subsequence of $\{Ax_k\}$. Equivalently, $A$ maps bounded sets to sets whose closures are compact or to use other terminology, $A$ maps bounded sets to sets which are precompact.

Lemma 19.3.6 Let $H$ be a separable Hilbert space and suppose $A \in \mathcal{L}(H, H)$ is a compact operator. Let $B$ denote the closed unit ball in $H$. Then $A$ is continuous as a map from $B$ with the weak topology into $H$ with the strong topology. For $u, v \in H$, $v \otimes u: H \to H$ is a compact operator. If $A$ is self adjoint and compact, the function

$$x \to (Ax, x)$$

is continuous on $B$ with respect to the weak topology on $B$. The function,

$$x \to (v \otimes u(x), x)$$

is continuous and the operator $u \otimes u$ is self adjoint.

Proof: Since $H$ is separable, it follows from Corollary 15.5.9 on Page 447 that $B$ can be considered as a metric space. Therefore, showing continuity reduces to showing convergent sequences are taken to convergent sequences. Let $x_n \to x$ weakly in $B$. Suppose $Ax_n$ does not converge to $Ax$. Then there exists a subsequence, still denoted by $\{x_n\}$ such that

$$||Ax_n - Ax|| \geq \varepsilon > 0 \quad (19.3.24)$$

for all $n$. Then since $A$ maps bounded sets to compact sets, there is a further subsequence, still denoted by $\{x_n\}$ such that $Ax_n$ converges to some $y \in H$. Therefore,

$$(y, w) = \lim_{n \to \infty} (Ax_n, w) = \lim_{n \to \infty} (x_n, A^*w)$$

$$= (x, A^*w) = (Ax, w)$$
which shows $Ax = y$ since $w$ is arbitrary. However, this contradicts (19.3.24).

Next consider the claim about $v \otimes u$. Letting \( \{x_n\} \) be a bounded sequence,

$$v \otimes u (x_n) = (x_n, u) v.$$  

There exists a weakly convergent subsequence of \( \{x_n\} \) say \( \{x_{n_k}\} \) converging weakly to \( x \in H \). Therefore,

$$||v \otimes u (x_{n_k}) - v \otimes u (x)|| = ||(x_{n_k}, u) - (x, u)|| ||v||$$

which converges to 0. Thus \( v \otimes u \) is compact as claimed. It takes bounded sets to precompact sets.

To verify the assertion about \( x \to (Ax, x) \), let \( x_n \to x \) weakly. Then

$$||(Ax_n, x_n) - (Ax, x)|| \leq ||(Ax_n, x_n) - (Ax_n, x_n)|| + ||(Ax, x_n) - (Ax, x)||$$

$$\leq ||Ax - Ax|| ||x_n|| + ||Ax_n - Ax|| ||x|| \leq 2 ||Ax_n - Ax||$$

which converges to 0.

$$||(v \otimes u (x_n), x_n) - (v \otimes u (x), x)||$$

$$= ||(x_n, u) (v, x_n) - (x, u) (v, x)||$$

and this converges to 0 by weak convergence. It follows from the definition that \( u \otimes u \) is self adjoint. This proves the lemma.

**Observation 19.3.7** Note that if \( A \) is any self adjoint operator,

$$\overline{(Ax, x)} = (x, Ax) = (Ax, x).$$

so \( (Ax, x) \) is real valued.

**Lemma 19.3.8** Let \( A \in \mathcal{L}(H, H) \) and suppose it is self adjoint and compact. Let \( B \) denote the closed unit ball in \( H \). Let \( e \in B \) be such that

$$||(Ae, e)|| = \max_{x \in B} ||(Ax, x)||.$$ 

Then letting \( \lambda = (Ae, e) \), it follows \( Ae = \lambda e \). If \( \lambda \neq 0 \), then ||e|| = 1 and if \( \lambda = 0 \), it can be assumed \( e = 0 \) so it is still the case \( Ae = \lambda e \).

**Proof:** From the above observation, \( (Ax, x) \) is always real and since \( A \) is compact, \( ||(Ax, x)|| \) achieves a maximum at \( e \). It remains to verify \( e \) is an eigenvector. Note that ||e|| = 1 whenever \( \lambda \neq 0 \) since otherwise ||(Ae, e)|| could be made larger by replacing \( e \) with \( e/||e|| \).
Suppose $\lambda = (Ae, e) > 0$. Then it is easy to verify that $\lambda I - A$ is a nonnegative $((\lambda I - A)x, x) \geq 0$ for all $x$) and self adjoint operator. Therefore, the Cauchy Schwarz inequality can be applied to write

$$((\lambda I - A)e, x) \leq ((\lambda I - A)e, e)^{1/2}((\lambda I - A)x, x)^{1/2} = 0$$

Since this is true for all $x$ it follows $Ae = \lambda e$.

Next suppose $\lambda = (Ae, e) < 0$. Then $-\lambda = (-Ae, e)$ and the previous result can be applied to $-A$ and $-\lambda$. Thus $-\lambda e = -Ae$ and so $Ae = \lambda e$.

Finally consider the case where $\lambda = 0$. Then $0 = (A0, 0)$ and so it suffices to take $e = 0$ as claimed. This proves the lemma.

With these lemmas here is a major theorem, the Hilbert Schmidt theorem.

**Theorem 19.3.9** Let $A \in \mathcal{L}(H, H)$ be a compact self adjoint operator on a Hilbert space. Then there exist real numbers $\{\lambda_k\}_{k=1}^{\infty}$ and vectors $\{e_k\}_{k=1}^{\infty}$ such that

$$||e_k|| = 1 \text{ if } \lambda_k \neq 0,$$
$$||e_k|| = 0 \text{ if } \lambda_k = 0,$$
$$(e_k, e_j)_H = 0 \text{ if } k \neq j,$$
$$Ae_k = \lambda_k e_k, \quad |\lambda_n| \geq |\lambda_{n+1}| \text{ for all } n,$$
$$\lim_{n \to \infty} \lambda_n = 0,$$
$$\lim_{n \to \infty} \left\| A - \sum_{k=1}^{n} \lambda_k (e_k \otimes e_k) \right\|_{\mathcal{L}(H, H)} = 0. \quad (19.3.25)$$

**Proof:** This is done by considering a sequence of compact self adjoint operators, $A, A_1, A_2, \cdots$. Here is how these are defined. Using Lemma [19.3.8] let $e_1, \lambda_1$ be given by that lemma such that

$$||(Ae_1, e_1)|| = \max_{x \in B} |(Ax, x)|, \quad \lambda_1 = (Ae_1, e_1).$$

Then by that lemma, $Ae_1 = \lambda_1 e_1$ and $||e_1|| = 1$ if $\lambda_1 \neq 0$ while $e_1 = 0$ if $\lambda_1 = 0$.

If $A_n$ has been obtained, use Lemma [19.3.8] to obtain $e_{n+1}$ and $\lambda_{n+1}$ such that

$$||(A_ne_{n+1}, e_{n+1})|| = \max_{x \in B} |(A_n x, x)|, \quad \lambda_{n+1} = (A_n e_{n+1}, e_{n+1}).$$

By that lemma again, $A_ne_{n+1} = \lambda_{n+1} e_{n+1}$ and $||e_{n+1}|| = 1$ if $\lambda_{n+1} \neq 0$ while $e_{n+1} = 0$ if $\lambda_{n+1} = 0$. Then

$$A_{n+1} = A_n - \lambda_{n+1} e_{n+1} \otimes e_{n+1}$$

Thus

$$A_n = A - \sum_{k=1}^{n} \lambda_k e_k \otimes e_k. \quad (19.3.26)$$
**Claim 1:** If \( k < n + 1 \) then \((e_{n+1}, e_k) = 0\). Also \( Ae_k = \lambda_k e_k \) for all \( k \).

**Proof of claim:** From the above,

\[
\lambda_{n+1} e_{n+1} = A_n e_{n+1} = Ae_{n+1} - \sum_{k=1}^{n} \lambda_k (e_{n+1}, e_k) e_k.
\]

If \( \lambda_{n+1} = 0 \), then \((e_{n+1}, e_k) = 0\) because \( e_{n+1} = 0 \). If \( \lambda_{n+1} \neq 0 \), then from the above and an induction hypothesis

\[
\lambda_{n+1} (e_{n+1}, e_j) = (Ae_{n+1}, e_j) - \sum_{k=1}^{n} \lambda_k (e_{n+1}, e_k)(e_k, e_j) = \lambda_j (e_{n+1}, e_j) - \lambda_j (e_{n+1}, e_j) = 0.
\]

To verify the second part of this claim,

\[
\lambda_{n+1} e_{n+1} = A_n e_{n+1} = Ae_{n+1} - \sum_{k=1}^{n} \lambda_k e_k (e_{n+1}, e_k) = Ae_{n+1}
\]

This proves the claim.

**Claim 2:** \(|\lambda_n| \geq |\lambda_{n+1}|\).

**Proof of claim:** From the definition of \( A_n \) and the definition of \( A_n e_k \),

\[
\lambda_{n+1} = (A_n e_{n+1}, e_{n+1}) = (A_{n-1} e_{n+1}, e_{n+1}) - \lambda_n |(e_n, e_{n+1})|^2 = (A_{n-1} e_{n+1}, e_{n+1})
\]

By the previous claim. Therefore,

\[
|\lambda_{n+1}| = |(A_{n-1} e_{n+1}, e_{n+1})| \leq |(A_{n-1} e_n, e_n)| = |\lambda_n|
\]

by the definition of \( |\lambda_n| \). (\( e_n \) makes \(|(A_{n-1} x, x)|\) as large as possible, not necessarily \(e_{n+1}\)).

**Claim 3:** \( \lim_{n \to \infty} \lambda_n = 0 \).

**Proof of claim:** If for some \( n \), \( \lambda_n = 0 \), then \( \lambda_k = 0 \) for all \( k > n \) by claim 2. Assume then that \( \lambda_k \neq 0 \) for any \( k \). Then if \( \lim_{k \to \infty} |\lambda_k| = \varepsilon > 0 \), contrary to the claim, \( ||e_k|| = 1 \) for all \( k \) and

\[
||A e_n - A e_m||^2 = ||\lambda_n e_n - \lambda_m e_m||^2 = \lambda_n^2 + \lambda_m^2 \geq 2\varepsilon^2
\]

which shows there is no Cauchy subsequence of \( \{A e_n\}_{n=1}^{\infty} \), which contradicts the compactness of \( A \). This proves the claim.

**Claim 4:** \( ||A_n|| \to 0 \)
Proof of claim: Let $x, y \in B$

\[
|\lambda_{n+1}| \geq \left| \left( A_n \frac{x+y}{2}, \frac{x+y}{2} \right) \right|
\]

\[
= \left| \frac{1}{4} (A_n x, x) + \frac{1}{4} (A_n y, y) + \frac{1}{2} (A_n x, y) \right|
\]

\[
\geq \frac{1}{2} |(A_n x, y)| - \frac{1}{4} |(A_n x, x) + (A_n y, y)|
\]

\[
\geq \frac{1}{2} |(A_n x, y)| - \frac{1}{4} (|(A_n x, x)| + |(A_n y, y)|)
\]

\[
\geq \frac{1}{2} |(A_n x, y)| - \frac{1}{2} |\lambda_{n+1}|
\]

and so

\[
3 |\lambda_{n+1}| \geq |(A_n x, y)|.
\]

It follows $||A_n|| \leq 3 |\lambda_{n+1}|$. This proves the claim.

By [19.3.26] this proves [19.3.25] and completes the proof.

19.3.2 Measurable Compact Operators

Here the operators will be of the form $A(s)$ where $s \in \Omega$ and $s \rightarrow A(s) x$ is strongly measurable and $A(s)$ is a compact operator in $\mathcal{L}(H, H)$.

**Theorem 19.3.10** Let $A(s) \in \mathcal{L}(H, H)$ be a compact self adjoint operator and $H$ is a separable Hilbert space such that $s \rightarrow A(s) x$ is strongly measurable. Then there exist real numbers $\{\lambda_k(s)\}_{k=1}^{\infty}$ and vectors $\{e_k(s)\}_{k=1}^{\infty}$ such that

\[
\|e_k(s)\| = 1 \text{ if } \lambda_k \neq 0,
\]

\[
\|e_k(s)\| = 0 \text{ if } \lambda_k = 0,
\]

\[
(e_k(s), e_j(s))_H = 0 \text{ if } k \neq j,
\]

\[
A(s)e_k(s) = \lambda_k(s)e_k(s),
\]

\[
|\lambda_n(s)| \geq |\lambda_{n+1}(s)| \text{ for all } n,
\]

\[
\lim_{n \rightarrow \infty} \lambda_n(s) = 0,
\]

\[
\lim_{n \rightarrow \infty} \left\| A(s) - \sum_{k=1}^{n} \lambda_k(s) (e_k(s) \otimes e_k(s)) \right\|_{\mathcal{L}(H,H)} = 0.
\]

The function $s \rightarrow \lambda_j(s)$ is measurable and $s \rightarrow e_j(s)$ is strongly measurable.

**Proof:** It is simply a repeat of the above proof of the Hilbert Schmidt theorem except at every step when the $e_k$ and $\lambda_k$ are defined, you use the Kuratowski measurable selection theorem, Theorem [19.3.4] on Page 645 to obtain $\lambda_k(s)$ is measurable and that $s \rightarrow e_k(s)$ is also measurable.
When you consider max_{x \in B} |(A_n(s)x, x)|, let \( \psi(x, s) = |(A_n(s)x, x)| \). Then \( \psi \) is continuous in \( x \) by Lemma 19.3.6 on Page 645 and it is measurable in \( s \) by assumption. Therefore, by the Kuratowski theorem, \( e_k(s) \) is measurable in the sense that inverse images of weakly open sets in \( B \) are measurable. However, by Lemma 19.1.9 on Page 630 this is the same as weakly measurable. Since \( H \) is separable, this implies \( s \rightarrow e_k(s) \) is also strongly measurable. The measurability of \( \lambda_k \) and \( e_k \) is the only new thing here and so this completes the proof.

### 19.4 Fubini’s Theorem For Bochner Integrals

Now suppose \((\Omega_1, \mathcal{F}, \mu)\) and \((\Omega_2, \mathcal{S}, \lambda)\) are two \( \sigma \) finite measure spaces. Recall the notion of product measure. There was a \( \sigma \) algebra, denoted by \( \mathcal{F} \times \mathcal{S} \) which is the smallest \( \sigma \) algebra containing the elementary sets, (finite disjoint unions of measurable rectangles) and a measure, denoted by \( \mu \times \lambda \) defined on this \( \sigma \) algebra such that for \( E \in \mathcal{F} \times \mathcal{S} \),

\[
s_1 \rightarrow \lambda(E_{s_1}), \quad (E_{s_1} \equiv \{s_2 : (s_1, s_2) \in E\})
\]

is \( \mu \) measurable and

\[
s_2 \rightarrow \mu(E_{s_2}), \quad (E_{s_2} \equiv \{s_1 : (s_1, s_2) \in E\})
\]

is \( \lambda \) measurable. In terms of nonnegative functions which are \( \mathcal{F} \times \mathcal{S} \) measurable,

\[
s_1 \rightarrow f(s_1, s_2) \text{ is } \mu \text{ measurable},
\]

\[
s_2 \rightarrow f(s_1, s_2) \text{ is } \lambda \text{ measurable},
\]

\[
s_1 \rightarrow \int_{\Omega_2} f(s_1, s_2) \, d\lambda \text{ is } \mu \text{ measurable},
\]

\[
s_2 \rightarrow \int_{\Omega_1} f(s_1, s_2) \, d\mu \text{ is } \lambda \text{ measurable},
\]

and the conclusion of Fubini’s theorem holds.

\[
\int_{\Omega_1 \times \Omega_2} f \, d(\mu \times \lambda) = \int_{\Omega_1} \int_{\Omega_2} f(s_1, s_2) \, d\lambda \, d\mu
\]

\[
= \int_{\Omega_2} \int_{\Omega_1} f(s_1, s_2) \, d\mu \, d\lambda.
\]

The following theorem is the version of Fubini’s theorem valid for Bochner integrable functions.

**Theorem 19.4.1** Let \( f : \Omega_1 \times \Omega_2 \rightarrow X \) be strongly measurable with respect to \( \mu \times \lambda \) and suppose

\[
\int_{\Omega_1 \times \Omega_2} \|f(s_1, s_2)\| \, d(\mu \times \lambda) < \infty. \quad (19.4.27)
\]
Then there exist a set of \( \mu \) measure zero, \( N \) and a set of \( \lambda \) measure zero, \( M \) such that the following formula holds with all integrals making sense.

\[
\int_{\Omega_1 \times \Omega_2} f(s_1, s_2) \, d(\mu \times \lambda) = \int_{\Omega_1} \int_{\Omega_2} f(s_1, s_2) \, \chi_N(s_1) \, d\lambda d\mu
\]

\[
= \int_{\Omega_2} \int_{\Omega_1} f(s_1, s_2) \, \chi_M(s_2) \, d\mu d\lambda.
\]

**Proof:** First note that from \[19.4.27\] and the usual Fubini theorem for nonnegative valued functions,

\[
\int_{\Omega_1 \times \Omega_2} ||f(s_1, s_2)|| \, d(\mu \times \lambda) = \int_{\Omega_1} \int_{\Omega_2} ||f(s_1, s_2)|| \, d\lambda d\mu
\]

and so

\[
\int_{\Omega_2} ||f(s_1, s_2)|| \, d\lambda < \infty \tag{19.4.28}
\]

for \( \mu \) a.e. \( s_1 \). Say for all \( s_1 \notin N \) where \( \mu(N) = 0 \).

Let \( \phi \in X' \). Then \( \phi \circ f \) is \( \mathcal{F} \times \mathcal{S} \) measurable and

\[
\int_{\Omega_1 \times \Omega_2} |\phi \circ f(s_1, s_2)| \, d(\mu \times \lambda)
\]

\[
\leq \int_{\Omega_1 \times \Omega_2} ||\phi|| \, ||f(s_1, s_2)|| \, d(\mu \times \lambda) < \infty
\]

and so from the usual Fubini theorem for complex valued functions,

\[
\int_{\Omega_1 \times \Omega_2} \phi \circ f(s_1, s_2) \, d(\mu \times \lambda) = \int_{\Omega_1} \int_{\Omega_2} \phi \circ f(s_1, s_2) \, d\lambda d\mu. \tag{19.4.29}
\]

Now also if you fix \( s_2 \), it follows from the definition of strongly measurable and the properties of product measure mentioned above that

\[
s_1 \rightarrow f(s_1, s_2)
\]

is strongly measurable. Also, by \[19.4.28\]

\[
\int_{\Omega_2} ||f(s_1, s_2)|| \, d\lambda < \infty
\]

for \( s_1 \notin N \). Therefore, by Theorem \[19.2.5\] \( s_2 \rightarrow f(s_1, s_2) \chi_{N^c}(s_1) \) is Bochner integrable. By \[19.4.28\] and \[19.2.6\]

\[
\int_{\Omega_1 \times \Omega_2} \phi \circ f(s_1, s_2) \, d(\mu \times \lambda)
\]

\[
= \int_{\Omega_1} \int_{\Omega_2} \phi \circ f(s_1, s_2) \, d\lambda d\mu
\]

\[
= \int_{\Omega_1} \int_{\Omega_2} \phi(f(s_1, s_2) \chi_{N^c}(s_1)) \, d\lambda d\mu
\]

\[
= \int_{\Omega_1} \phi \left( \int_{\Omega_2} f(s_1, s_2) \chi_{N^c}(s_1) \, d\lambda \right) \, d\mu. \tag{19.4.30}
\]
Each iterated integral makes sense and
\[
\begin{align*}
\int_{\Omega_1} \int_{\Omega_2} \phi \left( f(s_1, s_2) \mathcal{X}_{NC}(s_1) \right) d\lambda &= \phi \left( \int_{\Omega_2} f(s_1, s_2) \mathcal{X}_{NC}(s_1) d\lambda \right) \\
&= \phi \left( \int_{\Omega_2} f(s_1, s_2) \mathcal{X}_{NC}(s_1) d\lambda \right)
\end{align*}
\] (19.4.31)
is measurable because
\[
\begin{align*}
(s_1, s_2) &\rightarrow \phi \left( f(s_1, s_2) \mathcal{X}_{NC}(s_1) \right) \\
&= \phi \left( f(s_1, s_2) \mathcal{X}_{NC}(s_1) \right)
\end{align*}
\] is product measurable. Now consider the function,
\[
\begin{align*}
\int_{\Omega_1} \int_{\Omega_2} f(s_1, s_2) \mathcal{X}_{NC}(s_1) d\lambda.
\end{align*}
\] (19.4.32)
I want to show this is also Bochner integrable with respect to \(\mu\) so I can factor out \(\phi\) once again. Its measurability follows from the Pettis theorem and the above observation [13.2.3]. Also,
\[
\begin{align*}
\int_{\Omega_1} \int_{\Omega_2} \left\| f(s_1, s_2) \mathcal{X}_{NC}(s_1) \right\| d\lambda d\mu &\leq \int_{\Omega_1} \int_{\Omega_2} \left\| f(s_1, s_2) \right\| d\lambda d\mu \\
&= \int_{\Omega_1} \int_{\Omega_2} \left\| f(s_1, s_2) \right\| d(\mu \times \lambda) < \infty.
\end{align*}
\]
Therefore, the function in (19.4.32) is indeed Bochner integrable and so in (19.4.31) the \(\phi\) can be taken outside the last integral. Thus,
\[
\begin{align*}
\phi \left( \int_{\Omega_1 \times \Omega_2} f(s_1, s_2) d(\mu \times \lambda) \right) &= \int_{\Omega_1 \times \Omega_2} \phi \circ f(s_1, s_2) d(\mu \times \lambda) \\
&= \int_{\Omega_1} \int_{\Omega_2} \phi \circ f(s_1, s_2) d\lambda d\mu \\
&= \int_{\Omega_1} \int_{\Omega_2} \phi \left( f(s_1, s_2) \mathcal{X}_{NC}(s_1) \right) d\lambda d\mu \\
&= \phi \left( \int_{\Omega_1} \int_{\Omega_2} f(s_1, s_2) \mathcal{X}_{NC}(s_1) d\lambda d\mu \right).
\end{align*}
\]
Since \(X'\) separates the points,
\[
\int_{\Omega_1 \times \Omega_2} f(s_1, s_2) d(\mu \times \lambda) = \int_{\Omega_1} \int_{\Omega_2} f(s_1, s_2) \mathcal{X}_{NC}(s_1) d\lambda d\mu.
\]
The other formula follows from similar reasoning. This proves the theorem.
19.5. THE SPACES $L^p (\Omega; X)$

**Definition 19.5.1** $x \in L^p (\Omega; X)$ for $p \in [1, \infty)$ if $x$ is strongly measurable and

$$\int_\Omega ||x(s)||^p d\mu < \infty$$

Also

$$||x||_{L^p(\Omega;X)} \equiv ||x||_p \equiv \left(\int_\Omega ||x(s)||^p d\mu\right)^{1/p} \quad (19.5.33)$$

As in the case of scalar valued functions, two functions in $L^p (\Omega; X)$ are considered equal if they are equal a.e. With this convention, and using the same arguments found in the presentation of scalar valued functions it is clear that $L^p (\Omega; X)$ is a normed linear space with the norm given by 19.5.33. In fact, $L^p (\Omega; X)$ is a Banach space. This is the main contribution of the next theorem.

**Lemma 19.5.2** If $x_n$ is a Cauchy sequence in $L^p (\Omega; X)$ satisfying

$$\sum_{n=1}^{\infty} ||x_{n+1} - x_n||_p < \infty,$$

then there exists $x \in L^p (\Omega; X)$ such that $x_n (s) \to x (s)$ a.e. and

$$||x - x_n||_p \to 0.$$

**Proof:** Let

$$g_N (s) = \sum_{n=1}^{N} ||x_{n+1} (s) - x_n (s)||_X$$

Then by the triangle inequality,

$$\left(\int_\Omega g_N (s)^p d\mu\right)^{1/p} \leq \sum_{n=1}^{N} \left(\int_\Omega ||x_{n+1} (s) - x_n (s)||^p d\mu\right)^{1/p} \leq \sum_{n=1}^{\infty} ||x_{n+1} - x_n||_p < \infty.$$

Let

$$g (s) = \lim_{N \to \infty} g_N (s) = \sum_{n=1}^{\infty} ||x_{n+1} (s) - x_n (s)||_X.$$

By the monotone convergence theorem,

$$\left(\int_\Omega g (s)^p d\mu\right)^{1/p} = \lim_{N \to \infty} \left(\int_\Omega g_N (s)^p d\mu\right)^{1/p} < \infty.$$
Therefore, there exists a set of measure 0, \( E \), such that for \( s \notin E \), \( g(s) < \infty \). Hence, for \( s \notin E \),

\[
\lim_{N \to \infty} x_{N+1}(s)
\]

exists because

\[
x_{N+1}(s) = x_{N+1}(s) - x_1(s) + x_1(s) = \sum_{n=1}^{N} (x_{n+1}(s) - x_n(s)) + x_1(s).
\]

Thus, if \( N > M \), and \( s \) is a point where \( g(s) < \infty \),

\[
||x_{N+1}(s) - x_{M+1}(s)||_X \leq \sum_{n=M+1}^{N} ||x_{n+1}(s) - x_n(s)||_X
\]

\[
\leq \sum_{n=M+1}^{\infty} ||x_{n+1}(s) - x_n(s)||_X
\]

which shows that \( \{x_{N+1}(s)\}_{N=1}^{\infty} \) is a Cauchy sequence. Now let

\[
x(s) \equiv \begin{cases} 
\lim_{N \to \infty} x_N(s) & \text{if } s \notin E, \\
0 & \text{if } s \in E.
\end{cases}
\]

By Theorem 19.1.2, \( x_n(\Omega) \) is separable for each \( n \). Therefore, \( x(\Omega) \) is also separable. Also, if \( f \in X' \), then

\[
f(x(s)) = \lim_{N \to \infty} f(x_N(s))
\]

if \( s \notin E \) and \( f(x(s)) = 0 \) if \( s \in E \). Therefore, \( f \circ x \) is measurable because it is the limit of the measurable functions,

\[
f \circ x \mathcal{X}_E.
\]

Since \( x \) is weakly measurable and \( x(\Omega) \) is separable, Corollary 19.1.8 shows that \( x \) is strongly measurable. By Fatou’s lemma,

\[
\int_{\Omega} ||x(s) - x_N(s)||^p d\mu \leq \liminf_{M \to \infty} \int_{\Omega} ||x_M(s) - x_N(s)||^p d\mu.
\]

But if \( N \) and \( M \) are large enough with \( M > N \),

\[
\left( \int_{\Omega} ||x_M(s) - x_N(s)||^p d\mu \right)^{1/p} \leq \sum_{n=N}^{M} ||x_{n+1} - x_n||_p
\]

\[
\leq \sum_{n=N}^{\infty} ||x_{n+1} - x_n||_p < \varepsilon
\]

and this shows, since \( \varepsilon \) is arbitrary, that

\[
\lim_{N \to \infty} \int_{\Omega} ||x(s) - x_N(s)||^p d\mu = 0.
\]
19.5. THE SPACES $L^p(\Omega; X)$

It remains to show $x \in L^p(\Omega; X)$. This follows from the above and the triangle inequality. Thus, for $N$ large enough,

$$\left( \int_{\Omega} \|x(s)\|^p \, d\mu \right)^{1/p}$$

$$\leq \left( \int_{\Omega} \|x_N(s)\|^p \, d\mu \right)^{1/p} + \left( \int_{\Omega} \|x(s) - x_N(s)\|^p \, d\mu \right)^{1/p}$$

$$\leq \left( \int_{\Omega} \|x_N(s)\|^p \, d\mu \right)^{1/p} + \varepsilon < \infty.$$ 

This proves the lemma.

**Theorem 19.5.3** $L^p(\Omega; X)$ is complete. Also every Cauchy sequence has a subsequence which converges pointwise.

**Proof:** If $\{x_n\}$ is Cauchy in $L^p(\Omega; X)$, extract a subsequence $\{x_{n_k}\}$ satisfying

$$\|x_{n_{k+1}} - x_{n_k}\|_p \leq 2^{-k}$$

and apply Lemma 19.5.2. The pointwise convergence of this subsequence was established in the proof of this lemma. This proves the theorem because if a subsequence of a Cauchy sequence converges, then the Cauchy sequence must also converge.

**Observation 19.5.4** If the measure space is Lebesgue measure then you have continuity of translation in $L^p(\mathbb{R}^n; X)$ in the usual way. More generally, for $\mu$ a Radon measure on $\Omega$ a locally compact Hausdorff space, $C_c(\Omega; X)$ is dense in $L^p(\Omega; X)$. Here $C_c(\Omega; X)$ is the space of continuous $X$ valued functions which have compact support in $\Omega$. The proof of this little observation follows immediately from approximating with simple functions and then applying the appropriate considerations to the simple functions.

Clearly Fatou’s lemma and the monotone convergence theorem make no sense for functions with values in a Banach space but the dominated convergence theorem holds in this setting.

**Theorem 19.5.5** If $x$ is strongly measurable and $x_n(s) \to x(s)$ a.e. with

$$\|x_n(s)\| \leq g(s) \text{ a.e.}$$

where $g \in L^1(\Omega)$, then $x$ is Bochner integrable and

$$\int_{\Omega} x(s) \, d\mu = \lim_{n \to \infty} \int_{\Omega} x_n(s) \, d\mu.$$
Proof: \( \|x_n(s) - x(s)\| \leq 2g(s) \) a.e. so by the usual dominated convergence theorem,
\[
0 = \lim_{n \to \infty} \int_{\Omega} \|x_n(s) - x(s)\| \, d\mu.
\]
Also,
\[
\int_{\Omega} \|x_n(s) - x_m(s)\| \, d\mu
\leq \int_{\Omega} \|x_n(s) - x(s)\| \, d\mu + \int_{\Omega} \|x_m(s) - x(s)\| \, d\mu,
\]
and so \( \{x_n\} \) is a Cauchy sequence in \( L^1(\Omega; X) \). Therefore, by Theorem 19.5.3, there exists \( y \in L^1(\Omega; X) \) and a subsequence \( x_{n'} \) satisfying
\[
x_{n'}(s) \to y(s) \text{ a.e. and in } L^1(\Omega; X).
\]
But \( x(s) = \lim_{n' \to \infty} x_{n'}(s) \) a.e. and so \( x(s) = y(s) \) a.e. Hence
\[
\int_{\Omega} \|x(s)\| \, d\mu = \int_{\Omega} \|y(s)\| \, d\mu < \infty
\]
which shows that \( x \) is Bochner integrable. Finally, since the integral is linear,
\[
\left\| \int_{\Omega} x(s) \, d\mu - \int_{\Omega} x_n(s) \, d\mu \right\|
\leq \int_{\Omega} \|x(s) - x_n(s)\| \, d\mu,
\]
and this last integral converges to 0. This proves the theorem.

One can also give a version of the Vitali convergence theorem.

**Definition 19.5.6** Let \( \mathcal{A} \subseteq L^1(\Omega; X) \). Then \( \mathcal{A} \) is said to be uniformly integrable if for every \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that whenever \( \mu(E) < \delta \), it follows
\[
\int_E \|f\|_X \, d\mu < \varepsilon
\]
for all \( f \in \mathcal{A} \). It is bounded if
\[
\sup_{f \in \mathcal{A}} \int_{\Omega} \|f\|_X \, d\mu < \infty.
\]

**Theorem 19.5.7** Let \( (\Omega, \mathcal{F}, \mu) \) be a finite measure space and let \( X \) be a separable Banach space. Let \( \{f_n\} \subseteq L^1(\Omega; X) \) be uniformly integrable and bounded such that \( f_n(\omega) \to f(\omega) \) for each \( \omega \in \Omega \). Then \( f \in L^1(\Omega; X) \) and
\[
\lim_{n \to \infty} \int_{\Omega} \|f_n - f\|_X \, d\mu = 0.
\]
19.5. * THE SPACES $L^p(\Omega; X)$

**Proof:** Let $\varepsilon > 0$ be given. Then by uniform integrability there exists $\delta > 0$ such that if $\mu(E) < \delta$ then

$$\int_E ||f_n|| \, d\mu < \varepsilon/3.$$ 

By Fatou’s lemma the same inequality holds for $f$. Also Fatou’s lemma shows $f \in L^1(\Omega; X)$, $f$ being measurable because of Theorem [8.3.11].

By Egoroff’s theorem, Theorem 4.3.11, there exists a set of measure less than $\delta$, $E$ such that the convergence of $\{f_n\}$ to $f$ is uniform off $E$. Therefore,

$$\int_{\Omega} ||f - f_n|| \, d\mu \leq \int_E (||f||_X + ||f_n||_X) \, d\mu + \int_{E^C} ||f - f_n||_X \, d\mu$$

$$< \frac{2\varepsilon}{3} + \int_{E^C} (\mu(E) + 1) \frac{\varepsilon}{3} \, d\mu < \varepsilon$$

if $n$ is large enough. This proves the theorem.

Note that a convenient way to achieve uniform integrability is to simply say $\{f_n\}$ is bounded in $L^p(\Omega; X)$ for some $p > 1$. This follows from Hölder’s inequality.

$$\int_{\Omega} ||f_n|| \, d\mu \leq \left( \int_{\Omega} \mu \right)^{1/p'} \left( \int_{\Omega} ||f_n||^p \, d\mu \right)^{1/p}.$$

The following theorem is interesting.

**Theorem 19.5.8** Let $1 \leq p < \infty$ and let $p < r \leq \infty$. Then $L^r([0,T] ; X)$ is a Borel subset of $L^p([0,T] ; X)$. Letting $C([0,T] ; X)$ denote the functions having values in $X$ which are continuous, $C([0,T] ; X)$ is also a Borel subset of $L^p([0,T] ; X)$. Here the measure is ordinary one dimensional Lebesque measure on $[0,T]$.

**Proof:** First consider the claim about $L^r([0,T] ; X)$. Let

$$B_M \equiv \left\{ x \in L^p([0,T] ; X) : ||x||_{L^r([0,T]; X)} \leq M \right\}.$$

Then $B_M$ is a closed subset of $L^p([0,T] ; X)$. Here is why. If $\{x_n\}$ is a sequence of elements of $B_M$ and $x_n \to x$ in $L^p([0,T] ; X)$, then passing to a subsequence, still denoted by $x_n$, it can be assumed $x_n(s) \to x(s)$ a.e. Hence Fatou’s lemma can be applied to conclude

$$\int_0^T ||x(s)||^r \, ds \leq \lim inf_{n \to \infty} \int_0^T ||x_n(s)||^r \, ds \leq M^r < \infty.$$

Now $\bigcup_{M=1}^\infty B_M = L^r([0,T] ; X)$. Note this did not depend on the measure space used. It would have been equally valid on any measure space.

Consider now $C([0,T] ; X)$. The norm on this space is the usual norm, $||\cdot||_\infty$. The argument above shows $||\cdot||_\infty$ is a Borel measurable function on $L^p([0,T] ; X)$. This is because $B_M \equiv \left\{ x \in L^p([0,T] ; X) : ||x||_\infty \leq M \right\}$ is a closed, hence Borel subset of $L^p([0,T] ; X)$. Now let $\theta \in L(L^p([0,T] ; X), L^p(\mathbb{R}; X))$ such that
\( \theta(x(t)) = x(t) \) for all \( t \in [0, T] \) and also \( \theta \in \mathcal{L}(C([0, T]; X), BC(\mathbb{R}; X)) \) where \( BC(\mathbb{R}; X) \) denotes the bounded continuous functions with a norm given by

\[
\|x\| \equiv \sup_{t \in \mathbb{R}} \|x(t)\|, 
\]

and \( \theta x \) has compact support.

For example, you could define

\[
x(t) = \begin{cases} 
x(t) & \text{if } t \in [0, T] \\
x(2T - t) & \text{if } t \in [T, 2T] \\
x(-t) & \text{if } t \in [-T, 0] \\
0 & \text{if } t \notin [-T, 2T]
\end{cases}
\]

and let \( \Phi \in C_c^\infty(-T, 2T) \) such that \( \Phi(t) = 1 \) for \( t \in [0, T] \). Then you could let

\[
\theta x(t) \equiv \Phi(t) \bar{x}(t).
\]

Then let \( \{\phi_n\} \) be a mollifier and define

\[
\psi_n x(t) \equiv \phi_n * \theta x(t).
\]

It follows \( \psi_n x \) is uniformly continuous because

\[
\|\psi_n x(t) - \psi_n x(t')\|_X 
\leq \int_{\mathbb{R}} |\phi_n(t' - s) - \phi_n(t - s)| \|\theta x(s)\|_X \, ds 
\leq C \||x\|_p \left( \int_{\mathbb{R}} |\phi_n(t' - s) - \phi_n(t - s)|^{p'} \, ds \right)^{1/p'}
\]

Also for \( x \in C([0, T]; X) \), it follows from usual mollifier arguments that

\[
\|\psi_n x - x\|_{L^\infty([0, T]; X)} \to 0.
\]

Here is why. For \( t \in [0, T] \),

\[
\|\psi_n x(t) - x(t)\|_X 
\leq \int_{\mathbb{R}} \phi_n(s) \|\theta x(t - s) - \theta x(t)\|_X \, ds 
\leq C_\theta \int_{-1/n}^{1/n} \phi_n(s) \, ds \varepsilon = C_\theta \varepsilon
\]

provided \( n \) is large enough due to the compact support and consequent uniform continuity of \( \theta x \).

If \( \|\psi_n x - x\|_{L^\infty([0, T]; X)} \to 0 \), then \( \{\psi_n x\} \) must be a Cauchy sequence in \( C([0, T]; X) \) and this requires that \( x \) equals a continuous function a.e. Thus \( C([0, T]; X) \) consists exactly of those functions, \( x \) of \( L^p([0, T]; X) \) such that \( \|\psi_n x - x\|_\infty \to 0 \). It follows

\[
C([0, T]; X) =
\]
19.5. THE SPACES $L^p(\Omega; X)$

\[ \cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{k=m}^{\infty} \left\{ x \in L^p([0, T]; X) : \| \psi_k x - x \|_\infty \leq \frac{1}{n} \right\} . \quad (19.5.34) \]

It only remains to show

\[ S \equiv \{ x \in L^p([0, T]; X) : \| \psi_k x - x \|_\infty \leq \alpha \} \]

is a Borel set. Suppose then that $x_n \in S$ and $x_n \to x$ in $L^p([0, T]; X)$. Then there exists a subsequence, still denoted by $n$ such that $x_n \to x$ pointwise a.e. as well as in $L^p$. There exists a set of measure 0 such that for all $n$; and $t$ not in this set,

\[ \| \psi_k x_n(t) - x_n(t) \| \leq \alpha \]

Then

\[ \| \psi_k x_n(t) - x_n(t) - (\psi_k x(t) - x(t)) \| \leq \| \int_{-1/k}^{1/k} \phi_k(s) (\theta x_n(t - s) - \theta x(t - s)) ds \| \]

which converges to 0 as $n \to \infty$. It follows that for a.e. $t$,

\[ \| \psi_k x(t) - x(t) \| \leq \alpha. \]

Thus $S$ is closed and so the set in $L^p(0, T; X)$ is a Borel set. This proves the theorem.

As in the scalar case, the following lemma holds in this more general context.

**Lemma 19.5.9** Let $(\Omega, \mu)$ be a regular measure space where $\Omega$ is a locally compact Hausdorff space. Then $C_c(\Omega; X)$ the space of continuous functions having compact support and values in $X$ is dense in $L^p(0, T; X)$ for all $p \in [0, 1)$. For any $\sigma$ finite measure space, the simple functions are dense in $L^p(0, T; X)$.

**Proof:** First is it shown the simple functions are dense in $L^p(0, T; X)$. Let $f \in L^p(0, T; X)$ and let $\{x_n\}$ denote a sequence of simple functions which converge to $f$ pointwise which also have the property that

\[ \| x_n(s) \| \leq 2 \| f(s) \| \]

Then

\[ \int_{\Omega} \| x_n(s) - f(s) \|^p d\mu \to 0 \]

from the dominated convergence theorem. Therefore, the simple functions are indeed dense in $L^p(0, T; X)$.

Next suppose $(\Omega, \mu)$ is a regular measure space. If $x(s) \equiv \sum_i a_i \chi_{E_i}(s)$ is a simple function, then by regularity, there exist compact sets, $K_i$ and open sets, $V_i$
such that \( K_i \subseteq E_i \subseteq V_i \) and \( \mu (V_i \setminus K_i)^{1/p} < \varepsilon / \sum_i ||a_i|| \). Let \( K_i \prec h_i \prec V_i \). Then consider

\[
\sum_i a_i h_i \in C_c (\Omega).
\]

By the triangle inequality,

\[
\left( \int_{\Omega} \left\| \sum_i a_i h_i (s) - a_i X_{E_i} (s) \right\|^p d\mu \right)^{1/p} \\
\leq \sum_i \left( \int_{\Omega} \left\| a_i \right\|^p |h_i (s) - X_{E_i} (s)|^p d\mu \right)^{1/p} \\
\leq \sum_i \left( \int_{\Omega} \left\| a_i \right\|^p \mu (V_i \setminus K_i)^{1/p} \right) \\
\leq \sum_i \left\| a_i \right\| \mu (V_i \setminus K_i)^{1/p} < \varepsilon
\]

Since \( \varepsilon \) is arbitrary, this and the first part of the lemma shows \( C_c (\Omega; X) \) is dense in \( L^p (\Omega; X) \).

### 19.6 Measurable Representatives

In this section consider the special case where \( X = L^1 (B, \nu) \) where \( (B, \mathcal{F}, \nu) \) is a \( \sigma \) finite measure space and \( x \in L^1 (\Omega; X) \). Thus for each \( s \in \Omega \), \( x (s) \in L^1 (B, \nu) \). In general, the map

\[
(s, t) \rightarrow x (s) (t)
\]

will not be product measurable, but one can obtain a measurable representative. This is important because it allows the use of Fubini’s theorem on the measurable representative.

By Theorem 19.2.3, there exists a sequence of simple functions, \( \{x_n\} \), of the form

\[
x_n (s) = \sum_{k=1}^m a_k X_{E_k} (s) \quad (19.6.35)
\]

where \( a_k \in L^1 (B, \nu) \) which satisfy the conditions of Definition 19.2.3 and

\[
\|x_n - x_m\|_{L^1 (\Omega; L^1 (B))} \to 0 \text{ as } m, n \to \infty \quad (19.6.36)
\]
For such a simple function, you can assume the $E_k$ are disjoint and then
\[
\|x_n\|_{L^1(\Omega, L^1(B))} = \sum_{k=1}^{m} \|a_k\|_{L^1(B)} \mu(E_k) = \sum_{k=1}^{m} \int_B |a_k| \, d\mu(E_k) = \int_{\Omega} \int_B |a_k(t)| \, d\nu(t) \, \mathcal{X}_{E_k}(s) \, d\mu(s) = \int_{\Omega} \int_B |x_n| \, d\nu.
\]
Also, each $x_n$ is product measurable. Thus from 19.6.36,
\[
\|x_n - x_m\|_{L^1(\Omega, L^1(B))} = \int_{\Omega} \int_B |x_n - x_m| \, d\nu \, d\mu
\]
which shows that \(\{x_n\}\) is a Cauchy sequence in \(L^1(\Omega \times B, \mu \times \lambda)\). Then there exists \(y \in L^1(\Omega \times B, \mu \times \lambda)\) and a subsequence still called \(\{x_n\}\) such that
\[
\lim_{n \to \infty} \int_{\Omega} \int_B |x_n - y| \, d\nu \, d\mu = \lim_{n \to \infty} \int_{\Omega} \|x_n - y\|_{L^1(B)} \, d\mu = \|x_n - y\|_{L^1(\Omega, L^1(B))} = 0.
\]
Now consider 19.6.36. Since \(\lim_{m \to \infty} x_m(s) = x(s)\) in \(L^1(B)\), it follows from Fatou’s lemma that
\[
\|x_n - x\|_{L^1(\Omega, L^1(B))} \leq \liminf_{m \to \infty} \|x_n - x_m\|_{L^1(\Omega, L^1(B))} < \varepsilon
\]
for all \(n\) large enough. Hence
\[
\lim_{n \to \infty} \|x_n - x\|_{L^1(\Omega, L^1(B))} = 0
\]
and so
\[
x(s) = y(s) \text{ in } L^1(B) \text{ } \mu \text{ a.e. } s.
\]
In particular, for a.e. \(s\), it follows that
\[
x(s)(t) = y(s, t) \text{ for a.e. } t.
\]
Now \(\int_{\Omega} x(s) \, d\mu \in X = L^1(B, \nu)\) so it makes sense to ask for \((\int_{\Omega} x(s) \, d\mu)(t)\), at least \(\mu \text{ a.e. } t\). To find what this is, note
\[
\left\| \int_{\Omega} x_n(s) \, d\mu - \int_{\Omega} x(s) \, d\mu \right\|_X \leq \int_{\Omega} \|x_n(s) - x(s)\|_X \, d\mu.
\]
Therefore, since the right side converges to 0,
\[
\lim_{n \to \infty} \left\| \int_{\Omega} x_n(s) \, d\mu - \int_{\Omega} x(s) \, d\mu \right\|_X = \lim_{n \to \infty} \int_B \left( \int_{\Omega} x_n(s) \, d\mu \right)(t) - \left( \int_{\Omega} x(s) \, d\mu \right)(t) \, d\nu = 0.
\]
CHAPTER 19. THE BOCHNER INTEGRAL

But
\[ \left( \int_{\Omega} x_n(s) \, d\mu \right)(t) = \int_{\Omega} x_n(s,t) \, d\mu \text{ a.e. } t. \]

Therefore
\[ \lim_{n \to \infty} \int_B \left| \int_{\Omega} x_n(s,t) \, d\mu - \left( \int_{\Omega} x(s) \, d\mu \right)(t) \right| \, d\nu = 0. \] (19.6.37)

Also, since \( x_n \to y \) in \( L^1(\Omega \times B) \),
\[ 0 = \lim_{n \to \infty} \int_B \int_{\Omega} |x_n(s,t) - y(s,t)| \, d\mu \, d\nu \geq \]
\[ \lim_{n \to \infty} \int_B \left| \int_{\Omega} x_n(s,t) \, d\mu - \int_{\Omega} y(s,t) \, d\mu \right| \, d\nu. \] (19.6.38)

From (19.6.37) and (19.6.38)
\[ \int_{\Omega} y(s,t) \, d\mu = \left( \int_{\Omega} x(s) \, d\mu \right)(t) \text{ a.e. } t. \]

This proves the following theorem.

**Theorem 19.6.1** Let \( X = L^1(B) \) where \((B,F,\nu)\) is a \( \sigma \) finite measure space and let \( x \in L^1(\Omega; X) \). Then there exists a measurable representative, \( y \in L^1(\Omega \times B) \), such that
\[ x(s) = y(s, \cdot) \text{ a.e. } s \text{ in } \Omega, \text{ the equation in } L^1(B), \]
and
\[ \int_{\Omega} y(s,t) \, d\mu = \left( \int_{\Omega} x(s) \, d\mu \right)(t) \text{ a.e. } t. \]

19.7 Vector Measures

There is also a concept of vector measures.

**Definition 19.7.1** Let \( (\Omega, S) \) be a set and a \( \sigma \) algebra of subsets of \( \Omega \). A mapping
\[ F : S \to X \]
is said to be a vector measure if
\[ F(\bigcup_{i=1}^{\infty} E_i) = \sum_{i=1}^{\infty} F(E_i) \]
whenever \( \{E_i\}_{i=1}^{\infty} \) is a sequence of disjoint elements of \( S \). For \( F \) a vector measure,
\[ |F|(A) = \sup \{ \sum_{F \in \pi(A)} ||\mu(F)|| : \pi(A) \text{ is a partition of } A \}. \]
19.7. VECTOR MEASURES

This is the same definition that was given in the case where $F$ would have values in $\mathbb{C}$, the only difference being the fact that now $F$ has values in a general Banach space $X$ as the vector space of values of the vector measure. Recall that a partition of $A$ is a finite set, $\{F_1, \cdots, F_m\} \subseteq \mathcal{S}$ such that $\bigcup_{i=1}^m F_i = A$. The same theorem about $|F|$ proved in the case of complex valued measures holds in this context with the same proof. For completeness, it is included here.

**Theorem 19.7.2** If $|F|(\Omega) < \infty$, then $|F|$ is a measure on $\mathcal{S}$.

**Proof:** Let $E_1$ and $E_2$ be sets of $\mathcal{S}$ such that $E_1 \cap E_2 = \emptyset$ and let $\{A^1_1 \cdots A^i_n\} = \pi(E_i)$, a partition of $E_i$ which is chosen such that

$$|F|(E_i) - \varepsilon < \sum_{j=1}^{n_i} ||F(A^i_j)|| \quad i = 1, 2.$$

Consider the sets which are contained in either of $\pi(E_1)$ or $\pi(E_2)$, it follows this collection of sets is a partition of $E_1 \cup E_2$ which is denoted here by $\pi(E_1 \cup E_2)$. Then by the above inequality and the definition of total variation,

$$|F|(E_1 \cup E_2) \geq \sum_{F \in \pi(E_1 \cup E_2)} ||F(F)|| > |F|(E_1) + |F|(E_2) - 2\varepsilon,$$

which shows that since $\varepsilon > 0$ was arbitrary,

$$|F|(E_1 \cup E_2) \geq |F|(E_1) + |F|(E_2).$$

(19.7.39)

Let $\{E_j\}_{j=1}^\infty$ be a sequence of disjoint sets of $\mathcal{S}$ and let $E_\infty = \bigcup_{j=1}^\infty E_j$. Then by the definition of total variation there exists a partition of $E_\infty$, $\pi(E_\infty) = \{A_1, \cdots, A_n\}$ such that

$$|F|(E_\infty) - \varepsilon < \sum_{i=1}^n ||F(A_i)||.$$

Also,

$$A_i = \bigcup_{j=1}^\infty A_i \cap E_j$$

and so by the triangle inequality, $||F(A_i)|| \leq \sum_{j=1}^\infty ||F(A_i \cap E_j)||$. Therefore, by the above,

$$|F|(E_\infty) - \varepsilon \quad \leq \sum_{i=1}^n \sum_{j=1}^\infty ||F(A_i \cap E_j)||$$

$$= \sum_{j=1}^\infty \sum_{i=1}^n ||F(A_i \cap E_j)||$$

$$\leq \sum_{j=1}^\infty |F|(E_j)$$
because \( \{A_i \cap E_j\}_{i=1}^n \) is a partition of \( E_j \).

Since \( \varepsilon > 0 \) is arbitrary, this shows

\[
|F|(\bigcup_{j=1}^{\infty} E_j) \leq \sum_{j=1}^{\infty} |F|(E_j).
\]

Also, \( \text{(19.7.39)} \) implies that whenever the \( E_i \) are disjoint, \( |F|(\bigcup_{j=1}^{n} E_j) \geq \sum_{j=1}^{n} |F|(E_j) \).

Therefore,

\[
\sum_{j=1}^{\infty} |F|(E_j) \geq |F|(\bigcup_{j=1}^{n} E_j) \geq \sum_{j=1}^{n} |F|(E_j).
\]

Since \( n \) is arbitrary,

\[
|F|(\bigcup_{j=1}^{\infty} E_j) = \sum_{j=1}^{\infty} |F|(E_j)
\]

which shows that \( |F| \) is a measure as claimed. This proves the theorem.

**Definition 19.7.3** A Banach space is said to have the Radon Nikodym property if whenever

\[
(\Omega, \mathcal{S}, \mu) \text{ is a finite measure space}
\]

\[
F : \mathcal{S} \to X \text{ is a vector measure with } |F|(\Omega) < \infty
\]

\[
F \ll \mu
\]

then one may conclude there exists \( g \in L^1(\Omega; X) \) such that

\[
F(E) = \int_E g(s) \, d\mu
\]

for all \( E \in \mathcal{S} \).

Some Banach spaces have the Radon Nikodym property and some don’t. No attempt is made to give a complete answer to the question of which Banach spaces have this property but the next theorem gives examples of many spaces which do.

**Theorem 19.7.4** Suppose \( X' \) is a separable dual space. Then \( X' \) has the Radon Nikodym property.

**Proof:** Let \( F \ll \mu \) and let \( |F|(\Omega) < \infty \) for \( F : \mathcal{S} \to X' \), a vector measure. Pick \( x \in X \) and consider the map

\[
E \to F(E)(x)
\]

for \( E \in \mathcal{S} \). This defines a complex measure which is absolutely continuous with respect to \( |F| \). Therefore, by the Radon Nikodym theorem, there exists \( f_x \in L^1(\Omega, |F|) \) such that

\[
F(E)(x) = \int_E f_x(s) \, d|F|.
\] (19.7.40)
Claim: \(|f_x(s)| \leq |x|\) for \(|F|\) a.e. \(s\).

**Proof of claim:** Consider the closed ball in \(\mathbb{F}\), \(B(0,||x||)\) and let \(F = B(p, r)\) be an open ball contained in its complement. Let \(f_x^{-1}(B) \equiv E \in S\). I want to argue that \(|F|(E) = 0\) so suppose \(|F|(E) > 0\). Then

\[
|F|(E) ||x|| \geq ||F(E)|| ||x|| \geq |F(E)(x)|
\]
and so from (19.7.40),

\[
\frac{1}{|F|(E)} \left| \int_E f_x(s) d|F| \right| \leq ||x||. \tag{19.7.41}
\]
But on \(E, |f_x(s) - p| < r\) and so

\[
\frac{1}{|F|(E)} \left| \int_E f_x(s) d|F| - p \right| < r
\]
which contradicts (19.7.40) because \(B(p, r)\) was given to have empty intersection with \(B(0,||x||)\). Therefore, \(|F|(E) = 0\) as hoped. Now \(\mathbb{F} \setminus B(0,||x||)\) can be covered by countably many such balls and so \(|F|(\mathbb{F} \setminus B(0,||x||)) = 0\).

Denote the exceptional set of measure zero by \(N_x\). By Theorem 19.1.13, \(X\) is separable. Letting \(D\) be a dense, countable subset of \(X\), define

\[
N_1 = \bigcup_{x \in D} N_x.
\]
Thus

\[
|F|(N_1) = 0.
\]
For any \(E \in S, x, y \in D\), and \(a, b \in \mathbb{F}\),

\[
\int_E f_{ax + by}(s) d|F| = F(E)(ax + by) = aF(E)(x) + bF(E)(y)
\]
\[
= \int_E (af_x(s) + bf_y(s)) d|F|. \tag{19.7.42}
\]
Since (19.7.42) holds for all \(E \in S\), it follows

\[
f_{ax + by}(s) = af_x(s) + bf_y(s)
\]
for \(|F|\) a.e. \(s\) and \(x, y \in D\). Let \(\tilde{D}\) consist of all finite linear combinations of the form \(\sum_{i=1}^{m} a_i x_i\) where \(a_i\) is a rational point of \(\mathbb{F}\) and \(x_i \in D\). If

\[
\sum_{i=1}^{m} a_i x_i \in \tilde{D},
\]
the above argument implies

\[
f_{\sum_{i=1}^{m} a_i x_i}(s) = \sum_{i=1}^{m} a_i f_{x_i}(s) \text{ a.e.}
\]
Since \( \tilde{D} \) is countable, there exists a set, \( N_2 \), with
\[
|F|(N_2) = 0
\]
such that for \( s \notin N_2 \),
\[
\sum_{i=1}^{m} a_i x_i(s) = \sum_{i=1}^{m} a_i f_{x_i}(s) \quad (19.7.43)
\]
whenever \( \sum_{i=1}^{m} a_i x_i \in \tilde{D} \). Let
\[
N = N_1 \cup N_2
\]
and let
\[
\hat{h}_x(s) = \mathcal{X}_{N^c}(s) f_x(s)
\]
for all \( x \in \tilde{D} \). Now for \( x \in X \) define
\[
h_x(s) = \lim_{x' \to x} \{ \hat{h}_x(s) : x' \in \tilde{D} \}.
\]
This is well defined because if \( x' \) and \( y' \) are elements of \( \tilde{D} \), the above claim and \[
\int_E h_x(s) \, d|F| = \lim_{n \to \infty} \int_E \hat{h}_{x_n}(s) \, d|F| = \lim_{n \to \infty} F(E)(x_n) = F(E)(x). \quad (19.7.44)
\]
It follows from the density of \( \tilde{D} \) that for all \( x, y \in X \) and \( a, b \in \mathbb{F} \),
\[
|h_x(s)| \leq \|x\|, \quad h_{ax+by}(s) = ah_x(s) + bh_y(s), \quad (19.7.45)
\]
for all \( s \) because if \( s \in N \), both sides of the equation in \( 19.7.43 \) equal 0.

Let \( \theta(s) \) be given by
\[
\theta(s) = h_x(s).
\]
By \( 19.7.43 \) it follows that \( \theta(s) \in X' \) for each \( s \). Also
\[
\theta(s)(x) = h_x(s) \in L^1(\Omega)
\]
so \( \theta(\cdot) \) is weak * measurable. Since \( X' \) is separable, Theorem \( 19.1.12 \) implies that \( \theta \) is strongly measurable. Furthermore, by \( 19.7.43 \),
\[
||\theta(s)|| \equiv \sup_{||x|| \leq 1} |\theta(s)(x)| \leq \sup_{||x|| \leq 1} |h_x(s)| \leq 1.
\]
Therefore,
\[
\int_{\Omega} ||\theta(s)|| \, d|F| < \infty
\]
so \( \theta \in L^1(\Omega; X') \). By [19.7.46], if \( E \in \mathcal{S} \),

\[
\int_E h_x(s) \, d|F| = \int_E \theta(s)(x) \, d|F| = \left( \int_E \theta(s) \, d|F| \right)(x) = \left( \int_E \theta(s) \, d|F| \right)(x),
\]

(19.7.46)

From [19.7.46] and [19.7.40],

\[
\left( \int_E \theta(s) \, d|F| \right)(x) = F(E)(x)
\]

for all \( x \in X \) and therefore,

\[
\int_E \theta(s) \, d|F| = F(E).
\]

Finally, since \( F \ll \mu, |F| \ll \mu \) also and so there exists \( k \in L^1(\Omega) \) such that

\[
|F|(E) = \int_E k(s) \, d\mu
\]

for all \( E \in \mathcal{S} \), by the Radon Nikodym Theorem. It follows

\[
F(E) = \int_E \theta(s) \, d|F| = \int_E \theta(s) \, k(s) \, d\mu.
\]

Letting \( g(s) = \theta(s)k(s) \), this has proved the theorem.

**Corollary 19.7.5** Any separable reflexive Banach space has the Radon Nikodym property.

It is not necessary to assume separability in the above corollary. For the proof of a more general result, consult *Vector Measures* by Diestal and Uhl, [19].

### 19.8 The Riesz Representation Theorem

The Riesz representation theorem for the spaces \( L^p(\Omega; X) \) holds under certain conditions. The proof follows the proofs given earlier for scalar valued functions.

**Definition 19.8.1** If \( X \) and \( Y \) are two Banach spaces, \( X \) is isometric to \( Y \) if there exists \( \theta \in L(X, Y) \) such that

\[
\|\theta x\|_Y = \|x\|_X.
\]

This will be written as \( X \cong Y \). The map \( \theta \) is called an isometry.

The next theorem says that \( L^p(\Omega; X') \) is always isometric to a subspace of \((L^p(\Omega; X))'\) for any Banach space, \( X \).
Theorem 19.8.2 Let $X$ be any Banach space and let $(\Omega, S, \mu)$ be a finite measure space. Let $p \geq 1$ and let $1/p + 1/p' = 1$ (if $p = 1$, $p' \equiv \infty$). Then $L^{p'}(\Omega; X')$ is isometric to a subspace of $(L^p(\Omega; X))'$. Also, for $g \in L^{p'}(\Omega; X')$,

$$
\sup_{\|f\|_p \leq 1} \left| \int_\Omega g(s)(f(s)) \, d\mu \right| = \|g\|_{p'}.
$$

Proof: First observe that for $f \in L^p(\Omega; X)$ and $g \in L^{p'}(\Omega; X')$,

$$
s \mapsto g(s)(f(s))
$$

is a function in $L^1(\Omega)$. (To obtain measurability, write $f$ as a limit of simple functions. Holder’s inequality then yields the function is in $L^1(\Omega)$.) Define

$$
\theta : L^{p'}(\Omega; X') \to (L^p(\Omega; X))'
$$

by

$$
\theta g(f) = \int_\Omega g(s)(f(s)) \, d\mu.
$$

Holder’s inequality implies

$$
\|\theta g\| \leq \|g\|_{p'}.
$$

(19.8.47)

and it is also clear that $\theta$ is linear. Next it is required to show

$$
\|\theta g\| = \|g\|.
$$

This will first be verified for simple functions. Let

$$
g(s) = \sum_{i=1}^m c_i X_{E_i}(s)
$$

where $c_i \in X'$, the $E_i$ are disjoint and

$$
\bigcup_{i=1}^m E_i = \Omega.
$$

Then $\|g\| \in L^{p'}(\Omega)$. Let $\varepsilon > 0$ be given. By the scalar Riesz representation theorem, there exists $h \in L^p(\Omega)$ such that $\|h\|_p = 1$ and

$$
\int_\Omega \|g(s)||X' h(s)\, d\mu \geq \|g\|_{L^{p'}(\Omega; X')} - \varepsilon.
$$

Now let $d_i$ be chosen such that

$$
c_i(d_i) \geq \|c_i\|_{X'} - \varepsilon/\|h\|_{L^1(\Omega)}
$$

and $\|d_i\|_X \leq 1$. Let

$$
f(s) = \sum_{i=1}^m d_i h(s) X_{E_i}(s).
$$
Thus \( f \in L^p (\Omega; X) \) and \( \| f \|_{L^p(\Omega; X)} \leq 1 \). This follows from

\[
\| f \|_p^p = \int_\Omega \sum_{i=1}^m |d_i|_X^p |h(s)|^p X_E_i (s) \, d\mu
\]

\[
= \sum_{i=1}^m \left( \int_{E_i} |h(s)|^p \, d\mu \right) \| d_i \|_X^p \leq \int_\Omega |h|^p \, d\mu = 1.
\]

Also

\[
\| \theta g \| \geq |\theta g (f)| = \left| \int_\Omega g(s) (f(s)) \, d\mu \right| \geq \left| \int_\Omega g(s) \frac{\| c_i \|_{X'}}{\| h \|_{L^1(\Omega)}} h(s) X_E_i (s) \, d\mu \right|
\]

\[
\geq \left| \int_\Omega \| g(s) \|_{X'} h(s) \, d\mu \right| - \varepsilon \left| \int_\Omega h(s) \frac{\| c_i \|_{L^1(\Omega)}}{\| h \|_{L^1(\Omega)}} \, d\mu \right|
\]

\[
\geq \| g \|_{L^p'(\Omega; X')} - 2\varepsilon.
\]

Since \( \varepsilon \) was arbitrary,

\[
\| \theta g \| \geq \| g \| \tag{19.8.48}
\]

and from (19.8.47) this shows equality holds in (19.8.48) whenever \( g \) is a simple function.

In general, let \( g \in L^p' (\Omega; X') \) and let \( g_n \) be a sequence of simple functions converging to \( g \) in \( L^p' (\Omega; X') \). Then

\[
\| \theta g \| = \lim_{n \to \infty} \| \theta g_n \| = \lim_{n \to \infty} \| g_n \| = \| g \|.
\]

This proves the theorem and shows \( \theta \) is the desired isometry.

**Theorem 19.8.3** If \( X \) is a Banach space and \( X' \) has the Radon Nikodym property, then if \( (\Omega, S, \mu) \) is a finite measure space,

\[
(L^p (\Omega; X))' \cong L^{p'} (\Omega; X')
\]

and in fact the mapping \( \theta \) of Theorem 19.8.2 is onto.

**Proof:** Let \( l \in (L^p (\Omega; X))' \) and define \( F (E) \in X' \) by

\[
F (E) (x) \equiv l (X_E (\cdot) x).
\]

**Lemma 19.8.4** \( F \) defined above is a vector measure with values in \( X' \) and \( |F| (\Omega) < \infty \).

**Proof of the lemma:** Clearly \( F (E) \) is linear. Also

\[
\| F (E) \| = \sup_{|x| \leq 1} \| F (E) (x) \|.
\]
\[ \leq ||l|| \sup_{||x|| \leq 1} ||X_E (\cdot) x||_{L^p(\Omega, X)} \leq ||l|| \mu(E)^{1/p}. \]

Let \( \{E_i\}_{i=1}^{\infty} \) be a sequence of disjoint elements of \( S \) and let \( E = \bigcup_{n<\infty} E_n \).

\[
\left| F(E)(x) - \sum_{k=1}^{n} F(E_k)(x) \right| = \left| l(X_E (\cdot) x - \sum_{i=1}^{n} l(X_{E_i}(\cdot) x) \right|
\leq ||l|| \left| X_E (\cdot) x - \sum_{i=1}^{n} X_{E_i}(\cdot) x \right|_{L^p(\Omega, X)}
\leq ||l|| \mu \left( \bigcup_{k>n} E_k \right)^{1/p} ||l||. \tag{19.8.49}
\]

Since \( \mu(\Omega) < \infty \),

\[
\lim_{n \to \infty} \mu \left( \bigcup_{k>n} E_k \right)^{1/p} = 0
\]
and so inequality (19.8.49) shows that

\[
\lim_{n \to \infty} \left| F(E) - \sum_{k=1}^{n} F(E_k) \right|_{X'} = 0.
\]

To show \( |F|(\Omega) < \infty \), let \( \varepsilon > 0 \) be given, let \( \{H_1, \ldots, H_n\} \) be a partition of \( \Omega \), and let \( ||x_i|| \leq 1 \) be chosen in such a way that

\[
F(H_i)(x_i) > |F(H_i)| - \varepsilon/n.
\]

Thus

\[
-\varepsilon + \sum_{i=1}^{n} |F(H_i)| < \sum_{i=1}^{n} l(X_{H_i}(\cdot) x_i) \leq ||l|| \sum_{i=1}^{n} X_{H_i}(\cdot) x_i \]
\[
\leq ||l|| \left( \int_{\Omega} \sum_{i=1}^{n} X_{H_i}(s) d\mu \right)^{1/p} = ||l|| \mu(\Omega)^{1/p}.
\]

Since \( \varepsilon > 0 \) was arbitrary,

\[
\sum_{i=1}^{n} |F(H_i)| < ||l|| \mu(\Omega)^{1/p}.
\]

Since the partition was arbitrary, this shows \( |F|(\Omega) \leq ||l|| \mu(\Omega)^{1/p} \) and this proves the lemma.

Continuing with the proof of Theorem 19.8.3, note that

\( F \ll \mu \).
Since $X'$ has the Radon Nikodym property, there exists $g \in L^1(\Omega; X')$ such that

$$F(E) = \int_E g(s) \, d\mu.$$  

Also, from the definition of $F(E)$,

$$l\left(\sum_{i=1}^n x_i \chi_{E_i}(\cdot)\right) = \sum_{i=1}^n l(\chi_{E_i}(\cdot)x_i)$$

$$= \sum_{i=1}^n F(E_i)x_i = \sum_{i=1}^n \int_{E_i} g(s)(x_i) \, d\mu. \quad (19.8.50)$$

It follows from (19.8.50) that whenever $h$ is a simple function,

$$l(h) = \int_{\Omega} g(s)(h(s)) \, d\mu. \quad (19.8.51)$$

Let

$$G_n \equiv \{s : \|g(s)\|_{X'} \leq n\}$$

and let

$$j : L^p(G_n; X) \to L^p(\Omega; X)$$

be given by

$$jh(s) = \begin{cases} h(s) & \text{if } s \in G_n, \\ 0 & \text{if } s \notin G_n. \end{cases}$$

Letting $h$ be a simple function in $L^p(G_n; X)$,

$$j^*l(h) = l(jh) = \int_{G_n} g(s)(h(s)) \, d\mu. \quad (19.8.52)$$

Since the simple functions are dense in $L^p(G_n; X)$, and $g \in L^{p'}(G_n; X')$, it follows that (19.8.52) holds for all $h \in L^p(G_n; X)$. By Theorem (19.8.2),

$$\|g\|_{L^{p'}(G_n; X')} = \|j^*l\|_{(L^p(G_n; X))'} \leq \|l\|_{(L^p(\Omega; X))'}.$$

By the monotone convergence theorem,

$$\|g\|_{L^{p'}(\Omega; X')} = \lim_{n \to \infty} \|g\|_{L^{p'}(G_n; X')} \leq \|l\|_{(L^p(\Omega; X))'}.$$

Therefore $g \in L^{p'}(\Omega; X')$ and since simple functions are dense in $L^p(\Omega; X)$, (19.8.51) holds for all $h \in L^p(\Omega; X)$. Thus $l = \theta g$ and the theorem is proved because, by Theorem (19.8.2), $\|l\| = \|g\|$ and the mapping $\theta$ is onto because $l$ was arbitrary. 

As in the scalar case, everything generalizes to the case of $\sigma$ finite measure spaces. The proof is almost identical.
**Lemma 19.8.5** Let \((\Omega, \mathcal{S}, \mu)\) be a \(\sigma\) finite measure space and let \(X\) be a Banach space such that \(X'\) has the Radon Nikodym property. Then there exists a measurable function, \(r\) such that \(r(x) > 0\) for all \(x\), such that \(|r(x)| \leq M\) for all \(x\), and \(\int r\,d\mu < \infty\). For \(\Lambda \in (L^p(\Omega; X))', \ p \geq 1\), there exists a unique \(h \in L^p(\Omega; X'), \ L^\infty(\Omega; X')\) if \(p = 1\) such that

\[ \Lambda f = \int h(f) \, d\mu. \]

Also \(|h| = |\Lambda|\). (\(|h| = |h|_{p'}\) if \(p > 1\), \(|h|_{\infty}\) if \(p = 1\). Here

\[ \frac{1}{p} + \frac{1}{p'} = 1. \]

**Proof:** First suppose \(r\) exists as described. Also, to save on notation and to emphasize the similarity with the scalar case, denote the norm in the various spaces by \(|\cdot|\). Define a new measure \(\bar{\mu}\), according to the rule

\[ \bar{\mu}(E) \equiv \int_E r \, d\mu. \quad (19.8.53) \]

Thus \(\bar{\mu}\) is a finite measure on \(\mathcal{S}\). Now define a mapping, \(\eta : L^p(\Omega; X, \mu) \to L^p(\Omega; X, \bar{\mu})\) by

\[ \eta f = r^{-\frac{1}{p}} f. \]

Then

\[ ||\eta f||_{L^p(\bar{\mu})}^p = \int \left| r^{-\frac{1}{p}} f \right|^p r \, d\mu = ||f||_{L^p(\mu)}^p \]

and so \(\eta\) is one to one and in fact preserves norms. I claim that also \(\eta\) is onto. To see this, let \(g \in L^p(\Omega; X, \bar{\mu})\) and consider the function, \(r^{-\frac{1}{p}} g\). Then

\[ \int |r^{-\frac{1}{p}} g|^p \, d\mu = \int |g|^p \, r \, d\mu = \int |g|^p \, d\bar{\mu} < \infty \]

Thus \(r^{-\frac{1}{p}} g \in L^p(\Omega; X, \mu)\) and \(\eta \left( r^{-\frac{1}{p}} g \right) = g\) showing that \(\eta\) is onto as claimed. Thus \(\eta\) is one to one, onto, and preserves norms. Consider the diagram below which is descriptive of the situation in which \(\eta^*\) must be one to one and onto.

\[ \begin{array}{ccc}
  h, L^p(\bar{\mu}) & \xrightarrow{\eta^*} & L^p(\mu)', \Lambda \\
  L^p(\bar{\mu}) & \xrightarrow{\eta} & L^p(\mu), \Lambda \\
  \end{array} \]

Then for \(\Lambda \in L^p(\mu)', \) there exists a unique \(\tilde{\Lambda} \in L^p(\bar{\mu})\) such that \(\eta^* \tilde{\Lambda} = \Lambda, \|\tilde{\Lambda}\| = |\Lambda|\). By the Riesz representation theorem for finite measure spaces, there exists
19.8. THE RIESZ REPRESENTATION THEOREM

a unique \( h \in L^p (\mu) \equiv L^p (\Omega; X', \mu) \) which represents \( \Lambda \) in the manner described in the Riesz representation theorem. Thus \( \| h \|_{L^p (\mu)} = \| \Lambda \| \) and for all \( f \in L^p (\mu) \),

\[
\Lambda (f) = \eta^* \Lambda (f) \equiv \Lambda (\eta f) = \int h (\eta f) \, d\mu = \int r h \left( r^{-\frac{1}{p}} f \right) \, d\mu.
\]

Now

\[
\int \left| r \frac{r}{p} h \right|^{p'} \, d\mu = \int |h|^{p'} \, r \, d\mu = \| h \|_{L^p (\mu)}^{p'} < \infty.
\]

Thus \( \| r \frac{r}{p} h \|_{L^p (\mu)} = \| h \|_{L^p (\mu)}^{p'} = \| \Lambda \| = \| \Lambda \| \) and represents \( \Lambda \) in the appropriate way. If \( p = 1 \), then \( 1/p' \equiv 0 \). Now consider the existence of \( r \). Since the measure space is \( \sigma \) finite, there exist \( \{ \Omega_n \} \) disjoint, each having positive measure and their union equals \( \Omega \). Then define

\[
r (\omega) \equiv \sum_{n=1}^{\infty} \frac{1}{n^2} \mu (\Omega_n) \lambda_n (\omega).
\]

This proves the Lemma.

**Theorem 19.8.6** (Riesz representation theorem) Let \((\Omega, \mathcal{S}, \mu)\) be \( \sigma \) finite and let \( X' \) have the Radon Nikodym property. Then for

\[
| \Lambda (f) | = \eta^* \Lambda (f) \equiv \Lambda (\eta f) = \int h (\eta f) \, d\mu = \int r h \left( r^{-\frac{1}{p}} f \right) \, d\mu
\]

there exists a unique \( h \in L^q (\Omega, X', \mu) \) if \( p = 1 \) such that

\[
\Lambda f = \int h (f) \, d\mu.
\]

Also \( \| h \| = \| \Lambda \| \) if \( p > 1 \), \( \| h \|_q = \| h \|_\infty \) if \( p = 1 \). Here

\[
\frac{1}{p} + \frac{1}{q} = 1.
\]

**Proof:** The above lemma gives the existence part of the conclusion of the theorem. Uniqueness is done as before.

**Corollary 19.8.7** If \( X' \) is separable, then for \((\Omega, \mathcal{S}, \mu)\) a \( \sigma \) finite measure space,

\[
(\text{L}^p (\Omega; X))' \cong L^{p'} (\Omega; X').
\]

**Corollary 19.8.8** If \( X \) is separable and reflexive, then for \((\Omega, \mathcal{S}, \mu)\) a \( \sigma \) finite measure space,

\[
(\text{L}^p (\Omega; X))' \cong L^{p'} (\Omega; X').
\]
Corollary 19.8.9 If $X$ is separable and reflexive and $(\Omega, \mathcal{S}, \mu)$ a $\sigma$ finite measure space, then if $p \in (1, \infty)$, then $L^p(\Omega; X)$ is reflexive.

Proof: This is just like the scalar valued case.

Here is an interesting example. Obviously $L^\infty(0, T, H)$ is not separable with the normed topology. However, bounded sets turn out to be metric spaces which are complete and separable. This is the next lemma. A Polish space is a complete separable metric space. In this example, $H$ is a separable real Hilbert space or more generally a separable real Banach space.

Lemma 19.8.10 Let $B = \overline{B(0, L)}$ be a closed ball in $L^\infty(0, T, H)$. Then $B$ is a Polish space with respect to the weak * topology. The closure is taken with respect to the usual topology.

Proof: Let $\{z_k\}_{k=1}^\infty = X$ be a dense countable subspace in $L^1(0, T, H)$. You start with a dense countable set and then consider all finite linear combinations having coefficients in $\mathbb{Q}$. Then the metric on $B$ is

$$d(f, g) = \sum_{k=1}^\infty 2^{-k} \frac{|\langle f - g, z_k \rangle|_{L^\infty, L^1}}{1 + |\langle f - g, z_k \rangle|_{L^\infty, L^1}}$$

Is $B$ complete? Suppose you have a Cauchy sequence $\{f_n\}$. This happens if and only if $\{(f_n, z_k)\}_{k=1}^\infty$ is a Cauchy sequence for each $k$. Therefore, there exists $\xi(z_k) = \lim_{n \to \infty} (f_n, z_k)$. Then for $a, b \in \mathbb{Q}$, and $z, w \in X$

$$\xi(az + bw) = \lim_{n \to \infty} \langle f_n, az + bw \rangle = \lim_{n \to \infty} a \langle f_n, z \rangle + b \langle f_n, w \rangle = a\xi(z) + b\xi(w)$$

showing that $\xi$ is linear on $X$ a dense subspace of $L^1(0, T, H)$. Is $\xi$ bounded on this dense subspace with bound $L$? For $z \in X$

$$|\xi(z)| = \lim_{n \to \infty} |\langle f_n, z \rangle| \leq \lim_{n \to \infty} \|f_n\|_{L^\infty} \|z\|_{L^1} \leq L \|z\|_{L^1}$$

Hence $\xi$ is also bounded on this dense subset of $L^1(0, T, H)$. Therefore, there is a unique bounded linear extension of $\xi$ to all of $L^1(0, T, H)'$ is no larger than $L$. It follows from the Riesz representation theorem that there exists a unique $f \in L^\infty(0, T, H)$ such that for all $w \in L^1(0, T, H)$, $\xi(w) = \langle f, w \rangle$ and $\|f\| \leq L$. This $f$ is the limit of the Cauchy sequence $\{f_n\}$ in $B$. Thus $B$ is complete.

Is $B$ separable? Let $f \in B$. Let $\varepsilon > 0$ be given. Choose $M$ such that

$$\sum_{k=M+1}^\infty 2^{-k} < \frac{\varepsilon}{4}$$

Then the finite set $\{z_1, \ldots, z_M\}$ is uniformly integrable. There exists $\delta > 0$ such that if $m(S) < \delta$, then

$$\int_S |z_k|_H \, dm < \left(\frac{\varepsilon}{4 (1 + \|f\|_{L^\infty})}\right)$$
Then there is a sequence of simple functions \( \{ s_n \} \) which converge uniformly to \( f \) off a set of measure zero, \( N, \| s_n \|_{L^\infty} \leq \| f \|_{L^\infty} \). By regularity of the measure, there exists a continuous function with compact support \( h_n \) such that \( s_n = h_n \) off a set of measure no more than \( \frac{\delta}{4^n} \) and also \( \| h_n \|_{L^\infty} \leq \| f \|_{L^\infty} \). Then off a set of measure no more than \( \frac{1}{2} \delta \), \( h_n (r) \to f (r) \). Now by Egorov’s theorem and outer regularity, one can enlarge this exceptional set to obtain an open set \( S \) of measure no more than \( \delta/2 \) such that the convergence is uniform off this exceptional set. Thus \( f \) equals the uniform limit of continuous functions on \( S^c \). Define

\[
h (r) = \begin{cases} 
\lim_{n \to \infty} h_n (r) = f (r) & \text{on } S^c \\
0 & \text{on } S \setminus N \\
0 & \text{on } N
\end{cases}
\]

Then \( \| h \|_{L^\infty} \leq \| f \|_{L^\infty} \). Now consider

\[
h \ast \psi_m (r)
\]

where \( \psi_r \) is approximate identity.

\[
\psi_m (t) = \frac{1}{2} m \chi_{[-1/m,1/m]} (t) , \quad h \ast \psi_m (t) = \frac{1}{2} m \int_{-1/m}^{1/m} h (t - s) ds = \frac{1}{2} m \int_{-1/m}^{t+1/m} h (s) ds
\]

where we define \( \tilde{h} \) to be the 0 extension of \( h \) off \([0,T]\). This is a continuous function of \( t \). Also \( a.e.t \) is a Lebesgue point and so for \( a.e.t \),

\[
\left| \frac{1}{2} m \int_{-1/m}^{t+1/m} \tilde{h} (s) ds - \tilde{h} (t) \right| \to 0
\]

\[
|h \ast \psi_m (r)| \equiv \int_R \tilde{h} (r - s) \psi_m (s) ds \leq \| h \|_{L^\infty} \leq \| f \|_{L^\infty}
\]

Thus this continuous function is in \( L^\infty (0,T,H) \). Letting \( z = z_k \in L^1 (0,T,H) \) be one of those defined above,

\[
\int_0^T \langle h \ast \psi_m (t) - f (t) , z (t) \rangle dt \leq \int_0^T \langle h \ast \psi_m (t) - h (t) , z (t) \rangle dt + \int_0^T \| (h (t) - f (t)) , z (t) \| dt \tag{19.8.54}
\]

for \( a.e. \ t, h \ast \psi_m (t) - h (t) \to 0 \) and the integrand in the first integral is bounded by \( 2 \| f \|_{L^\infty} \| z (t) \|_H \) so by the dominated convergence theorem, as \( m \to \infty \), the first integral converges to 0. As to the second, it is dominated by

\[
\int_S \| (h (t) - f (t)) , z (t) \| dt \leq 2 \| f \|_{L^\infty} \int_S \| z (t) \| dt < \frac{2 \| f \|_{L^\infty}}{4 (1 + \| f \|_{L^\infty})} \leq \frac{\varepsilon}{2}
\]
Therefore, choosing $m$ large enough so that the first integral on the right is less than $\frac{\varepsilon}{4}$ for each $z_k$ for $k \leq M$, then for each of these,

$$d (f, h_{n\psi_m}) \leq \frac{\varepsilon}{4} + \sum_{k=1}^{M} 2^{-k} \frac{(\varepsilon/4) + (\varepsilon/2)}{1 + ((\varepsilon/4) + (\varepsilon/2))} = \frac{\varepsilon}{4} + \sum_{k=1}^{M} 2^{-k} \frac{3\varepsilon}{4} \frac{3\varepsilon}{4} + 1$$

which appears to show that $C ([0, T], H)$ is weak * dense in $L^\infty (0, T, H)$. However, this last space is obviously separable in terms of the norm topology. Let $D$ be a countable dense subset of $C ([0, T], H)$. For $f \in L^\infty (0, T, H)$ let $g \in C ([0, T], H)$ such that $d (f, g) < \frac{\varepsilon}{4}$. Then let $h \in D$ be so close to $g$ in $C ([0, T], H)$ that

$$\sum_{k=1}^{M} 2^{-k} \left| \frac{h-g, z_k}_{L^\infty, L^1} \right| < \frac{\varepsilon}{2}$$

Then

$$d (f, h) \leq d (f, g) + d (g, h) < \frac{\varepsilon}{4} + \frac{\varepsilon}{2} + \frac{\varepsilon}{4} = \varepsilon$$

It appears that $D$ is dense in $B$ in the weak * topology. ❑

19.9 Pointwise Behavior Of Weakly Convergent Sequences

There is an interesting little result which relates to weak limits in $L^2 (\Gamma, E)$ for $E$ a Banach space. I am not sure where to put this thing but think that this would be a good place for it. It obviously generalizes to $L^p$ spaces.

**Proposition 19.9.1** Let $E$ be a Banach space and let $\{u_n\}$ be a sequence in $L^2 (\Gamma, E)$ and let $G (x)$ be a weakly compact set in $E$, and $u_n (x) \in G (x)$ a.e. for each $n$. Let $\limsup \{u_n (x)\}$ denote the set of all weak limits of subsequences of $\{u_n (x)\}$ and let $H (x)$ be the closure of the convex hull of $\limsup \{u_n (x)\}$. Then if $u_n \to u$ weakly in $L^2 (\Gamma, E)$, then $u (x) \in H (x)$ for a.e. $x$.

**Proof:** Let $H = \{w \in L^2 (\Gamma, E) : w (x) \in H (x)$ a.e. $\}$. Then $H$ is convex. If you have $w_i \in H$, then since each $H (x)$ is convex, it follows that $\lambda w_1 (x) + (1-\lambda) w_2 (x) \in H$ for a.e. $x$ and $\lambda \in [0, 1]$. Is $H$ closed? Suppose you have $w_n \in H$ and $w_n \to w$ in $L^2 (\Gamma, E)$. Then there is a subsequence such that pointwise convergence happens a.e. and so since $H$ is closed, you have $w (x) \in H$ for a.e. $x$. Hence $H$ is also weakly closed in $L^2 (\Gamma, H)$. Thus if $u$ is the weak limit of $\{u_n\}$ in $L^2 (\Gamma, E)$, it must be the case that $u (x) \in H (x)$ a.e. ❑

As a case of this which might be pretty interesting, suppose $G (x)$ is not just weakly compact but also convex. Then $H (x) = G (x)$ and you can say that $u (x) \in H (x)$ a.e. whenever it is a weak limit in $L^2 (\Gamma, E)$ of functions $u_n$ for which $u_n (x) \in G (x)$.
19.10 Exercises

1. Show $L^1(\mathbb{R})$ is not reflexive. **Hint:** $L^1(\mathbb{R})$ is separable. What about $L^\infty(\mathbb{R})$?

2. If $f \in L^1(\mathbb{R}^n;X)$ for $X$ a Banach space, does the usual fundamental theorem of calculus work? That is, can you say $\lim_{r \to 0} \frac{1}{m(B(x,r))} \int_{B(x,r)} f(t) \, dm = f(x)$ a.e.?

3. Does the Vitali convergence theorem hold for Bochner integrable functions? If so, give a statement of the appropriate theorem and a proof.

4. Suppose $g \in L^1([a;b] ; X)$ where $X$ is a Banach space. Then if $\int_a^b g(t) \, d\phi(t) = 0$ for all $\phi \in C_c^\infty(a,b)$, then $g(t) = 0$ a.e. Show that this is the case. **Hint:** It will likely depend on the regularity properties of Lebesgue measure.

5. Suppose $f \in L^1([a;b] ; X)$ and for all $\phi \in C_c^\infty(a,b)$, $\int_a^b f(t) \phi'(t) \, dt = 0$. Then there exists a constant, $a \in X$ such that $f(t) = a$ a.e. **Hint:** Let

$$
\psi_\phi(x) = \int_a^x [\phi(t) - \phi_0(t)] \, dt, \quad \phi_0 \in C_c^\infty(a,b), \quad \int_a^b \phi_0(x) \, dx = 1
$$

Then explain why $\psi_\phi \in C_c^\infty(a,b)$, $\psi_\phi' = \phi - \left(\int_a^b \phi(y) \, dy\right) \phi_0$. Then use the assumption on $\psi_\phi$. Next use the above problem. Verify that

$$
f(y) = \int_a^b f(t) \, \phi_0(t) \, dt \text{ a.e. } y
$$

6. Let $f \in L^1([a,b] , X)$. Then we say that the weak derivative of $f$ is in $L^1([a,b] , X)$ if there is a function denoted as $f' \in L^1([a,b] , X)$ such that for all $\phi \in C_c^\infty(a,b)$,

$$
- \int_a^b f(t) \phi'(t) \, dt = \int_a^b f'(t) \, \phi(t) \, dt
$$

Show that this definition is well defined. Next, using the above problems, show that if $f, f' \in L^1([a,b] , X)$, it follows that there is a continuous function, denoted by $t \to \hat{f}(t)$ such that $\hat{f}(t) = f(t)$ a.e. $t$ and

$$
\hat{f}(t) = \hat{f}(a) + \int_0^t f'(s) \, ds
$$

Thus, unlike the classical definition of the derivative, when a function and its derivative are both in $L^1$, it has a representative $\hat{f}$ which equals the function a.e. such that $\hat{f}$ can be recovered from its derivative. Recall the well known example of this not working out which is based on the Cantor function which you should see in a real analysis course. This function had zero derivative a.e. and yet it climbed from 0 to 1 on the unit interval. Thus one could not recover it from integrating its classical derivative.
Chapter 20

The Derivative

20.1 Limits Of A Function

As in the case of scalar valued functions of one variable, a concept closely related to continuity is that of the **limit of a function**. The notion of limit of a function makes sense at points $x$, which are limit points of $D(f)$ and this concept is defined next. In all that follows $(V, ||-||)$ and $(W, ||-||)$ are two normed linear spaces. Recall the definition of limit point first.

**Definition 20.1.1** Let $A \subseteq W$ be a set. A point $x$, is a limit point of $A$ if $B(x, r)$ contains infinitely many points of $A$ for every $r > 0$.

**Definition 20.1.2** Let $f : D(f) \subseteq V \rightarrow W$ be a function and let $x$ be a limit point of $D(f)$. Then

$$\lim_{y \rightarrow x} f(y) = L$$

if and only if the following condition holds. For all $\varepsilon > 0$ there exists $\delta > 0$ such that if

$$0 < ||y - x|| < \delta, \text{ and } y \in D(f)$$

then,

$$||L - f(y)|| < \varepsilon.$$

**Theorem 20.1.3** If $\lim_{y \rightarrow x} f(y) = L$ and $\lim_{y \rightarrow x} f(y) = L_1$, then $L = L_1$.

**Proof:** Let $\varepsilon > 0$ be given. There exists $\delta > 0$ such that if $0 < ||y - x|| < \delta$ and $y \in D(f)$, then

$$||f(y) - L|| < \varepsilon, \text{ and } ||f(y) - L_1|| < \varepsilon.$$

Pick such a $y$. There exists one because $x$ is a limit point of $D(f)$. Then

$$||L - L_1|| \leq ||L - f(y)|| + ||f(y) - L_1|| < \varepsilon + \varepsilon = 2\varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, this shows $L = L_1$.

As in the case of functions of one variable, one can define what it means for $\lim_{y \rightarrow x} f(x) = \pm \infty$. 

679
Definition 20.1.4 If \( f(x) \in \mathbb{R}, \lim_{y \to x} f(x) = \infty \) if for every number \( l \), there exists \( \delta > 0 \) such that whenever \( ||y - x|| < \delta \) and \( y \in D(f) \), then \( f(x) > l \).

\[
\lim_{y \to x} f(x) = -\infty \text{ if for every number } l, \text{ there exists } \delta > 0 \text{ such that whenever } ||y - x|| < \delta \text{ and } y \in D(f), \text{ then } f(x) < l.
\]

The following theorem is just like the one variable version of calculus.

Theorem 20.1.5 Suppose \( f : D(f) \subseteq V \to \mathbb{F}^m \). Then for \( x \) a limit point of \( D(f) \),

\[
\lim_{y \to x} f(y) = L \quad (20.1.1)
\]

if and only if

\[
\lim_{y \to x} f_k(y) = L_k \quad (20.1.2)
\]

where \( f(y) \equiv (f_1(y), \cdots, f_p(y)) \) and \( L \equiv (L_1, \cdots, L_p) \).

Suppose here that \( f \) has values in \( W \), a normed linear space and

\[
\lim_{y \to x} f(y) = L, \quad \lim_{y \to x} g(y) = K
\]

where \( K, L \in W \). Then if \( a, b \in \mathbb{F} \),

\[
\lim_{y \to x} (af(y) + bg(y)) = aL + bK, \quad (20.1.3)
\]

If \( W \) is an inner product space,

\[
\lim_{y \to x} (f, g)(y) = (L, K) \quad (20.1.4)
\]

If \( g \) is scalar valued with \( \lim_{y \to x} g(y) = K \),

\[
\lim_{y \to x} f(y) g(y) = LK. \quad (20.1.5)
\]

Also, if \( h \) is a continuous function defined near \( L \), then

\[
\lim_{y \to x} h \circ f(y) = h(L). \quad (20.1.6)
\]

Suppose \( \lim_{y \to x} f(y) = L \). If \( ||f(y) - b|| \leq r \) for all \( y \) sufficiently close to \( x \), then \( |L - b| \leq r \) also.

**Proof:** Suppose \( 20.1.4 \). Then letting \( \varepsilon > 0 \) be given there exists \( \delta > 0 \) such that if \( 0 < ||y - x|| < \delta \), it follows

\[
|f_k(y) - L_k| \leq ||f(y) - L|| < \varepsilon
\]

which verifies \( 20.1.4 \).

Now suppose \( 20.1.5 \) holds. Then letting \( \varepsilon > 0 \) be given, there exists \( \delta_k \) such that if \( 0 < ||y - x|| < \delta_k \), then

\[
|f_k(y) - L_k| < \varepsilon.
\]
20.1. LIMITS OF A FUNCTION

Let \( 0 < \delta < \min (\delta_1, \cdots, \delta_p) \). Then if \( 0 < \|y-x\| < \delta \), it follows

\[
\|f(y) - L\|_{\infty} < \varepsilon
\]

Any other norm on \( F^m \) would work out the same way because the norms are all equivalent.

Each of the remaining assertions follows immediately from the coordinate descriptions of the various expressions and the first part. However, I will give a different argument for these.

The proof of 20.1.3 is left for you. Now 20.1.4 is to be verified. Let \( \varepsilon > 0 \) be given. Then by the triangle inequality,

\[
| (f,g)(y) - (L,K) | \leq \|f,g\|(y) - (f(y),K)\| + \|f(y),K\| - (L,K) | \\
\leq \|f(y)\| \|g(y) - K\| + \|K\| \|f(y) - L\|.
\]

There exists \( \delta_1 \) such that if \( 0 < \|y-x\| < \delta_1 \) and \( y \in D(f) \), then

\[
\|f(y) - L\| < 1,
\]

and so for such \( y \), the triangle inequality implies, \( \|f(y)\| < 1 + \|L\| \). Therefore, for \( 0 < \|y-x\| < \delta_1 \),

\[
| (f,g)(y) - (L,K) | \leq (1 + \|K\| + \|L\|) \|\|g(y) - K\| + \|f(y) - L\| |.
\]

(20.1.7)

Now let \( 0 < \delta_2 \) be such that if \( y \in D(f) \) and \( 0 < \|x-y\| < \delta_2 \),

\[
\|f(y) - L\| < \frac{\varepsilon}{2(1 + \|K\| + \|L\|)}, \quad \|g(y) - K\| < \frac{\varepsilon}{2(1 + \|K\| + \|L\|)}.
\]

Then letting \( 0 < \delta \leq \min (\delta_1, \delta_2) \), it follows from 20.1.7 that

\[
| (f,g)(y) - (L,K) | < \varepsilon
\]

and this proves 20.1.4.

The proof of 20.1.5 is left to you.

Consider 20.1.6. Since \( h \) is continuous near \( L \), it follows that for \( \varepsilon > 0 \) given, there exists \( \eta > 0 \) such that if \( \|y-L\| < \eta \), then

\[
\|h(y) - h(L)\| < \varepsilon
\]

Now since \( \lim_{y \to x} f(y) = L \), there exists \( \delta > 0 \) such that if \( 0 < \|y-x\| < \delta \), then

\[
\|f(y) - L\| < \eta.
\]

Therefore, if \( 0 < \|y-x\| < \delta \),

\[
\|h(f(y)) - h(L)\| < \varepsilon.
\]

It only remains to verify the last assertion. Assume \( \|f(y) - b\| \leq r \). It is required to show that \( \|L-b\| \leq r \). If this is not true, then \( \|L-b\| > r \). Consider
For these concepts without suffering and anguish.

The relation between continuity and limits is as follows.

**Theorem 20.1.6** For \( f : D (f) \to W \) and \( x \in D (f) \) a limit point of \( D (f) \), \( f \) is continuous at \( x \) if and only if

\[
\lim_{y \to x} f (y) = f (x).
\]

**Proof:** First suppose \( f \) is continuous at \( x \) a limit point of \( D (f) \). Then for every \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that if \( \| x - y \| < \delta \) and \( y \in D (f) \), then \( |f (x) - f (y)| < \varepsilon \). In particular, this holds if \( 0 < \| x - y \| < \delta \) and this is just the definition of the limit. Hence \( f (x) = \lim_{y \to x} f (y) \).

Next suppose \( x \) is a limit point of \( D (f) \) and \( \lim_{y \to x} f (y) = f (x) \). This means that if \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that for \( 0 < \| x - y \| < \delta \) and \( y \in D (f) \), it follows \( |f (y) - f (x)| < \varepsilon \). However, if \( y = x \), then \( |f (y) - f (x)| = |f (x) - f (x)| = 0 \) and so whenever \( y \in D (f) \) and \( \| x - y \| < \delta \), it follows \( |f (x) - f (y)| < \varepsilon \), showing \( f \) is continuous at \( x \).

**Example 20.1.7** Find \( \lim_{(x,y) \to (3,1)} \left( \frac{x^2 - 9}{x - 3}, y \right) \).

It is clear that \( \lim_{(x,y) \to (3,1)} \frac{x^2 - 9}{x - 3} = 6 \) and \( \lim_{(x,y) \to (3,1)} y = 1 \). Therefore, this limit equals (6, 1).

**Example 20.1.8** Find \( \lim_{(x,y) \to (0,0)} \frac{xy}{x^2 + y^2} \).

First of all, observe the domain of the function is \( \mathbb{R}^2 \setminus \{(0,0)\} \), every point in \( \mathbb{R}^2 \) except the origin. Therefore, \((0,0)\) is a limit point of the domain of the function so it might make sense to take a limit. However, just as in the case of a function of one variable, the limit may not exist. In fact, this is the case here. To see this, take points on the line \( y = 0 \). At these points, the value of the function equals 0. Now consider points on the line \( y = x \) where the value of the function equals 1/2. Since, arbitrarily close to \((0,0)\), there are points where the function equals 1/2 and points where the function has the value 0, it follows there can be no limit. Just take \( \varepsilon = 1/10 \) for example. You cannot be within 1/10 of 1/2 and also within 1/10 of 0 at the same time.

Note it is necessary to rely on the definition of the limit much more than in the case of a function of one variable and there are no easy ways to do limit problems for functions of more than one variable. It is what it is and you will not deal with these concepts without suffering and anguish.
20.2 Basic Definitions

The concept of derivative generalizes right away to functions defined on a normed linear space. However, no attempt will be made to consider derivatives from one side or another. This is because there isn’t a well defined side. However, it is certainly the case that there are more general notions which include such things. I will present a fairly general notion of the derivative of a function which is defined on a normed vector space which has values in a normed vector space.

In what follows, \( X, Y \) will denote normed vector spaces. Recall that \( \mathcal{L}(X,Y) \) will denote the \textbf{bounded linear transformations} from \( X \) to \( Y \).

Let \( U \) be an open set in \( X \), and let \( f : U \to Y \) be a function.

**Definition 20.2.1** A function \( g \) is \( o(v) \) if

\[
\lim_{\|v\| \to 0} \frac{g(v)}{\|v\|} = 0
\]  

(20.2.8)

A function \( f : U \to Y \) is differentiable at \( x \in U \) if there exists a linear transformation \( L \in \mathcal{L}(X,Y) \) such that

\[
f(x + v) = f(x) + Lv + o(v)
\]

This linear transformation \( L \) is the definition of \( Df(x) \). This derivative is often called the \textbf{Frechet derivative}.

In finite dimensions, the question whether a given function is differentiable is independent of the norm used on the finite dimensional vector space. That is, a function is differentiable with one norm if and only if it is differentiable with another norm. This is because all norms are equivalent on a finite dimensional space.

The definition (20.2.8) means the error,

\[
f(x + v) - f(x) - Lv
\]

converges to 0 faster than \( \|v\| \). Thus the above definition is equivalent to saying

\[
\lim_{\|v\| \to 0} \frac{\|f(x + v) - f(x) - Lv\|}{\|v\|} = 0
\]  

(20.2.9)

or equivalently,

\[
\lim_{y \to x} \frac{\|f(y) - f(x) - Df(x)(y - x)\|}{\|y - x\|} = 0.
\]  

(20.2.10)

The symbol \( o(v) \) should be thought of as an adjective. Thus, if \( t \) and \( k \) are constants,

\[
o(tv) = o(v), \quad k o(v) = o(v)
\]

and other similar observations hold.

**Theorem 20.2.2** The derivative is well defined.
Proof: First note that for a fixed vector \( v \), \( o( tv) = o(t) \). This is because

\[
\lim_{t \to 0} \frac{o(tv)}{|t|} = \lim_{t \to 0} \frac{|v||o(tv)|}{|t||v|} = 0
\]

Now suppose both \( L_1 \) and \( L_2 \) work in the above definition. Then let \( v \) be any vector and let \( t \) be a real scalar which is chosen small enough that \( tv + x \in U \). Then

\[
f(x + tv) = f(x) + L_1 tv + o(tv), \quad f(x + tv) = f(x) + L_2 tv + o(tv).
\]

Therefore, subtracting these two yields \( (L_2 - L_1)(tv) = o(tv) = o(t) \). Therefore, dividing by \( t \) yields \( (L_2 - L_1)(v) = \frac{o(t)}{t} \). Now let \( t \to 0 \) to conclude that \( (L_2 - L_1)(v) = 0 \). Since this is true for all \( v \), it follows \( L_2 = L_1 \). This proves the theorem.

Lemma 20.2.3 Let \( f \) be differentiable at \( x \). Then \( f \) is continuous at \( x \) and in fact, there exists \( K > 0 \) such that whenever \( |v| \) is small enough,

\[
|f(x + v) - f(x)| \leq K|v|
\]

Also if \( f \) is differentiable at \( x \), then

\[
o(||f(x + v) - f(x)||) = o(v)
\]

Proof: From the definition of the derivative,

\[
f(x + v) - f(x) = Df(x)v + o(v).
\]

Let \( |v| \) be small enough that \( \frac{o(||v||)}{||v||} < 1 \) so that \( ||o(v)|| \leq ||v|| \). Then for such \( v \),

\[
||f(x + v) - f(x)|| \leq ||Df(x)v|| + ||v||
\]

\[
\leq (||Df(x)|| + 1)||v||
\]

This proves the lemma with \( K = ||Df(x)|| + 1 \). Recall the operator norm discussed in Definition 6.1.3

The last assertion is implied by the first as follows. Define

\[
h(v) = \begin{cases} 
\frac{o(||f(x + v) - f(x)||)}{||f(x + v) - f(x)||} & \text{if } ||f(x + v) - f(x)|| \neq 0 \\
0 & \text{if } ||f(x + v) - f(x)|| = 0 
\end{cases}
\]

Then \( \lim_{||v|| \to 0} h(v) = 0 \) from continuity of \( f \) at \( x \) which is implied by the first part. Also from the above estimate,

\[
\frac{o(||f(x + v) - f(x)||)}{||v||} = h(v)\frac{||f(x + v) - f(x)||}{||v||} \leq h(v)(||Df(x)|| + 1)
\]

This establishes the second claim.

Here \( ||Df(x)|| \) is the operator norm of the linear transformation \( Df(x) \).
20.3 The Chain Rule

With the above lemma, it is easy to prove the chain rule.

**Theorem 20.3.1** (The chain rule) Let \( U \) and \( V \) be open sets \( U \subseteq X \) and \( V \subseteq Y \). Suppose \( f : U \to V \) is differentiable at \( x \in U \) and suppose \( g : V \to \mathbb{F}^q \) is differentiable at \( f(x) \in V \). Then \( g \circ f \) is differentiable at \( x \) and

\[
D(g \circ f)(x) = Dg(f(x)) \cdot Df(x).
\]

**Proof:** This follows from a computation. Let \( B(x,r) \subseteq U \) and let \( r \) also be small enough that for \( ||v|| \leq r \), it follows that \( f(x+v) \in V \). Such an \( r \) exists because \( f \) is continuous at \( x \). For \( ||v|| < r \), the definition of differentiability of \( g \) and \( f \) implies

\[
g(f(x+v)) - g(f(x)) = Dg(f(x))(f(x+v) - f(x)) + o(f(x+v) - f(x))
\]

\[
= Dg(f(x))[Df(x)v + o(v)] + o(f(x+v) - f(x))
\]

\[
= Dg(f(x))Df(x)v + o(v) + o(f(x+v) - f(x)) \quad (20.3.11)
\]

By Lemma 20.3.1, from the definition of the derivative \( D(g \circ f)(x) \) exists and equals \( Dg(f(x)) \cdot Df(x) \).

20.4 The Derivative Of A Compact Mapping

Here is a little definition about compact mappings. It turns out that if you have a differentiable mapping which is also compact, then the derivative must also be compact.

**Definition 20.4.1** Let \( C \in \mathcal{L}(X,Y) \). It is said to be compact if it takes bounded sets to precompact sets. If \( f \) is a function defined on an open subset \( U \) of \( X \), then \( f \) is called compact if \( f \) (bounded set) = (precompact).

**Theorem 20.4.2** Let \( f : U \subseteq X \to Y \) where \( f \) takes bounded sets to precompact sets. Then \( Df(x) \) also takes bounded sets in \( X \) to precompact sets in \( Y \).

**Proof:** If this is not so, then there exists a bounded set \( B \) in \( X \) and for some \( \varepsilon > 0 \) a sequence of points \( Df(x) b_n \) such that all these points are further apart than \( \varepsilon \). Without loss of generality, one can assume \( B = B(0,r), \) a ball. In fact, one can assume that \( r > 0 \) is as small as desired because if \( Df(x) B(0,r) \) is precompact, then so is \( Df(x) B(0,R), R > r \). Just get an \( \varepsilon \frac{r}{R} \) net \( \{Df(x) x_n\}_{n=1}^N \) for \( Df(x) B(0,r) \) and consider \( \{R \frac{r}{R} Df(x) x_n\}_{n=1}^N \cup_n B(Df(x) x_n, \varepsilon \frac{r}{R}) \) covers \( Df(x) B(0,r) \) and so \( \cup_n B(R \frac{r}{R} Df(x) x_n, \varepsilon) \) covers \( Df(x) B(0,R) \).
Choose \( r \) very small so that \( r < \varepsilon / 4 \) and

\[
f(x + x_n) - f(x) = Df(x)x_n + o(x_n), \quad \|o(x_n)\| < \|x_n\|
\]

and there are infinitely many \( Df(x)x_n \) further apart than \( \varepsilon, x_n \in B(0, r) \). Then consider \( B(x, r) \) and \( \{ f(x + x_n) \}_{n=1}^{\infty} \).

\[
\|f(x + x_n) - f(x + x_m)\| \geq \|Df(x)x_n - Df(x)x_m\| + \|o(x_n) - o(x_m)\| \\
\geq \varepsilon - \frac{2\varepsilon}{4} = \frac{\varepsilon}{2}
\]

contradicting the assertion that \( f \) takes bounded sets to precompact sets. \( \blacksquare \)

### 20.5 The Matrix Of The Derivative

The case of most interest here is the only one I will discuss. It is the case where \( X = \mathbb{R}^n \) and \( Y = \mathbb{R}^m \), the function being defined on an open subset of \( \mathbb{R}^n \). Of course this all generalizes to arbitrary vector spaces and one considers the matrix taken with respect to various bases. As above, \( f \) will be defined and differentiable on an open set \( U \subseteq \mathbb{R}^n \).

The matrix of \( Df(x) \) is the matrix having the \( i \)th column equal to \( Df(x)e_i \) and so it is only necessary to compute this. Let \( t \) be a small real number such that both

\[
\frac{f(x + te_i) - f(x)}{t} - Df(x)(te_i) = o(t)
\]

Therefore,

\[
\frac{f(x + te_i) - f(x)}{t} = Df(x)(e_i) + o(t)
\]

The limit exists on the right and so it exists on the left also. Thus

\[
\frac{\partial f(x)}{\partial x_i} = \lim_{t \to 0} \frac{f(x + te_i) - f(x)}{t} = Df(x)(e_i)
\]

and so the matrix of the derivative is just the matrix which has the \( i \)th column equal to the \( i \)th partial derivative of \( f \). Note that this shows that whenever \( f \) is differentiable, it follows that the partial derivatives all exist. It does not go the other way however as discussed later.

**Theorem 20.5.1** Let \( f : U \subseteq \mathbb{R}^n \to \mathbb{R}^m \) and suppose \( f \) is differentiable at \( x \). Then all the partial derivatives \( \frac{\partial f(x)}{\partial x_j} \) exist and if \( Jf(x) \) is the matrix of the linear transformation, \( Df(x) \) with respect to the standard basis vectors, then the \( ij \)th entry is given by \( \frac{\partial f(x)}{\partial x_j} \) also denoted as \( f_{i,j} \) or \( f_{i,x_j} \). It is the matrix whose \( i \)th column is

\[
\frac{\partial f(x)}{\partial x_i} = \lim_{t \to 0} \frac{f(x + te_i) - f(x)}{t}
\]
Of course there is a generalization of this idea called the directional derivative.

**Definition 20.5.2** In general, the symbol

\[ D_v f(x) \]

is defined by

\[
\lim_{t \to 0} \frac{f(x + tv) - f(x)}{t}
\]

where \( t \in \mathbb{F} \). In case \( |v| = 1 \) and the norm is the standard Euclidean norm, this is called the directional derivative. More generally, with no restriction on the size of \( v \) and in any linear space, it is called the Gateaux derivative. \( f \) is said to be Gateaux differentiable at \( x \) if there exists \( D_v f(x) \) such that

\[
\lim_{t \to 0} \frac{f(x + tv) - f(x)}{t} = D_v f(x)
\]

where \( v \to D_v f(x) \) is linear. Thus we say it is Gateaux differentiable if the Gateaux derivative exists for each \( v \) and \( v \to D_v f(x) \) is linear. \[ \square \]

What if all the partial derivatives of \( f \) exist? Does it follow that \( f \) is differentiable? Consider the following function, \( f : \mathbb{R}^2 \to \mathbb{R} \),

\[
f(x, y) = \begin{cases} 
\frac{xy}{x^2 + y^2} & \text{if } (x, y) \neq (0, 0) \\
0 & \text{if } (x, y) = (0, 0) 
\end{cases}
\]

Then from the definition of partial derivatives,

\[
\lim_{h \to 0} \frac{f(h, 0) - f(0, 0)}{h} = \lim_{h \to 0} \frac{0 - 0}{h} = 0
\]

and

\[
\lim_{h \to 0} \frac{f(0, h) - f(0, 0)}{h} = \lim_{h \to 0} \frac{0 - 0}{h} = 0
\]

However \( f \) is not even continuous at \( (0, 0) \) which may be seen by considering the behavior of the function along the line \( y = x \) and along the line \( x = 0 \). By Lemma 20.2.3 this implies \( f \) is not differentiable. Therefore, it is necessary to consider the correct definition of the derivative given above if you want to get a notion which generalizes the concept of the derivative of a function of one variable in such a way as to preserve continuity whenever the function is differentiable.

\[ ^1 \text{René Gateaux was one of the many young French men killed in world war I. This derivative is named after him, but it developed naturally from ideas used in the calculus of variations which were due to Euler and Lagrange back in the 1700’s.} \]
20.6 A Mean Value Inequality

The following theorem will be very useful in much of what follows. It is a version of the mean value theorem as is the next lemma.

Lemma 20.6.1 Let $Y$ be a normed vector space and suppose $h : [0,1] \rightarrow Y$ is differentiable and satisfies
\[ ||h'(t)|| \leq M. \]
Then
\[ ||h(1) - h(0)|| \leq M. \]

Proof: Let $\varepsilon > 0$ be given and let
\[ S = \{ t \in [0,1] : \text{for all } s \in [0,t], ||h(s) - h(0)|| \leq (M + \varepsilon) s \} \]
Then $0 \in S$. Let $t = \sup S$. Then by continuity of $h$ it follows
\[ ||h(t) - h(0)|| = (M + \varepsilon) t \] (20.6.12)
Suppose $t < 1$. Then there exist positive numbers, $h_k$ decreasing to 0 such that
\[ ||h(t + h_k) - h(0)|| > (M + \varepsilon)(t + h_k) \]
and now it follows from (20.6.12) and the triangle inequality that
\[ ||h(t + h_k) - h(t)|| + ||h(t) - h(0)|| = ||h(t + h_k) - h(t)|| + (M + \varepsilon) t > (M + \varepsilon)(t + h_k) \]
and so
\[ ||h(t + h_k) - h(t)|| > (M + \varepsilon)h_k \]
Now dividing by $h_k$ and letting $k \rightarrow \infty$
\[ ||h'(t)|| \geq M + \varepsilon, \]
a contradiction. Thus $t = 1$. ■

Theorem 20.6.2 Suppose $U$ is an open subset of $X$ and $f : U \rightarrow Y$ has the property that $Df(x)$ exists for all $x$ in $U$ and that, $x + t(y - x) \in U$ for all $t \in [0,1]$. (The line segment joining the two points lies in $U$.) Suppose also that for all points on this line segment,
\[ ||Df(x + t(y - x))|| \leq M. \]
Then
\[ ||f(y) - f(x)|| \leq M ||y - x||. \]
Proof: Let
\[ h(t) \equiv f(x + t(y - x)). \]
Then by the chain rule,
\[ h'(t) = Df(x + t(y - x))(y - x) \]
and so
\[ ||h'(t)|| = ||Df(x + t(y - x))(y - x)|| \leq M||y - x|| \]
by Lemma 20.6.1.

\[ ||h(1) - h(0)|| = ||f(y) - f(x)|| \leq M||y - x||. \]

Here is a little result which will help to tie the case of \( \mathbb{R}^n \) in to the abstract theory presented for arbitrary spaces.

**Theorem 20.6.3** Let \( X \) be a normed vector space having basis \( \{v_1, \cdots, v_n\} \) and let \( Y \) be another normed vector space having basis \( \{w_1, \cdots, w_m\} \). Let \( U \) be an open set in \( X \) and let \( f: U \to Y \) have the property that the Gateaux derivatives,
\[ D_{v_k}f(x) = \lim_{t \to 0} \frac{f(x + tv_k) - f(x)}{t} \]
exist and are continuous functions of \( x \). Then \( Df(x) \) exists and
\[ Df(x)v = \sum_{k=1}^{n} D_{v_k}f(x)a_k \]
where
\[ v = \sum_{k=1}^{n} a_kv_k. \]
Furthermore, \( x \to Df(x) \) is continuous; that is
\[ \lim_{y \to x} ||Df(y) - Df(x)|| = 0. \]

**Proof:** Let \( v = \sum_{k=1}^{n} a_kv_k. \) Then
\[ f(x + v) - f(x) = f\left(x + \sum_{k=1}^{n} a_kv_k\right) - f(x). \]
Then letting \( \sum_{k=1}^{0} = 0, f(x + v) - f(x) \) is given by
\[ \sum_{k=1}^{n} \left[ f\left(x + \sum_{j=1}^{k} a_jv_j\right) - f\left(x + \sum_{j=1}^{k-1} a_jv_j\right)\right]. \]
Consider the \( k \)th term in (20.6.13). Let

\[
h(t) = f\left(x + \sum_{j=1}^{k-1} a_j v_j + ta_k v_k\right) - f(x + ta_k v_k)
\]

for \( t \in [0, 1] \). Then

\[
h'(t) = a_k \lim_{h \to 0} \frac{1}{ah} \left[ f\left(x + \sum_{j=1}^{k-1} a_j v_j + (t + h) a_k v_k\right) - f(x + (t + h) a_k v_k) - \left( f\left(x + \sum_{j=1}^{k-1} a_j v_j + ta_k v_k\right) - f(x + ta_k v_k)\right)\right)
\]

and this equals

\[
\left(D_{v_k} f\left(x + \sum_{j=1}^{k-1} a_j v_j + ta_k v_k\right) - D_{v_k} f(x + ta_k v_k)\right) a_k
\]

(20.6.14)

Now without loss of generality, it can be assumed that the norm on \( X \) is given by

\[
||v|| = \max \left\{|a_k| : v = \sum_{j=1}^{n} a_k v_k\right\}
\]

because this is a finite dimensional space, all norms on \( X \) are equivalent. Therefore, from (20.6.14) and the assumption that the Gateaux derivatives are continuous,

\[
||h'(t)|| = \left\|\left(D_{v_k} f\left(x + \sum_{j=1}^{k-1} a_j v_j + ta_k v_k\right) - D_{v_k} f(x + ta_k v_k)\right) a_k\right\|
\]

\[
\leq \varepsilon |a_k| \leq \varepsilon ||v||
\]

provided \( ||v|| \) is sufficiently small. Since \( \varepsilon \) is arbitrary, it follows from Lemma (20.6.1) the expression in (20.6.13) is \( o(v) \) because this expression equals a finite sum of terms of the form \( h(1) - h(0) \) where \( ||h'(t)|| \leq \varepsilon ||v|| \) whenever \( ||v|| \) is small enough. Thus

\[
f(x + v) - f(x) = \sum_{k=1}^{n} [f(x + a_k v_k) - f(x)] + o(v)
\]
20.6. **A MEAN VALUE INEQUALITY**

\[
= \sum_{k=1}^{n} D_{v_k} f(x) a_k + \sum_{k=1}^{n} \left[ f(x + a_k v_k) - f(x) - D_{v_k} f(x) a_k \right] + o(v).
\]

Consider the \(k^{th}\) term in the second sum.

\[
f(x + a_k v_k) - f(x) - D_{v_k} f(x) a_k = a_k \left( \frac{f(x + a_k v_k) - f(x)}{a_k} - D_{v_k} f(x) \right)
\]

where the expression in the parentheses converges to 0 as \(a_k \to 0\). Thus whenever \(\|v\|\) is sufficiently small,

\[
\|f(x + a_k v_k) - f(x) - D_{v_k} f(x) a_k\| \leq \varepsilon |a_k| \leq \varepsilon \|v\|
\]

which shows the second sum is also \(o(v)\). Therefore,

\[
f(x + v) - f(x) = \sum_{k=1}^{n} D_{v_k} f(x) a_k + o(v).
\]

Defining

\[
Df(x) v = \sum_{k=1}^{n} D_{v_k} f(x) a_k
\]

where \(v = \sum_k a_k v_k\), it follows \(Df(x) \in \mathcal{L}(X,Y)\) and is given by the above formula.

It remains to verify \(x \to Df(x)\) is continuous.

\[
\|(Df(x) - Df(y)) v\|
\]

\[
\leq \sum_{k=1}^{n} \|(D_{v_k} f(x) - D_{v_k} f(y)) a_k\|
\]

\[
\leq \max \{|a_k|, k = 1, \ldots, n\} \sum_{k=1}^{n} \|D_{v_k} f(x) - D_{v_k} f(y)\|
\]

\[
= \|v\| \sum_{k=1}^{n} \|D_{v_k} f(x) - D_{v_k} f(y)\|
\]

(Note that \(\|v\| = \max \{|a_k|, k = 1, \ldots, n\} \) where \(v = \sum_k a_k v_k\) and so

\[
\|(Df(x) - Df(y)) v\| \leq \sum_{k=1}^{n} \|D_{v_k} f(x) - D_{v_k} f(y)\|
\]

which proves the continuity of \(Df\) because of the assumption the Gateaux derivatives are continuous.

In particular, if \(D_{v_k} f(x)\) exist and are continuous functions of \(x\), this shows that \(f\) is Gateaux differentiable and in fact the Gateaux derivatives are continuous. The following gives the corresponding result for functions defined on infinite dimensional spaces.
CHAPTER 20. THE DERIVATIVE

Theorem 20.6.4 Suppose \( f: U \to Y \) where \( U \) is an open set in \( X \), a normed linear space. Suppose that \( f \) is Gateaux differentiable on \( U \) and that the Gateaux derivative is continuous on an open set containing \( x \). Then \( f \) is Frechet differentiable at \( x \).

**Proof:** Denote by \( G(x) \in L(X,Y) \) the Gateaux derivative. Thus

\[
G(x) v = \lim_{\lambda \to 0} \frac{f(x + \lambda v) - f(x)}{\lambda}
\]

It is desired to show that \( G(x) = Df(x) \). Since \( G \) is continuous, one can obtain

\[
f(x + v) - f(x) = \int_0^1 G(x + tv) v dt
\]

where this is the ordinary Riemann integral.

\[
\left\| \frac{f(x + v) - f(x) - G(x) v}{\|v\|} \right\| = \left\| \int_0^1 G(x + tv) v dt - G(x) v \right\| = \left\| \int_0^1 G(x + tv) v dt - G(x) v \right\| \leq \frac{1}{\|v\|} \int_0^1 \|G(x + tv) - G(x)\| dt \|v\|
\]

which is small provided \( \|v\| \) is sufficiently small. Thus \( G(x) = Df(x) \) as hoped. ■

Recall the following.

**Lemma 20.6.5** Let \( \|x\| = \sup_{\|y^*\|_{X'} \leq 1} |\langle y^*, x \rangle| \).

**Proof:** Let \( f(kx) = k\|x\| \). Then

\[
\sup_{\|kx\| \leq 1} |\langle f, x \rangle| = \sup_{\|k\| \leq \|x\|} |k| \|x\| = 1
\]

Then by Hahn Banach theorem, there is \( y^* \in X' \) which extends \( f \) and \( \|y^*\| \leq 1 \). Then

\[
\|x\| \geq \sup_{\|z^*\|_{X'} \leq 1} |\langle z^*, x \rangle| \geq |\langle y^*, x \rangle| = \|x\| \quad \blacksquare
\]

One does not need continuity of \( G \) near \( x \). It suffices to have continuity at \( x \). Let \( y^* \in Y' \). Then by the mean value theorem,

\[
\langle y^*, f(x + v) \rangle - \langle y^*, f(x) \rangle = \langle y^*, G(x + tv) v \rangle, \quad t \in [0,1]
\]

Then

\[
\frac{1}{\|v\|} \|f(x + v) - f(x) - G(x) v\| = \frac{1}{\|v\|} \sup_{\|y^*\| \leq 1} |\langle y^*, f(x + v) - f(x) - G(x) v \rangle| = \frac{1}{\|v\|} \sup_{\|y^*\| \leq 1} |\langle y^*, G(x + tv) v - G(x) v \rangle| \leq \sup_{|t| \leq 1} \|G(x + tv) - G(x)\|_{L(X,Y)}
\]

which converges to 0 as \( \|v\| \to 0 \) thanks to continuity of \( G \) at \( x \). This proves the following.
Theorem 20.6.6 Suppose \( f : U \rightarrow Y \) where \( U \) is an open set in \( X \), a normed linear space. Suppose that \( f \) is Gateaux differentiable on \( U \) and that the Gateaux derivative is continuous at \( x \). Then \( f \) is Frechet differentiable at \( x \) and \( D_f(x)v = D_xf(x) \).

Example 20.6.7 Let \( X \) be \( C^2_0(\Omega) \) where \( \Omega \) is a bounded open set in \( \mathbb{R}^n \) consisting of those functions which are twice continuously differentiable and vanish near \( \partial \Omega \).

Then let \( f : X \rightarrow \mathbb{R} \) be defined by

\[
\int_{\Omega} \nabla u \cdot \nabla v dx
\]

Show \( f \) is differentiable at \( u \in X \).

Consider the Gateaux differentiability.

\[
\lim_{t \to 0} \frac{f(u + tv) - f(u)}{t} = \lim_{t \to 0} \frac{t \int_{\Omega} \nabla u \cdot \nabla v dx}{t} + t \frac{1}{2} \int_{\Omega} \nabla v \cdot \nabla v
\]

so it converges to

\[
\int_{\Omega} \nabla u \cdot \nabla v dx = -\int_{\Omega} \Delta uv dx
\]

the last step comes from the divergence theorem. Clearly \( v \rightarrow -\int_{\Omega} \Delta uv dx \) is linear and \( \mathbb{R} \) valued.

\[
\left| -\int_{\Omega} \Delta uv dx \right| \leq \|v\|_X \int_{\Omega} |\Delta u| dx \leq \|v\|_X m(\Omega) \|u\|_X
\]

Thus this appears to be in \( L(X, \mathbb{R}) \). This also shows that,

\[
\sup_{\|v\| \leq 1} |D_vf(u) - D_vf(\hat{u})| \leq m(\Omega) \|u - \hat{u}\|_X
\]

and so \( u \rightarrow D(\cdot)(u) \) is continuous as a map from \( X \) to \( L(X, \mathbb{R}) \) so it seems that this is a differentiable function and

\[
Df(u)(v) = -\int_{\Omega} \Delta uv dx
\]

Definition 20.6.8 Let \( f : U \rightarrow Y \) where \( U \) is an open set in \( X \). Then \( f \) is called \( C^1(U) \) if it Gateaux differentiable and the Gateaux derivative is continuous on \( U \).

As shown, this implies \( f \) is differentiable and the Gateaux derivative is the Frechet derivative. It is good to keep in mind the following simple example or variations of it.

Example 20.6.9 Define

\[
f(x) = \begin{cases} x^2 \sin \left( \frac{1}{x} \right) & x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}
\]

This function has the property that it is differentiable everywhere but is not \( C^1(\mathbb{R}) \). In fact the derivative fails to be continuous at 0.
20.7 Higher Order Derivatives

If \( f : U \subseteq X \to Y \) for \( U \) an open set, then
\[
x \to Df(x)
\]
is a mapping from \( U \) to \( \mathcal{L}(X,Y) \), a normed vector space. Therefore, it makes perfect sense to ask whether this function is also differentiable.

**Definition 20.7.1** The following is the definition of the second derivative.

\[
D^2f(x) \equiv D(Df(x)).
\]

Thus,
\[
Df(x + v) - Df(x) = D^2f(x)v + o(v).
\]

This implies
\[
D^2f(x) \in \mathcal{L}(X, \mathcal{L}(X,Y)), \quad D^2f(x)(u)(v) \in Y,
\]
and the map
\[
(u, v) \to D^2f(x)(u)(v)
\]
is a bilinear map having values in \( Y \). In other words, the two functions,
\[
u \to D^2f(x)(u)(v), \quad v \to D^2f(x)(u)(v)
\]
are both linear.

The same pattern applies to taking higher order derivatives. Thus,
\[
D^3f(x) \equiv D(D^2f(x))
\]
and \( D^3f(x) \) may be considered as a trilinear map having values in \( Y \). In general \( D^kf(x) \) may be considered a \( k \) linear map. This means the function
\[
(u_1, \ldots, u_k) \to D^kf(x)(u_1)\cdots(u_k)
\]
has the property
\[
u_j \to D^kf(x)(u_1)\cdots(u_j)\cdots(u_k)
\]
is linear.

Also, instead of writing
\[
D^2f(x)(u)(v), \quad D^3f(x)(u)(v)(w)
\]
the following notation is often used.
\[
D^2f(x)(u, v) \quad \text{or} \quad D^3f(x)(u, v, w)
\]
with similar conventions for higher derivatives than 3. Another convention which is often used is the notation
\[
D^kf(x)v^k
\]
instead of
\[ D^k f(x)(v, \ldots, v). \]

Note that for every \( k \), \( D^k f \) maps \( U \) to a normed vector space. As mentioned above, \( Df(x) \) has values in \( \mathcal{L}(X,Y) \), \( D^2 f(x) \) has values in \( \mathcal{L}(X, \mathcal{L}(X,Y)) \), etc. Thus it makes sense to consider whether \( D^k f \) is continuous. This is described in the following definition.

\textbf{Definition 20.7.2} Let \( U \) be an open subset of \( X \), a normed vector space, and let \( f : U \to Y \). Then \( f \) is \( C^k(U) \) if \( f \) and its first \( k \) derivatives are all continuous. Also, \( D^k f(x) \) when it exists can be considered a \( Y \) valued multi-linear function. Sometimes these are called tensors in case \( f \) has scalar values.

\section*{20.8 The Derivative And The Cartesian Product}

There are theorems which can be used to get differentiability of a function based on existence and continuity of the partial derivatives. A generalization of this was given above. Here a function defined on a product space is considered. It is very much like what was presented above and could be obtained as a special case but to reinforce the ideas, I will do it from scratch because certain aspects of it are important in the statement of the implicit function theorem.

The following is an important abstract generalization of the concept of partial derivative presented above. Instead of taking the derivative with respect to one variable, it is taken with respect to several but not with respect to others. This vague notion is made precise in the following definition. First here is a lemma.

\textbf{Lemma 20.8.1} Suppose \( U \) is an open set in \( X \times Y \). Then the set, \( U_y \) defined by
\[ U_y \equiv \{ x \in X : (x, y) \in U \} \]
is an open set in \( X \). Here \( X \times Y \) is a finite dimensional vector space in which the vector space operations are defined componentwise. Thus for \( a, b \in F \),
\[ a(x_1, y_1) + b(x_2, y_2) = (ax_1 + bx_2, ay_1 + by_2) \]
and the norm can be taken to be
\[ \|(x, y)\| \equiv \max (\|x\|, \|y\|) \]

\textbf{Proof:} In finite dimensions it doesn’t matter how this norm is defined because all are equivalent. It obviously satisfies most axioms of a norm. The only one which is not obvious is the triangle inequality. I will show this now.

\[
\|(x, y) + (x_1, y_1)\| \equiv \|(x + x_1, y + y_1)\| \equiv \max (\|x + x_1\|, \|y + y_1\|) \\
\leq \max (\|x\| + \|x_1\|, \|y\| + \|y_1\|) \\
\leq \max (\|x\|, \|y\|) + \max (\|x_1\|, \|y_1\|) \\
\equiv \|(x, y)\| + \|(x_1, y_1)\|
\]
Let $x \in U$. Then $(x, y) \in U$ and so there exists $r > 0$ such that

$$B((x, y), r) \in U.$$ 

This says that if $(u, v) \in X \times Y$ such that $||u - v|| < r$, then $(u, v) \in U$. Thus if

$$||u, y - (x, y)|| = ||u - x|| < r,$$

then $(u, y) \in U$. This has just said that $B(x, r)$, the ball taken in $X$ is contained in $U_Y$. This proves the lemma. □

Or course one could also consider

$$U_x = \{y : (x, y) \in U\}$$

in the same way and conclude this set is open in $Y$. Also, the generalization to many factors yields the same conclusion. In this case, for $x \in \prod_{i=1}^n X_i$, let

$$||x|| = \max \{||x_i||_{X_i} : x = (x_1, \cdots, x_n)\}$$

Then a similar argument to the above shows this is a norm on $\prod_{i=1}^n X_i$. Consider the triangle inequality.

$$||x_1, \cdots, x_n + (y_1, \cdots, y_n)|| = \max \{|x_i + y_i| : x = (x_1, \cdots, x_n)\} \leq \max \{|x_i|, |y_i|\}$$

$$\leq \max \{|x_i| + |y_i|\}$$

**Corollary 20.8.2** Let $U \subseteq \prod_{i=1}^n X_i$ be an open set and let

$$U_{(x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n)} = \{x \in \mathbb{F}^r : (x_1, \cdots, x_{i-1}, x, x_{i+1}, \cdots, x_n) \in U\}.$$

Then $U_{(x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n)}$ is an open set in $\mathbb{F}^r$.

**Proof:** Let $z \in U_{(x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n)}$. Then $(x_1, \cdots, x_{i-1}, z, x_{i+1}, \cdots, x_n) = x \in U$ by definition. Therefore, since $U$ is open, there exists $r > 0$ such that $B(x, r) \subseteq U$. It follows that for $B(z, r)$ denoting the ball in $X_i$, it follows that $B(z, r)_{X_i} \subseteq U_{(x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n)}$ because to say that $||z - w||_{X_i} < r$ is to say that

$$||x_1, \cdots, x_{i-1}, z, x_{i+1}, \cdots, x_n) - (x_1, \cdots, x_{i-1}, w, x_{i+1}, \cdots, x_n)|| < r$$

and so $w \in U_{(x_1, \cdots, x_{i-1}, x_{i+1}, \cdots, x_n)}$. □

Next is a generalization of the partial derivative.

**Definition 20.8.3** Let $g : U \subseteq \prod_{i=1}^n X_i \to Y$, where $U$ is an open set. Then the map

$$z \to g(x_1, \cdots, x_{i-1}, z, x_{i+1}, \cdots, x_n)$$

is a function from the open set in $X_i$,

$$\{z : x = (x_1, \cdots, x_{i-1}, z, x_{i+1}, \cdots, x_n) \in U\}$$
to $Y$. When this map is differentiable, its derivative is denoted by $D_ig(x)$. To aid in the notation, for $v \in X_i$, let $\theta_v \in \prod_{i=1}^n X_i$ be the vector $(0, \cdots, v, \cdots, 0)$ where the $v$ is in the $i$th slot and for $v \in \prod_{i=1}^n X_i$, let $v_i$ denote the entry in the $i$th slot of $v$. Thus, by saying
\[ z \to g(x_1, \cdots, x_{i-1}, z, x_{i+1}, \cdots, x_n) \]
is differentiable is meant that for $v \in X_i$ sufficiently small,
\[ g(x + \theta_v) - g(x) = D_ig(x)v + o(v). \]

Note $D_ig(x) \in \mathcal{L}(X_i, Y)$.

**Definition 20.8.4** Let $U \subseteq X$ be an open set. Then $f : U \to Y$ is $C^1(U)$ if $f$ is differentiable and the mapping
\[ x \to Df(x), \]
is continuous as a function from $U$ to $\mathcal{L}(X, Y)$.

With this definition of partial derivatives, here is the major theorem. Note the resemblance with the matrix of the derivative of a function having values in $\mathbb{R}^m$ in terms of the partial derivatives.

**Theorem 20.8.5** Let $g, U, \prod_{i=1}^n X_i,$ be given as in Definition 20.8.3. Then $g$ is $C^1(U)$ if and only if $D_ig$ exists and is continuous on $U$ for each $i$. In this case, $g$ is differentiable and
\[ Dg(x)(v) = \sum_k D_ig(x)v_k \tag{20.8.15} \]
where $v = (v_1, \cdots, v_n)$.

**Proof:** Suppose then that $D_ig$ exists and is continuous for each $i$. Note that
\[ \sum_{j=1}^k \theta_j v_j = (v_1, \cdots, v_k, 0, \cdots, 0). \]
Thus $\sum_{j=1}^n \theta_j v_j = v$ and define $\sum_{j=1}^0 \theta_j v_j \equiv 0$. Therefore,
\[ g(x + v) - g(x) = \sum_{k=1}^n \left[ g\left(x + \sum_{j=1}^k \theta_j v_j\right) - g\left(x + \sum_{j=1}^{k-1} \theta_j v_j\right)\right] \tag{20.8.16} \]
Consider the terms in this sum.
\[ g\left(x + \sum_{j=1}^k \theta_j v_j\right) - g\left(x + \sum_{j=1}^{k-1} \theta_j v_j\right) = g(x + \theta_k v_k) - g(x) + \tag{20.8.17} \]
\[
\left( g \left( x + \sum_{j=1}^{k} \theta_j v_j \right) - g \left( x + \theta_k v_k \right) \right) - \left( g \left( x + \sum_{j=1}^{k-1} \theta_j v_j \right) - g \left( x \right) \right)
\]

(20.8.18)

and the expression in 20.8.18 is of the form \( h(v_k) - h(0) \) where for small \( w \in X_k \),

\[
h(w) = g \left( x + \sum_{j=1}^{k-1} \theta_j v_j + \theta_k w \right) - g \left( x + \theta_k w \right).
\]

Therefore,

\[
Dh(w) = D_k g \left( x + \sum_{j=1}^{k-1} \theta_j v_j + \theta_k w \right) - D_k g \left( x + \theta_k w \right)
\]

and by continuity, \(||Dh(w)|| < \varepsilon|\) provided \(||v||| \) is small enough. Therefore, by Theorem 20.6.2, the mean value inequality, whenever \(||v||| \) is small enough,

\[
||h(v_k) - h(0)|| \leq \varepsilon ||v||
\]

which shows that since \( \varepsilon \) is arbitrary, the expression in 20.8.18 is \( o(v) \). Now in 20.8.17

\[
g(x + \theta_k v_k) - g(x) = D_k g(x) v_k + o(v) = D_k g(x) v_k + o(v).
\]

Therefore, referring to 20.8.10,

\[
g(x + v) - g(x) = \sum_{k=1}^{n} D_k g(x) v_k + o(v)
\]

which shows \( Dg(x) \) exists and equals the formula given in 20.8.17. Also \( x \to Dg(x) \) is continuous since each of the \( D_k g(x) \) are.

Next suppose \( g \) is \( C^1 \). I need to verify that \( D_k g(x) \) exists and is continuous. Let \( v \in X_k \) sufficiently small. Then

\[
g(x + \theta_k v) - g(x) = Dg(x) \theta_k v + o(\theta_k v) = Dg(x) \theta_k v + o(v)
\]

since \(||\theta_k v|| = ||v|||\). Then \( D_k g(x) \) exists and equals

\[
Dg(x) \circ \theta_k
\]

Now \( x \to Dg(x) \) is continuous. It is clear that \( \theta_k : X_k \to \prod_{i=1}^{n} X_i \) is also continuous because \( \theta_k v \) places \( v \) in the \( k^{th} \) position and \( 0 \) in every other position.

Note that the above argument also works at a single point \( x \). That is, continuity at \( x \) of the partials implies \( Dg(x) \) exists and is continuous at \( x \).
20.9  Mixed Partial Derivatives

Let $U$ be an open set in $\prod_{i=1}^n X_i$, where the norm is the one described above and let $f : U \to \mathbb{R}$ be a function for which the higher order partial derivatives of the sort described above exist. As in the case of functions defined on open sets of $\mathbb{R}^n$ one can ask whether the mixed partials are equal.

Results of this sort were known to Euler in around 1734. The theorem was proved by Clairaut some time later. It turns out that the mixed partial derivatives, if continuous will end up being equal. It will also work in the more general situation just described.

**Theorem 20.9.1** Let $U$ be an open subset of $\prod_{i=1}^n X_i$ where each $X_i$ is a normed linear space and $\|x\| = \max_i \|x_i\|_i$. Let $f : U \to \mathbb{R}$ have mixed partial derivatives $D_iD_j f$ and $D_jD_i f$. Then if these are continuous at $x \in U$, it follows they will be equal in the sense that $D_jD_i f(x)(u,v) = D_iD_j f(x)(v,u)$.

**Proof:** It suffices to assume that there are only two spaces and $U$ is an open subset of $X_1 \times X_2$ because one simply specializes to two of the variables in the general case. We denote the variable for $X_1$ as $x$ and the one from $X_2$ as $y$. Also, to simplify this, first assume $f$ has values in $\mathbb{R}$. Thus it will be denoted as $f$ rather than $f$. Since $U$ is open, there exists $r > 0$ such that $B((x,y),r) \subseteq U$. Now let $t,s$ be small real numbers and consider

$$\Delta (s,t) = \frac{1}{st} \{ f(x+tu,y+sv) - f(x+tu,y) - f(x,y+sv) + f(x,y) \}$$

Then $h'(t) = D_1 f(x+tu,y+sv)(u) - D_1 f(x+tu,y)(u)$. By the mean value theorem,

$$\Delta (s,t) = \frac{1}{s} h'(\theta t) = \frac{1}{s} D_1 f(x+\theta tu,y+sv)(u) - D_1 f(x+\theta tu,y)(u)$$

where $\theta \in (0,1)$. Now use the mean value theorem again to obtain

$$\Delta (s,t) = D_2 D_1 f(x+\theta tu,y+\alpha sv)(u,v), \alpha \in (0,1).$$

Similarly doing things in the other order writing

$$\Delta (s,t) = \frac{1}{st} \{ (f(x+tu,y+sv) - f(x,y+sv)) - (f(x+tu,y) - f(x,y)) \}$$

and taking the derivative first with respect to $s$ and next with respect to $t$, one can obtain

$$\Delta (s,t) = D_1 D_2 f(x+\hat{\theta} tu,y+\hat{\alpha} sv)(v)(u)$$

where $\hat{\theta}, \hat{\alpha}$ are also in $(0,1)$. Then letting $(s,t) \to (0,0)$ and using continuity of the mixed partial derivatives, one obtains that

$$D_2 D_1 f(x,y)(u)(v) = D_1 D_2 f(x,y)(v)(u)$$
Letting \( v = u \) yields the desired result.

The general case follows right away by applying this result to \( \langle y^*, f \rangle \). Thus one obtains
\[
\langle y^*, D_2 D_1 f (x, y) (u) \rangle = \langle y^*, D_1 D_2 f (x, y) (v) (u) \rangle
\]
for every \( y^* \in Y' \). Hence, since \( Y' \) separates the points, it follows that the mixed partials are equal. \( \blacksquare \)

It is necessary to assume the mixed partial derivatives are continuous in order to assert they are equal. The following is a well known example \([5]\).

**Example 20.9.2** Let
\[
f(x, y) = \begin{cases} 
x y (x^2 - y^2) & \text{if } (x, y) \neq (0, 0) \\
0 & \text{if } (x, y) = (0, 0)
\end{cases}
\]

From the definition of partial derivatives it follows immediately that \( f_x (0, 0) = f_y (0, 0) = 0 \). Using the standard rules of differentiation, for \( (x, y) \neq (0, 0) \),
\[
f_x = y \frac{x^4 - y^4 + 4x^2 y^2}{(x^2 + y^2)^2}, \quad f_y = x \frac{x^4 - y^4 - 4x^2 y^2}{(x^2 + y^2)^2}
\]
Now
\[
f_{xy} (0, 0) = \lim_{y \to 0} \frac{f_x (0, y) - f_x (0, 0)}{y} = \lim_{y \to 0} \frac{-y^4}{(y^2)^2} = -1
\]
while
\[
f_{yx} (0, 0) = \lim_{x \to 0} \frac{f_y (x, 0) - f_y (0, 0)}{x} = \lim_{x \to 0} \frac{x^4}{(x^2)^2} = 1
\]
showing that although the mixed partial derivatives do exist at \( (0, 0) \), they are not equal there.

Incidentally, the graph of this function appears very innocent. Its fundamental sickness is not apparent. It is like one of those whitened sepulchers mentioned in the Bible.
20.10 Implicit Function Theorem

Recall the following notation. \( \mathcal{L}(X,Y) \) is the space of bounded linear mappings from \( X \) to \( Y \) where here \( (X, \| \cdot \|_X) \) and \( (Y, \| \cdot \|_Y) \) are normed linear spaces. Recall that this means that for each \( L \in \mathcal{L}(X,Y) \)
\[
\|L\| \equiv \sup_{\|x\| \leq 1} \|Lx\| < \infty
\]
As shown earlier, this makes \( \mathcal{L}(X,Y) \) into a normed linear space. In case \( X \) is finite dimensional, \( \mathcal{L}(X,Y) \) is the same as the collection of linear maps from \( X \) to \( Y \). In what follows \( X,Y \) will be Banach spaces, complete normed linear spaces. Thus these are complete normed linear space and \( \mathcal{L}(X,Y) \) is the space of bounded linear maps. I will also cease trying to write the vectors in bold face partly to emphasize that these are not in \( \mathbb{R}^n \).

**Definition 20.10.1** Let \( (X, \| \cdot \|_X) \) and \( (Y, \| \cdot \|_Y) \) be two normed linear spaces. Then \( \mathcal{L}(X,Y) \) denotes the set of linear maps from \( X \) to \( Y \) which also satisfy the following condition. For \( L \in \mathcal{L}(X,Y) \),
\[
\lim_{\|x\| \leq 1} \|Lx\|_Y \equiv \|L\| < \infty
\]
Recall that this operator norm is less than infinity is always the case where \( X \) is finite dimensional. However, if you wish to consider infinite dimensional situations, you assume the operator norm is finite as a qualification for being in \( \mathcal{L}(X,Y) \). Then here is an important theorem.

**Theorem 20.10.2** If \( Y \) is a Banach space, then \( \mathcal{L}(X,Y) \) is also a Banach space.

**Proof:** Let \( \{L_n\} \) be a Cauchy sequence in \( \mathcal{L}(X,Y) \) and let \( x \in X \).
\[
\|L_nx - L_mx\| \leq \|x\| \|L_n - L_m\|.
\]
Thus \( \{L_nx\} \) is a Cauchy sequence. Let
\[
Lx = \lim_{n \to \infty} L_nx.
\]
Then, clearly, \( L \) is linear because if \( x_1, x_2 \) are in \( X \), and \( a, b \) are scalars, then
\[
L(ax_1 + bx_2) = \lim_{n \to \infty} L_n(ax_1 + bx_2) = \lim_{n \to \infty} (aL_nx_1 + bL_nx_2) = aLx_1 + bLx_2.
\]
Also \( L \) is bounded. To see this, note that \( \{\|L_n\|\} \) is a Cauchy sequence of real numbers because \( \|L_n - L_m\| \leq \|L_n - L_m\| \). Hence there exists \( K > \sup \{\|L_n\| : n \in \mathbb{N}\} \). Thus, if \( x \in X \),
\[
\|Lx\| = \lim_{n \to \infty} \|L_nx\| \leq K \|x\|.
\]

The following theorem is really nice. The series in this theorem is called the Neuman series.
Lemma 20.10.3 Let \((X, \| \cdot \|)\) be a Banach space, and if \(A \in \mathcal{L}(X, X)\) and \(\|A\| = r < 1\), then
\[
(I - A)^{-1} = \sum_{k=0}^{\infty} A^k \in \mathcal{L}(X, X)
\]
where the series converges in the Banach space \(\mathcal{L}(X, X)\). If \(\mathcal{O}\) consists of the invertible maps in \(\mathcal{L}(X, X)\), then \(\mathcal{O}\) is open and if \(\mathcal{I}\) is the mapping which takes \(A\) to \(A^{-1}\), then \(\mathcal{I}\) is continuous.

Proof: First of all, why does the series make sense?
\[
\left\| \sum_{k=p}^{q} A^k \right\| \leq \sum_{k=p}^{q} \|A^k\| \leq \sum_{k=p}^{q} \|A\|^k \leq \sum_{k=p}^{\infty} r^k \leq \frac{rp}{1-r}
\]
and so the partial sums are Cauchy in \(\mathcal{L}(X, X)\). Therefore, the series converges to something in \(\mathcal{L}(X, X)\) by completeness of this normed linear space. Now why is it the inverse?
\[
\sum_{k=0}^{\infty} A^k (I - A) = \lim_{n \to \infty} \sum_{k=0}^{n} A^k (I - A) = \lim_{n \to \infty} \left( \sum_{k=0}^{n} A^k - \sum_{k=1}^{n+1} A^k \right) = \lim_{n \to \infty} (I - A^{n+1}) = I
\]
because \(\|A^{n+1}\| \leq \|A\|^{n+1} \leq r^{n+1}\). Similarly,
\[
(I - A) \sum_{k=0}^{\infty} A^k = \lim_{n \to \infty} (I - A^{n+1}) = I
\]
and so this shows that this series is indeed the desired inverse.

Next suppose \(A \in \mathcal{O}\) so \(A^{-1} \in \mathcal{L}(X, X)\). Then suppose \(\|A - B\| < \frac{r}{1 + \|A^{-1}\|}, r < 1\). Does it follow that \(B\) is also invertible?
\[
B = A - (A - B) = A [I - A^{-1} (A - B)]
\]
Then \(\|A^{-1} (A - B)\| \leq \|A^{-1}\| \|A - B\| < r\) and so \([I - A^{-1} (A - B)]^{-1}\) exists. Hence
\[
B^{-1} = [I - A^{-1} (A - B)]^{-1} A^{-1}
\]
Thus \(\mathcal{O}\) is open as claimed. As to continuity, let \(A, B\) be as just described. Then using the Neumann series,
\[
\|\mathcal{I}A - \mathcal{I}B\| = \left\| A^{-1} - [I - A^{-1} (A - B)]^{-1} A^{-1} \right\|
\]
\[
= \left\| A^{-1} - \sum_{k=0}^{\infty} (A^{-1} (A - B))^k A^{-1} \right\| = \left\| \sum_{k=1}^{\infty} (A^{-1} (A - B))^k A^{-1} \right\|
\]
\[
\leq \sum_{k=1}^{\infty} \|A^{-1}\|^{k+1} \|A - B\|^k = \|A - B\| \|A^{-1}\|^2 \sum_{k=0}^{\infty} \|A^{-1}\|^k \frac{r^k}{(1 + \|A^{-1}\|)^k}
\]
\[
\leq \|B - A\| \|A^{-1}\|^2 \frac{1}{1-r}.
\]
Thus $\mathcal{I}$ is continuous at $A \in \mathcal{O}$. ■

**Lemma 20.10.4** Let

$$\mathcal{O} \equiv \{ A \in \mathcal{L}(X,Y) : A^{-1} \in \mathcal{L}(Y,X) \}$$

and let

$$\mathcal{J} : \mathcal{O} \to \mathcal{L}(Y,X), \quad \mathcal{J}A \equiv A^{-1}.$$ 

Then $\mathcal{O}$ is open and $\mathcal{J}$ is in $C^m(\mathcal{O})$ for all $m = 1, 2, \ldots$. Also

$$D\mathcal{J}(A)(B) = -\mathcal{J}(A)(B)\mathcal{J}(A). \quad (20.10.19)$$

In particular, $\mathcal{J}$ is continuous.

**Proof:** Let $A \in \mathcal{O}$ and let $B \in \mathcal{L}(X,Y)$ with

$$||B|| \leq \frac{1}{2} ||A^{-1}||^{-1}.$$ 

Then

$$||A^{-1}B|| \leq ||A^{-1}|| ||B|| \leq \frac{1}{2}$$

and so by Lemma 20.10.3,

$$(I + A^{-1}B)^{-1} \in \mathcal{L}(X,X).$$

It follows that

$$(A + B)^{-1} = (A(I + A^{-1}B))^{-1} = (I + A^{-1}B)^{-1}A^{-1} \in \mathcal{L}(Y,X).$$

Thus $\mathcal{O}$ is an open set.

Thus

$$(A + B)^{-1} = (I + A^{-1}B)^{-1}A^{-1} = \sum_{n=0}^{\infty} (-1)^n (A^{-1}B)^n A^{-1}$$

$$= [I - A^{-1}B + o(B)] A^{-1}$$

which shows that $\mathcal{O}$ is open and, also,

$$\mathcal{J}(A + B) - \mathcal{J}(A) = \sum_{n=0}^{\infty} (-1)^n (A^{-1}B)^n A^{-1} - A^{-1}$$

$$= -A^{-1}BA^{-1} + o(B)$$

$$= -\mathcal{J}(A)(B)\mathcal{J}(A) + o(B)$$

which demonstrates $\mathcal{J}$ is continuous. It follows from this that we can continue taking derivatives of $\mathcal{J}$. For $||B_1||$ small,

$$- [D\mathcal{J}(A + B_1)(B) - D\mathcal{J}(A)(B)] =$$
\[ \mathcal{J}(A + B_1)(B) \mathcal{J}(A + B_1) - \mathcal{J}(A)(B) \mathcal{J}(A) \]
\[ = \mathcal{J}(A + B_1)(B) \mathcal{J}(A + B_1) - \mathcal{J}(A)(B) \mathcal{J}(A + B_1) + \]
\[ \mathcal{J}(A)(B) \mathcal{J}(A + B_1) - \mathcal{J}(A)(B) \mathcal{J}(A) \]
\[ = [\mathcal{J}(A)(B_1) \mathcal{J}(A) + o(B_1)](B) \mathcal{J}(A + B_1) + \]
\[ \mathcal{J}(A)(B)[\mathcal{J}(A)(B_1) \mathcal{J}(A) + o(B_1)] \]
\[ = \mathcal{J}(A)(B_1) \mathcal{J}(A) + \mathcal{J}(A)(B) \mathcal{J}(A)(B_1) \mathcal{J}(A) + o(B_1) \]
and so
\[ D^2 \mathcal{J}(A)(B_1)(B) = \mathcal{J}(A)(B_1) \mathcal{J}(A)(B) \mathcal{J}(A) + \mathcal{J}(A)(B) \mathcal{J}(A)(B_1) \mathcal{J}(A) \]
which shows \( \mathcal{J} \) is \( C^2(\mathcal{O}) \). Clearly we can continue in this way which shows \( \mathcal{J} \) is in \( C^m(\mathcal{O}) \) for all \( m = 1, 2, \ldots \). 

Here are the two fundamental results presented earlier which will make it easy to prove the implicit function theorem. First is the fundamental mean value inequality.

**Theorem 20.10.5** Suppose \( U \) is an open subset of \( X \) and \( f : U \to Y \) has the property that \( Df (x) \) exists for all \( x \) in \( U \) and that, \( x + t(y-x) \in U \) for all \( t \in [0,1] \). (The line segment joining the two points lies in \( U \).) Suppose also that for all points on this line segment,
\[ ||Df(x + t(y-x))|| \leq M. \]
Then
\[ ||f(y) - f(x)|| \leq M |y - x|. \]

Next recall the following theorem about fixed points of a contraction map. It was Corollary 20.10.6

**Corollary 20.10.6** Let \( B \) be a closed subset of the complete metric space \( (X,d) \) and let \( f : B \to X \) be a contraction map
\[ d(f(x), f(\hat{x})) \leq rd(x, \hat{x}), \quad r < 1. \]
Also suppose there exists \( x_0 \in B \) such that the sequence of iterates \( \{f^n(x_0)\}_{n=1}^{\infty} \) remains in \( B \). Then \( f \) has a unique fixed point in \( B \) which is the limit of the sequence of iterates. This is a point \( x \in B \) such that \( f(x) = x \). In the case that \( B = \overline{B(x_0, \delta)} \), the sequence of iterates satisfies the inequality
\[ d(f^n(x_0), x_0) \leq \frac{d(x_0, f(x_0))}{1 - r} \]
and so it will remain in \( B \) if
\[ \frac{d(x_0, f(x_0))}{1 - r} < \delta. \]
The implicit function theorem deals with the question of solving, \( f(x, y) = 0 \) for \( x \) in terms of \( y \) and how smooth the solution is. It is one of the most important theorems in mathematics. The proof I will give holds with no change in the context of infinite dimensional complete normed vector spaces when suitable modifications are made on what is meant by \( \mathcal{L}(X, Y) \). There are also even more general versions of this theorem than to normed vector spaces.

Recall that for \( X, Y \) normed vector spaces, the norm on \( X \times Y \) is of the form
\[
\left\| (x, y) \right\| = \max \left( \|x\|, \|y\| \right).
\]

**Theorem 20.10.7** (implicit function theorem) Let \( X, Y, Z \) be Banach spaces and suppose \( U \) is an open set in \( X \times Y \). Let \( f : U \to Z \) be in \( C^1(U) \) and suppose
\[
f(x_0, y_0) = 0, \quad D_1 f(x_0, y_0)^{-1} \in \mathcal{L}(Z, X).
\]
Then there exist positive constants, \( \delta, \eta \), such that for every \( y \in B(y_0, \eta) \) there exists a unique \( x(y) \in B(x_0, \delta) \) such that
\[
f(x(y), y) = 0.
\]
Furthermore, the mapping, \( y \to x(y) \) is in \( C^1(B(y_0, \eta)) \).

**Proof:** Let \( T(x, y) \equiv x - D_1 f(x_0, y_0)^{-1} f(x, y) \). Therefore,
\[
D_1 T(x, y) = I - D_1 f(x_0, y_0)^{-1} D_1 f(x, y).
\]
by continuity of the derivative which implies continuity of \( D_1 T \), it follows there exists \( \delta > 0 \) such that if \( \|x-x_0\| < \delta \) and \( \|y-y_0\| < \delta \), then
\[
\|D_1 T(x, y)\| < \frac{1}{2}, \quad D_1 f(x, y)^{-1} \text{ exists}
\]
(20.10.23)
The second claim follows from Lemma [4.10.4]. By the mean value inequality, Theorem [4.10.2], whenever \( x, x' \in B(x_0, \delta) \) and \( y \in B(y_0, \delta) \),
\[
\|T(x, y) - T(x', y)\| \leq \frac{1}{2} \|x-x'\|.
\]
(20.10.24)
Also, it can be assumed \( \delta \) is small enough that for some \( M \) and all such \( (x, y) \),
\[
\|D_1 f(x_0, y_0)^{-1}\| \|D_2 f(x, y)\| < M
\]
(20.10.25)
Next, consider only \( y \) such that \( \|y-y_0\| < \eta \) where \( \eta \) is so small that
\[
\|T(x_0, y) - x_0\| < \frac{\delta}{3}
\]
Then for such \( y \), consider the mapping \( T_y(x) = T(x, y) \). Thus by Corollary [4.10.4], for each \( n \in \mathbb{N} \),
\[
\delta > \frac{2}{3} \delta \geq \frac{\|T_y(x_0) - x_0\|}{1 - (1/2)} \geq \|T_y^n(x_0) - x_0\|
\]
Then by the sequence of iterations of this map $T_y$ converges to a unique fixed point $x(y)$ in the ball $B(x_0, \delta)$. Thus, from the definition of $T$, $f(x(y), y) = 0$. This is the implicitly defined function.

Next we show that this function is Lipschitz continuous. For $y, \hat{y}$ in $B(y_0, \eta)$,

$$
\|T(x, y) - T(x, \hat{y})\| =
\left| \right| \left| D^1 f (x_0, y_0)^{-1} f(x, y) - D^1 f (x_0, y_0)^{-1} f(x, \hat{y}) \right| \right| \leq M \|y - \hat{y}\|
$$

thanks to the above estimate and the mean value inequality, Theorem 20.10.27. Note how convexity of $B(y_0, \eta)$ which says that the line segment joining $y, \hat{y}$ is contained in $B(y_0, \eta)$ is important to use this theorem. Then from this,

$$
\|x(y) - x(\hat{y})\| = \|T(x(y), y) - T(x(\hat{y}), \hat{y})\| \leq \|T(x(y), y) - T(x(y), \hat{y})\|
$$

$$
+ \|T(x(y), \hat{y}) - T(x(\hat{y}), \hat{y})\|
$$

$$
\leq M \|y - \hat{y}\| + \frac{1}{2} \|x(y) - x(\hat{y})\|
$$

Hence,

$$
\|x(y) - x(\hat{y})\| \leq 2M \|y - \hat{y}\| \quad (20.10.26)
$$

Finally consider the claim that this implicitly defined function is $C^1$.

$$
0 = f(x(y + u), y + u) - f(x(y), y)
$$

$$
= D^1 f(x(y), y)(x(y + u) - x(y)) + D^2 f(x(y), y)u
$$

$$
+ o(x(y + u) - x(y), u) \quad (20.10.27)
$$

Consider the last term. $o(x(y + u) - x(y), u) / \|u\|$ equals

$$
\left\{ \begin{array}{ll}
\frac{o(x(y + u) - x(y), u)}{\|x(y + u) - x(y), u\|} \max_{X \times Y} \|x(y + u) - x(y), u\| & \text{if } \|x(y + u) - x(y), u\|_{X \times Y} \neq 0 \\
0 & \text{if } \|x(y + u) - x(y), u\|_{X \times Y} = 0
\end{array} \right.
$$

Now the Lipschitz condition just established shows that

$$
\max_{\|u\|} \frac{\|x(y + u) - x(y)\|}{\|u\|}
$$

is bounded for nonzero $u$ sufficiently small that $y, y + u \in B(y_0, \eta)$. Therefore,

$$
\lim_{u \to 0} \frac{o(x(y + u) - x(y), u)}{\|u\|} = 0
$$

Then shows that

$$
0 = D^1 f(x(y), y)(x(y + u) - x(y)) + D^2 f(x(y), y)u + o(u)
$$

Therefore, solving for $x(y + u) - x(y)$, it follows that

$$
x(y + u) - x(y) = -D^1 f(x(y), y)^{-1} D^2 f(x(y), y)u + D^1 f(x(y), y)^{-1} o(u)
$$

$$
= -D^1 f(x(y), y)^{-1} D^2 f(x(y), y)u + o(u)
$$
and now, the continuity of the partial derivatives $D_1 f, D_2 f$, continuity of the map $A \to A^{-1}$, along with the continuity of $y \to x(y)$ shows that $y \to x(y)$ is $C^1$ with derivative equal to $-D_1 f (x(y), y)^{-1} D_2 f (x(y), y)$. ■

It is easy to give a version of this theorem in which the function $f$ also depends on a parameter $\lambda \in \Lambda$, a metric space.

**Corollary 20.10.8** Let $X, Y, Z$ be Banach spaces and suppose $U$ is an open set in $X \times Y$. Let $f : U \times \Lambda \to Z$ satisfy $f(\cdot, \cdot, \lambda)$ is in $C^1 (U)$ and suppose for each $\lambda$,

$$f (x_0, y_0, \lambda) = 0, \quad D_1 f (x_0, y_0, \lambda)^{-1} \in \mathcal{L}(Z, X). \quad (20.10.28)$$

Also suppose $(x, y) \to D_1 f (x, y, \lambda)$ is continuous uniformly in $\lambda$ and $D_2 (x, y, \lambda)$ is uniformly bounded in $\lambda$ for $(x, y)$ sufficiently close to $(x_0, y_0)$. Then there exist positive constants, $\delta, \eta$, such that for every $y \in B(y_0, \eta)$ there exists a unique $x(y, \lambda) \in B(x_0, \delta)$ such that

$$f (x(y, \lambda), y, \lambda) = 0. \quad (20.10.29)$$

Furthermore, the mapping, $y \to x(y, \lambda)$ is in $C^1 (B(y_0, \eta))$ and $\lambda \to x(y, \lambda)$ is continuous.

**Proof:** It is just a repeat of the above proof except you use the uniform contraction principle, Corollary 6.7.4 to get the fixed point. ■

The next theorem is a very important special case of the implicit function theorem known as the inverse function theorem. Actually one can also obtain the implicit function theorem from the inverse function theorem. It is done this way in [70], [77] and in [5].

**Theorem 20.10.9** (inverse function theorem) Let $x_0 \in U$, an open set in $X$, and let $f : U \to Y$ where $X, Y$ are finite dimensional normed vector spaces. Suppose

$$f \text{ is } C^1 (U), \quad \text{and } Df(x_0)^{-1} \in \mathcal{L}(Y, X). \quad (20.10.30)$$

Then there exist open sets $W$, and $V$ such that

$$x_0 \in W \subseteq U, \quad (20.10.31)$$

$$f : W \to V \text{ is one to one and onto}, \quad (20.10.32)$$

$$f^{-1} \text{ is } C^1, \quad (20.10.33)$$

**Proof:** Apply the implicit function theorem to the function

$$F(x, y) \equiv f(x) - y$$

where $y_0 \equiv f(x_0)$. Thus the function $y \to x(y)$ defined in that theorem is $f^{-1}$. Now let

$$W \equiv B(x_0, \delta) \cap f^{-1} (B(y_0, \eta))$$

and

$$V \equiv B(y_0, \eta). \quad ■$$
20.11 More Derivatives

When you consider a $C^k$ function $f$ defined on an open set $U$, you obtain the following

$$Df(x) \in \mathcal{L}(X,Y), D^2f(x) \in \mathcal{L}(X,\mathcal{L}(X,Y)), D^3f(x) \in \mathcal{L}(X,\mathcal{L}(X,\mathcal{L}(X,Y)))$$

and so forth. Thus they can each be considered as a linear transformation with values in some vector space. When you consider the vector spaces, you see that these can also be considered as multilinear functions on $X$ with values in $Y$. Now consider the product of two linear transformations $A(y)B(y)w$, where everything is given to make sense and here $w$ is an appropriate vector. Then if each of these linear transformations can be differentiated, you would do the following simple computation.

$$(A(y + u)B(y + u) - A(y)B(y))(w)$$

$$= (A(y + u)B(y + u) - A(y)B(y + u) + A(y)B(y + u) - A(y)B(y))(w)$$

$$= ((DA(y)u + o(u))B(y + u) + A(y)(DB(y)u + o(u)))(w)$$

$$= (DA(y)(u)B(y + u) + A(y)DB(y)(u) + o(u))(w)$$

Then

$$u \rightarrow (DA(y)(u)B(y) + A(y)DB(y)(u))(w)$$

is clearly linear and

$$(u,w) \rightarrow (DA(y)(u)B(y) + A(y)DB(y)(u))(w)$$

is bilinear and continuous as a function of $y$. By this we mean that for a fixed choice of $(u,w)$ the resulting $Y$ valued function just described is continuous. Now if each of $A, B, DA, DB$ can be differentiated, you could replace $y$ with $y + \hat{u}$ and do a similar computation to obtain as many differentiations as desired, the $k^{th}$ differentiation yielding a $k$ linear function. You can do this as long as $A$ and $B$ have derivatives. Now in the case of the implicit function theorem, you have

$$Dx(y) = -D_1f(x(y),y)^{-1}D_2f(x(y),y).$$

(20.11.34)

By Lemma 20.11.1 and the implicit function theorem and the chain rule, this is the situation just discussed. Thus $D^2x(y)$ can be obtained. Then the formula for it will only involve $Dx$ which is known to be continuous. Thus one can continue in this way finding derivatives till $f$ fails to have them. The inverse map never creates difficulties because it is differentiable of order $m$ for any $m$ thanks to Lemma 20.11.4.

Thus one can conclude the following corollary.

**Corollary 20.11.1** In the implicit and inverse function theorems, you can replace $C^1$ with $C^k$ in the statements of the theorems for any $k \in \mathbb{N}$. 
20.12 Lyapunov Schmidt Procedure

You have \( f : X \times \Lambda \rightarrow Y \) where here \( X, \Lambda \) are Banach spaces. Suppose \((0,0) \in X \times \Lambda \) and \( f (0,0) = 0 \). Then if \( D_1 f (0,0)^{-1} \) is in \( \mathcal{L}(Y,X) \), the implicit function theorem says that there exists \( x(\lambda) \) a \( C^p \) function such that locally \( f (x(\lambda), \lambda) = 0 \). So what if \( D_1 f (0,0) \) fails to be one to one? Sometimes this case is also considered. It may be that \( D_1 f (0,0) \) is one to one on some subspace and other nice things happen. In particular, suppose the following.

Letting \( X_2 = \text{ker} \, D_1 f (0,0) \) assume

\[
X = X_1 \oplus X_2, \quad \text{dim} \, (X_2) < \infty
\]

where \( X_1 \) is a closed subspace. Thus \( D_1 f (0,0) \) is one to one on \( X_1 \). We let

\[
Y_1 = D_1 f (0,0) (X_1)
\]

and suppose that \( Y = Y_1 \oplus Y_2 \) where \( \text{dim} \, (Y_2) < \infty \), \( Y_1 \) also a closed subspace.

\[
\begin{align*}
X_1 & \overset{D_1 f (0,0)}{\rightarrow} Y_1 = D_1 f (0,0) (X_1), \quad Y_1 \text{ closed} \quad < \infty \\
Y & = Y_1 \oplus Y_2, \quad \text{dim} \, (Y_2) < \infty
\end{align*}
\]

By the open mapping theorem, \( D_1 f (0,0)^{-1} \) is also continuous.

Let \( Q \) be a continuous projection onto \( Y_1 \) which is assumed to exist\(^1\) so that \((I - Q)\) is a projection onto \( Y_2 \). Then the equation \( f (x(\lambda), \lambda) = 0 \) can be written as the pair

\[
\begin{align*}
Q f (x, \lambda) & = 0 \\
(I - Q) f (x, \lambda) & = 0
\end{align*}
\]

Consider the top. For \( x = x_1 + x_2 \) where \( x_i \in X_i \), this is

\[
Q f (x_1 + x_2, \lambda) = 0
\]

Then if \( g (x_1, x_2, \lambda) = Q f (x_1 + x_2, \lambda) \), one has \( g : X_1 \times X_2 \times \Lambda \rightarrow Y_1 \)

\[
D_1 g (x_1, x_2, \lambda) h = D_1 Q f (x_1 + x_2, \lambda) h, \quad h \in X_1.
\]

Thus \( D_1 g (0,0,0)^{-1} \) is continuous by the open mapping theorem \( (D_1 f (0,0) \) is one to one on \( X_1 \), and by the implicit function theorem, there is a solution to

\[
Q f (x_1 + x_2, \lambda) = 0
\]

for \( x_1 = x_1 (x_2, \lambda) \). (Note how it is important that \( X_1 \) and \( Y_1 \) be Banach spaces.)

Then the other equation yields

\[
(I - Q) f (x_1 (x_2, \lambda) + x_2, \lambda) = 0
\]

\(^1\)In Hilbert space, the existence of this projection map is obvious and it is assumed that it exists here.
and so for fixed $\lambda$, this is a finite set of equations of a variable in a finite dimensional space.

This depends on being able to write $X = X_1 \oplus X_2$ where $X_1$ is closed, $X_2 = \ker D_1 f (0, 0)$, a similar situation for $Y = Y_1 \oplus Y_2$. So when does this happen? Are there conditions on $D_1 f (0, 0)$ which will cause it to occur?

There are such conditions. For example, $D_1 f (0, 0)$ could be a Fredholm operator defined in Definition [5.6.7]. The following are some easy examples in which all that nonsense about things being finite dimensional and part of a direct sum does not need to be considered.

**Example 20.12.1** Say $X = \mathbb{R}^2$ and $\Lambda = \mathbb{R}$. Let $f (x, y, \lambda) = x + xy + y^2 + \lambda$. Then

$$D_1 f (0, 0, 0) = (1, 0)$$

this $1 \times 2$ matrix mapping $\mathbb{R}^2$ to $\mathbb{R}$. Thus $X_2 = (0, \alpha)^T : \alpha \in \mathbb{R}$ and $X_1 = (\alpha, 0)^T : \alpha \in \mathbb{R}$. In this case, $Y_1 = \mathbb{R}$ and so $Q = I$. Thus the above reduces to the single equation

$$f ((\alpha, 0) + (0, \beta), \lambda) = 0$$

and so since $D_1 f (0, 0, 0)$ is one to one, $x_1 = (\alpha, 0) = x_1 ((0, \beta), \lambda)$. Of course this is completely obvious because if you consider $f$ in the natural way as a function of three variables, then the implicit function theorem immediately gives $x = x (y, \lambda)$ which is essentially the same result. We just write $(\alpha, 0)$ in place of $\alpha$. The first independent variable is a function of the other two.

**Example 20.12.2** Here is another easy example. $f : \mathbb{R}^2 \times \mathbb{R} \to \mathbb{R}^2$

$$f (x, y, \lambda) = \left( \begin{array}{c} x + xy + y^2 + \sin (\lambda) \\ x + y^2 - x^2 + \lambda \end{array} \right)$$

Then

$$D_1 f (x, y, \lambda) = \left( \begin{array}{cc} 1 + y & x + 2y \\ 1 - 2x & 2y \end{array} \right)$$

So

$$D_1 f ((0, 0), 0) = \left( \begin{array}{cc} 1 & 0 \\ 1 & 0 \end{array} \right)$$

Then

$$X_2 = \ker D_1 f ((0, 0), 0) = \left\{ \left( \begin{array}{c} 0 \\ \beta \end{array} \right) : \beta \in \mathbb{R} \right\}$$

and $X_1 = \left\{ \left( \begin{array}{c} \alpha \\ 0 \end{array} \right) : \alpha \in \mathbb{R} \right\}$ and clearly $D_1 f ((0, 0), 0)$ is indeed one to one on $X_1$.

$$D_1 f (0, 0) (X_1) = \left\{ \left( \begin{array}{c} y \\ y \end{array} \right) : y \in \mathbb{R} \right\} = Y_1.$$ In this case, let

$$Q \left( \begin{array}{c} \alpha \\ \beta \end{array} \right) = \left( \begin{array}{cc} \frac{\alpha + \beta}{\alpha^2 + \beta^2} & 1/2 \\ \frac{\alpha + \beta}{\alpha^2 + \beta^2} & 1/2 \end{array} \right) \left( \begin{array}{c} \alpha \\ \beta \end{array} \right)$$
so \((I - Q) = \begin{pmatrix} 1/2 & -1/2 \\ -1/2 & 1/2 \end{pmatrix}\). Thus the equations are

\[
Qf(x, \lambda) = 0 \\
(I - Q)f(x, \lambda) = 0
\]

This reduces to

\[
\begin{pmatrix}
-\frac{1}{2}x^2 + \frac{1}{2}xy + x + y^2 + \frac{1}{2}\lambda + \frac{1}{2}\sin \lambda \\
-\frac{1}{2}x^2 + \frac{1}{2}xy + x + y^2 + \frac{1}{2}\lambda + \frac{1}{2}\sin \lambda
\end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}
\]

Note how in both the top and the bottom, there is only one equation and one can solve for \(x\) in terms of \(y\); near \((0, 0, 0)\) which is what the above general argument shows. Of course you can see this directly using the implicit function theorem. Then can you solve for \(y = y(\lambda)\)? This would involve trying to solve for \(y\) as a function of \(\lambda\) in the following where \(x(y, \lambda)\) comes from the first equations.

\[
\frac{1}{2}x^2(y, \lambda) + \frac{1}{2}yx(y, \lambda) - \frac{1}{2}\lambda + \frac{1}{2}\sin \lambda = 0
\]

If you can do this, then you would have found \((x, y)\) as a function of \(\lambda\) for small \(\lambda\).

In this example, in the top equation, at \((0, 0, 0)\), \(x, y = 0\). Also \(x_{\lambda} = -1\) so \(x(y, \lambda) \approx -\lambda\) other than higher order terms for small \(y, \lambda\). Then in the bottom equation, for all variables very small, you would have \(\lambda^2 + y(-\lambda) - \lambda + \sin(\lambda) = 0\), \(y(\lambda) = -1 + \frac{\sin(\lambda)}{\lambda} + \lambda\) at least approximately. Thus it seems there is a nonzero solution to the equation \(f(x, y, \lambda) = 0\) which is valid for small \(\lambda, x, y\), this in addition to the zero solution. Note that for small nonzero \(\lambda, -1 + \frac{\sin(\lambda)}{\lambda} + \lambda \neq 0\). It equals approximately \(\lambda - \frac{\lambda^2}{3!}\) for small \(\lambda\) from the power series for \(\sin\).

In the next example, the same procedure gives a solution to a problem \(f((x, y), \lambda) = 0\) such that for small \(\lambda\), \((x, y)\) is a function of \(\lambda\) which is nonzero and \(f((0, 0), \lambda) = 0\). Thus for small \(\lambda\), there are two solutions to the nonlinear system of equations.

**Example 20.12.3** Let

\[
f((x, y), \lambda) = \begin{pmatrix} x + xy + y^2 + x\sin(\lambda) \\ x + y^2 - x^2 + x\lambda \end{pmatrix}
\]

In this case \(f((0, 0), \lambda) = 0\) even though \(\lambda\) might not be 0. The Lyapunov Schmidt procedure will be used to show that there are nonzero solutions \(x(\lambda), y(\lambda)\) such that \(f((x(\lambda), y(\lambda)), \lambda) = 0\).

At origin,

\[
D_1f((0, 0), 0) = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}
\]
Thus $X_1 = \text{span} (e_1)$ and $X_2 = \text{span} (e_2)$. Then $Y_1 = \text{span} (e_1 + e_2)$ and $Y_2 = \text{span} (e_1 - e_2)$. Also $D_1 f ((0,0),0)$ is one to one on $X_1$ and its range is $Y_1$. Then let

$$Q \left( \begin{array}{c} \alpha \\ \beta \end{array} \right) = \left( \begin{array}{c} \alpha + \frac{\beta}{2} \\ \frac{\alpha + \beta}{2} \end{array} \right) = \left( \begin{array}{cc} 1/2 & 1/2 \\ 1/2 & 1/2 \end{array} \right) \left( \begin{array}{c} \alpha \\ \beta \end{array} \right)$$

$$(I - Q) = \left( \begin{array}{cc} 1/2 & -1/2 \\ -1/2 & 1/2 \end{array} \right)$$

Then $Qf = 0$ is yields the equation

$$x + \frac{1}{2} x \lambda + \frac{1}{2} x \sin \lambda + \frac{1}{2} x y - \frac{1}{2} x^2 + y^2 = 0$$

Also $(I - Q)f = 0$ yields the equation

$$\frac{1}{2} x \sin \lambda - \frac{1}{2} x \lambda + \frac{1}{2} x y + \frac{1}{2} x^2 = 0$$

Now consider $x_y$ and $x_\lambda$ at $(0,0)$ from the first equation. Both of these are easily seen to be 0. Now consider $x_{yy}$. After some computations, this is seen to be $x_{yy} = -2$. Similarly, $x_{y\lambda} (0,0) = 0$, $x_{\lambda\lambda} (0,0) = 0$ also. Thus up to terms of degree 3,

$$x (y, \lambda) = -y^2 = \frac{1}{2} (-2) y^2$$

Place this in the bottom equation.

$$\frac{1}{2} y^2 \lambda - \frac{1}{2} y^2 \sin \lambda - \frac{1}{2} y^3 + \frac{1}{2} y^4 = 0$$

Now the idea is to find $y = y (\lambda)$, hopefully nonzero. Divide by $y^2$ and multiply by 2.

$$y^2 - y + \lambda - \sin \lambda = 0$$

Then for small $\lambda$ this is approximately equal to

$$y^2 - y + \frac{\lambda^3}{6} = 0$$

Then a solution for $y$ for small $\lambda$ is

$$y = \frac{1 + \sqrt{1 - \frac{2}{3} \lambda^3}}{2}$$

Of course there is another solution as well, when you replace the + with a minus sign. This is the one we want because when $\lambda = 0$ it reduces to $y = 0$. This shows that there exist solutions to the equations $f ((x,y),\lambda) = 0$ which for small $\lambda$ are approximately

$$(x (\lambda), y (\lambda)) = \left( -y^2, \frac{1 - \sqrt{1 - \frac{2}{3} \lambda^3}}{2} \right)$$
In terms of $\lambda$ very small,

\[
(x(\lambda), y(\lambda)) = \left( \frac{1}{6} \lambda^3 + \frac{1}{6} \sqrt{3} \sqrt[3]{3 - 2\lambda^3} - \frac{1}{2}, \frac{1}{2} \sqrt{1 - \frac{3}{3} \lambda^3} \right)
\]

Using a power series in $\lambda$ to approximate these functions, this reduces to

\[
(x(\lambda), y(\lambda)) = \left( -\frac{1}{36} \lambda^6, \frac{1}{6} \lambda^3 + \frac{1}{36} \lambda^6 + \frac{1}{108} \lambda^9 \right)
\]

where higher order terms are neglected. Thus there exist other solutions than the zero solution even though $\lambda$ may be nonzero. Note that in this example, $f((0, 0), \lambda) = 0$.

20.13 Analytic Functions

In calculus, there was a difference between functions of a real variable and functions of a complex variable. In the latter case the existence of a single derivative implied the existence of all derivatives and in fact the Taylor series converged to the function. It is reasonable to ask if a similar phenomenon occurs in the case of complex Banach spaces versus real Banach spaces. This section presents a quick introduction to this topic based on the assumption that the reader has had some exposure to complex analysis. Some of the details involving questions of convergence and term by term differentiation are left to the reader. Also if $h$ maps an open subset of $\mathbb{C}$ to a complex Banach space $X$, and has a first derivative, then the usual Cauchy integral formula,

\[
h(z) = \frac{1}{2\pi i} \int_C \frac{h(w)}{w - z} dw,
\]

holds if $C$ is a circle contained, together with its interior, in the open set on which $h$ has a derivative. The integral can be defined as the ordinary Riemann integral using Riemann sums or it can be defined in terms of a Bochner integral. These details are routine and are left to the reader. There are several equivalent definitions of an analytic function defined on a complex Banach space. The following is the one we will use since it resembles the familiar definition encountered in undergraduate complex variable courses.

**Definition 20.13.1** Let $X$ and $Y$ be complex Banach spaces and let $U \subseteq X$ be an open set. We say $f : U \to Y$ is analytic and bounded on $U$ if

\[
z \to f(x + zh) \text{ is analytic for } x \in U, h \in X \text{ and } |z| \text{ small enough exists for all } x \in U \text{ and also } \|f(x)\| \leq M < \infty \text{ for all } x \in U. \text{ Here } z \in \mathbb{C} \text{ and } x, h \in X.
\]
Let $h \in X^l$ and consider all $z \in C^l$ with $\|z\|_{C^l} = \max (|z_m|, m = 1, \ldots, l)$ sufficiently small. Let $C_1$ be a sufficiently small circle centered at 0. Then consider

$$z_m \to f \left( x + \sum_{m=1}^{l} z_m h_m \right)$$

which is analytic on and inside $C_1$. Thus using the Cauchy integral formula,

$$f \left( x + z_1 h_1 + \sum_{m=2}^{l} z_m h_m \right) = \frac{1}{2\pi i} \int_{C_1} \frac{f (x + w_1 h_1 + \sum_{m=2}^{l} z_m h_m)}{(w_1 - z_1)} dw_1$$

$$= \left( \frac{1}{2\pi i} \right)^2 \int_{C_1} \frac{1}{w_1 - z_1} \cdot \int_{C_1} \frac{f \left( x + w_1 h_1 + w_2 h_2 + \sum_{m=3}^{l} z_m h_m \right)}{(w_2 - z_2)} dw_2 dw_1 = \left( \frac{1}{2\pi i} \right)^l \int_{C_1} \ldots \int_{C_1} \frac{f \left( x + w_1 h_1 + w_2 h_2 + \cdots + w_l h_l \right)}{\prod_{m=1}^{l} (w_m - z_m)} dw_1 \cdots dw_l.$$

Consider the case when $l = 2$.

$$\left( \frac{1}{2\pi i} \right)^2 \int_{C_1} \int_{C_1} \frac{f (x + w_1 h_1 + w_2 h_2)}{(w_1 - z_1)(w_2 - z_2)} dw_2 dw_1 = \left( \frac{1}{2\pi i} \right)^2 \int_{C_1} \int_{C_1} f (x + w_1 h_1 + w_2 h_2) \cdot \sum_{k_2=0}^{\infty} \frac{z_2^{k_2}}{w_2^{k_2+1}} \sum_{k_1=0}^{\infty} \frac{z_1^{k_1}}{w_1^{k_1+1}} dw_2 dw_1 = \left( \frac{1}{2\pi i} \right)^2 \sum_{k_2=0}^{\infty} \sum_{k_1=0}^{\infty} \left( \int_{C_1} \int_{C_1} \frac{f (x + w_1 h_1 + w_2 h_2)}{w_2^{k_2+1} w_1^{k_1+1}} dw_2 dw_1 \right) z_2^{k_2} z_1^{k_1}.$$

Similarly, for arbitrary $l$, and letting $C$ be any circle centered at 0 with radius smaller than $\frac{1}{l}$,

$$f \left( x + \sum_{m=1}^{l} z_m h_m \right) = \sum_{k_l=0}^{\infty} \cdots \sum_{k_1=0}^{\infty} a_{k_1 \ldots k_l} (x, h_1, \ldots, h_l) z_1^{k_1} \cdots z_l^{k_l} \quad (20.13.35)$$

where

$$a_{k_1 \ldots k_l} (x, h_1, \ldots, h_l) = \left( \frac{1}{2\pi i} \right)^l \int_{C} \ldots \int_{C} \frac{f (x + \sum_{m=1}^{l} w_m h_m)}{\prod_{m=1}^{l} w_m^{k_m+1}} dw_1 \cdots dw_l. \quad (20.13.36)$$
Lemma 20.13.2 Let $l \geq 1$ and let $t_m \in \mathbb{C}$. Then if $h \in X^l$, then whenever $|z|$ is small enough, (20.13.35) holds. Also the coefficients satisfy

$$a_{k_1 \ldots k_l} (x, t_1 h_l, \ldots, t_l h_1) = \left( \prod_{m=1}^{l} t_m^{k_m} \right) a_{k_1 \ldots k_l} (x, h_l, \ldots, h_1)$$

(20.13.37)

and

$$\|a_{k_1 \ldots k_l} (x, h_l, \ldots, h_1)\| \leq C \prod_{m=1}^{l} |h_m|$$

(20.13.38)

for some constant $C$.

Proof: Let $C$ be small enough that the circles $t_m C$ for all $m = 1, \ldots, l$ and $C$ have radius less than $\frac{2}{\pi}$. First assume $t_m \neq 0$ for all $m$. Then

$$a_{k_1 \ldots k_l} (x, t_1 h_l, \ldots, t_l h_1)$$

$$= \left( \frac{1}{2\pi i} \right)^l \int_{C} \cdots \int_{C} f \left( x + \sum_{m=1}^{l} w_m t_m h_m \right)$$

$$\prod_{m=1}^{l} t_m^{k_m+1} dw_1 \cdots dw_l$$

Here we just multiplied and divided by $\prod_{m=1}^{l} t_m^{k_m+1}$.

$$= \left( \frac{1}{2\pi i} \right)^l \int_{t_1 C} \cdots \int_{t_l C} f \left( x + \sum_{m=1}^{l} u_m h_m \right)$$

$$\prod_{m=1}^{l} (u_m)^{k_m+1} du_1 \cdots du_l \prod_{m=1}^{l} t_m^{k_m}$$

$$= a_{k_1 \ldots k_l} (x, h_l, \ldots, h_1) \prod_{m=1}^{l} t_m^{k_m}.$$  

Formally, $w_i \in C$ and so $t_i w_i = u_i \in t_i C$. Then $t_i dw_i = du_i$ and so $dw_i = (1/t_i) du_i$. This is why $\prod_{m=1}^{l} t_m^{k_m+1}$ gets changed to $\prod_{m=1}^{l} t_m^{k_m}$.

If $t_m = 0$ for any $m$, the result of both sides in the above equals zero due to the fact that

$$\int_{C} \frac{1}{w_m^{k_m+1}} dw_m = 0$$

whenever $k_m \geq 1$.

To verify (20.13.38), use (20.13.37) to conclude

$$\|a_{k_1 \ldots k_l} (x, h_l \ldots h_1)\| \leq$$

$$\left\| a_{k_1 \ldots k_l} \left( x, \frac{h_l}{\|h_l\|}, \ldots, \frac{h_1}{\|h_1\|} \right) \right\| \prod_{m=1}^{l} |h_m|^k$$
and \[ \left\| a_{k_1 \ldots k_l} \left( x, \frac{h_1}{\|h\|}, \ldots, \frac{h_l}{\|h\|} \right) \right\| \] is bounded by
\[
\frac{M}{(2\pi)^l} \int_C \cdots \int_C \frac{1}{\prod_{m=1}^{l} |w_m|^k} d|w_1| \cdots d|w_l| = C. \]

**Lemma 20.13.3** Suppose

\[ g(x + zh) = g(x) + \sum_{m=1}^{\infty} b_m(x, h) z^m \]

for all \( z \) small enough. Then

\[ b_1(x, h_1 + h_2) = b_1(x, h_1) + b_1(x, h_2). \]

**Proof:** Recall that

\[ f \left( x + \sum_{m=1}^{l} z_m h_m \right) = \sum_{k_1=0}^{\infty} \cdots \sum_{k_1=0}^{\infty} a_{k_1 \ldots k_l} (x, h_1, \ldots, h_l) z_1^{k_1} \cdots z_l^{k_l} \]

and so one can write the following where \( g_{mn} \) is defined in the following expression.

\[ g(x + z_1 h_1 + z_2 h_2) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} g_{mn}(x, h_1, h_2) z_1^m z_2^n. \]

Thus,

\[ g(x + z_1 h_1) = \sum_{m=0}^{\infty} g_{m0}(x, h_1, h_2) z_1^m = g(x) + \sum_{m=1}^{\infty} b_m(x, h) z_1^m, \]

\[ g(x + z_2 h_2) = \sum_{n=0}^{\infty} g_{0n}(x, h_1, h_2) z_2^n = g(x) + \sum_{n=1}^{\infty} b_n(x, h) z_2^n \]

which implies

\[ g_{m0}(x, h_1, h_2) = b_m(x, h_1), \quad g_{0n}(x, h_1, h_2) = b_n(x, h_2). \]

Now let \( z_1 = z_2 = z \). Then

\[ g(x + z(h_1 + h_2)) = g(x) + \sum_{n=0}^{\infty} b_n(x, h_1 + h_2) z^n \]

\[ = g(x) + z(g_{10}(x, h_1, h_2) + g_{01}(x, h_1, h_2)) + \text{higher order terms in } z. \]

Therefore,

\[ b_1(x, h_1 + h_2) = g_{10}(x, h_1, h_2) + g_{01}(x, h_1, h_2) \]

\[ = b_1(x, h_1) + b_1(x, h_2). \]
Lemma 20.13.4 Suppose \( a(x, h_1, \ldots, h_l) \) is multilinear, \( (h_i \to a(x, h_1, \ldots, h_l) \) is linear),

\[
\|a(x, h_1, \ldots, h_l)\| \leq C \prod_{m=1}^{l} \|h_m\|,
\]

and

\[
D^{l-1}f(x + h_l)(h_{l-1}) \cdots (h_1) - D^{l-1}f(x)(h_{l-1}) \cdots (h_1) - a(x, h_1, \ldots, h_l) = o(\|h_l\|).
\]

Then \( D^l f(x) \) exists and

\[
D^l f(x)(h_{l-1}) \cdots (h_1) = a(x, h_1, \ldots, h_l).
\]

Proof: If \( l = 1 \), the conclusion is obvious and is nothing more than the definition of the derivative.

\[
f(x + h) - f(x) - a(x, h) = o(\|h\|)
\]

and so from the definition of the derivative, \( a(x, h) = Df(x)h \).

Next let \( n = 2 \). By assumption,

\[
Df(x + h)(h_1) - Df(x)(h_1) - a(x, h, h_1) = o(\|h\|).
\]

Let \( L(x) \) be defined by

\[
L(x)(h_1) \equiv a(x, h, h_1).
\]

Then \( L(x) \in \mathcal{L}(U, \mathcal{L}(X, Y)) \) because

\[
\|L(x)\| \equiv \sup_{\|h\| \leq 1} \|L(x)(h)\| \equiv \sup_{\|h\| \leq 1, \|h_1\| \leq 1} \|L(x)(h_1)\| \leq C.
\]

Also

\[
\sup_{\|h_1\| \leq 1} \|Df(x + h) - Df(x) - L(x)h\|
\]

\[
= \sup_{\|h_1\| \leq 1} \|Df(x + h)(h_1) - Df(x)(h_1) - L(x)(h_1)\|
\]

\[
= \sup_{\|h_1\| \leq 1} \|Df(x + h)(h_1) - Df(x)(h_1) - a(x, h, h_1)\| = o(\|h\|)
\]

and so \( L(x) = D^2 f(x) \). Continuing in this way, we verify the conclusion of the lemma.

Lemma 20.13.5 If \( f \) is analytic on \( U \), then \( f \in C^\infty(U) \). Also

Proof: By Lemma 20.13.3 applied to \( g = f \) and Lemma 20.13.2, \( Df(x) \) exists and

\[
Df(x)(h) = a_1(x, h).
\]
These lemmas implied that \( h \to a_1 (x, h) \) was linear. Suppose \( D^{l-1} f (x) \) exists for \( l \geq 2 \).

\[
f \left( x + \sum_{m=1}^{l} z_m h_m \right) = \sum_{n_l=0}^{\infty} \cdots \sum_{n_1=0}^{\infty} a_{n_l \cdots n_1} (x, h_l, \cdots, h_1) z_1^{n_1} \cdots z_l^{n_l}.
\]

Differentiate with respect to \( z_1, \cdots, z_{l-1} \) to obtain

\[
\sum_{n_l=0}^{\infty} \cdots \sum_{n_1=1}^{\infty} a_{n_l, n_{l-1}, \cdots, n_1} (x, h_1 \cdots h_l) \left( \prod_{m=1}^{l-1} n_m \right) z_1^{n_1-1} \cdots z_{l-1}^{n_{l-1}-1} z_l^{n_l} = D^{l-1} f \left( x + \sum_{m=1}^{l} z_m h_m + z_l h_l \right) (h_{l-1}) \cdots (h_1).
\]

Take \( z_i = 0 \) for \( i = 1, \cdots, l-1 \). Then

\[
D^{l-1} f (x + z_l h_l) (h_{l-1}) \cdots (h_1) = \sum_{n_l=0}^{\infty} a_{n_l, 1, \cdots, 1} (x, h_l, \cdots, h_1) z_l^{n_l}.
\] 

(20.13.39)

Now we apply Lemma 20.13.3 to the function

\[
z_l \to D^{l-1} f (x + z_l h_l) (h_{l-1}) \cdots (h_1)
\]

and conclude

\[
h_l \to a_{1, \cdots, 1} (x, h_l, \cdots, h_1)
\]

is linear. This involved taking \( n_l = 1 \) to get \( a_{1, \cdots, 1} (x, h_l, \cdots, h_1) \). Thus from

\[
D^{l-1} f (x + z_l h_l) (h_{l-1}) \cdots (h_1) - D^{l-1} f (x) (h_{l-1}) \cdots (h_1) = a_{1, \cdots, 1} (x, h_l, \cdots, h_1) z_l + o \left( z_l h_l \right).
\] 

(20.13.40)

From this equation, it follows that

\[
a_{1, \cdots, 1} \left( x, h_l, \cdots, h_l + \frac{h_l}{z_l} \cdots \frac{h_1}{z_l} \right) z_l - a_{1, \cdots, 1} (x, h_l, \cdots, h_l) z_l
\]

\[-a_{1, \cdots, 1} \left( x, h_l, \cdots, h_l + \frac{h_l}{z_l} \cdots \frac{h_1}{z_l} \right) z_l = o \left( z_l h_l \right)
\]

because for each \( z_l \), the left side of (20.13.40) is linear in \( h_l \) for each \( i \leq l-1 \). Dividing both sides of the above by \( z_l \) and then letting \( z_l \to 0 \), we see that \( a_{n_l \cdots 1} \) is linear in each of the \( h_l \). Denoting \( z_l h_l \) by \( h_l \),

\[
D^{l-1} f (x + h_l) (h_{l-1}) \cdots (h_1) - D^{l-1} f (x) (h_{l-1}) \cdots (h_1) = a_{1, \cdots, 1} (x, h_l, \cdots, h_1) + o (||h_l||)
\]

and so by Lemma 20.13.3, \( D f (x) \) exists and

\[
D f (x) (h_l) \cdots (h_1) = a_{1, \cdots, 1} (x, h_l, \cdots, h_1).
\]

With these lemmas, the main result can be established. This is the generalization of the well known result for analytic functions.
Theorem 20.13.6 Let $X$ and $Y$ be two complex Banach spaces and let $U$ be an open set in $X$. Then $f : U \to Y$ is analytic on $U$ if and only if $Df(x)$ exists for each $x \in U$ and in this case, $f \in C^\infty (U)$, and if $h \in X$, then whenever $z$ is small enough,

$$f (x + zh) = f (x) + \sum_{n=1}^{\infty} \frac{D^n f (x) h^n z^n}{n!}.$$

Proof: We know

$$f (x + zh) = f (x) + \sum_{n=1}^{\infty} a_n (x, h) z^n.$$

Differentiating, we obtain

$$D^k f (x + zh) h^k = k! a_k (x, h) + \sum_{n=k+1}^{\infty} n (n-1) \cdots (n-k+1) z^{n-k}.$$

Letting $z = 0$ this shows

$$D^k f (x) h^k = k! a_k (x, h)$$

and this proves half the theorem.

Conversely, if $Df(x)$ exists on $U$, it is clear that $f$ is analytic on some ball, $B(x,r) \subseteq U$, $z \to f (y + zh)$ is analytic for $y \in B(x,r)$ and small enough $z$. Therefore the formula involving the series follows. ■

20.14 Ordinary Differential Equations

In this section we give an application to ordinary differential equations. To begin with, here are two Banach spaces which will be of use. Let $Z$ be a complex Banach space and let $X$ be the space of functions mapping $B(0,1) \subseteq D_1$ to $Z$ such that the functions are continuous on $D_1$ and analytic on $B_1 \equiv B(0,1)$, the derivative is the restriction to $B_1$ of a continuous function defined on $D_1$, and the function equals 0 at 0.

$$X \equiv \{ \phi \in C (D_1, X) : \phi (0) = 0 \}$$

The norm on $X$ will be

$$||\phi||_X \equiv ||\phi||_\infty + ||\phi'||_\infty$$

where

$$||\phi||_\infty \equiv \sup \{ ||\phi (t)||_Z : t \in B_1 \}. $$

(Note that for a function continuous on $D_1$ it does not matter in the above definition of $||\cdot||_\infty$ whether we use $B_1$ or $D_1$ in the definition.) We define $Y$ to be the space of continuous functions which are defined on $D_1$ having values in $Z$ which are also analytic on $B_1$. The norm on $Y$ is defined as

$$||\phi||_\infty \equiv ||\phi||_Y .$$

Note that $B_1$ is in $C$. 

Lemma 20.14.1 The spaces $X$ and $Y$ with the given norms are Banach spaces and if $L : X \to Y$ is defined as $L\phi(t) = \phi'(t)$ for all $t \in B_1$, then $L$ is one to one, onto and continuous.

**Proof:** It is clear that $X$ and $Y$ are both normed linear spaces. It remains to show they are Banach spaces. Suppose $\{\phi_n\}$ is a Cauchy sequence in $X$. Then $\phi_n \to \phi$ uniformly and $\phi'_n \to \psi$ uniformly where $\psi$ and $\phi$ are continuous on $D_1$. We need to verify that $\psi = \phi'$ on $B_1$. Letting $C_1$ be the unit circle, the Cauchy integral formula implies for $t \in B_1$,

$$
\phi(t) = \lim_{n \to \infty} \phi_n(t) = \lim_{n \to \infty} \frac{1}{2\pi i} \int_{C_1} \phi_n(w) \frac{dw}{w - t} = \frac{1}{2\pi i} \int_{C_1} \phi(w) \frac{dw}{w - t}
$$

which shows $\phi'(t)$ exists on $B_1$. Also for $t \in B_1$,

$$
\psi(t) = \lim_{n \to \infty} \phi'_n(t) = \lim_{n \to \infty} \frac{1}{2\pi i} \int_{C_1} \frac{\phi_n(u)}{(w - t)^2} dw = \frac{1}{2\pi i} \int_{C_1} \frac{\phi(w)}{(w - t)^2} dw = \phi'(t).
$$

This shows $X$ is a Banach space. A similar argument using the Cauchy integral theorem shows $Y$ is a Banach space also. It is obvious that $L$ is continuous. It remains to show $L$ is one to one and onto.

Let $\phi \in Y$. We need to show $\phi = L\psi$ for some $\psi \in X$. Let

$$
\psi(t) = \int_{\Gamma} \phi(w) \, dw
$$

where $\Gamma$ is any piecewise smooth curve from 0 to $t$. By the Cauchy integral theorem, this definition is well defined and it is clear that $\psi(0) = 0$, $\psi'(t) = \phi(t)$, and $\psi$ is continuous on $D_1$. This shows $L$ is onto.

It only remains to show $L$ is one to one. Suppose $L\phi = 0$. Since $\phi(0) = 0$,

$$
\phi(t) = \int_0^1 \phi'(ts) \, ds = 0
$$

if $t \neq 0$. But $\phi(0)$ is given to equal zero. Thus $L$ is one to one as claimed. ■

**Theorem 20.14.2** Let $\Lambda$ and $Z$ be complex Banach spaces and let $W$ be an open subset of $\mathbb{C} \times Z \times \Lambda$ containing $(0, y_0, \lambda)$. Also let $f : W \to Z$ be analytic. Then there exists a unique $y = y(y_0, \lambda)$ solving

$$
y'(t, y, \lambda), y(0) = y_0
$$

valid for $t \in D_{\alpha} \equiv \overline{B(0, |\alpha|)}$ where $\alpha = \alpha(y_0, \lambda)$. Furthermore, the map

$$(t, y_0, \lambda) \to y(y_0, \lambda)(t)$$

is analytic.
Proof: Let \( \alpha s = t \) and define \( \phi (s) \equiv y(t) - y_0 \). Then \( y \) is a solution to (20.14.41) for \( t \in D_\alpha \) if and only if \( \phi \) is a solution for \( s \in D_1 \equiv B(0,1) \) to the equations

\[
\phi' (s) = \alpha f ( \alpha s, \phi (s) + y_0, \lambda ), \ \phi (0) = 0.
\]

Let \( X, Y, \) and \( L \) be given above and define

\[
\tilde{W} \equiv \{(\alpha, \hat{y}_0, \mu, \phi) \in \mathbb{C} \times Z \times \Lambda \times X : \text{for } s \in D_1, (s\alpha, \hat{y}_0 + \phi (s), \mu) \in W \}.
\]

For a given \( (\alpha, \hat{y}_0, \mu, \phi) \in \tilde{W}, \)

\[
\{(s\alpha, \hat{y}_0 + \phi (s), \mu) : s \in D_1 \}
\]

is a compact subset of \( W \). This is because you have \( s \to (\alpha, \hat{y}_0 + \phi (s), \mu) \) is the continuous image of a compact set which is assumed to be in \( W \). Consequently, the distance from this set to \( W^c \) is positive and so if \( (\beta, y_0, \lambda, \psi) \) is sufficiently close to \( (\alpha, \hat{y}_0, \mu, \phi) \) in \( \mathbb{C} \times Z \times \Lambda \times X \) it follows \( (\beta, y_0, \lambda, \psi) \) is also in \( \tilde{W} \). This shows \( \tilde{W} \) is an open subset of \( \mathbb{C} \times Z \times \Lambda \times X \).

Now define \( F : \tilde{W} \to Y \) (Recall that \( Y \) was a space of functions.) by

\[
F (\alpha, \hat{y}_0, \mu, \phi) (s) \equiv L\phi (s) - \alpha f (\alpha s, \phi (s) + \hat{y}_0, \mu).
\]

Then

\[
F (0, y_0, \lambda, 0) = L\phi = 0,
\]

and \( F \) is analytic in \( \tilde{W} \). Also

\[
D_4 F (0, y_0, \lambda, 0) \psi = L\psi = \psi'
\]

and so \( D_4 F (0, y_0, \lambda, 0) \in \mathcal{L} (X, Y) \), is one to one, onto and continuous by Lemma 20.14.1. By the open mapping theorem, its inverse is also continuous. Therefore, the conditions of the implicit function theorem are satisfied and so there exists \( r > 0 \) such that if

\[
|\alpha| + \|\mu - \lambda\| + \|\hat{y}_0 - y_0\| < r,
\]

then there exists a unique \( \phi \in X \) such that

\[
F (\alpha, \hat{y}_0, \mu, \phi) = 0,
\]

and \( \phi \) is an analytic function of \( (\alpha, \hat{y}_0, \mu) \). Fixing \( 0 < \alpha < r \), it follows

\[
(\hat{y}_0, \mu) \to y (\hat{y}_0, \mu)
\]

is analytic on an open subset of \( Z \times \Lambda \). Also \( t \to y (\hat{y}_0, \mu) (t) \) is an analytic function because of the definition of \( y \) in terms of \( \phi, \phi (s) \equiv y (t) - y_0 \). It follows that for \( t \in B (0, |\alpha|) \),

\[
(\hat{y}_0, \mu) \to y (\hat{y}_0, \mu) (t) \quad \text{and} \quad t \to y (\hat{y}_0, \mu) (t)
\]

are both analytic. \( \blacksquare \)
20.15 Exercises

1. Suppose \( L \in \mathcal{L}(X,Y) \) where \( X \) and \( Y \) are two finite dimensional normed vector spaces and suppose \( L \) is one to one. Show there exists \( r > 0 \) such that for all \( x \in X \),
   \[
   \|Lx\| \geq r \|x\|.
   \]
   \textbf{Hint:} Show that \( \|x\| \equiv \|Lx\| \) is a norm. Now suppose \( L \in \mathcal{L}(X,Y) \) is one to one and onto for \( X,Y \) Banach spaces. Explain why the same result holds. \textbf{Hint:} Recall open mapping theorem.

2. Suppose \( B \) is an open ball in \( X \), a Banach space, and \( f : B \to Y \) is differentiable. Suppose also there exists \( L \in \mathcal{L}(X,Y) \) such that
   \[
   ||Df(x) - L|| < k
   \]
   for all \( x \in B \). Show that if \( x_1, x_2 \in B \),
   \[
   ||f(x_1) - f(x_2) - L(x_1 - x_2)|| \leq k ||x_1 - x_2||.
   \]
   \textbf{Hint:} Consider \( Tx = f(x) - Lx \) and argue \( ||DT(x)|| < k \).

3. Let \( U \) be an open subset of \( X \), \( f : U \to Y \) where \( X,Y \) are finite dimensional normed linear spaces and suppose \( f \in C^1(U) \) and \( Df(x_0) \) is one to one. Then show \( f \) is one to one near \( x_0 \). \textbf{Hint:} Show using the assumption that \( f \) is \( C^1 \) that there exists \( \delta > 0 \) such that if
   \[
   x_1, x_2 \in B(x_0, \delta),
   \]
   then
   \[
   |f(x_1) - f(x_2) - Df(x_0)(x_1 - x_2)| \leq \frac{r}{2} |x_1 - x_2| \tag{20.15.42}
   \]
   then use Problem 4. In case \( X,Y \) are Banach spaces, assume \( Df(x_0) \) is one to one and onto.

4. Suppose \( U \subseteq X \) is an open subset of \( X \) a Banach space and that \( f : U \to Y \) is differentiable at \( x_0 \in U \) such that \( Df(x_0) \) is one to one and onto from \( X \) to \( Y \). \( (Df(x_0))^{-1} \in \mathcal{L}(Y,X) \) Then show that \( f(x) \neq f(x_0) \) for all \( x \) sufficiently near but not equal to \( x_0 \). In this case, you only know the derivative exists at \( x_0 \).

5. Suppose \( M \in \mathcal{L}(X,Y) \) where \( X \) and \( Y \) are finite dimensional linear spaces and suppose \( M \) is onto. Show there exists \( L \in \mathcal{L}(Y,X) \) such that
   \[
   LMx = Px
   \]
   where \( P \in \mathcal{L}(X,X) \), and \( P^2 = P \). Also show \( L \) is one to one and onto from \( X_1 \) to \( Y \). \textbf{Hint:} Let \( \{y_1 \cdots y_n\} \) be a basis of \( Y \) and let \( Mx_i = y_i \). Then define
   \[
   Ly = \sum_{i=1}^{n} \alpha_i x_i \text{ where } y = \sum_{i=1}^{n} \alpha_i y_i.
   \]
Show \( \{x_1, \cdots, x_n\} \) is a linearly independent set and show you can obtain \( \{x_1, \cdots, x_n, \cdots, x_m\} \), a basis for \( X \) in which \( Mx_j = 0 \) for \( j > n \). Then let

\[
P_x \equiv \sum_{i=1}^{n} \alpha_i x_i
\]

where

\[
x = \sum_{i=1}^{m} \alpha_i x_i.
\]

6. ↑ Let \( f : U \subseteq X \to Y \), \( f \) is \( C^1 \), and \( Df(x) \) is onto for each \( x \in U \). Then show \( f \) maps open subsets of \( U \) onto open sets in \( Y \). **Hint:** Let \( P = LDLf(x) \) as in Problem 5. Argue \( L \) maps open sets from \( Y \) to open sets of \( X_1 \equiv PX \) and \( L^{-1} \) maps open sets from \( X_1 \) to open sets of \( Y \). Then \( L \) has rank two and \( LDLf(x) = LDf(x) \) which is seen to be one to one and onto and in \( L(X_1, X_1) \). Therefore, if \( r \) is small enough, \( h(B(0, r)) \) equals an open set in \( X_1, V \). This is by the inverse function theorem. Hence \( L(f(x + B(0, r)) - f(x)) = V \) and so \( f(x + B(0, r)) - f(x) = L^{-1}(V) \), an open set in \( Y \).

7. Suppose \( U \subseteq \mathbb{R}^2 \) is an open set and \( f : U \to \mathbb{R}^3 \) is \( C^1 \). Suppose \( Df(s_0, t_0) \) has rank two and

\[
f(s_0, t_0) = \begin{pmatrix} x_0 \\ y_0 \\ z_0 \end{pmatrix}
\]

Show that for \((s, t)\) near \((s_0, t_0)\), the points \( f(s, t) \) may be realized in one of the following forms.

\[
\{(x, y, \phi(x, y)) : (x, y) \text{ near } (x_0, y_0)\},
\]

\[
\{(\phi(y, z), y, z) : (y, z) \text{ near } (y_0, z_0)\},
\]

or

\[
\{(x, \phi(x, z), z) : (x, z) \text{ near } (x_0, z_0)\}.
\]

This shows that parametrically defined surfaces can be obtained locally in a particularly simple form.

8. Let \( f : U \to Y \), \( Df(x) \) exists for all \( x \in U \), \( B(x_0, \delta) \subseteq U \), and there exists \( L \in \mathcal{L}(X, Y) \) such that \( L^{-1} \in \mathcal{L}(Y, X) \), and for all \( x \in B(x_0, \delta) \)

\[
||Df(x) - L|| < \frac{r}{||L^{-1}||}, \quad r < 1.
\]

Show that there exists \( \varepsilon > 0 \) and an open subset of \( B(x_0, \delta), V \), such that \( f : V \to B(f(x_0), \varepsilon) \) is one to one and onto. Also \( Df^{-1}(y) \) exists for each \( y \in B(f(x_0), \varepsilon) \) and is given by the formula

\[
Df^{-1}(y) = [Df(f^{-1}(y))]^{-1}.
\]
CHAPTER 20. THE DERIVATIVE

**Hint:** Let
\[ T_y (x) \equiv T (x, y) \equiv x - L^{-1} (f (x) - y) \]
for \(|y - f (x_0)| < \frac{(1-r)^k}{2|L|} \), consider \( \{ T^m_y (x_0) \} \). This is a version of the inverse function theorem for \( f \) only differentiable, not \( C^1 \).

9. Denote by \( C ([0, T], X) \) the space of functions which are continuous having values in \( X \) and define a norm on this linear space as follows.
\[
||f||_\lambda \equiv \max \{|f (t)| e^{\lambda t} : t \in [0, T]\}.
\]
Show for each \( \lambda \in \mathbb{R} \), this is a norm and that \( C ([0, T]; X) \) is a complete normed linear space with this norm.

10. Let \( f : [0, T] \times X \to X \) be continuous and suppose \( f \) satisfies a Lipschitz condition,
\[
|f (t, x) - f (t, y)| \leq K |x - y|
\]
and let \( x_0 \in X \). Show there exists a unique solution to the Cauchy problem,
\[
x' = f (t, x), \ x (0) = x_0,
\]
for \( t \in [0, T] \). **Hint:** Consider the map
\[
G : C ([0, T]; X) \to C ([0, T]; X)
\]
defined by
\[
Gx (t) \equiv x_0 + \int_0^t f (s, x (s)) \, ds,
\]
where the integral is defined componentwise. Show \( G \) is a contraction map for \( ||\cdot||_\lambda \) given in Problem 9 for a suitable choice of \( \lambda \) and that therefore, it has a unique fixed point in \( C ([0, T]; X) \). Next argue, using the fundamental theorem of calculus, that this fixed point is the unique solution to the Cauchy problem.

11. Use Theorem B.7.23 to give another proof of the above theorem. **Hint:** Use the same mapping and show that a large power is a contraction map.

12. Suppose you know that \( u (t) \leq a + \int_0^t k (s) u (s) \, ds \) where \( k (s) \geq 0 \) and \( k \) is in \( L^1 ([0, T]) \). Show that then \( u (t) \leq a \exp \left( \int_0^t k (s) \, ds \right) \). This is a version of Gronwall’s inequality. **Hint:** Let \( W (t) = \int_0^t k (s) u (s) \, ds \). Then explain why \( W' (t) - k (t) W (t) \leq ak (t) \). Now use the usual technique of an integrating factor you saw in beginning differential equations.

13. Use the above Gronwall’s inequality to establish a result of continuous dependence on the initial condition and \( f \) in the ordinary differential equation of Problem B.3.
14. The existence of partial derivatives does not imply continuity as was shown in an example. However, much more can be said than this. Consider

\[ f(x, y) = \begin{cases} \frac{(x^2 - y^4)^2}{(x^2 + y^4)^2} & \text{if } (x, y) \neq (0, 0), \\ 1 & \text{if } (x, y) = (0, 0). \end{cases} \]

Show the directional derivative of \( f \) at \((0, 0)\) exists and equals 0 for every direction. The directional derivative in the direction \((v_1, v_2)\) is defined as

\[ \lim_{t \to 0} \frac{f(x + tv_1, y + tv_2) - f(x, y)}{t}. \]

Now consider the curve \( x^2 = y^4 \) and the curve \( y = 0 \) to verify the function fails to be continuous at \((0, 0)\).

15. Let

\[ f(x, y) = \begin{cases} \frac{x^2y^4}{x^2 + y^8} & \text{if } (x, y) \neq (0, 0), \\ 0 & \text{if } (x, y) = (0, 0). \end{cases} \]

Show that this function is not continuous at \((0, 0)\) but that it has all directional derivatives at \((0, 0)\) and they all equal 0.

16. Let \( X_i \) be a normed linear space having norm \( \| \cdot \|_i \). Then we can make \( \prod_{i=1}^n X_i \) into a normed linear space by defining a norm on \( x \in \prod_{i=1}^n X_i \) by

\[ \| x \| \equiv \max \{ \| x_i \|_i : i = 1, \ldots, n \}. \]

Show this is a norm on \( \prod_{i=1}^n X_i \) as claimed.

17. Suppose \( f : U \subseteq X \times Y \to Z \) and \( D_2 f(x_0, y_0)^{-1} \in \mathcal{L}(X, Y) \) exists and \( f \) is \( C^1 \) so the conditions of the implicit function theorem are satisfied. Also suppose that all these are complex Banach spaces. Show that then the implicitly defined function \( y = y(x) \) is analytic. Thus, it has infinitely many derivatives and can be given as a power series as described above.
Chapter 21

Degree Theory, An Introduction

This chapter is on the Brouwer degree, a very useful concept with numerous and important applications. The degree can be used to prove some difficult theorems in topology such as the Brouwer fixed point theorem, the Jordan separation theorem, and the invariance of domain theorem. It also is used in bifurcation theory and many other areas in which it is an essential tool. The degree will be developed for \( \mathbb{R}^n \) first. When this is understood, it is not too difficult to extend to versions of the degree which hold in Banach space. There is more on degree theory in the book by Deimling \[35\] and much of the presentation here follows this reference. Another more recent book which is really good is \[40\]. This is a whole book on degree theory.

To give you an idea what the degree is about, consider a real valued \( C^1 \) function defined on an interval, \( I \), and let \( y \in f(I) \) be such that \( f'(x) \neq 0 \) for all \( x \in f^{-1}(y) \). In this case the degree is the sum of the signs of \( f'(x) \) for \( x \in f^{-1}(y) \), written as \( d(f, I, y) \).

In the above picture, \( d(f, I, y) \) is 0 because there are two places where the sign is 1 and two where it is \(-1\).

The amazing thing about this is the number you obtain in this simple manner
is a specialization of something which is defined for continuous functions and which has nothing to do with differentiability.

There are many ways to obtain the Brouwer degree. The method I will use here is due to Heinz [56] and appeared in 1959. It involves first studying the degree for functions in $C^\infty$ and establishing all its most important topological properties with the aid of an integral. Then when this is done, it is extended to general continuous functions.

When you have the topological degree, you can get all sorts of amazing theorems like the invariance of domain theorem and others. The first section contains fundamental theorems from measure theory.

21.1 Sard’s Lemma

The following lemma is a wonderful application of the Vitali covering theorem.

**Lemma 21.1.1** Let $h$ be differentiable on $U$. If $T \subseteq U$ and $m_p(T) = 0$, then $m_p(h(T)) = 0$.

**Proof:** For $k \in \mathbb{N}$

$$T_k \equiv \{x \in T : ||Dh(x)|| < k\}$$

and let $\varepsilon > 0$ be given. Since $T_k$ is a subset of a set of measure zero, it is measurable, but we don’t need to pay much attention to this fact. Now by outer regularity, there exists an open set $V$, containing $T_k$ which is contained in $\overline{U}$ such that $m_p(V) < \varepsilon$.

Let $x \in T_k$. Then by differentiability,

$$h(x + v) = h(x) + Dh(x)v + o(v)$$

and so there exist arbitrarily small $r_x < 1$ such that $B(x, 5r_x) \subseteq V$ and whenever $||v|| \leq 5r_x, ||o(v)|| < \frac{1}{k}||v||$. Thus

$$h(B(x, 5r_x)) \subseteq Dh(x)(B(0, 5r_x)) + h(x) + B(0, r_x) \subseteq B(0, k5r_x) + B(0, r_x) + h(x) \subseteq B(h(x), (5k + 1)r_x) \subseteq B(h(x), 6kr_x)$$

From the Vitali covering theorem, there exists a countable disjoint sequence of these balls, $\{B(x_i, r_i)\}_{i=1}^{\infty}$ such that $\{B(x_i, 5r_i)\}_{i=1}^{\infty} = \{\hat{B}_i\}_{i=1}^{\infty}$ covers $T_k$. Then letting $m_p$ denote the outer measure determined by $m_p$,

$$m_p(h(T_k)) \leq m_p\left(h\left(\bigcup_{i=1}^{\infty} \hat{B}_i\right)\right) \leq m_p\left(\bigcup_{i=1}^{\infty} h\left(\hat{B}_i\right)\right)$$

$$\leq \sum_{i=1}^{\infty} m_p\left(h\left(\hat{B}_i\right)\right) = \sum_{i=1}^{\infty} m_p(B(h(x_i), 6kr_x))$$

$$= \sum_{i=1}^{\infty} m_p(B(x_i, 6kr_x)) = (6k)^p \sum_{i=1}^{\infty} m_p(B(x_i, r_x))$$

$$\leq (6k)^p m_p(V) \leq (6k)^p \varepsilon$$
Since \( \varepsilon > 0 \) is arbitrary, this shows

\[
m_p (h (T_k)) = m_p (T_k) = 0.
\]

Now

\[
m_p (h (T)) = \lim_{k \to \infty} m_p (h (T_k)) = 0. \quad \blacksquare
\]

The following is Sard’s lemma. In the proof, it does not matter which norm you use in defining balls but it may be easiest to consider the norm

\[
\|x\| \equiv \max \{|x_i|, i = 1, \ldots, p\}
\]

It is a very simple proof because it uses the Vitali covering theorem to remove technical considerations.

**Lemma 21.1.2 (Sard)** Let \( U \) be an open set in \( \mathbb{R}^p \) and let \( h : U \to \mathbb{R}^p \) be differentiable. Let

\[
Z \equiv \{ x \in U : \det D_h (x) = 0 \}.
\]

Then \( m_p (h (Z)) = 0 \).

**Proof:** For convenience, assume the balls in the following argument come from \( \|\cdot\|_\infty \). First note that \( Z \) is a Borel set because \( h \) is continuous and so the component functions of the Jacobian matrix are each Borel measurable. Hence the determinant is also Borel measurable.

Suppose that \( U \) is a bounded open set. Let \( \varepsilon > 0 \) be given. Also let \( V \subseteq \mathbb{R}^p \) with \( m_p (Z) + \varepsilon > m_p (V) \).

Now let \( x \in Z \). Then since \( h \) is differentiable at \( x \), there exists \( \delta_x > 0 \) such that if \( r < \delta_x \), then \( B (x, r) \subseteq V \) and also \( o (v) < \eta \|v\| \) for \( \|v\| < \varepsilon \). Thus

\[
h (x + B (0, \varepsilon)) = h (B (x, \varepsilon)) \subseteq h (x) + D_h (x) (B (0, \varepsilon)) + B (0, \eta \varepsilon), \quad \eta < 1.
\]

Regard \( D_h (x) \) as an \( n \times n \) matrix, the matrix of the linear transformation \( D_h (x) \) with respect to the usual coordinates. Since \( x \in Z \), it follows that there exists an invertible matrix \( A \) such that \( AD_h (x) \) is in row reduced echelon form with a row of zeros on the bottom. Therefore,

\[
m_p (A (h (B (x, r)))) \leq m_p (AD_h (x) (B (0, r)) + AB (0, \varepsilon)) \tag{21.1.1}
\]

The diameter of \( AD_h (x) (B (0, r)) \) is no larger than \( \|A\| \|D_h (x)\| 2r \) and it lies in \( \mathbb{R}^{p-1} \times \{0\} \). The diameter of \( AB (0, \varepsilon) \) is no more than \( \|A\| (2r \varepsilon) \). Therefore, the measure of the right side in (21.1.1) is no more than

\[
\begin{align*}
&\left[ \|A\| \|D_h (x)\| 2r + \|A\| (2r \varepsilon) \right] r^{p-1} (r \varepsilon) \\
&\leq C \left( \|A\| \|D_h (x)\| \right) (2r)^p \varepsilon
\end{align*}
\]

That is,

\[
m_p (A (h (B (x, r)))) \leq C \left( \|A\| \|D_h (x)\| \right) (2r)^p \varepsilon
\]
Hence from the change of variables formula for linear maps,

\[ m_p(h(B(x,r))) \leq C \frac{||A||, ||Dh(x)||}{\det(A)} m_p(B(x,r)) \]

Then letting \( \delta_x \) be still smaller if necessary, corresponding to sufficiently small \( \eta \),

\[ m_p(h(B(x,r))) \leq \varepsilon m_p(B(x,r)) \]

The balls of this form constitute a Vitali cover of \( Z \). Hence, by the Vitali covering theorem, Corollary 11.4.6, there exists \( f \) such that \( m_p(h(B_i)) \leq \varepsilon m_p(B_i) \) and \( m_p(Z \setminus \cup_i B_i) = 0 \). Hence from Lemma 21.1.1,

\[ m_p(h(Z) \setminus \cup_i h(B_i)) \leq m_p(h(Z \setminus \cup_i B_i)) = 0 \]

Therefore,

\[ m_p(h(Z)) \leq \sum_i m_p(h(B_i)) \leq \varepsilon \sum_i m_p(B_i) \leq \varepsilon (m_p(V)) \leq \varepsilon (m_p(Z) + \varepsilon) . \]

Since \( \varepsilon \) is arbitrary, this shows \( m_p(h(Z)) = 0 \). What if \( U \) is not bounded? Then consider \( Z_n = Z \cap B(0,n) \). From what was just shown, \( h(Z_n) \) has measure 0 and so it follows that \( h(Z) \) also does, being the countable union of sets of measure zero.

\section{21.2 Preliminary Results}

In this chapter \( \Omega \) will refer to a bounded open set.

\begin{definition}
For \( \Omega \) a bounded open set, denote by \( C(\Omega) \) the set of functions which are restrictions of functions in \( C_c(\mathbb{R}^n) \) to \( \Omega \) and by \( C^m(\Omega) \), \( m \leq \infty \) the space of restrictions of functions in \( C^m_c(\mathbb{R}^n) \) to \( \Omega \). If \( f \in C(\Omega) \) the symbol \( f \) will also be used to denote a function defined on \( \mathbb{R}^n \) equalling \( f \) on \( \Omega \) when convenient. This saves the trouble of having to extend to all of \( \mathbb{R}^n \) using something like Theorem 14.2.3. The subscript \( c \) indicates that the functions have compact support. The norm in \( C(\Omega) \) is defined as follows.

\[ ||f||_{\infty} = \sup \{ |f(x)| : x \in \Omega \} . \]

If the functions take values in \( \mathbb{R}^n \) write \( C^m(\Omega; \mathbb{R}^n) \) or \( C(\Omega; \mathbb{R}^n) \) for these functions if there is no differentiability assumed. The norm on \( C(\Omega; \mathbb{R}^n) \) is defined in the same way as above,

\[ ||f||_{\infty} = \sup \{ |f(x)| : x \in \Omega \} . \]

Of course if \( m = \infty \), the notation means that there are infinitely many derivatives. Also, \( C(\Omega; \mathbb{R}^n) \) consists of functions which are continuous on \( \Omega \) that have values in \( \mathbb{R}^n \) and \( C^m(\Omega; \mathbb{R}^n) \) denotes the functions which have \( m \) continuous derivatives defined on \( \Omega \).

\end{definition}
Theorem 21.2.2 Let \( \Omega \) be a bounded open set in \( \mathbb{R}^n \) and let \( f \in C_c(\mathbb{R}^n) \). Then there exists \( g \in C_c^\infty(\mathbb{R}^n) \) with \( \|g - f\|_{\infty, \mathbb{R}^n} < \varepsilon \).

Proof: Form \( g = f \ast \psi_n \) for a mollifier \( \psi_n \). This will approximate \( f \) uniformly on \( \Omega \), and will be in \( C_c^\infty(\mathbb{R}^n) \). Using the Weierstrass approximation theorem, you could also get \( g \) to equal a polynomial for all \( x \in \Omega \).

Applying this result to the components of a vector valued function yields the following corollary.

Corollary 21.2.3 If \( f \in C(\overline{\Omega}; \mathbb{R}^n) \) for \( \Omega \) a bounded subset of \( \mathbb{R}^n \), then for all \( \varepsilon > 0 \), there exists \( g \in C^\infty(\overline{\Omega}; \mathbb{R}^n) \) such that

\[
\|g - f\|_{\infty} < \varepsilon.
\]

Lemma 14.3.1 on Page 411 will also play an important role in the definition of the Brouwer degree. Earlier it made possible an easy proof of the Brouwer fixed point theorem. Later in this chapter, it is used to show the definition of the degree is well defined. For convenience, here it is stated again.

Lemma 21.2.4 Let \( g : U \to \mathbb{R}^n \) be \( C^2 \) where \( U \) is an open subset of \( \mathbb{R}^n \). Then

\[
\sum_{j=1}^{n} \text{cof} \left( (Dg)_{ij} \right) = 0,
\]

where here \( (Dg)_{ij} \equiv g_{i,j} \equiv \frac{\partial g_i}{\partial x_j} \). Also, \( \text{cof} \left( (Dg)_{ij} \right) = \frac{\partial \det(Dg)}{\partial g_{i,j}} \).

Another simple result which will be used whenever convenient is the following lemma.

Lemma 21.2.5 Let \( K \) be a compact set and \( C \) a closed set in a complete normed vector space such that \( K \cap C = \emptyset \). Then

\[
\text{dist} \left( K, C \right) > 0.
\]

Proof: Let

\[
d \equiv \inf \{|\|k - c\| : k \in K, c \in C\} \]

Let \( \{k_n\}, \{c_n\} \) be such that

\[
d + \frac{1}{n} > \|k_n - c_n\|.
\]

Since \( K \) is compact, there is a subsequence still denoted by \( \{k_n\} \) such that \( k_n \to k \in K \). Then also

\[
\|c_n - c_m\| \leq \|c_n - k_n\| + \|k_n - k_m\| + \|c_m - k_m\|.
\]
If \( d = 0 \), then as \( m, n \to \infty \) it follows \( \| c_n - c_m \| \to 0 \) and so \( \{ c_n \} \) is a Cauchy sequence which must converge to some \( c \in C \). But then \( \| c - k \| = \lim_{n \to \infty} \| c_n - k_n \| = 0 \) and so \( c = k \in C \cap K \), a contradiction to these sets being disjoint.

In particular the distance between a point and a closed set is always positive if the point is not in the closed set. Of course this is obvious even without the above lemma. The above lemmas will be used now to prove technical lemmas which are the basis for everything.

**Definition 21.2.6** Let \( g \in C^\infty (\bar{\Omega}; \mathbb{R}^n) \) where \( \Omega \) is a bounded open set. Also let \( \phi \in C^\infty (B(0, \varepsilon)) \), \( \phi \geq 0 \), \( \int \phi dx = 1 \).

First, here is a technical lemma which is the reason it all works out. It is a result on homotopy invariance for functions which are \( C^1 \).

**Lemma 21.2.7** If \( h : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n \) is in \( C^\infty (\mathbb{R}^n \times \mathbb{R}, \mathbb{R}^n) \), and \( 0 \notin h(\partial \Omega \times [\alpha, \beta]) \) then for \( 0 < \varepsilon < \text{dist}(0, h(\partial \Omega \times [\alpha, \beta])) \),

\[
 t \to \int_\Omega \phi (h(x, t)) \det D_1 h(x, t) \, dx
\]

is constant for \( t \in (a, b) \), an open set which contains \( [\alpha, \beta] \).

**Proof:** By continuity, we can get such an open interval, \((a, b)\) such that it contains \([\alpha, \beta]\) and \( 0 \notin h(\partial \Omega \times [\alpha, \beta]) \). Let \( \varepsilon > 0 \) be such that for all \( t \in [a, b] \),

\[
 B(0, \varepsilon) \cap h(\partial \Omega \times [\alpha, \beta]) = \emptyset \quad (21.2.2)
\]

Define for \( t \in (a, b) \),

\[
 H(t) \equiv \int_\Omega \phi (h(x, t)) \det D_1 h(x, t) \, dx
\]

Then if \( t \in (a, b) \),

\[
 H'(t) = \int_\Omega \sum_\alpha \phi_{\varepsilon, \alpha} (h(x, t)) h_{\alpha, t} (x, t) \det D_1 h(x, t) \, dx \\
+ \int_\Omega \phi (h(x, t)) \sum_{\alpha, j} \det D_1 (h(x, t))_{\alpha j} h_{\alpha, t} \, dx \\
\equiv A + B.
\]

In this formula, the function \( \det \) is considered as a function of the \( n^2 \) entries in the \( n \times n \) matrix and the \( \alpha j \) represents the derivative with respect to the \( \alpha j^{th} \) entry \( h_{\alpha, j} \). Now as in the proof of Lemma 14.3.1 on Page 411:

\[
 \det D_1 (h(x, t))_{\alpha j} = (\text{cof} \, D_1 (h(x, t)))_{\alpha j}
\]
21.2. PRELIMINARY RESULTS

and so

\[ B = \int_\Omega \sum_\alpha \sum_j \phi_{\varepsilon} (h(x,t)) (\text{cof } D_1 (h(x,t)))_{\alpha j} h_{\alpha j} dx. \]

By hypothesis

\[ x \to \phi_{\varepsilon} (h(x,t)) (\text{cof } D_1 (h(x,t)))_{\alpha j} \]

is in \( C^\infty_c (\Omega) \) because if \( x \in \partial \Omega \), it follows that for all \( t \in [a,b] \)

\[ h(x,t) \notin B(0,\varepsilon) \]

and so \( \phi_{\varepsilon} (h(x,t)) = 0 \). Thus it equals 0 on \( \partial \Omega \). Therefore, integrate by parts and write

\[ B = -\int_\Omega \sum_\alpha \sum_j \frac{\partial}{\partial x_j} (\phi_{\varepsilon} (h(x,t))) (\text{cof } D_1 (h(x,t)))_{\alpha j} h_{\alpha j} dx + \]

\[ -\int_\Omega \sum_\alpha \sum_j \phi_{\varepsilon} (h(x,t)) (\text{cof } D (h(x,t)))_{\alpha j, j} h_{\alpha j} dx \]

The second term equals zero by Lemma 21.2.4. Simplifying the first term yields

\[ B = -\int_\Omega \sum_\alpha \sum_j \sum_\beta \phi_{\varepsilon, \beta} (h(x,t)) h_{\beta, j} h_{\alpha, t} (\text{cof } D_1 (h(x,t)))_{\alpha j} dx \]

\[ = -\int_\Omega \sum_\alpha \sum_\beta \phi_{\varepsilon, \beta} (h(x,t)) h_{\alpha, t} \sum_j h_{\beta, j} (\text{cof } D_1 (h(x,t)))_{\alpha j} dx \]

Now the sum on \( j \) is the dot product of the \( \beta \)th row with the \( \alpha \)th row of the cofactor matrix which equals zero unless \( \beta = \alpha \) because it would be a cofactor expansion of a matrix with two equal rows. When \( \beta = \alpha \), the sum on \( j \) reduces to

\[ \det (D_1 (h(x,t))) \]

Thus \( B \) reduces to

\[ -\int_\Omega \sum_\alpha \phi_{\varepsilon, \alpha} (h(x,t)) h_{\alpha, j} \sum_j h_{\alpha, j} (x,t) (\text{cof } D_1 (h(x,t)))_{\alpha j} dx \]

\[ = -\int_\Omega \sum_\alpha \phi_{\varepsilon, \alpha} (h(x,t)) h_{\alpha, t} \det (D_1 (h(x,t))) dx \]

Now \( A \) equals

\[ \int_\Omega \sum_\alpha \phi_{\varepsilon, \alpha} (h(x,t)) h_{\alpha, t} (x,t) \det D_1 h(x,t) dx \]

which is the same thing with opposite sign. Hence these sum to 0. Therefore, \( H'(t) = 0 \) and so \( H \) is a constant on \((a,b) \supseteq [\alpha, \beta]\). \qed

The following is a situation in which one only has continuity in \( t \). Of course the difficulty is that it is not yet clear whether the constant depends on \( \varepsilon \).
Corollary 21.2.8 If $h : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ is in $C_c((\mathbb{R}^n \times \mathbb{R})$, and for each $t \in [0, 1]$, $h(\cdot, t) \in C_c((\mathbb{R}^n$, and for each $t \in [0, 1]$, $h(\cdot, t) \in C_c((\mathbb{R}^n, \mathbb{R}^n)$, then for $\varepsilon$ small enough,

$$ t \to \int_{\Omega} \phi_\varepsilon (h(x, t)) \det D_1 h(x, t) \, dx $$

is constant for $t \in [0, 1]$.

Proof: Let $0 < 6\delta < \text{dist}(0, h(\partial \Omega \times [0, 1]))$. Now let $0 = t_0 < t_1 < \cdots < t_m = 1$. Also let $\hat{h}(x, t_k) = h(x, t_k)$ and for $t \in (t_{k-1}, t_k)$,

$$ \hat{h}(x, t) \equiv h(x, t_{k-1}) + \frac{t - t_{k-1}}{t_k - t_{k-1}} (h(x, t_k) - h(x, t_{k-1})) $$

Thus for fixed $x$, this gives a piecewise linear function approximating $t \to h(x, t)$. Let these $t_k$ be close enough together that on each $[t_{k-1}, t_k]$,

$$ \max_{t \in [t_{k-1}, t_k]} \| \hat{h}(\cdot, t) - h(\cdot, t) \|_\infty < \delta $$

It follows that on $[t_{k-1}, t_k]$, for $x \in \partial \Omega$,

$$ \min_{t \in [t_{k-1}, t_k]} \| \hat{h}(x, t) - 0 \| > \delta $$

This function $(x, t) \to \hat{h}(x, t)$ can be considered the restriction of a function in $C_c((\mathbb{R}^n \times \mathbb{R}; \mathbb{R}^n)$ and $0 \notin \hat{h}(\partial \Omega, t)$ for all $t \in [t_{k-1}, t_k]$. By Lemma 21.2.7, for all $\varepsilon$ small enough, say $\varepsilon < \delta$,

$$ \int_{\Omega} \phi_\varepsilon (\hat{h}(x, t)) \det (D_1 \hat{h}(x, t)) \, dx $$

is constant on this interval $[t_{k-1}, t_k]$.

This has shown that for $k, j \in \{0, 2, \cdots, m\}$,

$$ \int_{\Omega} \phi_\varepsilon (h(x, t_k)) \det (D_1 h(x, t_k)) \, dx = \int_{\Omega} \phi_\varepsilon (h(x, t_j)) \det (D_1 h(x, t_j)) \, dx $$

You could include $1/2$ in the partition. Then this would show that whatever the partition including this point,

$$ \int_{\Omega} \phi_\varepsilon (h(x, t_k)) \det (D_1 h(x, t_k)) \, dx = \int_{\Omega} \phi_\varepsilon (h(x, 1/2)) \det (D_1 h(x, 1/2)) \, dx $$

Thus this integral is constant for $t \in [0, 1]$ as claimed.

This corollary is applied later to the situation where $h(x, t)$ is of the form $h(x, t) - y(t)$ where $t \to y(t)$ is continuous and $y(t) \notin h(\partial \Omega, t)$.
21.3 Definitions And Elementary Properties

First is what is meant by two functions being homotopic.

Definition 21.3.1 \( \mathcal{U}_y \equiv \{ f \in C (\overline{\Omega}; \mathbb{R}^n) : y \notin f (\partial \Omega) \} \).

\( f \sim g \) if there exists a continuous function,

\[ h : \mathbb{R}^n \times [0, 1] \rightarrow \mathbb{R}^n \]

such that \( h (x, 1) = g (x) \) and \( h (x, 0) = f (x) \) for \( x \in \Omega \) and \( x \rightarrow h (x, t) \in \mathcal{U}_y \) for all \( t \in [0, 1] \) \( (y \notin h (\partial \Omega, t)) \). This function \( h \), is called a homotopy and \( f \) and \( g \) are homotopic.

Definition 21.3.2 For \( W \) an open set in \( \mathbb{R}^n \) and \( g \in C^1 (W; \mathbb{R}^n) \) \( y \) is called a regular value of \( g \) if whenever \( x \in g^{-1} (y) \), \( \det (Dg (x)) \neq 0 \). Note that if \( g^{-1} (y) = \emptyset \), it follows that \( y \) is a regular value from this definition. Denote by \( S_g \) the set of singular values of \( g \), those \( y \) such that \( \det (Dg (x)) = 0 \) for some \( x \in g^{-1} (y) \).

Lemma 21.3.3 The relation \( \sim \) is an equivalence relation and, denoting by \([f]\) the equivalence class determined by \( f \), it follows that \([f]\) is an open subset of

\[ \mathcal{U}_y \equiv \{ f \in C (\overline{\Omega}; \mathbb{R}^n) : y \notin f (\partial \Omega) \} . \]

Furthermore, \( \mathcal{U}_y \) is an open set in \( C (\overline{\Omega}; \mathbb{R}^n) \).

Let \( g \in C^\infty (\overline{\Omega}; \mathbb{R}^n) \) and \( y \notin g (\partial \Omega) \) so \( \dist (y, g (\partial \Omega)) > 5\delta \) for some positive \( \delta \). Then there exists \( g_1 \) such that \( \| g - g_1 \|_\infty < \delta \), \( y \) is a regular value of \( g_1 \), and

\[ \int_{\Omega} \phi \left( (1 - t) g (x) + t g_1 (x) - y \right) \det (D ((1 - t) g + t g_1)) (x) \, dx \]

is constant for \( t \in [0, 1] \).

Proof: In showing that \( \sim \) is an equivalence relation, it is easy to verify that \( f \sim f \) and that if \( f \sim g \), then \( g \sim f \). To verify the transitive property for an equivalence relation, suppose \( f \sim g \) and \( g \sim k \), with the homotopy for \( f \) and \( g \), the function \( h_1 \) and the homotopy for \( g \) and \( k \), the function \( h_2 \). Thus \( h_1 (x, 0) = f (x) \), \( h_1 (x, 1) = g (x) \) and \( h_2 (x, 0) = g (x) \), \( h_2 (x, 1) = k (x) \). Then define a homotopy of \( f \) and \( k \) as follows.

\[ h (x, t) = \begin{cases} h_1 (x, 2t) & \text{if } t \in [0, \frac{1}{2}] \\ h_2 (x, 2t - 1) & \text{if } t \in [\frac{1}{2}, 1] . \end{cases} \]

It is obvious that \( \mathcal{U}_y \) is an open subset of \( C (\overline{\Omega}; \mathbb{R}^n) \). If \( g \in \mathcal{U}_y \) then \( y \notin g (\partial \Omega) \) a compact set. Hence if \( f \) is close enough to \( g \), the same is true of \( f \).
Next consider the claim that $[f]$ is also an open set. If $f \in U_y$, there exists $\delta > 0$ such that $B(y, 2\delta) \cap f(\partial\Omega) = \emptyset$. Let $f_1 \in C(\overline{\Omega}; \mathbb{R}^n)$ with $\|f_1 - f\|_\infty < \delta$. Then if $t \in [0, 1]$, and $x \in \partial\Omega$

$$|f(x) + t(f_1(x) - f(x)) - y| \geq |f(x) - y| - t \|f - f_1\|_\infty > 2\delta - t\delta > 0.$$ 

Therefore, $B(f, \delta) \subseteq [f]$ because if $f_1 \in B(f, \delta)$, this shows that, letting $h(x, t) \equiv f(x) + t(f_1(x) - f(x))$, $f_1 \sim f$.

Consider the last claim. There exists $y_1 \in B(y, \delta)$ such that $y_1$ is a regular value of $g$ thanks to Sard’s theorem. Let $g_1(x) \equiv g(x) + y - y_1$ for all $x \in \overline{\Omega}$. Then $\|g - g_1\|_\infty < \delta$ and so it follows that for $t \in [0, 1]$, and $x \in \partial\Omega$,

$$|(1 - t)g(x) + tg_1(x)) - y| = |g(x) - y + t(y - y_1)|$$

$$\geq 5\delta - \delta > 0$$

Therefore, from Lemma 21.3.3, the integral is constant. Also $y$ is a regular value of $g_1$ because $g_1(x) = y$ if and only if $g(x) - y_1$ and $y_1$ is a regular value for $g$. □

21.3.1 The Degree For $C^\infty(\overline{\Omega}; \mathbb{R}^n)$

Here I will give a definition of the degree which works for all functions in $C^\infty(\overline{\Omega}; \mathbb{R}^n)$. These are the restrictions to $\overline{\Omega}$ of functions in $C^\infty_c(\mathbb{R}^n; \mathbb{R}^n)$.

**Definition 21.3.4** For $g \in C^\infty(\overline{\Omega}; \mathbb{R}^n)$, $y \notin g(\partial\Omega)$,

$$d(g, \Omega, y) \equiv \lim_{\varepsilon \to 0} \int_\Omega \phi_\varepsilon(g(x) - y) \det Dg(x) \, dx$$

The next lemma has to do with the existence of the limit in the definition of the degree and the fact that it is always an integer.

**Lemma 21.3.5** The above definition is well defined. In particular the limit exists. In fact

$$\int_\Omega \phi_\varepsilon(g(x) - y) \det Dg(x) \, dx$$

does not depend on $\varepsilon$ whenever $\varepsilon$ is small enough. If $y$ is a regular value for $g$ then for all $\varepsilon$ small enough,

$$\int_\Omega \phi_\varepsilon(g(x) - y) \det Dg(x) \, dx =$$

$$\sum \{\text{sgn}(\det Dg(x)) : x \in g^{-1}(y)\}$$

(21.3.3)

If $g, f \in U_y \cap C^\infty(\overline{\Omega}; \mathbb{R}^n)$, and

$$y \notin (tf + (1-t)g)(\partial\Omega), \text{ all } t \in [0, 1]$$

(21.3.4)
then
\[ d(f, \Omega, y) = d(g, \Omega, y) \]

If \( \text{dist} (y, g(\partial \Omega)) > 5\delta \) and \( y_1 \in B(y, \delta) \), then \( d(g, \Omega, y) = d(g, \Omega, y_1) \). Also, the appropriate integrals are equal. See the following picture for an illustration of this last claim. The degree has integer values.

**Proof:** If \( y \) is not a value of \( g \) then there is not much to show. For small enough \( \varepsilon \), you will get 0 in the integral.

**The case where \( y \) is a regular value**

First consider the case where \( y \) is a regular value of \( g \). I will show that in this case, the integral expression is eventually constant for small \( \varepsilon > 0 \) and equals the right side of Eq. (21.3.3). I claim the right side of this equation is actually a finite sum. This follows from the inverse function theorem because \( g^{-1}(y) \) is a closed, hence compact subset of \( \Omega \) due to the assumption that \( y \notin g(\partial \Omega) \). If \( g^{-1}(y) \) had infinitely many points in it, there would exist a sequence of distinct points \( \{x_k\} \subseteq g^{-1}(y) \).

Since \( \Omega \) is bounded, some subsequence \( \{x_{k_l}\} \) would converge to a limit point \( x_\infty \). By continuity of \( g \), it follows \( x_\infty \in g^{-1}(y) \) also and so \( x_\infty \in \Omega \). Therefore, since \( y \) is a regular value, there is an open set, \( U_{x_\infty} \), containing \( x_\infty \) such that \( g \) is one to one on this open set contradicting the assertion that \( \lim_{l \to \infty} x_{k_l} = x_\infty \). Therefore, this set is finite and so the sum is well defined.

Thus the right side of Eq. (21.3.3) is finite when \( y \) is a regular value. Next I need to show the left side of this equation is eventually constant and equals the right side. By what was just shown, there are finitely many points, \( \{x_i\}_{i=1}^m = g^{-1}(y) \). By the inverse function theorem, there exist disjoint open sets \( U_i \) with \( x_i \in U_i \), such that \( g \) is one to one on \( U_i \) with \( \det (Dg(x)) \) having constant sign on \( U_i \) and \( g(U_i) \) is an open set containing \( y \). Then let \( \varepsilon \) be small enough that \( B(y, \varepsilon) \subseteq \bigcap_{i=1}^m g(U_i) \) and let \( V_i = g^{-1}(B(y, \varepsilon)) \cap U_i \).
Therefore, for any \( \varepsilon \) this small,

\[
\int_{\Omega} \phi_{\varepsilon} (g(x) - y) \det Dg(x) \, dx = \sum_{i=1}^{m} \int_{V_i} \phi_{\varepsilon} (g(x) - y) \det Dg(x) \, dx
\]

The reason for this is as follows. The integrand on the left is nonzero only if \( g(x) - y \in B(0, \varepsilon) \) which occurs only if \( g(x) \in B(y, \varepsilon) \) which is the same as \( x \in g^{-1}(B(y, \varepsilon)) \). Therefore, the integrand is nonzero only if \( x \) is contained in exactly one of the disjoint sets, \( V_i \). Now using the change of variables theorem,

\[
(z = g(x) - y, g^{-1}(y + z) = x)
\]

\[
= \sum_{i=1}^{m} \int_{g(V_i) - y} \phi_{\varepsilon} (z) \det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)| \, dz
\]

By the chain rule, \( I = Dg(g^{-1}(y + z)) \) \( Dg^{-1}(y + z) \) and so

\[
\det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)|
\]

\[
= \text{sgn} (\det Dg(g^{-1}(y + z))) \det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)|
\]

\[
= \text{sgn} (\det Dg(g^{-1}(y + z)))
\]

Therefore, this reduces to

\[
\sum_{i=1}^{m} \text{sgn} (\det Dg(x_i)) \int_{g(V_i) - y} \phi_{\varepsilon} (z) \, dz =
\]

\[
= \sum_{i=1}^{m} \text{sgn} (\det Dg(x_i)) \int_{B(0, \varepsilon)} \phi_{\varepsilon} (z) \, dz = \sum_{i=1}^{m} \text{sgn} (\det Dg(x_i)).
\]

In case \( g^{-1}(y) = \emptyset \), there exists \( \varepsilon > 0 \) such that \( g(\overline{U}) \cap B(y, \varepsilon) = \emptyset \) and so for \( \varepsilon \) this small,

\[
\int_{\Omega} \phi_{\varepsilon} (g(x) - y) \det Dg(x) \, dx = 0.
\]
21.3. Definitions and Elementary Properties

Showing the integral is constant for small $\varepsilon$

Let $y \notin g(\partial \Omega)$. By Lemma 21.3.3, $y$ is a regular value of $g_1$ where

$$\int_{\Omega} \phi_\varepsilon (g(x) + t(g_1(x) - g(x)) - y) \det (D(g + t(g_1 - g))(x)) \, dx$$

is constant for $t \in [0, 1]$. Letting $\varepsilon$ be small enough, and $t = 0$ and then $1$,

$$\int_{\Omega} \phi_\varepsilon (g(x) - y) \det (Dg(x)) \, dx = \int_{\Omega} \phi_\varepsilon (g_1(x) - y) \det (Dg_1(x)) \, dx = d(g_1, \Omega, y)$$

Therefore, $\int_{\Omega} \phi_\varepsilon (g(x) - y) \det (Dg(x)) \, dx$ does not change for sufficiently small $\varepsilon$. Thus the limit exists and equals an integer. This shows the degree is an integer.

The next claim follows right away from the above. Suppose $0 \notin ((f + (1 - t)g)(\partial \Omega) - y$ for all $t \in [0, 1]$. Then choosing $\varepsilon$ small enough, it follows $d(f, \Omega, y) = d(g, \Omega, y)$ because the two integrals defining the degree for small $\varepsilon$ are equal, this by Lemma 21.3.3.

It also follows from the above argument and Lemma 21.3.3 that if $\text{dist} (y, g(\partial \Omega)) > 5\delta$ and if $y_1 \in B(y, \delta)$, then $d(g, \Omega, y_1) = d(g, \Omega, y)$ because the corresponding integrals are equal for all $\varepsilon$ small enough. ■

21.3.2 Definition Of The Degree For Continuous Functions

With the above results, it is now possible to extend the definition of the degree to continuous functions which have no differentiability. It is desired to preserve the homotopy invariance. This requires the following definition.

**Definition 21.3.6** Let $y \in \mathbb{R}^n \setminus f(\partial \Omega)$ where $f \in C(\overline{\Omega}; \mathbb{R}^n)$ Then

$$d(f, \Omega, y) = d(g, \Omega, y)$$

where $y \notin g(\partial \Omega), g \in C^\infty(\overline{\Omega}; \mathbb{R}^n)$ and $f \sim g$.

**Theorem 21.3.7** The definition of the degree given in Definition 21.3.3 is well defined, equals an integer, and satisfies the following properties. In what follows, $I(x) = x$.

1. $d(I, \Omega, y) = 1$ if $y \in \Omega$.
2. If $\Omega_i \subseteq \overline{\Omega}, \Omega_i$ open, and $\Omega_1 \cap \Omega_2 = \emptyset$ and if $y \notin f(\overline{\Omega} \setminus (\Omega_1 \cup \Omega_2))$, then $d(f, \Omega_1, y) + d(f, \Omega_2, y) = d(f, \Omega, y)$.
3. For $y \in \mathbb{R}^n \setminus f(\partial \Omega)$, if $d(f, \Omega, y) \neq 0$ then $f^{-1}(y) \cap \Omega \neq \emptyset$.
4. If $t \rightarrow y(t)$ is continuous $h: \overline{\Omega} \times [0, 1] \rightarrow \mathbb{R}^n$ is continuous and if $y(t) \notin h(\partial \Omega, t)$ for all $t$, then $t \rightarrow d(h(\cdot, t), \Omega, y(t))$ is constant.
5. \( d(f, \Omega, \cdot) \) is continuous and constant on every connected component of \( \mathbb{R}^n \setminus f(\partial \Omega) \).

6. \( d(g, \Omega, y) = d(f, \Omega, y) \) if \( g|_{\partial \Omega} = f|_{\partial \Omega} \).

**Proof:** First it is necessary to show the definition is well defined. There are two parts to this. First I need to show there exists \( g \) with the desired properties and then I need to show that it doesn’t matter which \( g \) I happen to pick. The first part is easy. Let \( \delta \) be small enough that

\[
B(y, \delta) \cap f(\partial \Omega) = \emptyset.
\]

Then by Lemma 21.3.3 there exists \( g \in C^\infty(\overline{\Omega}; \mathbb{R}^n) \) such that \( \|g - f\|_\infty < \delta \). It follows that for \( t \in [0, 1] \),

\[
y \notin (tg + (1 - t)f)(\partial \Omega)
\]

and so \( g \sim f \). The reason is that if \( x \in \partial \Omega \),

\[
|tg(x) + (1 - t)f(x) - y| \geq |f(x) - y| - t|g(x) - f(x)| > \delta - \delta = 0
\]

Now consider the second part. Suppose \( g \sim f \) and \( g_1 \sim f \). Then by Lemma 21.3.3 again

\[
g \sim g_1.
\]

Thus there is a function \( h : \overline{\Omega} \times [0, 1] \to \mathbb{R}^n \) such that \( h(x, 0) = g(x) \) and \( h(x, 1) = g_1(x) \). The difficulty is that it is only known that this function is continuous. It is not known that \( h(\cdot, t) \) is \( C^\infty(\overline{\Omega}; \mathbb{R}^n) \). Let \( \psi_\varepsilon \) be a mollifier. Thus it is infinitely differentiable, has support in \( B(0, \varepsilon) \) and \( \int_{\mathbb{R}^n} \psi_\varepsilon(x) \, dx = 1 \). Then define

\[
h_\varepsilon(x, t) \equiv h(\cdot, t) * \psi_\varepsilon(x) \equiv \int_{\mathbb{R}^n} h(x - u, t) \psi_\varepsilon(u) \, du.
\]

Then as \( \varepsilon \to 0 \), the convergence is uniform on \( \overline{\Omega} \times [0, 1] \). Now there exists \( \delta > 0 \) such that \( B(y, 6\delta) \cap h(\partial \Omega \times [0, 1]) = \emptyset \) for all \( t \). Hence, by uniform convergence, for \( \varepsilon \) small enough, \( B(y, 5\delta) \cap h_\varepsilon(\partial \Omega, t) = \emptyset \) for all \( t \) and in fact,

\[
\max_{t \in [0, 1]} \|h_\varepsilon(\cdot, t) - h(\cdot, t)\|_\infty < \delta.
\]

Then by Lemma 21.2.6, it follows that the following integral is constant for \( t \in [0, 1] \).

\[
\int_{\Omega} \phi_\varepsilon(h_\varepsilon(x, t) - y) \det(D_1 h_\varepsilon(\cdot, t)(x)) \, dx
\]

Thus, letting \( \varepsilon \) be smaller if necessary, \( d(h_\varepsilon(\cdot, 0), \Omega, y) = d(h_\varepsilon(\cdot, 1), \Omega, y) \). Since \( \|h_\varepsilon(\cdot, 1) - g_1\|_\infty < \delta \), it follows that \( y \notin \partial h_\varepsilon(x, 1) + (1 - t) g_1(x) \) for all \( x \in \partial \Omega \). Then by Lemma 21.3.3, formula 21.4.3,

\[
d(h_\varepsilon(\cdot, 1), \Omega, y) = d(g_1, \Omega, y)
\]

similarly,

\[
d(h_\varepsilon(\cdot, 0), \Omega, y) = d(g, \Omega, y)
\]
Therefore,
\[
d(g, \Omega, y) = d(h(y), \Omega, y) = d(h(1), \Omega, y) = d(g, \Omega, y)
\]
which implies \(d(g_1, \Omega, y) = d(g, \Omega, y)\). Thus the definition is well defined.

Now consider the properties. The first, is obvious since \(y\) is a regular value of \(I\).

Consider about \(y \notin f(\Omega \setminus (\Omega_1 \cup \Omega_2))\).

The assumption implies
\[
y \notin f(\Omega) \cup f(\partial \Omega_1) \cup f(\partial \Omega_2)
\]
Recall that \(y \notin f(\Omega \setminus (\Omega_1 \cup \Omega_2))\). Say
\[
\text{dist} (y, f(\Omega \setminus (\Omega_1 \cup \Omega_2))) > 5\delta, \delta > 0
\]
Then let \(g \in C^\infty (\Omega; \mathbb{R}^n)\) such that \(||f - g||_\infty < \delta\). It follows that \(f \sim g\) and so by definition,
\[
d(f, \Omega, y) = d(g, \Omega, y), \ d(f, \Omega_1, y) = d(g, \Omega_1, y), \ d(f, \Omega_2, y) = d(g, \Omega_2, y)
\]
since \(f(\Omega \setminus (\Omega_1 \cup \Omega_2))\) includes \(f(\partial \Omega) \cup f(\partial \Omega_1) \cup f(\partial \Omega_2)\). One can use for a homotopy \(tf + (1 - t)g\) in every case.

Hence
\[
d(f, \Omega, y) = \int_{\Omega_1} \phi_\varepsilon(g(x) - y) Dg(x) \, dx
\]
for all \(\varepsilon\) sufficiently small. However, \(\phi_\varepsilon(g(x) - y) = 0\) if \(x \notin \Omega_1 \cup \Omega_2\) whenever \(\varepsilon\) is sufficiently small, \((\varepsilon < \delta\) will do). Hence the above integral is
\[
\int_{\Omega_1} \phi_\varepsilon(g(x) - y) Dg(x) \, dx + \int_{\Omega_2} \phi_\varepsilon(g(x) - y) Dg(x) \, dx
\]
for all \(\varepsilon\) small enough, and hence
\[
d(f, \Omega, y) = d(g, \Omega, y) = d(g, \Omega_1, y) + d(g, \Omega_2, y)
\]
\[
= d(f, \Omega_1, y) + d(f, \Omega_1, y).
\]

Property \(3\) is very important because it can be used to deduce the existence of solutions to a nonlinear equation. Suppose \(f^{-1}(y) \cap \Omega = \emptyset\). I will show this
requires \( d(\mathbf{f}, \Omega, \mathbf{y}) = 0 \). It is assumed \( \mathbf{y} \notin \mathbf{f}(\partial \Omega) \) and so if \( \mathbf{f}^{-1}(\mathbf{y}) \cap \Omega = \emptyset \), then \( \mathbf{y} \notin \mathbf{f}(\overline{\Omega}) \). Choosing \( \mathbf{g} \in C^\infty(\overline{\Omega}; \mathbb{R}^n) \) such that \( ||\mathbf{f} - \mathbf{g}||_\infty \) is sufficiently small, it can be assumed
\[
\mathbf{y} \notin \mathbf{g}(\overline{\Omega}), \; \mathbf{y} \notin ((1 - t)\mathbf{f} + t\mathbf{g})(\partial \Omega) \; \text{for all} \; t \in [0,1].
\]
Then it follows from the definition of the degree
\[
d(\mathbf{f}, \Omega, \mathbf{y}) = d(\mathbf{g}, \Omega, \mathbf{y}) \equiv \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(\mathbf{g}(\mathbf{x}) - \mathbf{y}) D\mathbf{g}(\mathbf{x}) \, d\mathbf{x} = 0
\]
because eventually \( \varepsilon \) is smaller than the distance from \( \mathbf{y} \) to \( \mathbf{g}(\overline{\Omega}) \) and so
\[
\phi_\varepsilon(\mathbf{g}(\mathbf{x}) - \mathbf{y}) = 0
\]
for all \( \mathbf{x} \in \Omega \).

Consider \( \mathbf{h} \). There is a \( \delta > 0 \) such that \( B(\mathbf{y}(t), 6\delta) \cap \mathbf{h}(\partial \Omega, t) \) for all \( t \). If this were not so, there would be a sequence \( \{t_k\} \subseteq [0,1] \); \( \{\mathbf{x}_k\} \subseteq \partial \Omega \) such that
\[
\text{dist}(\mathbf{y}(t_k), \mathbf{h}(\mathbf{x}_k, t_k)) \leq 1/k.
\]
Now taking a convergent subsequence \( t_k \to t \in [0,1] \), \( \mathbf{x}_k \to \mathbf{x} \in \partial \Omega \), it follows from continuity that \( \mathbf{y}(t) = \mathbf{h}(\mathbf{x}, t) \) which is a contradiction. Let \( \psi_\varepsilon \) be a mollifier and let \( \mathbf{h}_\varepsilon(\mathbf{x}, t) \equiv \mathbf{h}(\cdot, t) * \psi_\varepsilon(\mathbf{x}) \). Then by the uniform convergence, whenever \( \varepsilon \) is sufficiently small, \( B(\mathbf{y}(t), 5\delta) \cap \mathbf{h}_\varepsilon(\partial \Omega, t) = \emptyset \) because for all \( t \),
\[
||\mathbf{h}(\cdot, t) - \mathbf{h}_\varepsilon(\cdot, t)||_\infty < \delta.
\]
Therefore, \( \mathbf{h}(\cdot, t) \sim \mathbf{h}_\varepsilon(\cdot, t) \) for all \( t \) since \( \mathbf{y}(t) \notin (1 - \lambda)\mathbf{h}(\partial \Omega, t) + \lambda \mathbf{h}_\varepsilon(\partial \Omega, t), \lambda \in [0,1] \). To see this, let \( \mathbf{x} \in \partial \Omega \)
\[
| (1 - \lambda) \mathbf{h}(\mathbf{x}, t) + \lambda \mathbf{h}_\varepsilon(\mathbf{x}, t) - \mathbf{y}(t) |
\geq | \mathbf{h}(\mathbf{x}, t) - \mathbf{y}(t) | - \lambda | \mathbf{h}(\mathbf{x}, t) - \mathbf{h}_\varepsilon(\mathbf{x}, t) |
\geq 6\delta - \lambda \delta \geq 5\delta > 0
\]
Then from the definition of the degree above, which was shown above to be well defined, it follows that for all \( t \),
\[
d(\mathbf{h}(\cdot, t), \Omega, \mathbf{y}(t)) = d(\mathbf{h}_\varepsilon(\cdot, t), \Omega, \mathbf{y}(t))
\]
and the expression on the right is constant in \( t \) thanks to Corollary \( \# \).

Property \( \# \) about being constant on connected components is done by showing \( \mathbf{y} \to d(\mathbf{f}, \Omega, \mathbf{y}) \) is continuous. Then, since it is integer valued, it must be constant on every connected component of \( \mathbf{f}(\partial \Omega)^C \). Suppose \( \text{dist}(\mathbf{y}, \mathbf{f}(\partial \Omega)) = 5\delta > 0 \) and suppose \( \hat{\mathbf{y}} \in B(\mathbf{y}, \delta) \). Let \( \mathbf{y}(t) \equiv t\mathbf{y} + (1 - t)\hat{\mathbf{y}}, t \in [0,1] \). Then \( \mathbf{y}(t) \notin \mathbf{f}(\partial \Omega) \) and so by \( \# \)
\[
d(\mathbf{f}, \Omega, \mathbf{y}(t))
\]
is a constant. Letting \( t = 0 \) and then letting \( t = 1 \), it follows that \( d(\mathbf{f}, \Omega, \mathbf{y}) = d(\mathbf{f}, \Omega, \hat{\mathbf{y}}) \) showing that in fact \( \mathbf{y} \to d(\mathbf{f}, \Omega, \mathbf{y}) \) is locally constant. Hence it is
21.4. BORSUK’S THEOREM

In this section is an important theorem which can be used to verify that \(d(f, \Omega, y) \neq 0\). This is significant because when this is known, it follows from Theorem 21.3.7 that \(f^{-1}(y) \neq \emptyset\). In other words there exists \(x \in \Omega\) such that \(f(x) = y\).

Definition 21.4.1 A bounded open set, \(\Omega\) is symmetric if \(-\Omega = \Omega\). A continuous function, \(f : \Omega \rightarrow \mathbb{R}^n\) is odd if \(f(-x) = -f(x)\).
Suppose $\Omega$ is symmetric and $g \in C^\infty (\overline{\Omega}; \mathbb{R}^n)$ is an odd map for which $0$ is a regular value. Then the chain rule implies $Dg (-x) = Dg (x)$ and so $d (g, \Omega, 0)$ must equal an odd integer because if $x \in g^{-1} (0)$, it follows that $-x \in g^{-1} (0)$ also and since $Dg (-x) = Dg (x)$, it follows the overall contribution to the degree from $x$ and $-x$ must be an even integer. Also $0 \in g^{-1} (0)$ and so the degree equals an even integer added to $\text{sgn} \ (\det Dg (0))$, an odd integer, either $-1$ or $1$. It seems reasonable to expect that something like this would hold for an arbitrary continuous odd function defined on symmetric $\Omega$. In fact this is the case and this is next. The following lemma is the key result used. This approach is due to Gromov [72]. See also Deimling [77] which is where I found this argument.

The idea is to start with a smooth odd map and approximate it with a smooth odd map which also has $0$ a regular value.

**Lemma 21.4.2** Let $g \in C^\infty (\overline{\Omega}; \mathbb{R}^n)$ be an odd map. Then for every $\varepsilon > 0$, there exists $h \in C^\infty (\overline{\Omega}; \mathbb{R}^n)$ such that $h$ is also an odd map, $||h - g||_\infty < \varepsilon$, and $0$ is a regular value of $h$. Here $\Omega$ is a symmetric bounded open set. In addition, $d (g, \Omega, 0)$ is an odd integer.

**Proof:** In this argument $\eta > 0$ will be a small positive number and $C$ will be a constant which depends only on the diameter of $\Omega$. Let $h_0 (x) = g (x) + \eta x$ where $\eta$ is chosen such that $\det Dh_0 (0) \neq 0$. Note that $h_0$ is odd, close to $g$ and so $0$ is a value of $h_0$ thanks to $h_0 (0) = 0$. The idea is to modify $h_0$ such that for all $x \in h^{-1} (0), \det Dh_0 (x) \neq 0$.

Let $\Omega_i \equiv \{x \in \Omega : x_i \neq 0\}$. In other words, leave out the plane $x_i = 0$ from $\Omega$ in order to obtain $\Omega_i$. A succession of modifications is about to take place on $\Omega_1, \Omega_1 \cup \Omega_2, \Omega_1 \cup \Omega_2 \cup \Omega_3$, etc. Finally a function will be obtained on $\bigcup_{j=1}^n \Omega_j$ which is everything except $0$.

Define $h_1 (x) = h_0 (x) - y^1 x_1^3$ where $|y^1| < \eta$ and $y^1 = (y_1^1, \ldots, y_4^1)$ is a regular value of the function, $x \mapsto \frac{h_0 (x)}{x_1^4}$, for $x \in \Omega_1$. The existence of $y^1$ follows from Sard’s lemma because this function is in $C^\infty (\Omega_1; \mathbb{R}^n)$. Thus $h_1 (x) = 0$ if and only if $y^1 = \frac{h_0 (x)}{x_1^4}$. Since $y^1$ is a regular value, it follows that for such $x$ satisfying $h_1 (x) = 0$,

$$\det \left( \frac{h_{0i,j} (x) x_1^3 - \frac{\partial}{\partial x_j} (x_1^3) h_0i (x)}{x_1^6} \right) = 0$$

implying that

$$\det \left( \frac{h_{0i,j} (x) x_1^3 - \frac{\partial}{\partial x_j} (x_1^3) y^1_j x_1^3}{x_1^6} \right) \neq 0$$

This shows $0$ is a regular value of $h_1$ on the set $\Omega_1$ and it is clear $h_1$ is an odd map in $C^\infty (\overline{\Omega}; \mathbb{R}^n)$ and $||h_1 - g||_\infty \leq C \eta$ where $C$ depends only on the diameter of $\Omega$. 

744

**CHAPTER 21. DEGREE THEORY, AN INTRODUCTION**
21.4. BORSUK’S THEOREM

Now suppose for some \( k \) such that \( 1 \leq k < n \) there exists an odd mapping \( h_k \) in \( C^\infty (\overline{\Omega}; \mathbb{R}^n) \) such that \( 0 \) is a regular value of \( h_k \) on \( \cup_{i=1}^k \Omega_i \) and \( ||h_k - g||_\infty \leq C\eta \). Sard’s theorem implies there exists \( y^{k+1} \) a regular value of the function \( x \to h_k(x)/x_{k+1}^3 \) defined on \( \Omega_{k+1} \) such that \( ||y^{k+1}|| < \eta \) and let \( h_{k+1}(x) \equiv h_k(x) - y^{k+1}x_{k+1}^3 \). As before, \( h_{k+1}(x) = 0 \) if and only if \( h_k(x)/x_{k+1}^3 = y^{k+1} \), a regular value of \( x \to h_k(x)/x_{k+1}^3 \). Consider such \( x \) for which \( h_{k+1}(x) = 0 \). First suppose \( x \in \Omega_{k+1} \). Then

\[
\det \left( \frac{h_{k,j}(x)}{x_{k+1}^3} \frac{\partial}{\partial x_j} (x_{k+1}^3) y_{k+1} \right) \neq 0
\]

which implies that whenever \( h_{k+1}(x) = 0 \) and \( x \in \Omega_{k+1} \),

\[
\det \left( h_{k,j}(x) - \frac{\partial}{\partial x_j} (x_{k+1}^3) y_{k+1} \right) = \det (Dh_{k+1}(x)) \neq 0.
\] (21.4.5)

However, if \( x \in \cup_{i=1}^k \Omega_i \) but \( x \notin \Omega_{k+1} \), then \( x_{k+1} = 0 \) since \( \Omega_{k+1} \) consists of those \( x \) such that \( x_{k+1} \neq 0 \), and so the left side of (21.4.5) reduces to \( \det (h_{k,j}(x)) \) which is not zero because \( 0 \) is assumed a regular value of \( h_k \) on \( \cup_{i=1}^k \Omega_i \). Therefore, \( 0 \) is a regular value for \( h_{k+1} \) on \( \cup_{i=1}^k \Omega_i \). (For \( x \in \cup_{i=1}^k \Omega_i \), either \( x \in \Omega_{k+1} \) or \( x \notin \Omega_{k+1} \). If \( x \in \Omega_{k+1} \), \( 0 \) is a regular value by the construction above. In the other case, \( 0 \) is a regular value by the induction hypothesis.) Also \( h_{k+1} \) is odd and in \( C^\infty (\overline{\Omega}; \mathbb{R}^n) \), and \( ||h_{k+1} - g||_\infty \leq C\eta \).

Let \( h = h_n \). Then \( 0 \) is a regular value of \( h \) for \( x \in \cup_{j=1}^n \Omega_j \). The point of \( \Omega \) which is not in \( \cup_{j=1}^n \Omega_j \) is \( 0 \). If \( x = 0 \), then from the construction, \( Dh(0) = Dh_0(0) \) and so \( 0 \) is a regular value of \( h \) for \( x \in \Omega \). By choosing \( \eta \) small enough, it follows \( ||h - g||_\infty < \varepsilon \).

For the last part, let \( 3\delta = \text{dist} (g(\partial \Omega), 0) \) and let \( h \) be as described above with \( ||h - g||_\infty < \delta \). Then \( 0 \notin (h + (1 - t) g)(\partial \Omega) \) and so by the homotopy invariance of the degree, \( t \to d((h + (1 - t) g)(\Omega, 0)) \) is constant for \( t \in [0, 1] \). Therefore,

\[
d(g, \Omega, 0) = d(h, \Omega, 0)
\]

So what is \( d(h, \Omega, 0) \)? Since \( 0 \) is a regular value and \( h \) is odd,

\[
h^{-1}(0) = \{x_1, \ldots, x_r, -x_1, \ldots, -x_r, 0\}.
\]

So consider \( Dh(x) \) and \( Dh(-x) \).

\[
Dh(-x)u + o(u) = h(-x + u) - h(-x) = -h(x + (-u)) + h(x) = -(Dh(x)(-u)) + o(-u) = Dh(x)(u) + o(u)
\]

Hence \( Dh(x) = Dh(-x) \) and so the determinants of these two are the same. It
follows that
\[ d(h, \Omega, 0) = \sum_{i=1}^{r} \text{sgn}(\det(Dh(x_i))) + \sum_{i=1}^{r} \text{sgn}(\det(Dh(-x_i))) + \text{sgn}(\det(Dh(0))) \]
\[ = 2m \pm 1 \text{ some integer } m \]
an odd integer. ■

**Theorem 21.4.3** (Borsuk) Let \( f \in C(\overline{\Omega}; \mathbb{R}^n) \) be odd and let \( \Omega \) be symmetric with \( 0 = 2f(\partial \Omega) \). Then \( d(f, \Omega, 0) \) equals an odd integer.

**Proof:** Let \( \psi \) be a mollifier which is symmetric, \( \psi(-x) = \psi(x) \). Also recall that \( f \) is the restriction to \( \overline{\Omega} \) of a continuous function, still denoted as \( f \) which is defined on all of \( \mathbb{R}^n \). Let \( g \) be the odd part of this function. That is,
\[ g(x) \equiv \frac{1}{2}(f(x) - f(-x)) \]
Since \( f \) is odd, \( g = f \) on \( \overline{\Omega} \). Then
\[ g_n(-x) = g \ast \psi_n(-x) = \int_{\mathbb{R}^n} g(-x - y) \psi_n(y) \, dy \]
\[ = \int_{\mathbb{R}^n} g(x + y) \psi_n(y) \, dy = - \int_{\mathbb{R}^n} g(x - (y)) \psi_n(-y) \, dy = -g_n(x) \]
Thus \( g_n \) is odd and is infinitely differentiable. Let \( 3\delta = \text{dist}(f(\partial \Omega), 0) \) and let \( n \) be large enough that \( \|g_n - f\|_\infty < \delta \). Then \( 0 \notin (tg_n + (1-t)f)(\partial \Omega) \) for \( t \in [0,1] \) and so by homotopy invariance,
\[ d(f, \Omega, 0) = d(g, \Omega, 0) = d(g_n, \Omega, 0) \]
and by Lemma 21.4.2 this is an odd integer. ■

### 21.5 Applications

With these theorems it is possible to give easy proofs of some very important and difficult theorems.

**Definition 21.5.1** If \( f: U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}^n \) where \( U \) is an open set. Then \( f \) is locally one to one if for every \( x \in U \), there exists \( \delta > 0 \) such that \( f \) is one to one on \( B(x, \delta) \).

As a first application, consider the invariance of domain theorem. This result says that a one to one continuous map takes open sets to open sets. It is an amazing result which is essential to understand if you wish to study manifolds. In fact, the following theorem only requires \( f \) to be locally one to one. First here is a lemma which has the main idea.
Lemma 21.5.2 Let \( g : \overline{B(0,r)} \to \mathbb{R}^n \) be one to one and continuous where here \( B(0,r) \) is the ball centered at 0 of radius \( r \) in \( \mathbb{R}^n \). Then there exists \( \delta > 0 \) such that
\[
g(0) + B(0,\delta) \subseteq g(B(0,r)).
\]
The symbol on the left means: \( \{ g(0) + x : x \in B(0,\delta) \} \).

Proof: For \( t \in [0,1] \), let
\[
h(x, t) = g\left( \frac{x}{1+t} \right) - g\left( \frac{-tx}{1+t} \right)
\]
Then for \( x \in \partial B(0,r) \), \( h(x, t) \neq 0 \) because if this were so, the fact \( g \) is one to one implies
\[
\frac{x}{1+t} = \frac{-tx}{1+t}
\]
and this requires \( x = 0 \) which is not the case since \( \|x\| = r \). Then \( d(h(\cdot, t), B(0,r), 0) \) is constant. Hence it is an odd integer for all \( t \) thanks to Borsuk’s theorem, because \( h(\cdot, 1) \) is odd. Now let \( B(0,\delta) \) be such that \( B(0,\delta) \cap h(\partial\Omega, 0) = \emptyset \). Then \( d(h(\cdot, 0), B(0,r), 0) = d(h(\cdot, 0), B(0,r), z) \) for \( z \in B(0,\delta) \) because the degree is constant on connected components of \( \mathbb{R}^n \setminus h(\partial\Omega, 0) \). Hence \( z = h(x, 0) = g(x) - g(0) \) for some \( x \in B(0,r) \). Thus
\[
g(B(0,r)) \supseteq g(0) + B(0,\delta).
\]

Now with this lemma, it is easy to prove the very important invariance of domain theorem.

A function \( f \) is locally one to one on an open set \( \Omega \) if for every \( x_0 \in \Omega \), there exists \( B(x_0, r) \subseteq \Omega \) such that \( f \) is one to one on \( B(x_0, r) \).

Theorem 21.5.3 (invariance of domain) Let \( \Omega \) be any open subset of \( \mathbb{R}^n \) and let \( f : \Omega \to \mathbb{R}^n \) be continuous and locally one to one. Then \( f \) maps open subsets of \( \Omega \) to open sets in \( \mathbb{R}^n \).

Proof: Let \( \overline{B(x_0,r)} \subseteq \Omega \) where \( f \) is one to one on \( \overline{B(x_0,r)} \). Let \( g \) be defined on \( B(0,r) \) given by
\[
g(x) = f(x + x_0)
\]
Then \( g \) satisfies the conditions of Lemma 21.5.2, being one to one and continuous. It follows from that lemma there exists \( \delta > 0 \) such that
\[
f(\Omega) \supseteq f(B(x_0, r)) = f(x_0 + B(0,r))
\]
\[
= g(B(0,r)) \supseteq g(0) + B(0,\delta)
\]
\[
= f(x_0) + B(0,\delta) = B(f(x_0), \delta)
\]
This shows that for any \( x_0 \in \Omega \), \( f(x_0) \) is an interior point of \( f(\Omega) \) which shows \( f(\Omega) \) is open.

With the above, one gets easily the following amazing result. It is something which is clear for linear maps but this is a statement about continuous maps.
Corollary 21.5.4 If \( n > m \) there does not exist a continuous one to one map from \( \mathbb{R}^n \) to \( \mathbb{R}^m \).

**Proof:** Suppose not and let \( f \) be such a continuous map,
\[
f(x) \equiv (f_1(x), \ldots, f_m(x))^T.
\]
Then let \( g(x) \equiv (f_1(x), \ldots, f_m(x), 0, \ldots, 0)^T \) where there are \( n - m \) zeros added in. Then \( g \) is a one to one continuous map from \( \mathbb{R}^n \) to \( \mathbb{R}^n \) and so \( g(\mathbb{R}^n) \) would have to be open from the invariance of domain theorem and this is not the case.

Corollary 21.5.5 If \( f \) is locally one to one and continuous, \( f : \mathbb{R}^n \to \mathbb{R}^n \), and
\[
\lim_{|x| \to \infty} |f(x)| = \infty,
\]
then \( f \) maps \( \mathbb{R}^n \) onto \( \mathbb{R}^n \).

**Proof:** By the invariance of domain theorem, \( f(\mathbb{R}^n) \) is an open set. It is also true that \( f(\mathbb{R}^n) \) is a closed set. Here is why. If \( f(x_k) \to y \), the growth condition ensures that \( \{x_k\} \) is a bounded sequence. Taking a subsequence which converges to \( x \in \mathbb{R}^n \) and using the continuity of \( f \), it follows \( f(x) = y \). Thus \( f(\mathbb{R}^n) \) is both open and closed which implies \( f \) must be an onto map since otherwise, \( \mathbb{R}^n \) would not be connected.

The next theorem is the famous Brouwer fixed point theorem.

**Theorem 21.5.6 (Brouwer fixed point)** Let \( B = \overline{B(0,r)} \subseteq \mathbb{R}^n \) and let \( f : B \to B \) be continuous. Then there exists a point \( x \in B \), such that \( f(x) = x \).

**Proof:** Assume there is no fixed point. Consider \( h(x,t) \equiv tf(x) - x \) for \( t \in [0,1] \). Then for \( \|x\| = r \),
\[
0 \notin tf(x) - x, t \in [0,1]
\]
By homotopy invariance,
\[
t \to d(tf - I, B, 0)
\]
is constant. But when \( t = 0 \), this is \( d(-I, B, 0) = (-1)^n \neq 0 \). Hence \( d(f - I, B, 0) \neq 0 \) so there exists \( x \) such that \( f(x) - x = 0 \).

It is easy to generalize this to an arbitrary closed bounded convex set \( K \) in \( \mathbb{R}^n \) as follows. You use the fact that \( K \) is a retract, Theorem 14.2.5. Thus there exists a mapping \( P \) which is continuous and maps all of \( \mathbb{R}^n \) to \( K \) and fixed points of \( K \). In particular, \( P \) maps \( \overline{B(0,r)} \) to \( K \). Thus there exists \( x \in \overline{B(0,r)} \) such that \( f(P(x)) = x \). But then \( x \in K \) and so \( P(x) = x \). Thus \( f(x) = x \).

You can also use standard stuff from Hilbert space to get this. Let \( K \) be a closed bounded convex set and let \( f : K \to K \) be continuous. Let \( P \) be the projection map onto \( K \). Then \( P \) is continuous because \( |Px - Py| \leq |x - y| \). Recall why this
From the material on Hilbert space, 
\[(x - Px, y - Px) \leq 0, \quad (y - Py, Px - Py) \leq 0 \] 
so 
\[(y - Py, Py - Px) \geq 0\]

Hence, subtracting the first from the last,
\[(y - Py - (x - Px), Py - Px) \geq 0\]

consequently,
\[|x - y||Py - Px| \geq (y - x, Py - Px) \geq |Py - Px|^2\]

and so 
\[|Py - Px| \leq |y - x|\] as claimed.

Let 
\[r \] be so large that 
\[K \subseteq B(0, r)\]. Then consider 
\[f \circ P\]. This map takes 
\[B(0, r)\] to 
\[K\]. Therefore, being the composition of continuous functions, it is continuous and so has a fixed point in 
\[B(0, r)\] denoted as 
\[x\]. Hence 
\[f(P(x)) = x\]. Now, since 
\[f\] maps into 
\[K\], it follows that 
\[x \in K\]. Hence 
\[Px = x\] and so 
\[f(x) = x\]. This has proved the following general Brouwer fixed point theorem.

**Theorem 21.5.7** Let 
\[f : K \to K\] be continuous where 
\[K\] is compact and convex and nonempty, 
\[K \subseteq \mathbb{R}^n\]. Then 
\[f\] has a fixed point.

**Definition 21.5.8** 
\[f\] is a retract of 
\[B(0, r)\] onto 
\[\partial B(0, r)\] if 
\[f\] is continuous, 
\[f(B(0, r)) \subseteq \partial B(0, r)\]

and 
\[f(x) = x\] for all 
\[x \in \partial B(0, r)\].

**Theorem 21.5.9** There does not exist a retraction of 
\[B(0, r)\] onto its boundary, 
\[\partial B(0, r)\].

**Proof:** Suppose 
\[f\] were such a retraction. Then for all 
\[x \in \partial B(0, r)\], 
\[f(x) = x\] and so from the properties of the degree, the one which says if two functions agree on 
\[\partial \Omega\], then they have the same degree, 
\[1 = d(I, B(0, r), 0) = d(f, B(0, r), 0)\]

which is clearly impossible because 
\[f^{-1}(0) = \emptyset\] which implies 
\[d(f, B(0, r), 0) = 0\].

You should now use this theorem to give another proof of the Brouwer fixed point theorem.

The proofs of the next two theorems make use of the Tietze extension theorem, Theorem [21.5.10].

**Theorem 21.5.10** Let 
\[\Omega\] be a symmetric open set in 
\[\mathbb{R}^n\] such that 
\[0 \in \Omega\] and let 
\[f : \partial \Omega \to V\] be continuous where 
\[V\] is an 
\[m\] dimensional subspace of 
\[\mathbb{R}^n\], 
\[m < n\]. Then 
\[f(x) = f(x)\] for some 
\[x \in \partial \Omega\].
Proof: Suppose not. Using the Tietze extension theorem or Theorem 14.2.3, extend \( f \) to all of \( \mathbb{R}^n \), \( f(\overline{\Omega}) \subseteq V \). (Here the extended function is also denoted by \( f \).) Let \( g(x) = f(x) - f(-x) \). Then \( 0 \notin g(\partial\Omega) \) and so for some \( r > 0 \), \( B(0,r) \subseteq \mathbb{R}^n \setminus g(\partial\Omega) \). For \( z \in B(0,r) \),
\[
d(g, \Omega, z) = d(g, \Omega, 0) \neq 0
\]
because \( B(0,r) \) is contained in a component of \( \mathbb{R}^n \setminus g(\partial\Omega) \) and Borsuk’s theorem implies that \( d(g, \Omega, 0) \neq 0 \) since \( g \) is odd. Hence
\[
V \supseteq g(\Omega) \supseteq B(0,r)
\]
and this is a contradiction because \( V \) is \( m \) dimensional. ■

This theorem is called the Borsuk Ulam theorem. Note that it implies there exist two points on opposite sides of the surface of the earth which have the same atmospheric pressure and temperature, assuming the earth is symmetric and that pressure and temperature are continuous functions. The next theorem is an amusing result which is like combing hair. It gives the existence of a “cowlick”.

**Theorem 21.5.11** Let \( n \) be odd and let \( \Omega \) be an open bounded set in \( \mathbb{R}^n \) with \( 0 \in \Omega \). Suppose \( f : \partial\Omega \to \mathbb{R}^n \setminus \{0\} \) is continuous. Then for some \( x \in \partial\Omega \) and \( \lambda \neq 0 \), \( f(x) = \lambda x \).

Proof: Using the Tietze extension theorem or Theorem 14.2.3, extend \( f \) to all of \( \mathbb{R}^n \). Also denote the extended function by \( \tilde{f} \). Suppose for all \( x \in \partial\Omega \), \( f(x) \neq \lambda x \) for all \( \lambda \in \mathbb{R} \). Then
\[
0 \notin t f(x) + (1-t) x, \quad (x, t) \in \partial\Omega \times [0,1]
\]
\[
0 \notin t f(x) - (1-t) x, \quad (x, t) \in \partial\Omega \times [0,1]
\]
Thus there exists a homotopy of \( f \) and \( I \) and a homotopy of \( f \) and \( -I \). Then by the homotopy invariance of degree,
\[
d(f, \Omega, 0) = d(I, \Omega, 0), \quad d(f, \Omega, 0) = d(-I, \Omega, 0).
\]
But this is impossible because \( d(I, \Omega, 0) = 1 \) but \( d(-I, \Omega, 0) = (-1)^n = -1 \). ■

### 21.6 The Product Formula

This section is on the product formula for the degree which is used to prove the Jordan separation theorem. To begin with here is a lemma which is similar to an earlier result except here there are \( r \) points.

**Lemma 21.6.1** Let \( y_1, \ldots, y_r \) be points not in \( f(\partial\Omega) \) and let \( \delta > 0 \). Then there exists \( \tilde{f} \in C^2(\overline{\Omega} ; \mathbb{R}^n) \) such that \( \|\tilde{f} - f\|_\infty < \delta \) and \( y_i \) is a regular value for \( \tilde{f} \) for each \( i \).
21.6. THE PRODUCT FORMULA

**Proof:** Let \( f_0 \in C^2(\Omega; \mathbb{R}^n) \), \( ||f_0 - f||_\infty < \frac{\delta}{2} \). Let \( \bar{y}_1 \) be a regular value for \( f_0 \) and \( |\bar{y}_1 - y_1| < \frac{\delta}{3r} \). Let \( f_1(x) \equiv f_0(x) + y_1 - \bar{y}_1 \). Thus \( y_1 \) is a regular value of \( f_1 \) because \( Df_1(x) = Df_0(x) \) and if \( f_1(x) = y_1 \), this is the same as having \( f_0(x) = \bar{y}_1 \) where \( \bar{y}_1 \) is a regular value of \( f_0 \). Then also

\[
||f - f_1||_\infty \leq ||f - f_0||_\infty + ||f_0 - f_1||_\infty \\
= ||f - f_0||_\infty + |y_1| \\
< \frac{\delta}{3r} + \frac{\delta}{2}.
\]

Suppose now there exists \( f_k \in C^2(\Omega; \mathbb{R}^n) \) with each of the \( y_i \) for \( i = 1, \cdots, k \) a regular value of \( f_k \) and

\[
||f - f_k||_\infty < \frac{\delta}{2} + \frac{k}{r} \left( \frac{\delta}{3} \right).
\]

Then letting \( S_k \) denote the singular values of \( f_k \), Sard’s theorem implies there exists \( \bar{y}_{k+1} \) such that

\[
|\bar{y}_{k+1} - y_{k+1}| < \frac{\delta}{3r}
\]

and

\[
\bar{y}_{k+1} \notin S_k \cup \cup_{i=1}^k (S_k + y_{k+1} - y_i).
\]

(21.6.6)

Let

\[
f_{k+1}(x) \equiv f_k(x) + y_{k+1} - \bar{y}_{k+1}.
\]

(21.6.7)

If \( f_{k+1}(x) = y_i \) for some \( i \leq k \), then

\[
f_k(x) + y_{k+1} - y_i = \bar{y}_{k+1}
\]

and so \( f_k(x) \) is a regular value for \( f_k \) since by \( 21.6.6 \), \( \bar{y}_{k+1} \notin S_k + y_{k+1} - y_i \) and so \( f_k(x) \notin S_k \). Therefore, for \( i \leq k \), \( y_i \) is a regular value of \( f_{k+1} \) since by \( 21.6.7 \), \( Df_{k+1} = Df_k \). Now suppose \( f_{k+1}(x) = y_{k+1} \). Then

\[
y_{k+1} = f_k(x) + y_{k+1} - \bar{y}_{k+1}
\]

so \( f_k(x) = \bar{y}_{k+1} \) implying that \( f_k(x) = \bar{y}_{k+1} \notin S_k \). Hence \( \det Df_{k+1}(x) = \det Df_k(x) \neq 0 \). Thus \( y_{k+1} \) is also a regular value of \( f_{k+1} \). Also,

\[
||f_{k+1} - f|| \leq ||f_{k+1} - f_k|| + ||f_k - f|| \\
\leq \frac{\delta}{3r} + \frac{\delta}{2} + \frac{k}{r} \left( \frac{\delta}{3} \right) = \frac{\delta}{2} + \frac{k+1}{r} \left( \frac{\delta}{3} \right).
\]

Let \( \bar{f} \equiv f_r \). Then

\[
||f - \bar{f}||_\infty < \frac{\delta}{2} + \left( \frac{\delta}{3} \right) < \delta
\]

and each of the \( y_i \) is a regular value of \( \bar{f} \).
**Definition 21.6.2** Let the connected components of $\mathbb{R}^n \setminus f(\partial \Omega)$ be denoted by $K_i$. From the properties of the degree listed in Theorem 21.3.7, $d(f, \Omega, \cdot)$ is constant on each of these components. Denote by $d(f, \Omega, K_i)$ the constant value on the component, $K_i$.

The product formula considers the situation depicted in the following diagram in which $y \notin g(f(\partial \Omega))$ and the $K_i$ are the connected components of $\mathbb{R}^n \setminus f(\partial \Omega)$.

$$
\Omega \xrightarrow{f} K_1 \xrightarrow{g} \mathbb{R}^n
$$

The following diagram may be helpful in remembering what it says.

$$
\begin{array}{c}
K_3 \\
\Omega \xrightarrow{f} K_1 \xrightarrow{g} \bullet y \\
K_2
\end{array}
$$

**Lemma 21.6.3** Let $f \in C(\overline{\Omega}; \mathbb{R}^n)$, $g \in C^2(\mathbb{R}^n, \mathbb{R}^n)$, and $y \notin g(f(\partial \Omega))$. Suppose also that $y$ is a regular value of $g$. Then the following product formula holds where $K_i$ are the bounded components of $\mathbb{R}^n \setminus f(\partial \Omega)$.

$$
d(g \circ f, \Omega, y) = \sum_{i=1}^{\infty} d(f, \Omega, K_i) d(g, K_i, y) .
$$

All but finitely many terms in the sum are zero.

**Proof:** First note that if $K_i$ is unbounded, $d(f, \Omega, K_i) = 0$ because there exists a point, $z \in K_i$ such that $f^{-1}(z) = \emptyset$ due to the fact that $f(\overline{\Omega})$ is compact and is consequently bounded. Thus it makes no difference in the above formula whether the $K_i$ are arbitrary components or only bounded components. Let $\{x^i_j\}_{j=1}^{m_i}$ denote the points of $g^{-1}(y)$ which are contained in $K_i$, the $i^{th}$ bounded component of $\mathbb{R}^n \setminus f(\partial \Omega)$. Then $m_i < \infty$ because if not, there would exist a limit point $x$ for this sequence. Then $g(x) = y$ and so $x \notin f(\partial \Omega)$. Thus $\det(Dg(x)) \neq 0$ and so by the inverse function theorem, $g$ would be one to one on an open ball containing $x$ which contradicts having $x$ a limit point.

Note also that $g^{-1}(y) \cap f(\overline{\Omega})$ is a compact set covered by the components of $\mathbb{R}^n \setminus f(\partial \Omega)$ because by assumption, $g^{-1}(y) \cap f(\partial \Omega) = \emptyset$. It follows $g^{-1}(y) \cap f(\overline{\Omega})$ is covered by finitely many of these components. It is not in $f(\partial \Omega)$. 

21.6. THE PRODUCT FORMULA

The only terms in the above sum which are nonzero are those corresponding to \( K_i \) having nonempty intersection with \( g^{-1}(y) \cap f(\Omega) \). The other components contribute 0 to the above sum because if \( K_i \cap g^{-1}(y) = \emptyset \), it follows from Theorem 21.3.7 that \( d(g, K_i, y) = 0 \). If \( K_i \) does not intersect \( f(\Omega) \), then \( d(f, \Omega, K_i) = 0 \). Therefore, the above sum is actually a finite sum since \( g^{-1}(y) \cap f(\Omega) \), being a compact set, is covered by finitely many of the \( K_i \). Thus there are no convergence problems.

Let \( d(f, \Omega, K_i) = d(f, \Omega, u_{ij}^i) \) where the \( \{u_{ij}^i\}_{j=1}^{m_i} \) are the points in \( g^{-1}(y) \cap K_i \). By Lemma 21.6.1, there exists \( \tilde{f} \) such that \( \|\tilde{f} - f\|_\infty \) is very small and each of the \( u_{ij}^i \) are regular values for \( \tilde{f} \). If \( \|\tilde{f} - f\|_\infty \) is small enough, then \( (f + t(\tilde{f} - f)) \) \((\partial \Omega)\) does not contain any of the \( u_{ij}^i \). This is so because by the definition of \( u_{ij}^i \) they are in some \( K_i \) and these are connected components of \( \mathbb{R}^n \setminus f(\partial \Omega) \). Thus

\[
\begin{align*}
\d (f, \Omega, K_i) &= d(f, \Omega, u_{ij}^i) = d(\tilde{f}, \Omega, u_{ij}^i)
\end{align*}
\]

by the homotopy invariance of the degree, this for each \( j = 1, 2, \ldots, m_i \). Also if \( \|\tilde{f} - f\|_\infty \) is small enough, one can have \( (g \circ f + t (g \circ \tilde{f} - g \circ f)) \) \((\partial \Omega)\) does not contain \( y \) for all \( t \in [0, 1] \). Hence by homotopy invariance again,

\[
\begin{align*}
\d (g \circ f, \Omega, y) &= d(g \circ \tilde{f}, \Omega, y).
\end{align*}
\] (21.6.8)

Now \( \tilde{f}^{-1}(u_{ij}^i) \) is a finite set because \( \tilde{f}^{-1}(u_{ij}^i) \subseteq \Omega \), a bounded open set and \( u_{ij}^i \) is a regular value. It follows from 21.6.8

\[
\begin{align*}
\d (g \circ f, \Omega, y) &= d(g \circ \tilde{f}, \Omega, y)
\end{align*}
\]

= \( \sum_{i=1}^{m_i} \sum_{j=1}^{m_i} \sum_{z \in \tilde{f}^{-1}(u_{ij}^i)} \sgn \det Dg \left( \frac{u_{ij}^i}{\tilde{f}(z)} \right) \sgn \det D\tilde{f}(z) \)

= \( \sum_{i=1}^{m_i} \sum_{j=1}^{m_i} \sgn \det Dg(u_{ij}^i) d(\tilde{f}, \Omega, x_{ij}^i) \)

= \( \sum_{i=1}^{\infty} d(g, K_i, y) d(\tilde{f}, \Omega, x_{ij}^i) \)

= \( \sum_{i=1}^{\infty} d(g, K_i, y) d(f, \Omega, K_i) \). \( \blacksquare \)

With this lemma, the following is the product formula.
Let \( f \) from \( \Omega \) to \( \mathbb{R}^n \), \( \mathbb{R}^n \setminus f(\partial \Omega) \) be the bounded components of \( \mathbb{R}^n \setminus f(\partial \Omega) \) for \( f \in C(\overline{\Omega}; \mathbb{R}^n) \), let \( g \in C(\mathbb{R}^n, \mathbb{R}^n) \), and suppose that \( y \not\in g(f(\partial \Omega)) \). Then
\[
d(g \circ f, \Omega, y) = \sum_{i=1}^{\infty} d(g, K_i, y) d(f, \Omega, K_i).
\] (21.6.9)

All but finitely many terms in the sum are zero.

**Proof:** Let \( \sup \{|\tilde{g}(z) - g(z)| : z \in f(\overline{\Omega})\} \) be sufficiently small that
\[
y \notin (g \circ f + t (\tilde{g} \circ f - g \circ f))(\partial \Omega), \quad t \in [0, 1]
\]
\( \tilde{g} \) being \( C^2(\mathbb{R}^n, \mathbb{R}^n) \) with \( y \) a regular value of \( \tilde{g} \). It follows that
\[
d(g \circ f, \Omega, y) = d(\tilde{g} \circ f, \Omega, y).
\] (21.6.10)

Now also, the \( K_i \) are the open components of \( \mathbb{R}^n \setminus f(\partial \Omega) \) and so \( \partial K_i \subseteq f(\partial \Omega) \) (if \( x \in \partial K_i \), then if \( x \not\in f(\partial \Omega) \), it would be in a ball contained in one of the \( K_j \) and so could not be in \( \partial K_j \)) and so if \( z \in \partial K_i \), then \( g(z) \in g(f(\partial \Omega)) \). Consequently, for \( t \in [0, 1] \),
\[
y \notin (g + t (\tilde{g} - g))(\partial K_i)
\]
\( y \) is not in the larger set \( (g \circ f + t (\tilde{g} \circ f - g \circ f))(\partial \Omega) \) which shows that, by homotopy invariance,
\[
d(g, K_i, y) = d(\tilde{g}, K_i, y).
\] (21.6.11)

Therefore, by Lemma 21.6.3,
\[
d(g \circ f, \Omega, y) = d(\tilde{g} \circ f, \Omega, y) = \sum_{i=1}^{\infty} d(\tilde{g}, K_i, y) d(f, \Omega, K_i)
\]
\[
= \sum_{i=1}^{\infty} d(g, K_i, y) d(f, \Omega, K_i)
\]
and the sum has only finitely many non zero terms. \( \blacksquare \)

Note there are no convergence problems because these sums are actually finite sums because, as in the previous lemma, \( g^{-1}(y) \cap f(\overline{\Omega}) \) is a compact set covered by the components of \( \mathbb{R}^n \setminus f(\partial \Omega) \) and so it is covered by finitely many of these components. For the other components, \( d(f, \Omega, K_i) = 0 \) or else \( d(g, K_i, y) = 0 \).

The following theorem is the Jordan separation theorem, a major result. A homeomorphism is a function which is one to one onto and continuous having continuous inverse. Before the theorem, here is a helpful lemma.

**Lemma 21.6.5** Let \( \Omega \) be a bounded open set in \( \mathbb{R}^n \), \( f \in C(\overline{\Omega}; \mathbb{R}^n) \), and suppose \( \{\Omega_i\}_{i=1}^{\infty} \) are disjoint open sets contained in \( \Omega \) such that
\[
y \notin f(\overline{\Omega} \setminus \bigcup_{i=1}^{\infty} \Omega_i)
\]
21.6. \textsc{The Product Formula} \hspace{1cm} 755

Then

$$d(f, \Omega, y) = \sum_{j=1}^{\infty} d(f, \Omega_j, y)$$

where the sum has all but finitely many terms equal to 0.

\textbf{Proof:} By assumption, the compact set $f^{-1}(y) \equiv \{x \in \Omega : f(x) = y\}$ has empty intersection with

$$\bigcap_{j=1}^{\infty} \Omega_j$$

and so this compact set is covered by finitely many of the $\Omega_j$, say $\{\Omega_1, \cdots, \Omega_{n-1}\}$ and

$$y \notin f\left(\bigcup_{j=n}^{\infty} \Omega_j\right).$$

By Theorem 21.3.7 and letting $O = \bigcup_{j=n}^{\infty} \Omega_j$,

$$d(f, \Omega, y) = \sum_{j=1}^{n-1} d(f, \Omega_j, y) + d(f, O, y) = \sum_{j=1}^{\infty} d(f, \Omega_j, y)$$

because $d(f, O, y) = 0$ as is $d(f, \Omega_j, y)$ for every $j \geq n$. 

\textbf{Lemma 21.6.6} Define $\partial U$ to be those points $x$ with the property that for every $r > 0$, $B(x, r)$ contains points of $U$ and points of $U^C$. Then for $U$ an open set,

$$\partial U = \overline{U} \setminus U$$

Let $C$ be a closed subset of $\mathbb{R}^n$ and let $K$ denote the set of components of $\mathbb{R}^n \setminus C$. Then if $K$ is one of these components, it is open and

$$\partial K \subseteq C$$

\textbf{Proof:} Let $x \in \overline{U} \setminus U$. If $B(x, r)$ contains no points of $U$, then $x \notin \overline{U}$. If $B(x, r)$ contains no points of $U^C$, then $x \notin \overline{U} \setminus U$. Therefore, $\overline{U} \setminus U \subseteq \partial U$.

Now let $x \in \partial U$. If $x \in U$, then since $U$ is open there is a ball containing $x$ which is contained in $U$ contrary to $x \in \partial U$. Therefore, $x \notin U$. If $x$ is not a limit point of $U$, then some ball containing $x$ contains no points of $U$ contrary to $x \in \partial U$. Therefore, $x \in \overline{U} \setminus U$ which shows the two sets are equal.

Why is $K$ open for $K$ a component of $\mathbb{R}^n \setminus C$? This is obvious because in $\mathbb{R}^n$ an open ball is connected. Thus if $k \in K$, let $B(k, r) \subseteq C^C$, it follows $K \cup B(k, r)$ is connected and contained in $C^C$. Thus $K \cup B(k, r)$ is connected, contained in $C^C$, and therefore is contained in $K$ because $K$ is maximal with respect to being connected and contained in $C^C$.

Now for $K$ a component of $\mathbb{R}^n \setminus C$, why is $\partial K \subseteq C$? Let $x \in \partial K$. If $x \notin C$, then $x \in K_1$, some component of $\mathbb{R}^n \setminus C$. If $K_1 \neq K$ then $x$ cannot be a limit point of $K$ and so it cannot be in $\partial K$. Therefore, $K = K_1$ but this also is a contradiction because if $x \in \partial K$ then $x \notin K$.

I will give a shorter version of the proof and a longer version. First is the shorter version which leaves out a few details which may or may not be clear. Sometimes, it seems to me that when you put in too many details, one loses the forest by stumbling around hitting trees. It may still have too many details.
Theorem 21.6.7 (Jordan separation theorem) Let \( f \) be a homeomorphism of \( C \) and \( f(C) \) where \( C \) is a compact set in \( \mathbb{R}^n \). Then \( \mathbb{R}^n \setminus C \) and \( \mathbb{R}^n \setminus f(C) \) have the same number of connected components.

**Proof:** Denote by \( K \) the bounded components of \( \mathbb{R}^n \setminus C \) and denote by \( L \), the bounded components of \( \mathbb{R}^n \setminus f(C) \). Also, using the Tietze extension theorem, there exists \( \bar{f} \) an extension of \( f \) to all of \( \mathbb{R}^n \) which maps into a bounded set and let \( \bar{f}^{-1} \) be an extension of \( f^{-1} \) to all of \( \mathbb{R}^n \) which also maps into a bounded set. Pick \( K \subseteq C \) and take \( y \in K \). Then \( \partial K \subseteq C \) and so

\[ y \notin \bar{f}^{-1}(\bar{f}(\partial K)) \]

Since \( \bar{f}^{-1} \circ \bar{f} \) equals the identity \( I \) on \( \partial K \), it follows from the properties of the degree that

\[ 1 = d(I, K, y) = d(\bar{f}^{-1} \circ \bar{f}, K, y) . \]

Recall that if two functions agree on the boundary, then they have the same degree. Let \( H \) denote the set of bounded components of \( \mathbb{R}^n \setminus f(C) \). These will be as large as those in \( L \) and if a set in \( L \) intersects one of these larger \( H \) then \( H \) contains the component in \( L \). By the product formula,

\[ 1 = d(\bar{f}^{-1} \circ \bar{f}, K, y) = \sum_{H \in \mathcal{H}} d(\bar{f}, K, H) \, d(\bar{f}^{-1}, H, y) , \quad (21.6.12) \]

the sum being a finite sum from the product formula. That is, there are finitely many \( H \) involved in the sum, the other terms being zero.

What about those sets of \( \mathcal{H} \) which contain no set of \( \mathcal{L} \)? These sets also have empty intersection with all sets of \( \mathcal{L} \). Therefore, for \( H \) one of these, \( H \subseteq f(C) \). Therefore,

\[ d(\bar{f}^{-1}, H, y) = d(f^{-1}, H, y) = 0 \]

because \( y \in K \) a component of \( \mathbb{R}^n \setminus C \), but for \( u \in H \subseteq f(C) \), \( f^{-1}(u) \subseteq C \) so \( f^{-1}(u) \neq y \) implying that \( d(f^{-1}, H, y) = 0 \). Thus in \( \mathbb{R}^n \setminus C \) all such terms are zero. Then letting \( \mathcal{H}_1 \) be those sets of \( \mathcal{H} \) which contain (intersect) some sets of \( \mathcal{L} \), the above sum reduces to

\[ \sum_{H \in \mathcal{H}_1} d(\bar{f}, K, H) \, d(\bar{f}^{-1}, H, y) = \sum_{H \in \mathcal{H}_1} d(\bar{f}, K, H) \sum_{L \in \mathcal{L}_H} d(\bar{f}^{-1}, L, y) = \sum_{H \in \mathcal{H}_1} \sum_{L \in \mathcal{L}_H} d(\bar{f}, K, H) \, d(\bar{f}^{-1}, L, y) \]

where \( \mathcal{L}_H \) are those sets of \( \mathcal{L} \) contained in \( H \). If \( \mathcal{L}_H = \emptyset \), the above shows that the second sum is 0 with the convention that \( \sum_{\emptyset} = 0 \). Now \( d(\bar{f}, K, H) = d(\bar{f}, K, L) \) where \( L \in \mathcal{L}_H \). Therefore,

\[ \sum_{H \in \mathcal{H}_1} \sum_{L \in \mathcal{L}_H} d(\bar{f}, K, H) \, d(\bar{f}^{-1}, L, y) = \sum_{H \in \mathcal{H}_1} \sum_{L \in \mathcal{L}_H} d(\bar{f}, K, L) \, d(\bar{f}^{-1}, L, y) \]
As noted above, there are finitely many \( H \in \mathcal{H} \) which are involved. \( \mathbb{R}^n \setminus f(C) \subseteq \mathbb{R}^n \setminus f(\partial K) \) and so every \( L \) must be contained in some \( H \in \mathcal{H}_1 \). It follows that the above reduces to

\[
\sum_{L \in \mathcal{L}} d(\overline{f}, K, L) d\left( f^{-1}, L, y \right)
\]

Thus from 21.6.12,

\[
1 = \sum_{L \in \mathcal{L}} d(\overline{f}, K, L) d\left( f^{-1}, L, y \right) = \sum_{L \in \mathcal{L}} d(\overline{f}, K, L) d\left( f^{-1}, L, K \right)
\]

(21.6.13)

Let \(|\mathcal{K}|\) denote the number of components in \( \mathcal{K} \) and similarly, \(|\mathcal{L}|\) denotes the number of components in \( \mathcal{L} \). Thus

\[
|\mathcal{K}| = \sum_{K \in \mathcal{K}} 1 = \sum_{K \in \mathcal{K}} \sum_{L \in \mathcal{L}} d(\overline{f}, K, L) d\left( f^{-1}, L, K \right)
\]

Similarly,

\[
|\mathcal{L}| = \sum_{L \in \mathcal{L}} 1 = \sum_{L \in \mathcal{L}} \sum_{K \in \mathcal{K}} d(\overline{f}, K, L) d\left( f^{-1}, L, K \right)
\]

If \(|\mathcal{K}| < \infty\), then

\[
\sum_{K \in \mathcal{K}} \sum_{L \in \mathcal{L}} d(\overline{f}, K, L) d\left( f^{-1}, L, K \right) < \infty.
\]

The summation which equals 1 is a finite sum and so is the outside sum. Hence we can switch the order of summation and get

\[
|\mathcal{K}| = \sum_{L \in \mathcal{L}} \sum_{K \in \mathcal{K}} d(\overline{f}, K, L) d\left( f^{-1}, L, K \right) = |\mathcal{L}|
\]

A similar argument applies if \(|\mathcal{L}| < \infty\). Thus if one of these numbers is finite, so is the other and they are equal. It follows that \(|\mathcal{L}| = |\mathcal{K}|\).

Now is the same proof with more details included.

**Theorem 21.6.8 (Jordan separation theorem)** Let \( f \) be a homeomorphism of \( C \) and \( f(C) \) where \( C \) is a compact set in \( \mathbb{R}^n \). Then \( \mathbb{R}^n \setminus C \) and \( \mathbb{R}^n \setminus f(C) \) have the same number of connected components.

**Proof:** Denote by \( \mathcal{K} \) the bounded components of \( \mathbb{R}^n \setminus C \) and denote by \( \mathcal{L} \), the bounded components of \( \mathbb{R}^n \setminus f(C) \). Also, using the Tietze extension theorem, there exists \( \overline{f} \) an extension of \( f \) to all of \( \mathbb{R}^n \) which maps into a bounded set and let \( \overline{f}^{-1} \) be an extension of \( f^{-1} \) to all of \( \mathbb{R}^n \) which also maps into a bounded set. Pick \( K \in \mathcal{K} \) and take \( y \in K \). Then

\[
y \notin \overline{f}^{-1}(\overline{f}(\partial K))
\]

because by Lemma 21.6.6, \( \partial K \subseteq C \) and on \( C, \overline{f} = f \). Thus the right side is of the form

\[
\overline{f}^{-1}\left( \frac{f(C)}{\overline{f}(\partial K)} \right) = f^{-1}(f(\partial K)) \subseteq C
\]
and \( y \notin C \). Since \( \overline{f^{-1}} \circ f \) equals the identity \( I \) on \( \partial K \), it follows from the properties of the degree that

\[
1 = d(I, K, y) = d\left( \overline{f^{-1}} \circ f, K, y \right).
\]

Recall that if two functions agree on the boundary, then they have the same degree. Let \( \mathcal{H} \) denote the set of bounded components of \( \mathbb{R}^n \setminus f(\partial K) \). (These will be as large as those in \( \mathcal{L} \) ) By the product formula,

\[
1 = d\left( \overline{f^{-1}} \circ f, K, y \right) = \sum_{H \in \mathcal{H}} d(H, K, H) d\left( \overline{f^{-1}}, H, y \right), \tag{21.6.14}
\]

the sum being a finite sum from the product formula. It might help to consult the following diagram.

Now letting \( x \in L \in \mathcal{L} \), if \( S \) is a connected set containing \( x \) and contained in \( \mathbb{R}^n \setminus f(C) \), then it follows \( S \) is contained in \( \mathbb{R}^n \setminus f(\partial K) \) because \( \partial K \subseteq C \). Therefore, every set of \( \mathcal{L} \) is contained in some set of \( \mathcal{H} \). Furthermore, if any \( L \in \mathcal{L} \) has nonempty intersection with \( H \in \mathcal{H} \) then it must be contained in \( H \). This is because

\[
L = (L \cap H) \cup (L \cap \partial H) \cup \left( L \cap \overline{H}^C \right).
\]

Now by Lemma 21.6.7,

\[
L \cap \partial H \subseteq L \cap f(\partial K) \subseteq L \cap f(C) = \emptyset.
\]

Since \( L \) is connected, \( L \cap \overline{H}^C = \emptyset \). Letting \( \mathcal{L}_H \) denote those sets of \( \mathcal{L} \) which are contained in \( H \) equivalently having nonempty intersection with \( H \), if \( p \in H \cup \mathcal{L}_H = H \setminus \cup \mathcal{L} \), then \( p \in H \cap f(C) \) and so

\[
H = (\cup \mathcal{L}_H) \cup (H \cap f(C)) \tag{21.6.15}
\]

Claim 1:

\[
\overline{H} \setminus \cup \mathcal{L}_H \subseteq f(C).
\]

**Proof of the claim:** Suppose \( p \in \overline{H} \setminus \cup \mathcal{L}_H \) but \( p \notin f(C) \). Then \( p \in L \in \mathcal{L} \). It must be the case that \( L \) has nonempty intersection with \( H \) since otherwise \( p \) could not be in \( \overline{H} \). However, as shown above, this requires \( L \subseteq H \) and now by \( 21.6.7 \) and \( p \notin \cup \mathcal{L}_H \), it follows \( p \in f(C) \) after all. This proves the claim.

Claim 2: \( y \notin \overline{f^{-1}}(\overline{H} \setminus \cup \mathcal{L}_H) \). Recall \( y \in K \in \mathcal{K} \) the bounded components of \( \mathbb{R}^n \setminus C \).
21.6. **THE PRODUCT FORMULA**

**Proof of the claim:** If not, then \( \overline{f^{-1}}(z) = y \) where \( z \in \overline{H} \cup \mathcal{L}_H \subseteq f(C) \) and so \( z = f(w) \) for some \( w \in C \) and so \( y = f^{-1}(f(w)) = w \in C \) contrary to \( y \in K \), a component of \( \mathbb{R}^n \setminus C \).

Now every set of \( \mathcal{L} \) is contained in some set of \( \mathcal{H} \). What about those sets of \( \mathcal{H} \) which contain no set of \( \mathcal{L} \) so that \( \mathcal{L}_H = \emptyset \)? From 21.6.15 it follows \( H \subseteq f(C) \). Therefore,

\[
d\left(\overline{f^{-1}}, H, y\right) = d\left(f^{-1}, H, y\right) = 0
\]

because \( y \in K \) a component of \( \mathbb{R}^n \setminus C \). Therefore, letting \( \mathcal{H}_1 \) denote those sets of \( \mathcal{H} \) which contain some set of \( \mathcal{L} \), 21.6.15 is of the form

\[
1 = \sum_{H \in \mathcal{H}_1} d\left(\overline{f}, H, y\right) d\left(\overline{f^{-1}}, H, y\right).
\]

and it is still a finite sum because the terms in the sum are 0 for all but finitely many \( H \in \mathcal{H}_1 \). I want to expand \( d\left(\overline{f^{-1}}, H, y\right) \) as a sum of the form

\[
\sum_{L \in \mathcal{L}_H} d\left(\overline{f^{-1}}, L, y\right)
\]

using Lemma 21.6.5. Therefore, I must verify

\[
y \notin \overline{f^{-1}}(\overline{H} \cup \mathcal{L}_H)
\]

but this is just **Claim 2**. By Lemma 21.6.5, I can write the above sum in place of \( d\left(\overline{f^{-1}}, H, y\right) \). Therefore,

\[
1 = \sum_{H \in \mathcal{H}_1} d\left(\overline{f}, K, H\right) d\left(\overline{f^{-1}}, H, y\right) = \sum_{H \in \mathcal{H}_1} d\left(\overline{f}, K, H\right) \sum_{L \in \mathcal{L}_H} d\left(\overline{f^{-1}}, L, y\right)
\]

where there are only finitely many \( H \) which give a nonzero term and for each of these, there are only finitely many \( L \) in \( \mathcal{L}_H \) which yield \( d\left(\overline{f^{-1}}, L, y\right) \neq 0 \). Now the above equals

\[
= \sum_{H \in \mathcal{H}_1} \sum_{L \in \mathcal{L}_H} d\left(\overline{f}, K, H\right) d\left(\overline{f^{-1}}, L, y\right) . \tag{21.6.16}
\]

By definition,

\[
d\left(\overline{f}, K, H\right) = d\left(\overline{f}, K, x\right)
\]

where \( x \) is any point of \( H \). In particular \( d\left(\overline{f}, K, H\right) = d\left(\overline{f}, K, L\right) \) for any \( L \in \mathcal{L}_H \). Therefore, the above reduces to

\[
= \sum_{L \in \mathcal{L}} d\left(\overline{f}, K, L\right) d\left(\overline{f^{-1}}, L, y\right). \tag{21.6.17}
\]
Here is why. There are finitely many $H \in \mathcal{H}_1$ for which the term in the double sum of 21.6.16 is not zero, say $H_1, \ldots, H_m$. Then the above sum in 21.6.17 equals

$$\sum_{k=1}^{m} \sum_{L \in \mathcal{L}_{H_k}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, y \right) + \sum_{L \in \mathcal{L} \setminus \bigcup_{k=1}^{m} \mathcal{L}_{H_k}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, y \right)$$

The second sum equals 0 because those $L$ are contained in some $H \in \mathcal{H}$ for which

$$0 = d(\bar{f}, K, H) d \left( \bar{f}^{-1}, H, y \right) = d(\bar{f}, K, H) \sum_{L \in \mathcal{L}_H} d \left( \bar{f}^{-1}, L, y \right)$$

$$= \sum_{L \in \mathcal{L}_H} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, y \right).$$

Therefore, the sum in 21.6.17 reduces to

$$\sum_{k=1}^{m} \sum_{L \in \mathcal{L}_{H_k}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, y \right)$$

which is the same as the sum in 21.6.16. Therefore, 21.6.17 does follow. Then the sum in 21.6.17 reduces to

$$= \sum_{L \in \mathcal{L}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right)$$

and all but finitely many terms in the sum are 0.

By the same argument,

$$1 = \sum_{K \in \mathcal{K}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right)$$

and all but finitely many terms in the sum are 0. Letting $|\mathcal{K}|$ denote the number of elements in $\mathcal{K}$, similar for $\mathcal{L}$,

$$|\mathcal{K}| = \sum_{K \in \mathcal{K}} 1 = \sum_{K \in \mathcal{K}} \left( \sum_{L \in \mathcal{L}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right) \right)$$

$$|\mathcal{L}| = \sum_{L \in \mathcal{L}} 1 = \sum_{L \in \mathcal{L}} \left( \sum_{K \in \mathcal{K}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right) \right)$$

Suppose $|\mathcal{K}| < \infty$. Then you can switch the order of summation in the double sum for $|\mathcal{K}|$ and so

$$|\mathcal{K}| = \sum_{K \in \mathcal{K}} \left( \sum_{L \in \mathcal{L}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right) \right)$$

$$= \sum_{L \in \mathcal{L}} \left( \sum_{K \in \mathcal{K}} d(\bar{f}, K, L) d \left( \bar{f}^{-1}, L, K \right) \right) = |\mathcal{L}|$$
21.7. A FUNCTION WITH VALUES IN SMALLER DIMENSIONS

It follows that if either \(|K|\) or \(|L|\) is finite, then they are equal. Thus if one is infinite, so is the other. This proves the theorem because if \(n > 1\) there is exactly one unbounded component to both \(\mathbb{R}^n \setminus C\) and \(\mathbb{R}^n \setminus f(C)\) and if \(n = 1\) there are exactly two unbounded components. ■

As an application, here is a very interesting little result. It has to do with \(d(f,\Omega, f(x))\) in the case where \(f\) is one to one and \(\Omega\) is connected. You might imagine this should equal 1 or \(-1\) based on one dimensional analogies. In fact this is the case and it is a nice application of the Jordan separation theorem and the product formula.

**Proposition 21.6.9** Let \(\Omega\) be an open connected bounded set in \(\mathbb{R}^n, n \geq 1\) such that \(\mathbb{R}^n \setminus \partial \Omega\) consists of two, three if \(n = 1\), connected components. Let \(f \in C(\Omega; \mathbb{R}^n)\) be continuous and one to one. Then \(f(\Omega)\) is the bounded component of \(\mathbb{R}^n \setminus f(\partial \Omega)\) and for \(y \in f(\Omega)\), \(d(f, \Omega, y)\) either equals 1 or \(-1\).

**Proof:** First suppose \(n \geq 2\). By the Jordan separation theorem, \(\mathbb{R}^n \setminus f(\partial \Omega)\) consists of two components, a bounded component \(B\) and an unbounded component \(U\). Using the Tietze extension theorem, there exists \(g\) defined on \(\mathbb{R}^n\) such that \(g = f^{-1}\) on \(f(\Omega)\). Thus on \(\partial \Omega, g \circ f = id\). It follows from this and the product formula that

\[
1 = d(id, \Omega, g(y)) = d(g \circ f, \Omega, g(y)) = d(g, B, g(y)) d(f, \Omega, B) + d(f, \Omega, U) d(g, U, g(y)) = d(g, B, g(y)) d(f, \Omega, B)
\]

The reduction happens because \(d(f, \Omega, U) = 0\) as explained above. Since \(U\) is unbounded, there are points in \(U\) which cannot be in the compact set \(f(\Omega)\). For such, the degree is 0 but the degree is constant on \(U\), one of the components of \(f(\partial \Omega)\). Therefore, \(d(f, \Omega, B) \neq 0\) and so for every \(z \in B\), it follows \(z \in f(\Omega)\). Thus \(B \subseteq f(\Omega)\). On the other hand, \(f(\Omega)\) cannot have points in both \(U\) and \(B\) because it is a connected set. Therefore \(f(\Omega) \subseteq B\) and this shows \(B = f(\Omega)\). Thus \(d(f, \Omega, B) = d(f, \Omega, y)\) for each \(y \in B\) and the above formula shows this equals either 1 or \(-1\) because the degree is an integer. In the case where \(n = 1\), the argument is similar but here you have 3 components in \(\mathbb{R}^1 \setminus f(\partial \Omega)\) so there are more terms in the above sum although two of them give 0. ■

21.7 A Function With Values In Smaller Dimensions

Recall that we have the degree defined \(d(f, \Omega, y)\) for continuous functions on \(\bar{\Omega}\) and \(y \notin f(\partial \Omega)\). It had properties as follows.

1. \(d(id, \Omega, y) = 1\) if \(y \in \Omega\).

2. If \(\Omega_i \subseteq \Omega, \Omega_i\) open, and \(\Omega_1 \cap \Omega_2 = \emptyset\) and if \(y \notin f(\overline{\Omega} \setminus (\Omega_1 \cup \Omega_2))\), then \(d(f, \Omega_1, y) + d(f, \Omega_2, y) = d(f, \Omega, y)\).
3. If \( y \notin f(\overline{\Omega} \setminus \Omega_1) \) and \( \Omega_1 \) is an open subset of \( \Omega \), then
\[
d(f, \Omega, y) = d(f, \Omega_1, y).
\]

4. For \( y \in \mathbb{R}^n \setminus f(\partial \Omega) \), if \( d(f, \Omega, y) \neq 0 \) then \( f^{-1}(y) \cap \Omega \neq \emptyset \).

5. If \( t \to y(t) \) is continuous \( h : \Omega \times [0,1] \to \mathbb{R}^n \) is continuous and if \( y(t) \notin h(\partial \Omega, t) \) for all \( t \), then \( t \to d(h(\cdot, t), \Omega, y(t)) \) is constant.

6. \( d(\cdot, \Omega, y) \) is defined and constant on
\[
\{ g \in C(\overline{\Omega}; \mathbb{R}^n) : ||g-f||_\infty < r \}
\]
where \( r = \text{dist}(y, f(\partial \Omega)) \).

7. \( d(f, \Omega, \cdot) \) is constant on every connected component of \( \mathbb{R}^n \setminus f(\partial \Omega) \).

8. \( d(g, \Omega, y) = d(f, \Omega, y) \) if \( g|_{\partial \Omega} = f|_{\partial \Omega} \).

**Theorem 21.7.1** Let \( \Omega \) be a bounded open set in \( \mathbb{R}^n \) and let \( f \in C(\overline{\Omega}; \mathbb{R}^m) \) where \( \mathbb{R}^m_n = \{ x \in \mathbb{R}^n : x_k = 0 \text{ for } k > m \} \). Thus, \( x \) concludes with a column of \( n-m \) zeros. Let \( y \in \mathbb{R}^m_n \setminus (id-f)(\partial \Omega) \). Then \( d(id-f, \Omega, y) = d(id-f|_{\Omega \cap \mathbb{R}^m_n}, \Omega \cap \mathbb{R}^m_n, y) \).

**Proof:** To save space, let \( g = id-f \). Then there is no loss of generality in assuming at the outset that \( y \) is a regular value for \( g \). Indeed, everything above was reduced to this case. Then for \( x \in g^{-1}(y) \) and letting \( x_m \) be the first \( m \) variables for \( x \),
\[
Dg(x) = \begin{pmatrix}
D_{x_m}g(x) & * \\
0 & I_{n-m}
\end{pmatrix}
\]

Then it follows that
\[
0 \neq \det(Dg(x)) = \det\left( \begin{pmatrix}
D_{x_m}g(x) & * \\
0 & I_{n-m}
\end{pmatrix} \right) = \det\left( \begin{pmatrix}
D_{x_m}g(x) & 0 \\
0 & I_{n-m}
\end{pmatrix} \right) = \det(D_{x_m}g(x))
\]

This last is just the determinant of the derivative of the function which results from restricting \( g \) to the first \( m \) variables. Now \( y \in \mathbb{R}^m_n \) and \( f \) also is given to have values in \( \mathbb{R}^m_n \) so if \( g(x) = y \), then you have \( x - f(x) = y \) which requires \( x \in \mathbb{R}^m_n \) also. Therefore, \( g^{-1}(y) \) consists of points in \( \mathbb{R}^m_n \) only. Thus, \( y \) is also a regular value of the function which results from restricting \( g \) to \( \mathbb{R}^m_n \cap \Omega \).

\[
d(id-f, \Omega, y) = d(g, \Omega, y)
\]

\[
= \sum_{x \in g^{-1}(y)} \text{sign}(\det(Dg(x)))
\]

\[
= \sum_{x \in g^{-1}(y)} \text{sign}(\det(D_{x_m}g(x))) \equiv d(id-f|_{\Omega \cap \mathbb{R}^m_n}, \Omega \cap \mathbb{R}^m_n, y) \quad \blacksquare
\]
Recall that for \( g \in C^2(\overline{\Omega}; \mathbb{R}^n) \),

\[
d (g, \Omega, y) \equiv \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon (g(x) - y) \det Dg(x) \, dx
\]

In fact, it can be shown that the degree is unique based on its Properties, 1,2,5 above. It involves reducing to linear maps and then some complicated arguments involving linear algebra. It is done in [35]. Here we will be a little less ambitious. The following lemma will be useful when extending the degree to finite dimensional normed linear spaces and from there to Banach spaces. It is motivated by the following diagram.

Let \( \theta^{-1} : \Omega \to \Omega \) and \( \theta \) be an isomorphism of \( \mathbb{R}^n \). That is, \( \theta \) is one to one onto and linear. Then

\[
d (\theta^{-1} \circ g \circ \theta, \theta^{-1} (\Omega), \theta^{-1} y) = d (g, \Omega, y)
\]

**Proof:** It suffices to consider \( g \in C^2(\overline{\Omega}; \mathbb{R}^n) \) for which \( y \) is a regular value because you can get such a \( \tilde{g} \) with \( \| \tilde{g} - g \|_\infty < \delta \) where

\[
B \left( y, 2\delta \right) \cap g(\partial \Omega) = \emptyset.
\]

Thus \( B \left( y, \delta \right) \cap \tilde{g}(\partial \Omega) = \emptyset \) and so \( d (g, \Omega, y) = d (\tilde{g}, \Omega, y) \). One can assume similarly that \( \| \tilde{g} - g \|_\infty \) is sufficiently small that

\[
d (\theta^{-1} g \circ \theta, \theta^{-1} (\Omega), \theta^{-1} y) = d (\theta^{-1} \tilde{g} \circ \theta, \theta^{-1} (\Omega), \theta^{-1} y)
\]

because both \( \theta \) and \( \theta^{-1} \) are continuous. Thus it suffices to consider at the outset \( g \in C^2(\overline{\Omega}; \mathbb{R}^n) \). Then from the definition of degree for \( C^2 \) maps,

\[
d (\theta^{-1} \circ g \circ \theta, \theta^{-1} (\Omega), \theta^{-1} y) = \lim_{\varepsilon \to 0} \int_{\theta^{-1} \Omega} \phi_\varepsilon \left( (\theta^{-1} \circ g \circ \theta)(z) - \theta^{-1} y \right) \det D (\theta^{-1} \circ g \circ \theta)(z) \, dz
\]

Now \( D (\theta^{-1} \circ g \circ \theta)(z) = \theta^{-1} D (g \circ \theta)(z) = \theta^{-1} D g (\theta(z)) \theta z \). Changing the variables \( x = \theta z, z = \theta^{-1} x \), this last integral equals

\[
\int_{\Omega} \phi_\varepsilon \left( (\theta^{-1} g \circ \theta)(\theta^{-1} (x)) - \theta^{-1} y \right) \det D g (x) \det \theta \left| \det \theta^{-1} \right|^2 \, dx = \int_{\Omega} \phi_\varepsilon \left( \theta^{-1} g (x) - \theta^{-1} y \right) \det \theta^{-1} \det D g (x) \, dx
\]

Recall that \( \phi_\varepsilon \) is a mollifier which is nonzero only in \( B (0, \varepsilon) \). Now

\[
ge^{-1} (y) = \{ x_1, \cdots, x_m \} = (\theta^{-1} g)^{-1} (\theta^{-1} y)
\]
and so \( g(x_i) = y \) and \( \theta^{-1}g(x_i) = \theta^{-1}y \). By the inverse function theorem, there exist disjoint open sets \( U_i \) with \( x_i \in U_i \), such that \( \theta^{-1}g \) is one to one on \( U_i \) with \( \det (D(\theta^{-1}g)(x_i)) = \det (\theta^{-1}) \det Dg(x) \) having constant sign on \( U_i \) and \( \theta^{-1}g(U_i) \) is an open set containing \( \theta^{-1}y \). Then let \( \varepsilon \) be small enough that \( B(\theta^{-1}y, \varepsilon) \subseteq \cap_{i=1}^m \theta^{-1}g(U_i) \) and let \( V_i \equiv (\theta^{-1}g)^{-1}(B(\theta^{-1}y, \varepsilon)) \cap U_i \). Thus for small \( \varepsilon \), the \( V_i \) are disjoint open sets in \( \Omega \) and

\[
\int_\Omega \phi(x) (\theta^{-1}g(x) - \theta^{-1}y) \det Dg(x) |\det \theta^{-1}| dx = \sum_{i=1}^m \int_{V_i} \phi(x) (\theta^{-1}(g(x) - y)) \det Dg(x) |\det \theta^{-1}| dx
\]

Now just let \( z = g(x) - y \) and change the variables.

\[
= \sum_{i=1}^m |\det \theta^{-1}| \int_{g(V_i) - y} \phi(x) (\theta^{-1}z) \det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)| dz
\]

By the chain rule, \( I = Dg(g^{-1}(y + z)) Dg^{-1}(y + z) \) and so

\[
\det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)| = \sgn (\det Dg(g^{-1}(y + z))).
\]

\[
\det Dg(g^{-1}(y + z)) |\det Dg^{-1}(y + z)| = \sgn (\det Dg(g^{-1}(y + z)))
\]

\[
= \sgn (\det Dg(x)) = \sgn (\det Dg(x_i)).
\]

and so it all reduces to

\[
\sum_{i=1}^m \sgn (\det Dg(x_i)) \int_{g(V_i) - y} \phi(x) (\theta^{-1}z) dz = \sum_{i=1}^m \sgn (\det Dg(x_i)) \int_{\theta B(0, \varepsilon)} |\det \theta^{-1}| \phi(x) (\theta^{-1}z) dz = \sum_{i=1}^m \sgn (\det Dg(x_i)) \int_{B(0, \varepsilon)} |\det \theta| \phi(x) (w) |\det \theta| dw = \sum_{i=1}^m \sgn (\det Dg(x_i)) = d(g, \Omega, y). \]

What about functions which have values in finite dimensional vector spaces?
21.7. A FUNCTION WITH VALUES IN SMALLER DIMENSIONS

**Theorem 21.7.3** Let \( \Omega \) be an open bounded set in \( V \) a real normed \( n \) dimensional vector space. Then there exists a topological degree \( d(f, \Omega, y) \) for \( f \in C(\Omega, V) \), \( y \notin f(\partial \Omega) \) which satisfies all the properties of the degree for functions having values in \( \mathbb{R}^n \) described above,

1. \( d(id, \Omega, y) = 1 \) if \( y \in \Omega \).

2. If \( \Omega_i \subseteq \Omega, \Omega_i \) open, and \( \Omega_1 \cap \Omega_2 = \emptyset \) and if \( y \notin f(\overline{\Omega \setminus (\Omega_1 \cup \Omega_2)}) \), then
   \[ d(f, \Omega_1, y) + d(f, \Omega_2, y) = d(f, \Omega, y). \]

3. If \( y \notin f(\overline{\Omega \setminus \Omega_1}) \) and \( \Omega_1 \) is an open subset of \( \Omega \), then
   \[ d(f, \Omega, y) = d(f, \Omega_1, y). \]

4. For \( y \in \mathbb{R}^n \setminus f(\partial \Omega) \), if \( d(f, \Omega, y) \neq 0 \) then \( f^{-1}(y) \cap \Omega \neq \emptyset \).

5. If \( t \to y(t) \) is continuous \( h : \Omega \times [0, 1] \to \mathbb{R}^n \) is continuous and if \( y(t) \notin h(\partial \Omega, t) \) for all \( t \), then \( t \to d(h(v, t), \Omega, y(t)) \) is constant.

6. \( d(\cdot, \Omega, y) \) is defined and constant on
   \[ \{ g \in C(\overline{\Omega}; \mathbb{R}^n) : \| g - f \|_{\infty} < r \} \]
   where \( r = \text{dist}(y, f(\partial \Omega)). \)

7. \( d(f, \Omega, \cdot) \) is constant on every connected component of \( \mathbb{R}^n \setminus f(\partial \Omega) \).

8. \( d(g, \Omega, y) = d(f, \Omega, y) \) if \( g|_{\partial \Omega} = f|_{\partial \Omega} \).

**Proof:** There is an isomorphism \( \theta : \mathbb{R}^n \to V \) which also preserves all topological properties. This follows from the properties of finite dimensional vector spaces. In fact, every algebraic isomorphism is automatically a homeomorphism preserving all topological properties. Then it is pretty easy to see what the degree should be.

\[ d(f, \Omega, y) = d(\theta^{-1} \circ f \circ \theta, \theta^{-1}(\Omega), \theta^{-1}y) \]

Then by standard material on finite dimensional vector spaces, the norm on \( V \) is equivalent to the norm defined by \( |v| = \| \theta^{-1}v \|_{\mathbb{R}^n} \). Hence all of those properties hold. By Lemma 21.8.2 this definition does not depend on the particular isomorphism used. If \( \theta \) is another one, then one would need to verify that

\[ d(\theta^{-1} \circ f \circ \theta, \theta^{-1}(\Omega), \theta^{-1}y) = d(\hat{\theta}^{-1} \circ f \circ \hat{\theta}, \hat{\theta}^{-1}(\Omega), \hat{\theta}^{-1}y) \]

However, you could use that lemma to conclude that

\[ d(\hat{\theta}^{-1} \circ f \circ \hat{\theta}, \hat{\theta}^{-1}(\Omega), \hat{\theta}^{-1}y) = d(\alpha^{-1} \circ \hat{\theta}^{-1} \circ f \circ \hat{\theta} \circ \alpha, \alpha^{-1} \hat{\theta}^{-1}(\Omega), \alpha^{-1} \hat{\theta}^{-1}y) \]

where \( \alpha \) is such that \( \hat{\theta} \circ \alpha = \theta \). Then this verifies the appropriate equation. ■

Next one considers what happens when the function \( I - f \) has values in a smaller dimensional subspace.
Theorem 21.7.4 Let $\Omega$ be a bounded open set in $V$ an $n$ dimensional normed linear space and let $f \in C(\overline{\Omega}; V_m)$ where $V_m$ is an $m$ dimensional subspace. Let $y \in V_m \setminus (I - f)(\partial \Omega)$. Then $d(I - f, \Omega, y) = d((I - f)|_{\overline{\Omega \setminus V_m}}, \Omega \cap V_m, y)$.

Proof: Letting $\{v_1, \cdots , v_m\}$ be a basis for $V_m$, let a basis for $V$ be

$$\{v_1, \cdots , v_m, v_{m+1}, \cdots , v_n\}$$

Let $\theta$ be the isomorphism which satisfies $\theta e_i = v_i$ where the $e_i$ denotes the standard basis vectors for $\mathbb{R}^n$. Then from the above,

$$d(I - f, \Omega, y) = d(\theta^{-1} \circ (I - f) \circ \theta, \theta^{-1} \Omega, \theta^{-1} y)$$

$$= d\left(\theta^{-1} \circ (I - f) \circ \theta |_{\overline{\Omega \setminus V_m}}, \theta^{-1} (\Omega \cap \mathbb{R}^n, \theta^{-1} y)\right)$$

$$= d((I - f)|_{\overline{\Omega \setminus V_m}}, \Omega \cap V_m, y).$$

21.8 The Leray Schauder Degree

This is a very important generalization to Banach spaces. It turns out you can define the degree of $I - F$ where $F$ is a compact mapping. To recall what one of these is, here is the definition.

Definition 21.8.1 Let $\Omega$ be a bounded open set in $X$ a Banach space and let $F : \overline{\Omega} \to X$ be continuous. Then $F$ is called compact if $F(B)$ is precompact whenever $B$ is bounded. That is, if $\{x_n\}$ is a bounded sequence, then there is a subsequence $\{x_{n_k}\}$ such that $\{F(x_{n_k})\}$ converges.

Theorem 21.8.2 Let $F : \overline{\Omega} \to X$ as above be compact. Then for each $\varepsilon > 0$, there exists $F_\varepsilon : \overline{\Omega} \to X$ such that $F$ has values in a finite dimensional subspace of $X$ and $\sup_{x \in \overline{\Omega}} \|F_\varepsilon(x) - F(x)\| < \varepsilon$. In addition to this, $(I - F)^{-1}(\text{compact set}) = \text{compact set}$. (This is called “proper”.)

Proof: It is known that $\overline{F(\Omega)}$ is compact. Therefore, there is an $\varepsilon$ net for $F(\Omega)$, $\{F_{\varepsilon_k}\}_{k=1}^n$ satisfying

$$\overline{F(\Omega)} \subseteq \cup_k B(F_{\varepsilon_k}, \varepsilon)$$

Now let

$$\phi_k(Fx) \equiv (\varepsilon - \|Fx - F_{\varepsilon_k}\|)^+$$

Thus this is equal to 0 if $\|F_{\varepsilon_k} - Fx\| \geq \varepsilon$ and is positive if $\|F_{\varepsilon_k} - Fx\| < \varepsilon$. Then consider

$$F_\varepsilon(x) \equiv \sum_{k=1}^n F(x_k) \frac{\phi_k(Fx)}{\sum_i \phi_i(Fx)}$$
It clearly has values in span \( \{F x_k\}_{k=1}^{m_{\varepsilon}} \). How close is it to \( F(x) \)? Say \( F x \in B(F x_k, \varepsilon) \). Then for such \( x \), \( \|F(x) - F(x_k)\| < \varepsilon \) by definition. Hence

\[
\|F(x) - F_{\varepsilon}(x)\| = \sum_{k : \|F(x) - F x_k\| < \varepsilon} \|F(x_k) - F(x)\| \frac{\phi_k(F x)}{\sum_i \phi_i(F x)} < \varepsilon \sum_k \frac{\phi_k(F x)}{\sum_i \phi_i(F x)} = \varepsilon
\]

Of course \( x \) is arbitrary and so

\[
\sup_{x \in \Omega} \|F_{\varepsilon}(x) - F(x)\| < \varepsilon.
\]

Next consider the second claim. Let \( K \) be compact. Consider \( \{x_k\} \subseteq (I - F)^{-1}(K) \).

It is necessary to show that it has a convergent subsequence. Then \( \{(I - F)(x_k)\} \) is a sequence in \( K \) and so it has a convergent subsequence still denoted with subscript \( k \) such that \( (I - F)(x_k) \rightarrow y \). The \( x_k \) are in a bounded set \( \Omega \) and so, from compactness of \( F \), there is a further subsequence, still denoted with subscript \( k \) such that \( F x_k \rightarrow z \). It follows that \( x_k \rightarrow y - z \) and hence every sequence in \( (I - F)^{-1}(K) \) has a convergent subsequence.

**Corollary 21.8.3** Let \( F : \Omega \rightarrow X \) as above be compact. Then for each \( \varepsilon > 0 \), there exists \( F_{\varepsilon} : \Omega \rightarrow X \) such that \( F \) has values in a finite dimensional subspace of \( X \) and \( \sup_{x \in \Omega} \|F_{\varepsilon}(x) - F(x)\| < \varepsilon \). In addition to this, \( (I - F)^{-1} \) (compact set) = compact set. (This is called “proper”.) If \( \Omega \) is symmetric and \( F \) is odd \( (F(-x) = -F(x)) \) then one can also assume \( F_{\varepsilon} \) is also odd.

**Proof:** Suppose \( \Omega \) is symmetric in that \( x \in \Omega \) iff \( -x \in \Omega \). Suppose also that \( F \) is odd. Thus \( F(\Omega) \) is also symmetric. Thus \( \overline{F(\Omega)} \) is compact and symmetric. If \( y \in F(\Omega) \), then \( y = Fx \) and so \( -y = -F(x) = F(-x) \in F(\Omega) \). Choose the \( \varepsilon \) net to be symmetric. That is, you have \( (F x)_k \) in the net if and only if \( -(F x)_k \) is in the net. Just add them in if needed. Therefore, there is an \( \varepsilon \) net for \( F(\Omega) \), \( \{(F x)_k\}_{k=-m_{\varepsilon}}^{m_{\varepsilon}} \) satisfying

\[
\overline{F(\Omega)} \subseteq \bigcup_k B(F x_k, \varepsilon), \{F x_k\} \text{ is symmetric.}
\]

Number these so that

\[
F x_{-k} = -F x_k = F(-x_k), |k| \leq m_{\varepsilon}.
\]

Now let

\[
\phi_k(F x) \equiv (\varepsilon - \|F x - F x_k\|)^+.
\]
\[ \phi_{-k}(F_x) = (\varepsilon - \|F_x - F_{x-k}\|)^+ \]
\[ = (\varepsilon - \|F_x + F_{x_k}\|)^+ \]
\[ = (\varepsilon - \|F_x - (-F_{x_k})\|)^+ \]
\[ = \phi_k(-F_x) \]

that is, \( \phi_{-k} \) is centered at \(-F_{x_k}\) while \( \phi_k \) is centered at \( F_{x_k} \), each function equal to 0 off \( B(F_{x_k}, \varepsilon) \) and is positive on \( B(F_{x_k}, \varepsilon) \). Then consider

\[ F_{\varepsilon}(x) = \sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F(x_k) \frac{\phi_k(F_x)}{\sum_i \phi_i(F_x)} \]

\[ F_{\varepsilon}(-x) = -\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F(-x_k) \frac{\phi_{-k}(F_x)}{\sum_i \phi_{-i}(F_x)} = -\sum_{k=-m_{\varepsilon}}^{m_{\varepsilon}} F(-x_k) \frac{\phi_{-k}(F_x)}{\sum_i \phi_{-i}(F_x)} = F_{\varepsilon}(x) \]

The rest of the argument is the same. \( \square \)

Now let \( F : \overline{\Omega} \rightarrow X \) be compact and consider \( I - F \). Is \( (I - F)(\partial \Omega) \) closed? Suppose \( (I - F)x_k \rightarrow y \). Then \( K = y \cup \{(I - F)x_k\}_{k=1}^{\infty} \) is a compact set because if you have any open cover, one of the open sets contains \( y \) and hence it contains all \( (I - F)x_k \) except for finitely many which can then be covered by finitely many open sets in the open cover. Hence, since \( (I - F) \) is proper, \( (I - F)^{-1}(K) \) is compact. It follows that there is a subsequence, still called \( x_k \) such that \( x_k \rightarrow x \in (I - F)^{-1}(K) \). Then by continuity of \( F \),

\[ (I - F)(x_k) \rightarrow (I - F)(x) \]
\[ (I - F)(x_k) \rightarrow y \]

It follows \( y = (I - F)x \) and so in fact \( (I - F)(\partial \Omega) \) is closed.

**Lemma 21.8.4** If \( F : \overline{\Omega} \rightarrow X \) is compact and \( \Omega \) is a bounded open set in \( X \), then \( (I - F)(\partial \Omega) \) is closed.

**Justification for definition of Leray Schauder Degree**

Now let \( y \notin (I - F)(\partial \Omega) \), a closed set. Hence dist \((y, (I - F)(\partial \Omega)) = 4\delta > 0 \). Now let \( F_k \) be a sequence of approximations to \( F \) which have values in an increasing sequence of finite dimensional subsets \( V_k \) each of which contains \( y \). Thus \( \lim_{k \rightarrow \infty} \sup_{x \in \overline{\Omega}} \|F(x) - F_k(x)\| = 0 \). Consider

\[ d(I - F_k|_{V_k}, \Omega \cap V_k, y) \]
Each of these is a well defined integer according to Theorem 21.7.3. For all $k$ large enough,
\[ \sup_{x \in \Omega} \| (I - F_k)(x) - (I - F_k)(x) \| < \delta \]
Hence, for all such $k$,
\[ B(y, 3\delta) \cap (I - F_k)(\partial \Omega) = \emptyset, \text{ that is } \text{dist}(y, (I - F_k)(\partial \Omega)) > 3\delta \quad (21.8.18) \]
Note that this implies
\[ \text{dist}(y, (I - F_k)(\Omega \cap V)) > 3\delta \]
for any subspace $V$. If $k < l$ are two such indices, then consider
\[ d(I - F_k|_{V_k}, \Omega \cap V_k, y), d(I - F_l|_{V_l}, \Omega \cap V_l, y) \]
Are they equal? Let $V = V_k + V_l$. Then by Theorem 21.7.3,
\[ d(I - F_l|_{V_l}, \Omega \cap V_l, y) = d(I - F_l|_{V}, \Omega \cap V, y) \]
\[ d(I - F_k|_{V_k}, \Omega \cap V_k, y) = d(I - F_k|_{V}, \Omega \cap V, y) \]
So what about $d(I - F_l|_{V}, \Omega \cap V, y), d(I - F_k|_{V}, \Omega \cap V, y)$? Are these equal?
\[ \sup_{x \in \Omega \cap W} \| F_l(x) - F_k(x) \| \leq \sup_{x \in \Omega \cap W} \| F_l(x) - F(x) \| + \sup_{x \in \Omega \cap W} \| F(x) - F_k(x) \| < 2\delta \]
This implies for
\[ h(x, t) = t(I - F_l)(x) + (1 - t)(I - F_k)(x), \]
and $x \in \Omega \cap V, y \notin h(\partial(\Omega \cap V), t)$ for all $t \in [0, 1]$. To see this, let $x \in \partial \Omega$
\[ \| t(I - F_l)(x) + (1 - t)(I - F_k)(x)\| - y \|
= \| t(I - F_k)(x) + t(F_kx - F_lx)\| + (1 - t)(I - F_k)(x)\| - y \|
= \| (I - F_k)(x) + t(F_kx - F_lx)\| \geq 3\delta - t2\delta \geq \delta \]
Hence
\[ d(I - F_l|_{V}, \Omega \cap V, y) = d(I - F_k|_{V}, \Omega \cap V, y) \]
and so
\[ \lim_{k \to \infty} d(I - F_k|_{V_k}, \Omega \cap V_k, y) \]
exists. A similar argument shows that this limit is independent of the sequence $\{F_k\}$ of approximating functions having values in a finite dimensional space. Thus we have the following definition of the Leray Schauder degree.
Definition 21.8.5 Let $X$ be a Banach space and let $F : X \to X$ be compact. That is, $F(\Omega)$ is precompact whenever $\Omega$ is bounded. Let $\Omega$ be a bounded open set in $X$ and let $y \notin (I - F) (\partial \Omega)$. Let $F_k$ be a sequence of operators which have values in finite dimensional spaces $V_k$ such that $V_k \subseteq V_{k+1}$, $y \in V_k$, and $\lim_{k \to \infty} \sup_{x \in \Omega} \| F(x) - F_k(x) \| = 0$. Then

$$D(I - F, \Omega, y) = \lim_{k \to \infty} d(I - F_k|_{V_k}, \Omega \cap V_k, y)$$

In fact, the sequence on the right is eventually constant. So

$$D(I - F, \Omega, y) = d(I - F_k|_{V_k}, \Omega \cap V_k, y)$$

for all $k$ sufficiently large.

The main properties of the Leray Schauder degree follow from the corresponding properties of Brouwer degree.

Theorem 21.8.6 Let $D$ be the Leray Schauder degree just defined and let $\Omega$ be a bounded open set $y \in (I - F) (\partial \Omega)$ where $F$ is always a compact mapping. Then the following properties hold:

1. $D(I, \Omega, y) = 1$

2. If $\Omega_1 \subseteq \Omega$ where $\Omega_1$ is open, $\Omega_1 \cap \Omega_2 = \emptyset$, and $y \notin \overline{\Omega} \setminus (\Omega_1 \cup \Omega_2)$ then

$$D(I - F, \Omega, y) = D(I - F, \Omega_1, y) + D(I - F, \Omega_2, y)$$

3. If $t \to y(t)$ is continuous $h : \overline{\Omega} \times [0, 1] \to X$ is continuous, $(x, t) \to h(x, t)$ is compact, $(I - h) (\partial \Omega, t)$ and if $y(t) \notin (I - h) (\partial \Omega, t)$ for all $t$, then $t \to D((I - h)(\cdot, t), \Omega, y(t))$ is constant.

Proof: The mapping $x \to 0$ is clearly compact. Then an approximating sequence is $F_k, F_k x = 0$ for all $k$. Then

$$D(I, \Omega, y) = \lim_{k \to \infty} d(I|_{V_k}, \Omega \cap V_k, y) = 1$$

For the second part, let $k$ be large enough that for $U = \Omega, \Omega_1, \Omega_2$,

$$D(I - F, U, y) = d(I - F_k|_{V_k}, U \cap V_k, y)$$

where $F_k$ is the sequence of approximating functions having finite dimensional range. Then the result follows from the Brouwer degree. In fact,

$$D(I - F, \Omega, y) = d(I - F_k|_{V_k}, \Omega \cap V_k, y)$$

$$= d(I - F_k|_{V_k}, \Omega_1 \cap V_k, y) + d(I - F_k|_{V_k}, \Omega_2 \cap V_k, y)$$

$$= D(I - F, \Omega_1, y) + D(I - F, \Omega_2, y)$$
21.8. THE LERAY-SCHAUDER DEGREE

this does the second claim of the theorem. Now consider the third one about homotopy invariance.

**Claim:** If \( \text{dist} (y, (I - F) \partial \Omega) \geq 6\delta \), and if \( \|y - z\| < \delta \), then

\[
D (I - F, \Omega, y) = D (I - F, \Omega, z)
\]

**Proof of claim:** Let \( F_k \) be the approximations and include both \( y, z \) in all the finite dimensional subspaces \( V_k \). Then for \( k \) large enough, \( \sup_{x \in \overline{\Omega}} \|F(x) - F_k(x)\| < \delta \) and also,

\[
D (I - F, \Omega, y) = d ((I - F_k) |_{V_k}, \Omega \cap V_k, y)
\]
\[
D (I - F, \Omega, z) = d ((I - F_k) |_{V_k}, \Omega \cap V_k, z)
\]

Now for \( x \in \partial (\Omega \cap V_k) \),

\[
\|(I - F_k) (x) - y\| \geq \|(I - F) (x) + (F(x) - F_k(x)) - y\|
\]
\[
\geq \|(I - F) (x) - y\| - \|F(x) - F_k(x)\|
\]
\[
> 6\delta - \delta = 5\delta
\]

Hence \( \text{dist} (y, (I - F_k) \partial \Omega) \geq 5\delta \) while \( \|y - z\| < \delta \). Hence

\[
d ((I - F_k) |_{V_k}, \Omega \cap V_k, y) = d ((I - F_k) |_{V_k}, \Omega \cap V_k, z)
\]

by Theorem 21.8.8.

From compactness of \( h \), there is an \( \varepsilon \) net for \( h (\overline{\Omega} \times [0, 1]) \), \( \{h (x_k, t_k)\} \) such that

\[
h (\overline{\Omega} \times [0, T]) \subseteq \bigcup_{k=1}^{n} B (h (x_k, t_k), \varepsilon). \]

Say the \( t_k \) are ordered. Then, as before,

\[
\phi_k (x) = (\varepsilon - \|h (x, t) - h (x_k, t_k)\|)^+
\]
\[
h_t (x, t) = \sum_{k=1}^{n} h (x_k, t) \frac{\phi_k (h (x, t))}{\sum \phi_i (h (x, t))}
\]

Then this is clearly continuous and has values in \( \text{span} ((h (x_k, t_k))_{k=1}^{n}) \). How well does it approximate? Say \( h (x, t) \in h (\overline{\Omega} \times [0, T]) \). Then it is in some

\[
B (h (x_k, t_k), \varepsilon),
\]

maybe several. Thus letting \( K (x, t) \) be those indices \( k \) such that

\[
h (x, t) \in B (h (x_k, t_k), \varepsilon)
\]

\[
\|h_t (x, t) - h (x, t)\| \leq \sum_{k \in K (x, t)} \|h (x_k, t) - h (x, t)\| \frac{\phi_k (h (x, t))}{\sum \phi_i (h (x, t))}
\]
\[
\leq \frac{\varepsilon \sum_{k=1}^{n} \phi_k (h (x, t))}{\sum \phi_i (h (x, t))} = \varepsilon
\]
Now here is a claim.

**Claim:** There exists $\delta > 0$ such that for all $t \in [0, 1]$, 
\[
\text{dist} \left( y(t), (I - h)(\partial \Omega, t) \right) > 6\delta
\]

**Proof of claim:** If not, there is $(x_n, t_n) \in \partial \Omega \times [0, 1]$ such that 
\[
\|y(t_n) - (I - h)(x_n, t_n)\| < 1/n
\]

Then $h(x_n, t_n)$ is in a compact set because of compactness of $h$. Also, the $y(t_n)$ are in a compact set because $y$ is continuous and $y([0, T])$ must therefore be compact. It follows that $(x_n, t_n)$ must be in a compact subset of $\partial \Omega \times [0, 1]$. It follows there is a subsequence, still denoted as $(x_n, t_n)$ which converges to $(x, t)$ in $\partial \Omega \times [0, 1]$. Then by continuity, $\|y(t) - (I - h)(x, t)\| = 0$ contrary to assumption. This proves the claim.

As with $h$ there exists a sequence $\{y_k(t)\}$ such that $y_k(t) \to y(t)$ uniformly in $t \in [0, 1]$ but $y_k$ has values in a finite dimensional subspace of $X, Y_k$. Choose $k_0$ large enough that for all $t \in [0, 1], \|y(t) - y_{k_0}(t)\| < \delta$. Thus by the first claim, 
\[
D(h(\cdot, t), \Omega, y(t)) = D(h(\cdot, t), \Omega, y_{k_0}(t))
\]
for all $t$. Also, 
\[
\text{dist} \left( y_0(t), (I - h)(\partial \Omega, t) \right) > 5\delta
\]

From the above, let $h_k \to h$ uniformly on $\overline{\Omega} \times [0, 1]$ but $h_k$ has values in a finite dimensional subspace $V_k$. Let all the $V_k$ contain the values of $y_{k_0}$ and so, for all $k$ large enough, 
\[
\sup_{\overline{\Omega} \times [0, T]} \|h(t, x) - h_k(t, x)\| < \delta
\]
so for such $k$,
\[
\text{dist} \left( y_0(t), (I - h_k)(\partial (\Omega \cap V_k), t) \right) \geq \text{dist} \left( y_0(t), (I - h_k)(\partial \Omega, t) \right) > 4\delta
\]

Then 
\[
D(h(\cdot, t), \Omega, y(t)) = D(h(\cdot, t), \Omega, y_{k_0}(t)) = \lim_{k \to \infty} d \left( h_k(\cdot, t) \big|_{\overline{\Omega \cap V_k}}, \Omega \cap V_k, y_{k_0}(t) \right)
\]
and 
\[
d \left( h_k(\cdot, t) \big|_{\overline{\Omega \cap V_k}}, \Omega \cap V_k, y_{k_0}(t) \right)
\]
is constant in $t$ for all large enough $k$. Thus 
\[
D(h(\cdot, t), \Omega, y(t)) = \lim_{k \to \infty} a_k, \ a_k \text{ independent of } t.
\]

One of the nice results which follows right away from this is the Schauder fixed point theorem.

**Theorem 21.8.7** Let $B = \overline{B(0, r)}$ and let $F : B \to B$ be compact. Then $F$ has a fixed point.
21.8. THE LERAY SCHAUDER DEGREE

**Proof:** Suppose it does not. Then consider \( D(I - tF, B(0, r), 0) \). If \( t = 1 \), \( 0 \notin (I - tF)(\partial B) \) since otherwise, there would be a fixed point. If \( t < 1 \) there is no point of \( \partial B \) which \( I - tF \) sends to 0 because if so,

\[
x - tFx = 0, \quad \|x\| = 1, \quad \|Fx\| \leq 1.
\]

Therefore, by homotopy invariance, \( t \to D(I - tF, B(0, r), 0) \) is constant for \( t \in [0, 1] \). It must equal \( D(I - F, B(0, r), 0) = D(I, B(0, r), 0) = 1 \).

Therefore, there exists \( x \in B(0, r) \) such that \((I - F)(x) = 0\) so \( F \) which means \( F \) has a fixed point after all. \( \square \)

One can get an improved version of this easily.

**Theorem 21.8.8** Let \( K \) be a closed bounded convex subset of a Banach space \( X \) and suppose \( F : K \to K \) is compact. Then \( F \) has a fixed point.

**Proof:** By Theorem 14.2.5, \( K \) is a retract. Thus there is a continuous function \( R : X \to K \) which leaves points of \( K \) unchanged. Then you consider \( F \circ R \). It is still a compact mapping obviously. Let \( B(0, r) \) be so large that it contains \( K \). Then from the above theorem, it has a fixed point in \( \overline{B(0, r)} \) denoted as \( x \). Then \( F(R(x)) = x \). But \( F(R(x)) \in K \) and so \( x \in K \). Hence \( Rx = x \) and so \( Fx = x \). \( \Box \)

There is an easy modification of the above which is often useful. If \( F : X \to F(X) \) where \( F(X) \) is bounded and in a compact set, and \( F \) is a compact map, then you could consider \( F : \text{conv}(F(X)) \to F(X) \subseteq \text{conv}(F(X)) \) where here \( \text{conv}(F(X)) \) is a closed bounded convex subset of \( X \). Then by the Schauder theorem, there is a fixed point for \( F \).

Here is an easy application of this theorem to ordinary differential equations.

**Theorem 21.8.9** Let \( g : [0, T] \times \mathbb{R}^n \to \mathbb{R}^n \) be continuous. Let \( F : C([0, T]; \mathbb{R}^n) \to C([0, T]; \mathbb{R}^n) \) be given by

\[
F(y)(t) = y_0 + \int_0^t g(s, y(s)) \, ds
\]

Suppose that whenever

\[
y(s) = F(y)(s), \quad \text{for } s \leq t,
\]

it follows that \( \max_{s \in [0, t]} |y(s)| < M, \ |y_0| < M \). Then there exists a solution to the integral equation

\[
y(t) = y_0 + \int_0^t g(s, y(s)) \, ds
\]

for \( t \in [0, T] \).
\textbf{Proof:} Let \( r_M \) be the radial projection in \( \mathbb{R}^n \) onto \( \overline{B(0,M)} \). Then \( F \circ r_M \) is compact because \( |g(s,r_M y)| \) is bounded. It also maps into a compact subset of \( C([0,T];\mathbb{R}^n) \) thanks to the Arzela Ascoli theorem. Then by the Schauder fixed point theorem, there exists a solution \( y = F \circ r_M \) to
\begin{equation*}
y(t) = y_0 + \int_0^t g(s, r_M y(s)) \, ds\end{equation*}
Then for \( s \in [0, \hat{T}] \) where \( \hat{T} \) is the largest such that \( \|y(s)\| \leq M \) for \( s \in [0, \hat{T}] \). Thus on \( [0, \hat{T}] \), \( r_M \) has no effect. If \( \hat{T} < T \), then by the estimate, \( |y(\hat{T})| < M \).
Hence \( \hat{T} \) is not really the last. Thus \( \hat{T} = T \).

The Schauder alternative or Schaefer fixed point theorem is as follows [33].

\textbf{Theorem 21.8.10} Let \( f : X \to X \) be a compact map. Then either

1. There is a fixed point for \( tf \) for all \( t \in [0, 1] \) or
2. For every \( r > 0 \), there exists a solution to \( x = tf(x) \) for \( t \in (0, 1) \) such that \( \|x\| > r \).

\textbf{Proof:} Suppose there is \( t_0 \in [0, 1] \) such that \( t_0 f \) has no fixed point. Then \( t_0 \neq 0 \) so \( t_0 f \) obviously has a fixed point if \( t_0 = 0 \). Thus \( t_0 \in (0, 1] \). Then let \( r_M \) be the radial retraction onto \( \overline{B(0,M)} \). By Schauder’s theorem there exists \( x \in \overline{B(0,M)} \) such that \( t_0 r_M f(x) = x \). Then if \( \|f(x)\| \leq M \), \( r_M \) has no effect and so \( t_0 f(x) = x \) which is assumed not to take place. Hence \( \|f(x)\| > M \) and so \( \|r_M f(x)\| = M \) so \( \|x\| = t_0 M \). Also \( t_0 r_M f(x) = t_0 M \frac{f(x)}{\|f(x)\|} = x \) and so \( x = t f(x), t = t_0 \frac{M}{\|f(x)\|} < 1 \).
Since \( M \) is arbitrary, it follows that the solutions to \( x = tf(x) \) for \( t \in (0, 1) \) are unbounded. It was just shown that there is a solution to \( x = tf(x), t < 1 \) such that \( \|x\| = t_0 M \) where \( M \) is arbitrary. Thus the second of the two alternatives holds. \( \blacksquare \)

There is a lot more on degree theory in [31]. Here is a very interesting theorem from this reference which pertains specifically to infinite dimensional spaces.

\textbf{Theorem 21.8.11} Let \( X \) be an infinite dimensional Banach space and let \( 0 \notin \partial \Omega \) where \( \Omega \) is an open bounded subset of \( X \). Let \( F : \overline{\Omega} \to X \) be compact. Suppose that \( F x \neq \lambda x \) for all \( x \in \partial \Omega \) and that \( 0 \notin F(\partial \Omega) \). Then \( D(I - F, \Omega, 0) = 0 \).

\textbf{Proof:} Recall that \( D(I - F, \Omega, 0) = \lim_{k \to \infty} d(I - F_k, \Omega \cap V_k, 0) \) where \( F_k \) has values in a finite dimensional subspace \( V_k \),
\begin{equation*}
\sup_{x \in \Omega} \|F_k(x) - F(x)\| < 1/k
\end{equation*}
Since the dimension of \( X \) is infinite, it can always be assumed that \( \text{span}(-F_k(\Omega)) \) is a proper subspace of \( V_k \) and this will be assumed. This is where it is significant that the dimension of \( X \) is infinite. Also recall that in the limit, eventually \( d(I - F_k, \Omega \cap V_k, 0) \) is a constant. Then the fact that \( F x \neq \lambda x \) for all \( x \in \partial \Omega \) will persist for \( F_k \) for all \( k \) large enough.
21.8. THE LERAY SCHAUDER DEGREE

If not, then there exists $x_k \in \partial \Omega$, $F_k x_k = \lambda_k x_k$ for some $x_k \in \partial \Omega$ and $\lambda_k \in [0, 1]$. Then there are subsequence $\lambda_k \to 0 \in [0, 1]$. Then

$$F x_k - \lambda_k x_k \to 0$$

because it is uniformly close to $F_k x_k - \lambda_k x_k$. Now by assumption $0 \notin F(\partial \Omega)$. If $\lambda_0 = 0$, then you would have $F x_k \to 0$ which does not happen because $0$ is at a positive distance from $F(\partial \Omega)$. Hence for all $k$ large enough,

$$F_k x \neq \lambda x$$

for all $\lambda \in [0, 1]$. Pick $k$ sufficiently large that in the limit for the Leray Schauder degree $d(I - F_k, \Omega \cap V_k, 0)$ remains constant. Then for $\lambda \in [0, 1]$,

$$d(\lambda I - F_k, \Omega \cap V_k, 0) = d(-F_k, \Omega \cap V_k, 0) = d(-F_k, \Omega \cap V_k, p)$$

for all $p \notin \text{span}(F_k(\bar{\Omega}))$ which is also close enough to $0$. Hence, since the degree of this last equals $0$ for such $p$, it follows that

$$d(I - F_k, \Omega \cap V_k, 0) = 0$$

Hence $D(I - F, \Omega, 0) = 0$ as claimed. ■

This theorem implies a very strange fixed point theorem. It is strange because it only applies to infinite dimensions.

**Corollary 21.8.12** Let $X$ be an infinite dimensional Banach space. Let $0 \in \Omega_0 \subseteq \Omega$ be two open sets. Let $F : \Omega \to X$ be a compact mapping which satisfies

1. $\|Fx\| \leq \|x\|$ for $x \in \partial \Omega_0$
2. $\|Fx\| \geq \|x\|$ for $x \in \partial \Omega$

Then $F$ has a fixed point in $\overline{\Omega \setminus \Omega_0}$.

**Proof:** First note that $\overline{\Omega \setminus \Omega_0}$ is like an annulus with both edges included. Suppose $F$ does not have a fixed point in $\overline{\Omega \setminus \Omega_0}$. What if $t = 1$ and $x \in \partial \Omega_0$? Could $0 = (I - F)(x)$? If so, the fixed point is obtained so assume this is not so. Then for $t < 1$ and $x \in \partial \Omega$, if you have $x = t^{-1} F x$, this would mean that $\|Fx\| = t \|x\|$ and $\|Fx\| < \|x\|$ which is assumed not to happen. Hence for $t \in (0, 1)$ we can assume that $0 \notin (I - t^{-1} F)(\partial \Omega)$. If $(I - F)(x) = 0$ for $x \notin \partial \Omega_0$ then the fixed point has been found. For $t \in (0, 1)$, you can’t have $t^{-1} (I - F)(x) = 0$ for $x \in \partial \Omega_0$ because then you would have $\|x\| = t \|Fx\|$ and so $\|Fx\| > \|x\|$ which is assumed not to happen. Therefore, we can assume that for $x \in \partial \Omega_0$, $(I - t F)(x) \neq 0$. Therefore,

$$D(I - F, \Omega_0, 0) = D(I, \Omega_0, 0) = 1$$

by homotopy invariance. Also from properties of the degree,

$$D(I - F, \Omega_0, 0) + D(I - F, \Omega \setminus \overline{\Omega_0}, 0) = D(I - F, \Omega, 0)$$
Recall that this is true if \( 0 \notin (I - F) (\Omega - \Omega_0) \) which is assumed to take place when we assume there is no fixed point. It is desired to use the above theorem so we need to consider \( F (\partial \Omega) \) and whether 0 is in this set. Condition 2 implies 0 is not in this set. Then Theorem 21.8.11 implies that \( D(I - F, \Omega, 0) = 0 \) and so \( D(I - F, \Omega \setminus \Omega_0, 0) = -1 \). Hence there is a fixed point in \( \Omega \setminus \Omega_0 \) after all contrary to the assumption that there was no such thing. 

This only works in infinite dimensions. Consider an annulus in \( \mathbb{R}^2 \) and let \( F \) be a rotation through an angle of 30 degrees. It clearly has no fixed point but the above conditions are satisfied. This seems very interesting, something which happens in infinite dimensions but not in finite dimensions.

### 21.9 Exercises

1. Show the Brouwer fixed point theorem is equivalent to the nonexistence of a continuous retraction onto the boundary of \( B(0, r) \).

2. Using the Jordan separation theorem, prove the invariance of domain theorem \( n \geq 2 \). Thus an open ball goes to some open. **Hint:** You might consider \( B(x, r) \) and show \( f \) maps the inside to one of two components of \( \mathbb{R}^n \setminus f(\partial B(x, r)) \). etc.

3. Give a version of Proposition 21.6.9 which is valid for the case where \( n = 1 \).

4. It was shown that if \( f \) is locally one to one and continuous, \( f : \mathbb{R}^n \to \mathbb{R}^n \), and 
   \[
   \lim_{|x| \to \infty} |f(x)| = \infty,
   \]
   then \( f \) maps \( \mathbb{R}^n \) onto \( \mathbb{R}^n \). Suppose you have \( f : \mathbb{R}^m \to \mathbb{R}^n \) where \( f \) is one to one and \( \lim_{|x| \to \infty} |f(x)| = \infty \). Show that \( f \) cannot be onto.

5. Can there exist a one to one onto continuous map, \( f \) which takes the unit interval \([0, 1]\) to the unit disk \( B(0, 1) \)? **Hint:** Think in terms of invariance of domain.

6. Let \( m < n \) and let \( B_m(0, r) \) be the ball in \( \mathbb{R}^m \) and \( B_n(0, r) \) be the ball in \( \mathbb{R}^n \). Show that there is no one to one continuous map from \( B_m(0, r) \) to \( B_n(0, r) \). **Hint:** It is like the above problem.

7. Consider the unit disk, 
   \[
   \left\{ (x, y) : x^2 + y^2 \leq 1 \right\} \equiv D
   \]
   and the annulus 
   \[
   \left\{ (x, y) : \frac{1}{2} \leq x^2 + y^2 \leq 1 \right\} \equiv A
   \]
   Is it possible there exists a one to one onto continuous map \( f \) such that \( f(D) = A \)? Thus \( D \) has no holes and \( A \) is really like \( D \) but with one hole punched...
21.9. EXERCISES

out. Can you generalize to different numbers of holes? **Hint:** Consider the invariance of domain theorem. The interior of $D$ would need to be mapped to the interior of $A$. Where do the points of the boundary of $A$ come from? Consider Theorem 6.9.3.

8. Suppose $C$ is a compact set in $\mathbb{R}^n$ which has empty interior and $f : C \rightarrow \Gamma \subseteq \mathbb{R}^n$ is one to one onto and continuous with continuous inverse. Could $\Gamma$ have nonempty interior? Show also that if $f$ is one to one and onto then if it is continuous, so is $f^{-1}$.

9. Let $K$ be a nonempty closed and convex subset of $\mathbb{R}^n$. Recall $K$ is convex means that if $x, y \in K$, then for all $t \in [0, 1]$, $tx + (1-t)y \in K$. Show that if $x \in \mathbb{R}^n$ there exists a unique $z \in K$ such that

$$|x - z| = \min \{|x - y : y \in K\}$$

This $z$ will be denoted as $P_\pi x$. **Hint:** First note you do not know $K$ is compact. Establish the parallelogram identity if you have not already done so,

$$|u - v|^2 + |u + v|^2 = 2|u|^2 + 2|v|^2.$$  

Then let $\{z_k\}$ be a minimizing sequence,

$$\lim_{k \rightarrow \infty} |z_k - x|^2 = \inf \{|x - y : y \in K\} = \lambda.$$  

Now using convexity, explain why

$$\left|\frac{z_k - z_m}{2}\right|^2 + \left|x - \frac{z_k + z_m}{2}\right|^2 = 2\left|\frac{x - z_k}{2}\right|^2 + 2\left|\frac{x - z_m}{2}\right|^2$$

and then use this to argue $\{z_k\}$ is a Cauchy sequence. Then if $z_i$ works for $i = 1, 2$, consider $(z_1 + z_2)/2$ to get a contradiction.

10. In Problem 6 show that $P_\pi x$ satisfies the following variational inequality.

$$(x - P_\pi x) \cdot (y - P_\pi x) \leq 0$$

for all $y \in K$. Then show that $|P_\pi x_1 - P_\pi x_2| \leq |x_1 - x_2|$. **Hint:** For the first part note that if $y \in K$, the function $t \rightarrow |x - (P_\pi x + t(y - P_\pi x))|^2$ achieves its minimum on $[0, 1]$ at $t = 0$. For the second part,

$$(x_1 - P_\pi x_1) \cdot (P_\pi x_2 - P_\pi x_1) \leq 0, \ (x_2 - P_\pi x_2) \cdot (P_\pi x_1 - P_\pi x_2) \leq 0.$$  

Explain why

$$(x_2 - P_\pi x_2 - (x_1 - P_\pi x_1)) \cdot (P_\pi x_2 - P_\pi x_1) \geq 0$$

and then use a some manipulations and the Cauchy Schwarz inequality to get the desired inequality. Thus $P$ is called a retraction onto $K$.  

11. Establish the Brouwer fixed point theorem for any convex compact set in \( \mathbb{R}^n \).
   **Hint:** If \( K \) is a compact and convex set, let \( R \) be large enough that the closed ball, \( D(0, R) \supseteq K \). Let \( P \) be the projection onto \( K \) as in Problem 10 above. If \( f \) is a continuous map from \( K \) to \( K \), consider \( f \circ P \). You want to show \( f \) has a fixed point in \( K \).

12. Suppose \( D \) is a set which is homeomorphic to \( \overline{B(0, 1)} \). This means there exists a continuous one to one map, \( h \) such that \( h(\overline{B(0, 1)}) = D \) such that \( h^{-1} \) is also one to one. Show that if \( f \) is a continuous function which maps \( D \) to \( D \) then \( f \) has a fixed point. Now show that it suffices to say that \( h \) is one to one and continuous. In this case the continuity of \( h^{-1} \) is automatic. Sets which have the property that continuous functions taking the set to itself have at least one fixed point are said to have the fixed point property. Work Problem 7 using this notion of fixed point property. What about a solid ball and a donut? Could these be homeomorphic?

13. Suppose \( \Omega \) is any open bounded subset of \( \mathbb{R}^n \) which contains \( 0 \) and that \( f : \overline{\Omega} \rightarrow \mathbb{R}^n \) is continuous with the property that
   \[ f(x) \cdot x \geq 0 \]
   for all \( x \in \partial\Omega \). Show that then there exists \( x \in \overline{\Omega} \) such that \( f(x) = 0 \). Give a similar result in the case where the above inequality is replaced with \( \leq \).
   **Hint:** You might consider the function
   \[ h(t, x) = tf(x) + (1 - t)x \]

14. Suppose \( \Omega \) is an open set in \( \mathbb{R}^n \) containing \( 0 \) and suppose that \( f : \overline{\Omega} \rightarrow \mathbb{R}^n \) is continuous and \( |f(x)| \leq |x| \) for all \( x \in \partial\Omega \). Show \( f \) has a fixed point in \( \overline{\Omega} \).
   **Hint:** Consider \( h(t, x) = tf(x) + (1 - t)x \) for \( t \in [0, 1] \). If \( t = 1 \) and some \( x \in \partial\Omega \) is sent to \( 0 \), then you are done. Suppose therefore, that no fixed point exists on \( \partial\Omega \). Consider \( t < 1 \) and use the given inequality.

15. Let \( \Omega \) be an open bounded subset of \( \mathbb{R}^n \) and let \( f, g : \overline{\Omega} \rightarrow \mathbb{R}^n \) both be continuous such that
   \[ |f(x)| - |g(x)| > 0 \]
   for all \( x \in \partial\Omega \). Show that then
   \[ d(f - g, \Omega, 0) = d(f, \Omega, 0) \]
   Show that if there exists \( x \in f^{-1}(0) \), then there exists \( x \in (f - g)^{-1}(0) \).
   **Hint:** You might consider \( h(t, x) = (1 - t)f(x) + t(f(x) - g(x)) \) and argue \( 0 \notin h(t, \partial\Omega) \) for \( t \in [0, 1] \).

16. Suppose \( f : \mathbb{R}^n \rightarrow \mathbb{R}^n \) is continuous and satisfies
   \[ |f(x) - f(y)| \geq \alpha |x - y|, \quad \alpha > 0, \]
Show that \( f \) must map \( \mathbb{R}^n \) onto \( \mathbb{R}^n \). \textbf{Hint:} First show \( f \) is one to one. Then use invariance of domain. Next show, using the inequality, that the points not in \( f(\mathbb{R}^n) \) must form an open set because if \( y \) is such a point, then there can be no sequence \( \{f(x_n)\} \) converging to it. Finally recall that \( \mathbb{R}^n \) is connected. It is obvious that \( f \) is one to one. This follows from the inequality. If \( U \) are the points not in the image of \( f \); then \( U \) must be open because if not, then for \( y \) one of these points, there would be a sequence \( f(x_n) \to y \). Then by the inequality, \( \{x_n\} \) is a Cauchy sequence and so it converges to \( x \). Thus \( f(x) = \lim_{n \to \infty} f(x_n) = y \). Now by invariance of domain, \( f(\mathbb{R}^n) \) is open. However, \( \mathbb{R}^n \) is connected and so in fact, \( U \) is empty.

17. Let \( f : \mathbb{C} \to \mathbb{C} \) where \( \mathbb{C} \) is the field of complex numbers. Thus \( f \) has a real and imaginary part. Letting \( z = x + iy \),
\[
    f(z) = u(x, y) + iv(x, y)
\]
Recall that the norm in \( \mathbb{C} \) is given by \( |x + iy| = \sqrt{x^2 + y^2} \) and this is the usual norm in \( \mathbb{R}^2 \) for the ordered pair \( (x, y) \). Thus complex valued functions defined on \( \mathbb{C} \) can be considered as \( \mathbb{R}^2 \) valued functions defined on some subset of \( \mathbb{R}^2 \). Such a complex function is said to be analytic if the usual definition holds. That is
\[
    f'(z) = \lim_{h \to 0} \frac{f(z + h) - f(z)}{h}.
\]
In other words,
\[
    f(z + h) = f(z) + f'(z)h + o(h) \quad (21.9.19)
\]
at a point \( z \) where the derivative exists. Let \( f(z) = z^n \) where \( n \) is a positive integer. Thus \( z^n = p(x, y) + iq(x, y) \) for \( p, q \) suitable polynomials in \( x \) and \( y \). Show this function is analytic. Next show that for an analytic function and \( u \) and \( v \) the real and imaginary parts, the Cauchy Riemann equations hold.
\[
    u_x = v_y, \quad u_y = -v_x.
\]
In terms of mappings show \( 21.9.18 \) has the form
\[
    \left( \begin{array}{c}
        u(x + h_1, y + h_2) \\
        v(x + h_1, y + h_2)
    \end{array} \right) \\
    = \left( \begin{array}{c}
        u(x, y) \\
        v(x, y)
    \end{array} \right) + \left( \begin{array}{c}
        u_x(x, y) \\
        v_x(x, y)
    \end{array} \right) \left( \begin{array}{c}
        h_1 \\
        h_2
    \end{array} \right) + o(h)
\]
\[
    = \left( \begin{array}{c}
        u(x, y) \\
        v(x, y)
    \end{array} \right) + \left( \begin{array}{c}
        u_x(x, y) \\
        v_x(x, y)
    \end{array} \right) \left( \begin{array}{c}
        h_1 \\
        h_2
    \end{array} \right) + o(h)
\]
where \( h = (h_1, h_2)^T \) and \( h \) is given by \( h_1 + ih_2 \). Thus the determinant of the above matrix is always nonnegative. Letting \( B_r \) denote the ball \( B(0, r) = B((0, 0), r) \) show
\[
    d(f, B_r, 0) = n.
\]
where \( f(z) = z^n \). In terms of mappings on \( \mathbb{R}^2 \),

\[
\begin{pmatrix}
u(x, y) \\
v(x, y)
\end{pmatrix}
\]

Thus show

\[
\operatorname{d}(f, B_r, 0) = n.
\]

**Hint:** You might consider

\[
g(z) \equiv \prod_{j=1}^{n} (z - a_j)
\]

where the \( a_j \) are small real distinct numbers and argue that both this function and \( f \) are analytic but that \( 0 \) is a regular value for \( g \) although it is not so for \( f \). However, for each \( a_j \) small but distinct \( \operatorname{d}(f, B_r, 0) = \operatorname{d}(g, B_r, 0) \).

18. Using Problem 17, prove the fundamental theorem of algebra as follows. Let \( p(z) \) be a nonconstant polynomial of degree \( n \),

\[
p(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots
\]

Show that for large enough \( r \), \( |p(z)| > |p(z) - a_n z^n| \) for all \( z \in \partial B(0, r) \). Now from Problem 15 you can conclude \( \operatorname{d}(p, B_r, 0) = \operatorname{d}(f, B_r, 0) = n \) where \( f(z) = a_n z^n \).

19. The proof of Sard’s lemma made use of the hard Vitali covering theorem. Here is another way to do something similar. Let \( U \) be a bounded open set and let \( f : U \to \mathbb{R}^n \) be in \( C^1(U) \). Let \( S \) denote the set of \( x \in U \) such that \( Df(x) \) has rank less than \( n \). Thus it is a closed set. Let \( U_m = \{ x \in U : \|Df(x)\| \leq m \} \), a closed set. It suffices to show that for \( S_m \equiv U_m \cap S \), \( f(S_m) \) has measure zero because \( f(S) = \bigcup_m f(S_m) \) these sets increasing in \( m \). By definition of differentiability,

\[
\lim_{k \to \infty} \sup_{\|v\| \leq 1/k} \frac{\|f(x + v) - f(x) - Df(x)v\|}{\|v\|} = 0
\]

for each \( x \in U \). Explain why the above function of \( x \) is measurable. Now by Eggeroff’s theorem, there is measurable set \( A \) of measure less than \( \frac{\varepsilon}{m^n \text{meas}} \) such that off \( A \), the convergence is uniform. Let \( C_k \) be a countable union of non overlapping half open rectangles one of which is of the form \( \bigcap_{i=1}^{n} (a_i, b_i) \) such that each has diameter less than \( 2^{-k} \). Consider the half open rectangles which have nonempty intersection with \( S_m \setminus A, I_k \). Then repeat the argument given in the first section of this chapter. Show that for \( k \) large enough, the rank condition and uniform convergence above implies that \( m_n (\cup \{ f(I) : I \in I_k \}) \) is less than \( \varepsilon \). Now show that \( f(A) \) is contained in a set of measure no more than \( m^n 10^n \frac{\varepsilon}{m^n \text{meas}} = 2\varepsilon \). Thus \( f(S_m) \) has measure no more than \( 3\varepsilon \). Since \( \varepsilon \) is arbitrary, this establishes the desired conclusion.
20. Let $X$ be a Banach space and let $\Omega$ be a symmetric and bounded open set. Let $F : \Omega \to X$ be odd and compact $0 \notin (I - F)(\partial \Omega)$. Show using Corollary 21.8.3 that $D(I - F, \Omega, 0)$ is an odd integer.

21. Let $F$ be compact. Suppose $I - F$ is one to one on $\overline{B(0, r)}$. Then using similar reasoning to the finite dimensional case, show that there is a $\delta > 0$ such that

$$(I - F)(0) + B(0, \delta) \subseteq (I - F)(B(0, r))$$

22. Let $F$ be compact. Suppose $I - F$ is locally one to one on an open set $\Omega$. Show that $(I - F)$ maps open sets to open sets. This is a version of invariance of domain.

23. Suppose $(I - F)$ is locally one to one and $F$ is compact. Suppose also that

$$\lim_{\|x\| \to \infty} \|(I - F)x\| = \infty.$$ 

Show that $(I - F)$ is onto.

24. As a variation of the above problem, suppose $F : X \to X$ is compact and

$$\lim_{\|x\| \to \infty} \frac{\|F(x)\|}{\|x\|} = 0$$

Then $I - F$ is onto. Note that $I - F$ is not one to one.

25. Suppose $F$ is compact and $\|(I - F)x - (I - F)y\| \geq \alpha \|x - y\|$. Show that then $(I - F)$ is onto.

26. The Jordan curve theorem is: Let $C$ denote the unit circle,

$$(x, y) \in \mathbb{R}^2 : x^2 + y^2 = 1.$$

Suppose $\gamma : C \to \Gamma \subseteq \mathbb{R}^2$ is one to one onto and continuous. Then $\mathbb{R}^2 \setminus \Gamma$ consists of two components, a bounded component (called the inside) $U_1$ and an unbounded component (called the outside), $U_2$. Also the boundary of each of these two components of $\mathbb{R}^2 \setminus \Gamma$ is $\Gamma$ and $\Gamma$ has empty interior. Using the Jordan separation theorem, prove this important result.

27. This problem is from [30] Recall Theorem 4.13. It allowed you to say that $D(I - F, \Omega, 0) = 0$ provided $0 \notin F(\partial \Omega)$ and $\lambda x \neq Fx$ for all $x \in \partial \Omega$, $\lambda \in [0, 1]$. This was for $F$ compact and defined on an infinite dimensional space $X$. Suppose now that $F$ is compact and $F : \Omega \to X$ where $0 \in \Omega$ an open set in $X$. Suppose also that $F(0) = 0$ and that

$$\liminf_{x \to 0} \frac{\|F(x)\|}{\|x\|} = \lim_{r \to 0^+} \inf \left\{ \frac{\|F(x)\|}{\|x\|} : \|x\| \leq r \right\} = \infty$$

Show that there is a sequence $\alpha_n \to 0$ each $\alpha_n \neq 0$, and for some $x_n \neq 0, x_n - \alpha_n F(x_n) = 0$. Note that when $\alpha = 0$, there is only one solution to $(I - \alpha F)(x) = 0$, but this says that there are many small $\alpha_n \neq 0$ for which there is a nonzero solution to $(I - \alpha_n F)(x) = 0$. That is there exist arbitrarily
small $\alpha_n$ such that $(I - \alpha_n) F(x_n) = 0$. This says that 0 is a bifurcation point for $I - \alpha F$. **Hint:** Let $\alpha_n \downarrow 0$ and pick $r_n$ such that for all $\|x\| = r_n$,

$$\|\alpha_n F(x)\| > \|x\|$$

Thus $0 \notin \overline{\alpha_n F(\partial B(0, r_n))}$ and also $\alpha_n F(x) \neq \lambda x$ for all $x \in \partial B(0, r_n)$. Use the theorem to conclude that

$$D(I - \alpha_n F, B(0, r_n), 0) = 0$$

and then consider the homotopy $I - \alpha_n t F$. If it sends no point of $\partial B(0, r_n)$ to 0 then you would have

$$D(I - \alpha_n t F, B(0, r_n), 0) = D(I, B(0, r_n), 0) = 1$$
Chapter 22

Critical Points

22.1 Mountain Pass Theorem In Hilbert Space

This is from Evans \([11]\). It is an interesting theorem. See also \([12]\) for more general versions. It has to do with differentiable functions defined on a Hilbert space \(H\). Thus \(I : H \to \mathbb{R}\) will be differentiable. Then the following is the Palais Smale condition.

**Definition 22.1.1** A functional \(I\) satisfies the Palais Smale conditions means that if \(\{I(u_k)\}\) is a bounded sequence and \(I'(u_k) \to 0\), then \(\{u_k\}\) is precompact. That is, it has a subsequence which converges.

It will be assumed that \(I\) is \(C^1(H; \mathbb{R})\) and also that \(I'\) is Lipschitz on bounded sets. By \(I'(u)\) is meant the element of \(H\) such that

\[
I(u + v) = I(u) + \langle I'(u), v \rangle_H + o(v)
\]

Such exists because of the Riesz representation theorem. Note that, from the assumption that \(I'\) is Lipschitz continuous, it follows that \(I'\) is bounded on every bounded set.

First is a deformation theorem. The notation \([I(u) \in S]\) means \(\{u : I(u) \in S\}\).

**Theorem 22.1.2** Let \(I\) be \(C^1\), \(I\) is non constant, satisfy the Palais Smale condition, and \(I'\) is Lipschitz continuous on bounded sets. Also suppose that \(c \in \mathbb{R}\) is such that either \([I(u) \in [c - \delta, c + \delta]] = \emptyset\) for some \(\delta > 0\) or \([I(u) \in [c - \delta, c + \delta]] \neq \emptyset\) for all \(\delta > 0\) and \(\text{IF } I(u) = c\), then \(I'(u) \neq 0\). Then for each sufficiently small \(\varepsilon > 0\), there is a constant \(\delta \in (0, \varepsilon)\) and a function \(\eta : [0,1] \times H \to H\) such that

1. \(\eta(0,u) = u\)
2. \(\eta(1,u) = u\) on \([I(u) \notin (c - \varepsilon, c + \varepsilon)]\)
3. \(I(\eta(t,u)) \leq I(u)\)
4. \( \eta (1, [I (u) \leq c + \delta]) \subseteq [I (u) \leq c - \delta] \)

The main part of this conclusion is the statement about \( u \to \eta (1, u) \) contained in parts 2. and 4. The other two parts are there to facilitate these two although they are certainly interesting for their own sake.

**Proof:** Suppose \([I (u) \in [c - \delta, c + \delta]] = \emptyset \) for some \( \delta > 0 \). Then \([I (u) \leq c + \delta/2] \subseteq [I (u) \leq c - \delta/2] \) and you could take \( \varepsilon = \delta \) and let \( \eta (t, u) = u \). Therefore, assume \([I (u) \in [c - \delta, c + \delta]] \neq \emptyset \) for all \( \delta > 0 \). Since \( I \) is nonconstant, \( \varepsilon > 0 \) can be chosen small enough that \([I (u) \notin (c - \varepsilon, c + \varepsilon)] \neq \emptyset \). Always let \( \varepsilon \) be this small.

**Claim 1:** For all small enough \( \varepsilon > 0 \), if \( u \in [I (u) \in [c - \varepsilon, c + \varepsilon]] \), \( I' (u) \neq 0 \) and in fact, for such \( \varepsilon \), there exists \( \sigma (\varepsilon) > 0 \) such that \( \sigma (\varepsilon) < \varepsilon \), \( ||I' (u)|| > \sigma (\varepsilon) \) for all \( u \in [I (u) \in [c - \varepsilon, c + \varepsilon]] \).

**Proof of Claim 1:** If claim is not so, then there is \( \{u_k\}, \varepsilon_k, \sigma_k \to 0, ||I' (u_k)|| < \sigma_k \), and \( I (u_k) \in [c - \varepsilon_k, c + \varepsilon_k] \) but \( ||I' (u_k)|| \leq \sigma_k \). However, from the Palais Smale condition, there is a subsequence, still denoted as \( u_k \) which converges to some \( u \). Now \( I (u_k) \in [c - \varepsilon_k, c + \varepsilon_k] \) and so \( I (u) = c \) while \( I' (u) = 0 \) contrary to the hypothesis. This proves Claim 1. From now on, \( \varepsilon \) will be sufficiently small.

Now define for \( \delta < \varepsilon \) (The description of small \( \delta \) will be described later.)

\[
A \equiv [I (u) \notin (c - \varepsilon, c + \varepsilon)] \\
B \equiv [I (u) \in [c - \delta, c + \delta]]
\]

Thus \( A \) and \( B \) are disjoint closed sets. Recall that it is assumed that \( B \neq \emptyset \) since otherwise, there is nothing to prove. Also it is assumed throughout that \( \varepsilon > 0 \) is such that \( A \neq \emptyset \) thanks to \( I \) not being constant. Thus these are nonempty sets and we do not have to fuss with worrying about meaning when one is empty.

**Claim 2:** For any \( u \), \( \text{dist} (u, A) + \text{dist} (u, B) > 0 \).

This is so because if not, then both would be zero and this requires that \( u \in A \cap B \) since these sets are closed. But \( A \cap B = \emptyset \).

Now define a function

\[
g (u) \equiv \frac{\text{dist} (u, A)}{\text{dist} (u, A) + \text{dist} (u, B)}
\]

It is a continuous function of \( u \) which has values in \([0, 1]\). Consider the ordinary differential initial value problem

\[
\eta' (t, u) + g (u) h (||I' (\eta (t, u))||) I' (\eta (t, u)) = 0 \quad (22.1.1)
\]

\[
\eta (0, u) = u \quad (22.1.2)
\]

where \( r \to h (r) \) is a decreasing function which has values in \((0, 1]\) and equals 1 for \( r \in [0, 1]\) and equals \( 1/r \) for \( r > 1 \). Here \( u \) is given and the \( \eta' \) is the time derivative is with respect to \( t \). Thus, by assumption, the function

\[
\eta \to g (u) h (||I' (\eta)||) I' (\eta)
\]
is Lipschitz continuous on bounded sets and so there exists a solution to the above initial value problem valid for all \( t \in [0,1] \). To see this, you can let \( P \) be the projection map onto the closed ball of radius \( M > \|u\| \) and the system

\[
\eta'(t, u) + g(u) h (||I'(P(\eta(t,u)))||) I'(P(\eta(t,u))) = 0
\]

\[
\eta(0, u) = u
\]

Then by Lipschitz continuity, there is a global solution for all \( t \geq 0 \). Hence there is a local solution to 22.1.1, 22.1.2. Note that

\[
\|g(u) h (||I'(P(\eta(s,u)))||) I'(P(\eta(s,u)))\| \leq 1
\]

Taking inner products with \( \eta(t,u) \), and integrating \( \int_0^t \) for this local solution,

\[
\frac{1}{2} \|\eta(t,u)\|^2 - \frac{1}{2} \|u\|^2 + \int_0^t g(u) h (||I'(P\eta(s,u))||) I'(P\eta(s,u), \eta(s,u)) ds = 0
\]

\[
\frac{1}{2} \|\eta(t,u)\|^2 \leq \frac{1}{2} \|u\|^2 + \int_0^t g(u) h (||I'(P\eta(t,u))||) ||I'(P\eta(t,u))|| \|\eta(s,u)\| ds
\]

It follows that for \( t \leq 1 \),

\[
\|\eta(t,u)\|^2 \leq \|u\|^2 + 2 \int_0^t \|\eta(s,u)\| ds
\]

\[
\leq \|u\|^2 + 1 + \int_0^t \|\eta(s,u)\|^2 ds
\]

and so from Gronwall’s inequality, for \( t \leq 1 \),

\[
\|\eta(t,u)\|^2 \leq \left( \|u\|^2 + 1 \right) e^t
\]

Thus we pick \( M > e \left( \|u\|^2 + 1 \right) \) and then we obtain that for \( t \in [0,1] \), the projection map does not change anything. Hence there exists a solution to 22.1.1, 22.1.2 on \([0,1]\) as desired.

Then for this solution, \( \eta(0,u) = u \) because of the above initial condition. If \( u \in [I(u) \notin [c-\epsilon, c+\epsilon]] \), then \( u \in A \) and so \( g(u) = 0 \) so \( \eta(t,u) = u \) for all \( t \in [0,1] \). This gives the first two conditions. Consider the third.

\[
\frac{d}{dt} (I(\eta(t,u))) = (I'(\eta), \eta') = - (I'(\eta), g(u) h (||I'(\eta)||) I'(\eta))
\]

\[
= -g(u) h (||I'(\eta)||) ||I'(\eta)||^2
\]

and so this implies the third condition since it says that the function \( t \rightarrow I(\eta(t,u)) \) is decreasing.
It remains to consider the last condition. This involves choosing $\delta$ still smaller if necessary. It is desired to verify that

$$\eta(1, [I(u) \leq c + \delta]) \subseteq [I(u) \leq c - \delta]$$

Suppose it is not so. Then there exists $u \in [I(u) \leq c + \delta]$ but $I(\eta(1, u)) > c - \delta$.

$$c - \delta < I(\eta(1, u)) = I(u) - \int_0^1 (I'(\eta), g(u) h(\|I'(\eta)\|) I'(\eta)) dt$$

$$= I(u) - g(u) \int_0^1 h(\|I'(\eta)\|) \|I'(\eta(t, u))\|^2 dt$$

$$< c + \delta - g(u) \int_0^1 h(\|I'(\eta)\|) \|I'(\eta(t, u))\|^2 dt$$

Then

$$c - 2\delta + g(u) \int_0^1 h(\|I'(\eta(t, u))\|) \|I'(\eta(t, u))\|^2 dt < c$$

If $I(u) \leq c - \delta$, there is nothing to show because in this case $I(\eta(1, u)) \leq I(u) \leq c - \delta$. Hence we can assume that $I(u) > c - \delta$ and also that $I(u) \leq c + \delta$. Thus $u \in B$ and so $g(u) = 1$. Thus

$$c - 2\delta + \int_0^1 h(\|I'(\eta(t, u))\|) \|I'(\eta(t, u))\|^2 dt < c$$

Also, it is being assumed that $I(\eta(1, u)) > c - \delta$ and so by the third conclusion shown above, $\eta(t, u) \in B$ for $t \in [0, 1]$. We also know that for such values of $\eta(t, u), \|I'(\eta(t, u))\| \geq \sigma(\varepsilon)$ from Claim 1. If $\|I'(\eta(t, u))\| > 1$, the integrand equals $\|I'(\eta(t, u))\| \geq \sigma(\varepsilon)$. If $\|I'(\eta(t, u))\| \leq 1$, the integrand is $\|I'(\eta(t, u))\|^2 \geq \sigma(\varepsilon)^2$. Thus

$$c - 2\delta + \int_0^1 \min(\sigma(\varepsilon), \sigma(\varepsilon)^2) dt < c$$

and the only restriction on $\delta$ was that it should be smaller than $\varepsilon$. Although it was not mentioned above, $\delta$ was chosen so small that $-2\delta + \min(\sigma(\varepsilon), \sigma(\varepsilon)^2) > 0$. Hence this yields a contradiction. Thus the last conclusion is verified. ■

Imagine a valley surrounded by a ring of mountains. On the other side of this ring of mountains, there is another low place. Then there must be some path from the valley to the exterior low place which goes through a point where the gradient equals 0, the gradient being the gradient of a function $f$ which gives the altitude of the land. This is the idea of the mountain pass theorem. The critical point where $\nabla f = 0$ is the mountain pass.

**Theorem 22.1.3** Let $H$ be a Hilbert space and let $I : H \to \mathbb{R}$ be a $C^1$ functional having $I'$ Lipschitz continuous and such that $I$ satisfies the Palais Smale condition.
Suppose \( I (0) = 0 \) and \( I (u) \geq a > 0 \) for all \( \| u \| = r \). Suppose also that there exists \( v, \| v \| > r \) such that \( I (v) \leq 0 \). Then define

\[
\Gamma \equiv \{ g \in C ([0, 1]; H) : g (0) = 0, g (1) = v \}
\]

Let

\[
c \equiv \inf_{g \in \Gamma} \max_{0 \leq t \leq 1} I (g (t))
\]

Then \( c \) is a critical value of \( I \) meaning that there exists \( u \) such that \( I (u) = c \) and \( I' (u) = 0 \). In particular, there is \( u \neq 0 \) such that \( I' (u) = 0 \).

**Proof:** First note that \( c \geq a > 0 \). Suppose \( c \) is not a critical value. Then by the deformation theorem, for \( \varepsilon > 0, \varepsilon \) sufficiently small, there is \( \eta : H \to H \) and a \( \delta < \varepsilon \) small enough that

\[
\eta ([I (u) \leq c + \delta]) \subseteq [I (u) \leq c - \delta]
\]

and \( \eta \) leaves unchanged \( [I (u) \notin (c - \varepsilon, c + \varepsilon)] \). Then there is \( g \in \Gamma \) such that

\[
\max_{t \in [0, 1]} I (g (t)) < c + \delta
\]

Then in particular, \( I (g (t)) < c + \delta \) for every \( t \). Hence you look at \( \eta \circ g \). We know that \( g (0), g (1) \) are both in the set \( [I (u) \notin (c - \varepsilon, c + \varepsilon)] \) because they are both 0 and so \( \eta \) leaves these unchanged. Hence \( \eta \circ g \in \Gamma \) and

\[
I (\eta \circ g (t)) \leq c - \delta
\]

for all \( t \in [0, 1] \). Thus

\[
c = \inf_{g \in \Gamma} \max_{0 \leq t \leq 1} I (g (t)) \leq \max_{t \in [0, 1]} I (\eta \circ g (t)) \leq c - \delta
\]

which is clearly a contradiction. ■

The Palais Smale conditions are pretty restrictive. For example, let \( I (x) = \cos x \). Thus \( I : \mathbb{R} \to \mathbb{R} \). Then let \( u_k = k \pi \). Clearly \( I (u_k) \) is bounded and \( \lim_{k \to \infty} I (u_k) = 0 \) but \( \{u_k\} \) is not precompact. However, here is a simple case which does satisfy the Palais Smale conditions.

**Example 22.1.4** Let \( I : \mathbb{R}^d \to \mathbb{R} \) satisfy \( \lim_{|x| \to \infty} I (x) = \infty \). Then \( I \) satisfies the Palais Smale conditions.

The growth condition implies that if \( I (x_k) \) is bounded, then so is \( \{x_k\} \) and so this sequence is precompact. Nothing needs to be said about \( I' (x_k) \).

### 22.1.1 A Locally Lipschitz Selection, Pseudogradient

When you have a functional \( \phi \) defined on a Banach space \( X \), \( \phi' (u) \) is in \( X' \) and it isn’t obvious how you can understand it in terms of an element in \( X \) like what is done with Hilbert space using the Riesz representation theorem. However, there is something called a pseudogradient which is defined next.
**Definition 22.1.5** Let \( \phi : X \to \mathbb{R} \) be \( C^1 \). Then \( v \) is a pseudogradient for \( \phi \) at \( x \) if the following hold.

1. \( \|v\|_X \leq 2\|\phi'(x)\|_{X'} \)
2. \( \|\phi'(x)\|_{X'}^2 \leq \langle \phi'(x), v \rangle \)

A pseudogradient field \( V \) is a locally Lipschitz selection of \( G(x) \) where \( G(x) \) is defined to be the set of pseudogradients of \( \phi \) at \( x \). Thus \( V(x) \in G(x) \) and \( V(x) \) is a pseudogradient for \( \phi \) at each \( x \) a regular point of \( \phi \).

Note how this generalizes the case of Hilbert space. In the Hilbert space case, you have \( \phi'(x) \) which technically is in \( H' \) and you have the gradient, written here as \( \nabla \phi \) which is in \( H \) such that \( \langle \nabla \phi(x), v \rangle_H = \langle \phi'(x), v \rangle_{H',H} \); the existence of \( \nabla \phi(x) \) coming from the Riesz representation theorem which also gives that \( \nabla \phi(x) = R^{-1}\phi'(x) \) and so \( \|\nabla \phi(x)\|_H = \|\phi'(x)\|_{H'} \), so the above two conditions hold for the gradient field except for one thing. Why is \( x \mapsto \nabla \phi(x) \) locally Lipschitz. We don’t know this, but with a pseudogradient field, we do. Also, the pseudogradient field is only required at regular points of \( \phi \) where \( \phi'(x) \neq 0 \). If you had strict inequalities holding in the above definition, then they would continue to hold for \( \tilde{x} \) near \( x \). Thus if you had

\[
\|v\|_X < 2\|\phi'(x)\|_{X'}, \quad \|\phi'(x)\|_{X'}^2 < \langle \phi'(x), v \rangle
\]

and \( \Gamma(x) \) were the set of such \( v \), then there would be an open set \( U \) containing \( x \) such that \( \cap_{\tilde{x} \in U} \Gamma(\tilde{x}) \neq \emptyset \). In fact, the intersection would contain \( v \).

This very nice lemma is from Gasinski L. and Papageorgiou N. (1989). It is a lovely application of Stone’s theorem and partitions of unity for a metric space.

**Lemma 22.1.6** Let \( Y \) be a metric space and let \( X \) be a normed linear space. (We will want to add in \( X \).) Let \( \Gamma : Y \to \mathcal{P}(X) \) such that \( \Gamma(y) \) is a nonempty convex set. Suppose that for each \( y \in Y \), there exists an open set \( U \) containing \( y \) such that

\[
\emptyset \neq \cap_{\tilde{y} \in U} \Gamma(\tilde{y})
\]

Then there exists a locally Lipschitz map \( \gamma : Y \to X \) such that \( \gamma(y) \in \Gamma(y) \) for all \( y \).

**Proof:** Let \( U \) denote the collection of all open sets \( U \) such that the nonempty intersection described above holds. Let \( V \) be a locally finite open refinement which also covers. Thus for any \( V \in \mathcal{V} \)

\[
\emptyset \neq \cap_{\tilde{y} \in V} \Gamma(\tilde{y})
\]

because it is a smaller intersection. Let \( \{\phi_V\}_{V \in \mathcal{V}} \) be a partition of unity subordinate to the open covering \( \mathcal{V} \). In fact, we can have \( \phi_V \) locally Lipschitz. This follows from
22.1. MOUNTAIN PASS THEOREM IN HILBERT SPACE

the above construction of the partition of unity in Theorem 14.1.1. Pick \( x_\in \cap_{\hat{y} \in V} \Gamma(\hat{y}) \). Then consider

\[
\gamma(y) = \sum_{V \in \mathcal{V}} x_V \phi_V(y)
\]

It is clearly locally Lipschitz because near any point \( y \), it is a finite sum of Lipschitz functions. Pick \( y \in Y \). Then it is in some \( V \in \mathcal{V} \). In fact, it is finitely many, \( V_1, \ldots, V_n \) and for other \( V \in \mathcal{V} \), \( \phi_V(y) = 0 \). Therefore,

\[
\gamma(y) = \sum_{i=1}^{n} x_{V_i} \phi_{V_i}(y)
\]

which is a convex combination of the \( x_{V_i} \). Now \( x_{V_i} \in \cap_{\hat{y} \in V_i} \Gamma(\hat{y}) \subseteq \Gamma(y) \), this for each \( i \). Hence this is a convex combination of points in a nonempty convex set \( \Gamma(y) \). Thus \( \gamma(y) \in \Gamma(y) \). ■

The following lemma says that if \( \phi \) is \( C^1 \) on \( X \), then it has a pseudogradient field on \( \{ x : \phi'(x) \neq 0 \} \), the set of regular points.

**Lemma 22.1.7** Let \( \phi \) be a \( C^1 \) function defined on \( X \) a Banach space. Then there exists a pseudogradient field for \( \phi \) on the set of regular points. \( (V(x) \in G(x) \text{ and } x \rightarrow V(x) \text{ is locally Lipschitz on the set of regular points.}) \)

**Proof:** First consider whether \( G(x) \), the set of pseudogradients of \( \phi \) at \( x \) is nonempty for \( \phi'(x) \neq 0 \). From the definition of the operator norm, there exists \( u \) such that \( \| u \|_{X} = 1 \) and \( \langle \phi'(x), u \rangle \geq \delta \| \phi'(x) \|_{X} \) where \( \delta \in (0, 1) \). Then let

\[
v = ru \| \phi'(x) \|_{X}, \text{ where } r \in (1, 2).
\]

\[
\langle \phi'(x), v \rangle = \langle \phi'(x), ru \| \phi'(x) \|_{X} \rangle = r \langle \phi'(x), u \rangle \| \phi'(x) \|_{X} \geq r \delta \| \phi'(x) \|^2
\]

Then choose \( r, \delta \) such that \( r \delta > 1 \) and \( r < 2 \). Then if these were chosen this way in the above reasoning, it follows that

\[
\| v \| < 2 \| \phi'(x) \| \text{ and } \langle \phi'(x), v \rangle > \| \phi'(x) \|^2.
\]

That \( \phi'(x) \neq 0 \) is needed to insure that the above strict inequalities hold.

Thus, letting \( Y \) be the metric space consisting of the regular points of \( \phi \), the continuity of \( \phi' \) implies that the above inequalities persist for all \( y \) close enough to \( x \). Thus there is an open set \( U \) containing \( x \) such that \( v \) satisfies the above inequalities for \( x \) replaced with arbitrary \( y \in U \). Thus

\[
v \in \cap_{y \in U} G(y)
\]

Since it is clear that each \( G(y) \) is convex, Lemma 22.1.6 implies the existence of a locally Lipschitz selection from \( G \). That is \( x \rightarrow V(x) \) is locally Lipschitz and \( V(x) \in G(x) \) for all regular \( x \). ■

It will be important to consider \( y' = f(y) \) where \( f \) is locally Lipschitz and \( y \) is just in a Banach space. This is more complicated than in Hilbert space because of the lack of a convenient projection map.
**Theorem 22.1.8** Let \( f : U \to X \) be locally Lipschitz where \( X \) is a Banach space and \( U \) is an open set. Then there exists a unique local solution to the IVP

\[
y' = f(y), \quad y(0) = y_0 \in U
\]

**Proof:** Let \( B \) be a closed ball of radius \( R \) centered at \( y_0 \) such that \( f \) has Lipschitz constant \( K \) on \( B \). Then

\[
y_1(t) = y_0 + \int_0^t f(y_0) \, ds
\]

and if \( y_n(t) \) has been obtained,

\[
y_{n+1}(t) = y_0 + \int_0^t f(y_n(s)) \, ds \quad (22.1.3)
\]

Now \( t < T \) where \( T \) is so small that \( \|f(y_0)\| e^{KT} < R \).

**Claim:** \( \|y_n(t) - y_{n-1}(t)\| \leq \|f(y_0)\| t^n K^{n-1} \frac{1}{(n-1)!} \).

**Proof of claim:** First

\[
\|y_1(t) - y_0\| \leq \int_0^t \|f(y_0)\| \, ds \leq \|f(y_0)\| t
\]

Now suppose it is so for \( n \). Then

\[
\|y_{n+1}(t) - y_n(t)\| \leq \int_0^t \|f(y_n(s)) - f(y_{n-1}(s))\| \, ds
\]

By induction, \( y_n(s), y_{n-1}(s) \) are still in \( B \). This is because

\[
\|y_n(t) - y_0\| \leq \sum_{k=1}^{n} \|y_k(t) - y_{k-1}(t)\|
\]

\[
\leq \sum_{k=1}^{n} \|f(y_0)\| \frac{1}{(k-1)!} t^k K^{k-1}
\]

\[
\leq \|f(y_0)\| t e^{KT} < R
\]  

(22.1.4)

showing that \( y_n(t) \) stays in \( B \). Then since all values of the iterates remain in \( B \), induction gives

\[
\|y_{n+1}(t) - y_n(t)\| \leq \int_0^t K \|y_n(s) - y_{n-1}(s)\| \, ds
\]

\[
\leq K \int_0^t \|f(y_0)\| \frac{1}{(n-1)!} s^n K^{n-1} \, ds = K^n \frac{1}{(n-1)!} \|f(y_0)\| \int_0^t s^n \, ds
\]

\[
= K^n \frac{1}{n!} \|f(y_0)\| t^{n+1}
\]
22.1. MOUNTAIN PASS THEOREM IN HILBERT SPACE

which proves the claim. Since the inequality of the claim shows that \( \|y_n - y_{n-1}\| \) is summable, it follows that \( \{y_n\} \) is a Cauchy sequence in \( C([0,T],X) \). It satisfies \( \|y_n - y_0\| < R \) and so \( y_n \) converges uniformly to some \( y \in C([0,T],X) \). Hence one can pass to a limit in \( 22.1.8 \) and obtain

\[
y(t) = y_0 + \int_0^t f(y(s)) \, ds
\]

for \( t \in [0,T] \). Also \( \|y(t) - y_0\| \leq R \) and on \( B(y_0,R) \), \( f \) is Lipschitz continuous so Gronwall’s inequality gives uniqueness of solutions which remain in \( B \). ■

Here is an alternate proof which other than the ugly lemma, seems more elegant to me. However, it is a useful lemma.

**Lemma 22.1.9** Define

\[
\gamma(x) = \begin{cases} 
\frac{x}{\|x - y_0\|} & \text{if } \|x - y_0\| \leq R \\
y_0 + \frac{x - y_0}{\|x - y_0\|}R & \text{if } \|x - y_0\| > R
\end{cases}
\]

Then \( \|\gamma(x) - \gamma(y)\| \leq 3\|x - y\| \) for all \( x, y \in X \). Thus

\[
\|\gamma(x) - y_0\| \leq R.
\]

**Proof:** In case both of \( x, y \) are in \( B = \overline{B(y_0,R)} \), there is nothing to show. Suppose then that \( \|y - y_0\| \leq R \) but \( \|x - y_0\| > R \). Then, assuming \( y - y_0 \neq 0 \),

\[
\|\gamma(x) - \gamma(y)\| = \left\| y_0 + \frac{x - y_0}{\|x - y_0\|}R - y \right\| = \left\| \frac{x - y_0}{\|x - y_0\|}R - (y - y_0) \right\|
\]

\[
= \left\| \frac{x - y_0}{\|x - y_0\|}R - \frac{y - y_0}{\|y - y_0\|}(y - y_0) \right\|
\]

\[
\leq \left\| \frac{x - y_0}{\|x - y_0\|}R - \frac{y - y_0}{\|y - y_0\|}(y - y_0) \right\| + \left\| R \frac{y - y_0}{\|y - y_0\|} - \frac{y - y_0}{\|y - y_0\|}(y - y_0) \right\| = A + B
\]

Now

\[
A \leq \left\| \frac{x - y_0}{\|x - y_0\|}R - \frac{y - y_0}{\|y - y_0\|}R \right\| \leq R \frac{\|x - y_0\|\|y - y_0\| - (y - y_0)\|x - y_0\|}{\|x - y_0\|\|y - y_0\|}
\]

\[
\leq \frac{R}{\|x - y_0\|\|y - y_0\|} \left( \|x - y_0\|\|y - y_0\| - (y - y_0)\|y - y_0\| \right)
\]

\[
\leq \frac{R}{\|x - y_0\|\|y - y_0\|} (\|x - y\| + \|y - y_0\|\|y - x\|)
\]

\[
\leq \frac{R}{\|x - y_0\|\|y - y_0\|} (\|x - y\| + \|y - x\|) < 2\|y - x\|
\]
In case $y = y_0$, you have

$$\|\gamma(x) - \gamma(y)\| = \left\| \frac{x - y_0}{\|x - y_0\|} R \right\| = \left\| \frac{x - y}{\|x - y_0\|} R \right\| < \|x - y\|$$

The only other case is where both $x, y$ are in $X \setminus B$. In this case, you get

$$\|\gamma(x) - \gamma(y)\| = \left\| y_0 + \frac{x - y_0}{\|x - y_0\|} R - \left( y_0 + \frac{y - y_0}{\|y - y_0\|} R \right) \right\| \leq 2 \|x - y\|$$

by the same reasoning used above to estimate $A$. ■

Alternate Proof of Theorem 22.1.8: Let $B$ be a closed ball of radius $R$ centered at $y_0$ such that $f$ has Lipschitz constant $K$ on $B$. Let $\gamma$ be as in Lemma 22.1.9. Consider $g(x) = f(\gamma(x))$. Then

$$\|g(x) - g(y)\| = \|f(\gamma(x)) - f(\gamma(y))\| \leq K \|\gamma(x) - \gamma(y)\| \leq 3K \|x - y\|.$$

Now consider for $y \in C([0,T], X)$

$$Fy(t) = y_0 + \int_0^t g(y(s)) \, ds$$

Then

$$\|Fy(t) - Fz(t)\| \leq \int_0^t K \|y(s) - z(s)\| \, ds$$

Thus, iterating this inequality, it follows that a large enough power of $F$ is a contraction map. Therefore, there is a unique fixed point. Now letting $y$ be this fixed point,

$$\|y(t) - y_0\| \leq \int_0^t 3K \|y(s) - y_0\| \, ds + \|f(y_0)\| T$$

It follows that

$$\|y(t) - y_0\| \leq \|f(y_0)\| T e^{3KT}$$

Choosing $T$ small enough, it follows that $\|y(t) - y_0\| < R$ on $[0,T]$ and so $\gamma$ has no effect. Thus this yields a local solution to the initial value problem. ■

In the case that $U = X$, the above argument shows that there exists a solution on some $[0,T)$ where $T$ is maximal.

$$y(t) = y_0 + \int_0^t f(y(s)) \, ds, \quad t < T$$

Suppose $T < \infty$. Suppose $\int_0^T \|f(y(s))\| \, ds < \infty$. Then you can consider $y_0 + \int_0^T f(y(s)) \, ds$ as an initial condition for the equation and obtain a unique solution
22.1. MOUNTAIN PASS THEOREM IN HILBERT SPACE

Then one could consider \( \hat{y}(t) = y(t) \) for \( t < T \) and for \( t \geq T \), \( \hat{y}(t) = z(t) \). Then for \( t \in [T, T + \delta] \),

\[
\begin{align*}
\hat{y}(t) &= z(t) = y_0 + \int_0^T f(y(s)) \, ds + \int_T^t f(\hat{y}(s)) \, ds \\
&= y_0 + \int_0^T f(y(s)) \, ds + \int_T^t f(\hat{y}(s)) \, ds
\end{align*}
\]

and so in fact, for all \( t \in [0, T + \delta] \),

\[
\hat{y}(t) = y_0 + \int_0^t f(\hat{y}(s)) \, ds
\]

contrary to the maximality of \( T \). Hence it cannot be the case that \( T < \infty \). Thus it must be the case that \( \int_0^T \| f(y(s)) \| \, ds = \infty \) if the solution is not global.

From the above observation, here is a corollary.

**Corollary 22.1.10** Let \( f : X \to X \) be locally Lipschitz where \( X \) is a Banach space. Then there exists a unique local solution to the IVP

\[ y' = f(y), \quad y(0) = y_0 \]

If \( f \) is bounded, then in fact the solutions exists on \([0, T]\) for any \( T > 0 \).

**Proof:** Say \( \| f(x) \| \leq M \) for all \( M \). Then letting \([0, \hat{T}]\) be the maximal interval, it must be the case that \( \int_0^T \| f(y(t)) \| \, dt = \infty \), but this does not happen if \( f \) is bounded. \( \blacksquare \)

Note that this conclusion holds just as well if \( f \) has linear growth, \( \| f(u) \| \leq a + b \| u \| \) for \( a, b \geq 0 \). One just uses an application of Gronwall’s inequality to verify a similar conclusion.

One can also give a simple modification of these theorems as follows.

**Corollary 22.1.11** Suppose \( f : X \to X \) is continuous and \( f \) is locally Lipschitz on \( U \), an open subset of \( X \), a Banach space. Suppose also that \( f(x) = 0 \) for all \( x \notin U \) and that \( \| f(x) \| < M \) for all \( x \in X \). Then there exists a solution to the IVP

\[ y' = f(y), \quad y(0) = y_0 \]

for \( t \in [0, T] \) for any \( T > 0 \).

**Proof:** Let \( T \) be given. If \( y_0 \notin U \), there is nothing to show. The solution is \( y(t) \equiv y_0 \). Suppose then that \( y_0 \in U \). Then by Theorem 22.1.8, there exists a unique solution to the initial value problem on an interval \([0, \hat{T}]\) of maximal length. If \( \hat{T} = T \), then as \( t_n \to T, \{ y(t_n) \} \) must converge. This is because for \( t_m < t_n \),

\[
\| y(t_n) - y(t_m) \| \leq M |t_n - t_m|
\]

For any \( T > 0 \).
showing that this is a Cauchy sequence. Since all such sequences lead to a Cauchy sequence, it must be the case that \( \lim_{t \to T} y(t) \) exists. Thus it equals

\[
y_0 + \int_0^T f(y(t)) \, dt
\]

We let \( y(T) \) equal the above and it follows from Gronwall’s inequality that there is a unique solution to the IVP on \([0, T]\) so the claim is true in this case.

Otherwise, if \( \hat{T} < T \), then one can define

\[
y(\hat{T}) \equiv y_0 + \int_0^{\hat{T}} f(y(s)) \, ds
\]

If \( y(\hat{T}) \in U \), then by the assumption that \( f \) is bounded, one could consider a new initial condition and extend the solution further violating the maximality of the length of \([0, \hat{T}]\). Therefore, it must be the case that \( y(\hat{T}) \in U^c \). Then the solution is

\[
\dot{y}(t) = \begin{cases} y(t), & t < \hat{T} \\ y(\hat{T}), & t > \hat{T} \end{cases}
\]

because \( f\left(y\left(\hat{T}\right)\right) = 0 \) by assumption. ■

One could also change the above argument for Corollary 22.1.11 to include the case that \( f \) has linear growth.

### 22.1.2 Mountain Pass Theorem In Banach Space

In this section, is a more general version of the mountain pass theorem. It is generalized in two ways. First, the space is not a Hilbert space and second, the derivative of the functional is not assumed to be Lipschitz. Instead of using \( I' \) one uses the pseudogradient in an appropriate differential equation. This is a significant generalization because there is no convenient projection map from \( X' \) to \( X \) like there is in Hilbert space. This is why the use of the pseudogradient is so interesting. For many more considerations of this sort of thing, see [52]. First is a deformation theorem. Here \( I \) will be defined on a Banach space \( X \) and \( I'(x) \in X' \). First recall the Palais Smale conditions.

#### Definition 22.1.12

A functional \( I \) satisfies the Palais Smale conditions means that if \( \{I(u_k)\} \) is a bounded sequence and \( I'(u_k) \to 0 \), then \( \{u_k\} \) is precompact. That is, it has a subsequence which converges.

Here is a picture which illustrates the main conclusion of the following theorem. The idea is that you modify the functional on some set making it smaller and leaving it unchanged off that set.
Theorem 22.1.13 Let $I$ be $C^1$, $I$ is non constant, satisfy the Palais Smale condition, and $I'$ is bounded on bounded sets. Also suppose that $c \in \mathbb{R}$ is such that either $I^{-1}([c - \delta, c + \delta]) = \emptyset$ for some $\delta > 0$ or $I^{-1}([c - \delta, c + \delta]) \neq \emptyset$ for all $\delta > 0$ and \textbf{IF} $I(u) = c$, then $I'(u) \neq 0$. Then for each sufficiently small $\varepsilon > 0$, there is a constant $\delta \in (0, \varepsilon)$ and a function $\eta : [0, 1] \times X \to X$ such that

1. $\eta(0, u) = u$
2. $\eta(1, u) = u$ on $I^{-1}(X \setminus (c - \varepsilon, c + \varepsilon))$
3. $I(\eta(t, u)) \leq I(u)$
4. $\eta(1, I^{-1}(-\infty, c + \delta)) \subseteq I^{-1}(-\infty, c - \delta]$, so $I(\eta(1, u)) \leq c - \delta$ if $I(u) \leq c + \delta$.

The main part of this conclusion is the statement about $u \to \eta(1, u)$ contained in parts 2. and 4. The other two parts are there to facilitate these two although they are certainly interesting for their own sake.

\textbf{Proof}: Suppose $I^{-1} \left( \left[ c - \hat{\delta}, c + \frac{\hat{\delta}}{2} \right] \right) = \emptyset$ for some $\hat{\delta} > 0$. Then

$$I^{-1} \left( (-\infty, c + \frac{\hat{\delta}}{2}) \right) \subseteq I^{-1} \left( (-\infty, c - \frac{\hat{\delta}}{2}) \right)$$

and you could take $\varepsilon = \hat{\delta}$ and let $\eta(t, u) = u$. The conclusion holds with $\delta = \hat{\delta}/2$.

Therefore, assume $I^{-1}([c - \delta, c + \delta]) \neq \emptyset$ for all $\delta > 0$. Since $I$ is nonconstant, $\varepsilon > 0$ can be chosen small enough that

$$I^{-1}(X \setminus (c - \varepsilon, c + \varepsilon)) \neq \emptyset.$$

Always let $\varepsilon$ be this small. Note that $I$ nonconstant is part of the assumptions.

\textbf{Claim 1}: For all small enough $\varepsilon > 0$, if $u \in I^{-1}([c - \varepsilon, c + \varepsilon])$, then $I'(u) \neq 0$ and in fact, for such $\varepsilon$, there exists $\sigma(\varepsilon) > 0$, such that $\sigma(\varepsilon) < \min(\varepsilon, 1), \|I'(u)\| > \sigma(\varepsilon)$ for all $u \in I^{-1}([c - \varepsilon, c + \varepsilon])$. 
Proof of Claim 1: If the claim is not so, then there is \( \{u_k\}, \varepsilon_k, \sigma_k \to 0, \|I' (u_k)\|_{X'} < \sigma_k \), and \( I (u_k) \in [c - \varepsilon_k, c + \varepsilon_k] \) but \( \|I' (u_k)\|_{X'} \leq \sigma_k \). However, from the Palais Smale condition, there is a subsequence, still denoted as \( u_k \) which converges to some \( u \). Now \( I (u_k) \in [c - \varepsilon_k, c + \varepsilon_k] \) and so \( I (u) = c \) while \( I' (u) = 0 \) contrary to the hypothesis. This proves Claim 1. From now on, \( \varepsilon \) will be sufficiently small that this holds.

Now define for \( \delta < \varepsilon \) (The precise description of small \( \delta \) will be described later. However, it will be \( \delta < \sigma (\varepsilon) / 2 \), but this exact description is only used at the end.)

\[
A \equiv I^{-1} (X \setminus (c - \varepsilon, c + \varepsilon)) \\
B \equiv I^{-1} ([c - \delta, c + \delta])
\]

Thus \( A \) and \( B \) are disjoint closed sets. Recall that it is assumed that \( B \neq \emptyset \) since otherwise, there is nothing to prove. Also it is assumed throughout that \( \varepsilon > 0 \) is such that \( A \neq \emptyset \) thanks to \( I \) not being constant. Thus these are nonempty sets and we do not have to fuss with worrying about meaning when one is empty.

Claim 2: For any \( u \), \( \operatorname{dist} (u, A) + \operatorname{dist} (u, B) > 0 \).

This is so because if not, then both summands would be zero and this requires that \( u \in A \cap B \) since these sets are closed. But \( A \cap B = \emptyset \).

Now define a function

\[
g(u) = \frac{\operatorname{dist} (u, A)}{\operatorname{dist} (u, A) + \operatorname{dist} (u, B)}
\]

It is a continuous function of \( u \) which has values in \([0, 1]\). It is 1 on \( B \) and 0 on \( A \). Also define \( V (x) \) as a pseudogradient field for \( I \) on the regular points of \( I \). At points where \( I' (x) = 0 \), let \( V (x) = 0 \). Recall what this means:

\[
\|I' (x)\|_{X'}^2 \leq \langle I' (x), V (x) \rangle, \quad \|V (x)\|_X \leq 2 \|I' (x)\|_{X'}.
\]

and also \( V \) is locally Lipschitz on the regular points of \( I \). Thus \( x \to V (x) \) is continuous on \( X \), thanks to continuity of \( I' \), satisfies the above inequalities, and is locally Lipschitz on \( U = \{x : I' (x) \neq 0\} \). It exists because of Lemma 22.1.14.

Consider the ordinary differential initial value problem

\[
\eta' (t, u) + g(u) h (\|V (\eta (t, u))\|) V (\eta (t, u)) = 0 \quad (22.1.6)
\]

\[
\eta (0, u) = u \quad (22.1.7)
\]

where \( r \to h (r) \) is a decreasing function which has values in \((0, 1]\) and equals 1 for \( r \in [0, 1] \) and equals \( 1/r \) for \( r > 1 \).

Here \( u \) is given and the \( \eta' \) is the time derivative is with respect to \( t \). By Corollary 22.1.13, there exists a solution to this for \( t \in [0, 1] \).
Then for this solution, \( \eta (0, u) = u \) because of the above initial condition. If \( u \in I^{-1} (X \setminus [c - \varepsilon, c + \varepsilon]) \), then \( u \in A \) and so \( g(u) = 0 \) so \( \eta (t, u) = u \) for all \( t \in [0, 1] \). This gives the first two conditions. Consider the third.

\[
\frac{d}{dt} (I(\eta(t, u))) = \langle I'(\eta), \eta' \rangle = -\langle I'(\eta), g(u) h (\|V(\eta(t, u))\|) V(\eta(t, u)) \rangle \\
= -g(u) h (\|V(\eta(t, u))\|) \langle I'(\eta), V(\eta(t, u)) \rangle \\
\leq -g(u) h (\|V(\eta(t, u))\|) \|I'(\eta)\|_{X'}^2 \leq 0
\]

this last inequality from the inequalities of (22.1.8) and so this implies the third condition since it says that the function \( t \to I(\eta(t, u)) \) is decreasing.

It remains to consider the last condition. This involves an appropriate choice of small \( \delta \). It was chosen small and now it will be seen how small. It is desired to verify that

\[ \eta (1, I^{-1} ((-\infty, c + \delta])) \subseteq I^{-1} ((-\infty, c - \delta]) \]

Suppose it is not so. Then there exists \( u \in (c - \delta, c + \delta] \) but \( I(\eta (1, u)) > c - \delta \). We can assume that \( I(u) \in (c - \delta, c + \delta] \) because if \( I(u) \leq c - \delta \), then so is \( I(\eta (1, u)) \) from what was just shown. Hence \( g(u) = 1 \). Then using the fact that \( g(u) = 1 \),

\[
c - \delta < I(\eta (1, u)) = I(u) + \int_0^1 \frac{d}{dt} (I(\eta)) \, dt \\
= I(u) - \int_0^1 \langle I'(\eta), h (\|V(\eta)\|) V(\eta) \rangle \, dt \\
= I(u) + \int_0^1 -h (\|V(\eta)\|) \langle I'(\eta), V(\eta) \rangle \, dt \\
\leq I(u) + \int_0^1 \left( -h (\|V(\eta)\|) \|I'(\eta)\|_{X'}^2 \right) \, dt
\]

Then

\[
c - \delta + \int_0^1 h (\|V(\eta)\|) \|I'(\eta)\|_{X'}^2 \, dt < I(u) \leq c + \delta
\]

Thus

\[
c - 2\delta + \int_0^1 h (\|V(\eta)\|) \|I'(\eta)\|_{X'}^2 \, dt < c
\]

Also, it is being assumed that \( I(\eta (1, u)) > c - \delta \) and so by the third conclusion shown above, \( \eta (t, u) \in B \) for \( t \in [0, 1] \). We also know that for such values of \( \eta (t, u), \|I'(\eta(t, u))\| \geq \sigma (\varepsilon) \) from Claim 1. Now

\[
\|I'(x)\|_{X'}^2 \leq \langle I'(x), V(x) \rangle \leq \|I'(x)\| \|V(x)\|
\]

and so

\[
\|V(\eta(t, u))\|_X \geq \|I'(\eta(t, u))\|_{X'} \geq \sigma (\varepsilon) . \quad (22.1.8)
\]
Thus the above inequality yields
\[ c - 2\delta + \int_0^1 h(\|V(\eta)\|) \sigma(\varepsilon)^2 \, dt < c \]

Now what is the value of \( h(\|V(\eta)\|) \)? From 22.1.8
\[ h(\|V(\eta(t,u))\|_X) \leq h(\|I'(\eta(t,u))\|_{X'}) \leq h(\sigma(\varepsilon)) \leq \frac{1}{\sigma(\varepsilon)} \]

In fact, \( \sigma(\varepsilon) < 1 \) so \( h(\sigma(\varepsilon)) = 1 \) so the above estimate, while correct is sloppy. Hence
\[ c - 2\delta + \int_0^1 \frac{1}{\sigma(\varepsilon)} \sigma(\varepsilon)^2 \, dt < c \]

So far it was only assumed \( \delta < \varepsilon \). As indicated above, \( \delta \) was chosen small enough that \( -2\delta + \sigma(\varepsilon) > 0 \). Hence this yields a contradiction. Thus the last conclusion is verified. \( \blacksquare \)

Imagine a valley surrounded by a ring of mountains. On the other side of this ring of mountains, there is another low place. Then there must be some path from the valley to the exterior low place which goes through a point where the gradient equals 0, the gradient being the gradient of a function \( f \) which gives the altitude of the land. This is the idea of the mountain pass theorem. The critical point where \( \nabla f = 0 \) is the mountain pass.

**Theorem 22.1.14** Let \( X \) be a Banach space and let \( I : X \to \mathbb{R} \) be a \( C^1 \) functional having \( I' \) bounded on bounded sets and such that \( I \) satisfies the Palais Smale condition. Suppose \( I(0) = 0 \) and \( I(u) \geq a > 0 \) for all \( \|u\| = r \). Suppose also that there exists \( v, \|v\| > r \) such that \( I(v) = 0 \). Then define
\[ \Gamma = \{ g \in C([0,1];X) : g(0) = 0, g(1) = v \} \]
Let
\[ c = \inf_{g \in \Gamma} \max_{0 \leq t \leq 1} I(g(t)) \]

Then \( c \) is a critical value of \( I \) meaning that there exists \( u \) such that \( I(u) = c \) and \( I'(u) = 0 \). In particular, there is \( u \neq 0 \) such that \( I'(u) = 0 \).

**Proof:** First note that \( c \geq a > 0 \). Suppose \( c \) is not a critical value. Then either \( I^{-1}((c - \delta, c + \delta)) = \emptyset \) for some \( \delta > 0 \) in which case the conclusion of the deformation theorem, (Theorem 22.1.13) holds, or for all \( \delta > 0 \), \( I^{-1}((c - \delta, c + \delta)) \neq \emptyset \) and if \( I(u) = c \), then \( I'(u) \neq 0 \) in which case the deformation theorem also holds. Then by this theorem, for \( \varepsilon > 0, \varepsilon \) sufficiently small, \( \varepsilon < c \), there is \( \eta : X \to X \) and a \( \delta < \varepsilon \) small enough that
\[ \eta(I^{-1}((\infty, c + \delta])) \subseteq I^{-1}((\infty, c - \delta)) \]
and \( \eta \) leaves unchanged \( I^{-1}(X \setminus (c - \varepsilon, c + \varepsilon)) \). Then there is \( g \in \Gamma \) such that
\[ \max_{t \in [0,1]} I(g(t)) < c + \delta \]
Then in particular, $I(g(t)) < c + \delta$ for every $t$. Hence you look at $\eta \circ g$. We know that $g(0), g(1)$ are both in the set $[I(u) \notin (c - \varepsilon, c + \varepsilon)]$ because they are both 0 or less than 0 and so $\eta$ leaves these unchanged. Hence $\eta \circ g \in \Gamma$ and

$$I(\eta \circ g(t)) \leq c - \delta$$

for all $t \in [0, 1]$. Thus

$$c = \inf_{g \in \Gamma} \max_{0 \leq t \leq 1} I(g(t)) \leq \max_{t \in [0, 1]} I(\eta \circ g(t)) \leq c - \delta$$

which is clearly a contradiction. \qed
Chapter 23

Nonlinear Operators

In this chapter, is a discussion of various kinds of nonlinear operators. Some standard references on these operators are \[36\], \[37\], \[21\], \[23\], \[12\], \[82\], \[105\], \[24\] and references listed there. The most important examples of these operators seem to be due to Brezis in the 1960’s and these things have been generalized and used by many others since this time. I am following many of these, but the stuff about maximal monotone operators is mainly from Barbu \[12\]. I am trying to include all the necessary basic results such as fixed point theorems which are needed to prove the main theorems and also to rewrite in a manner understandable to me.

It seems like the main issue is the following. When does \(\langle f_n, x_n \rangle\) converge to \(\langle f, x \rangle\) given that \(f_n\) and \(x_n\) both converge weakly to \(f\) and \(x\) respectively? There is no problem in finite dimensions because in finite dimensions, there is only one meaning for convergence. However, in infinite dimensions, there certainly is a problem as can be instantly realized by consideration of the Riemann Lebesgue lemma, for example. You know that \(\int_{-\pi}^{\pi} f(x) \sin(nx) \, dx \to 0\) so \(\sin(nx)\) converges weakly to 0 but \(\int_{-\pi}^{\pi} \sin^2(nx) \, dx\) certainly does not converge to 0.

The idea behind all of these considerations is that \(f_n\) is to come from some nonlinear operator which has properties which will allow one to successfully pass to a limit. When the operator is linear, there usually is no problem because the graph is a subspace and so if it is closed, it will also be weakly closed. Thus, if \(x_n \to x\) weakly and \(Lx_n \to f\) weakly, then \(f = Lx\). However, nothing like this happens with nonlinear operators. Consideration of when this happens is the purpose of this catalogue of nonlinear operators, and also to generalize to set valued operators. First is a section on single valued nonlinear operators and then the case of set valued nonlinear operators is discussed.

23.1 Some Nonlinear Single Valued Operators

Here is an assortment of nonlinear operators which are useful in applications to nonlinear partial differential equations. Generalizations of the notion of a pseudo-
monotone map will be presented later to include the case of set valued pseudomonotone maps. This is on the single valued version of some of these and these ideas originate with Brezis in the 1960’s. A good description is given in Lions \[82\].

**Definition 23.1.1** For a real Banach space, \( A : V \to V' \) is a pseudomonotone map if whenever

\[
\lim_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0
\]

and

\[
\lim_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0
\]

it follows that for all \( v \in V \),

\[
\lim_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle.
\]

The half arrows denote weak convergence.

If \( V \) is finite dimensional, then pseudomonotone maps are continuous. Also the property of being pseudomonotone is preserved when restriction is made to finite dimensional spaces. The notation is explained in the following diagram.

\[
\begin{align*}
W' &\overset{i}{\to} V' \\
W &\overset{i^*}{\to} V
\end{align*}
\]

The map \( i \) is just the inclusion map. \( i^*w \equiv w \) and \( i^* \) is the usual adjoint map. \( \langle i^*f, w \rangle_{W', W} \equiv \langle f, iw \rangle_{V', V} = \langle f, w \rangle_{V', V} \). Thus \( i^*Ai(w) \in W' \) and it is defined by

\[
\langle i^*Ai(w), z \rangle_{W', W} \equiv \langle Aw, z \rangle_{V', V}
\]

in other words, you restrict \( A \) to \( W \) and only consider what the resulting functional does to things in \( W \).

**Proposition 23.1.2** Let \( V \) be finite dimensional and let \( A : V \to V' \) be pseudomonotone and bounded (meaning \( A \) maps bounded sets to bounded sets). Then \( A \) is continuous. Also, if \( A : V \to V' \) is pseudomonotone and bounded, and if \( W \subseteq V \) is a finite dimensional subspace, then \( i^*Ai \) is pseudomonotone as a map from \( W \) to \( W' \).

**Proof:** Say \( u_n \to u \). Does it follow that \( Au_n \to Au \)? If not, then there is a subsequence such that \( Au_n \to \xi \neq Au \) thanks to \( \{Au_n\} \) being bounded. Then the \( \limsup \) condition holds obviously. In fact the limit of \( \langle Au_n, u_n - u \rangle \) exists and equals 0. Hence for all \( v \),

\[
\lim_{n \to \infty} \inf \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle
\]

Therefore,

\[
\langle \xi, u - v \rangle \geq \langle Au, u - v \rangle
\]
for all \( v \) and so in fact \( \xi = Au \) after all. Thus \( A \) must be continuous.

As to the second part of this proposition, if you have \( w_n \to w \) in \( W \), then in fact convergence takes place strongly because weak and strong convergence are the same in finite dimensions. Hence the same argument given above holds to show that \( i^*Ai \) is continuous.

**Definition 23.1.3** \( A : V \to V' \) is monotone if for all \( v, u \in V \),
\[ \langle Au - Av, u - v \rangle \geq 0, \]
and \( A \) is Hemicontinuous if for all \( v, u \in V \),
\[ \lim_{t \to 0^+} \langle A (u + t (v - u)), u - v \rangle = \langle Au, u - v \rangle. \]

**Theorem 23.1.4** Let \( V \) be a Banach space and let \( A : V \to V' \) be monotone and hemicontinuous. Then \( A \) is pseudomonotone.

**Proof:** Let \( A \) be monotone and Hemicontinuous. First here is a claim.

**Claim:** If \( 23.1.1 \) and \( 23.1.2 \) hold, then \( \lim_{n \to \infty} \langle Au_n, u_n - u \rangle = 0 \).

**Proof of the claim:** Since \( A \) is monotone,
\[ \langle Au_n - Au, u_n - u \rangle \geq 0 \]
so
\[ \langle Au_n, u_n - u \rangle \geq \langle Au, u_n - u \rangle. \]

Therefore,
\[ 0 = \liminf_{n \to \infty} \langle Au, u_n - u \rangle \leq \liminf_{n \to \infty} \langle Au_n, u_n - u \rangle \leq \limsup_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0. \]

Now using that \( A \) is monotone again, then letting \( t > 0 \),
\[ \langle Au_n - A (u + t (v - u)), u_n - u + t (u - v) \rangle \geq 0 \]
and so
\[ \langle Au_n, u_n - u + t (u - v) \rangle \geq \langle A (u + t (v - u)), u_n - u + t (u - v) \rangle. \]
Taking the lim inf on both sides and using the claim and \( t > 0 \),
\[ t \liminf_{n \to \infty} \langle Au_n, u - v \rangle \geq t \langle A (u + t (v - u)), (u - v) \rangle. \]
Next divide by \( t \) and use the Hemicontinuity of \( A \) to conclude that
\[ \liminf_{n \to \infty} \langle Au_n, u - v \rangle \geq \langle Au, u - v \rangle. \]

From the claim,
\[ \liminf_{n \to \infty} \langle Au_n, u - v \rangle = \liminf_{n \to \infty} \left( \langle Au_n, u_n - v \rangle + \langle Au_n, u - u_n \rangle \right) \]
\[ = \liminf_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle. \]

Monotonicity is very important in the above proof. The next example shows that even if the operator is linear and bounded, it is not necessarily pseudomonotone.
Example 23.1.5 Let $H$ be any Hilbert space (complete inner product space, more on these later) and let $A : H \to H'$ be given by

$$\langle Ax, y \rangle = (-x, y)_H.$$ 

Then $A$ fails to be pseudomonotone.

**Proof:** Let $\{x_n\}_{n=1}^\infty$ be an orthonormal set of vectors in $H$. Then Parsevall’s inequality implies

$$\|x\|^2 \geq \sum_{n=1}^{\infty} |(x_n, x)|^2$$

and so for any $x \in H, \lim_{n \to \infty} (x_n, x) = 0$. Thus $x_n \to 0 \equiv x$. Also

$$\lim_{n \to \infty} \sup \langle Ax_n, x_n - x \rangle =$$

$$\lim_{n \to \infty} \sup \langle Ax_n, x_n - 0 \rangle = \lim_{n \to \infty} \sup \left(-\|x_n\|^2\right) = -1 \leq 0.$$ 

If $A$ were pseudomonotone, we would need to be able to conclude that for all $y \in H,$

$$\lim_{n \to \infty} \inf \langle Ax_n, x_n - y \rangle \geq \langle Ax, x - y \rangle = 0.$$ 

However,

$$\lim_{n \to \infty} \inf \langle Ax_n, x_n - 0 \rangle = -1 < 0 = \langle A0, 0 - 0 \rangle.$$ 

The following proposition is useful.

**Proposition 23.1.6** Suppose $A : V \to V'$ is pseudomonotone and bounded where $V$ is separable. Then it must be demicontinuous. This means that if $u_n \to u$, then $Au_n \to Au$. In case that $V$ is reflexive, you don’t need the assumption that $V$ is separable.

**Proof:** Since $u_n \to u$ is strong convergence and since $Au_n$ is bounded, it follows

$$\lim_{n \to \infty} \sup \langle Au_n, u_n - u \rangle = \lim_{n \to \infty} \langle Au_n, u_n - u \rangle = 0.$$ 

Suppose this is not so that $Au_n$ converges weakly to $Au$. Since $A$ is bounded, there exists a subsequence, still denoted by $n$ such that $Au_n \to \xi$ weak*. I need to verify $\xi = Au$. From the above, it follows that for all $v \in V$

$$\langle Au, u - v \rangle \leq \lim_{n \to \infty} \inf \langle Au_n, u_n - v \rangle$$

$$= \lim_{n \to \infty} \inf \langle Au_n, u - v \rangle = \langle \xi, u - v \rangle$$

Hence $\xi = Au$. ■

There is another type of operator which is more general than pseudomonotone.
Definition 23.1.7 Let $A : V \to V'$ be an operator. Then $A$ is called type $M$ if whenever $u_n \rightharpoonup u$ and $Au_n \rightharpoonup \xi$, and

$$\limsup_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi, u \rangle$$

it follows that $Au = \xi$.

Proposition 23.1.8 If $A$ is pseudomonotone, then $A$ is type $M$.

Proof: Suppose $A$ is pseudomonotone and $u_n \rightharpoonup u$ and $Au_n \rightharpoonup \xi$, and

$$\limsup_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi, u \rangle$$

Then

$$\limsup_{n \to \infty} \langle Au_n, u_n - u \rangle = \limsup_{n \to \infty} \langle Au_n, u_n \rangle - \langle \xi, u \rangle \leq 0$$

Hence

$$\liminf_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle$$

for all $v \in V$. Consequently, for all $v \in V$,

$$\langle Au, u - v \rangle \leq \liminf_{n \to \infty} \langle Au_n, u_n - v \rangle$$

$$= \liminf_{n \to \infty} \langle Au_n, u - v \rangle + \langle Au_n, u_n - u \rangle$$

$$\leq \langle \xi, u - v \rangle + \liminf_{n \to \infty} \langle Au_n, u_n - u \rangle \leq \langle \xi, u - v \rangle$$

and so $Au = \xi$. ■

An interesting result is the following which states that a monotone linear function added to a type $M$ is also type $M$.

Proposition 23.1.9 Suppose $A : V \to V'$ is type $M$ and suppose $L : V \to V'$ is monotone, bounded and linear. Then $L + A$ is type $M$. Let $V$ be separable or reflexive so that the weak convergences in the following argument are valid.

Proof: Suppose $u_n \rightharpoonup u$ and $Au_n + Lu_n \rightharpoonup \xi$ and also that

$$\limsup_{n \to \infty} \langle Au_n + Lu_n, u_n \rangle \leq \langle \xi, u \rangle$$

Does it follow that $\xi = Au + Lu$? Suppose not. There exists a further subsequence, still called $n$ such that $Lu_n \rightharpoonup Lu$. This follows because $L$ is linear and bounded. Then from monotonicity,

$$\langle Lu_n, u_n \rangle \geq \langle Lu, u \rangle + \langle L(u), u_n - u \rangle$$

Hence with this further subsequence, the lim sup is no larger and so

$$\limsup_{n \to \infty} \langle Au_n, u_n \rangle + \lim_{n \to \infty} \langle Lu_n, u \rangle + \langle L(u), u_n - u \rangle \leq \langle \xi, u \rangle$$
and so
\[ \lim_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi - Lu, u \rangle \]
It follows since \( A \) is type \( M \) that \( Au = \xi - Lu \), which contradicts the assumption that \( \xi \neq Au + Lu \).

There is also the following useful generalization of the above proposition.

**Corollary 23.1.10** Suppose \( A : V \to V' \) is type \( M \) and suppose \( L : W \to W' \) is monotone, bounded and linear where \( V \subseteq W \) and \( V \) is dense in \( W \) so that \( W' \subseteq V' \). Then for \( u_0 \in W \) define \( M(u) = L(u - u_0) \). Then \( M + A \) is type \( M \). Let \( V \) be separable or reflexive so that the weak convergences in the following argument are valid.

**Proof:** Suppose \( u_n \rightharpoonup u \) and \( Au_n + Mu_n \rightharpoonup \xi \) and also that
\[ \lim_{n \to \infty} \langle Au_n + Mu_n, u_n \rangle \leq \langle \xi, u \rangle \]
Does it follow that \( \xi = Au + Mu \)? Suppose not. By assumption, \( u_n \rightharpoonup u \) and so,
\[ u_n - u_0 \rightharpoonup u - u_0 \text{ weak convergence in } W \]
since \( L \) is bounded, there is a further subsequence, still called \( n \) such that
\[ Mu_n = L(u_n - u_0) \rightharpoonup L(u - u_0) = Mu \]
Since \( M \) is monotone,
\[ \langle Mu_n - Mu, u_n - u \rangle \geq 0 \]
Thus
\[ \langle Mu_n, u_n \rangle - \langle Mu_n, u \rangle - \langle Mu, u_n \rangle + \langle Mu, u \rangle \geq 0 \]
and so
\[ \langle Mu_n, u_n \rangle \geq \langle Mu_n, u \rangle + \langle Mu, u_n - u \rangle \]
Hence with this further subsequence, the lim sup is no larger and so
\[ \langle \xi, u \rangle \geq \lim_{n \to \infty} \langle Au_n + Mu_n, u_n \rangle \]
\[ \geq \lim_{n \to \infty} \left( \langle Au_n, u_n \rangle + \langle Mu_n, u \rangle + \langle Mu, u_n - u \rangle \right) \]
\[ = \lim_{n \to \infty} \langle Au_n, u_n \rangle + \lim_{n \to \infty} \left( \langle Mu_n, u \rangle + \langle M(u), u_n - u \rangle \right) \leq \langle \xi, u \rangle \]
and so
\[ \lim_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi - Mu, u \rangle \]
It follows since \( A \) is type \( M \) that \( Au = \xi - Mu \), which contradicts the assumption that \( \xi \neq Au + Mu \).

The following is Browder’s lemma. It is a very interesting application of the Brouwer fixed point theorem.
Lemma 23.1.11 (Browder) Let $K$ be a convex closed and bounded set in $\mathbb{R}^n$ and let $A : K \to \mathbb{R}^n$ be continuous and $f \in \mathbb{R}^n$. Then there exists $x \in K$ such that for all $y \in K$,

$$(f - Ax, y - x)_{\mathbb{R}^n} \leq 0$$

If $K$ is convex, closed, bounded subset of $V$ a finite dimensional vector space, then the same conclusion holds. If $f \in V'$, there exists $x \in K$ such that for all $y \in K$,

$$\langle f - Ax, y - x \rangle_{V', V} \leq 0$$

Proof: Let $P_K$ denote the projection onto $K$. Thus $P_K$ is Lipschitz continuous.

$$x \to P_K (f - Ax + x)$$

is a continuous map from $K$ to $K$. By the Brouwer fixed point theorem, it has a fixed point $x \in K$. Therefore, for all $y \in K$,

$$(f - Ax + x - x, y - x) = (f - Ax, y - x) \leq 0$$

As to the second claim. Consider the following diagram.

$$\begin{array}{c}
\mathbb{R}^n \\
\theta \\
\mathbb{R}^n \quad \theta^* \\
\uparrow \\
V' \\
\downarrow \\
V
\end{array}$$

where

$$\theta (x) = \sum_{i=1}^{n} x_i v_i$$

Thus $\theta$ and $\theta^*$ are both continuous linear and one to one and onto. Hence there is $x \in \theta^{-1}K$ a closed convex and bounded subset of $\mathbb{R}^n$ such that $x = \theta^{-1}u, u \in K$, and

$$\langle \theta^* f - \theta^* A \theta (\theta^{-1}u), \theta^{-1} y - \theta^{-1}u \rangle_{\mathbb{R}^n} \equiv \langle f - Ay, y - u \rangle_{V', V} \leq 0$$

for all $y \in K$. \[ \blacksquare \]

From this lemma, there is an interesting theorem on surjectivity.

Proposition 23.1.12 Let $A : V \to V'$ be continuous and coercive,

$$\lim_{\|v\| \to \infty} \frac{\langle A (v + v_0), v \rangle}{\|v\|_{V'}} = \infty$$

for some $v_0$. Then for all $f \in V'$, there exists $v \in V$ such that $Av = f$.

Proof: Define the closed convex sets $B_n \equiv \overline{B(v_0, n)}$. By Browder’s lemma, there exists $x_n$ such that

$$\langle f - Av_n, y - v_n \rangle \leq 0$$

for all $y \in B_n$. Then taking $y = v_0$,

$$\langle Av_n, v_n - v_0 \rangle \leq \langle f, v_n - v_0 \rangle$$
letting $w_n = v_n - v_0$,
\[ \langle A(w_n + v_0), w_n \rangle \leq \langle f, w_n \rangle \]
and so
\[ \frac{\langle A(w_n + v_0), w_n \rangle}{\|w_n\|} \leq \|f\| \]
which implies that the $\|w_n\|$ and hence the $\|v_n\|$ are bounded. It follows that for large $n$, $v_n$ is an interior point of $B_n$. Therefore,
\[ \langle f - Av_n, z \rangle_{V',V} \leq 0 \]
for all $z$ in some open ball centered at $v_0$. Hence $f - Av_n = 0$. ■

Lemma 23.1.13 Let $A : V \to V'$ be type $M$ and bounded and suppose $V$ is reflexive or $V$ is separable. Then $A$ is demicontinuous.

Proof: Suppose $u_n \to u$ and $Au_n$ fails to converge weakly to $Au$. Then there is a further subsequence, still denoted as $u_n$ such that $Au_n \rightharpoonup \zeta \neq Au$. Then thanks to the strong convergence, you have
\[ \limsup_{n \to \infty} \langle Au_n, u_n \rangle = \langle \zeta, u \rangle \]
which implies $\zeta = Au$ after all. ■

With these lemmas and the above proposition, there is a very interesting surjectivity result.

Theorem 23.1.14 Let $A : V \to V'$ be type $M$, bounded, and coercive
\[ \lim_{\|u\| \to \infty} \frac{\langle A(u + u_0), u \rangle}{\|u\|} = \infty, \tag{23.1.4} \]
for some $u_0$, where $V$ is a separable reflexive Banach space. Then $A$ is surjective.

Proof: Since $V$ is separable, there exists an increasing sequence of finite dimensional subspaces \{\$V_n\$\} such that $\bigcup_n V_n = V$ and each $V_n$ contains $u_0$. Say $\text{span}(v_1, \cdots, v_n) = V_n$. Then consider the following diagram.

\[
\begin{array}{ccc}
V_n' & \xrightarrow{i} & V' \\
V_n & \xrightarrow{i} & V
\end{array}
\]

The map $i$ is the inclusion map. Consider the map $i^*Ai$. By Lemma 23.1.13 this map is continuous.
\[ \frac{\langle i^*Ai(v + u_0), v \rangle_{V_n'}}{\|v\|} = \frac{\langle A(v + u_0), v \rangle_{V',V}}{\|v\|} \]
Hence $i^*Ai$ is coercive. Let $f \in V'$. Then from Proposition 23.1.12 there exists $x_n$ such that
\[ i^*Av_n = i^*f \]
In other words,
\[ \langle Av_n, y \rangle_{V'V} = \langle f, y \rangle_{V'V} \] (23.1.5)
for all \( y \in V_n \). Letting \( y \equiv v_n - u_0 \equiv w_n \),
\[ \langle A(w_n + u_0), w_n \rangle = \langle f, w_n \rangle \]
Then from the coercivity condition (23.1.4), the \( w_n \) are bounded independent of \( n \). Hence this is also true of the \( v_n \). Since \( V \) is reflexive, there is a subsequence, still called \( \{v_n\} \) which converges weakly to \( v \in V \). Since \( A \) is bounded, it can also be assumed that \( Av_n \rightharpoonup \zeta \in V' \). Then
\[ \limsup_{n \to \infty} \langle Av_n, v_n \rangle = \limsup_{n \to \infty} \langle f, v_n \rangle = \langle f, v \rangle \]
Also, passing to the limit in (23.1.5),
\[ \langle \zeta, y \rangle = \langle f, y \rangle \]
for any \( y \in V_n \), this for any \( n \). Since the union of these \( V_n \) is dense, it follows that the above equation holds for all \( y \in V \). Therefore, \( f = \zeta \) and so
\[ \limsup_{n \to \infty} \langle Av_n, v_n \rangle = \limsup_{n \to \infty} \langle f, v_n \rangle = \langle f, v \rangle = \langle \zeta, v \rangle \]
Since \( A \) is type \( M \), \( Av = \zeta = f \). 

You can generalize pseudomonotone slightly without any trouble.

**Definition 23.1.15** Let \( V \) be a Banach space and let \( K \) be a closed convex nonempty subset of \( V \). Then \( A : K \to V' \) is pseudomonotone if similar conditions hold as above. That is, if
\[ u_n \rightharpoonup u \] (23.1.6)
and
\[ \limsup_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0 \] (23.1.7)
it follows that for all \( v \in K \),
\[ \liminf_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle. \] (23.1.8)

Then it is easy to give a nice result on variational inequalities.

**Proposition 23.1.16** Let \( K \) be a closed convex nonempty subset of \( V \) a separable reflexive Banach space. Let \( A : K \to V' \) be pseudomonotone and bounded. Also assume that either \( K \) is bounded or there is a coercivity condition
\[ \lim_{\|u\| \to \infty} \frac{\langle Au, u - u_0 \rangle}{\|u\|} = \infty, \ u_0 \in K \]
then for \( f \in V' \), there exists \( u \in K \) such that for all \( v \in K \),
\[ \langle Au, u - v \rangle \leq \langle f, u - v \rangle \]
Proof: Let $V_n$ be finite dimensional spaces whose union is dense in $V, \cdots V_n \subseteq V_{n+1} \cdots$, each containing $u_0$, $n > \|u_0\|$. By a repeat of the proof of Proposition 23.1.2, $i^* A_i$ will be continuous on $K$. Therefore, by Browder's lemma, there exists $u_n \in K_n \equiv K \cap B(0, n) \cap V_n$ such that for all $v \in K_n$,

$$\langle i^* f - i^* A_i u_n, v - u_n \rangle_{V_n^*, V_n} = (f - A u_n, v - u_n)_{V^*, V} \leq 0$$

Now assume we don’t know that $K$ is bounded. In case it is bounded, the argument simplifies. In the harder case, the coercivity condition implies that the $u_n$ are bounded in $V$. This follows from letting $v = u_0$ in the above inequality. Thus

$$\langle f, u_n - u_0 \rangle \geq \langle A u_n, u_n - u_0 \rangle$$

Hence

$$\frac{\langle A u_n, u_n - u_0 \rangle}{\|u_n\|} \leq \frac{\|f\| \|u_n - u_0\|}{\|u_n\|}$$

The right side is bounded and so it follows that the left side is also bounded. Therefore, $\|u_n\|$ must be bounded. Taking a subsequence and using the assumption that $V$ is reflexive, we can obtain

$$u_n \to u \text{ weakly in } V$$

By the fact that convex closed sets are weakly closed also, it follows that $u \in K$. Also, given $M$, eventually all $\|u_n\|$ and $\|u\|$ are less than $M$. Now from the inequality,

$$\langle A u_n, u_n - v \rangle \leq \langle f, u_n - v \rangle$$

Thus

$$\langle A u_n, u_n - u \rangle + \langle A u_n, u - v \rangle \leq \langle f, u_n - u \rangle + \langle f, u - v \rangle$$

Then taking $\limsup_{n \to \infty}$ one gets

$$\limsup_{n \to \infty} \langle A u_n, u_n - u \rangle + \langle \xi, u - v \rangle \leq \langle f, u - v \rangle$$

This holds for $v \in K_m$ where $m$ is arbitrary. Hence one could let $v_m \to u$. Thus eventually $\|v_m\| < M$ and so for large $m, v_m \in K_m$. Then it follows that

$$\limsup_{n \to \infty} \langle A u_n, u_n - u \rangle \leq 0.$$

Consequently, by the assumption that $A$ is pseudomonotone on $K$, for every $v \in K$,

$$\langle A u, u - v \rangle \leq \liminf_{n \to \infty} \langle A u_n, u_n - v \rangle \tag{*}$$

for all $v \in K$. Then from the inequality obtained from Browder’s lemma,

$$\langle A u_n, u_n - v \rangle_{V^*, V} \leq \langle f, u_n - v \rangle_{V^*, V}$$

and so $*$ implies on taking $\liminf$ that for all $v \in K$,

$$\langle A u, u - v \rangle_{V^*, V} \leq \langle f, u - v \rangle_{V^*, V} \blacksquare$$
23.2 Duality Maps

The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space.

Definition 23.2.1 A Banach space is said to be strictly convex if whenever \( \|x\| = \|y\| \) and \( x \neq y \), then
\[
\left\| \frac{x + y}{2} \right\| < \|x\|.
\]

\( F : X \to X' \) is said to be a duality map if it satisfies the following: a.) \( \|F(x)\| = \|x\|^{p-1} \). b.) \( F(x)(x) = \|x\|^p \), where \( p > 1 \).

Duality maps exist. Here is why. Let \( F(x) = \{x^* : \|x^*\| \leq \|x\|^{p-1} \text{ and } x^*(x) = \|x\|^p\} \).

Then \( F(x) \) is not empty because you can let \( f(x) = \|x\|^p \). Then \( f \) is linear and defined on a subspace of \( X \). Also
\[
\sup_{\|\alpha x\| \leq 1} |f(\alpha x)| = \sup_{\|\alpha x\| \leq 1} |\alpha| \|x\|^p \leq \|x\|^{p-1}
\]

Also from the definition,
\[
f(x) = \|x\|^p
\]

and so, letting \( x^* \) be a Hahn Banach extension, it follows \( x^* \in F(x) \). Also, \( F(x) \) is closed and convex. It is clearly closed because if \( x^*_n \to x^* \), the condition on the norm clearly holds and also the other one does too. It is convex because
\[
\|x^* \lambda + (1 - \lambda) y^*\| \leq \|x^*\| + (1 - \lambda) \|y^*\| \leq \lambda \|x\|^{p-1} + (1 - \lambda) \|x\|^{p-1}
\]

If the conditions hold for \( x^* \), then we can show that in fact \( \|x^*\| = \|x\|^{p-1} \).

This is because
\[
\|x^*\| \geq x^* \left( \frac{x}{\|x\|} \right) = \frac{1}{\|x\|} |x^*(x)| = \|x\|^{p-1}.
\]

Now how many things are in \( F(x) \) assuming the norm on \( X' \) is strictly convex? Suppose \( x_1^* \) and \( x_2^* \) are two things in \( F(x) \). Then by convexity, so is \( (x_1^* + x_2^*)/2 \). Hence by strict convexity, if the two are different, then
\[
\left\| \frac{x_1^* + x_2^*}{2} \right\| = \|x\|^{p-1} < \frac{1}{2} \|x_1^*\| + \frac{1}{2} \|x_2^*\| = \|x\|^{p-1}
\]

which is a contradiction. Therefore, \( F \) is an actual mapping.

What are some of its properties? First is one which is similar to the Cauchy Schwarz inequality. Since \( p - 1 = p/p' \),
\[
\sup_{\|y\| \leq 1} |\langle Fx, y \rangle| = \|x\|^{p/p'}
\]
and so for arbitrary $y \neq 0$,
\[
|\langle Fx, y \rangle | = \|y\| \left| \left\langle \frac{Fx}{\|y\|}, y \right\rangle \right| \leq \|y\| \|x\|^{\frac{p}{p'}}
\]
\[
= |\langle Fy, y \rangle |^{\frac{1}{p'}} |\langle Fx, x \rangle |^{\frac{1}{p'}}
\]

Next we can show that $F$ is monotone.
\[
\langle Fx - Fy, x - y \rangle \geq \|x\|^p + \|y\|^p - \|x\|^{\frac{p}{p'}} - \|y\|^{\frac{p}{p'}} \|x\|
\]
\[
\geq \|x\|^p + \|y\|^p - \left( \frac{\|y\|^p}{p} + \frac{\|x\|^p}{p'} \right) - \left( \frac{\|y\|^p}{p} + \frac{\|x\|^p}{p'} \right) = 0
\]

Next it can be shown that $F$ is hemicontinuous. By the construction, $F(x + ty)$ is bounded as $t \to 0$. Let $t \to 0$ be a subsequence such that
\[
F(x + ty) \to \xi \text{ weak }^*
\]

Then we ask: Does $\xi$ do what it needs to do in order to be $F(x)$? The answer is yes. First of all $\|F(x + ty)\| = \|x + ty\|^{p-1} \to \|x\|^{p-1}$. The set
\[
\left\{ x^* : \|x^*\| \leq \|x\|^{p-1} + \varepsilon \right\}
\]
is closed and convex and so it is weak* closed as well. For all small enough $t$, it follows $F(x + ty)$ is in this set. Therefore, the weak limit is also in this set and it follows $\|\xi\| \leq \|x\|^{p-1} + \varepsilon$. Since $\varepsilon$ is arbitrary, it follows $\|\xi\| \leq \|x\|^{p-1}$. Is $\xi(x) = \|x\|^p$? We have
\[
\|x\|^p = \lim_{t \to 0} \|x + ty\|^p = \lim_{t \to 0} \langle F(x + ty), x + ty \rangle
\]
\[
= \lim_{t \to 0} \langle F(x + ty), x \rangle = \langle \xi, x \rangle
\]
and so, $\xi$ does what it needs to do to be $F(x)$. This would be clear if $\|\xi\| = \|x\|^{p-1}$. However, $\|\xi, x\| = \|x\|^p$ and so $\|\xi\| \geq \left( \frac{\xi, x}{\|x\|^p} \right) = \|x\|^{p-1}$. Thus $\|\xi\| = \|x\|^{p-1}$ which shows $\xi$ does everything it needs to do to equal $F(x)$ and so it is $F(x)$. Since this conclusion follows for any convergent sequence, it follows that $F(x + ty)$ converges to $F(x)$ weakly as $t \to 0$. This is what it means to be hemicontinuous. This proves the following theorem. One can show also that $F$ is demicontinuous which means strongly convergent sequences go to weakly convergent sequences. Here is a proof for the case where $p = 2$. You can clearly do the same thing for arbitrary $p$.

**Lemma 23.2.2** Let $F$ be a duality map for $p = 2$ where $X, X'$ are reflexive and have strictly convex norms. (If $X$ is reflexive, there is always an equivalent strictly convex norm [2].) Then $F$ is demicontinuous.
23.2. DUALITY MAPS

Proof: Say \( x_n \to x \). Then does it follow that \( Fx_n \to Fx \)? Suppose not. Then there is a subsequence, still denoted as \( x_n \) such that \( x_n \to x \) but \( Fx_n \to y \neq Fx \) where here \( \to \) denotes weak convergence. This follows from the Eberlein Smulian theorem. Then

\[
\langle y, x \rangle = \lim_{n \to \infty} \langle Fx_n, x_n \rangle = \lim_{n \to \infty} \|x_n\|^2 = \|x\|^2
\]

Also, there exists \( z, \|z\| = 1 \) and \( \langle y, z \rangle \geq \|y\| - \varepsilon \). Then

\[
\|y\| - \varepsilon \leq \langle y, z \rangle = \lim_{n \to \infty} \langle Fx_n, z \rangle \leq \lim \inf_{n \to \infty} \|Fx_n\| = \lim \inf_{n \to \infty} \|x_n\| = \|x\|
\]

and since \( \varepsilon \) is arbitrary, \( \|y\| \leq \|x\| \). It follows from the above construction of \( Fx \), that \( y = Fx \) after all, a contradiction. \( \blacksquare \)

Theorem 23.2.3 Let \( X \) be a reflexive Banach space with \( X' \) having strictly convex norm\(^1\). Then for \( p > 1 \), there exists a mapping \( F : X \to X' \) which is bounded, monotone, hemicontinuous, coercive in the sense that \( \lim_{\|x\| \to \infty} \langle Fx, x \rangle / \|x\| = \infty \), which also satisfies the inequalities

\[
\|\langle Fx, y \rangle \| \leq \langle \langle Fx, x \rangle \rangle^{1/p'} |\langle Fy, y \rangle \rangle^{1/p}
\]

Note that these conclusions about duality maps show that they map onto the dual space.

The duality map was onto and it was monotone. This was shown above. Consider the form of a duality map for the \( L^p \) spaces. Let \( F : L^p \to (L^p)' \) be the one which satisfies

\[
\|Ff\| = \|f\|^{p-1}, \; \langle Ff, f \rangle = \|f\|^p
\]

Then in this case,

\[
Ff = |f|^{p-2} \overline{f}
\]

This is because it does what it needs to do.

\[
\|Ff\|_{L^{p'}} = \left( \int_{\Omega} \left( |f|^{p-1} \right)^{p'} d\mu \right)^{1/p'} = \left( \int_{\Omega} \left( |f|^{p/p'} \right)^{p'} d\mu \right)^{1/p'} = \left( \int_{\Omega} |f|^p d\mu \right)^{1-(1/p)} = \left( \left( \int_{\Omega} |f|^p d\mu \right)^{1/p} \right)^{p-1} = \|f\|_{L^p}^{p-1}
\]

while it is obvious that

\[
\langle Ff, f \rangle = \int_{\Omega} |f|^p d\mu = \|f\|_{L^p(\Omega)}^p.
\]

Now here is an interesting inequality which I will only consider in the case where the quantities are real valued.

\(^1\)It is known that if the space is reflexive, then there is an equivalent norm which is strictly convex. However, in most examples, this strict convexity is obvious.
Lemma 23.2.4 Let \( p \geq 2 \). Then for \( a, b \) real numbers,
\[
\left( |a|^{p-2} a - |b|^{p-2} b \right) (a - b) \geq C |a - b|^p
\]
for some constant \( C \) independent of \( a, b \).

**Proof:** There is nothing to show if \( a = b \). Without loss of generality, assume \( a > b \). Also assume \( p > 2 \). There is nothing to show if \( p = 2 \). I want to show that there exists a constant \( C \) such that for \( a > b \),
\[
\frac{|a|^{p-2} a - |b|^{p-2} b}{|a - b|^{p-1}} \geq C
\]
(23.2.9)

First assume also that \( b \geq 0 \). Now it is clear that as \( a \to \infty \), the quotient above converges to 1. Take the derivative of this quotient. This yields
\[
(p - 1) |a - b|^{p-2} \frac{|a|^{p-2} |a - b| - \left( |a|^{p-2} a - |b|^{p-2} b \right)}{|a - b|^{2p-2}}
\]
Now remember \( a > b \). Then the above reduces to
\[
(p - 1) |a - b|^{p-2} \frac{|b|^{p-2} - |a|^{p-2}}{|a - b|^{2p-2}}
\]
Since \( b \geq 0 \), this is negative and so 1 would be a lower bound. Now suppose \( b < 0 \). Then the above derivative is negative for \( b < a \leq -b \) and then it is positive for \( a > -b \). It equals 0 when \( a = -b \). Therefore the quotient in (23.2.9) achieves its minimum value when \( a = -b \). This value is
\[
\frac{|-b|^{p-2} (-b) - |b|^{p-2} b}{|-b - b|^{p-1}} = \frac{|b|^{p-2} - 2b}{|2b|^{p-1}} = \frac{|b|^{p-2}}{|2b|^{p-2}} = \frac{1}{2^{p-2}}.
\]
Therefore, the conclusion holds whenever \( p \geq 2 \). That is
\[
\left( |a|^{p-2} a - |b|^{p-2} b \right) (a - b) \geq \frac{1}{2^{p-2}} |a - b|^p.
\]
This proves the lemma.

However, in the context of strictly convex norms on the reflexive Banach space \( X \), the following important result holds. I will give it first for the case where \( p = 2 \) since this is the case of most interest.

**Theorem 23.2.5** Let \( X \) be a reflexive Banach space and \( X, X' \) have strictly convex norms as discussed above. Let \( F \) be the duality map with \( p = 2 \). Then \( F \) is strictly monotone. This means
\[
\langle Fu - Fv, u - v \rangle \geq 0
\]
and it equals 0 if and only if \( u - v \).
Proof: First why is it monotone? By definition of $F$, $(F(u), u) = \|u\|^2$ and $\|F(u)\| = \|u\|$. Then

$$|\langle Fu, v \rangle| = \left| \left\langle Fu, \frac{v}{\|v\|} \right\rangle \right| \|v\| \leq \|Fu\| \|v\| = \|u\| \|v\|$$

Hence

$$(Fu - Fv, u - v) = \|u\|^2 + \|v\|^2 - \langle Fu, v \rangle - \langle Fv, u \rangle \geq \|u\|^2 + \|v\|^2 - 2 \|u\| \|v\| \geq 0$$

Now suppose $\|x\| = \|y\| = 1$ but $x \neq y$. Then

$$\left\langleFx, \frac{x + y}{2}\right\rangle \leq \left\| \frac{x + y}{2} \right\| < \frac{\|x\| + \|y\|}{2} = 1$$

It follows that

$$\frac{1}{2} \langle Fx, x \rangle + \frac{1}{2} \langle Fx, y \rangle = \frac{1}{2} + \frac{1}{2} \langle Fx, y \rangle < 1$$

and so

$$\langle Fx, y \rangle < 1$$

For arbitrary $x, y$, $x/\|x\| \neq y/\|y\|$

$$(Fx, y) = \|x\| \|y\| \left\langle F\left(\frac{x}{\|x\|}\right), \left(\frac{y}{\|y\|}\right)\right\rangle$$

It is easy to check that $F(\alpha x) = \alpha F(x)$. Therefore,

$$|\langle Fx, y \rangle| = \|x\| \|y\| \left\langle F\left(\frac{x}{\|x\|}\right), \left(\frac{y}{\|y\|}\right)\right\rangle < \|x\| \|y\|$$

Now say that $x \neq y$ and consider

$$\langle Fx - Fy, x - y \rangle$$

First suppose $x = \alpha y$. Then the above is

$$\langle F(\alpha y) - Fy, (\alpha - 1) y \rangle = (\alpha - 1) \left( \langle F(\alpha y), y \rangle - \|y\|^2 \right)$$

$$= (\alpha - 1) \left( \langle \alpha F(y), y \rangle - \|y\|^2 \right)$$

$$= (\alpha - 1)^2 \|y\|^2 > 0$$

The other case is that $x/\|x\| \neq y/\|y\|$ and in this case,

$$\langle Fx - Fy, x - y \rangle = \|x\|^2 + \|y\|^2 - \langle Fx, y \rangle - \langle Fy, x \rangle$$

$$> \|x\|^2 + \|y\|^2 - 2 \|x\| \|y\| \geq 0$$

Thus $F$ is strictly monotone as claimed.

As mentioned, this will hold for any $p > 1$. Here is a proof in the case that the Banach space is real which is the usual case of interest. First here is a simple observation.
Observation 23.2.6  Let \( p > 1 \). Then \( x \to |x|^{p-2} x \) is strictly monotone. Here \( x \in \mathbb{R} \).

To verify this observation,

\[
\frac{d}{dx} \left( (x^2)^{\frac{p-2}{2}} x \right) = \frac{1}{x^2} (p-1) (x^2)^{\frac{1}{2}p} > 0
\]

Theorem 23.2.7  Let \( X \) be a real reflexive Banach space and \( X, X' \) have strictly convex norms as discussed above. Let \( F \) be the duality map for \( p > 1 \). Then \( F \) is strictly monotone. This means

\[
\langle Fu - Fv, u - v \rangle \geq 0
\]

and it equals 0 if and only if \( u - v \).

Proof:  First why is it monotone? By definition of \( F \), \( \langle F(u), u \rangle = \|u\|^p \) and \( \|F(u)\| = \|u\|^{p-1} \). Then

\[
\|\langle Fu, v \|v\| \rangle \| v \| \leq \|F u\| \|v\| = \|u\|^{p-1} \|v\|
\]

Hence

\[
\langle Fu - Fv, u - v \rangle = \|u\|^p - \|v\|^p - \langle Fu, v \rangle - \langle Fv, u \rangle \geq \|u\|^p - \|v\|^p - \|u\|^{p-1} \|v\| - \|u\| \|v\|^{p-1}
\]

\[
\geq \|u\|^p - \|v\|^p - \left( \frac{\|u\|^p}{p} + \frac{\|v\|^p}{p} \right) - \left( \frac{\|u\|^p}{p} + \frac{\|v\|^p}{p} \right) = 0
\]

Now suppose \( \|x\| = \|y\| = 1 \) but \( x \neq y \). Then

\[
\left\langle Fx, \frac{x + y}{2} \right\rangle = \|x\|^{p-1} \left\| \frac{x + y}{2} \right\| < \frac{\|x\| + \|y\|}{2} = 1
\]

It follows that

\[
\frac{1}{2} \langle Fx, x \rangle + \frac{1}{2} \langle Fx, y \rangle = \frac{1}{2} + \frac{1}{2} \langle Fx, y \rangle < 1
\]

and so

\[
\langle Fx, y \rangle < 1
\]

It is easy to check that for nonzero \( \alpha \), \( F(\alpha x) = |\alpha|^{p-2} \alpha F(x) \). This is because

\[
\| |\alpha|^{p-2} \alpha F(x) \| = |\alpha|^{p-1} \|x\|^{p-1} = \|\alpha x\|^{p-1}
\]

\[
\left\langle |\alpha|^{p-2} \alpha F(x), \alpha x \right\rangle = |\alpha|^p \|x\|^p = \|\alpha x\|^p
\]
23.2. DUALITY MAPS

and so, since $|\alpha|^{p-2} \alpha F(x)$ acts like $F(\alpha x)$, it is $F(\alpha x)$. It follows that for arbitrary $x, y$, such that $x/\|x\| \neq y/\|y\|$

$\langle Fx, y \rangle = \|x\|^{p-1} \|y\| \left( F\left( \frac{x}{\|x\|} \right), \left( \frac{y}{\|y\|} \right) \right)$

Therefore,

$\langle Fx, y \rangle = \|x\|^{p-1} \|y\| \left( F\left( \frac{x}{\|x\|} \right), \left( \frac{y}{\|y\|} \right) \right) < \|x\|^{p-1} \|y\|$ \hspace{1cm} (23.2.10)

Now say that $x \neq y$ and consider

$\langle Fx - Fy, x - y \rangle$

First suppose $x = \alpha y$. This is the case where $x$ is a multiple of $y$. Then the above is

$\langle F(\alpha y) - Fy, (\alpha - 1) y \rangle = (\alpha - 1) \left( \langle F(\alpha y), y \rangle - \|y\|^p \right)$

$= (\alpha - 1) \left( |\alpha|^{p-2} \alpha \|y\|^p - \|y\|^p \right) = (\alpha - 1) \left( |\alpha|^{p-2} \alpha - 1 \right) \|y\|^p > 0$

by the above observation that $x \rightarrow |x|^{p-2} x$ is strictly monotone. Similarly, $\langle Fx - Fy, x - y \rangle > 0$ if $y = \alpha x$ for $\alpha \neq 1$.

Thus the desired result holds in the case that one vector is a multiple of the other. The other case is that neither vector is a multiple of the other. Thus, in particular, $x/\|x\| \neq y/\|y\|$, and in this case, it follows from

$\langle Fx - Fy, x - y \rangle = \|x\|^p + \|y\|^p - \langle Fx, y \rangle - \langle Fy, x \rangle$

$\geq \|x\|^p + \|y\|^p - \|x\|^{p-1} \|y\| - \|y\|^{p-1} \|x\|$

Thus $F$ is strictly monotone as claimed. □

Another useful observation about duality maps for $p = 2$ is that $\|F^{-1} y^*\|_V = \|y^*\|_{V'}$. This is because

$\|y^*\|_{V'} = \|FF^{-1} y^*\|_{V'} = \|F^{-1} y^*\|_V$

also from similar reasoning,

$\langle y^*, F^{-1} y^* \rangle = \langle FF^{-1} y^*, F^{-1} y^* \rangle = \|F^{-1} y^*\|_V^2 = \|y^*\|_{V'}^2$.

You can give specific inequalities in certain cases. Here is a nice little inequality which will allow this.

**Theorem 23.2.8** Let $p \geq 2$ then for $x, y \in \mathbb{R}^n$,

$$\left( |x|^{p-2} x - |y|^{p-2} y, x - y \right) \geq \frac{1}{2^{p-1}} |x - y|^p \quad (*)$$
Proof: We have \((x, y) = \frac{1}{2} (|x|^2 + |y|^2 - |x - y|^2)\). Consider the following.

\[
\frac{1}{2} \left( \frac{|x|^{p-2} + |y|^{p-2}}{|x - y|^{p-2}} \right) |x - y|^p + \frac{1}{2} \left( \frac{|x|^{p-2} - |y|^{p-2}}{|x - y|^{p-2}} \right) (|x|^2 - |y|^2)
\]

Multiplying this out gives

\[
\frac{1}{2} \left( |x|^{p-2} + |y|^{p-2} \right) (|x|^2 + |y|^2 - 2(x, y)) + \frac{1}{2} \left( |x|^p - |x|^2 |y|^{p-2} + |y|^p - |x|^{p-2} |y|^2 \right)
\]

This yields

\[
\frac{1}{2} \left[ |x|^p + |y|^{p-2} |x|^2 + |x|^{p-2} |y|^2 + |y|^p - \left( 2(x, y) |x|^{p-2} + 2(x, y) |y|^p \right) \right] + \frac{1}{2} \left( |x|^p + |y|^p - \left( |x|^2 |y|^{p-2} + |x|^{p-2} |y|^2 \right) \right)
\]

It simplifies to

\[
|x|^p + |y|^p - 2(x, y) \left( |x|^{p-2} + |y|^{p-2} \right)
\]

On the left side of \(*\), when you multiply it out, you get

\[
|x|^p - |x|^{p-2} (x, y) - |y|^{p-2} (x, y) + |y|^p
\]

which is exactly the same thing. Therefore,

\[
\left( |x|^{p-2} x - |y|^{p-2} y, x - y \right) = \frac{1}{2} \left( \frac{|x|^{p-2} + |y|^{p-2}}{|x - y|^{p-2}} \right) |x - y|^p \quad (**)
\]

Suppose first that \(p \geq 3\). Now \(p \geq 3\) and so \(|x|^{p-2}\) is convex. Hence

\[
\left| \frac{x + (-y)}{2} \right|^{p-2} \leq \frac{1}{2} \left( |x|^{p-2} + |y|^{p-2} \right)
\]

and so

\[
\left| |x|^{p-2} x - |y|^{p-2} y, x - y \right| \geq \left| \frac{x - y}{2} \right|^{p-2} \frac{1}{|x - y|^{p-2}} |x - y|^p = \frac{1}{2^{p-2}} |x - y|^p
\]

Next suppose \(p > 2\). There is nothing to show if \(p = 2\). Then for a positive integer \(m\), you can get \(m(p - 2) > 1\). Then

\[
\left( |x|^{p-2} + |y|^{p-2} \right)^m \geq |x|^{m(p-2)} + |y|^{m(p-2)} \geq 2^{1-m(p-2)} |x - y|^{m(p-2)}
\]
Thus we can raise both sides of the above to $1/m$ and conclude

$$|x|^{p-2} + |y|^{p-2} \geq 2^{1/(m-(p-2))} |x - y|^{p-2}$$

Then we use this in ** to obtain

$$\left( |x|^{p-2} x - |y|^{p-2} y, x - y \right) \geq \frac{1}{2} \left( \frac{|x|^{p-2} + |y|^{p-2}}{|x - y|^{p-2}} \right) |x - y|^p$$

$$\geq \frac{1}{2} \frac{1}{2^{(p-2)-(1/m)}} |x - y|^p \geq \frac{1}{2^{p-1}} |x - y|^p \quad \blacksquare$$

### 23.3 Penalization And Projection Operators

In this section, $X$ will be a reflexive Banach space such that $X, X'$ has a strictly convex norm. Let $K$ be a closed convex set in $X$. Then the following lemma is obtained.

**Lemma 23.3.1** Let $K$ be closed and convex nonempty subset of $X$ a reflexive Banach space which has strictly convex norm. Then there exists a projection map $P$ such that $Px \in K$ and for all $y \in K$,

$$\|y - x\| \geq \|x - Px\|$$

**Proof**: Let $\{y_n\}$ be a minimizing sequence for $y \to \|y - x\|$ for $y \in K$. Thus

$$d \equiv \inf \{\|y - x\| : y \in K \} = \lim_{n \to \infty} \|y_n - x\|$$

Then obviously $\{y_n\}$ is bounded. Hence there is a subsequence, still denoted by $n$ such that $y_n \to w \in K$. Then

$$\|w - x\| \leq \lim_{n \to \infty} \|y_n - x\| = d$$

How many closest points to $x$ are there? Suppose $w_1$ is another one. Then

$$\left\| \frac{w_1 + w}{2} - x \right\| = \left\| \frac{w_1 - x + w - x}{2} \right\| < \left\| \frac{w_1 - x}{2} \right\| + \left\| \frac{w - x}{2} \right\| = d$$

contradicting the assumption that both $w, w_1$ are closest points to $x$. Therefore, $Px$ consists of a single point. $\blacksquare$

Denote by $F$ the duality map such that $\langle Fx, x \rangle = \|x\|^2$. This is described earlier but there is also a very nice treatment which is somewhat different in [12]. Everything can be generalized and is in [82] but here I will only consider this case. First here is a useful result.

**Proposition 23.3.2** Let $F$ be the duality map just described. Let $\phi(x) = \frac{\|x\|^2}{2}$. Then $F(x) = \partial \phi(x)$. 
Proof: This follows from
\[ \langle Fx, y - x \rangle \leq \langle Fx, y \rangle - \langle Fx, x \rangle \leq \langle Fx, x \rangle^{1/2} \langle Fy, y \rangle^{1/2} - \langle Fx, x \rangle \]
\[ \leq \frac{\langle Fy, y \rangle}{2} + \frac{\langle Fx, x \rangle}{2} = \frac{\|y\|^2}{2} - \frac{\|x\|^2}{2} \]
\[
\]
Next is a really nice result about the characterization of $Px$ in terms of $F$.

**Proposition 23.3.3** Let $K$ be a nonempty closed convex set in $X$ a reflexive Banach space in which both $X, X'$ have strictly convex norms. Then $w \in K$ is equal to $Px$ if and only if
\[ \langle F(x - w), y - w \rangle \leq 0 \]
for every $y \in K$.

Proof: First suppose the condition. Then for $y \in K$, it follows from the above proposition about the subgradient,
\[ \frac{1}{2} \|x - y\|^2 - \frac{1}{2} \|x - w\|^2 \geq \langle F(x - w), w - y \rangle \geq 0 \]
and so since this holds for all $y$ it follows that
\[ \|x - y\| \geq \|x - w\| \]
for all $y$ which says that $w = Px$.

Next, using the subgradient idea again, for $\theta \in [0, 1]$, suppose $w = Px$ then for $y \in K$ arbitrary,
\[ 0 \geq \frac{1}{2} \|x - w\|^2 - \frac{1}{2} \|x - (w + \theta (y - w))\|^2 \geq \langle F(x - (w + \theta (y - w))), \theta (y - x) \rangle \]
Now divide by $\theta$ and let $\theta \downarrow 0$ and use the hemicontinuity of $F$ given above. Then
\[ 0 \geq \langle F(x - w), y - x \rangle \]

**Definition 23.3.4** An operator of penalization is an operator $f : X \to X'$ such that $f = 0$ on $K$, $f$ is monotone and nonzero off $K$ as well as demicontinuous. (Strong convergence goes to weak convergence.) Actually, in applications, it is usually easy to give an ad hoc description of an appropriate penalization operator.

**Proposition 23.3.5** Let $K$ be a closed convex nonempty subset of $X$ a reflexive Banach space such that $X, X'$ have strictly convex norms. Then
\[ f(x) = F(x - Px) \]
is an operator of penalization. Here $P$ is the projection onto $K$. 
**Proof:** First, observe that $f(x)$ is 0 on $K$ and nonzero off $K$. Why is it monotone?

$$\langle F(x - Px) - F(x_1 - Px_1), x - x_1 \rangle$$

$$= \langle F(x - Px) - F(x_1 - Px_1), x - Px - (x_1 - Px_1) \rangle$$

$$+ \langle F(x - Px) - F(x_1 - Px_1), Px - Px_1 \rangle$$

The first term is $\geq 0$ because $F$ is monotone. As to the second, it equals

$$\langle F(x - Px), Px - Px_1 \rangle + \langle F(x_1 - Px_1), Px_1 - Px \rangle$$

and both of these are $\geq 0$ because of Proposition 23.3.3 which characterizes the projection map.

Now why is this hemicontinuous? Let $x_n \to x$. Then $Px_n$ is clearly bounded. Taking a subsequence, it can be assumed that $Px_n \to \xi$ weakly. Is $\xi = Px$?

$$\|x - Px\| \leq \|x - Px_n\| \leq \|x - x_n\| + \|x_n - Px_n\|$$

$$\|x_n - Px_n\| \leq \|x_n - Px\| \leq \|x_n - x\| + \|x - Px\|$$

It follows that

$$\|x - Px\| - \|x_n - Px_n\| \leq \|x - x_n\|$$

$$\|x_n - Px_n\| - \|x - Px\| \leq \|x - x_n\|$$

Hence $\|x_n - Px_n\| \to \|x - Px\|$. However, from convexity and strong lower semicontinuity implying weak lower semicontinuity,

$$\|x - \xi\| \leq \liminf_{n \to \infty} \|x_n - Px_n\| = \|x - Px\|$$

and so $\xi = Px$ because there is only one value in $Px$. This has shown that, thanks to uniqueness of $Px$, $x_n \to x$ implies $Px_n \to Px$ weakly.

Next we show that $f$ is demicontinuous. Suppose $x_n \to x$. Then from what was just shown, $Px_n \to Px$ weakly. Thus $x_n - Px_n \to x - Px$ weakly. Then

$$\limsup_{n \to \infty} \langle F(x_n - Px_n), x_n - Px_n - (x - Px) \rangle$$

$$= \limsup_{n \to \infty} \langle F(x_n - Px_n), Px_n - Px \rangle \leq 0$$

from Proposition 23.3.3 which characterizes the projection map. It follows that, since $F$ is monotone hemicontinuous and bounded, it is also pseudomonotone and so for all $v$

$$\liminf_{n \to \infty} \langle F(x_n - Px_n), (x_n - Px_n) - v \rangle$$

$$\geq \langle F(x - Px), (x - Px) - v \rangle$$

Now $F(x_n - Px_n)$ is bounded. If it converges to $\xi$, then

$$\liminf_{n \to \infty} \langle F(x_n - Px_n), (x_n - Px_n) - v \rangle$$

\[
\leq \limsup_{n \to \infty} \left[ \langle F(x_n - Px_n), (x_n - Px_n) - (x - Px) \rangle \\
+ \langle F(x_n - Px_n), (x - Px) - v \rangle \right] \\
\leq \langle \xi, (x - Px) - v \rangle
\]

It follows that

\[
\langle \xi, (x - Px) - v \rangle \geq \liminf_{n \to \infty} \langle F(x_n - Px_n), (x_n - Px_n) - v \rangle \\
\geq \langle F(x - Px), (x - Px) - v \rangle
\]

Since \( v \) is arbitrary, it follows that \( \xi = F(x - Px) \). Hence \( F(x_n - Px_n) \to F(x - Px) \) weakly. Thus this is demicontinuous. ■

### 23.4 Set-Valued Maps, Pseudomonotone Operators

In the abstract theory of partial differential equations and variational inequalities, it is important to consider set-valued maps from a Banach space to the power set of its dual. In this section we give an introduction to this theory by proving a general result on surjectivity for a class of such operators.

To begin with, if \( A : X \to P(Y) \) is a set-valued map, define the graph of \( A \) by

\[
G(A) = \{(x, y) : y \in Ax\}.
\]

First consider a map \( A \) which maps \( C^n \) to \( P(C^n) \) which satisfies

\[
Ax \text{ is compact and convex.} \tag{23.4.11}
\]

and also the condition that if \( O \) is open and \( O \supseteq Ax \), then there exists \( \delta > 0 \) such that if

\[
y \in B(x, \delta), \text{ then } Ay \subseteq O. \tag{23.4.12}
\]

This last condition is sometimes referred to as upper semicontinuity. In words, \( A \) is upper semicontinuous and has values which are compact and convex. As to the last condition of upper semicontinuity, here is the formal definition.

**Definition 23.4.1** Let \( F : X \to P(Y) \) be a set valued function. Then \( F \) is upper semicontinuous at \( x \) if for every open \( V \supseteq F(x) \) there exists an open set \( U \) containing \( x \) such that whenever \( \tilde{x} \in U \), it follows that \( F(\tilde{x}) \subseteq V \).

**Lemma 23.4.2** Let \( A \) satisfy \(\ref{23.4.12} \). Then \( AK \) is a subset of a compact set whenever \( K \) is compact. Also the graph of \( A \) is closed if \( Ax \) is closed.

**Proof:** Let \( x \in K \). Then \( Ax \) is compact and contained in some open set whose closure is compact, \( U_x \). By assumption \(\ref{23.4.12} \) there exists an open set \( V_x \) containing \( x \) such that if \( y \in V_x \), then \( Ay \subseteq U_x \). Let \( V_{x_1}, \ldots, V_{x_m} \) cover \( K \). Then \( AK \subseteq \cup_{k=1}^m U_{x_k} \), a compact set.
To see the graph of \( A \) is closed when \( Ax \) is closed, let \( x_k \to x, y_k \to y \) where \( y_k \in Ax_k \). Then letting \( O = Ax+B(0,r) \) it follows from \ref{lem:open} that \( y_k \in Ax_k \subseteq O \) for all \( k \) large enough. Therefore, \( y \in Ax+B(0,2r) \) and since \( r > 0 \) is arbitrary and \( Ax \) is closed it follows \( y \in Ax \). ■

Also, there is a general consideration relative to upper semicontinuous functions.

**Lemma 23.4.3** If \( f \) is upper semicontinuous on some set \( K \) and \( g \) is continuous and defined on \( f(K) \), then \( g \circ f \) is also upper semicontinuous.

**Proof:** Let \( x_n \to x \) in \( K \). Let \( U \supseteq g \circ f (x) \). Is \( g \circ f (x_n) \in U \) for all \( n \) large enough? We have \( f(x) \in g^{-1}(U) \), an open set. Therefore, if \( n \) is large enough, \( f(x_n) \in g^{-1}(U) \). It follows that for large enough \( n \), \( g \circ f (x_n) \in U \) and so \( g \circ f \) is upper semicontinuous on \( K \). ■

The next theorem is an application of the Brouwer fixed point theorem. First define an \( n \) simplex, denoted by \([x_0,\ldots,x_n]\), to be the convex hull of the \( n+1 \) points, \( \{x_0,\ldots,x_n\} \) where \( \{x_i-x_0\}_{i=1}^n \) are independent. Thus

\[
[x_0,\ldots,x_n] = \left\{ \sum_{i=0}^{n} t_i x_i : \sum_{i=0}^{n} t_i = 1, \ t_i \geq 0 \right\}.
\]

Since \( \{x_i-x_0\}_{i=1}^n \) is independent, the \( t_i \) are uniquely determined. If two of them are

\[
\sum_{i=0}^{n} t_i x_i = \sum_{i=0}^{n} s_i x_i
\]

Then

\[
\sum_{i=0}^{n} t_i (x_i - x_0) = \sum_{i=0}^{n} s_i (x_i - x_0)
\]

so \( t_i = s_i \) for \( i \geq 1 \). Since the \( s_i \) and \( t_i \) sum to 1, it follows that also \( s_0 = t_0 \). If \( n \leq 2 \), the simplex is a triangle, line segment, or point. If \( n \leq 3 \), it is a tetrahedron, triangle, line segment, or point. To say that \( \{x_i-x_0\}_{i=1}^n \) are independent is to say that \( \{x_i-x_0\}_{i \neq r} \) are independent for each fixed \( r \). Indeed, if \( x_i - x_r = \sum_{j \neq i,r} c_j (x_j - x_r) \), then you would have

\[
x_i - x_0 + x_0 - x_r = \sum_{j \neq i,r} c_j (x_j - x_0) + \left( \sum_{j \neq i,r} c_j \right) x_0
\]

and it follows that \( x_i - x_0 \) is a linear combination of the \( x_j - x_0 \) for \( j \neq i \), contrary to assumption. A collection of simplices is a tiling of \( \mathbb{R}^n \) if \( \mathbb{R}^n \) is contained in their union and if \( S_1, S_2 \) are two simplices in the tiling, with

\[
S_j = [x_0^j,\ldots,x_n^j],
\]

then

\[
S_1 \cap S_2 = [x_0^1,\ldots,x_n^1]
\]
where
\[ \{ x_{k_0}, \ldots, x_{k_r} \} \subseteq \{ x_0^1, \ldots, x_n^1 \} \cap \{ x_0^2, \ldots, x_n^2 \} \]
or else the two simplices do not intersect. The collection of simplices is said to be locally finite if, for every point, there exists a ball containing that point which also intersects only finitely many of the simplices in the collection. It is left to the reader to verify that for each \( \varepsilon > 0 \), there exists a locally finite tiling of \( \mathbb{R}^n \) which is composed of simplices which have diameters less than \( \varepsilon \). The local finiteness ensures that for each \( \varepsilon \) the vertices have no limit point. To see how to do this, consider the case of \( \mathbb{R}^2 \). Tile the plane with identical small squares and then form the triangles indicated in the following picture. It is clear something similar can be done in any dimension. Making the squares identical ensures that the little triangles are locally finite.

In general, you could consider \([0, 1]^n\). The point at the center is \((1/2, \cdots, 1/2)\). Then there are \(2n\) faces. Form the \(2n\) pyramids having this point along with the \(2^{n-1}\) vertices of the face. Then use induction on each of these faces to form smaller dimensional simplices tiling that face. Corresponding to each of these \(2n\) pyramids, it is the union of the simplices whose vertices consist of the center point along with those of these new simplices tiling the chosen face. In general, you can write any \(n\) dimensional cube as the translate of a scaled \([0, 1]^n\). Thus one can express each of identical cubes as a tiling of \(m(n)\) simplices of the appropriate size and thereby obtain a tiling of \(\mathbb{R}^n\) with simplices. A ball will intersect only finitely many of the cubes and hence finitely many of the simplices. To get their diameters small as desired, just use \([0, r]^n\) instead of \([0, 1]^n\).

Thus one can give a function any value desired on these vertices and extend appropriately to the rest of the simplex and obtain a continuous function.

The Kakutani fixed point theorem is a generalization of the Brouwer fixed point theorem from continuous single valued maps to upper semicontinuous maps which have closed convex values.

**Theorem 23.4.4** Let \(K\) be a compact convex subset of \(\mathbb{R}^n\) and let \(A : K \to \mathcal{P}(K)\) such that \(Ax\) is a closed convex subset of \(K\) and \(A\) is upper semicontinuous. Then there exists \(x\) such that \(x \in Ax\). This is the “fixed point”.

**Proof:** Let there be a locally finite tiling of \(\mathbb{R}^n\) consisting of simplices having diameter no more than \(\varepsilon\). Let \(Px\) be the point in \(K\) which is closest to \(x\). For each vertex \(x_k\), pick \(A_x x_k \in Ap x_k\) and define \(A_x\) on all of \(\mathbb{R}^n\) by the following rule. If
\[ x \in [x_0, \ldots, x_n], \]
23.4. SET-VALUED MAPS, PSEUDOMONOTONE OPERATORS

so \( x = \sum_{i=0}^{n} t_i x_i, t_i \in [0,1], \sum_i t_i = 1, \) then

\[ A_x x \equiv \sum_{k=0}^{n} t_k A_x x_k. \]

Now by construction \( A_x x_k \in AP x_k \in K \) and so \( A_x \) is a continuous map defined on \( \mathbb{R}^n \) with values in \( K \) thanks to the local finiteness of the collection of simplices. By the Brouwer fixed point theorem \( A_x \) has a fixed point \( x_\varepsilon \) in \( K \), \( A_x x_\varepsilon = x_\varepsilon \).

\[ x_\varepsilon = \sum_{k=0}^{n} t_k^\varepsilon A_x x_k^\varepsilon, \ A_x x_k^\varepsilon \in AP x_k^\varepsilon \in K \]

where a simplex containing \( x_\varepsilon \) is

\[ [x_0^\varepsilon, \ldots, x_n^\varepsilon], \ x_\varepsilon = \sum_{k=0}^{n} t_k^\varepsilon x_k^\varepsilon \]

Also, \( x_\varepsilon \in K \) and is closer than \( \varepsilon \) to each \( x_k^\varepsilon \) so each \( x_k^\varepsilon \) is within \( \varepsilon \) of \( K \). It follows that for each \( k \), \( |P x_k^\varepsilon - x_k^\varepsilon| < \varepsilon \) and so

\[ \lim_{\varepsilon \to 0} |P x_k^\varepsilon - x_k^\varepsilon| = 0 \]

By compactness of \( K \), there exists a subsequence, still denoted with the subscript of \( \varepsilon \) such that for each \( k \), the following convergences hold as \( \varepsilon \to 0 \)

\[ t_k^\varepsilon \to t_k, \ A_x x_k^\varepsilon \to y_k, \ P x_k^\varepsilon \to z_k, \ x_k^\varepsilon \to z_k \]

Any pair of the \( x_k^\varepsilon \) are within \( \varepsilon \) of each other. Hence, any pair of the \( P x_k^\varepsilon \) are within \( \varepsilon \) of each other because \( P \) reduces distances. Therefore, in fact, \( z_k \) does not depend on \( k \).

\[ \lim_{\varepsilon \to 0} P x_k^\varepsilon = \lim_{\varepsilon \to 0} x_k^\varepsilon = z, \ \lim_{\varepsilon \to 0} x_\varepsilon = \lim_{\varepsilon \to 0} \sum_{k=0}^{n} t_k^\varepsilon x_k^\varepsilon = \sum_{k=0}^{n} t_k z = z \]

By upper semicontinuity of \( A \), for all \( \varepsilon \) small enough,

\[ AP x_k^\varepsilon \subseteq Az + B (0, r) \]

In particular, since \( A_x x_k^\varepsilon \in AP x_k^\varepsilon \),

\[ A_x x_k^\varepsilon \in Az + B (0, r) \] for \( \varepsilon \) small enough

Since \( r \) is arbitrary and \( Az \) is closed, it follows

\[ y_k \in Az. \]

It follows that since \( K \) is closed,

\[ x_\varepsilon \to z = \sum_{k=0}^{n} t_k y_k, \ t_k \geq 0, \sum_{k=0}^{n} t_k = 1 \]
Now by convexity of $Az$ and the fact just shown that $y_k \in Az$,

$$z = \sum_{k=0}^{n} t_k y_k \in Az$$

and so $z \in Az$. This is the fixed point.

One can replace $\mathbb{R}^n$ with $\mathbb{C}^n$ in the above theorem because it is essentially $\mathbb{R}^{2n}$. Also the theorem holds with no change for any finite dimensional normed linear space since these are homeomorphic to $\mathbb{R}^n$ or $\mathbb{C}^n$.

**Lemma 23.4.5** Suppose $A : \mathbb{C}^n \to \mathcal{P}(\mathbb{C}^n)$ satisfies $Ax$ is compact and convex, and $A$ is upper semicontinuous, and $K$ is a nonempty compact convex set in $\mathbb{C}^n$. Then if $y \in \mathbb{C}^n$ there exists $[x, w] \in G(A)$ such that $x \in K$ and

$$\Re(y - w, z - x) \leq 0$$

for all $z \in K$.

**Proof:** Tile $\mathbb{C}^n$ with $2n$ simplices such that the collection is locally finite and each simplex has diameter less than $\varepsilon < 1$. This collection of simplices is determined by a countable collection of vertices. For each vertex $x$, pick $A_x \in AX$ and define $A_x$ on all of $\mathbb{C}^n$ by the following rule. If

$$x \in [x_0, \ldots, x_{2n}],$$

so $x = \sum_{i=0}^{2n} t_i x_i$, then

$$A_x x \equiv \sum_{k=0}^{2n} t_k A_x x_k.$$ 

Thus $A_x$ is a continuous map defined on $\mathbb{C}^n$ thanks to the local finiteness of the collection of simplices. Let $P_K$ denote the projection on the convex set $K$. By the Brouwer fixed point theorem, there exists a fixed point, $x_\varepsilon \in K$ such that

$$P_K (y - A_x x_\varepsilon + x_\varepsilon) = x_\varepsilon.$$ 

By Corollary 17.1.9 this requires

$$\Re(y - A_x x_\varepsilon, z - x_\varepsilon) \leq 0$$

for all $z \in K$.

Suppose $x_\varepsilon \in [x_0, \ldots, x_{2n}]$ so $x_\varepsilon = \sum_{k=0}^{2n} t_k^\varepsilon x_k^\varepsilon$. Then since $x_\varepsilon$ is contained in $K$, a compact set, and the diameter of each simplex is less than 1, it follows that $A_x x_\varepsilon$ is contained in $A(K + B(0,1))$, which is contained in a compact set thanks to Lemma 23.4.2. The reason is that $A$ is assumed to take bounded sets to bounded sets and $K + B(0,1)$ is a bounded set.

From the Heine Borel theorem, there exists a sequence $\varepsilon \to 0$ such that

$$t_k^\varepsilon \to t_k, x_\varepsilon \to x \in K, A_x x_\varepsilon \to y_k$$
for \( k = 0, \ldots, 2n \). Since the diameter of the simplex containing \( x_e \) converges to 0, it follows

\[
x^e_k \to x, \quad A^e x^e_k \to y_k.
\]

By upper semicontinuity, it follows that for all \( r > 0 \), \( A^e x^e_k \subseteq A^e x + B(0, r) \) for all \( \varepsilon \) small enough. Since \( A^e x^e_k \in A^e x^e_k \), and \( A^e x \) is closed, this implies \( y_k \in A^e x \). Since \( A^e x \) is convex,

\[
\sum_{k=1}^{2n} t_k y_k \in A^e x.
\]

Hence for all \( z \in K \),

\[
\Re \left( y - \sum_{k=1}^{2n} t_k y_k, z - x \right) = \lim_{\varepsilon \to 0} \Re \left( y - \sum_{k=1}^{2n} t_k^e A^e x^e_k, z - x \right)
\]

\[
= \lim_{\varepsilon \to 0} \Re \left( y - A^e x_e, z - x_e \right) \leq 0.
\]

Let \( w = \sum_{k=1}^{2n} t_k y_k \). □

You could replace \( A \) with \( A \circ P_K \) in the above and assume only that \( A \) is only defined on \( K \). This is because \( x \in K \).

**Lemma 23.4.6** Suppose in addition to 23.4.11 and 23.4.12 (compact convex valued and upper semicontinuous) \( A \) is coercive,

\[
\lim_{|x| \to \infty} \inf \left\{ \frac{\Re (y, x)}{|x|} : y \in A^e x \right\} = \infty.
\]

Then \( A \) is onto.

**Proof:** Let \( y \in \mathbb{C}^n \) and let \( K_r = \overline{B(0, r)} \). By Lemma 23.4.6 there exists \( x_r \in K_r \) and \( w_r \in A^e x_r \) such that

\[
\Re (y - w_r, z - x_r) \leq 0
\]

for all \( z \in K_r \). Letting \( z = 0 \),

\[
\Re (w_r, x_r) \leq \Re (y, x_r).
\]

Therefore,

\[
\inf \left\{ \frac{\Re (w, x_r)}{|x_r|} : w \in A^e x_r \right\} \leq |y|.
\]

It follows from the assumption of coercivity that \( |x_r| \) is bounded independent of \( r \). Therefore, picking \( r \) strictly larger than this bound, 23.4.12 implies

\[
\Re (y - w_r, v) \leq 0
\]

for all \( v \) in some open ball containing \( 0 \). Therefore, for all \( v \) in this ball

\[
\Re (y - w_r, v) = 0
\]

and hence this holds for all \( v \in \mathbb{C}^n \) and so \( y = w_r \in A^e x_r \). This proves the lemma.
Lemma 23.4.7 Let $F$ be a finite dimensional Banach space of dimension $n$, and let $T$ be a mapping from $F$ to $\mathcal{P}(F')$ such that (23.4.11) and (23.4.12) both hold for $F'$ in place of $\mathbb{C}^n$. Then if $T$ is also coercive,
\[
\lim_{||u|| \to \infty} \inf \left\{ \frac{\text{Re} y^*(u)}{||u||} : y^* \in T u \right\} = \infty, \tag{23.4.14}
\]
it follows $T$ is onto.

Proof: Let $|\cdot|$ be an equivalent norm for $F$ such that there is an isometry of $\mathbb{C}^n$ and $F, \theta$. Now define $A : \mathbb{C}^n \to \mathcal{P}(\mathbb{C}^n)$ by $Ax \equiv \theta^* T \theta x$.

Thus $y \in Ax$ means that there exists $z^* \in T \theta x$ such that
\[
(w, y)_{\mathbb{C}^n} = z^*(\theta w)
\]
for all $w \in \mathbb{C}^n$. Then $A$ satisfies the conditions of Lemma 23.4.7 and so $A$ is onto. Consequently $T$ is also onto. □

With these lemmas, it is possible to prove a very useful result about a class of mappings which map a reflexive Banach space to the power set of its dual space. For more theorems about these mappings and their applications, see [90]. In the discussion below, we will use the symbol, $\rightharpoonup$, to denote weak convergence.

Definition 23.4.8 Let $V$ be a reflexive Banach space. We say $T : V \to \mathcal{P}(V')$ is pseudomonotone if the following conditions hold.

$Tu$ is closed, nonempty, convex. \hspace{1cm} (23.4.15)

If $F$ is a finite dimensional subspace of $V$, then if $u \in F$ and $W \supseteq Tu$ for $W$ a weakly open set in $V'$, then there exists $\delta > 0$ such that
\[
v \in B(u, \delta) \cap F \text{ implies } Tv \subseteq W. \tag{23.4.16}
\]

If $u_k \rightharpoonup u$ and if $u_k^* \in Tu_k$ is such that
\[
\limsup_{k \to \infty} \text{Re } u_k^*(u_k - u) \leq 0,
\]
then for all $v \in V$, there exists $u^*(v) \in Tu$ such that
\[
\lim_{k \to \infty} \inf_{u_k} \text{Re } u_k^*(u_k - v) \geq \text{Re } u^*(v)(u - v). \tag{23.4.17}
\]

We say $T$ is coercive if
\[
\lim_{||v|| \to \infty} \inf \left\{ \frac{\text{Re } z^*(v)}{||v||} : z^* \in Tv \right\} = \infty. \tag{23.4.18}
\]
In the case that $T$ takes bounded sets to bounded sets so it is a bounded set valued operator, it turns out you don’t have to consider the second of the above conditions about the upper semicontinuity. It follows from the other conditions. It is convenient to use the notation
\[
\langle u^*, v \rangle = u^*(v), \quad u^* \in V', \quad v \in V.
\]
and this will be used interchangably with the earlier notation from now on.

The next lemma has to do with upper semicontinuity being obtained from simpler conditions.

**Lemma 23.4.9** Let $T : X \to P(X')$ satisfy conditions [23.4.15] and [23.4.17] above and suppose $T$ is bounded ($Tx$ for $x$ in a bounded set is bounded). Then if $x_n \to x$ in $X$, and if $U$ is a weakly open set containing $Tx$, then $Tx_n \subseteq U$ for all $n$ large enough. If fact the limit condition [23.4.17] can be weakened to the following more general condition: If $u_k \rightharpoonup u$, and
\[
\limsup_{k \to \infty} \Re u^*_k (u_k - u) \leq 0, \tag{**}
\]
then there exists a subsequence still denoted as $\{u_k\}$, such that if $u_k^* \in Tu_k$, then for all $v \in V$, there exists $u^*(v) \in Tu$ such that
\[
\liminf_{k \to \infty} \Re u^*_k (u_k - v) \geq \Re u^*(v) (u - v). \tag{23.4.19}
\]
(This weaker condition says that if the lim sup condition holds for the original sequence, then there is a subsequence such that the lim inf condition holds for all $v$. In particular, for this subsequence, the lim sup condition continues to hold.)

**Proof:** If this is not true, there exists $x_n \to x$, also a weakly open set $U$, containing $Tx$ and $z_n \in Tx_n$, but $z_n \notin U$. Then, taking a further subsequence, we can assume $z_n \to z$ weakly and $z \notin U$. Then the strong convergence implies
\[
\limsup_{n \to \infty} \Re \langle z_n, x_n - x \rangle \leq 0
\]
By assumption, there is a subsequence still denoted with $n$ such that for any $y$,
\[
\liminf_{k \to \infty} \Re \langle z_n, x_n - y \rangle \geq \Re \langle z(y), x - y \rangle, \quad \text{some } z(y) \in T(x)
\]
Then in particular, for this subsequence,
\[
0 \geq \limsup_{n \to \infty} \Re \langle z_n, x_n - x \rangle \geq \liminf_{n \to \infty} \Re \langle z_n, x_n - x \rangle \geq \Re \langle z(x), x - x \rangle = 0
\]
so for this subsequence,
\[
\lim_{n \to \infty} \Re \langle z_n, x_n - x \rangle = 0
\]
Therefore, if $y \in X$ there exists $z(y) \in Tx$ such that
\[
\Re \langle z, x - y \rangle = \liminf_{n \to \infty} \Re \langle z_n, x_n - y \rangle \geq \Re \langle z(y), x - y \rangle.
\]
Letting \( w = x - y \), this shows, since \( y \in X \) is arbitrary, that the following inequality holds for every \( w \in X \). (If you have \( w \in X \), then you just choose \( y = x - w \).)

\[
\text{Re}\langle z, w \rangle \geq \text{Re}\langle z (x - w), w \rangle, \quad z (x - w) \in Tx.
\]

In particular, we may replace \( w \) with \(-w\) and obtain

\[
\text{Re}\langle z, -w \rangle \geq \text{Re}\langle z (x + w), -w \rangle,
\]

which implies

\[
\text{Re}\langle z (x - w), w \rangle \leq \text{Re}\langle z, w \rangle \leq \text{Re}\langle z (x + w), w \rangle.
\]

Therefore, there exists, \( \lambda \in [0, 1] \),

\[
z_\lambda (y) \equiv \lambda z (x - w) + (1 - \lambda) z (x + w) \in Ax
\]

such that

\[
\text{Re}\langle z, w \rangle = \text{Re}\langle z_\lambda (y), w \rangle.
\]

But this is a contradiction to \( z \notin Tx \) because if \( z \notin Tx \), it follows from separation theorems there exists \( w \in X \) such that for all \( z_1 \in Tx \),

\[
\text{Re}\langle z, w \rangle > \text{Re}\langle z_1, w \rangle.
\]

You pick that \( w \) in the above. Therefore, \( z \in Tx \) which contradicts the assumption that \( z_n \) and consequently \( z \) are not contained in \( U \).

What if \( T : V \to \mathcal{P}(V') \) for \( V \) a finite dimensional vector space such that \( T \) is upper semicontinuous and bounded? If \( u_n \to u \) weakly, then this also happens strongly because the weak convergence and strong convergence are the same in finite dimensions. Therefore, by upper semicontinuity, there is a subsequence still denoted with \( n \) and \( z_n \in Tu_n \) such that \( z_n \to z \) for some \( z \). Then since \( Tu \) is closed, we must have \( z \in Tu \) thanks to upper semicontinuity. Then for this subsequence and arbitrary \( v \),

\[
\liminf_{n \to \infty} \text{Re} z_n (u_n - v) = \text{Re} z (u - v)
\]

Also, this limit condition holds whenever \( u_n \to u \) and \( z_n \to z \) even without an assumption that \( T \) is bounded. This mostly proves the following.

**Proposition 23.4.10** Let \( V \) be finite dimensional and let \( T : V \to \mathcal{P}(V) \) be upper semicontinuous with closed values. Then if \( u_n \to u \) and \( z_n \in Tu_n \) with \( z_n \to z \), then

\[
\liminf_{n \to \infty} \text{Re} z_n (u_n - v) = \text{Re} z (u - v), \quad z \in Tu
\]

If \( T \) is bounded, and \( u_n \to u \), then if \( v \) is given,

\[
\liminf_{n \to \infty} \text{Re} z_n (u_n - v) = \text{Re} z (u - v), \quad \text{some } z \in Tu
\]
23.4. SET-VALUED MAPS, PSEUDOMONOTONE OPERATORS

Proof: Consider the last claim and suppose the limit condition does not hold for some \( v \). Then take a subsequence such that

\[
\lim \inf_{n \to \infty} \Re z_n(u_n - v) = \lim_{n \to \infty} \Re z_n(u_n - v)
\]

By boundedness, there is a further subsequence such that \( z_n \to z \). Then from upper semicontinuity and \( Tu \) being closed, \( z \in Tu \) and so

\[
\lim_{n \to \infty} \Re z_n(u_n - v) = \lim \inf_{n \to \infty} \Re z_n(u_n - v) = \Re z(u - v) \quad \blacksquare
\]

This more general limit condition is sometimes useful if not essential to use. The following is a definition of this more general condition used in the above lemma.

Definition 23.4.11 Say \( T : V \to \mathcal{P}(V') \) is modified bounded pseudomonotone if the following conditions hold.

\( Tu \) is closed, nonempty, convex. \hspace{1cm} (23.4.20)

\( T \) is bounded meaning it takes bounded sets to bounded sets.

If \( u_k \rightharpoonup u \) and if

\[
\lim \sup_{k \to \infty} \Re u_k^*(u_k - u) \leq 0,
\]

then there exists a subsequence, still denoted as \( \{u_k\} \) such that if \( u_k^* \in Tu_k \) then for all \( v \in V \), there exists \( u^*(v) \in Tu \) such that

\[
\lim \inf_{k \to \infty} \Re u_k^*(u_k - v) \geq \Re u^*(v)(u - v). \hspace{1cm} (23.4.21)
\]

In this limit condition, there is a subsequence which works for all \( v \). However, the preservation of lower semicontinuity happens under even less.

Definition 23.4.12 Say \( T : V \to \mathcal{P}(V') \) is generalized bounded pseudomonotone if the following conditions hold.

\( Tu \) is closed, nonempty, convex. \hspace{1cm} (23.4.22)

\( T \) is bounded meaning it takes bounded sets to bounded sets.

If \( u_k \rightharpoonup u \) and if

\[
\lim \sup_{k \to \infty} \Re u_k^*(u_k - u) \leq 0,
\]

then if \( v \) is given there exists a subsequence, still denoted as \( \{u_k\} \) possibly depending on \( v \) such that if \( u_k^* \in Tu_k \) then, there exists \( u^*(v) \in Tu \) such that

\[
\lim \inf_{k \to \infty} \Re u_k^*(u_k - v) \geq \Re u^*(v)(u - v). \hspace{1cm} (23.4.23)
\]

This is more general because in this situation, the subsequence depends on the choice of \( v \).
In case $T$ is single valued, this condition is equivalent to type M.

**Proposition 23.4.13** A single valued bounded operator $T : V \to V'$, $V$ reflexive is generalized bounded pseudomonotone then it is bounded and type M.

**Proof:** Suppose that $u_n \to u$ weakly and $Tu_n \to \xi$ weakly and $\limsup_{n \to \infty} \langle Tu_n, u_n \rangle \leq \langle \xi, u \rangle$. Then

$$\limsup_{n \to \infty} \langle Tu_n, u_n - u \rangle \leq 0$$

and so there is a subsequence depending on $v$ and a further one depending on $u$ such that

$$\liminf_{n \to \infty} \langle Tu_n, u_n - v \rangle \geq \langle Tu, u - v \rangle$$

The first in the above shows with the lim sup condition that $\lim_{n \to \infty} \langle Tu_n, u_n - u \rangle = 0$. Therefore, the second condition implies

$$\langle \xi, u - v \rangle \geq \langle Tu, u - v \rangle$$

since $v$ is arbitrary, it follows that $\xi = Tu$. Thus $T$ is type M. ■

If $T$ is generalized bounded pseudomonotone, then it is upper semicontinuous from the strong to the weak topology.

**Lemma 23.4.14** Let $T : X \to \mathcal{P}(X')$ satisfy conditions 23.4.12 and 23.4.17 above and suppose $T$ is bounded. Then if $x_n \to x$ in $X$, and if $U$ is a weakly open set containing $Tx$, then $Tx_n \subseteq U$ for all $n$ large enough. If fact the limit condition 23.4.14 can be weakened to the following more general condition: If $u_k \to u$, and

$$\limsup_{k \to \infty} \Re u_k^*(u_k - u) \leq 0,$$  

then for each $v$, there exists a subsequence still denoted as $\{u_k\}$, possibly depending on $v$ such that if $u_k^* \in T u_k$, then there exists $u^*(v) \in Tu$ such that

$$\liminf_{k \to \infty} \Re u_k^*(u_k - v) \geq \Re u^*(v)(u - v).$$  

(23.4.24)

(This weaker condition says that if the lim sup condition holds for the original sequence, then for given $v$ there is a subsequence such that the lim inf condition holds for that $v$. In particular, for this subsequence, the lim sup condition continues to hold.)

**Proof:** If this is not true, there exists $x_n \to x$, and a weakly open set $U$, containing $Tx$ and $z_n \in Tx_n$, but $z_n \notin U$. Then, taking a further subsequence, we can assume $z_n \to z$ weakly and $z \notin U$. Then the strong convergence implies

$$\limsup_{n \to \infty} \Re \langle z_n, x_n - x \rangle \leq 0$$
23.5. **SUM OF PSEUDOMONOTONE OPERATORS**

By separation theorems, there exists \( w \) such that for all \( \hat{w} \in T(x) \),

\[
\text{Re} \langle z, w \rangle < \text{Re} \langle \hat{w}, w \rangle
\]

(*)

Thus, choose \( y \) such that \( w = x - y \). By assumption, there is a subsequence still denoted with \( n \) such that

\[
\liminf_{k \to \infty} \text{Re} \langle z_n, x_n - y \rangle \geq \text{Re} \langle z(y), x - y \rangle, \text{ some } z(y) \in T(x)
\]

\[
\liminf_{k \to \infty} \text{Re} \langle z_n, x_n - x \rangle \geq \text{Re} \langle z(x), x - x \rangle = 0, \text{ some } z(x) \in T(x)
\]

To get this subsequence, get one which goes with \( y \) and then note that the \( \limsup \) only gets smaller when you go to a subsequence. Hence you can apply the condition to get a further subsequence which goes with \( x \). By doing so, the \( \liminf \) condition for \( y \) is strengthened. Then in particular, for this subsequence,

\[
0 \geq \limsup_{n \to \infty} \text{Re} \langle z_n, x_n - x \rangle \geq \liminf_{n \to \infty} \text{Re} \langle z_n, x_n - x \rangle \geq \text{Re} \langle z(x), x - x \rangle = 0
\]

so for this subsequence,

\[
\lim \text{Re} \langle z_n, x_n - x \rangle = 0
\]

Therefore, from the assumed condition, there is a further subsequence such that

\[
\text{Re} \langle z, x - y \rangle = \liminf_{n \to \infty} \text{Re} \langle z_n, x_n - y \rangle \geq \text{Re} \langle z(y), x - y \rangle, \text{ } z(y) \in T(x)
\]

Since \( w = x - y \),

\[
\text{Re} \langle z, w \rangle \geq \text{Re} \langle z(y), w \rangle
\]

where \( z(y) \in Tx \). which contradicts *. Thus \( z \in U \) as claimed. ■

### 23.5 Sum Of Pseudomonotone Operators

One of the nice properties of pseudomonotone maps is that when you add two of them, you get another one. I will give a proof in the case that the two pseudomonotone maps are both bounded. It is probably true in general, but as just noted, it is less trouble to verify if you don’t have to worry about as many conditions. I will also assume the spaces are all real so it will not be necessary to constantly write the real part. Actually, we do a slightly more general version which says that a bounded pseudomonotone added to a modified bounded pseudomonotone is a modified bounded pseudomonotone. First is the theorem about the sum of two bounded set valued pseudomonotone operators.

**Theorem 23.5.1** Say \( A, B \) are set valued bounded pseudomonotone operators. Then their sum is also a set valued bounded pseudomonotone operator. Also, if \( u_n \to u \) weakly, \( z_n \to z \) weakly, \( z_n \in A(u_n) \), and \( w_n \to w \) weakly with \( w_n \in A(u_n) \), then if \( \limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0 \), it follows that

\[
\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle \geq \langle z(v) + w(v), u - v \rangle, \text{ } z(v) \in A(u), w(v) \in B(u),
\]

and \( z \in A(u), w \in B(u) \).
**Proof:** Say \( z_n \in A(u_n) \), \( w_n \in B(u_n) \), \( u_n \to u \) weakly and
\[ \limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0. \]

**Claim:** Both of \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \), \( \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \) are no larger than 0.

**Proof of the claim:** Suppose \( \limsup_{n \to \infty} \langle w_n, u_n - u \rangle = \delta > 0 \). Then take a subsequence such that the \( \limsup \) equals \( \lim \). The \( \limsup \) only gets smaller when you go to a subsequence. Thus, continuing to denote the subsequence with \( n \) we still have \( \limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0 \). But from the fact that we just took a subsequence for which the \( \limsup = \lim \),
\[ \limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \limsup_{n \to \infty} \langle z_n, u_n - u \rangle + \limsup_{n \to \infty} \langle w_n, u_n - u \rangle + \delta \leq 0 \]
and so \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle = -\delta < 0 \). Therefore by the limit condition,
\[ \liminf_{n \to \infty} \langle z_n, u_n - u \rangle \geq \langle z(u), u - u \rangle = 0 \]
and so \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \geq 0 \). Thus the claim is established. We have
\[ \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \leq 0, \quad \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0 \]
Thus we can apply the limit condition to the two operators separately. This refers to the original sequence now. If \( v \) is given, then
\[ \liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \quad \liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle \]
where \( w(v) \in B(u) \) and \( z(v) \in A(u) \). Thus
\[ \liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle \geq \liminf_{n \to \infty} \langle z_n, u_n - v \rangle + \liminf_{n \to \infty} \langle w_n, u_n - v \rangle \]
\[ \geq \langle w(v) + z(v), u - v \rangle \]
and \( w(v) + z(v) \in A(u) + B(u) \) which shows that the sum is pseudomonotone.

In addition, from the claim, we know that
\[ \liminf_{n \to \infty} \langle z_n, u_n - u \rangle \geq \langle z(u), u - u \rangle = 0, \]
similar for \( w_n \). Thus \( \liminf_{n \to \infty} \langle z_n, u_n - u \rangle \geq 0 \geq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \) so \( \lim_{n \to \infty} \langle z_n, u_n - u \rangle = 0 \), similar for \( \langle w_n, u_n - u \rangle \). Therefore, if \( z_n \to z \) weakly and \( w_n \to w \) weakly,
\[ \langle z, u - v \rangle = \lim_{n \to \infty} \langle z_n, u - v \rangle = \lim_{n \to \infty} \left[ \langle z_n, u - u_n \rangle + \langle z_n, u_n - v \rangle \right] \]
\[ \geq \liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle, \quad z(v) \in A(u) \]
23.5. SUM OF PSEUDOMONOTONE OPERATORS

It follows that $\langle z, u - v \rangle \geq \langle z(v), u - v \rangle$ for all $v$ which could be violated using separation theorems if $z$ is not in $A(u)$. Thus $z \in A(u)$. Similarly $w \in B(u)$.

The above is the main result but we can attempt to see what happens if one of the operators is only modified pseudomonotone.

Note that if $B$ is bounded pseudomonotone, then it is certainly modified bounded pseudomonotone.

Theorem 23.5.2 Suppose $A, B : X \to P(X')$ are both pseudomonotone and bounded. Then so is their sum. If $A$ is bounded pseudomonotone and $B$ is modified bounded pseudomonotone, then $A + B$ is modified bounded pseudomonotone.

Proof: It is clear that $Ax + Bx$ is closed and convex because this is true of both of the sets in the sum. It is also bounded because both terms in the sum are bounded. It only remains to verify the limit condition. Suppose then that

$$u_n \to u \text{ weakly}$$

Will the limit condition hold for $A + B$ when applied to this further subsequence? Suppose $z_n \in Ax_n, w_n \in Bx_n$ and

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0 \quad (23.5.25)$$

Is there a subsequence such that the $\liminf$ condition holds? From the above,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle + \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \quad (23.5.26)$$

and so, if the second term $\leq 0$, since $B$ is modified bounded pseudomonotone, there is a subsequence, still denoted with $n$ for which

$$\liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \; w(v) \in B(u) \quad (*)$$

for all $v$. In particular,

$$\liminf_{n \to \infty} \langle w_n, u_n - u \rangle \geq \langle w(u), u - u \rangle = 0$$

Hence you would have $\liminf_{n \to \infty} \langle w_n, u_n - u \rangle \geq 0 \geq \limsup_{n \to \infty} \langle w_n, u_n - u \rangle$ and so $\lim_{n \to \infty} \langle w_n, u_n - u \rangle = 0$ for this subsequence still denoted with $n$. Hence for this subsequence,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0$$

Then using that $A$ is bounded pseudomonotone, $\lim_{n \to \infty} \langle z_n, u_n - u \rangle = 0$ also. If follows for any $v$,

$$\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle$$
CHAPTER 23. NONLINEAR OPERATORS

Then from this it is routine to establish the modified pseudomonotone limit condition for the sum $A + B$. For the subsequence just described, still denoted with $n$,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0$$

and *. In fact, you would have for any $v$,

$$\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle, \ z(v) \in A(u)$$

$$\liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \ w(v) \in A(u)$$

Then you would get

$$\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle = \liminf_{n \to \infty} \left( \langle z_n, u_n - v \rangle + \langle w_n, u_n - v \rangle \right)$$

$$\geq \liminf_{n \to \infty} \langle z_n, u_n - v \rangle + \liminf_{n \to \infty} \langle w_n, u_n - v \rangle$$

$$\geq \langle z(v), u - v \rangle + \langle w(v), u - v \rangle$$

and $z(v) + w(v) \in (A + B)(u)$.

Returning to 23.5.26, the other case to consider is that

$$\limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0$$

Then in this case, the assumption that $A$ is pseudomonotone implies that for any $v$,

$$\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle, \ z(v) \in A(u) \quad (***)$$

No subsequence here. However, if you use a subsequence, the inequality is only strengthened. In particular,

$$0 \geq \liminf_{n \to \infty} \langle z_n, u_n - u \rangle = \langle z(u), u - u \rangle = 0 \geq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle$$

and so for the original sequence,

$$\lim_{n \to \infty} \langle z_n, u_n - u \rangle = 0.$$
and so for this subsequence, \( \lim_{n \to \infty} \langle w_n, u_n - u \rangle = 0 \). Then for this subsequence, it follows from *** and ****,

\[
\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle = \liminf_{n \to \infty} \left( \langle z_n, u_n - v \rangle + \langle w_n, u_n - v \rangle \right)
\geq \liminf_{n \to \infty} \langle z_n, u_n - v \rangle + \liminf_{n \to \infty} \langle w_n, u_n - v \rangle
\geq \langle z(v), u - v \rangle + \langle w(v), u - v \rangle
\]

We continue to be in the situation of 23.5.25 and we are asking for a subsequence such that the \( \liminf \) condition will hold for the subsequence. Suppose this \( \liminf \) condition is not obtained for any subsequence. The desired \( \liminf \) condition will hold for a subsequence if either \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \) or \( \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \) is \( \leq 0 \). This was shown above. Therefore, if there is no subsequence yielding the \( \liminf \) condition, you must have both of these strictly positive. Say \( \delta > 0 \) is smaller than both. Let \( n \) denote a subsequence such that

\[
\limsup_{n \to \infty} \langle z_n, u_n - u \rangle = \lim_{n \to \infty} \langle z_n, u_n - u \rangle > \delta > 0.
\]

If, for this new subsequence, \( \limsup_{n \to \infty} \langle w_n, u_n - u \rangle < 0 \), then, since the \( \limsup \) gets smaller for a subsequence,

\[
\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \lim_{n \to \infty} \langle z_n, u_n - u \rangle + \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \leq 0
\]
then you could apply the above argument and obtain a further subsequence for which the \( \liminf \) condition would hold for the sum. Thus, we must have for this new subsequence,

\[
\limsup_{n \to \infty} \langle w_n, u_n - u \rangle \geq 0.
\]

Then, using this subsequence,

\[
0 \geq \limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \geq \delta + \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \geq \delta
\]

which is a contradiction. Thus the \( \liminf \) condition must hold for some subsequence. In case both are bounded and pseudomonotone, things are easier. You don’t have to take a subsequence. ■

It is not entirely clear whether the sum of modified bounded pseudomonotone operators is modified bounded pseudomonotone. This is because when you go to a subsequence, the \( \limsup \) gets smaller and so it is not entirely clear whether the subsequence for \( A \) will continue to yield the limit condition if a further subsequence is taken.

In fact, you can add a bounded pseudomonotone to a generalized bounded pseudomonotone and get a generalized bounded pseudomonotone. The proof is just like the above and is given next.

**Theorem 23.5.3** Suppose \( A, B : X \to \mathcal{P}(X') \). If \( A \) is bounded pseudomonotone and \( B \) is generalized bounded pseudomonotone, then \( A + B \) is generalized bounded pseudomonotone.
**Proof:** It is clear that $Ax + Bx$ is closed and convex because this is true of both of the sets in the sum. It is also bounded because both terms in the sum are bounded. It only remains to verify the limit condition. Suppose then that 

$$u_n \to u \text{ weakly}$$

Will the limit condition hold for $A + B$ when applied to this further subsequence? Suppose $z_n \in Ax_n, w_n \in Bx_n$ and

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0$$

(23.5.27)

If $v$ is given, is there a subsequence such that the $\liminf$ condition holds? From the above,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle + \limsup_{n \to \infty} \langle w_n, u_n - u \rangle$$

(23.5.28)

and so, if the second term $\leq 0$, since $B$ is modified bounded pseudomonotone, there is a subsequence, still denoted with $n$ for which

$$\liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \quad w(v) \in B(u) \quad (*)$$

You just get a subsequence which works for $v$ and note that the $\limsup$ condition is only strengthened for the subsequence and then obtain a further subsequence which goes with $u$ to get the second condition along with the first. Note that $\liminf$ gets bigger when you go to a subsequence so if $(*)$ holds for the first subsequence, then it holds even better for the second.

Hence you would have, for this subsequence depending on $v$

$$\liminf_{n \to \infty} \langle w_n, u_n - u \rangle \geq 0 \geq \limsup_{n \to \infty} \langle w_n, u_n - u \rangle$$

and so $\lim_{n \to \infty} \langle w_n, u_n - u \rangle = 0$ for this subsequence still denoted with $n$. Hence for this subsequence,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0$$

Then using that $A$ is bounded pseudomonotone, $\lim_{n \to \infty} \langle z_n, u_n - u \rangle = 0$ also. If follows for any $v$,

$$\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle$$

Then from this it is routine to establish the modified pseudomonotone limit condition for the sum $A + B$. For the subsequence just described, still denoted with $n$,

$$\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0$$
and $\star$. In fact, you would have
\[
\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle, \ z(v) \in A(u)
\]
\[
\liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \ w(v) \in A(u)
\]
Then you would get
\[
\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle = \liminf_{n \to \infty} ((z_n, u_n - v) + (w_n, u_n - v)) \\
\geq \liminf_{n \to \infty} ((z_n, u_n - v)) + \liminf_{n \to \infty} ((w_n, u_n - v)) \\
\geq (z(v), u - v) + (w(v), u - v)
\]
and $z(v) + w(v) \in (A + B)(u)$.

Returning to 23.5.28, the other case to consider is that
\[
\limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0
\]
Then in this case, the assumption that $A$ is pseudomonotone implies that for any $v$,
\[
\liminf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle, \ z(v) \in A(u) \quad (***)
\]
No subsequence here. In particular,
\[
0 \geq \liminf_{n \to \infty} \langle z_n, u_n - u \rangle = (z(u), u - u) = 0 \geq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle
\]
and so for the original sequence,
\[
\lim_{n \to \infty} \langle z_n, u_n - u \rangle = 0.
\]
Then back to 23.5.28,
\[
\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \leq 0
\]
Now by assumption that $B$ is generalized bounded pseudomonotone, there is a subsequence, still denoted with $n$ such that for the given $v$,
\[
\liminf_{n \to \infty} \langle w_n, u_n - v \rangle \geq \langle w(v), u - v \rangle, \ w(v) \in B(u). \quad (****)
\]
Then taking a further subsequence to go with $u$ in the third inequality below, the first inequality is preserved and
\[
0 \geq \limsup_{n \to \infty} \langle w_n, u_n - u \rangle \geq \liminf_{n \to \infty} \langle w_n, u_n - u \rangle \geq \langle w(u), u - u \rangle = 0
\]
and so for this further subsequence, $\lim_{n \to \infty} \langle w_n, u_n - u \rangle = 0$. Then for this subsequence, it follows from $\star \star \star$, and $\star \star \star \star$,
\[
\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle = \liminf_{n \to \infty} ((z_n, u_n - v) + (w_n, u_n - v)) \\
\geq \liminf_{n \to \infty} ((z_n, u_n - v)) + \liminf_{n \to \infty} ((w_n, u_n - v)) \\
\geq (z(v), u - v) + (w(v), u - v)
\]
We continue to be in the situation of and we are asking for a subsequence such that the lim inf condition will hold for some subsequence depending on \( v \). Suppose this lim inf condition is not obtained for any subsequence. The desired lim inf condition will hold for a subsequence if either \( \lim sup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0 \) or \( \lim sup_{n \to \infty} \langle w_n, u_n - u \rangle \leq 0 \). This was shown above. Therefore, if there is no subsequence yielding the lim inf condition, you must have both of these strictly positive. Say \( \delta > 0 \) is smaller than both. Let \( n \) denote a subsequence such that
\[
\lim sup_{n \to \infty} \langle z_n, u_n - u \rangle = \lim_{n \to \infty} \langle z_n, u_n - u \rangle > \delta > 0.
\]
If, for this new subsequence, \( \lim sup_{n \to \infty} \langle w_n, u_n - u \rangle < 0 \), then, since the lim sup gets smaller for a subsequence,
\[
\lim sup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle = \lim_{n \to \infty} \langle z_n, u_n - u \rangle + \lim sup_{n \to \infty} \langle w_n, u_n - u \rangle \leq 0
\]
then you could apply the above argument and obtain a further subsequence for which the lim inf condition would hold for the sum. Thus, we must have for this new subsequence,
\[
\lim sup_{n \to \infty} \langle w_n, u_n - u \rangle \geq 0.
\]
Then, using this subsequence,
\[
0 \geq \lim sup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \geq \delta + \lim sup_{n \to \infty} \langle w_n, u_n - u \rangle \geq \delta
\]
which is a contradiction. Thus the lim inf condition must hold for some subsequence.

The following is mostly in \([90]\).

**Theorem 23.5.4** Let \( V \) be a reflexive Banach space and let \( T : V \to \mathcal{P}(V') \) be pseudomonotone, bounded, and coercive. Then \( T \) is onto. More generally, the same holds if \( T \) is modified or generalized bounded pseudomonotone and coercive.

**Proof:** The proof is for modified bounded pseudomonotone since this is more general. Let \( \mathcal{F} \) be the set of finite dimensional subspaces of \( V \) and let \( F \in \mathcal{F} \). Then define \( T_F \) as
\[
T_F \equiv i_F^* T_i F
\]
where here \( i_F \) is the identity map from \( F \) to \( V \). Then \( T_F \) satisfies the conditions of Lemma \([43.4]\) thanks to Lemma \([43.3.4] \) or Lemma \([43.3.3] \) and so \( T_F \) is onto \( \mathcal{P}(F') \). Let \( w^* \in V' \). Then since \( T_F \) is onto, there exists \( u_F \in F \) such that
\[
i_F^* w^* \in i_F^* T_i F u_F.
\]
Thus for each finite dimensional subspace \( F \), there exists \( u_F \in F \) such that for all \( v \in F \),
\[
\langle w^*, v \rangle = \langle u_F^*, v \rangle, \quad u_F^* \in Tu_F.
\]
(23.5.29)
Replacing \( v \) with \( u \) in \[23.5.29\],

\[
\langle u^*_F, u_F \rangle \over \|u_F\| = \langle w^*, u_F \rangle \over \|u_F\| = \|w^*\|.
\]

Therefore, the assumption that \( T \) is coercive implies \( \{u_F : F \in \mathcal{F}\} \) is bounded in \( V \). Now define

\[
W_F \equiv \cup \{u_{F'} : F' \supseteq F\}.
\]

Then \( W_F \) is bounded and if \( \overline{W_F} \equiv \) weak closure of \( W_F \), then

\[
\{W_F : F \in \mathcal{F}\}
\]

is a collection of nonempty weakly compact (since \( V \) is reflexive and the \( u_F \) were just shown bounded) sets having the finite intersection property because \( W_F \neq \emptyset \) for each \( F \). (If \( F_i, i = 1, \ldots, n \) are finite dimensional subspaces, let \( F \) be a finite dimensional subspace which contains all of these. Then \( W_F \neq \emptyset \) and \( W_F \subseteq \cap_{i=1}^n \overline{W_{F_i}} \).) Thus there exists

\[
u \in \cap \{W_F : F \in \mathcal{F}\}.
\]

I will show \( w^* \in Tu \). If \( w^* \notin Tu \), a closed convex set, there exists \( v \in V \) such that

\[
\text{Re} \langle w^*, u - v \rangle < \text{Re} \langle u^*, u - v \rangle \tag{23.5.30}
\]

for all \( u^* \in Tu \). This follows from the separation theorems. (These theorems imply there exists \( z \in V \) such that

\[
\text{Re} \langle w^*, z \rangle < \text{Re} \langle u^*, z \rangle
\]

for all \( u^* \in Tu \). Define \( u - v \equiv z \).)

Now let \( F \supseteq \{u, v\} \). Since \( u \in \overline{W_F} \), a weakly sequentially compact set, there exists a sequence, \( \{u_k\} \), such that

\[
u_k \rightharpoonup u, u_k \in W_F.
\]

Then since \( F \supseteq \{u, v\} \), there exists \( u_k^* \in Tu_k \) such that

\[
\langle u_k^*, u_k - u \rangle = \langle w^*, u_k - u \rangle.
\]

Therefore,

\[
\limsup_{k \to \infty} \text{Re} \langle u_k^*, u_k - u \rangle = \limsup_{k \to \infty} \text{Re} \langle w^*, u_k - u \rangle = 0.
\]

It follows by the assumption that \( T \) is modified bounded pseudomonotone or generalized bounded pseudomonotone and the pseudomonotone limit condition, a further subsequence corresponding to \( v \) such that the following holds for the \( v \) defined above in \[23.5.30\],

\[
\liminf_{k \to \infty} \text{Re} \langle u_k^*, u_k - v \rangle \geq \text{Re} \langle u^* (v), u - v \rangle, u^* (v) \in Tu.
\]
But since \( v \in F, \text{Re} \langle u^*_k, u_k - v \rangle = \text{Re} \langle w^*, u_k - v \rangle \) and so

\[
\lim \inf_{k \to \infty} \text{Re} \langle u^*_k, u_k - v \rangle = \lim \inf_{k \to \infty} \text{Re} \langle w^*, u_k - v \rangle = \text{Re} \langle w^*, u - v \rangle,
\]

so from Proposition 3.5.30, \( \text{Re} \langle w^*, u - v \rangle < \text{Re} \langle u^*, u - v \rangle \) for all \( u^* \in Tu \),

\[
\text{Re} \langle w^*, u - v \rangle = \lim \inf_{k \to \infty} \text{Re} \langle u^*_k, u_k - v \rangle \geq \text{Re} \langle u^* (v), u - v \rangle > \text{Re} \langle w^*, u - v \rangle,
\]
a contradiction. Thus, \( w^* \in Tu \).

This is likely a good place to put an extremely interesting convergence theorem. It is a version of one in Aubin and Cellina. It is a perfectly marvelous use of the fact that the weak and strong closures of a convex set are the same.

**Proposition 23.5.5** Let \( X, Y \) be Banach spaces, and let \( F : (0, T) \times X \to P(Y) \) be a multifunction such that

1. The values of \( F \) are nonempty, closed and convex subsets of \( Y \)
2. For a.e. \( t \in (0, T) \), \( F(t, \cdot) \) is upper semicontinuous from \( X \) into \( Y \) with the weak topology

Then let \( x_n : (0, T) \to X, y_n : (0, T) \to Y \) be measurable functions such that the sequence \( \{x_n\} \) converges a.e. on \( (0, T) \) to a function \( x : (0, T) \to X \) and \( y_n \) converges weakly in \( L^1(0, T; Y) \) to \( y \in L^1(0, T, Y) \). If \( y_n(t) \in F(t, x_n(t)) \) for all \( n \in \mathbb{N} \) and a.e. \( t \), then \( y(t) \in F(t, x(t)) \) for a.e. \( t \in (0, T) \).

**Proof:** It is given that \( y_n \to y \) weakly in \( L^1(0, T; Y) \). It is too bad that this does not confer pointwise convergence of some subsequence. However, what can be said is this:

\[
\text{weak closure of } \text{co} \left( \bigcup_{k=n}^{\infty} y_k \right) = \text{strong closure of } \text{co} \left( \bigcup_{k=n}^{\infty} y_k \right)
\]

Here co signifies the convex hull. Thus something is in \( \text{co} \left( \bigcup_{k=n}^{\infty} y_k \right) \) means it is of the form

\[
v_n = \sum_{k=n}^{\infty} c_k^n y_k \quad (*)
\]

where all but finitely many of the \( c_k^n \) are zero and they sum to 1, each being a number in \([0, 1]\). Now it is given that \( y \) is in the weak closure of \( \text{co} \left( \bigcup_{k=n}^{\infty} y_k \right) \). In fact \( y_n \) converges weakly to \( y \). Therefore, from the above observation, \( y \) is in the strong closure of \( \text{co} \left( \bigcup_{k=n}^{\infty} y_k \right) \). Let \( v_n \) be of the form in (*) and let it converge in \( L^1(0, T; Y) \) to \( y \). Then there is a subsequence, still denoted as \( v_n \) such that for a.e. \( t \),

\[
v_n(t) \to y(t) \quad \text{in } Y
\]

Pick such a \( t \).
23.6. GENERALIZED GRADIENTS

If \( y(t) \notin F(t, x(t)) \), there exist numbers \( k > l \) and \( y^* \in Y' \) such that
\[
\langle y^*, y(t) \rangle > k > l > \langle y^*, z \rangle \quad \text{for all } z \in F(t, x(t)).
\]
This follows from separation theorems due to the assumption that \( F(t, x(t)) \) is a closed convex set. Thus for all \( n \) large enough,
\[
\langle y^*, v_n(t) \rangle > k > l > \langle y^*, z \rangle \quad \text{for all } z \in F(t, x(t)).
\]
\[(**)
Let \( k - l > 2\varepsilon > 0 \). Consider
\[
F(t, x(t)) + B_{y^*}(0, \varepsilon)
\]
where the ball signifies all \( z \in Y \) such that
\[
|\langle y^*, z \rangle| < \varepsilon
\]
By the weak upper semicontinuity assumption of \( F(t, \cdot) \) and \( x_n(t) \to x(t) \), it follows that for \( k \) large enough,
\[
y_k(t) \in F(t, x_k(t)) \subseteq F(t, x(t)) + B_{y^*}(0, \varepsilon)
\]
Now \( v_n \) is a convex combination of \( y_k \) for \( k \geq n \) and so it follows that for \( n \) large enough,
\[
v_n(t) \in F(t, x(t)) + B_{y^*}(0, \varepsilon)
\]
which says that there exists \( z_n \in F(t, x(t)) \) such that
\[
|\langle y^*, v_n(t) \rangle - \langle y^*, z_n \rangle| < \varepsilon
\]
However, this is a contradiction to \( ** \) because it says two things are closer than \( \varepsilon \) and also farther than \( k - l > 2\varepsilon \). Thus \( y(t) \in F(t, x(t)) \). ■

It does not use that the measure space is Lebesgue measure on \([0, T]\) that I can see. I think it appears to work for \([0, T]\) replaced with \( \Omega \) and \( t \) replaced with \( \omega \in \Omega \) where \((\Omega, \mathcal{F}, \mu)\) is just some measure space.

23.6 Generalized Gradients

This is an interesting theorem, but one might wonder if there are easy to verify examples of such possibly set valued mappings. In what follows consider only real spaces because the essential ideas are included in this case which is also the case of most use in applications. Of course, you might with some justification, make the claim that the following is not really very easy to verify any more than the original definition.

**Definition 23.6.1** Let \( V \) be a real reflexive Banach space and let \( f : V \to \mathbb{R} \) be a locally Lipschitz function, meaning that \( f \) is Lipschitz near every point of \( V \) although \( f \) need not be Lipschitz on all of \( V \). Under these conditions,
\[
f^0(x, y) \equiv \lim_{\mu \to 0^+} \sup_{h \to 0} \frac{f(x + h + \mu y) - f(x + h)}{\mu} \quad \text{(23.6.31)}
\]
and $\partial f (x) \subseteq X'$ is defined by

$$\partial f (x) \equiv \{ x^* \in X' : x^* (y) \leq f^0 (x, y) \text{ for all } y \in X \}. \quad (23.6.32)$$

The set just described is called the generalized gradient. In \[23.6.31\] we mean the following by the right hand side.

$$\lim_{(r, \delta) \to (0, 0)} \sup \left\{ \frac{f (x + h + \mu y) - f (x + h)}{\mu} : \mu \in (0, r), h \in B (0, \delta) \right\}$$

I will show, following [90], that these generalized gradients of locally Lipschitz functions are sometimes pseudomonotone. First here is a lemma.

**Lemma 23.6.2** Let $f$ be as described in the above definition. Then $\partial f (x)$ is a closed, bounded, convex, and non empty subset of $V'$. Furthermore, for $x^* \in \partial f (x)$,

$$\| x^* \| \leq \text{Lip}_x (f). \quad (23.6.33)$$

**Proof:** It is left as an exercise to verify the assertions that $\partial f (x)$ is closed, and convex. It follows directly from the definition. To verify this set is bounded, let $\text{Lip}_x (f)$ denote a Lipschitz constant valid near $x \in V$ and let $x^* \in \partial f (x)$. Then choosing $y$ with $\| y \| = 1$ and $x^* (y) \geq \frac{1}{2} \| x^* \|$,\n
$$\frac{1}{2} \| x^* \| = x^* (y) \leq f^0 (x, y). \quad (23.6.34)$$

Also, for small $\mu$ and $h$,

$$\left| \frac{f (x + h + \mu y) - f (x + h)}{\mu} \right| \leq \text{Lip}_x (f) \| y \| = \text{Lip}_x (f).$$

Therefore, $f^0 (x, y) \leq \text{Lip}_x (f)$ and so \[23.6.34\] shows $\| x^* \| \leq 2 \text{Lip}_x (f)$.

The interesting part of this Lemma is that $\partial f (x) \neq \emptyset$. To verify this first note that the definition of $f^0$ implies that $y \mapsto f^0 (x, y)$ is a gauge function. Now fix $y \in V$ and define on $\mathbb{R} y$ a linear map $x^*_0$ by

$$x^*_0 (\alpha y) \equiv \alpha f^0 (x, y).$$

Then if $\alpha \geq 0$,

$$x^*_0 (\alpha y) = \alpha f^0 (x, y) = f^0 (x, \alpha y).$$

If $\alpha < 0$,

$$x^*_0 (\alpha y) \equiv \alpha f^0 (x, y) = \lim_{\mu \to 0^+} \inf_{h \to 0} \frac{(-\alpha) f (x + h) - (-\alpha) f (x + h + \mu y)}{\mu} = (-\alpha) \lim_{\mu \to 0^+} \inf_{h \to 0} \frac{f (x + h - \mu y) - f (x + h)}{\mu} \leq$$
23.6. GENERALIZED GRADIENTS

\((-\alpha) f^0 (x, -y) = f^0 (x, \alpha y)\).

Therefore, \(x^*_n (\alpha y) \leq f^0 (x, \alpha y)\) for all \(\alpha\). By the Hahn Banach theorem there is an extension of \(x^*_n\) to all of \(V\), \(x^*\) which satisfies,

\[ x^* (y) \leq f^0 (x, y) \]

for all \(y\). It remains to verify \(x^*\) is continuous. This follows easily from

\[ |x^* (y)| = \max (x^* (-y), x^* (y)) \leq \max (f^0 (x, y), f^0 (x, -y)) \leq \operatorname{Lip}_x (f) \|y\|, \]

which verifies \(\text{23.6.33}\) and proves the lemma.

This lemma has verified the first condition needed in the definition of pseudomonotone. The next lemma verifies that these generalized subgradients satisfy the second of the conditions needed in the definition. In fact somewhat more than is needed in the definition is shown.

**Lemma 23.6.3** Let \(U\) be weakly open in \(V'\) and suppose \(\partial f (x) \subseteq U\). Then \(\partial f (z) \subseteq U\) whenever \(z\) is close enough to \(x\).

**Proof:** Suppose to the contrary there exists \(z_n \to x\) but \(z^*_n \in \partial f (z_n) \setminus U\).

From the first lemma, we may assert that \(\|z^*_n\| \leq 2 \operatorname{Lip}_x (f)\) for all \(n\) large enough. Therefore, there is a subsequence, still denoted by \(n\) such that \(z^*_n\) converges weakly to \(z^* \notin U\).

**Claim:** \(f^0 (x, y) \geq \limsup_{n \to \infty} f^0 (x_n, y)\).

**Proof of the claim:** There exists \(\delta > 0\) such that if \(\mu, \|h\| < \delta\), then

\[ \varepsilon + f^0 (x, y) \geq \frac{f (x + h + \mu y) - f (x + h)}{\mu}. \]

Thus, for \(\|h\| < \delta\),

\[ \varepsilon + f^0 (x, y) \geq \frac{f (x_n + (x - x_n) + h + \mu y) - f (x_n + (x - x_n) + h)}{\mu}. \]

Now let \(\|h'\| < \frac{\delta}{2}\) and let \(n\) be so large that \(\|x - x_n\| < \frac{\delta}{2}\). Suppose \(\|h'\| < \frac{\delta}{2}\). Then choosing \(h \equiv h' - (x - x_n)\), it follows the above inequality holds because \(\|h\| < \delta\).

Therefore, if \(\|h'\| < \frac{\delta}{2}\), and \(n\) is sufficiently large,

\[ \varepsilon + f^0 (x, y) \geq \frac{f (x_n + h' + \mu y) - f (x_n + h')}{\mu}. \]

Consequently, for all \(n\) large enough,

\[ \varepsilon + f^0 (x, y) \geq f^0 (x_n, y) \]

which proves the claim.
Now with the claim,

\[ z^*(y) = \lim sup_{n \to \infty} z^*_n(y) \leq \lim sup_{n \to \infty} f^0(x_n, y) \leq f^0(x, y) \]

so \( z^* \in \partial f(x) \) contradicting the assumption that \( z^* \notin U \). This proves the lemma.

It is necessary to assume more on \( f^0 \) in order to obtain the third axiom defining pseudomonotone. The following theorem describes the situation.

**Theorem 23.6.4** Let \( f : V \to V' \) be locally Lipschitz and suppose it satisfies the condition that whenever \( x_n \) converges weakly to \( x \) and

\[ \lim sup_{n \to \infty} f^0(x_n, x - x_n) \geq 0 \]

it follows that

\[ \lim sup_{n \to \infty} f^0(x_n, z - x_n) \leq f^0(x, z - x) \]

for all \( z \in V \). Then \( \partial f \) is pseudomonotone.

**Proof:** and both are satisfied thanks to Lemmas 23.6.1 and 23.6.2. It remains to verify 23.6.1. To do so, I will adopt the convention that \( x^* \in \partial f(x) \). Suppose

\[ \lim sup_{n \to \infty} x^*_n(x_n - x) \leq 0. \quad (23.6.35) \]

This implies \( \lim inf_{n \to \infty} x^*_n(x - x_n) \geq 0 \). Thus,

\[ 0 \leq \lim inf_{n \to \infty} x^*_n(x - x_n) \leq \lim inf_{n \to \infty} f^0(x_n, x - x_n) \]

\[ \leq \lim sup_{n \to \infty} f^0(x_n, x - x_n), \]

which implies, by the above assumption that for all \( z \),

\[ \lim sup_{n \to \infty} x^*_n(z - x_n) \leq \lim sup_{n \to \infty} f^0(x_n, z - x_n) \leq f^0(x, z - x). \quad (23.6.36) \]

In particular, this holds for \( z = x \) and this implies \( \lim sup_{n \to \infty} x^*_n(x - x_n) \leq 0 \) which along with 23.6.35 yields

\[ \lim_{n \to \infty} x^*_n(x_n - x) = 0 \quad (23.6.37) \]

Now let \( z \) be arbitrary. There exists a subsequence, \( n_k \), depending on \( z \) such that

\[ \lim_{k \to \infty} x^*_n(x_n - z) = \lim inf_{n \to \infty} x^*_n(x_n - z) \cdot \]

Now from Lemma 23.6.1 and its proof, the \( ||x^*_n|| \) are all bounded by \( Lip_x(f) \) whenever \( n \) is large enough. Therefore, there is a further subsequence, still denoted by \( n_k \) such that

\( x^*_n \) converges weakly to \( x^*(z) \).
We need to verify that $x^*(z) \in \partial f(x)$. To do so, let $y$ be arbitrary. Then from the definition,
\[ x^*_n (y - x_n) \leq f^0(x_n, y - x_n). \tag{23.6.38} \]
From (23.6.37) we can take the lim sup of both sides and obtain, using (23.6.36)
\[ x^*(z)(y - x) \leq \limsup f^0(x_n, y - x_n) \leq f^0(x, y - x). \]
Since $y$ is arbitrary, this shows $x^*(z) \in \partial f(x)$ and proves the theorem.

23.7 Maximal Monotone Operators

Here it is assumed that the spaces are all real spaces to simplify the presentation.

**Definition 23.7.1** Let $A : D(A) \subseteq X \to \mathcal{P}(X)$ be a set valued map. It is said to be monotone if whenever $y_i \in Ax_i$,
\[ \langle y_1 - y_2, x_1 - x_2 \rangle \geq 0 \]
Denote by $\mathcal{G}(A)$ the graph of $A$ consisting of all pairs $(x, y)$ where $y \in Ax$. Such a monotone operator is said to be maximal monotone if
\[ F + A \]
is onto where $F$ is the duality map with $p = 2$.

Actually, it is more usual to say that the graph is maximal monotone if the graph is monotone and there is no monotone graph which properly contains the given graph. However, the two conditions are equivalent and I am more used to using the version in the above definition.

There is a fundamental result about these which is given next.

**Theorem 23.7.2** Let $X, X'$ be reflexive and have strictly convex norms. Let $A$ be a monotone set valued map as just described. Then if $\lambda F + A$ is onto for some $\lambda > 0$, then whenever
\[ \langle y - z, x - u \rangle \geq 0 \text{ for all } [x, y] \in \mathcal{G}(A) \]
it follows that $z \in Au$ and $u \in D(A)$. That is, the graph is maximal.

**Proof:** Suppose that for all $[x, y] \in \mathcal{G}(A)$,
\[ \langle y - z, x - t \rangle \geq 0 \]
Does it follow that $z \in At$? By assumption, $z + \lambda F(t) = \lambda F\hat{x} + \hat{\xi}$, $\hat{\xi} \in A\hat{x}$. Then replacing $y$ with $\hat{\xi}$ and $x$ with $\hat{x}$,
\[ \langle \hat{\xi} - (\lambda F\hat{x} + \hat{\xi} - \lambda Ft), \hat{x} - t \rangle \geq 0 \]
CHAPTER 23. NONLINEAR OPERATORS

and so

\[ \lambda \langle Ft - F\hat{x}, t - \hat{x} \rangle \leq 0 \]

which implies from Theorem 23.2.5 that \( t = \hat{x} \) and so the graph of \( A \) is indeed maximal monotone.

\[ z + \lambda F(t) = \lambda F\hat{x} + \xi \Rightarrow z = \xi \in A\hat{x} = At \]

Note that this would have worked with no change if the duality map had been for arbitrary \( p > 1 \).

23.7.1 The min max Theorem

In fact, these two conditions are equivalent. This is shown in [12]. We give a proof of this here. First it is necessary to prove a min max theorem. The proof given follows Brezis [23] which is where I found it. Here is the min max theorem. A function \( f \) is convex if

\[ f(\lambda x + (1 - \lambda)y) \leq \lambda f(x) + (1 - \lambda)f(y) \]

It is concave if the inequality is turned around. It can be shown that in finite dimensions, convex functions are automatically continuous, similar for concave functions. Recall the following definition of upper and lower semicontinuous functions defined on a metric space and having values in \([0, \infty] \).

**Definition 23.7.3** A function is upper semicontinuous if whenever \( x_n \to x \), it follows that \( f(x) \geq \limsup_{n\to\infty} f(x_n) \) and it is lower semicontinuous if \( f(x) \leq \liminf_{n\to\infty} f(x_n) \).

**Lemma 23.7.4** If \( F \) is a set of functions which are upper semicontinuous, then \( g(x) \equiv \inf \{ f(x) : f \in F \} \) is also upper semicontinuous. Similarly, if \( F \) is a set of functions which are lower semicontinuous, then if \( g(x) \equiv \sup \{ f(x) : f \in F \} \) it follows that \( g \) is lower semicontinuous.

**Proof:** Let \( f \in F \) where these functions are upper semicontinuous. Then if \( x_n \to x \), and \( g(x) \equiv \inf \{ f(x) : f \in F \} \),

\[ f(x) \geq \limsup_{n\to\infty} f(x_n) \geq \limsup_{n\to\infty} g(x_n) \]

Since this is true for each \( f \in F \), then it follows that you can take the infimum and obtain \( g(x) \geq \limsup_{n\to\infty} g(x_n) \). Similarly, lower semicontinuity is preserved on taking sup. ☐

Note that in a metric space, the above definitions up upper and lower semicontinuity in terms of sequences are equivalent to the definitions that

\[ f(x) \geq \limsup_{r\to0} \{ f(y) : y \in B(x, r) \} \]

\[ f(x) \leq \liminf_{r\to0} \{ f(y) : y \in B(x, r) \} \]
Here is a technical lemma which will make the proof shorter. It seems fairly interesting also.

**Lemma 23.7.5** Suppose $H : A \times B \to \mathbb{R}$ is strictly convex in the first argument and concave in the second argument where $A, B$ are compact convex nonempty subsets of Banach spaces $E, F$ respectively and $x \to H(x, y)$ is lower semicontinuous while $y \to H(x, y)$ is upper semicontinuous. Let

$$H(g(y), y) = \min_{x \in A} H(x, y)$$

Then $g(y)$ is uniquely defined and also for $t \in [0, 1]$,

$$\lim_{t \to 0} g(y + t(z - y)) = g(y).$$

**Proof:** First suppose both $z, w$ yield the definition of $g(y)$. Then

$$H \left( \frac{z + w}{2}, y \right) < \frac{1}{2} H(z, y) + \frac{1}{2} H(w, y)$$

which contradicts the definition of $g(y)$. As to the existence of $g(y)$ this is nothing more than the theorem that a lower semicontinuous function defined on a compact set achieves its minimum.

Now consider the last claim about "hemicontinuity". For all $x \in A$, it follows from the definition of $g$ that

$$H(g(y + t(z - y)), y + t(z - y)) \leq H(x, y + t(z - y))$$

By concavity of $H$ in the second argument,

$$(1 - t) H(g(y + t(z - y)), y) + t H(g(y + t(z - y)), z) \quad (23.7.39)$$

$$\leq H(x, y + t(z - y)) \quad (23.7.40)$$

Now let $t_n \to 0$. Does $g(y + t_n (z - y)) \to g(y)$? Suppose not. By compactness, $g(y + t_n (z - y))$ is in a compact set and so there is a further subsequence, still denoted by $t_n$ such that

$$g(y + t_n (z - y)) \to \hat{x} \in A$$

Then passing to a limit in (23.7.40), one obtains, using the upper semicontinuity in one and lower semicontinuity in the other the following inequality.

$$H(\hat{x}, y) \leq \lim_{n \to \infty} \inf (1 - t_n) H(g(y + t_n (z - y)), y) +$$

$$\lim_{n \to \infty} t_n H(g(y + t_n (z - y)), z)$$

$$\leq \lim_{n \to \infty} \inf \left( (1 - t_n) H(g(y + t_n (z - y)), y) + t_n H(g(y + t_n (z - y)), z) \right)$$
\[
\limsup_{n \to \infty} H(x + t_n (z - y)) \leq H(x, y)
\]
This shows that \( \hat{x} = g(y) \) because this holds for every \( x \). Since \( t_n \to 0 \) was arbitrary, this shows that in fact
\[
\lim_{t \to 0^+} g(y + t(z - y)) = g(y)
\]
Now with this preparation, here is the min-max theorem. A norm is called strictly convex if whenever \( x \neq y ; x + y^2 < \|x\|^2 + \|y\|^2 \).

**Theorem 23.7.6** Let \( E, F \) be Banach spaces with \( E \) having a strictly convex norm. Also suppose that \( A \subseteq E, B \subseteq F \) are compact and convex sets and that \( H : A \times B \to \mathbb{R} \) is such that
\[
x \to H(x, y) \text{ is convex}
\]
\[
y \to H(x, y) \text{ is concave}
\]
Thus \( H \) is continuous in each variable in the case of finite dimensional spaces. Here assume that \( x \to H(x, y) \) is lower semicontinuous and \( y \to H(x, y) \) is upper semicontinuous. Then
\[
\min_{x \in A} \max_{y \in B} H(x, y) = \max_{y \in B} \min_{x \in A} H(x, y)
\]
This condition is equivalent to the existence of \( (x_0, y_0) \in A \times B \) such that
\[
H(x_0, y) \leq H(x_0, y_0) \leq H(x, y_0) \text{ for all } x, y \quad (23.7.41)
\]
**Proof:** One part of the main equality is obvious.
\[
\max_{y \in B} H(x, y) \geq H(x, y) \geq \min_{x \in A} H(x, y)
\]
and so for each \( x \),
\[
\max_{y \in B} H(x, y) \geq \max_{y \in B} \min_{x \in A} H(x, y)
\]
and so
\[
\min_{x \in A} \max_{y \in B} H(x, y) \geq \max_{y \in B} \min_{x \in A} H(x, y) \quad (23.7.42)
\]
Next consider the other direction.
Define \( H_\varepsilon(x, y) \equiv H(x, y) + \varepsilon \|x\|^2 \) where \( \varepsilon > 0 \). Then \( H_\varepsilon \) is strictly convex in the first variable. This results from the observation that
\[
\left\| \frac{x + y}{2} \right\|^2 < \left( \frac{\|x\| + \|y\|}{2} \right)^2 \leq \frac{1}{2} \left( \|x\|^2 + \|y\|^2 \right),
\]
Then by Lemma 23.7.5 there exists a unique \( x = g(y) \) such that
\[
H_\varepsilon(g(y), y) \equiv \min_{x \in A} H_\varepsilon(x, y)
\]
and also, whenever \( y, z \in A \),
\[
\lim_{t \to 0^+} g(y + t(z - y)) = g(y).
\]

Thus \( H_\varepsilon(g(y), y) = \min_{x \in A} H_\varepsilon(x, y) \). But also this shows that \( y \to H_\varepsilon(g(y), y) \)

is the minimum of functions which are upper semicontinuous and so this function

is also upper semicontinuous. Hence there exists \( y^* \) such that

\[
\max_{y \in B} H_\varepsilon(g(y), y) = H_\varepsilon(g(y^*), y^*) = \max_{y \in B} \min_{x \in A} H_\varepsilon(x, y) \quad (23.7.43)
\]

Thus from concavity in the second argument and what was just defined, for \( t \in (0, 1) \),
\[
H_\varepsilon(g(y^*), y^*) \geq H_\varepsilon(g((1-t)y^* + ty), (1-t)y^* + ty)
\]
\[
\geq (1-t) H_\varepsilon(g((1-t)y^* + ty), y^*) + t H_\varepsilon(g((1-t)y^* + ty), y)
\]
\[
\geq (1-t) H_\varepsilon(g(y^*), y^*) + t H_\varepsilon(g((1-t)y^* + ty), y) \quad (23.7.44)
\]

This is because \( \min_x H_\varepsilon(x, y^*) \equiv H_\varepsilon(g(y^*), y^*) \) so \( H_\varepsilon(g((1-t)y^* + ty), y^*) \geq H_\varepsilon(g(y^*), y^*) \). Then subtracting the first term on the right, one gets
\[
t H_\varepsilon(g(y^*), y^*) \geq t H_\varepsilon(g((1-t)y^* + ty), y)
\]

and cancelling the \( t \),
\[
H_\varepsilon(g(y^*), y^*) \geq H_\varepsilon(g((1-t)y^* + ty), y)
\]

Now apply Lemma \[\text{23.7.42}\] and let \( t \to 0^+ \). This along with lower semicontinuity yields
\[
H_\varepsilon(g(y^*), y^*) \geq \lim_{t \to 0^+} \inf_{t \to 0} H_\varepsilon(g((1-t)y^* + ty), y) = H_\varepsilon(g(y^*), y) \quad (23.7.45)
\]

Hence for every \( x, y \)
\[
H_\varepsilon(x, y^*) \geq H_\varepsilon(g(y^*), y^*) \geq H_\varepsilon(g(y^*), y)
\]

Thus
\[
\min_x H_\varepsilon(x, y^*) \geq H_\varepsilon(g(y^*), y^*) \geq \max_y H_\varepsilon(g(y^*), y)
\]

and so
\[
\max_{y \in B} \min_{x \in A} H_\varepsilon(x, y) \geq \min_x H_\varepsilon(x, y^*) \geq H_\varepsilon(g(y^*), y^*) \geq \max_y H_\varepsilon(g(y^*), y) = \min_{x \in A} \max_{y \in B} H_\varepsilon(x, y)
\]

Thus, letting \( C = \max \{ ||x|| : x \in A \} \)
\[
\varepsilon C^2 + \max_{y \in B} \min_{x \in A} H(x, y) \geq \min_{x \in A} \max_{y \in B} H(x, y)
\]
Since $\varepsilon$ is arbitrary, it follows that

$$\max_{y \in B} \min_{x \in A} H(x, y) \geq \min_{x \in A} \max_{y \in B} H(x, y)$$

This proves the first part because it was shown above in Chapter 23.6.41 that

$$\min_{x \in A} \max_{y \in B} H(x, y) \geq \max_{y \in B} \min_{x \in A} H(x, y)$$

Now consider Chapter 23.6.41 about the existence of a “saddle point” given the equality of min max and max min. Let

$$\alpha = \max_{y \in B} \min_{x \in A} H(x, y) = \min_{x \in A} \max_{y \in B} H(x, y)$$

Then from

$$y \to \min_{x \in A} H(x, y) \quad \text{and} \quad x \to \max_{y \in B} H(x, y)$$

being upper semicontinuous and lower semicontinuous respectively, there exist $y_0$ and $x_0$ such that

$$\alpha = \min_{x \in A} H(x, y_0) = \max_{y \in B} \min_{x \in A} H(x, y) = \max_{y \in B} \min_{x \in A} H(x, y)$$

Then

$$\alpha = \max_{y \in B} H(x_0, y) \geq H(x_0, y_0)$$

$$\alpha = \min_{x \in A} H(x, y_0) \leq H(x_0, y_0)$$

so in fact $\alpha = H(x_0, y_0)$ and from the above equalities,

$$H(x_0, y_0) = \alpha = \min_{x \in A} H(x, y_0) \leq H(x, y_0)$$

$$H(x_0, y_0) = \alpha = \max_{y \in B} H(x_0, y) \geq H(x_0, y)$$

and so

$$H(x_0, y) \leq H(x_0, y_0) \leq H(x, y)$$

Thus if the min max condition holds, then there exists a saddle point, namely $(x_0, y_0)$.

Finally suppose there is a saddle point $(x_0, y_0)$ where

$$H(x_0, y) \leq H(x_0, y_0) \leq H(x, y)$$

Then

$$\min_{x \in A} \max_{y \in B} H(x, y) \leq \max_{y \in B} H(x_0, y) \leq H(x_0, y_0) \leq \min_{x \in A} H(x, y_0) \leq \max_{y \in B} \min_{x \in A} H(x, y)$$
However, as noted above, it is always the case that
\[
\max_{y \in B} \min_{x \in A} H(x, y) \leq \min_{x \in A} \max_{y \in B} H(x, y) \tag{1}
\]

Of course all of this works with no change if you have \(E, F\) reflexive Banach spaces and the sets \(A, B\) are just closed and bounded and convex. Then you just use the fact that the functional is weakly lower semicontinuous in the first variable and weakly upper semicontinuous in the second. Recall that lower semicontinuous and convex implies weakly lower semicontinuity. Then just use weak convergence instead of strong convergence in the above argument. Recall that closed bounded and convex sets with the weak topology can be considered metric spaces. I think the above is most interesting in finite dimensions. Of course in this case, you can simply assume the norm is the standard Euclidean norm and there is then no need to assume one of the norms is strictly convex. It comes automatically. Just use an equivalent norm which is strictly convex.

### 23.7.2 Equivalent Conditions For Maximal Monotone

Next is the theorem about the graph being maximal being equivalent to the operator being maximal monotone. It is a very convenient result to have. The proof is a modified version of one in Barbu [12]. It is based on the following lemma also in Barbu. This is a little like the Browder lemma but is based on the min max theorem above. It is also a very interesting argument.

**Lemma 23.7.7** Let \(E\) be a finite dimensional Banach space and let \(K\) be a convex and compact subset of \(E\). Let \(\mathcal{G}(A)\) be a monotone subset of \(E \times E'\) such that \(D(A) \subseteq K\) and \(B\) is a single valued monotone and continuous operator from \(E\) to \(E'\). Then there exists \(x \in K\) such that
\[
\langle Bx + v, u - x \rangle_{E', E} \geq 0 \text{ for all } [u, v] \in \mathcal{G}(A).
\]

If \(B\) is coercive
\[
\lim_{\|x\| \to \infty} \frac{\langle Bx, x \rangle}{\|x\|} = \infty,
\]
and \(0 \in D(A)\), then one can assume only that \(K\) is convex and closed.

**Proof:** Let \(T : E \to K\) be the multivalued operator defined by
\[
Ty := \left\{ x \in K : \langle By + v, u - x \rangle_{E', E} \geq 0 \text{ for all } [u, v] \in \mathcal{G}(A) \right\}
\]
Here \(y \in E\) and it is desired to show that \(Ty \neq \emptyset\) for all \(y \in K\). For \([u, v] \in \mathcal{G}(A)\), let
\[
K_{u,v} := \left\{ x \in K : \langle By + v, u - x \rangle_{E', E} \geq 0 \right\}
\]
Then \(K_{u,v}\) is a closed, hence compact subset of \(K\). The thing to do is to show that \(\cap_{[u,v] \in \mathcal{G}(A)} K_{u,v} = Ty \neq \emptyset\) whenever \(y \in K\). Then one argues that \(T\) is set
valued, has convex compact values and is upper semicontinuous. Then one applies
the Kakutani fixed point theorem to get \( x \in Tx \).

Since these sets \( K_{u,v} \) are compact, it suffices to show that they satisfy the finite
intersection property. Thus for \( \{[u_i,v_i]\}_{i=1}^n \) a finite set of elements of \( \mathcal{G}(A) \), it is
necessary to show that there exists a solution \( x \) to the inequalities
\[
(u_i - x, By + v_i) \geq 0, \quad i = 1, 2, \ldots, n
\]
and then it follows from finite intersection property that there exists
\[
x \in \cap_{[u,v] \in \mathcal{G}(A)} K_{u,v}
\]
which is what was desired. Let \( P_n \) be all \( \bar{\lambda} = (\lambda_1, \ldots, \lambda_n) \) such that each \( \lambda_k \geq 0 \)
and \( \sum_{k=1}^n \lambda_k = 1 \). Let \( H : P_n \times P_n \to \mathbb{R} \) be given by
\[
H (\bar{\mu}, \bar{\lambda}) = \sum_{i=1}^n \mu_i \left( By + v_i, \sum_{j=1}^n \lambda_j u_j - u_i \right)
\]
Then this is both convex and concave in both \( \bar{\mu}, \bar{\lambda} \) and so by Theorem 23.7.6, there
exists \( \bar{\mu}_0, \bar{\lambda}_0 \) both in \( P_n \) such that for all \( \bar{\mu}, \bar{\lambda} \),
\[
H (\bar{\mu}, \bar{\lambda}_0) \leq H (\bar{\mu}_0, \bar{\lambda}_0) \leq H (\bar{\mu}_0, \bar{\lambda})
\]
However, plugging in \( \bar{\mu} = \bar{\lambda} \) in 23.7.40,
\[
H (\bar{\lambda}, \bar{\lambda}) = \sum_{i=1}^n \lambda_i \left( By + v_i, \sum_{j=1}^n \lambda_j u_j - u_i \right)
\]
\[
= \sum_{i=1}^n \left( By + v_i, \sum_{j=1}^n \lambda_i \lambda_j u_j - \lambda_i u_i \right)
\]
\[
= \sum_{i=1}^n \left( B y + v_i, \sum_{j=1}^n (\lambda_i \lambda_j u_j - \lambda_i \lambda_j u_i) \right)
\]
\[
= \left( B y, \sum_{i=1}^n \sum_{j=1}^n (\lambda_i \lambda_j u_j - \lambda_i \lambda_j u_i) \right) + \sum_{i=1}^n \left( v_i, \sum_{j=1}^n (\lambda_i \lambda_j u_j - \lambda_i \lambda_j u_i) \right)
\]
The first term obviously equals 0. Consider the second. This term equals
\[
\sum_{i=1}^n \sum_{j=1}^n \lambda_i \lambda_j \langle v_i, (u_j - u_i) \rangle
\]
The terms equal 0 when \( j = i \) or they come in pairs
\[
\lambda_i \lambda_j \langle v_i, (u_j - u_i) \rangle + \lambda_i \lambda_j \langle v_j, (u_i - u_j) \rangle
\]
\[
= \lambda_i \lambda_j \langle (v_i, (u_j - u_i)) - (v_j, (u_j - u_i)) \rangle
\]
\[
= \lambda_i \lambda_j \langle (v_i, (u_j - u_i)) - (v_j, (u_j - u_i)) \rangle \leq 0
\]
23.7. MAXIMAL MONOTONE OPERATORS

by monotonicity of \( A \). Hence \( H \left( \tilde{\lambda}, \tilde{\lambda} \right) \leq 0 \). Then from \( 23.4.4 \), for all \( \bar{\mu} \)

\[
H \left( \bar{\mu}, \tilde{\lambda}_0 \right) \leq H \left( \bar{\mu}_0, \tilde{\lambda}_0 \right) \leq H \left( \bar{\mu}_0, \bar{\mu}_0 \right) \leq 0
\]

It follows that

\[
\sum_{i=1}^m \mu_i \left( B y + v_i, \sum_{j=1}^n \lambda_j^0 u_j - u_i \right) \leq 0
\]

\[
\sum_{i=1}^m \mu_i \left( B y + v_i, u_i - \sum_{j=1}^n \lambda_j^0 u_j \right) \geq 0
\]

where \( \tilde{\lambda}_0 \equiv (\lambda_1^0, \cdots, \lambda_n^0) \). This is true for any choice of \( \bar{\mu} \). In particular, you could let \( \bar{\mu} \) equal 1 in the \( i \)th position and 0 elsewhere and conclude that for all \( i = 1, \cdots, n, \)

\[
\left( B y + v_i, u_i - \sum_{j=1}^n \lambda_j^0 u_i \right) \geq 0
\]

so you let \( x = \sum_{j=1}^n \lambda_j^0 u_j \) and this shows that \( T y \neq \emptyset \) because the sets \( K_{u,v} \) have the finite intersection property.

Thus \( T : K \rightarrow \mathcal{P}(K) \) and for each \( y \in K, Ty \neq \emptyset \). In fact this is true for any \( y \) but we are only considering \( y \in K \). Now \( Ty \) is clearly a closed subset of \( K \). It is also clearly convex. Is it upper semicontinuous? Let \( y_k \rightarrow y \) and consider \( Ty_k + B(0, r) \). Is \( Ty_k \in Ty + B(0, r) \) for all \( k \) large enough? If not, then there is a subsequence, denoted as \( z_k \in Ty_k \) which is outside this open set \( Ty + B(0, r) \). Then taking a further subsequence, still denoted as \( z_k \), it follows that \( z_k \rightarrow z \notin Ty + B(0, r) \). Now

\[
\left( B y_k + v, u - z_k \right) \geq 0 \text{ all } [u, v] \in \mathcal{G}(A)
\]

Therefore, from continuity of \( B, \)

\[
\left( B y + v, u - z \right) \geq 0 \text{ all } [u, v] \in \mathcal{G}(A)
\]

which means \( z \in Ty \) contrary to the assumption that \( T \) is not upper semicontinuous. Since \( T \) is upper semicontinuous and maps to compact convex sets, it follows from Theorem 4.8.10 that \( T \) has a fixed point \( x \in Tx \). Hence there exists a solution \( x \) to

\[
\left( B x + v, u - x \right) \geq 0 \text{ all } [u, v] \in \mathcal{G}(A)
\]

Next suppose that \( K \) is only closed and convex but \( B \) is coercive and \( 0 \in D(A) \). Then let \( K_n = \overline{B(0, n)} \cap K \) and let \( A_n \) be the restriction of \( A \) to \( \overline{B(0, n)} \). It follows that there exists \( x_n \in K_n \) such that for all \( [u, v] \in \mathcal{G}(A_n) \),

\[
\left( B x_n + v, u - x_n \right) \geq 0
\]

Then since \( 0 \in D(A) \), one can pick \( v_0 \in A0 \) and obtain

\[
\left( B x_n + v_0, -x_n \right) \geq 0, \left( v_0, -x_n \right) \geq \left( B x_n, x_n \right)
\]
from which it follows from coercivity of $B$ that the $x_n$ are bounded independent of $n$. Say $\|x_n\| < C$. Then there is a subsequence still denoted as $x_n$ such that $x_n \to x \in K$, thanks to the assumption that $K$ is closed and convex. Let $[u, v] \in \mathcal{G}(A)$. Then for all $n$ large enough $\|u\| < n$ and so

$$\langle Bx_n + v, u - x_n \rangle \geq 0$$

Then letting $n \to \infty$ and using the continuity of $B$,

$$\langle Bx + v, u - x \rangle \geq 0$$

Since $[u, v]$ was arbitrary, this proves the lemma. ■

**Observation 23.7.8** If you have a monotone set valued function, then its graph can always be considered a subset of the graph of a maximal monotone graph. If $A$ is monotone, then let $\mathcal{F}$ be $\mathcal{G}(B)$ such that $\mathcal{G}(B) \supseteq \mathcal{G}(A)$ and $B$ is monotone. Partially order by set inclusion. Then let $C$ be a maximal chain. Let $\mathcal{G}(\hat{A}) = \cup C$.

If $[x_1, y_1] \in \mathcal{G}(\hat{A})$, then both are in some $B \in C$. Hence $(y_1 - y_2, x_1 - x_2) \geq 0$ so monotone and must be maximal monotone because if $\langle z - v, x - u \rangle \geq 0$ for all $[u, v] \in \mathcal{G}(\hat{A})$ and $[x, z] \notin \hat{A}$, then you could include this ordered pair and contradict maximality of the chain $C$.

Next is an interesting theorem which comes from this lemma. It is an infinite dimensional version of the above lemma.

**Theorem 23.7.9** Let $X$ be a reflexive Banach space and let $K$ be a closed convex subset of $X$. Let $A, B$ be monotone such that

1. $D(A) \subseteq K, 0 \in D(A)$.
2. $B$ is single valued, hemicontinuous, bounded and coercive mapping $X$ to $X'$.

Then there exists $x \in K$ such that

$$\langle Bx + v, u - x \rangle_{X', X} \geq 0 \text{ for all } [u, v] \in \mathcal{G}(A)$$

Before giving the proof, here is an easy lemma.

**Lemma 23.7.10** Let $E$ be finite dimensional and let $B : E \to E'$ be monotone and hemicontinuous. Then $B$ is continuous.

**Proof:** The space can be considered a finite dimensional Hilbert space ($\mathbb{R}^n$) and so weak and strong convergence are exactly the same. First it is desired to show that $B$ is bounded. Suppose it is not. Then there exists $\|x_k\|_E = 1$ but $\|Bx_n\|_{E'} \to \infty$. Since finite dimensional, there is a subsequence still denoted as $x_k$ such that $x_k \to x, \|x\|_E = 1$.

$$\langle Bx_k - Bx, x_k - x \rangle \geq 0$$
Hence
\[ \left\langle Bx_k - Bx, \frac{x_k - x}{\|Bx_k\|_{E'}} \right\rangle \geq 0 \]
Then taking another subsequence, written with index \( k \), it can be assumed that
\[ Bx_k / \|Bx_k\| \rightarrow y^* \in E', \|y^*\|_{E'} = 1 \]
Hence,
\[ \langle y^*, x_k - x \rangle \geq 0 \]
for all \( x \in E \), but this requires that \( y^* = 0 \), a contradiction. Thus \( B \) is monotone, hemicontinuous, and bounded. It follows from Theorem 23.1.4 which says that monotone and hemicontinuous operators are pseudomonotone and Proposition 23.1.6 which says that bounded pseudomonotone operators are demicontinuous that \( B \) is demicontinuous, hence continuous because, as just noted above, weak and strong convergence are the same for finite dimensional spaces. In case \( B \) is bounded, then this follows from Proposition 23.1.6 above. It is pseudomonotone and bounded hence demicontinuous and weak and strong convergence is the same in finite dimensions.

**Proof of Theorem 23.7.9**: Let \( \{X_n\} \) be an increasing sequence of finite dimensional subspaces. Let \( \hat{A} \) be maximal monotone on \( \cup_n X_n \) and extending \( A \). By this is meant that the graph of \( \hat{A} \) contains the graph of \( A \) restricted to \( \cup_n X_n \), \( \hat{A} \) is monotone and there is no other larger graph with these properties. See the above observation. Let \( j_n : X_n \rightarrow X \) be the inclusion map and \( j_n^* : X' \rightarrow X'_n \) be the dual map. Then \( j_n^* \hat{A} j_n \equiv A_n \) and \( j_n^* B j_n \equiv B_n \) have monotone graphs from \( X_n \) to \( \mathcal{P}(X'_n) \) with \( B_n \) being continuous and single valued. This follows from the hemicontinuity and the above lemma which states that on finite dimensional spaces, hemicontinuity and monotonicity imply continuity. Then
\[ [u, v] \in \mathcal{G}(A_n) \]
means
\[ u \in D(A) \cap X_n \text{ and } v \in j_n^* \hat{A} j_n (u) = j_n^* \hat{A} (u) \text{ since } u \in X_n \]
Then from Lemma 23.7.6, there exists \( x_n \in X_n \) such that
\[ \langle B_n x_n + v_n, u_n - x_n \rangle_{X', X} \geq 0 \text{ all } [u_n, v_n] \in \mathcal{G}(A_n) \]

That is, there exists \( x_n \in K \cap X_n \) such that for all \( u \in D(\hat{A}) \cap X_n, [u, v] \in \mathcal{G}(\hat{A}) \)
\[ \langle Bx_n + v, u - x_n \rangle_{X', X} \geq 0 \]  \hspace{1cm} (23.7.48)
Then
\[ \langle v, u - x_n \rangle \geq \langle Bx_n, x_n - u \rangle \]  \hspace{1cm} (23.7.49)
From the assumption that \( 0 \in D(\hat{A}) \), one can let \( u = 0 \) and then pick \( v_0 \in A0 \). Then the above reduces to
\[ \langle v_0, -x_n \rangle \geq \langle Bx_n, x_n \rangle \]
By coercivity of $B$, these $x_n$ are all bounded and so by the Eberlien Smulian theorem, there is a subsequence $\{x_n\}$ which satisfies

\[
x_n \rightharpoonup x \text{ weakly in } X
\]
\[
Bx_n \rightharpoonup y \text{ weakly in } X'
\]

Then from (23.7.48)

\[
\langle v, u - x_n \rangle + \langle Bx_n, u \rangle \geq \langle Bx_n, x_n \rangle
\]

Then it follows that

\[
\langle v, u - x_n \rangle + \langle Bx_n, u \rangle - \langle Bx_n, x \rangle \geq \langle Bx_n, x_n - x \rangle
\]

It follows that

\[
\limsup_{n \to \infty} \langle Bx_n, x_n - x \rangle \leq \langle v, u - x \rangle + \langle y, u \rangle - \langle y, x \rangle
\]

\[
= \langle v + y, u - x \rangle
\]

**Claim:** $\limsup_{n \to \infty} \langle Bx_n, x_n - x \rangle \leq 0$.

**Proof of claim:** This is so if $\langle v + y, u - x \rangle \leq 0$ for some $[u, v] \in G\left(\hat{A}\right)$. If $\langle v + y, u - x \rangle$ is greater than 0 for all $[u, v]$, then since $\hat{A}$ is maximal, it would follow that $-y \in Ax$. Now consider (23.7.48).

\[
\langle v, u - x \rangle \geq \limsup_{n \to \infty} \langle Bx_n, x_n \rangle - \langle y, u \rangle
\]

Since $x \in D\left(\hat{A}\right)$, you could put in $u = x$ in the above and obtain

\[
0 \geq \limsup_{n \to \infty} \langle Bx_n, x_n \rangle - \langle y, x \rangle = \limsup_{n \to \infty} \langle Bx_n, x_n - x \rangle
\]

which shows the claim is true.

Since $B$ is monotone and hemicontinuous, it satisfies the pseudomonotone condition, Theorem 23.1.4. Hence for any $z$,

\[
\langle y, x - z \rangle \geq \limsup_{n \to \infty} \langle Bx_n, x_n - x \rangle + \limsup_{n \to \infty} \langle Bx_n, x - z \rangle
\]

\[
\geq \limsup_{n \to \infty} \left(\langle Bx_n, x_n - x \rangle + \langle Bx_n, x - z \rangle\right)
\]

\[
\geq \liminf_{n \to \infty} \left(\langle Bx_n, x_n - z \rangle\right) \geq \langle Bx, x - z \rangle
\]

Since $z$ is arbitrary, this shows that $y = Bx$. It follows from (23.7.48) that for any $[u, v] \in G\left(\hat{A}\right)$,

\[
\langle Bx_n + v, u - x_n \rangle = \langle Bx_n + v, u - x \rangle + \langle Bx_n + v, x - x_n \rangle \geq 0
\]

\[
\langle Bx_n + v, u - x \rangle \geq \langle Bx_n, x_n - x \rangle \geq \langle Bx, x_n - x \rangle
\]
23.7. MAXIMAL MONOTONE OPERATORS

Now take a limit of both sides and use the fact that \( y = Bx \) to obtain
\[
(Bx + v, u - x) \geq 0
\]
for all \([u, v] \in \mathcal{G}(\hat{A})\). Here \( \hat{A} \) extends \( A \) on \( \cup_n X_n \). Why does it follow from this that there exists an \( x \) such that the inequality holds for all \([u, v] \in \mathcal{G}(A)\)?

Let \( V \) be a finite dimensional subspace.
\[
K_V \equiv \left\{ x \in K : (Bx + v, u - x)_{X',X} \geq 0 \text{ for all } [u, v] \in \mathcal{G}(A), u \in V \right\}.
\]
Then from the above argument, \( K_V \neq \emptyset \). You just choose your subspaces \( X_n \) to all include \( V \). Also, from coercivity of \( B \) and the above argument, these \( K_V \) are all bounded and weakly closed. Hence they are weakly compact. Then if you have finitely many of them, you can let your subspaces include each \( V \) and conclude that these \( K_V \) have finite intersection property and so there exists \( x \in \cap_V K_V \) which gives the desired \( x \).

Note that there is only one place where \( 0 \in D(A) \) was used and it was to get the estimate. In the argument,
\[
(v, u - x_n) \geq (Bx_n, x_n - u)
\]
and it was convenient to be able to take \( u = 0 \). However, you could also assume other things on \( B \) such as that it satisfies an estimate of the form
\[
\|Bx\| \leq C \|x\| + C
\]
and if you did this, you could also obtain the necessary estimate as follows.
\[
\begin{align*}
(v, u - x_n) & \geq (Bx_n, x_n - u) \\
(v, u - x_n) + (Bx_n, u) & \geq (Bx_n, x_n) \\
\|v\| \left(\|u\| + \|x_n\|\right) + \left(\|C \|x_n\| + C\right) \|u\| & \geq (Bx_n, x_n)
\end{align*}
\]
and then pick some \([u, v]\). Thus the following corollary comes right away. This would have worked just as well if you had an estimate of the form
\[
\|Bx\| \leq C \|x\|^{p-1} + C, \ p > 1
\]

**Corollary 23.7.11** Let \( X \) be a reflexive Banach space and let \( K \) be a closed convex subset of \( X \). Let \( A, B \) be monotone such that

1. \( D(A) \subseteq K \)

2. \( B \) is single valued, hemicontinuous, bounded and coercive mapping \( X \) to \( X' \) which satisfies the estimate
\[
\|Bx\| \leq C \|x\| + C \text{ or more generally } \|Bx\| \leq C \|x\|^{p-1} + C, \ p > 1
\]
Then there exists \( x \in K \) such that
\[
(Bx + v, u - x)_{X',X} \geq 0 \quad \text{for all } [u, v] \in G(A)
\]

Now here is the equivalence between maximal monotone graph and having \( F + A \) be onto. It was already shown that if \( \lambda F + A \) is onto, then the graph of \( A \) is maximal monotone in the sense that there is no monotone operator whose graph properly contains the graph of \( A \). This was Theorem 23.7.2 above which is stated here as a reminder of what it said.

**Theorem 23.7.12** Let \( X, X' \) be reflexive and have strictly convex norms. Let \( A \) be a monotone set valued map as just described. Then if \( \lambda F + A \) onto, for some \( \lambda > 0 \), then whenever
\[
\langle z, x - u \rangle \geq 0 \quad \text{for all } [x, y] \in G(A)
\]

it follows that \( z \in Au \) and \( u \in D(A) \). That is, the graph is maximal.

**Theorem 23.7.13** Let \( X \) be a strictly convex reflexive Banach space. Suppose the graph of \( A : X \to \mathcal{P}(X) \) is maximal monotone in the sense that it is monotone and no monotone graph can properly contain the graph of \( A \). Then for all \( \lambda > 0, \lambda F + A \) is onto. Conversely, if for some \( \lambda > 0, \lambda F + A \) is onto, then the graph of \( A \) is maximal with respect to being monotone.

**Proof:** In Theorem 23.7.9, let \( Bx = \lambda F(x) - y_0 \). Then from the properties of the duality map, Theorem 23.7.8 above, it follows that \( B \) satisfies the necessary conditions to use the result of Corollary 23.7.11 with \( K = X \). This \( B \) is monotone hemicontinuous, and coercive. Thus there exists \( x \) such that for all \( [u, v] \in G(A) \),
\[
\langle \lambda F(x) - y_0 + v, u - x \rangle_{X',X} \geq 0 \\
\langle v - (y_0 - \lambda F(x)), u - x \rangle_{X',X} \geq 0
\]

By maximality of the graph, it follows that \( x \in D(A) \) and
\[
y_0 - \lambda F(x) \in A(x), \quad y_0 = \lambda F(x) + A(x)
\]
so \( \lambda F + A \) is onto as claimed. The converse was proved in Theorem 23.7.2.

Note that this theorem holds if \( F \) is a duality map for \( p > 1 \). That is, \( \langle Fx, x \rangle = \|x\|^p, \|Fx\| = \|x\|^{p-1} \).

Suppose \( A : X \to \mathcal{P}(X) \) is maximal monotone. Then let \( z \in X \) and define a new mapping \( \hat{A} \) as follows.

\[
D(\hat{A}) \equiv \{ x : x - x_0 \in D(A) \}, \quad \hat{A}(x) \equiv A(x - x_0)
\]
23.7. MAXIMAL MONOTONE OPERATORS

**Proposition 23.7.14** Let $A, \hat{A}$ be as just defined. Then $\hat{A}$ is also maximal monotone.

**Proof:** From Theorem 23.7.13 it suffices to show that graph of $\hat{A}$ is monotone and is maximal. Suppose then that $x_i^* \in \hat{A} x_i$. Then

$$\langle x_i^* - x_0^*, x_1 - x_2 \rangle = \langle x_i^* - x_0^*, x_1 - x_0 - (x_2 - x_0) \rangle$$

by definition, $x_i^* \in A(x_i - x_0)$ and so the above is $\geq 0$. Next suppose for all $[x,x^*] \in \mathcal{G}(\hat{A})$,

$$\langle x^* - z^*, x - z \rangle \geq 0$$

Does it follow that $[z,z^*] \in \mathcal{G}(\hat{A})$? The above says that

$$\langle x^* - z^*, x - x_0 - (z - x_0) \rangle \geq 0$$

whenever $x-x_0 \in D(A)$ and $x^* \in A(x-x_0)$. Hence, since $A$ is given to be maximal monotone, $z-x_0 \in D(A)$ and $z^* \in A(z-x_0)$ which says that $z^* \in \hat{A}(z)$. Thus $\hat{A}$ is maximal monotone by the Theorem 23.7.13.

23.7.3 Surjectivity Theorems

As an interesting example of this theorem, here is another result in Barbu [12]. It is interesting because it is not assumed $B$ is bounded.

**Theorem 23.7.15** Let $B : X \to X'$ be monotone hemicontinuous. Then $B$ is maximal monotone. If $B$ is coercive, then $B$ is also onto. Here $X$ is a strictly convex reflexive Banach space.

**Proof:** Suppose $B$ is not maximal monotone. Then there exists $(x_0, x_0^*) \in X \times X'$ such that for all $x$,

$$\langle Bx - x_0^*, x - x_0 \rangle \geq 0$$

and yet $x_0^* \neq Bx_0$. This is going to be a contradiction. Let $u \in X$ and consider $x_t = tx_0 + (1-t)u$, $t \in (0,1)$. Then consider

$$\langle Bx_t - x_0^*, x_t - x_0 \rangle$$

However, $x_t - x_0 = tx_0 + (1-t)u - x_0 = (1-t)(u-x_0)$ and so, for each $t \in (0,1)$,

$$0 \leq \langle Bx_t - x_0^*, x_t - x_0 \rangle = (1-t) \langle Bx_t - x_0^*, u - x_0 \rangle$$

Divide by $(1-t)$ and then let $t \uparrow 1$. This yields the following by hemicontinuity.

$$\langle Bx_0 - x_0^*, u - x_0 \rangle \geq 0$$

which holds for all $u$. Hence $Bx_0 = x_0^*$ after all. Thus $B$ is indeed maximal monotone.
Next suppose $B$ is coercive. Let $F$ be the duality map (or the duality map for arbitrary $p > 1$). Then from Theorem 23.7.13 there exists a solution $x_\lambda$ to

$$\lambda Fx_\lambda + Bx_\lambda = x_0^* \in X'$$  \hspace{1cm} (23.7.50)

Then the $x_\lambda$ are bounded because, doing both sides to $x_\lambda$,

$$\lambda \|x_\lambda\|^2 + \langle Bx_\lambda, x_\lambda \rangle = \langle x_0^*, x_\lambda \rangle$$

and so

$$\frac{\langle Bx_\lambda, x_\lambda \rangle}{\|x_\lambda\|} \leq \|x_0^*\|$$

Thus the coercivity of $B$ implies that the $x_\lambda$ are bounded. There exists a subsequence such that

$$x_\lambda \rightharpoonup x \text{ weakly.}$$

Then from the equation $\|\lambda Fx_\lambda\| = \lambda \|x_\lambda\|$ and so,

$$Bx_\lambda \rightarrow x_0^* \text{ strongly.}$$

Since $B$ is monotone and hemicontinuous, it satisfies the pseudomonotone condition, Theorem 23.1.4. The above strong convergence implies

$$\lim_{\lambda \rightarrow 0} \langle Bx_\lambda, x_\lambda - x \rangle = 0$$

Hence for all $y$,

$$\liminf_{\lambda \rightarrow 0} \langle Bx_\lambda, x_\lambda - y \rangle = \liminf_{\lambda \rightarrow 0} \langle Bx_\lambda, x - y \rangle = \langle x_0^*, x - y \rangle \geq \langle Bx, x - y \rangle$$

Since $y$ is arbitrary, this shows that $x_0^* = Bx$ and so $B$ is onto as claimed. \[\square\]

Again, note that it really didn’t matter about the particular duality map used, although the usual one was featured in the argument.

There are some more things which can be said about maximal monotone operators. To include some of these, here is a very interesting lemma found in [12].

**Lemma 23.7.16** Let $X$ be a Banach space and suppose that

$$x_n \rightarrow 0, \quad \|x_n^*\| \rightarrow \infty$$

Then denoting by $D_r$ the closed disk centered at 0 with radius $r$. It follows that for every $D_r$, there exists $y_0 \in D_r$ and a subsequence with index $n_k$ such that

$$\langle x_{n_k}^*, x_{n_k} - y_0 \rangle \rightarrow -\infty$$

**Proof:** Suppose this is not true. Then there exists $D_r$ which has the property that for all $u \in D_r$,

$$\langle x_{n_k}^*, x_{n_k} - u \rangle \geq C_u$$
for all $n$. Now let
\[ E_k \equiv \{ y \in D_r : \langle x^*_n, x_n - y \rangle \geq -k \ \text{for all} \ \ n \} \]

Then this is a closed set, being the intersection of closed sets. Also, by assumption, the union of these $E_k$ equals $D_r$ which is a complete metric space. Hence one of these $E_k$ must have nonempty interior by the Bair category theorem, say for $k_0$. Say $B(y, \varepsilon) \subseteq D_r$. Then for all $\|u - y\| < \varepsilon$,
\[ \langle x^*_n, x_n - u \rangle \geq -k_0 \ \text{for all} \ \ n \]

Of course $-y \in D_r$ also, and so there is $C$ such that
\[ \langle x^*_n, x_n + y \rangle \geq C \ \text{for all} \ \ n \]

Then
\[ \langle x^*_n, 2x_n + y - u \rangle \geq C - k_0 \ \text{for all} \ \ n \]

whenever $\|y - u\| < \varepsilon$. Now recall that $x_n \to 0$. Consider only $u$ such that $\|y - u\| < \varepsilon/2$. Therefore, for all $n$ large enough, the expression $2x_n + y - u$ for such $u$ contains a small ball centered at the origin, say $D_\delta$. (The set of all $y - u$ for $u$ closer to $y$ than $\varepsilon/2$ is the ball $B(0, \varepsilon/2)$ and then the $2x_n$ does not move it by much provided $n$ is large enough.) Therefore,
\[ \langle x^*_n, v \rangle \geq C - k_0 \]

for all $\|v\| \leq \delta$. This contradicts the assumption that $\|x^*_n\| \to \infty$. $\blacksquare$

**Corollary 23.7.17** Let $X$ be a Banach space and suppose that

\[ x_n \to x, \quad \|x^*_n\| \to \infty \]

Then denoting by $D_r$ the closed disk centered at $x$ with radius $r$. It follows that for every $D_r$, there exists $y_0 \in D_r$ and a subsequence with index $n_k$ such that
\[ \langle x^*_n, x_{n_k} - y_0 \rangle \to -\infty \]

**Proof:** It follows that $x_n - x \to 0$. Therefore, from Lemma 23.7.10, for every $r > 0$, there exists $\hat{y}_0 \in B(0, r)$ and a subsequence $x_{n_k}$ such that
\[ \langle x^*_n, (x_{n_k} - x) - \hat{y}_0 \rangle \to -\infty \]

Thus
\[ \langle x^*_n, x_{n_k} - (x + \hat{y}_0) \rangle \to -\infty \]

Just let $y_0 = x + \hat{y}_0$. Then $y_0 \in D_r$ and satisfies the desired conditions. $\blacksquare$

**Definition 23.7.18** A set valued mapping $A : D(A) \to P(X)$ is locally bounded at $x \in D(A)$ if whenever $x_n \to x$, $x_n \in D(A)$ it follows that
\[ \limsup_{n \to \infty} \{ \|x^*_n\| : x^*_n \in Ax_n \} < \infty. \]
**Lemma 23.7.19** A set valued operator $A$ is locally bounded at $x \in \overline{D(A)}$ if and only if there exists $r > 0$ such that $A$ is bounded on $\overline{B(x,r)} \cap D(A)$.

**Proof:** Say the limit condition holds. Then if no such $r$ exists, it follows that $A$ is unbounded on every $B(x,r) \cap D(A)$. Hence, you can let $r_n \to 0$ and pick $x_n \in B(x,r_n) \cap D(A)$ with $x_n^* \in Ax_n$ such that $\|x_n^*\| > n$, violating the limit condition. Hence some $r$ exists such that $A$ is bounded on $\overline{B(x,r)} \cap D(A)$. Conversely, suppose $A$ is bounded on $\overline{B(x,r)} \cap D(A)$ by $M$. Then if $x_n \to x$, it follows that for all $n$ large enough, $x_n \in B(x,r)$ and so if $x_n^* \in Ax_n$, $\|x_n^*\| \leq M$. Hence $\limsup_{n \to \infty} \{\|x_n^*\| : x_n^* \in Ax_n\} \leq M < \infty$ which verifies the limit condition. ■

With this definition, here is a very interesting result.

**Theorem 23.7.20** Let $A : D(A) \to X'$ be monotone. Then if $x$ is an interior point of $D(A)$, it follows that $A$ is locally bounded at $x$.

**Proof:** You could use Corollary 23.7.11. If $x$ is an interior point of $D(A)$, and $A$ is not locally bounded, then there exists $x_n \to x$ and $x_n^* \in Ax_n$ such that $\|x_n^*\| \to \infty$. Then by Corollary 23.7.11 there exists $y_0$ close to $x$, in $D(A)$ and a subsequence $x_{n_k}$ such that

$$\langle x_{n_k}^*, x_{n_k} - y_0 \rangle \to -\infty$$

Letting $y_0^* \in A y_0$,

$$\langle x_{n_k}^* - y_0^*, x_{n_k} - y_0 \rangle \geq 0$$

and so

$$\langle x_{n_k}^*, x_{n_k} - y_0 \rangle \geq \langle y_0^*, x_{n_k} - y_0 \rangle$$

and the right side is bounded below because it converges to $\langle y_0^*, x - y_0 \rangle$ and this is a contradiction. ■

Does the same proof work if $x$ is a limit point of $D(A)$? No. Suppose $x$ is a limit point of $D(A)$ if $A$ is not locally bounded, then there exists $x_n \to x, x_n \in D(A)$ and $x_n^* \in Ax_n$ and $\|x_n^*\| \to \infty$. Then there exists $y_0$ close to $x$ such that $\langle x_{n_k}^*, x_{n_k} - y_0 \rangle \to -\infty$ but now everything crashes in flames because it is not known that $y_0 \in D(A)$.

It follows from the above theorem that if $A$ is defined on all of $X$ and is maximal monotone, then it is locally bounded everywhere. Now here is a very interesting result which is like the one which involves monotone and hemi-continuous conditions. It is in 52.

**Theorem 23.7.21** Let $A : X \to \mathcal{P}(X')$ be monotone and satisfies the following conditions:

1. If $\lambda_n \to \lambda, \lambda_n \in [0,1]$ and $z_n \in A(u + \lambda_n(v-u))$, then if $B$ is any weakly open set containing 0, $z_n \in A(u) + B$ for all $n$ large enough. (Upper semicontinuous into weak topology along a line segment)

2. $A(x)$ is closed and convex.

Then one can conclude that $A$ is maximal monotone.
**Proof:** Let \( \hat{\mathcal{A}} \) be a monotone extension of \( A \). Let \( [\hat{u}, \hat{w}] \) be such that \( \hat{w} \in \hat{\mathcal{A}}(\hat{u}) \). Now also by assumption, \( A(x) \) is not just convex but also closed.

If \( [\hat{u}, \hat{w}] \) is not in the graph of \( A \), then by separation theorems, there is \( u \) such that

\[
\langle x^*, u \rangle < \langle \hat{w}, u \rangle \quad \text{for all} \quad x^* \in A(\hat{u})
\]

Then for \( \lambda > 0 \), let \( x_\lambda \equiv \hat{u} + \lambda u \), \( x_\lambda^* \in A(x_\lambda) \). Then from monotonicity of \( \hat{\mathcal{A}} \),

\[
0 \leq \langle x_\lambda^* - \hat{w}, x_\lambda - \hat{u} \rangle = \lambda \langle x_\lambda^* - \hat{w}, u \rangle
\]

Thus

\[
\langle x_\lambda^* - \hat{w}, u \rangle \geq 0
\]

By Theorem 23.7.20, the monotonicity of \( A \) on \( X \) implies \( A \) is locally bounded also. Thus in particular, \( Ax \) for small \( x \) is contained in a bounded set. Now by that hemicontinuity assumption, you can get a subsequence \( \lambda_n \to 0 \) for which \( x_\lambda \) converges weakly to \( x^* \in A\hat{u} \). Therefore, passing to the limit in the above, we get

\[
\langle x^* - \hat{w}, x_\lambda - \hat{u} \rangle = \langle x^* - \hat{w}, u \rangle \geq 0
\]

\[
\langle x^*, u \rangle \geq \langle \hat{w}, u \rangle > \langle x^*, u \rangle
\]

a contradiction. Thus there is no proper extension and this shows that \( A \) is maximal monotone. \( \Box \)

Recall the definition of a pseudomonotone operator.

**Definition 23.7.22** A set valued operator \( B \) is quasi-bounded if whenever \( x \in D(B) \) and \( x^* \in Bx \) are such that

\[
|x^*, x| \leq M,
\]

it follows that \( |x^*| \leq K_M \). Bounded would mean that if \( \|x\| \leq M \), then \( |x^*| \leq K_M \).

Here you only know this if there is another condition.

By Proposition 23.7.23, an example of a quasi-bounded operator is a maximal monotone operator \( G \) for which \( 0 \in \text{int}(D(G)) \).

Then there is a useful result which gives examples of quasi-bounded operators.

**Proposition 23.7.23** Let \( A : D(A) \subseteq X \to \mathcal{P}(X') \) be maximal monotone and suppose \( 0 \in \text{int}(D(A)) \). Then \( A \) is quasi-bounded.

**Proof:** From local boundedness, Theorem 23.7.20, there exists \( \delta, C > 0 \) such that

\[
\sup\{|x^*| : x^* \in A(x) \text{ for } \|x\| \leq \delta\} < C
\]

Now suppose that \( \|x\|, |(x^*, x)| \leq M \). Then letting \( \|y\| \leq \delta, y^* \in Ay \),

\[
0 \leq \langle x^* - y^*, x - y \rangle = \langle x^*, x \rangle - \langle x^*, y \rangle - \langle y^*, x \rangle + \langle y^*, y \rangle
\]
and so for $\|y\| \leq \delta$, 
$$\langle x^*, y \rangle \leq \langle x^*, x \rangle - \langle y^*, x \rangle + \langle y^*, y \rangle \leq M + MC + C\delta$$

Hence, $\|x^*\| \leq M + MC + C\delta = KM$. □

This is actually quite a restrictive requirement and leaves out a lot which would be interesting.

**Definition 23.7.24** Let $V$ be a reflexive Banach space. We say $T : V \to \mathcal{P}(V')$ is pseudomonotone if the following conditions hold.

$$Tu\text{ is closed, nonempty, convex.} \quad (23.7.51)$$

If $F$ is a finite dimensional subspace of $V$, then if $u \in F$ and $W \supseteq Tu$ for $W$ a weakly open set in $V'$, then there exists $\delta > 0$ such that

$$v \in B(u, \delta) \cap F \text{ implies } Tv \subseteq W. \quad (23.7.52)$$

If $u_k \to u$ and if $u_k^* \in Tu_k$ is such that

$$\limsup_{k \to \infty} u_k^*(u_k - u) \leq 0,$$

then for all $v \in V$, there exists $u^*(v) \in Tu$ such that

$$\liminf_{k \to \infty} u_k^*(u_k - v) \geq u^*(v)(u - v). \quad (23.7.53)$$

Then here is an interesting result [36].

**Theorem 23.7.25** Suppose $A : X \to \mathcal{P}(X')$ is maximal monotone. That is, $D(A) = X$. Then $A$ is pseudomonotone.

**Proof:** Consider the first condition. Say $x_1^* \in Ax$. Let $u^* \in Au$. For $\lambda \in [0, 1]$,

$$\langle \lambda x_1^* + (1 - \lambda)x_2^*, x - u \rangle = \lambda \langle x_1^* - u^*, x - u \rangle + (1 - \lambda) \langle x_2^* - u^*, x - u \rangle \geq 0$$

and so, since $[u, u^*]$ is arbitrary, it follows that $\lambda x_1^* + (1 - \lambda)x_2^* \in Ax$. Thus $Ax$ is convex. Is it closed? Say $x_n^* \in Ax$ and $x_n^* \to x^*$. Is it the case that $x^* \in D(A)$? Let $[u, u^*] \in \mathcal{G}(A)$ be arbitrary. Then

$$\langle x^* - u^*, x - u \rangle = \lim_{n \to \infty} \langle x_n^* - u^*, x_n - u \rangle \geq 0$$

and so $Ax$ is also closed.

Consider the second condition. It is to show that if $x_n \to x$ in $V$ a finite dimensional subspace and if $U$ is a weakly open set containing $0$, then eventually $Ax_n \subseteq Ax + U$. Suppose then that this is not the case. Then there exists $x_n^*$ outside of $Ax + U$ but in $Ax_n$. Since $A$ is locally bounded at $x$, it follows that the $\|x_n^*\|$.
are bounded. Thus there is a subsequence, still denoted as $x_n$ and $x_n^*$ such that $x_n^* \to x^*$ weakly and $x^* \notin Ax + U$. Now let $[u, u^*] \in G(A)$.

\[
\langle x^* - u^*, x - u \rangle = \lim_{n \to \infty} \langle x_n^* - u^*, x_n - u \rangle \geq 0
\]

and since $[u, u^*]$ is arbitrary, it follows that $x^* \in Ax$ and so is inside $Ax + U$. Thus the second condition holds also.

Consider the third. Say $x_k \to x$ weakly and letting $x_k \in Ax$, suppose

\[
\limsup_{k \to \infty} \langle x_k^*, x_k - x \rangle \leq 0,
\]

Is it the case that there exists $x^* (y) \in Ax$ such that

\[
\liminf_{k \to \infty} \langle x_k^*, x_k - y \rangle \geq \langle x^* (y), x - y \rangle?
\]

The proof goes just like it did earlier in the case of single valued pseudomonotone operators. It is just a little more complicated. First, let $x^* \in Ax$.

\[
\langle x_k^* - x^*, x_k - x \rangle \geq 0
\]

and so

\[
\liminf_{k \to \infty} \langle x_k^*, x_k - x \rangle \geq \liminf_{k \to \infty} \langle x_k^*, x_k - x \rangle = 0 \geq \limsup_{k \to \infty} \langle x_k^*, x_k - x \rangle
\]

Thus

\[
\lim_{k \to \infty} \langle x_k^*, x_k - x \rangle = 0.
\]

Now let $x_t^* \in A (x + t (y - x)), t \in (0, 1)$, where here $y$ is arbitrary. Then

\[
\langle x_n^* - x_t^*, x_n - x + t (x - y) \rangle \geq 0
\]

Hence

\[
\liminf_{n \to \infty} \langle x_n^*, x_n - x + t (x - y) \rangle \geq \liminf_{n \to \infty} \langle x_t^*, x_n - x + t (x - y) \rangle
\]

and so from the above limit,

\[
t \liminf_{n \to \infty} \langle x_n^*, x - y \rangle \geq t \langle x_t^*, x - y \rangle
\]

Cancel the $t$.

\[
\liminf_{n \to \infty} \langle x_n^*, x - y \rangle = \liminf_{n \to \infty} \langle x_n^*, x_n - y \rangle \geq \langle x_t^*, x - y \rangle
\]

Now you have a fixed $y$ and $x_t^* \in A (x + t (y - x))$. The subspace determined by $x, y$ is finite dimensional. Also it was shown above that $A$ is locally bounded at $x$ and so there is a subsequence, still denoted as $x_t^*$ such that $x_t^* \to x^*(y)$ weakly.
Now from the upper semicontinuity on finite dimensional spaces shown above, for every $S$ a finite subset of $X$ and $\varepsilon > 0$, it follows that for all $t$ small enough,

$$x^*_t \in Ax + B_S (0, \varepsilon)$$

Thus $x^*(y) \in Ax$. Hence, there exists $x^*(y) \in Ax$ such that

$$\liminf_{n \to \infty} \langle x^*_n, x_n - y \rangle \geq \langle x^*(y), x - y \rangle \quad \square$$

I found this in a paper by Peng. It is a very nice result.

**Proposition 23.7.26** Let $X$ and $Y$ be reflexive Banach spaces with $Y \subseteq X'$. Let $1 < p < \infty$ and let $q = \frac{p}{p-1} = p'$ so $\frac{1}{p} + \frac{1}{q} = 1$. Let $F : [0, T] \times X \to \mathcal{P}(Y)$ be multivalued and satisfies.

1. $F (\cdot, x)$ has a measurable selection for each $x \in X$
2. $F (t, \cdot)$ is maximal monotone for a.e. $t \in [0, T]$
3. $\|y\|_Y \leq \rho_1 (t) + \rho_2 \|x\|_X^{p-1}$ where $y \in F (t, x)$ for a.e. $t$, and where $\rho_1 \in L^q (0, T)$ and $\rho_2 > 0$

Let $0 \leq a < b \leq T$ with $b - a = \tau$. Define

$$F_{\tau} x \equiv \left\{ \frac{1}{\tau} \int_a^b y(t) \, dt : t \to y(t) \text{ is measurable and } y(t) \in F (t, x) \text{ a.e. } t \in (a, b) \right\}$$

Then $F_{\tau} : X \to \mathcal{P}(Y)$ is maximal monotone.

**Proof:** First note that $F_{\tau} x$ is convex and nonempty. To see this, say $z, \tilde{z}$ are in $F_{\tau} x$. and let $y, \tilde{y}$ be the corresponding functions. Then for $\lambda \in [0, 1]$

$$\lambda z + (1 - \lambda) \tilde{z} = \frac{1}{\tau} \int_a^b (\lambda y(t) + (1 - \lambda) \tilde{y}(t)) \, dt$$

and $\lambda y(t) + (1 - \lambda) \tilde{y}(t) \in F (t, x)$ because $F (t, \cdot)$ is maximal monotone which implies that the set values are convex.

Next is a claim that $F_{\tau} x$ is closed and also has the property that if $z_n \in F_{\tau} x_n$ and if $x_n \to x$ strongly in $X$ and $z_n \to z$ weakly in $Y$, then $z \in F_{\tau} x$. Let $y_n (t) \in F (t, x_n)$ a.e. such that $z_n = \frac{1}{\tau} \int_a^b y_n (t) \, dt$. These $x_n$ are bounded and so by the assumed estimate, it follows that the $y_n$ are bounded in $L^q (0, T; Y)$. Therefore, there is a subsequence, still denoted with $n$ such that $y_n \to \tilde{y}$ weakly in $L^q (0, T; Y)$. Now this means that $\tilde{y}$ is in the weak closure of the convex hull of $\{y_k : k \geq n\}$. However, this is the same as the strong closure because convex and closed is the same as convex and weakly closed. Therefore, there are functions

$$\lim_{n \to \infty} \sum_{k=n}^\infty c_k^k y_k = \tilde{y} \text{ strongly in } L^q (0, T; Y) \text{ where } \sum_{k=n}^\infty c_k^n = 1, c_k^n \geq 0,$$
23.7. MAXIMAL MONOTONE OPERATORS

and only finitely many are nonzero. Thus a subsequence still denoted with subscript $n$ also converges to $\hat{y}(t)$ for each $t$ off a set of measure zero. The function $F(t, \cdot)$ is maximal monotone and defined on $X$ and so it is pseudomonotone by Theorem 23.7.23. The estimate also shows that it is bounded. Therefore, as shown in the section on set valued pseudomonotone operators, $x \rightarrow F(t, x)$ is upper semicontinuous from strong to weak topology. Thus, for large $n$ depending on $t$, all of the $F(t, x_n)$ are contained in $F(t, x) + B_S(0, r/2)$ where $S$ is a finite subset of points of $X$.

$$B \equiv B_S(0, r/2) \equiv \left\{ w^* : |w^*(x)| < \frac{r}{2} \text{ for all } x \in S \right\}$$

Thus, for a fixed $t$ not in the exceptional set, off which the above pointwise convergence takes place, $\hat{y}(t) \in F(t, x) + D$ where

$$D \equiv \{ w^* : |w^*(x)| \leq r \text{ for all } x \in S \}$$

Since $S, r$ are arbitrary, separation theorems imply that $\hat{y}(t) \in F(t, x)$ for $t$ off a set of measure zero: If not, there would exist $u \in X$ such that $\hat{y}(t)(u) > l > l - \delta > p(u)$ for all $p \in F(t, x)$. But then you could take $r = \delta/2$ and $B_u(0, \delta/2)$ and find that $\hat{y}(t) = p + w^*$ where $p \in F(t, x)$ and $|w^*(u)| \leq \delta$. Hence $p(u) = \hat{y}(t)(u) - w^*(u) > l - \delta > p(u)$ an obvious contradiction. Is $z \in F_x$? Certainly so if $z = \frac{1}{\tau} \int_a^b \hat{y}(t) \, dt$. Letting $\phi \in X$,

$$\langle z, \phi \rangle = \lim_{n \to \infty} \langle z_n, \phi \rangle = \lim_{n \to \infty} \left\langle \frac{1}{\tau} \int_a^b y_n(t) \, dt, \phi \right\rangle = \lim_{n \to \infty} \left\langle \frac{1}{\tau} \int_a^b \sum_{k=a}^n c_k y_k(t) \, dt, \phi \right\rangle$$

$$= \left\langle \frac{1}{\tau} \int_a^b \hat{y}(t) \, dt, \phi \right\rangle$$

Since $\phi$ is arbitrary, it follows that $z = \frac{1}{\tau} \int_a^b \hat{y}(t) \, dt$ and so $z \in F_x$.

Is $F_x$ monotone? Say $z, \hat{z}$ are in $F_x(x), F_x(\hat{x})$ respectively. Consider

$$\langle z - \hat{z}, x - \hat{x} \rangle = \left\langle \frac{1}{\tau} \int_a^b y(t) - \hat{y}(t) \, dt, x - \hat{x} \right\rangle = \frac{1}{\tau} \int_a^b \langle y(t) - \hat{y}(t), x - \hat{x} \rangle \, dt$$

but $y(t) \in F(t, x)$ similar for $\hat{y}$ and so the above is $\geq 0$. Thus $F_x$ is indeed monotone. This has also shown that $F_x$ satisfies the necessary modified hemicontinuity condition of Theorem 23.7.21 to conclude that $F_x$ is indeed maximal monotone because it has convex closed values, the hemicontinuity condition, and is monotone.

Suppose $T$ is a bounded pseudomonotone operator and $S$ is a maximal monotone operator, both defined on a strictly convex reflexive Banach space. What of their sum? Is $(T + S)(x)$ convex and closed? Say $t_i \in Tx$ and $s_i \in Sx$ is it the case that $\theta (s_1 + t_1) + (1 - \theta)(s_2 + t_2) \in (T + S)(x)$ whenever $\theta \in [0, 1]$? Of course this is so. Thus $T + S$ has convex values. Does it have closed values? Suppose $\{s_n + t_n\}$ converges to $z \in X', s_n \in Sx, t_n \in Tx$. Is $z \in (T + S)(x)$? Taking a subsequence, and using the assumption that $T$ is bounded, it can be assumed that
CHAPTER 23. NONLINEAR OPERATORS

\( t_n \to t \in T x \) weakly. Therefore, \( s_n \) must also converge weakly and so it converges to some \( s = z - t \in S x \). Convex and closed implies weakly closed. Thus \( T + S \) has closed convex values. Is it upper semicontinuous on finite dimensional subspaces? Suppose \( x_n \to x \) in a finite dimensional subspace \( F \). Does it follow that

\[
(S + T) x_n \subseteq (S + T) x + B(0, r)
\]

for all \( n \) sufficiently large? It is known that \( S x_n \subseteq S x + B(0, r/2) \) and \( T x_n \subseteq T x + B(0, r/2) \) whenever \( n \) is sufficiently large and so it follows that

\[
(S + T) x_n \subseteq (S + T) x + B(0, r/2) + B(0, r/2) \subseteq (S + T) x + B(0, r)
\]

whenever \( n \) is large enough.

What of the pseudomonotone condition? Suppose

\[
\limsup_{n \to \infty} \langle u^*_n + v^*_n, x_n - x \rangle \leq 0
\]

where \( u^*_n \in S x_n \) and \( v^*_n \in T x_n \) where \( x_n \to x \) weakly. Is it the case that for every \( y \), there exists \( u^* \in S x \) and \( v^* \in T x \) such that

\[
\liminf_{n \to \infty} \langle u^*_n + v^*_n, x_n - y \rangle \geq \langle u^* + v^*, x - y \rangle
\]

By monotonicity,

\[
0 \geq \limsup_{n \to \infty} \langle u^*_n + v^*_n, x_n - x \rangle \geq \limsup_{n \to \infty} \langle u^*_n + v^*_n, x_n - x \rangle
\]

\[
= \limsup_{n \to \infty} \langle v^*_n, x_n - x \rangle
\]

Hence

\[
\limsup_{n \to \infty} \langle v^*_n, x_n - x \rangle \leq 0
\]

which implies

\[
\liminf_{n \to \infty} \langle v^*_n, x_n - x \rangle \geq \langle v^*, x - x \rangle = 0 \geq \limsup_{n \to \infty} \langle v^*_n, x_n - x \rangle
\]

showing that

\[
\lim_{n \to \infty} \langle v^*_n, x_n - x \rangle = 0 \quad (23.7.54)
\]

It follows that if \( y \) is given, there exists \( v^* \in T(x) \) such that

\[
\liminf_{n \to \infty} \langle v^*_n, x_n - y \rangle \geq \langle v^*, x - y \rangle
\]

Now let \( u^*_t \in S(x + t(y - x)) \) for \( t > 0 \). Thus

\[
\langle u^*_n - u^*_t, x_n - x + t(x - y) \rangle \geq 0
\]

\[
\langle u^*_n, x_n - x + t(x - y) \rangle \geq \langle u^*_t, x_n - x + t(x - y) \rangle
\]
Then using the above and the convergence in §23.7.54,
\[
\liminf_{n \to \infty} \langle u_n^* + v_n^*, x_n - y \rangle \geq \liminf_{n \to \infty} \langle u_n^* + v_n^*, x_n - y \rangle
\]
\[= \langle u_t^*, x - y \rangle + \langle v^*, x - y \rangle \]
Now as before where it was shown that maximal monotone and defined on $X$ implied pseudomonotone, and the theorem which says that maximal monotone operators are locally bounded on the interior of their domains, it follows that there exists a sequence, still denoted as $u_t^*$ which converges to something called $u^*$. Then as before, the subspace spanned by $x, y$ is finite dimensional and so from upper semicontinuity, for all $t$ small enough,
\[u_t^* \in S(x) + B(0, r)\]
Note that weak convergence is the same as strong on finite dimensional spaces. Since this is true for all $r$ and $S(x)$ is closed, it follows that $u^* \in S(x)$. Thus, passing to a limit as $t \to 0$ one gets $u^* \in S(x), v^* \in T(x)$, and
\[\liminf_{n \to \infty} \langle u_n^* + v_n^*, x_n - y \rangle \geq \langle u^* + v^*, x - y \rangle\]
This proves the following generalization of Theorem 23.7.25.

**Theorem 23.7.27** Let $T, S : X \to P(X')$ where $X$ is a strictly convex reflexive Banach space and suppose $T$ is bounded and pseudomonotone while $S$ is maximal monotone. Then $T + S$ is pseudomonotone.

Also, there is an interesting result which is based on the obvious observation that if $A$ is maximal monotone, then so is $A(x) \equiv A(x_0 + x)$.

**Lemma 23.7.28** Let $A$ be maximal monotone. Then for each $\lambda > 0$,
\[x \to \lambda F(x) - x_0 \to Ax\]
is onto.

**Proof:** Let $\hat{A}(x) \equiv A(x_0 + x)$ so as earlier, $\hat{A}$ is maximal monotone. Then let $y^* \in X'$. Then there exists $y$ such that $\hat{A}(y) + \lambda F(y) \ni y^*$. Now define $x \equiv y + x_0$. Then
\[\hat{A}(y) + \lambda F(y) \ni y^*, \hat{A}(x - x_0) + \lambda F(x - x_0) \ni y^*, A(x) + \lambda F(x - x_0) \ni y^* \]

**Definition 23.7.29** Let $A : D(A) \to P(X')$ be maximal monotone. Let $A^{-1} : A(D(A)) \to P(X')$ be defined as follows.
\[x \in A^{-1}x^* \text{ if and only if } x^* \in Ax\]

**Observation 23.7.30** $A^{-1}$ is also maximal monotone. This is easily seen as follows. $[x, y] \in \mathcal{G}(A)$ if and only if $[y, x] \in \mathcal{G}(A^{-1})$. 

Earlier, it was shown that if $B$ is monotone and hemicontinuous and coercive, then it was onto. It was not necessary to assume that $B$ is bounded. The same thing holds for $A$ maximal monotone. This will follow from the next result. Recall that a maximal monotone operator is locally bounded at every interior point of its domain which was shown above. Also it appears to not be possible to show that a maximal monotone operator is locally bounded at a limit point of $A(D(A))$. The following result is in [12] although he claims a better result than what I am proving here in which it is only necessary to verify $A^{-1}$ is locally bounded at every point of $A(D(A))$. However, I was unable to follow the argument and so I am proving another theorem with the same argument he uses. It looks like a typo to me but I often have trouble following hard theorems so I am not sure. Anyway, the following is the best I can do. I think it is still a very interesting result.

**Theorem 23.7.31** Suppose $A^{-1}$ is locally bounded at every point of $A(D(A))$. Then in fact $A(D(A)) = X'$ and in fact $A(D(A)) = A(D(A))$.

**Proof:** This is done by showing that $A(D(A))$ is both open and closed. Since it is nonempty, it must be all of $X'$ because $X'$ is connected. First it is shown that $A(D(A))$ is closed. Suppose $y_n \in Ax_n$ and $y_n \to y$. Does it follow that $y \in A(D(A))$? Since $y$ is a limit point of $A(D(A))$, it follows that $A^{-1}$ is locally bounded at $y$. Thus there is a subsequence still denoted by $y_n$ such that $y_n \to y$ and for $x_n \in A^{-1}y_n$ or in other words, $y_n \in Ax_n$, it follows that $x_n$ is bounded. Hence there exists a subsequence, still denoted with the subscript $n$ such that $x_n \to x$ weakly and $y_n \to y$ strongly. Hence if $[u,v] \in G(A)$,

$$
(y - u, x - v) = \lim_{n \to \infty} \langle y_n - u, x_n - x \rangle \geq 0
$$

Since $[u,v]$ is arbitrary and $A$ is maximal monotone, it follows that $y \in Ax$ or in other words, $x \in A^{-1}y$ and $y \in A(D(A))$. Thus $A(D(A))$ is closed.

Next consider why $A(D(A))$ is open. Let $y_0 \in A(D(A))$. Then there exists $D_r \equiv \overline{B(y_0,r)}$ centered at $y_0$ such that $A^{-1}$ is bounded on $D_r$. Since $A$ is maximal monotone, for each $y \in X'$ there is a solution $x_\varepsilon$ to the inclusion

$$
y \in \varepsilon F(x_\varepsilon - x_0) + Ax_\varepsilon, \ y \equiv y - \varepsilon F(x_\varepsilon - x_0) \in Ax_\varepsilon
$$

Consider only $y \in B(y_0, \frac{r}{2})$.

$$
\langle (y - \varepsilon F(x_\varepsilon - x_0)) - y_0, x_\varepsilon - x_0 \rangle \geq 0
$$

Then using $\langle Fz, z \rangle = \|z\|^2$,

$$
\|y - y_0\| \|x_\varepsilon - x_0\| \geq \langle y - y_0, x_\varepsilon - x_0 \rangle \geq \varepsilon \|x_\varepsilon - x_0\|^2
$$

and so $\varepsilon \|x_\varepsilon - x_0\| = \varepsilon \| F(x_\varepsilon - x_0)\| \leq \|y - y_0\| < r/2$. Thus $x_\varepsilon$ stays in $B(y_0, r)$. Thus $y_\varepsilon$ is closer to $y_0$ than $r/2$ while $y_\varepsilon$ is within $r/2$ of $y$. It follows that the $x_\varepsilon$ are bounded and so $x_\varepsilon - x_0$ is bounded and so $\varepsilon F(x_\varepsilon - x_0) \to 0$. Thus
y_ε → y strongly. Since the x_ε are bounded, there exists a further subsequence, still denoted as x_ε such that x_ε → x, some point of X. Then if [u, v] ∈ G(A),

\[ \langle y_ε - v, x_ε - u \rangle \geq 0 \]

and letting ε → 0 using the strong convergence of y_ε one obtains

\[ \langle y - v, x - u \rangle \geq 0 \]

which shows that y ∈ Ax. Thus B(y_0, y) ⊆ A(D(A)) 1= D(A^{-1}) and so A(D(A)) is open.  

The proof featured the usual duality map.

Note that as part of the proof A(D(A)) was shown to be closed so although it was assumed at the outset that A^{-1} was locally bounded on A(D(A)), this is the same as saying that A^{-1} is locally bounded on A(D(A)).

**Corollary 23.7.32** Suppose A : D(A) → P(X') is maximal monotone and coercive. Then A is onto.

**Proof:** From Theorem 23.7.31 it suffices to show that A^{-1} is locally bounded at y* ∈ A(D(A)). The case of an interior point follows from Theorem 23.7.20. Assume then that y* is a limit point of A(D(A)). Of course this includes the case of interior points. Then there exists y*_n → y* where y*_n ∈ Ax_n. Then

\[ \frac{\langle y*_n, x_n \rangle}{\|x_n\|} \leq \|y*_n\| \]

and the right side is bounded. Hence by coercivity, so is \|x_n\|. Therefore, there is a further subsequence, still denoted as x_n such that x_n → x weakly while y*_n → y* strongly. Then letting [u, v*] ∈ G(A),

\[ \langle y* - v*, x - u \rangle = \lim_{n \to \infty} \langle y*_n - v*, x_n - u \rangle \geq 0 \]

Hence y* ∈ Ax and y* ∈ A(D(A)). Thus A^{-1} is locally bounded on A(D(A)) and so A is onto from the above theorem.

**23.7.4 Approximation Theorems**

This section continues following Barbu [12]. Always it is assumed that the situation is of a real reflexive Banach space X having strictly convex norm and its dual X'. As observed earlier, there exists a solution x_λ to the inclusion

\[ 0 \in F(x_λ - x) + λA(x_λ) \]

To see this, you consider \( \hat{A} \) (y) ≡ A (x + y). Then \( \hat{A} \) is also maximal monotone and so there exists a solution to

\[ 0 \in F(\hat{x}) + λ\hat{A}(\hat{x}) = F(\hat{x}) + λA(x + \hat{x}) \]
Now let $x = x + \delta$ so $\delta = x - x$. Hence

$$0 \in F(x - x) + \lambda Ax$$

Here you could have $F$ the duality map for any given $p > 1$.

The symbol $\lim sup_{n, n \to \infty} a_{mn}$ means $\lim_{N \to \infty} (\sup_{m \geq N, n \geq N} a_{mn})$. Then here is a simple observation.

**Lemma 23.7.33** Suppose $\lim sup_{n, n \to \infty} a_{mn} \leq 0$. Then $\lim sup_{m \to \infty} (\lim sup_{n \to \infty} a_{mn}) \leq 0$.

**Proof:** There exists $N$ such that if both $m, n \geq N, a_{mn} \leq \varepsilon$. Then

$$\lim sup_{n \to \infty} a_{mn} = \lim sup_{n, n \to \infty, n > N} a_{mn} \leq \varepsilon$$

Thus also

$$\lim sup_{m, n \to \infty} (\lim sup_{n \to \infty} a_{mn}) = \lim sup_{m \to \infty, m \geq N} (\lim sup_{n \to \infty} a_{mn}) \leq \varepsilon.$$  

The argument will be based on the following lemma.

**Lemma 23.7.34** Let $A : D(A) \to \mathcal{P}(X')$ be maximal monotone and let $v_n \in Au_n$ and $u_n \to u$, $v_n \to v$ weakly. Also suppose that

$$\lim sup_{m, n \to \infty} \langle v_n - v_m, u_n - u_m \rangle \leq 0$$

or

$$\lim sup_{n \to \infty} \langle v_n - v, u_n - u \rangle \leq 0$$

Then $[u, v] \in \mathcal{G}(A)$ and $\langle v_n, u_n \rangle \to \langle v, u \rangle$.

**Proof:** By monotonicity,

$$\lim_{m, n \to \infty} \langle v_n - v_m, u_n - u_m \rangle = 0$$

Suppose then that $\langle v_n, u_n \rangle$ fails to converge to $\langle v, u \rangle$. Then there is a subsequence, still denoted with subscript $n$ such that $\langle v_n, u_n \rangle \to \mu \neq \langle v, u \rangle$. Let $\varepsilon > 0$. Then there exists $M$ such that if $n, m > M$, then

$$|\langle v_n, u_n \rangle - \mu| < \varepsilon, |\langle v_n - v_m, u_n - u_m \rangle| < \varepsilon$$

Then if $m, n > M$,

$$|\langle v_n - v_m, u_n - u_m \rangle| = |\langle v_n, u_n \rangle + \langle v_m, u_m \rangle - \langle v_n, u_m \rangle - \langle v_m, u_n \rangle| < \varepsilon$$
Hence it is also true that

\[ |\langle v_n, u_n \rangle + \langle v_m, u_m \rangle - \langle v_n, u_m \rangle| \leq |2\mu - (\langle v_n, u_m \rangle + \langle v_m, u_n \rangle)| < 3\varepsilon \]

Now take a limit first with respect to \( n \) and then with respect to \( m \) to obtain

\[ |2\mu - (\langle v, u \rangle + \langle v, u \rangle)| < 3\varepsilon \]

Since \( \varepsilon \) is arbitrary, \( \mu = \langle v, u \rangle \) after all. Hence the claim that \( \langle v_n, u_m \rangle \to \langle v, u \rangle \) is verified. Next suppose \( [x, y] \in \mathcal{G}(A) \) and consider

\[ \langle v - y, u - x \rangle = \langle v, u \rangle - \langle v, x \rangle - \langle y, u \rangle + \langle y, x \rangle \]

\[ = \lim_{n \to \infty} (\langle v_n, u_n \rangle - \langle v_n, x \rangle - \langle y, u_n \rangle + \langle y, x \rangle) \]

\[ = \lim_{n \to \infty} (v_n - y, u_n - x) \geq 0 \]

and since \([x, y]\) is arbitrary, it follows that \( v \in Au \).

Next suppose \( \limsup_{n \to \infty} \langle v_n - v, u_n - u \rangle \leq 0 \). It is not known that \( [u, v] \in \mathcal{G}(A) \).

\[ \limsup_{n \to \infty} (\langle v_n, u_n \rangle - \langle v_n, u_n \rangle - \langle v_n, u \rangle + \langle v, u \rangle) \leq 0 \]

\[ \limsup_{n \to \infty} (\langle v_n, u_n \rangle - \langle v, u \rangle \leq 0 \]

Thus \( \limsup_{n \to \infty} \langle v_n, u_n \rangle \leq \langle v, u \rangle \). Now let \( [x, y] \in \mathcal{G}(A) \)

\[ \langle v - y, u - x \rangle = \langle v, u \rangle - \langle v, x \rangle - \langle y, u \rangle + \langle y, x \rangle \]

\[ \geq \limsup_{n \to \infty} (\langle v_n, u_n \rangle - \langle v_n, x \rangle - \langle y, u_n \rangle + \langle y, x \rangle) \]

\[ \geq \liminf_{n \to \infty} (v_n - y, u_n - x) \geq 0 \]

Hence \( [u, v] \in \mathcal{G}(A) \). Now

\[ \limsup_{n \to \infty} \langle v_n - v, u_n - u \rangle \leq 0 \leq \liminf_{n \to \infty} \langle v_n - v, u_n - u \rangle \]

the second coming from monotonicity and the fact that \( v \in Au \). Therefore,

\[ \lim_{n \to \infty} \langle v_n - v, u_n - u \rangle = 0 \]

which shows that \( \lim_{n \to \infty} \langle v_n, u_n \rangle = \langle v, u \rangle \). ■

**Definition 23.7.35** Let \( x_\lambda \) just defined

\[ 0 \in F(x_\lambda - x) + \lambda A x_\lambda \]
be denoted by $J_\lambda x$ and define also

$$A_\lambda (x) = -\lambda^{-(p-1)} F (x_\lambda - x) = -\lambda^{-(p-1)} F (J_\lambda x - x).$$

This is for $F$ a duality map with $p > 1$. Thus for the usual duality map, you would have

$$A_\lambda (x) = -\lambda^{-1} F (J_\lambda x - x)$$

Recall how this $x_\lambda$ is defined. In general,

$$0 \in F (J_\lambda x - x) + \lambda^{p-1} A x_\lambda$$

Thus, from the definition,

$$A_\lambda (x) \in A (J_\lambda x)$$

Formally, and to help remember what is going on, you are looking at a generalization of

$$A_\lambda x = -A + \lambda^{-1} x = \frac{1}{\lambda} \left( x - (I + \lambda A)^{-1} x \right)$$

This is in the case where $F = I$ to keep things simpler. You have $0 = x_\lambda - x + \lambda A x_\lambda$ and so formally $x_\lambda = (I + \lambda A)^{-1} x$. Thus you are looking at $\frac{1}{\lambda} (x - x_\lambda) = \frac{1}{\lambda} \left( x - (I + \lambda A)^{-1} x \right) = A_\lambda x$. In fact, this is exactly what you do when you are in a single Hilbert space. This is just a generalization to mappings between Banach spaces and their duals.

Then there are some things which can be said about these operators. It is presented for the general duality map for $p > 1$.

**Theorem 23.7.36** The following hold. Here $X$ is a reflexive Banach space with strictly convex norm. $A : D (A) \to \mathcal{P} (X')$ is maximal monotone. Then

1. $J_\lambda$ and $A_\lambda$ are bounded single valued operators defined on $X$. Bounded means they take bounded sets to bounded sets. Also $A_\lambda$ is a monotone operator.

2. $A_\lambda, J_\lambda$ are demicontinuous. That is, strongly convergent sequences are mapped to weakly convergent sequences.

3. For every $x \in D (A), \| A_\lambda (x) \| \leq |A x| \equiv \inf \{ \| y^* \| : y^* \in A x \}$. For every $x \in \text{conv} (D (A))$, it follows that $\lim_{\lambda \to 0} J_\lambda (x) = x$. The new symbol means the closure of the convex hull. It is the closure of the set of all convex combinations of points of $D (A)$.

**Proof:** 1.) It is clear that these are single valued operators. What about the assertion that they are bounded? Let $y^* \in A x_\lambda$ such that the inclusion defining $x_\lambda$ becomes an equality. Thus

$$F (x_\lambda - x) + \lambda^{p-1} y^* = 0$$
Then let $x_0 \in D(A)$ be given.

$$\langle F(x_\lambda - x), x_\lambda - x \rangle + \lambda^{p-1} \langle y^*, x_\lambda - x_0 \rangle + \lambda^{p-1} \langle y^*, x_0 - x \rangle = 0$$

Then by monotonicity of $A$,

$$\|x_\lambda - x\|^p + \lambda^{p-1} \langle y^*, x_\lambda - x_0 \rangle + \lambda^{p-1} \langle y^*, x_0 - x \rangle \leq 0$$

It follows that

$$\|x_\lambda - x\|^p \leq \lambda^{p-1} \|y^*\| \|x_\lambda - x_0\| + \lambda^{p-1} \|y^*\| \|x_0 - x\|$$

Hence if $x$ is in a bounded set, it follows the resulting $x_\lambda = J\lambda x$ remain in a bounded set. Now from the definition of $A_\lambda$, it follows that this is also a bounded operator.

Why is $A_\lambda$ monotone?

$$0 \leq \langle A_\lambda x - A_\lambda y, x - y \rangle = \langle A_\lambda x - A_\lambda y, x - J_\lambda x - (y - J_\lambda y) \rangle$$

$$+ \langle A_\lambda x - A_\lambda y, J_\lambda x - J_\lambda y \rangle$$

$$= \left( \lambda^{- (p-1)} F(J_\lambda x - x) - \lambda^{- (p-1)} F(J_\lambda y - y), J_\lambda x - x - (J_\lambda y - y) \right)$$

$$+ \langle A_\lambda x - A_\lambda y, J_\lambda x - J_\lambda y \rangle$$

and both terms are nonnegative, the first because $F$ is monotone so indeed $A_\lambda$ is monotone.

2.) What of the demicontinuity of $A_\lambda$? This one is really tricky. Suppose $x_n \to x$. Does it follow that $A_\lambda x_n \to A_\lambda x$ weakly? The proof will be based on a pair of equations. These are

$$\lim_{m,n \to \infty} \langle F(J_\lambda x_n - x_n) - F(J_\lambda x_m - x_m), J_\lambda x_n - x_n - (J_\lambda x_m - x_m) \rangle = 0$$

and

$$\lim_{m,n \to \infty} \langle A_\lambda (x_n) - A_\lambda (x_m), J_\lambda x_n - J_\lambda x_m \rangle = 0$$

When these have been established, Lemma (23.7.34) is used to get the desired result for a subsequence. It will be shown that every sequence has a subsequence which gives the right sort of weak convergence and from this the desired weak convergence of $A_\lambda x_n$ to $A_\lambda x$ follows.

$$0 \in F(J_\lambda x_n - x_n) + \lambda^{p-1} A(J_\lambda x_n)$$

$$0 \in F(J_\lambda x - x) + \lambda^{p-1} A(J_\lambda x)$$

$$-\lambda^{- (p-1)} F(J_\lambda x - x) \in A(J_\lambda x)$$

$$-\lambda^{- (p-1)} F(J_\lambda x_n - x_n) \in A(J_\lambda x_n)$$

Note also that for a given $x$ there is only one solution $J_\lambda x$ to $0 \in F(J_\lambda x - x) + \lambda^{p-1} A(J_\lambda x)$. By monotonicity of $F$,

$$0 \leq \langle F(J_\lambda x_n - x_n) - F(J_\lambda x_m - x_m), x_m - x_n + J_\lambda x_n - J_\lambda x_m \rangle$$
Then from the above,
\[
\langle F (J_\lambda x_n - x_n) - F (J_\lambda x_m - x_m), x_n - x_m \rangle \\
\leq \langle F (J_\lambda x_n - x_n) - F (J_\lambda x_m - x_m), J_\lambda x_n - J_\lambda x_m \rangle
\]

Now from the boundedness of these operators, the left side of the above inequality converges to 0 as \( n, m \to \infty \). Thus

\[
\lim \inf_{m,n \to \infty} \langle F (J_\lambda x_n - x_n) - F (J_\lambda x_m - x_m), J_\lambda x_n - J_\lambda x_m \rangle \geq 0 \quad (23.7.55)
\]

\[
\lim \inf_{m,n \to \infty} \left\langle -\lambda^{p-1} A_\lambda (x_n) - (-\lambda^{p-1} A_\lambda (x_m)), J_\lambda x_n - J_\lambda x_m \right\rangle \geq 0
\]

\[
\lim \inf_{m,n \to \infty} \left\langle \lambda^{p-1} \overline{A_\lambda (x_m)} - \lambda^{p-1} \overline{A_\lambda (x_n)}, J_\lambda x_n - J_\lambda x_m \right\rangle \geq 0
\]

The expression on the left in the above is non positive. Multiplying by \(-1\),

\[
0 \geq \lim \sup_{m,n \to \infty} \langle A_\lambda (x_n) - A_\lambda (x_m), J_\lambda x_n - J_\lambda x_m \rangle
\]

\[
\geq \lim \inf_{m,n \to \infty} \langle A_\lambda (x_n) - A_\lambda (x_m), J_\lambda x_n - J_\lambda x_m \rangle \geq 0 \quad (23.7.56)
\]

Thus, in fact, the expression in (23.7.56) converges to 0. By boundedness considerations and the strong convergence given,

\[
\lim_{m,n \to \infty} \langle F (J_\lambda x_n - x_n) - F (J_\lambda x_m - x_m), J_\lambda x_n - x_n - (J_\lambda x_m - x_m) \rangle = 0
\]

(23.7.57)

From boundedness again, there is a subsequence still denoted with the subscript \( n \) such that

\[ J_\lambda x_n - x_n \to a - x, \quad F (J_\lambda x_n - x_n) \to b \] both weakly.

Since \( F \) is maximal monotone, (Theorem 23.7.3) it follows from Lemma 23.7.3 that \([a - x, b] \in G (F)\) and so in fact \( F (a - x) = b\). Thus this has just shown that \( F (J_\lambda x_n - x_n) \to F (a - x)\). Next consider 23.7.3. We have \( J_\lambda x_n \to a \) weakly and \( A_\lambda (x_n) = -\lambda^{-(p-1)} F (J_\lambda x_n - x_n) \to -\lambda^{-(p-1)} b \) weakly. Then from Lemma 23.7.3 again, \([a, -\lambda^{-(p-1)} b] \in G (A)\) so \(-\lambda^{-(p-1)} b \in A (a)\) so \( b \in -\lambda^{p-1} A (a)\).

But it was just shown that \( b = F (a - x)\) and so

\[ F (a - x) \in -\lambda^{p-1} A (a) \quad \text{so} \quad 0 \in F (a - x) + \lambda^{p-1} A (a), \quad \text{so} \quad a = J_\lambda x. \]

As noted at the beginning, there is only one solution to this inclusion for a given \( x \) and it is \( a = J_\lambda x\). This has shown that in terms of weak convergence,

\[ A_\lambda (x_n) \to -\lambda^{-(p-1)} b = -\lambda^{-(p-1)} F (a - x) = -\lambda^{-(p-1)} F (J_\lambda x - x) \equiv A_\lambda (x) \]
This has shown that $A_\lambda$ is demicontinuous. Also it has shown that $J_\lambda$ is also demicontinuous. (This result is a lot nicer in Hilbert space.)

3.) Why is $\|A_\lambda(x)\| \leq |Ax|$ whenever $x \in D(A)$?

$$A_\lambda(x) = -\lambda^{-(p-1)} F(J_\lambda x - x)$$

where $0 \in F(J_\lambda x - x) + \lambda^{p-1} A(J_\lambda x)$. Therefore, $A_\lambda(x) \in A(J_\lambda x)$. Then letting $[u,v] \in \mathcal{G}(A)$,

$$0 \leq \langle v - A_\lambda(x) , u - J_\lambda x \rangle$$

In particular, if $y \in Ax$

$$0 \leq \langle y - A_\lambda(x) , x - J_\lambda x \rangle = \langle y + \lambda^{-(p-1)} F(J_\lambda x - x) , x - J_\lambda x \rangle$$

Hence

$$\lambda^{-(p-1)} \|J_\lambda x - x\|^{p} \leq \|y\| \|J_\lambda x - x\|$$

and so

$$\lambda^{-(p-1)} \|J_\lambda x - x\|^{p-1} = \lambda^{-(p-1)} \|F(J_\lambda x - x)\| = \|A_\lambda(x)\| \leq \|y\|$$

and since $y \in Ax$ is arbitrary, $\|A_\lambda(x)\| \leq |Ax| = \inf \{\|y\| : y \in Ax\}$.

Next consider the claim that for all $x \in \text{conv}(D(A))$, it follows that

$$\lim_{\lambda \to 0} J_\lambda(x) = x.$$

Let $[u,v] \in \mathcal{G}(A)$ and $x$ is arbitrary.

$$0 \leq \langle v - A_\lambda(x) , u - J_\lambda x \rangle = \langle v + \lambda^{-(p-1)} F(J_\lambda x - x) , u - J_\lambda x \rangle$$

$$= \langle v + \lambda^{-(p-1)} F(J_\lambda x - x) , u - x \rangle + \langle v + \lambda^{-(p-1)} F(J_\lambda x - x) , x - J_\lambda x \rangle$$

Thus

$$\|J_\lambda x - x\|^{p} \leq \lambda^{p-1} \langle v, u - x \rangle + \langle F(J_\lambda x - x) , u - x \rangle + \lambda^{p-1} \langle v, x - J_\lambda x \rangle \quad (23.7.58)$$

for $x$ arbitrary and $u$ anything in $D(A)$. It follows that (23.7.58) holds for any $u \in \text{conv}(D(A))$ where $x_n \to x$. Then

$$\|J_\lambda x - x\|^{p} \leq \lambda^{p-1} \langle v, x_n - x \rangle + \langle F(J_\lambda x - x) , x_n - x \rangle + \lambda^{p-1} \langle v, x - J_\lambda x \rangle$$

$$\leq \lambda^{p-1} \|v\| \|x_n - x\| + \|J_\lambda x - x\|^{p-1} \|x_n - x\| + \lambda^{p-1} \|v\| \|J_\lambda x - x\|$$

You have something like this: $y_\lambda = \|J_\lambda x - x\| , a_n = \|x_n - x\|,

$$y_\lambda^{p} \leq \lambda^{p-1} \|v\| a_n + y_\lambda^{p-1} a_n + \lambda^{p-1} \|v\| y_\lambda \quad , \quad y_\lambda \geq 0$$

where $p > 1$ and $a_n \to 0$. Then

$$\limsup_{\lambda \to 0} y_\lambda^{p} \leq \limsup_{\lambda \to 0} y_\lambda^{p-1} a_n$$
and so,
\[ \limsup_{\lambda \to 0} y_{\lambda} \leq a_n \]

Hence
\[ \limsup_{\lambda \to 0} \| J_{\lambda} x - x \| \leq \| x_n - x \| \]

Since \( x_n \) is arbitrary, it follows that for every \( \varepsilon > 0 \),
\[ \limsup_{\lambda \to 0} \| J_{\lambda} x - x \| \leq \varepsilon \]

and so in fact, \( \limsup_{\lambda \to \infty} \| J_{\lambda} x - x \| = 0 \). \( \blacksquare \)

Now here is an interesting corollary.

**Corollary 23.7.37** Let \( A \) be maximal monotone. \( A : X \to X' \) where \( X \) is a strictly convex reflexive Banach space. Then \( \overline{D(A)} \) is convex.

**Proof:** It is known that \( J_{\lambda} : X \to D(A) \) for any \( \lambda \). Also, if \( x \in \overline{D(A)} \), then it was shown that \( J_{\lambda} x \to x \). Clearly
\[ \overline{\text{conv}(D(A))} \supseteq \overline{D(A)} \]

Now if \( x \) is in the set on the left, \( J_{\lambda} x \to x \) and so in fact, since \( J_{\lambda} x \in D(A) \), it must be the case that \( x \in \overline{D(A)} \). Thus the two sets are the same and so in fact, \( \overline{D(A)} \) is closed and convex. \( \blacksquare \)

Note that this implies that \( A(D(A)) \) is also convex. This is because \( A^{-1} \) described above, is maximal monotone with domain \( A(D(A)) \).

Next is a useful generalization of some of the earlier material used to establish the above results on approximation. It will include the general case of \( F \) a duality map for \( p > 1 \).

**Proposition 23.7.38** Suppose \( A : X \to P(X') \) where \( X \) is a reflexive Banach space with strictly convex norm. Suppose also that \( A \) is maximal monotone. Then if \( \lambda_n \to 0 \) and if \( x_n \to x \) weakly, \( A_{\lambda_n} x_n \to x^* \) weakly, and
\[ \limsup_{n,m \to \infty} \langle A_{\lambda_n} x_n - A_{\lambda_n} x_m, x_n - x_m \rangle \leq 0 \]

Then
\[ \lim_{n,m \to \infty} \langle A_{\lambda_n} x_n - A_{\lambda_n} x_m, x_n - x_m \rangle = 0, \]
\([x, x^*] \in \mathcal{G}(A)\), and \( \langle A_{\lambda_n} x_n, x_n \rangle \to \langle x^*, x \rangle \).

**Proof:** Let \( \alpha = \limsup_{n \to \infty} \langle A_{\lambda_n} x_n, x_n \rangle \). It is finite because the expression is bounded independent of \( n \). Then
\[ \limsup_{m \to \infty} \left( \limsup_{n \to \infty} \left( \frac{\langle A_{\lambda_n} x_n, x_n \rangle + \langle A_{\lambda_n} x_m, x_m \rangle}{\| A_{\lambda_n} x_n + A_{\lambda_n} x_m \|} \right) \right) \leq 0 \]
Thus
\[
\limsup_{m \to \infty} (\alpha + \langle A_{\lambda_m} x_m, x_m \rangle - [\langle x^*, x_m \rangle + \langle A_{\lambda_m} x_m, x \rangle]) \leq 0
\]
and so
\[
2\alpha - 2 \langle x^*, x \rangle \leq 0
\]
The next simple observation is that
\[
\|A_{\lambda_n} x_n\| = \left\|\lambda_n^{-(p-1)} F (J_{\lambda_n} x_n - x_n)\right\| \leq C
\]
due to the weak convergence. Hence \(\lambda_n^{-(p-1)} \|J_{\lambda_n} x_n - x_n\|^{p-1} \leq C\) and so
\[
\|J_{\lambda_n} x_n - x_n\| \leq \lambda_n^{1/(p-1)}.
\]
Thus if \([u, u^*] \in \mathcal{G}(A)\),
\[
\liminf_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, x_n - u \rangle = \liminf_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, J_{\lambda_n} x_n - u \rangle \geq 0
\]
because \(A_{\lambda} x \in AJ_{\lambda} x\). However, the left side satisfies
\[
0 \leq \liminf_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, x_n - u \rangle \leq \limsup_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, x_n - u \rangle
\]
\[
= \limsup_{n \to \infty} \left(\langle A_{\lambda_n} x_n, x_n \rangle - \langle A_{\lambda_n} x_n, u \rangle - \langle u^*, x_n \rangle + \langle u^*, u \rangle\right)
\]
\[
= \alpha - \langle x^*, u \rangle - \langle u^*, x \rangle + \langle u^*, u \rangle \leq \langle x^*, x \rangle - \langle x^*, u \rangle - \langle u^*, x \rangle + \langle u^*, u \rangle
\]
\[
= \langle x^* - u^*, x - u \rangle
\]
and this shows that \([x, x^*] \in \mathcal{G}(A)\) since \([u, u^*]\) was arbitrary.

Next let \([u, u^*] \in \mathcal{G}(A)\). Then thanks to (23.7.59),
\[
0 \leq \liminf_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, J_{\lambda_n} x_n - u \rangle = \liminf_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, x_n - u \rangle
\]
\[
\leq \limsup_{n \to \infty} \langle A_{\lambda_n} x_n - u^*, x_n - u \rangle
\]
\[
= \limsup_{n \to \infty} \left(\langle A_{\lambda_n} x_n, x_n \rangle - \langle A_{\lambda_n} x_n, u \rangle - \langle u^*, x_n \rangle + \langle u^*, u \rangle\right)
\]
\[
= \limsup_{n \to \infty} \langle A_{\lambda_n} x_n, x_n \rangle - \langle x^*, u \rangle - \langle u^*, x \rangle + \langle u^*, u \rangle
\]
\[
\leq \langle x^*, x \rangle - \langle x^*, u \rangle - \langle u^*, x \rangle + \langle u^*, u \rangle = \langle x^* - u^*, x - u \rangle
\]
In particular, you could let \([u, u^*] = [x, x^*]\) and conclude that
\[
\lim_{n \to \infty} \langle A_{\lambda_n} x_n - x^*, x_n - x \rangle = \lim_{n \to \infty} \left(\langle A_{\lambda_n} x_n, x_n \rangle - \langle A_{\lambda_n} x_n, x \rangle + \langle x^*, x \rangle - \langle x^*, x_n \rangle\right)
\]
\[
= \lim_{n \to \infty} \langle A_{\lambda_n} x_n, x_n \rangle - \langle x^*, x \rangle + \langle x^*, x \rangle - \langle x^*, x \rangle = 0
\]
which shows that \(\lim_{n \to \infty} \langle A_{\lambda_n} x_n, x_n \rangle = \langle x^*, x \rangle\). Then it follows from this that
\[
\lim_{n,m \to \infty} \langle A_{\lambda_n} x_n - A_{\lambda_m} x_m, x_n - x_m \rangle = 0
\]
For the rest of this, the usual duality map for \(p = 2\) will be used. It may be that one could change this, but I don’t have a need to do it right now so from now on, \(F\) will be the usual thing.
23.7.5 Sum Of Maximal Monotone Operators

To begin with, here is a nice lemma.

**Lemma 23.7.39** Let \(0 \in D(A)\) and let \(A\) be maximal monotone and let \(B : X \to X'\) be monotone hemicontinuous, bounded, and coercive. Then \(B + A\) is also maximal monotone. Also \(B + A\) is onto.

**Proof:** By Theorem 23.7.9, there exists \(x \in D(A)\) such that for all \([u, u^*] \in G(A)\),
\[
\langle Bx + Fx - y^* + u^*, u - x \rangle \geq 0
\]
Hence for all \([u, u^*]\),
\[
\langle u^* - (y^* - (Bx + Fx)), u - x \rangle \geq 0
\]
It follows that
\[
y^* - (Bx + Fx) \in Ax
\]
and so \(y^* \in Bx + Ax + Fx\) showing that \(B + A\) is maximal monotone because it added to \(F\) is onto. As to the last claim, just don’t add in \(F\) in the argument. Thus for all \([u, u^*]\),
\[
\langle Bx - y^* + u^*, u - x \rangle \geq 0
\]
Then the rest is as before. You find that \(y^* - Bx \in Ax\). ■

**Corollary 23.7.40** Suppose instead of \(0 \in D(A)\), it is known that \(x_0 \in D(A)\) and
\[
\lim_{\|x\| \to \infty} \frac{\langle B(x_0 + x), x \rangle}{\|x\|} = \infty
\]
Then if \(B\) is monotone and hemicontinuous and \(A\) is maximal monotone, then \(B + A\) is onto.

**Proof:** Let \(\hat{A}(x) \equiv A(x_0 + x)\) so in fact \(0 \in D(\hat{A})\). Then letting \(\hat{B}\) be defined similarly, it follows from the above lemma that if \(y^* \in X'\), there exists \(x\) such that
\[
y^* \in \hat{A}x + \hat{B}x \equiv A(x_0 + x) + B(x_0 + x)\]
■

**Lemma 23.7.41** Let \(0\) be on the interior of \(D(A)\) and also in \(D(B)\). Also let \(0 \in B(0)\) and \(0 \in A(0)\). Then if \(A, B\) are maximal monotone, so is \(A + B\).

**Proof:** Note that, since \(0 \in A(0)\), if \(x^* \in Ax\), then \(\langle x^*, x \rangle \geq 0\). Also note that \(\|B_\lambda(0)\| \leq |B(0)| = 0\) and so also \(\langle B_\lambda x, x \rangle \geq 0\). It is necessary to show that \(F + A + B\) is onto. However, \(B_\lambda\) is monotone hemicontinuous, bounded and coercive. Hence, by Lemma 23.7.9, \(B_\lambda + A\) is maximal monotone. If \(x^* \in X'\) is given, there exists a solution to
\[
x^* \in Fx_\lambda + B_\lambda x_\lambda + Ax_\lambda
\]
Do both sides to \(x_\lambda\) and let \(x_\lambda^* \in Ax_\lambda\) be such that equality holds in the above.

\[
x^* = Fx_\lambda + B_\lambda x_\lambda + x_\lambda^*
\]  
(23.7.60)

Then

\[
\langle x^*, x_\lambda \rangle = \|x_\lambda\|^2 + \langle x_\lambda^*, x_\lambda \rangle
\]

It follows that

\[
\|x_\lambda\| \leq \|x^*\|, \quad \langle x^*, x_\lambda \rangle \leq \|x^*\| \|x_\lambda\| \leq \|x^*\|^2
\]  
(23.7.61)

Next, 0 is on the interior of \(D(A)\) and so from Theorem 23.7.20, there exists \(\rho > 0\) such that if \(y^* \in Ax\) for \(\|x\| \leq \rho\), then \(\|y^*\| < M\) and in fact, all such \(x\) are in \(D(A)\). Now let

\[
y_\lambda = \frac{1}{2\|x_\lambda\|} F^{-1}(x_\lambda^*) \quad \text{so} \quad \|y_\lambda\| < \rho
\]

Thus \(y_\lambda \in D(A)\) and if \(y_\lambda^* \in Ay_\lambda\), then \(\|y_\lambda^*\| < M\). Then for such bounded \(y_\lambda^*\),

\[
0 \leq \langle y_\lambda^* - x_\lambda^*, y_\lambda - x_\lambda \rangle = \langle y_\lambda^*, y_\lambda \rangle - \langle y_\lambda^*, x_\lambda \rangle - \langle y_\lambda^*, x_\lambda \rangle + \langle x_\lambda^*, x_\lambda \rangle
\]

Then

\[
\frac{1}{2} \|x_\lambda^*\| = \left\langle x_\lambda^*, \frac{1}{2\|x_\lambda\|} F^{-1}(x_\lambda^*) \right\rangle = \langle x_\lambda^*, y_\lambda \rangle - \langle y_\lambda^*, x_\lambda \rangle + \langle x_\lambda^*, x_\lambda \rangle
\]

\[
\leq M\rho + M \|x_\lambda\| + \langle x_\lambda^*, x_\lambda \rangle
\]

From 23.7.61

\[
\|x_\lambda^*\| \leq 2 \left( M\rho + M \|x^*\| + \|x^*\|^2 \right)
\]

Thus from 23.7.61, \(x_\lambda, x_\lambda^*, Fx_\lambda\) are all bounded. Hence it follows from 23.7.60 that \(B_\lambda x_\lambda\) is also bounded. Therefore, there is a sequence, \(\lambda_n \to 0\) such that

\[
x_\lambda \to z \text{ weakly}
\]

\[
x_\lambda^* \to u^* \text{ weakly}
\]

\[
F x_\lambda \to u^* \text{ weakly}
\]

\[
B_\lambda x_\lambda \to b^* \text{ weakly}
\]

Using 23.7.60, it follows that

\[
\langle Fx_{\lambda_n} + x_{\lambda_n}^* + B_{\lambda_n} x_{\lambda_n} - (F x_{\lambda_m} + x_{\lambda_m}^* + B_{\lambda_m} x_{\lambda_m}), x_{\lambda_n} - x_{\lambda_m} \rangle = 0
\]

Thus

\[
\langle Fx_{\lambda_n} + x_{\lambda_n}^* - (F x_{\lambda_m} + x_{\lambda_m}^*), x_{\lambda_n} - x_{\lambda_m} \rangle + \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle = 0
\]  
(23.7.62)
Now $F + A$ is surely monotone and so
\[
\lim_{m,n \to \infty} \sup \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle \leq 0
\]
By Proposition 23.7.38, $b^* \in Bz$ and
\[
\lim_{m,n \to \infty} \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle = 0
\]
Then returning to Proposition 23.7.62,
\[
\lim_{m,n \to \infty} \langle F x_{\lambda_n} + x_{\lambda_n}^* - (F x_{\lambda_m} + x_{\lambda_m}^*), x_{\lambda_n} - x_{\lambda_m} \rangle \leq 0
\]
Now from Lemma 23.7.39, $F + A$ is maximal monotone. Hence Proposition 23.7.38 applies again and it follows that $u^* + w^* \in Fz + Az$. Then passing to the limit as $n \to \infty$ in
\[
x^* = F x_{\lambda_n} + B_{\lambda_n} x_{\lambda_n} + x_{\lambda_n}^*
\]
it follows that
\[
x^* = u^* + b^* + w^* = Fz + Az + Bz
\]
and this shows that $A + B$ is maximal monotone because $x^*$ was arbitrary. ■

You don’t need to assume all that stuff about $0 \in A(0), 0 \in B(0), 0$ on interior of $D(A)$ and so forth.

**Theorem 23.7.42** Suppose $A, B$ are maximal monotone and the interior of $D(A)$ has nonempty intersection with $D(B)$. Then $A + B$ is maximal monotone.

**Proof:** Let $x_0$ be on the interior of $D(A)$ and also in $D(B)$. Let $\hat{A}(x) = A(x_0 + x) - x_0^*$ where $x_0^* \in A(x_0)$. Thus $0 \in D(\hat{A})$ and $0 \in \hat{A}(0)$. Do the same thing for $B$ to get $\hat{B}$ defined similarly. Are these still maximal monotone? Suppose for all $[u, u^*] \in G(\hat{A})$
\[
\langle y^* - u^*, y - u \rangle \geq 0
\]
Does it follow that $y^* \in \hat{A}y$? It is given that $u^* \in A(x_0 + u)$. The above implies for all $[u, u^*] \in G(\hat{A})$
\[
\langle y^* + x_0^* - (u^* + x_0^*), (y + x_0) - (u + x_0) \rangle \geq 0
\]
and since $u + x_0$ is a generic element of $D(A)$ for $u \in D(\hat{A})$, the above implies $y^* + x_0^* \in A(y + x_0)$ and so $y \in A(y + x_0) - x_0^* = \hat{A}(y)$. Hence the graph is maximal. Similar for $\hat{B}$. Thus the lemma can be applied to $\hat{A}, \hat{B}$ to conclude that the sum of these is maximal monotone. Now a repeat of the above reasoning which shows that $\hat{A}$ is maximal monotone shows that the fact that $\hat{A} + \hat{B}$ is maximal monotone implies that $A + B$ is also. You just shift with $-x_0$ instead of $x_0$. It amounts to nothing more than the observation that maximal graphs don’t lose their maximality by shifting their ranges and domains. ■
Suppose $B, A$ are maximal monotone. Does there always exist a solution $x$ to
\[ x^* \in Fx + B\lambda x + Ax \]  
(23.7.63)

Consider the monotone hemicontinuous and bounded operator $F + B\lambda I$ defined by
\[ \left( \hat{F} + \hat{B}_\lambda \right) (x) \equiv \left( \hat{F} + \hat{B}_\lambda \right) (x + x_0) \]
also coercive for some $x_0 \in D(A)$? If so, the existence of the desired solution to the above inclusion follows from Corollary 23.7.40. Then for all $\|x\|$ large enough that $\|x + x_0\| > \|x_0\|$, we have
\[
\frac{\langle F(x + x_0) + B\lambda (x + x_0), x \rangle}{\|x\|} \\
= \frac{\langle F(x + x_0), x \rangle}{\|x\|} + \frac{\langle B\lambda (x + x_0) - B\lambda (x_0), x \rangle}{\|x\|} + \frac{\langle B\lambda (x_0), x \rangle}{\|x\|} \\
\geq \frac{1}{2} \frac{\langle F(x + x_0), x \rangle}{\|x + x_0\|} - \|B\lambda (x_0)\| \\
\geq \frac{1}{2} \frac{\langle F(x + x_0), x + x_0 \rangle}{\|x + x_0\|} \quad \text{for } \frac{\langle F(x + x_0), x \rangle}{\|x\|} - \|B\lambda (x_0)\| \\
\geq \frac{1}{2} \|x + x_0\|^2 - \frac{1}{2} \|x + x_0\| - \|B\lambda (x_0)\| \\
= \frac{1}{2} \|x + x_0\|^2 - \frac{1}{2} \|x + x_0\| - \|B\lambda (x_0)\| \\
\frac{\langle F(x + x_0) + B\lambda (x + x_0), x \rangle}{\|x\|} = \infty
\]
which shows that
\[
\lim_{\|x\| \to \infty} \frac{\langle F(x + x_0) + B\lambda (x + x_0), x \rangle}{\|x\|} = \infty
\]
and so by Corollary 23.7.40, there exists a solution to 23.7.63. This shows half of the following interesting theorem which is another version of the above major result.

**Theorem 23.7.43** Suppose $A, B$ are maximal monotone operators. Then for each $x^* \in X'$, there exists a solution $x$ to
\[ x^* \in Fx + B\lambda x + Ax \lambda, \lambda > 0 \]
(23.7.64)

If for $\lambda \in (0, \delta), \{B\lambda x_\lambda\}$ is bounded, then there exists a solution $x$ to
\[ x^* \in Fx + Bx + Ax \]
Proof: The existence of a solution to the inclusion comes from the above discussion. The last claim follows from almost a repeat of the last part of the proof of the above theorem. Since \( \{B_\lambda x_\lambda\} \) is given to be bounded for \( \lambda \in (0, \delta) \), there is a sequence, \( \lambda_n \to 0 \) such that

\[
x_{\lambda_n} \to z \text{ weakly}
\]

\[
x^*_\lambda \to w^* \text{ weakly}
\]

\[
Fx_{\lambda} \to u^* \text{ weakly}
\]

\[
B_{\lambda_n} x_{\lambda_n} \to b^* \text{ weakly}
\]

Using it follows that

\[
\langle Fx_{\lambda_n} + x^*_\lambda, B_{\lambda_n} x_{\lambda_n} - (Fx_{\lambda_m} + x^*_\lambda_m + B_{\lambda_m} x_{\lambda_m}), x_{\lambda_n} - x_{\lambda_m} \rangle = 0
\]

Thus

\[
\langle Fx_{\lambda_n} + x^*_\lambda, (Fx_{\lambda_m} + x^*_\lambda_m), x_{\lambda_n} - x_{\lambda_m} \rangle
\]

\[
+ \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle = 0 \tag{23.7.65}
\]

Now \( F + A \) is surely monotone and so

\[
\lim_{m,n \to \infty} \sup \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle \leq 0
\]

By Proposition, \( b^* \in Bz \) and

\[
\lim_{m,n \to \infty} \langle B_{\lambda_n} x_{\lambda_n} - B_{\lambda_m} x_{\lambda_m}, x_{\lambda_n} - x_{\lambda_m} \rangle = 0
\]

Then returning to

\[
\lim_{m,n \to \infty} \sup \langle Fx_{\lambda_n} + x^*_\lambda, (Fx_{\lambda_m} + x^*_\lambda_m), x_{\lambda_n} - x_{\lambda_m} \rangle \leq 0
\]

Now from Corollary, \( F + A \) is maximal monotone (In fact, \( F + A \) is onto). Hence Proposition applies again and it follows that \( u^* + w^* \in Fz + Az \).

Then passing to the limit as \( n \to \infty \) in

\[
x^* = Fx_{\lambda_n} + B_{\lambda_n} x_{\lambda_n} + x^*_\lambda_n
\]

it follows that

\[
x^* = u^* + b^* + w^* = Fz + Az + Bz
\]
23.7. MAXIMAL MONOTONE OPERATORS

23.7.6 Convex Functions, An Example

As before, $X$ will be a Banach space in what follows. Sometimes it will be a reflexive Banach space and in this case, it will be assumed that the norm is strictly convex.

**Definition 23.7.44** Let $\phi : X \to (-\infty, \infty]$. Then $\phi$ is convex if whenever $t \in [0,1], x, y \in X$,

$$\phi(tx + (1-t)y) \leq t\phi(x) + (1-t)\phi(y)$$

The epigraph of $\phi$ is defined by

$$\text{epi}(\phi) \equiv \{(x, y) : y \geq \phi(x)\}$$

When $\text{epi}(\phi)$ is closed in $X \times (-\infty, \infty]$, we say that $\phi$ is lower semicontinuous, l.s.c. The function is called proper if $\phi(x) < \infty$ for some $x$. The collection of all such $x$ is called $D(\phi)$, the domain of $\phi$.

This definition of lower semicontinuity is equivalent to the usual definition.

**Lemma 23.7.45** The above definition of lower semicontinuity is equivalent to the assertion that whenever $x_n \to x$, it follows that $\phi(x) \leq \lim \inf_{n \to \infty} \phi(x_n)$. In case that $\phi$ is convex, lower semicontinuity is equivalent to weak lower semicontinuity. That is $\text{epi}(\phi)$ is closed if and only if $\text{epi}(\phi)$ is weakly closed. In this case, the limit condition: If $x_n \to x$ weakly, then $\phi(x) \leq \lim \inf_{n \to \infty} \phi(x_n)$ is valid.

**Proof:** Suppose the limit condition holds. Why is $\text{epi}(\phi)$ closed? Why is $X \times (-\infty, \infty] \setminus \text{epi}(\phi) \equiv \text{epi}(\phi)^C$ open? Let $(x, \alpha) \in \text{epi}(\phi)^C$. Then $\alpha < \phi(x)$, $\alpha + \delta < \phi(x)$. Consider $B(x, r) \times (\alpha - \frac{\delta}{2}, \alpha + \frac{\delta}{2})$. If every such open set contains a point of $\text{epi}(\phi)$, then there exists $x_n \to x, y_n < \alpha + \frac{\delta}{2}, y_n \geq \phi(x_n)$. Hence, from the limit condition,

$$\phi(x) \leq \lim \inf_{n \to \infty} \phi(x_n) \leq \lim \inf_{n \to \infty} y_n \leq \alpha + \frac{\delta}{2} < \alpha + \delta < \phi(x)$$

a contradiction. It follows that there exists $r > 0$ such that $B(x, r) \times (\alpha - \frac{\delta}{2}, \alpha + \frac{\delta}{2}) \cap \text{epi}(\phi) = \emptyset$. Since $\text{epi}(\phi)^C$ is open, it follows that $\text{epi}(\phi)$ is closed.

Next suppose $\text{epi}(\phi)$ is closed. Why does the limit condition hold? Suppose $x_n \to x$. Then $(x_n, \phi(x_n)) \in \text{epi}(\phi)$. There is a subsequence such that

$$\alpha \equiv \lim_{n \to \infty} \inf_{\phi(x_n)} \phi(x_n) = \lim_{k \to \infty} \phi(x_{n_k})$$

and so $(x_{n_k}, \phi(x_{n_k})) \to (x, \alpha)$. Since $\text{epi}(\phi)$ is closed, this means $(x, \alpha) \in \text{epi}(\phi)$. Hence

$$\alpha \equiv \lim_{n \to \infty} \phi(x_n) \geq \phi(x) .$$

Consider the last claim. In this case, $\text{epi}(\phi)$ is convex. If it is closed, then it is weakly closed thanks to separation theorems: If $(x, \alpha) \in \text{epi}(\phi)^C$, then $\alpha < \infty$ and so there exists $(x^*, \beta) \in (X \times \mathbb{R})^\prime$ and $l$ such that for all $(t, \gamma) \in \text{epi}(\phi)$,

$$x^* (t) + \beta \gamma > l > x^* (x) + \alpha \beta$$
Then \( B(x^*, \beta) ((x, \alpha), \delta) \) is a weakly open set containing \((x, \alpha)\). For \( \delta \) small enough, it does not intersect epi \((\phi)\) since if not so, there would exist \((t_n, \gamma_n) \in \text{epi} (\phi) \cap B(x^*, \beta) ((x, \alpha), \frac{1}{n}) \) and so

\[
x^* (t_n) + \beta \gamma_n \to x^* (x) + \alpha \beta
\]

counter to the above inequality. Thus epi \((\phi)\) is weakly closed. Also, if epi \((\phi)\) is weakly closed, then it is obviously strongly closed.

What of the limit condition using weak convergence instead of strong convergence? Say \( x_n \to x \) weakly. Does it follow that if epi \((\phi)\) is weakly closed that \( \phi (x) \leq \liminf_{n \to \infty} \phi (x_n) \)? It is just as above. There is a subsequence such that 

\[
\alpha \equiv \liminf_{n \to \infty} \phi (x_n) = \lim_{k \to \infty} \phi (x_{n_k})
\]

and so \((x_{n_k}, \phi (x_{n_k})) \to (x, \alpha)\) weakly. Since epi \((\phi)\) is weakly closed, this means \((x, \alpha) \in \text{epi} (\phi)\). Hence 

\[
\alpha \equiv \liminf_{n \to \infty} \phi (x_n) \geq \phi (x). \quad \blacksquare
\]

There is also another convenient characterization of what it means for a function to be lower semicontinuous.

**Lemma 23.7.46** Let \( \phi : X \to (-\infty, \infty] \). Then \( \phi \) is lower semicontinuous if and only if \( \phi^{-1} ((a, \infty]) \) is open for any \( a \in \mathbb{R} \).

**Proof:** Suppose first that epi \((\phi)\) is closed. Consider \( x \in \phi^{-1} ((a, \infty]) \). Thus \( \phi (x) > a \). Thus \((x, a) \in \text{epi} (\phi)^C\) because \( a < \phi (x) \). Since epi \((\phi)\) is closed, there exists \( r, \varepsilon > 0 \) such that

\[
B (x, r) \times (a - \varepsilon, a + \varepsilon) \subseteq \text{epi} (\phi)^C
\]

Hence if \( y \in B (x, r) \), it follows that \( \phi (y) \geq a + \varepsilon \) since otherwise there would be a point of epi \((\phi)^C\) in this open set \( B (x, r) \times (a - \varepsilon, a + \varepsilon) \). Hence \( B (x, r) \subseteq \phi^{-1} ((a, \infty]) \).

Conversely, suppose \( \phi^{-1} ((a, \infty]) \) is open for any \( a \) and let \((x, b) \in \text{epi} (\phi)^C\). Then \( \phi (x) > b \). Thus there exists \( B (x, r) \) such that for \( y \in B (x, r) \), it follows that \( \phi (y) > b \). That is, \( y \in \phi^{-1} ((b, \infty]) \). So consider \( B (x, r) \times (-\infty, b) \). If \((y, a) \in B (x, r) \times (-\infty, b) \), then since \( \phi (y) > b, a < \phi (y) \) and so there is no point of intersection between epi \((\phi)\) and this open set \( B (x, r) \times (-\infty, b) \). \( \blacksquare \)

Of course one can define upper semicontinuous the same way that \( \phi^{-1} (-\infty, a) \) is open. Thus a function is continuous if and only if it is both upper and lower semicontinuous.

In case \( X \) is reflexive, the limit condition implies that epi \((\phi)\) is weakly closed. Suppose \((x, \alpha)\) is a weak limit point of epi \((\phi)\). Then by the Eberlein Smulian theorem, there is a subsequence of points of \( X, (x_n, \alpha_n) \) which converges weakly to \((x, \alpha)\). Thus if the limit condition holds,

\[
\phi (x) \leq \liminf_{n \to \infty} \phi (x_n) \leq \liminf_{n \to \infty} \alpha_n = \alpha
\]
and so \((x, \alpha) \in \text{epi}(\phi)\). If \(X\) is not reflexive, this isn't all that clear because it is not clear that a limit point is the limit of a sequence. However, one could consider a limit condition involving nets and get a similar result.

**Definition 23.7.47** Let \(\phi : X \to (-\infty, \infty]\) be convex lower semicontinuous, and proper. Then

\[
\partial \phi(x) = \{x^* : \phi(y) - \phi(x) \geq \langle x^*, y - x \rangle \text{ for all } y\}
\]

The domain of \(\partial \phi\), denoted as \(D(\partial \phi)\) is just the set of all \(x\) for which \(\partial \phi(x) \neq \emptyset\). Note that \(D(\partial \phi) \subseteq D(\phi)\) since if \(x \notin D(\phi)\), the defining inequality could not hold for all \(y\) because the left side would be \(-\infty\) for some \(y\).

**Theorem 23.7.48** For \(X\) a real Banach space, let \(\phi(x) = \frac{1}{2} ||x||^2\). Then \(F(x) = \partial \phi(x)\). Here \(F\) was the set valued map satisfying \(x^* \in Fx\) means

\[
||x^*|| = \langle Fx, x^* \rangle = ||x||^2.
\]

**Proof:** Let \(x^* \in F(x)\). Then

\[
\langle x^*, y - x \rangle = \langle x^*, y \rangle - \langle x^*, x \rangle \\
\leq ||x|| ||y|| - ||x||^2 \leq \frac{1}{2} ||y||^2 - \frac{1}{2} ||x||^2.
\]

This shows \(F(x) \subseteq \partial \phi(x)\).

Now let \(x^* \in \partial \phi(x)\). Then for all \(t \in \mathbb{R}\),

\[
\langle x^*, ty \rangle = \langle x^*, (ty + x) - x \rangle \leq \frac{1}{2} \left(||x + ty||^2 - ||x||^2\right). \tag{23.7.66}
\]

Now if \(t > 0\), divide both sides by \(t\). This yields

\[
\langle x^*, y \rangle \leq \frac{1}{2t} \left(||x|| + t ||y||\right)^2 - ||x||^2) \\
= \frac{1}{2t} \left(2t ||x|| ||y|| + t^2 ||y||^2\right).
\]

Letting \(t \to 0\),

\[
\langle x^*, y \rangle \leq ||x|| ||y||. \tag{23.7.67}
\]

Next suppose \(t = -s\), where \(s > 0\) in \text{epi}(\phi). Then, since when you divide by a negative, you reverse the inequality, for \(s > 0\)

\[
\langle x^*, y \rangle \geq \frac{1}{2s} \left(||x||^2 - ||x - sy||^2\right) \\
= \frac{1}{2s} \left(||x - sy||^2 - 2||x - sy|| ||sy|| + ||sy||^2 - ||x - sy||^2\right). \tag{23.7.68}
\]

\[
= \frac{1}{2s} \left(-2 ||x - sy|| ||sy|| + ||sy||^2\right). \tag{23.7.69}
\]
Taking a limit as \( s \to 0 \) yields
\[
\langle x^*, y \rangle \geq -\|x\| \|y\|.
\] (23.7.70)

It follows from 23.7.70 and 23.7.67 that
\[
\|\langle x^*, y \rangle\| \leq \|x\| \|y\|
\]
and that, therefore, \( \|x^*\| \leq \|x\| \) and \( \|\langle x^*, x \rangle\| \leq \|x\|^2 \). Now return to 23.7.69 and let \( y = x \). Then
\[
\langle x^*, x \rangle \geq \frac{1}{2s} \left[ -2 \|x - sx\| \|sx\| + \|sx\|^2 \right] = -\|x\|^2 (1 - s) + s \|x\|^2
\]
Letting \( s \to 1 \),
\[
\langle x^*, x \rangle \geq \|x\|^2.
\]
Since it was already shown that \( \|\langle x^*, x \rangle\| \leq \|x\|^2 \), this shows \( \langle x^*, x \rangle = \|x\|^2 \) and also \( \|x^*\| \leq \|x\| \). Thus
\[
\|x^*\| \geq \left\langle \frac{x^*}{\|x\|} \right\rangle = \|x\|
\]
so in fact \( x^* \in F(x) \). ■

The next result gives conditions under which the subgradient is onto. This means that if \( y^* \in X' \), then there exists \( x \in X \) such that \( y^* \in \partial \phi(x) \).

**Theorem 23.7.49** Suppose \( X \) is a reflexive Banach space and suppose \( \phi : X \to (-\infty, \infty] \) is convex, proper, l.s.c., and for all \( y^* \in X' \), \( x \to \phi(x) - \langle y^*, x \rangle \) is coercive,
\[
\lim_{\|x\| \to \infty} \phi(x) - \langle y^*, x \rangle = \infty
\]
Then \( \partial \phi \) is onto.

**Proof:** The function \( x \to \phi(x) - y^*(x) \equiv \psi(x) \) is convex, proper, l.s.c., and coercive. Let
\[
\lambda \equiv \inf \{ \phi(x) - \langle y^*, x \rangle : x \in X \}
\]
and let \( \{x_n\} \) be a minimizing sequence satisfying
\[
\lambda = \lim_{n \to \infty} \phi(x_n) - \langle y^*, x_n \rangle
\]
By coercivity,
\[
\lim_{\|x\| \to \infty} \phi(x) - \langle y^*, x \rangle = \infty
\]
and so this minimizing sequence is bounded. By the Eberlein Smulian theorem, Theorem 15.5.12, there is a weakly convergent subsequence \( x_{n_k} \to x \). By Lemma 23.7.61,
\[
\lambda = \phi(x) - \langle y^*, x \rangle \leq \lim_{k \to \infty} \inf \phi(x_{n_k}) - \langle y^*, x_{n_k} \rangle = \lambda
\]
so there exists $x$ which minimizes $x \to \phi (x) - \langle y^* , x \rangle \equiv \psi (x)$. Therefore, $0 \in \partial \psi (x)$ because

$$\psi (y) - \psi (x) \geq 0 = \langle 0, y - x \rangle$$

Thus, $0 \in \partial \psi (x) = \partial \phi (x) - y^*$.

Now let $\phi$ be a convex proper lower semicontinuous function defined on $X$ where $X$ is a reflexive Banach space with strictly convex norm. Consider $\partial \phi$. Is it maximal monotone? Is it the case that $F + \partial \phi$ is onto? First of all, is $\partial \phi$ monotone? Let $x^* \in \partial \phi (x), y^* \in \partial \phi (y)$. Then

$$\phi (y) - \phi (x) \geq \langle x^*, y - x \rangle$$

$$\phi (x) - \phi (y) \geq \langle y^*, x - y \rangle$$

Hence adding these yields

$$\langle y^* - x^*, x - y \rangle \leq 0, \langle y^* - x^*, y - x \rangle \geq 0.$$ 

Yes, $\partial \phi$ is certainly monotone. Is it maximal monotone?

**Theorem 23.7.50** Let $\phi$ be convex, proper, and lower semicontinuous on $X$ where $X$ is a reflexive Banach space having strictly convex norm. Then $\partial \phi$ is maximal monotone.

**Proof:** It is necessary to show that $F + \partial \phi$ is onto. To do this, let

$$\psi (x) \equiv \frac{1}{2} \|x\|^2 + \phi (x) - \langle y^* , x \rangle$$

where $y^*$ is a given element of $X'$ and the idea is to show that $y^* \in F (x) + \partial \phi (x)$ for some $x$. Then by separation theorems, $\phi (x) \geq b + \langle z^*, x \rangle$ for some $b, z^*$. Hence it is clear that $\psi$ is convex, lower semicontinuous and coercive in the sense that

$$\lim_{\|x\| \to \infty} \psi (x) = \infty$$

It follows that any minimizing sequence for $\psi$ is bounded. Hence by the weak lower semicontinuity, this function has a minimum at $x_0$ say. Thus

$$\frac{1}{2} \|x_0\|^2 + \phi (x_0) - \langle y^*, x_0 \rangle \leq \frac{1}{2} \|x\|^2 + \phi (x) - \langle y^*, x \rangle$$

for all $x$. Then

$$\frac{1}{2} \|x_0\|^2 - \frac{1}{2} \|x\|^2 + \langle y^*, x - x_0 \rangle \leq \phi (x) - \phi (x_0)$$

Now from Theorem 23.7.50,

$$\langle F (x), x_0 - x \rangle \leq \frac{1}{2} \|x_0\|^2 - \frac{1}{2} \|x\|^2$$
and so, the above reduces to
\[
\langle F(x), x_0 - x \rangle + \langle y^*, x - x_0 \rangle \leq \phi(x) - \phi(x_0)
\]
Next let \( x = x_0 + t(z - x_0), t \in (0,1) \), where \( z \) is arbitrary. Then
\[
-t \langle F(x_0 + t(z - x_0)), z - x_0 \rangle + t \langle y^*, z - x_0 \rangle \leq \phi(x_0 + t(z - x_0)) - \phi(x_0)
\]
and so, by convexity,
\[
-t \langle F(x_0 + t(z - x_0)), z - x_0 \rangle + t \langle y^*, z - x_0 \rangle \leq (1 - t) \phi(x_0) + t \phi(z) - \phi(x_0)
\]
\[
t \langle y^*, z - x_0 \rangle \leq t (\phi(z) - \phi(x_0)) + t \langle F(x_0 + t(z - x_0)), z - x_0 \rangle
\]
Now cancel the \( t \) on both sides to obtain
\[
\langle y^*, z - x_0 \rangle \leq (\phi(z) - \phi(x_0)) + \langle F(x_0 + t(z - x_0)), z - x_0 \rangle
\]
By the fact that \( F \) is hemicontinuous, actually demicontinuous, one can let \( t \downarrow 0 \) and obtain
\[
\langle y^*, z - x_0 \rangle \leq (\phi(z) - \phi(x_0)) + \langle F(x_0), z - x_0 \rangle
\]
This says that \( y^* - F(x_0) \in \partial \phi(x_0) \) from the definition of what \( \partial \phi(x_0) \) means. ■

There is a much harder approach to this theorem which is based on a theorem about when the subgradient of a sum equals the sum of the subgradients. This major theorem is given next. Much of the above is in [12], but I don’t remember where I found the following proof.

**Theorem 23.7.51.** Let \( \phi_1 \) and \( \phi_2 \) be convex, l.s.c. and proper having values in \((-\infty, \infty]\). Then
\[
\partial (\lambda \phi_1)(x) = \lambda \partial \phi_1(x), \quad \partial (\phi_1 + \phi_2)(x) \supseteq \partial \phi_1(x) + \partial \phi_2(x) \quad (23.7.71)
\]
if \( \lambda > 0 \). If there exists \( \varphi \in \text{dom} \phi_1 \cap \text{dom} \phi_2 \) and \( \phi_1 \) is continuous at \( \varphi \) then for all \( x \in X \),
\[
\partial (\phi_1 + \phi_2)(x) = \partial \phi_1(x) + \partial \phi_2(x). \quad (23.7.72)
\]

**Proof:** If \( \lambda \geq 1 \) is obvious so we only need to show \( 0 < \lambda < 1 \). Suppose \( \varphi \) is as described. It is clear \( \phi_1 + \phi_2 \) holds whenever \( x \notin \text{dom} \phi_1 \cap \text{dom} \phi_2 \) since then \( \partial (\phi_1 + \phi_2) = \emptyset \). Therefore, assume
\[
x \in \text{dom} \phi_1 \cap \text{dom} \phi_2
\]
in what follows. Let \( x^* \in \partial (\phi_1 + \phi_2)(x) \). Is \( x^* \) is the sum of an element of \( \partial \phi_1(x) \) and \( \partial \phi_2(x) \)? Does there exist \( x^*_1 \) and \( x^*_2 \) such that for every \( y \),
\[
x^* (y - x) = x^*_1 (y - x) + x^*_2 (y - x)
\]
\[
\leq \phi_1(y) - \phi_1(x) + \phi_2(y) - \phi_2(x)?
\]
If so, then
\[ \phi_1(y) - \phi_1(x) - x^*(y-x) \geq \phi_2(x) - \phi_2(y) . \]
Define
\[ C_1 \equiv \{(y,a) \in X \times \mathbb{R} : \phi_1(y) - \phi_1(x) - x^*(y-x) \leq a \} , \]
\[ C_2 \equiv \{(y,a) \in X \times \mathbb{R} : a \leq \phi_2(x) - \phi_2(y) \} . \]
I will show \( \text{int} (C_1) \cap C_2 = \emptyset \) and then by Theorem 16.2.14 there exists an element of \( X' \) which does something interesting.

Both \( C_1 \) and \( C_2 \) are convex and nonempty. Say \( y_1, y_2 \in C_1 \) and \( t \in [0,1] \). Then
\[ \phi_1((ty_1) + (1-t)y_2) - \phi_1(x) - x^*((ty_1) + (1-t)y_2) - x \]
\[ \leq t\phi(y_1) + (1-t)\phi(y_2) - (t\phi_1(x) + (1-t)\phi(x)) \]
\[ = (tx^*(y_1-x) + (1-t)x^*(y_2-x)) \]
\[ \leq ta + (1-t)a = a \]
so \( C_1 \) is indeed convex. The case of \( C_2 \) is similar.

\( C_1 \) is nonempty because it contains \( (x, \phi_1(x) - x^*(x-x)) \) since
\[ \phi_1(x) - \phi_1(x) - x^*(t-x) \leq \phi_1(x) - \phi_1(x) - x^*(x-x) \]
\( C_2 \) is also nonempty because it contains \( (x, \phi_2(x) - \phi_2(x)) \) since
\[ \phi_2(x) - \phi_2(x) \leq \phi_2(x) - \phi_2(x) \]
In addition to this,
\[ (x, \phi_1(x) - x^*(x-x) - \phi_1(x) + 1) \in \text{int} (C_1) \]
due to the assumed continuity of \( \phi_1 \) at \( x \) and so \( \text{int} (C_1) \neq \emptyset \). If \( (y,a) \in \text{int} (C_1) \) then
\[ \phi_1(y) - x^*(y-x) - \phi_1(x) \leq a - \varepsilon \]
whenever \( \varepsilon \) is small enough. Therefore, if \( (y,a) \) is also in \( C_2 \), the assumption that \( x^* \in \partial (\phi_1 + \phi_2)(x) \) implies
\[ a - \varepsilon \geq \phi_1(y) - x^*(y-x) - \phi_1(x) \geq \phi_2(x) - \phi_2(y) \geq a , \]
a contradiction. Therefore \( \text{int} (C_1) \cap C_2 = \emptyset \) and so by Theorem 16.2.14, there exists \( (w^*, \beta) \in X' \times \mathbb{R} \) with
\[ (w^*, \beta) \neq (0,0) , \]
and
\[ w^*(y) + \beta a \geq w^*(y_1) + \beta a_1 , \]
whenever \( (y,a) \in C_1 \) and \( (y_1, a_1) \in C_2 \).

Claim: \( \beta > 0 \).
Proof of claim: If $\beta < 0$ let

$$a = \phi_1 (\bar{x}) - x^* (\bar{x} - x) - \phi_1 (x) + 1,$$

$$a_1 = \phi_2 (x) - \phi_2 (\bar{x}), \text{ and } y = y_1 = \bar{x}.$$  

Then from \[23.7.74\]

$$\beta (\phi_1 (\bar{x}) - x^* (\bar{x} - x) - \phi_1 (x) + 1) \geq \beta (\phi_2 (x) - \phi_2 (\bar{x})).$$

Dividing by $\beta$ yields

$$\phi_1 (\bar{x}) - x^* (\bar{x} - x) - \phi_1 (x) + 1 \leq \phi_2 (x) - \phi_2 (\bar{x})$$

and so

$$\phi_1 (\bar{x}) + \phi_2 (\bar{x}) - (\phi_1 (x) + \phi_2 (x)) + 1 \leq x^* (\bar{x} - x)$$

$$\leq \phi_1 (\bar{x}) + \phi_2 (\bar{x}) - (\phi_1 (x) + \phi_2 (x)),$$

a contradiction. Therefore, $\beta \geq 0$.

Now suppose $\beta = 0$. Letting

$$a = \phi_1 (\bar{x}) - x^* (\bar{x} - x) - \phi_1 (x) + 1,$$

$$(\bar{x}, a) \in \text{int } (C_1),$$

and so there exists an open set $U$ containing 0 and $\eta > 0$ such that

$$\bar{x} + U \times (a - \eta, a + \eta) \subseteq C_1.$$  

Therefore, \[23.7.74\] applied to $(\bar{x} + z, a) \in C_1$ and $(\bar{x}, \phi_2 (x) - \phi_2 (\bar{x})) \in C_2$ for $z \in U$ yields

$$w^* (\bar{x} + z) \geq w^* (\bar{x})$$

for all $z \in U$. Hence $w^* (z) = 0$ on $U$ which implies $w^* = 0$, contradicting \[23.7.74\]. This proves the claim.

Now with the claim, it follows $\beta > 0$ and so, letting $z^* = w^*/\beta$, \[23.7.74\] and Lemma \[16.2.15\] implies

$$z^* (y) + a \geq z^* (y_1) + a_1 \quad (23.7.75)$$

whenever $(y, a) \in C_1$ and $(y_1, a_1) \in C_2$. In particular,

$$(y, \phi_1 (y) - \phi_1 (x) - x^* (y - x)) \in C_1 \quad (23.7.76)$$

because

$$\phi_1 (y) - \phi_1 (x) - x^* (y - x) \leq \phi_1 (y) - x^* (y - x) - \phi_1 (x)$$

and

$$(y_1, \phi_2 (x) - \phi_2 (y_1)) \in C_2. \quad (23.7.77)$$
by similar reasoning so letting $y = x$,

$$z^*(x) + \left(\phi_1(x) - x^*(x - x) - \phi_1(x)\right) \geq z^*(y_1) + \phi_2(x) - \phi_2(y_1).$$

Therefore,

$$z^*(y_1 - x) \leq \phi_2(y_1) - \phi_2(x)$$

for all $y_1$ and so $z^* \in \partial \phi_2(x)$. Now let $y_1 = x$ in (23.7.47) and using (23.7.48) and (23.7.49), it follows

$$z^*(y) + \phi_1(y) - x^*(y - x) - \phi_1(x) \geq z^*(x)$$

$$\phi_1(y) - \phi_1(x) \geq x^*(y - x) - z^*(y - x)$$

and so $x^* - z^* \in \partial \phi_1(x)$ so letting $x^* = z^* + (x^* - z^*) \in \partial \phi_1(x) + \partial \phi_1(x)$.

**Corollary 23.7.52** Let $\phi : X \to (-\infty, \infty)$ be convex, proper, and lower semicontinuous. Here $X$ is a Banach space. Then $\partial \phi$ is maximal monotone.

**Proof:** Let $\psi(x) = \frac{1}{2} \|x\|^2$. There exists $x^*$ and some number $b$ such that $\phi(x) \geq b + \langle x^*, x \rangle$. Therefore, $\psi + \phi$ is convex, lower semicontinuous, and bounded. It follows $\partial (\psi + \phi)$ is onto by Theorem 23.7.41. However, $\psi$ is continuous everywhere, in particular at every point of the domain of $\phi$. Therefore, $\partial \psi + \partial \phi = \partial (\phi + \psi)$ and by Theorem 23.7.48, this shows that $F + \partial \phi$ is onto.

It seems to me that the above are the most important results about convex proper lower semicontinuous functions. However, there are many other very interesting properties known.

**Proposition 23.7.53** Let $\phi : X \to (-\infty, \infty)$ be convex proper and lower semicontinuous. Then $D(\partial \phi)$ is dense in $D(\phi)$ and so $D(\partial \phi) = D(\phi)$.

**Proof:** Let $x_\lambda$ be the solution to $0 \in F(x_\lambda - x) + \lambda \partial \phi(x_\lambda)$. Here $x \in D(\phi)$. Say $u^*_\lambda \in \partial \phi(x_\lambda)$ such that the inclusion becomes an equality. Then

$$0 = \langle F(x_\lambda - x) + \lambda u^*_\lambda, x_\lambda - x \rangle = \|x_\lambda - x\|^2 - \lambda (u^*_\lambda, x - x_\lambda)$$

Hence, letting $z^*, b$ be such that $\phi(y) \geq b + \langle z^*, y - x \rangle$,

$$\lambda (\phi(x) - [b + \langle z^*, x_\lambda - x \rangle]) \geq \lambda (\phi(x) - \phi(x_\lambda)) \geq \|x_\lambda - x\|^2$$

$$\lambda \phi(x) - \lambda b \geq \|x_\lambda - x\|^2 - \lambda \|z^*\| \|x_\lambda - x\|$$

$$\geq \|x_\lambda - x\|^2 - \lambda \left(\frac{\|z^*\|^2}{2} + \frac{\|x_\lambda - x\|^2}{2}\right)$$
Thus
\[ \lambda \phi(x) - \lambda b + \lambda \frac{\|z^*\|^2}{2} \geq \left( 1 - \frac{\lambda}{2} \right) \|x - x\|^2 \]

It follows that \( x_\lambda \to x \). This shows that \( D(\phi) \subseteq \bar{D}(\partial \phi) \) and so \( \bar{D}(\phi) \subseteq \bar{D}(\partial \phi) \).

There is a really amazing theorem, Moreau’s theorem. It is in \([23],[12]\) and \([105]\). It involves approximating a convex function with one which is differentiable, at least in the case where you have a Hilbert space. In the general case considered in this chapter, the function is continuous.

**Theorem 23.7.54** Let \( \phi \) be a convex lower semicontinuous proper function defined on \( X \). Define \( A \equiv \partial \phi \), \( A_\lambda = (\partial \phi)_\lambda \)

\[ \phi_\lambda(x) = \min_{y \in X} \left( \frac{1}{2\lambda} \|x - y\|^2 + \phi(y) \right) \]

Then the function is well defined, convex, Gateaux differentiable,

\[ D_z \phi_\lambda(x) \equiv \lim_{t \downarrow 0} \frac{\phi_\lambda(x + tz) - \phi_\lambda(x)}{t} = \langle A_\lambda x, z \rangle \]

so the Gateaux derivative is just \( A_\lambda x \) and for all \( x \in X \),

\[ \lim_{\lambda \to 0} \phi_\lambda(x) = \phi(x) \]

In addition,

\[ \phi_\lambda(x) = \frac{1}{2\lambda} \|x - J_\lambda x\|^2 + \phi(J_\lambda(x)) \]

(23.7.78)

where \( J_\lambda x \) is as before, the solution to

\[ 0 \in F(J_\lambda x - x) + \lambda \partial \phi(J_\lambda x) \]

**Proof:** First of all, why does the minimum take place? By the convexity, closed epigraph, and assumption that \( \phi \) is proper, separation theorems apply and one can say that there exists \( z^* \) such that for all \( y \in H \),

\[ \frac{1}{2\lambda} \|x - y\|^2 + \phi(y) \geq \frac{1}{2\lambda} \|x - y\|^2 + (z^*, y) + c \]

(23.7.79)

It follows easily that a minimizing sequence is bounded and so from lower semicontinuity which implies weak lower semicontinuity due to convexity, there exists \( y_x \) such that

\[ \min_{y \in H} \left( \frac{1}{2\lambda} \|x - y\|^2 + \phi(y) \right) = \left( \frac{1}{2\lambda} \|x - y_x\|^2 + \phi(y_x) \right) \]

Why is \( \phi_\lambda \) convex? For \( \theta \in [0, 1] \),

\[ \phi_\lambda(\theta x + (1 - \theta) z) \equiv \frac{1}{2\lambda} \|\theta x + (1 - \theta) z - y_{\theta x + (1 - \theta) z}\|^2 + \phi(y_{\theta x + (1 - \theta) z}) \]
\[ \frac{1}{2\lambda} \| \theta x + (1 - \theta) z - (\theta y_x + (1 - \theta) y_z) \|^2 + \phi (\theta y_x + (1 - \theta) y_z) \leq \frac{\theta}{2\lambda} \| x - y_x \|^2 + \frac{1 - \theta}{2\lambda} \| z - y_z \|^2 + \theta \phi (y_x) + (1 - \theta) \phi (y_z) = \theta \phi (x) + (1 - \theta) \phi (z) \]

So is there a formula for \( y_x \)? Since it involves minimization of the functional, it follows that
\[ 0 \in -\frac{1}{\lambda} F (x - y_x) + \partial \phi (y_x) = \frac{1}{\lambda} F (y_x - x) + \partial \phi (y_x) \]
Recall that if \( \psi (x) = \frac{1}{2} \| x \|^2 \), then \( \partial \psi (x) = F (x) \). Thus
\[ y_x = J_\lambda x \]
because this was how \( J_\lambda x \) was defined. Therefore,
\[ \phi (x) = \frac{1}{2\lambda} \| x - J_\lambda x \|^2 + \phi (J_\lambda (x)) = \frac{\lambda}{2} \| A x \|^2 + \phi (J_\lambda x), \quad A = \partial \phi \]
It follows from this equation that
\[ \phi (J_\lambda x) \leq \phi (x), \quad (23.7.80) \]
the second inequality following from taking \( y = x \) in the definition of \( \phi \).

Next consider the claim about \( \phi (x) \uparrow \psi (x) \). First suppose that \( x \in D (\phi) \).
Then from Proposition 23.7.83, \( x \in D (\partial \phi) \) and so from the material on approximations, Theorem 23.7.80, it follows that \( J_\lambda x \to x \). Hence from (23.7.80) and lower semicontinuity of \( \phi \),
\[ \phi (x) \leq \lim \inf_{\lambda \to 0} \phi (J_\lambda x) \leq \lim \inf_{\lambda \to 0} \phi (x) \leq \lim \sup_{\lambda \to 0} \phi (x) \leq \phi (x) \]
showing that in this case, \( \lim_{\lambda \to 0} \phi (x) = \phi (x) \). Next suppose \( x \notin D (\phi) \) so that \( \phi (x) = \infty \). Why does \( \phi (x) \to \infty ? \) Suppose not. Then from the description of \( \phi \) given above and using the fact that the epigraph is closed and convex, there would exist a subsequence, still denoted as \( \lambda \) such that
\[ C \geq \phi (x) = \frac{1}{2\lambda} \| x - J_\lambda x \|^2 + \phi (J_\lambda (x)) \geq \frac{1}{2\lambda} \| x - J_\lambda x \|^2 + \| z^*, x - J_\lambda x \| + b \]
Then multiplying by \( \lambda \), it follows that for a suitable constant \( M \),
\[ \| x - J_\lambda x \|^2 \leq M \lambda + \lambda M \| x - J_\lambda x \| \]
and so a use of the quadratic formula implies
\[ \| x - J_\lambda x \| \leq \frac{M}{2} \left( 1 + \sqrt{5} \right) \lambda \]
Hence \( J_\lambda x \to x \) and so in [23.7.81] it follows from lower semicontinuity again that
\[
\infty = \phi(x) \leq \lim_{\lambda \to 0} \inf \phi(J_\lambda x) \leq \lim_{\lambda \to 0} \inf \phi_\lambda(x) \leq \lim_{\lambda \to 0} \sup \phi_\lambda(x) \leq \phi(x)
\]
and so again, \( \lim_{\lambda \to 0} \phi_\lambda(x) = \infty \). Also note that if \( \lambda > \mu \), then
\[
\min_{y \in X} \left( \frac{1}{2\lambda} \|x - y\|^2 + \phi(y) \right) \leq \min_{y \in X} \left( \frac{1}{2\mu} \|x - y\|^2 + \phi(y) \right)
\]
because for a given \( y \), \( \frac{1}{\lambda} \|x - y\|^2 + \phi(y) \leq \frac{1}{\mu} \|x - y\|^2 + \phi(y) \). Thus \( \phi_\lambda(x) \uparrow \phi(x) \).

Next consider the claim about the Gateaux differentiability. Using the description [23.7.78]
\[
\phi_\lambda(y) - \phi_\lambda(x) = \frac{1}{2\lambda} \|y - J_\lambda y\|^2 + \phi(J_\lambda(y)) - \left( \frac{1}{2\mu} \|x - J_\mu x\|^2 + \phi(J_\mu(x)) \right) \tag{23.7.81}
\]
Using the fact that if \( \psi(x) = \|x\|^2 \), then \( \partial \psi(x) = Fx \), and that \( A_\lambda x \in \partial \phi(J_\lambda x) \),
\[
\geq \lambda^{-1} \langle F(x - J_\lambda x), (y - J_\lambda y) - (x - J_\lambda x) \rangle + \langle A_\lambda x, J_\lambda(y) - J_\lambda(x) \rangle
\]
\[
= \langle A_\lambda (x), (y - J_\lambda y) - (x - J_\lambda x) \rangle + \langle A_\lambda x, J_\lambda(y) - J_\lambda(x) \rangle = \langle A_\lambda x, y - x \rangle
\]
Hence
\[
(\phi_\lambda(y) - \phi_\lambda(x)) - \langle A_\lambda x, y - x \rangle \geq 0
\]
Also from [23.7.81]
\[
\frac{1}{2\lambda} \|y - J_\lambda y\|^2 - \frac{1}{2\lambda} \|x - J_\lambda x\|^2 = - \left( \frac{1}{2\lambda} \|x - J_\lambda x\|^2 - \frac{1}{2\lambda} \|y - J_\lambda y\|^2 \right)
\]
\[
\leq - \frac{1}{\lambda} \langle F(y - J_\lambda y), (x - J_\lambda x) - (y - J_\lambda y) \rangle = \langle A_\lambda y, (y - J_\lambda y) - (x - J_\lambda x) \rangle
\]
Similarly, from [23.7.81]
\[
\phi(J_\lambda(y)) - \phi(J_\lambda(x)) = - (\phi(J_\lambda(x)) - \phi(J_\lambda(y))) \leq - \langle A_\lambda (y), J_\lambda(x) - J_\lambda(y) \rangle = \langle A_\lambda(y), J_\lambda(y) - J_\lambda(x) \rangle
\]
It follows that
\[
\langle A_\lambda(y), J_\lambda(y) - J_\lambda(x) \rangle + \langle A_\lambda y, (y - J_\lambda y) - (x - J_\lambda x) \rangle \geq (\phi_\lambda(y) - \phi_\lambda(x)) \geq \langle A_\lambda x, y - x \rangle
\]
and so
\[
\langle A_\lambda(y), y - x \rangle \geq (\phi_\lambda(y) - \phi_\lambda(x)) \geq \langle A_\lambda x, y - x \rangle
\]
Therefore,
\[
\langle A_\lambda(y) - A_\lambda(x), y - x \rangle \geq (\phi_\lambda(y) - \phi_\lambda(x)) - \langle A_\lambda x, y - x \rangle \geq 0
\]
Next let \( y = x + tz \) for \( t > 0 \). Then
\[
t (A_\lambda (x + tz) - A_\lambda (x), z) \geq (\phi_\lambda (x + tz) - \phi_\lambda (x)) - t \langle A_\lambda x, z \rangle \geq 0
\]
Using the demicontinuity of \( A_\lambda \), you can divide by \( t \) and pass to a limit to obtain
\[
\lim_{t \downarrow 0} \frac{\phi_\lambda (x + tz) - \phi_\lambda (x)}{t} = \langle A_\lambda x, z \rangle.
\]
A much better theorem is available in case \( X = X' = H \) a Hilbert space. In this case \( \phi_\lambda \) is also Frechet differentiable. See Theorem 32.3.24 which is presented later. Everything is much nicer in the Hilbert space setting because \( F \) is just replaced with the identity and the approximations are defined more easily.

Then one can show that \( J_\lambda \) is Lipschitz continuous and many other nice things happen.

Next is an interesting result about when the sum of a maximal monotone operator and a subgradient is also maximal monotone. A version of this is well known in the case of a single Hilbert space. In the case of a single Hilbert space, this result can be used to produce very regular solutions to evolution equations for functions which have values in the Hilbert space. You would get this by letting \( X = X' \) equal to a Hilbert space and your maximal monotone operator \( A \) would be defined on \( L^2 (0, T; H) \) a space of Hilbert space valued functions which are square integrable. Then you could take \( Lu = u' \) with domain equal to those functions in \( X \) which are equal to 0 at the left end of the interval for example. This is done more generally later. In this case the duality map is just the identity. The next theorem includes the case of two different spaces. I am not sure whether this is a useful result at this time, in terms of evolution equations. However, it is good to have conditions which show that the sum of two maximal monotone operators is maximal monotone.

\textbf{Theorem 23.7.55} Let \( X \) be a reflexive Banach space with strictly convex norm and let \( \Phi \) be non negative, convex, proper, and lower semicontinuous. Suppose also that \( A : D (A) \rightarrow \mathcal{P} (X') \) is a maximal monotone operator and there exists
\[
\xi \in D (A) \cap D (\Phi).
\]

Suppose also that
\[
\Phi (J_\lambda x) \leq \Phi (x) + C \lambda
\]

Then \( A + \partial \Phi \) is maximal monotone.
Proof: Recall that
\[ A_{\lambda}x = -\lambda^{-1} F(J_{\lambda}x - x), \text{ where } 0 \in F(J_{\lambda}x - x) + \lambda \partial \Phi (J_{\lambda}x) \]
Let \( y^* \in X' \). From Theorem 23.7.43 there exists \( x_\lambda \in H \) such that
\[ y^* \in Fx_\lambda + A_{\lambda}x_\lambda + \partial \Phi (x_\lambda). \]
It is desired to show that \( A_{\lambda}x_\lambda \) is bounded. From the above,
\[ y^* - Fx_\lambda - A_{\lambda}x_\lambda \leq \Phi (J_{\lambda}x_\lambda) - \Phi (x_\lambda) \leq C \lambda \]
and so
\[ (y^* - Fx_\lambda - A_{\lambda}x_\lambda, (\lambda) F^{-1} (A_{\lambda}x)) \leq C \lambda \]
which implies
\[ \langle y^* - Fx_\lambda - A_{\lambda}x_\lambda, (-\lambda) F^{-1} (A_{\lambda}x) \rangle \leq C \lambda \]
and so
\[ \langle y^* - Fx_\lambda - A_{\lambda}x_\lambda, -F^{-1} (A_{\lambda}x) \rangle \leq C \]
Hence
\[ \langle y^* - Fx_\lambda, -F^{-1} (A_{\lambda}x) \rangle + \| A_{\lambda}x_\lambda \|^2 \leq C \]
I claim \( \{ \| x_\lambda \| \} \) are bounded independent of \( \lambda \).
By 23.7.83 and monotonicity of \( A_{\lambda} \),
\[ \Phi (\xi) - \Phi (x_\lambda) \geq \langle y^* - Fx_\lambda - A_{\lambda}x_\lambda, \xi - x_\lambda \rangle \]
\[ \geq \langle y^* - Fx_\lambda, \xi - x_\lambda \rangle - \langle A_{\lambda}x_\lambda, \xi - x_\lambda \rangle \]
\[ \geq \langle y^* - Fx_\lambda, \xi - x_\lambda \rangle - \langle A_{\lambda}\xi, \xi - x_\lambda \rangle \]
\[ = \langle y^*, \xi \rangle - \langle y^*, x_\lambda \rangle - \langle Fx_\lambda, \xi \rangle + \| x_\lambda \|^2 - \| \xi - x_\lambda \| \| A_{\lambda}\xi \| \]
\[ \geq - \| y^* \| \| \xi \| - \| y^* \| \| x_\lambda \| - \| x_\lambda \| \| \xi \| - \| \xi \| \| A_{\lambda}\xi \| - \| x_\lambda \| \| A_{\lambda}\xi \| + \| x_\lambda \|^2 \]
Therefore, there exist constants, \( C_1 \) and \( C_2 \), depending on \( \xi \) and \( y^* \) but not on \( \lambda \) such that
\[ \Phi (\xi) \geq \Phi (x_\lambda) + \| x_\lambda \|^2 - C_1 \| x_\lambda \| - C_2. \]
Since \( \Phi \geq 0 \), the above shows that \( \| x_\lambda \| \) is indeed bounded. Now from 23.7.83 it follows that \( \{ A_{\lambda}x_\lambda \} \) is bounded for small positive \( \lambda \). By Theorem 23.7.43 there exists a solution \( x \) to
\[ y^* \in Fx + Ax + \partial \Phi (x) \]
and since \( y^* \) is arbitrary, this shows that \( A + \partial \Phi \) is maximal monotone. ■
23.8 Perturbation Theorems

In this section gives surjectivity of the sum of a pseudomonotone set valued map with a linear maximal monotone map and also with another maximal monotone operator added in. It generalizes the surjectivity results given earlier because one could have 0 for the maximal monotone linear operator. The theorems developed here lead to nice results on evolution equations because the linear maximal monotone operator can be something like a time derivative and $X$ can be some sort of an $L^p$ space for functions having values in a suitable Banach space. This is presented later in the material on Bochner integrals.

The notation $\langle z^*, u \rangle_{V', V}$ will mean $z^*(u)$ in this section. We will not worry about the order either. Thus

$$\langle u, z^* \rangle \equiv z^*(u) \equiv \langle z^*, u \rangle$$

This is just convenient in writing things down. Also, it is assumed that all Banach spaces are real to simplify the presentation. It is also usually assumed that the Banach spaces are reflexive. Thus we can regard

$$(V \times V')' = V' \times V$$

and $\langle (y^*, x), (u, v^*) \rangle \equiv \langle y^*, u \rangle + \langle x, v^* \rangle$. It is known \[\square\] that for a reflexive Banach space, there is always an equivalent strictly convex norm. It is therefore, assumed that the norm for the reflexive Banach space is strictly convex.

**Definition 23.8.1** Let $L : D(L) \subseteq V \to V'$ be a linear map where we always assume $D(L)$ is dense in $V$. Then

$$D(L^*) \equiv \{ u \in V : |\langle Lv, u \rangle| \leq C \|v\| \text{ for all } v \in D(L) \}$$

For such $u$, it follows that on a dense subset of $V$, namely $D(L), v \to \langle Lz, u \rangle$ is a continuous linear map. Hence there exists a unique element of $V'$, denoted as $L^*u$ such that for all $v \in D(L),$

$$\langle Lv, u \rangle_{V', V} = \langle L^*u, v \rangle_{V', V}$$

Thus

$$L : D(L) \subseteq V \to V'$$

$$L^* : D(L^*) \subseteq V \to V'$$

There is an interesting description of $L^*$ in terms of $L$ which will be quite useful.

**Proposition 23.8.2** Let $\tau : V \times V' \to V' \times V$ be given by $\tau (a, b) \equiv (-b, a)$. Also for $S \subseteq X$ a reflexive Banach space,

$$S^\perp \equiv \{ z^* \in X' : \langle z^*, s \rangle = 0 \text{ for all } s \in S \}$$

Also denote by $\mathcal{G}(L) \equiv \{ (x, Lx) : x \in D(L) \}$. Then

$$\mathcal{G}(L^*) = (\tau \mathcal{G}(L))^\perp$$
**Proof:** Let \( (x, L^*x) \in \mathcal{G}(L^*) \). This means that
\[
|\langle Ly, x \rangle| \leq C \|y\| \quad \text{for all } y \in D(L)
\]
and \( \langle Ly, x \rangle = \langle L^*x, y \rangle \) for all \( y \in D(L) \). Let \( (y, Ly) \in \mathcal{G}(L) \). Then \( \tau(y, Ly) = \langle -Ly, y \rangle \). Then
\[
\langle (x, L^*x), (-Ly, y) \rangle = \langle x, -Ly \rangle + \langle L^*x, y \rangle = -\langle x, Ly \rangle + \langle x, L^*y \rangle = 0
\]
Thus \( \mathcal{G}(L^*) \subseteq (\tau \mathcal{G}(L))^\perp \). Next suppose \( (x, y^*) \in (\tau \mathcal{G}(L))^\perp \). This means that if \( (u, Lu) \in \mathcal{G}(L) \), then
\[
\langle (x, y^*), (-Lu, u) \rangle = \langle x, -Lu \rangle + \langle y^*, u \rangle = 0
\]
and so for all \( u \in D(L) \),
\[
\langle y^*, u \rangle = \langle x, Lu \rangle
\]
and so \( x \in D(L^*) \). Hence for all \( u \in D(L) \),
\[
\langle y^*, u \rangle = \langle x, Lu \rangle = \langle L^*x, u \rangle
\]
Then, since \( D(L) \) is dense, it follows that \( y^* = L^*x \) and so \( (x, y) \in \mathcal{G}(L^*) \). Thus these are the same. \( \blacksquare \)

Theorem 23.5.4 is a very nice surjectivity result for set valued pseudomonotone operators. We recall what it said here. Recall the meaning of coercive.

\[
\lim_{\|v\| \to \infty} \inf \left\{ \frac{\langle z^*, v \rangle}{\|v\|} : z^* \in Tv \right\} = \infty
\]

In this section, we use the convenient notation \( \langle z^*, x \rangle_{\mathcal{V}', \mathcal{V}} = z^*(x) \).

**Theorem 23.8.3** Let \( V \) be a reflexive Banach space and let \( T : V \to \mathcal{P}(V') \) be pseudomonotone, bounded and coercive. Then \( T \) is onto. More generally, this continues to hold if \( T \) is modified bounded pseudomonotone.

Recall the definition of pseudomonotone.

**Definition 23.8.4** For \( X \) a reflexive Banach space, we say \( A : X \to \mathcal{P}(X') \) is pseudomonotone if the following hold.

1. The set \( Au \) is nonempty, closed and convex for all \( u \in X \).
2. If \( F \) is a finite dimensional subspace of \( X \), \( u \in F \), and \( U \) is a weakly open set in \( V' \) such that \( Au \subseteq U \), then there exists a \( \delta > 0 \) such that if \( v \in B_{\delta}(u) \cap F \) then \( Av \subseteq U \). (Weakly upper semicontinuous on finite dimensional subspaces.)
3. If \( u_i \to u \) weakly in \( X \) and \( u_i^* \in Au_i \) is such that
\[
\limsup_{i \to \infty} \langle u_i^*, u_i - u \rangle \leq 0,
\]
then, for each \( v \in X \), there exists \( u^*(v) \in Au \) such that
\[
\liminf_{i \to \infty} \langle u_i^*, u_i - v \rangle \geq \langle u^*(v), u - v \rangle.
\]
Also recall the definition of modified bounded pseudomonotone. It is just the above except that the limit condition is replaced with the following condition: If \( u_i \to u \) weakly in \( X \) and

\[
\limsup_{i \to \infty} \langle u_i^*, u_i - u \rangle \leq 0,
\]

then there exists a subsequence, still denoted as \( \{u_i\} \) such that for each \( v \in X \), there exists \( u^*(v) \in Au \) such that

\[
\liminf_{i \to \infty} \langle u_i^*, u_i - v \rangle \geq \langle u^*(v), u - v \rangle.
\]

(23.8.89)

Also recall that this more general limit condition along with the assumption \( 1 \) and the assumption that \( A \) is bounded is sufficient to obtain condition \( 2 \). This was Lemma 23.4.9 proved earlier and stated here for convenience.

Lemma 23.8.5

Let \( A : X \to \mathcal{P}(X') \) satisfy conditions \( 1 \) and \( 2 \) above and suppose \( A \) is bounded. Also suppose the condition that if \( x_n \to x \) weakly and \( \limsup_{n \to \infty} \langle z_n, x_n - x \rangle \leq 0 \) implies there exists a subsequence \( \{x_{n_k}\} \) such that for any \( y 

\[
\liminf_{n \to \infty} \langle z_{n_k}, x_n - y \rangle \geq \langle z(y), x - y \rangle
\]

for \( z(y) \) some element of \( Ax \). Then if this weaker condition holds, you have that if \( U \) is a weakly open set containing \( Ax \), then \( Ax_n \subseteq U \) for all \( n \) large enough.

Definition 23.8.6

Now let \( L : D(L) \subseteq V \to V' \) such that \( L \) is linear, monotone, \( D(L) \) is dense in \( V \), \( L \) is closed, and \( L^* \) is monotone. Let \( A : V \to \mathcal{P}(V') \) be a bounded operator. Then \( A \) is called \( L \) pseudomonotone if \( Au \) is closed and convex in \( V' \) and for any sequence \( \{u_n\} \subseteq D(L) \) such that \( u_n \to u \) weakly in \( V \) and \( Lu_n \to Lu \) weakly in \( V' \), and for \( z^*_n \in Au_n \),

\[
\limsup_{n \to \infty} \langle z^*_n, u_n - u \rangle \leq 0
\]

then for every \( v \in V \), there exists \( z^*(v) \in Au \) such that

\[
\liminf_{n \to \infty} \langle z^*_n, u_n - v \rangle \geq \langle z^*(v), u - v \rangle
\]

It is called \( L \) modified bounded pseudomonotone if the above \( \liminf \) condition holds for some subsequence whenever \( u_n \to u \) weakly and \( Lu_n \to Lu \) weakly and \( \limsup_{n \to \infty} \langle z^*_n, u_n - u \rangle \leq 0 \).

Lemma 23.8.7

Suppose \( X \) is the Banach space

\[
X = D(L), \quad \|u\|_X = \|u\|_V + \|Lu\|_{V'},
\]

where \( L \) is as described in the above definition. Also assume that \( A \) is bounded. Then if \( A \) is \( L \) pseudomonotone, it follows that \( A \) is pseudomonotone as a map from \( X \) to \( \mathcal{P}(X') \). If \( A \) is \( L \) modified bounded pseudomonotone, then \( A \) is modified bounded pseudomonotone as a map from \( X \) to \( \mathcal{P}(X') \).
**Proof:** Is \( A \) bounded? Of course, because the norm of \( X \) is stronger than the norm on \( V \). Is \( Au \) convex and closed? This also follows because \( X \subseteq V \). It is clear that \( Au \) is convex. If \( \{z_n\} \subseteq Au \) and \( z_n \to z \) in \( X' \), then does it follow that \( z \in Au \)? Since \( A \) is bounded, there is a further subsequence which converges weakly to \( w \) in \( V' \). However, \( Au \) is convex and closed so it is weakly closed. Hence \( w \in Au \) and also \( w = z \). It only remains to verify the pseudomonotone limit condition. Suppose then that \( u_n \to u \) weakly in \( X \) and for \( z_n^* \in Au_n \),

\[
\limsup_{n \to \infty} \langle z_n^*, u_n - u \rangle \leq 0
\]

Then it follows that \( Lu_n \to Lu \) weakly in \( V' \) and \( u_n \to u \) weakly in \( V \) so \( u \in X \). Hence the assumption that \( A \) is \( L \) pseudomonotone implies that for every \( v \in V \), and for every \( v \in X \), there exists \( z^*(v) \in Au \subseteq V' \subseteq X' \) such that

\[
\liminf_{n \to \infty} \langle z_n^*, u_n - v \rangle \geq \langle z^*(v), u - v \rangle
\]

The last claim goes the same way. You just have to take a subsequence. \( \blacksquare \)

Then we have the following major surjectivity result. In this theorem, we will assume for simplicity that all spaces are real spaces. Versions of this appear to be due to Brezis [14] and Lions [15]. Of course the theorem holds for complex spaces as well. You just need to use \( \text{Re} \{ \} \) instead of \( \{ \} \).

**Theorem 23.8.8** Let \( L : D(L) \subseteq V \to V' \) where \( D(L) \) is dense, \( L \) is monotone, \( L \) is closed, and \( L^* \) is monotone, \( L \) a linear map. Let \( A : V \to \mathcal{P}(V') \) be \( L \) pseudomonotone, bounded, coercive. Then \( L + A \) is onto. Here \( V \) is a reflexive Banach space such that the norms for \( V \) and \( V' \) are strictly convex. In case that \( A \) is strictly monotone \( \langle (Au - Av, u - v) \rangle > 0 \) implies \( u \neq v \) the solution \( u \) to \( f \in Lu + Au \) is unique. If, in addition to this, \( \langle Au - Av, u - v \rangle \geq r \|u - v\|_V \) where \( U \) is some Banach space containing \( V \), and \( r \) is a positive strictly increasing function for which \( \lim_{t \to 0^+} r(t) = 0 \), then the map \( f \to u \) where \( f \in Lu + Au \) is continuous as a map from \( V' \) to \( U \). The conclusion holds if \( A \) is only \( L \) modified bounded pseudomonotone.

**Proof:** Let \( F \) be the duality map for \( p = 2 \). Consider the Banach space \( X \) given by

\[
X = D(L), \quad \|u\|_X \equiv \|u\|_V + \|Lu\|_{V'}
\]

This is isometric with the graph of \( L \) with the graph norm and so \( X \) is reflexive. Now define a set valued map \( G_\varepsilon \) on \( X \) as follows. \( z^* \in G_\varepsilon(u) \) means there exists \( w^* \in Au \) such that

\[
\langle z^*, v \rangle_{X'} = \varepsilon \langle Lv, F^{-1}(Lu) \rangle_{V'} + \langle Lu, v \rangle_{V'} + \langle w^*, v \rangle_{V'}
\]

It follows from Lemma [14] that \( G_\varepsilon \) is the sum of a set valued \( L \) modified bounded pseudomonotone operator with an operator which is demicontinuous, bounded, and
monotone, hence pseudomonotone. Thus by Lemma 23.5.2 it is $L$ modified bounded pseudomonotone. Is it coercive?

$$\lim_{\|u\|_X \to \infty} \inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \langle F^{-1}(Lu), u \rangle_{V^*, V} + \langle Lu, u \rangle_{V^*, V}}{\|u\|_X^2} : z^* \in Au \right\} = \infty?$$

It equals

$$\lim_{\|u\|_X \to \infty} \inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \langle FF^{-1}(Lu), F^{-1}(Lu) \rangle_{V^*, V} + \langle Lu, u \rangle_{V^*, V}}{\|u\|_X^2} : z^* \in Au \right\}$$

and this is

$$\geq \lim_{\|u\|_X \to \infty} \inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \|F^{-1}(Lu)\|_{V^*}^2}{\|u\|_X^2} : z^* \in Au \right\}$$

$$= \lim_{\|u\|_X \to \infty} \inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \|Lu\|_{V^*}^2}{\|u\|_{V^*}^2 + \|Lu\|_{V^*}} : z^* \in Au \right\}$$

because $L$ is monotone. Now let $M$ be an arbitrary positive number. By assumption, there exists $R$ such that if $\|u\|_V > R$, then

$$\inf \left\{ \frac{\langle z^*, u \rangle}{\|u\|_V} : z^* \in Au \right\} > M$$

and so for every $z^* \in Au$,

$$\frac{\langle z^*, u \rangle}{\|u\|_V} > M, \quad \langle z^*, u \rangle > M \|u\|_V$$

Thus if $\|u\|_V > R$,

$$\inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \|Lu\|_{V^*}^2}{\|u\|_V + \|Lu\|_{V^*}} : z^* \in Au \right\} \geq \frac{M \|u\|_V + \varepsilon \|Lu\|_{V^*}^2}{\|u\|_V + \|Lu\|_{V^*}}$$

I claim that if $\|u\|_X$ is large enough, the above is larger than $M/2$. If not, then there exists $\{u_n\}$ such that $\|u_n\|_X \to \infty$ but the right side is less than $M/2$. First say $\|Lu_n\|$ is bounded. then there is an obvious contradiction since the right hand side then converges to $M$. Thus it can be assumed that $\|Lu_n\|_{V^*} \to \infty$. Hence, for all $n$ large enough, $\varepsilon \|Lu\|_{V^*}^2 > M \|Lu_n\|_{V^*}$. However, this implies the right side is larger than

$$\frac{M \|u_n\|_V + \varepsilon \|Lu_n\|_{V^*}^2}{\|u_n\|_V + \|Lu_n\|_{V^*}} = M > M/2$$

This is a contradiction. Hence the right side is larger than $M/2$ for all $n$ large enough. It follows since $M$ is arbitrary, that

$$\lim_{\|u\|_X \to \infty} \inf \left\{ \frac{\langle z^*, u \rangle + \varepsilon \|Lu\|_{V^*}^2}{\|u\|_V + \|Lu\|_{V^*}} : z^* \in Au \right\} = \infty$$
It follows from Theorem 23.5.4 that if \( f \in V' \), there exists \( u_\varepsilon \) such that for all \( v \in D(L) = X \),

\[
\varepsilon \langle Lv, F^{-1}(Lu_\varepsilon) \rangle_{V',V} + \langle Lu_\varepsilon, v \rangle_{V',V} + \langle w^*_\varepsilon, v \rangle_{V',V} = \langle f, v \rangle, \quad w^*_\varepsilon \in Au_\varepsilon \tag{23.8.91}
\]

First we get an estimate.

\[
\varepsilon \langle Lu_\varepsilon, F^{-1}(Lu_\varepsilon) \rangle_{V',V} + \langle Lu_\varepsilon, u_\varepsilon \rangle_{V',V} + \langle w^*_\varepsilon, u_\varepsilon \rangle_{V',V} = \langle f, u_\varepsilon \rangle
\]

Hence it follows from the coercivity of \( A \) that \( \|u_\varepsilon\|_V \) is bounded independent of \( \varepsilon \).

Thus the \( w^*_\varepsilon \) are also bounded in \( V' \) because it is assumed that \( A \) is bounded. Now from the equation solved \( 23.8.91 \), it follows that \( D(L) = X \) is dense in \( V \) that

\[
\varepsilon L^*\left( F^{-1}(Lu_\varepsilon) \right) + Lu_\varepsilon + w^*_\varepsilon = f \tag{23.8.92}
\]

Then act on \( F^{-1}(Lu_\varepsilon) \) on both sides. From monotonicity of \( L^* \), this yields \( \|Lu_\varepsilon\|_V \), is bounded independent of \( \varepsilon > 0 \). Thus there is a subsequence still denoted with a subscript of \( \varepsilon \) such that

\[
u_\varepsilon \rightharpoonup u \text{ in } V
\]

\[
Lu_\varepsilon \rightharpoonup Lu \text{ in } V'
\]

This because of the fact that the graph of \( L \) is closed, hence weakly closed. Thus \( u \in X \). Also

\[
w^*_\varepsilon \rightharpoonup w^* \text{ in } V'.
\]

It follows that we can pass to a limit in \( 23.8.92 \) and obtain

\[
Lu + w^* = f \tag{23.8.93}
\]

Now by assumption on \( A \), it is \( L \) modified bounded pseudomonotone and so there is a subsequence, still denoted as \( u_\varepsilon \) such that the \( \liminf \) pseudomonotone limit condition holds. This will be what is referred to in what follows. Then

\[
\langle \varepsilon L^*\left( F^{-1}(Lu_\varepsilon) \right), u_\varepsilon - u \rangle + \langle Lu_\varepsilon, u_\varepsilon - u \rangle + \langle w^*_\varepsilon, u_\varepsilon - u \rangle = \langle f, u_\varepsilon - u \rangle
\]

and so,

\[
\varepsilon \langle F^{-1}(Lu_\varepsilon), Lu_\varepsilon - Lu \rangle + \langle Lu_\varepsilon, u_\varepsilon - u \rangle + \langle w^*_\varepsilon, u_\varepsilon - u \rangle = \langle f, u_\varepsilon - u \rangle
\]

using the monotonicity of \( L \),

\[
\varepsilon \langle Lu_\varepsilon - Lu, F^{-1}(Lu_\varepsilon) - F^{-1}(Lu) \rangle + \varepsilon \langle Lu_\varepsilon - Lu, F^{-1}(Lu) \rangle + \langle Lu, u_\varepsilon - u \rangle + \langle w^*_\varepsilon, u_\varepsilon - u \rangle \leq \langle f, u_\varepsilon - u \rangle
\]
Now using monotonicity of \( F^{-1} \),
\[
\varepsilon \left\langle Lu_x - Lu, F^{-1}(Lu) \right\rangle + \left\langle Lu, u_x - u \right\rangle + \left\langle w^*_\varepsilon, u_x - u \right\rangle \leq \left\langle f, u_x - u \right\rangle
\]
and so, passing to a limit as \( \varepsilon \to 0 \),
\[
\limsup_{\varepsilon \to 0} \left\langle w^*_\varepsilon, u_x - u \right\rangle \leq 0
\]
It follows that for all \( v \in X = D(L) \) there exists \( w^* (v) \in Au \)
\[
\liminf_{\varepsilon \to 0} \left\langle w^*_\varepsilon, u_x - v \right\rangle \geq \left\langle w^* (v), u - v \right\rangle
\]
But the left side equals
\[
\liminf_{\varepsilon \to 0} \left[ \left\langle w^*_\varepsilon, u_x - u \right\rangle + \left\langle w^*_\varepsilon, u - v \right\rangle \right] \\
\leq \limsup_{\varepsilon \to 0} \left\langle w^*_\varepsilon, u_x - u \right\rangle + \left\langle w^*, u - v \right\rangle \leq \left\langle w^*, u - v \right\rangle
\]
and so
\[
\left\langle w^*, u - v \right\rangle \geq \left\langle w^* (v), u - v \right\rangle
\]
for all \( v \).

Is \( w^* \in Au \)? Suppose not. Then \( Au \) is a closed convex set and \( w^* \) is not in it. Hence, since \( V \) is reflexive, there exists \( z \in V \) such that whenever \( y^* \in Au, \left\langle w^*, z \right\rangle < \left\langle y^*, z \right\rangle \). Now simply choose \( v \) such that \( u - v = z \) and it follows that
\[
\left\langle w^* (v), u - v \right\rangle > \left\langle w^*, u - v \right\rangle \geq \left\langle w^* (v), u - v \right\rangle
\]
which is clearly a contradiction. Hence \( w^* \in Au \). Thus from \( \text{[22]} \) this has shown that \( L + A \) is onto.

Consider the claim about uniqueness and continuous dependence. Say you have \( f_i \in Lu_i + Au_i, i = 1, 2 \). Let \( z^*_i \in Au_i \) be such that equality holds in the two inclusions. Then
\[
f_1 - f_2 = z^*_1 - z^*_2 + Lu_1 - Lu_2
\]
It follows that
\[
\left\langle f_1 - f_2, u_1 - u_2 \right\rangle = \left\langle z^*_1 - z^*_2 + Lu_1 - Lu_2, u_1 - u_2 \right\rangle \geq r (\|u_1 - u_2\|)
\]
Thus if \( f_1 = f_2 \), then \( u_1 = u_2 \). If \( f_n \to f \) in \( V' \), then \( r (\|u - u_n\|) \to 0 \) where \( u_n \) goes with \( f_n \) and \( u \) with \( f \) as just described, and so \( u_n \to u \) because the coercivity estimate given above shows that the \( u_n \) and \( u \) are all bounded. Thus the map just described is continuous.

The following lemma is interesting in terms of the hypotheses of the above theorem. \( \text{[22]} \)

**Lemma 23.8.9** Let \( L : D(L) \to X' \) where \( D(L) \) is dense and \( L \) is a closed operator. Then \( L \) is maximal monotone if and only if both \( L, L^* \) are monotone.
Proof: Suppose both \( L, L^* \) are monotone. One must show that \( \lambda F + L \) is onto. However, \( F \) is monotone and hemicontinuous (actually demicontinuous) and coercive. Hence the fact that \( \lambda F + L \) is onto follows from Theorem 23.8.8. Next suppose \( L \) is maximal monotone. If \( L \) is maximal monotone, then for every \( \varepsilon > 0 \) there exists a solution \( u_\varepsilon \) such that \( \varepsilon Lu_\varepsilon + F(u_\varepsilon - u) = 0 \). Here \( u \in D(L^*) \). This is from Lemma 23.8.8. It is originally due to Browder [24]. Then
\[
\varepsilon \langle Lu_\varepsilon, u_\varepsilon \rangle + \langle F(u_\varepsilon - u), u_\varepsilon \rangle = 0
\]
and so \( \langle F(u_\varepsilon - u), u_\varepsilon \rangle \leq 0 \). Then
\[
\langle F(u_\varepsilon - u), u_\varepsilon - u \rangle \leq \langle F(u_\varepsilon - u), u \rangle
\]
so \( \|u_\varepsilon - u\|^2 \leq \|u_\varepsilon - u\| \|u\| \) and so
\[
\|u_\varepsilon - u\| \leq \|u\|
\]
Thus the \( u_\varepsilon \) are bounded.

Next let \( v \in D(L) \).
\[
\|u_\varepsilon - u\|^2 = \langle F(u_\varepsilon - u), u_\varepsilon - u \rangle = \langle F(u_\varepsilon - u), u_\varepsilon - v \rangle + \langle F(u_\varepsilon - u), v - u \rangle
\]
\[
\leq \varepsilon \langle Lu_\varepsilon, v - u_\varepsilon \rangle + \langle F(u_\varepsilon - u), v - u \rangle \leq \varepsilon \langle Lv, v - u_\varepsilon \rangle + \langle F(u_\varepsilon - u), v - u \rangle
\]
Hence
\[
\limsup_{\varepsilon \to 0} \|u_\varepsilon - u\|^2 \leq \limsup_{\varepsilon \to 0} \left( \varepsilon \langle Lv, v - u_\varepsilon \rangle + \langle F(u_\varepsilon - u), v - u \rangle \right)
\]
\[
\leq \limsup_{\varepsilon \to 0} \langle F(u_\varepsilon - u), v - u \rangle \leq \limsup_{\varepsilon \to 0} \|u_\varepsilon - u\| \|v - u\|
\]
and so \( u_\varepsilon \to u \) strongly. Also
\[
\langle F(u_\varepsilon - u), u_\varepsilon \rangle = -\varepsilon \langle Lu_\varepsilon, u_\varepsilon \rangle \leq 0
\]
Then
\[
\langle L^* u, u \rangle = \lim_{\varepsilon \to 0} \langle L^* u, u_\varepsilon \rangle = \lim_{\varepsilon \to 0} \langle Lu_\varepsilon, u \rangle = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \langle -F(u_\varepsilon - u), u \rangle
\]
\[
= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \langle F(u_\varepsilon - u), u_\varepsilon - u \rangle - \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \langle F(u_\varepsilon - u), u_\varepsilon \rangle
\]
Both of these last terms are nonnegative, the first obviously and the second from the above where it was shown that \( \langle F(u_\varepsilon - u), u_\varepsilon \rangle \leq 0 \). \( \square \)

In the hypotheses of Theorem 23.8.8, one could have simply said that \( L \) is closed, linear, densely defined and maximal monotone. One can also show that if \( L \) is maximal monotone, then it must be densely defined. This is done in [24].

One can go further in obtaining a perturbation theorem like the above. Let linear \( L \) be densely defined with \( L \) closed and \( L, L^* \) monotone. In short, \( L \) is densely defined and maximal monotone, \( L : X \to X' \). Let \( A \) be a set valued linear pseudomonotone operator which is coercive and bounded. Also let \( B : D(B) \to P(X) \) be maximal monotone. It is of interest to consider whether \( L + A + B \) is onto \( X' \). In considering this, I will add further assumptions as needed. First note that \( \langle Lx, x \rangle = \langle Lx - L0, x - 0 \rangle \geq 0 \).
23.8. PERTURBATION THEOREMS

**Definition 23.8.10** Define
\[
\limsup_{m,n \to \infty} a_{m,n} = \lim_{k \to \infty} \sup \{a_{m,n} : \min (m, n) \geq k\}
\]

Then \( \limsup_{m,n \to \infty} a_{m,n} \geq \limsup_{n \to \infty} (\limsup_{m \to \infty} a_{m,n}) \). To see this, suppose \( a > \limsup_{m,n \to \infty} a_{m,n} \). Then there exist \( k \) such that whenever \( m, n > k \),
\[
a_{m,n} < a
\]

It follows that for \( m \geq k \),
\[
\limsup_{n \to \infty} a_{m,n} \leq a
\]

Hence
\[
\limsup_{m \to \infty} \left( \limsup_{n \to \infty} a_{m,n} \right) \leq a
\]

Since \( a > \limsup_{m,n \to \infty} a_{m,n} \) is arbitrary, it follows that
\[
\limsup_{m \to \infty} \left( \limsup_{n \to \infty} a_{m,n} \right) \leq \limsup_{m,n \to \infty} a_{m,n}.
\]

Then the following lemma is useful. I found this result in a paper by Gasinski, Migorski and Ochal. They begin with the following interesting lemma or something like it which is similar to some of the ideas used in the section on approximation of maximal monotone operators.

**Lemma 23.8.11** Suppose \( A \) is a set valued operator, \( A : X \to P(X) \) and \( u^*_n \in Au_n \). Suppose also that \( u_n \to u \) weakly and \( u^*_n \to u^* \) weakly. Suppose also that
\[
\limsup_{m,n \to \infty} \langle u^*_n - u^*_m, u_n - u_m \rangle \leq 0
\]

Then one can conclude that
\[
\limsup_{n \to \infty} \langle u^*_n, u_n - u \rangle \leq 0
\]

**Proof:** Let \( \alpha = \limsup_{n \to \infty} \langle u^*_n, u_n \rangle \). It is a finite number because these sequences are bounded. Then using the weak convergence,
\[
0 \geq \limsup_{m \to \infty} \left( \limsup_{n \to \infty} \langle u^*_n - u^*_m, u_n - u_m \rangle \right)
\]
\[
= \limsup_{m \to \infty} \left( \limsup_{n \to \infty} \left( \langle u^*_n, u_n \rangle + \langle u^*_m, u_m \rangle - \langle u^*_n, u_m \rangle - \langle u^*_m, u_n \rangle \right) \right)
\]
\[
= \limsup_{m \to \infty} \left( \alpha + \langle u^*_m, u_m \rangle - \langle u^*, u_m \rangle - \langle u^*_m, u \rangle \right)
\]
\[
= \left( \alpha + \langle u^*, u \rangle - \langle u^*, u \rangle \right) = 2\alpha - 2\langle u^*, u \rangle
\]

Now
\[
\limsup_{n \to \infty} \langle u^*_n, u_n - u \rangle = \alpha - \langle u^*, u \rangle \leq 0.
\]
To begin with, consider the approximate problem which is to determine whether \( L + A + B \) is onto. Here \( B_\lambda x = -\lambda^{-1} F(x_\lambda - x) \) where \( 0 \in F(x_\lambda - x) + \lambda Bx \).

In the notation given above, \( B_\lambda x = -\lambda^{-1} F(J_\lambda x - x) \). Then by Theorem 23.7.36, \( B_\lambda \) is monotone, demicontinuous, and bounded. In addition, we assume \( 0 \in D(B) \).

Then for \( x \in X^* \),

\[
\langle B_x, x \rangle = \langle B_\lambda 0, x \rangle \geq -|B(0)||x|
\]  

(23.8.94)

**Lemma 23.8.12** Let \( A \) be pseudomonotone, bounded and coercive and let \( 0 \in D(B) \). Then if \( y^* \in X' \), there exists a solution \( x_\lambda \) to

\[
y^* = Lx_\lambda + Ax_\lambda + Bx_\lambda
\]

**Proof:** From the inequality 23.8.94, \( A + B_\lambda \) is coercive. It is also bounded and pseudomonotone. It is pseudomonotone from Theorem 23.7.27. Therefore, there exists a solution \( x_\lambda \) by Theorem 23.8.8.

Acting on \( x_\lambda \) and using the inequality 23.8.94, it follows that these solutions \( x_\lambda \) lie in a bounded set. The details follow. Letting \( z_\lambda^* \in Ax_\lambda \) be such that equality holds in the above inclusion,

\[
y^* = Lx_\lambda + z_\lambda^* + Bx_\lambda
\]

(23.8.95)

Thus, from coercivity, \( x_\lambda \) are bounded. Then since \( A \) is bounded, the \( z_\lambda^* \) are all bounded also independent of \( \lambda \). The top line shows also that

\[
\langle y^*, x_\lambda \rangle \geq \langle Lx_\lambda, x_\lambda \rangle + \langle z_\lambda^*, x_\lambda \rangle + \langle B_\lambda x_\lambda, x_\lambda \rangle \geq \langle z_\lambda^*, x_\lambda \rangle + \langle B_\lambda x_\lambda, x_\lambda \rangle
\]

\[
\geq \frac{\langle z_\lambda^*, x_\lambda \rangle}{\|x_\lambda\|} - |B(0)||x_\lambda|
\]

Thus, from coercivity, \( x_\lambda \) are bounded. Then since \( A \) is bounded, the \( z_\lambda^* \) are all bounded also independent of \( \lambda \). The top line shows also that

\[
\langle y^*, x_\lambda \rangle = \langle Lx_\lambda, x_\lambda \rangle + \langle z_\lambda^*, x_\lambda \rangle + \langle B_\lambda x_\lambda, x_\lambda \rangle \geq \langle z_\lambda^*, x_\lambda \rangle + \langle B_\lambda x_\lambda, x_\lambda \rangle
\]

\[
\geq \langle B_\lambda x_\lambda, x_\lambda \rangle - M \geq -|B(0)||x_\lambda| - M
\]

(23.8.96)

where \( \langle z_\lambda^*, x_\lambda \rangle \leq M \) for all \( \lambda \). Hence there is a constant \( M \) such that

\[
\langle B_\lambda x_\lambda, x_\lambda \rangle \leq M
\]

**Definition 23.8.13** A set valued operator \( B \) is quasi-bounded if whenever \( x \in D(B) \) and \( x^* \in Bx \) are such that

\[
\langle x^*, x \rangle, \|x\| \leq M,
\]

it follows that \( \|x^*\| \leq K_M \). Bounded would mean that if \( \|x\| \leq M \), then \( \|x^*\| \leq K_M \). Here you only know this if there is another condition.
Lemma 23.8.14 In the above situation, suppose the maximal monotone operator $B$ is quasi-bounded and $|\langle B\lambda x, x \rangle| \leq M$. Then the $B\lambda x$ are bounded. Also

$$\|J\lambda x - x\| \leq M\lambda$$

**Proof:** Now $B\lambda x \in BJ\lambda x$

$$-|B(0)| \|x\| \leq \langle B\lambda x, x \rangle = \langle B\lambda x, J\lambda x \rangle + \langle B\lambda x, x - J\lambda x \rangle$$

$$= \langle B\lambda x, J\lambda x \rangle + \lambda^{-1} F(J\lambda x - x \lambda, J\lambda x - x \lambda)$$

$$= \langle B\lambda x, J\lambda x \rangle + \lambda^{-1} \|J\lambda x - x\|^2 \leq M$$

This inequality shows that $J\lambda x - x \lambda \to 0$ and so $J\lambda x$ is bounded as is $x \lambda$ which was shown above. Also $B\lambda x \in BJ\lambda x$ and since $B$ is quasi-bounded, it follows that $B\lambda x$ is bounded.

Assume from now on that $B$ is quasi-bounded. Then the estimate \[23.8.97\] and this lemma shows that $B\lambda x$ is also bounded independent of $\lambda$. Thus, adjusting the constants, there exists an estimate of the form

$$\|x\| + \|J\lambda x\| + \|B\lambda x\| + \|z^*\| + \|Lx\| \leq C, \quad \|x - J\lambda x\| \leq \sqrt{\lambda} M \quad (23.8.97)$$

Let $\lambda = 1/n$. Also denote by $J_n$ the the operator $J_{1/n}$ to save notation. There exists a subsequence

$$x_n \to x \text{ weakly},$$

$$J_n x_n \to x \text{ weakly},$$

$$B_n x_n \to g^* \text{ weakly},$$

$$z^*_n \to z^* \text{ weakly},$$

$$Lx_n \to Lx \text{ weakly}$$

Now from the inclusion satisfied,

$$0 = \langle z^*_n - z^*_m, x_n - x_m \rangle + \langle B_n x_n - B_m x_m, x_n - x_m \rangle \quad (23.8.98)$$

Consider that last term. $B_n x_n \in BJ_n x_n$ similar for $B_m x_m$. Hence this term is of the form

$$\langle B_n x_n - B_m x_m, x_n - x_m \rangle \geq \langle B_n x_n - B_m x_m, (x_n - J_n x_n) - (x_m - J_m x_m) \rangle$$

From the estimate \[46.3.11\],

$$\langle B_n x_n - B_m x_m, x_n - x_m \rangle \geq \langle B_n x_n - B_m x_m, (x_n - J_n x_n) - (x_m - J_m x_m) \rangle$$
and

\[ |\langle B_n x_n - B_m x_m, (x_n - J_n x_n) - (x_m - J_m x_m) \rangle| \leq 2C \left( \sqrt{\frac{1}{n}} + \sqrt{\frac{1}{m}} \right) \]

Then from (23.8.98),

\[ 0 \geq \langle z_n^* - z_m^*, x_n - x_m \rangle + e_{n,m} \]

where \( e_{n,m} \to 0 \) as \( n, m \to \infty \). Hence

\[ \lim_{m,n \to \infty} \sup_{n} \langle z_n^* - z_m^*, x_n - x_m \rangle \leq 0 \]

From Lemma (23.8.11),

\[ \lim_{n \to \infty} \sup_{n} \langle z_n^*, x_n - x \rangle \leq 0 \]

Hence, since \( A \) is pseudomonotone, for every \( y \), there exists \( z^* (y) \in Ax \) such that

\[ \lim_{n \to \infty} \inf_{n} \langle z_n^*, x_n - y \rangle \geq \langle z^* (y), x - y \rangle \]

In particular, if \( x = y \), this shows that

\[ \lim_{n \to \infty} \inf_{n} \langle z_n^*, x_n - x \rangle \geq \lim_{n \to \infty} \sup_{n} \langle z_n^*, x_n - x \rangle \]

showing that

\[ \lim_{n \to \infty} \langle z_n^*, x_n \rangle = \langle z^*, x \rangle \]

Next, returning to the inclusion solved,

\[ 0 = Lx_n + z_n^* + B_n x_n \]

Act on \( (x_n - x) \). Then from monotonicity of \( L \),

\[ 0 \geq \langle Lx, x_n - x \rangle + \langle z_n^*, x_n - x \rangle + \langle B_n x_n, x_n - x \rangle \]

Thus, taking \( \lim \sup \) of both sides,

\[ \lim_{n \to \infty} \sup_{n} \langle B_n x_n, x_n - x \rangle = \lim_{n \to \infty} \sup_{n} \langle B_n x_n, J_n x_n - x \rangle \leq 0 \]

Hence

\[ \lim_{n \to \infty} \sup_{n} \langle B_n x_n, J_n x_n \rangle \leq \langle g^*, x \rangle \]

Letting \([a, b^*] \in G(B)\),

\[ \langle B_n x_n - b^*, J_n x_n - a \rangle = \langle B_n x_n, J_n x_n \rangle - \langle B_n x_n, a \rangle - \langle b^*, J_n x_n \rangle + \langle b^*, a \rangle \]

Then taking \( \lim \sup \),

\[ 0 \leq \lim_{n \to \infty} \sup_{n} \langle B_n x_n - b^*, J_n x_n - a \rangle \]

\[ \leq \langle g^*, x \rangle - \langle g^*, a \rangle - \langle b^*, x \rangle + \langle b^*, a \rangle = \langle g^* - b^*, x - a \rangle \]
It follows that $g^* \in B(x)$ and $x \in D(B)$.

Thus, passing to the limit in the equation where, as explained $\lambda = 1/n$, one obtains

$$y^* = Lu + z^* + g^*$$

where $z^* \in Ax$ and $g^* \in Bx$. This proves the following nice generalization of the above perturbation theorem.

**Theorem 23.8.15** Let $B$ be maximal monotone from $X$ to $\mathcal{P}(X')$, $0 \in D(B)$, and $B$ is quasi-bounded as explained above. Let $A : X \rightarrow \mathcal{P}(X')$ be pseudomonotone, bounded, and coercive. Also let $L$ be a densely defined linear operator such that both $L$ and $L^*$ are monotone. (That is, $L$ is linear and maximal monotone.) Then $L + A + B$ is onto $X'$. 
Chapter 24

Integrals And Derivatives

24.1 The Fundamental Theorem Of Calculus

The version of the fundamental theorem of calculus found in Calculus has already been referred to frequently. It says that if \( f \) is a Riemann integrable function, the function
\[
x \rightarrow \int_a^x f(t) \, dt,
\]
has a derivative at every point where \( f \) is continuous. It is natural to ask what occurs for \( f \) in \( L^1 \). It is an amazing fact that the same result is obtained aside from a set of measure zero even though \( f \), being only in \( L^1 \) may fail to be continuous anywhere. Proofs of this result are based on some form of the Vitali covering theorem presented above. In what follows, the measure space is \((\mathbb{R}^n, \mathcal{S}, m)\) where \( m \) is \( n \)-dimensional Lebesgue measure although the same theorems can be proved for arbitrary Radon measures \( m \). To save notation, \( m \) is written in place of \( m_n \).

By Lemma 10.1.9 on Page 259 and the completeness of \( m \), the Lebesgue measurable sets are exactly those measurable in the sense of Caratheodory. Also, to save on notation \( m \) is also the name of the outer measure defined on all of \( \mathcal{P}(\mathbb{R}^n) \) which is determined by \( m_n \). Recall
\[
B(p, r) = \{ x : |x - p| < r \}. \quad (24.1.1)
\]
Also define the following.
\[
\text{If } B = B(p, r), \text{ then } \hat{B} = B(p, 5r). \quad (24.1.2)
\]

The first version of the Vitali covering theorem presented above will now be used to establish the fundamental theorem of calculus. The space of locally integrable functions is the most general one for which the maximal function defined below makes sense.
Definition 24.1.1  \( f \in L^1_{\text{loc}}(\mathbb{R}^n) \) means \( f \chi_{B(0,R)} \in L^1(\mathbb{R}^n) \) for all \( R > 0 \). For \( f \in L^1_{\text{loc}}(\mathbb{R}^n) \), the Hardy Littlewood Maximal Function, \( Mf \), is defined by

\[
Mf(x) \equiv \sup_{r>0} \frac{1}{m(B(x,r))} \int_{B(x,r)} |f(y)| dy.
\]

Theorem 24.1.2  If \( f \in L^1(\mathbb{R}^n) \), then for \( \alpha > 0 \),

\[
\overline{m}([Mf > \alpha]) \leq \frac{5^n}{\alpha} \|f\|_1.
\]

(Here and elsewhere, \([Mf > \alpha] \equiv \{x \in \mathbb{R}^n : Mf(x) > \alpha\}\) with other occurrences of \([ \ ]\) being defined similarly.)

Proof: Let \( S \equiv [Mf > \alpha] \). For \( x \in S \), choose \( r_x > 0 \) with

\[
\frac{1}{m(B(x,r_x))} \int_{B(x,r_x)} |f| \, dm > \alpha.
\]

The \( r_x \) are all bounded because

\[
m(B(x,r_x)) < \frac{1}{\alpha} \int_{B(x,r_x)} |f| \, dm < \frac{1}{\alpha} \|f\|_1.
\]

By the Vitali covering theorem, there are disjoint balls \( B(x_i, r_i) \) such that

\[
S \subseteq \bigcup_{i=1}^{\infty} B(x_i, 5r_i)
\]

and

\[
\frac{1}{m(B(x_i, r_i))} \int_{B(x_i, r_i)} |f| \, dm > \alpha.
\]

Therefore

\[
\overline{m}(S) \leq \sum_{i=1}^{\infty} m(B(x_i, 5r_i)) = 5^n \sum_{i=1}^{\infty} m(B(x_i, r_i)) \leq \frac{5^n}{\alpha} \sum_{i=1}^{\infty} \int_{B(x_i, r_i)} |f| \, dm \leq \frac{5^n}{\alpha} \int_{\mathbb{R}^n} |f| \, dm,
\]

the last inequality being valid because the balls \( B(x_i, r_i) \) are disjoint. This proves the theorem.

Note that at this point it is unknown whether \( S \) is measurable. This is why \( \overline{m}(S) \) and not \( m(S) \) is written.

The following is the fundamental theorem of calculus from elementary calculus.
Lemma 24.1.3 Suppose \( g \) is a continuous function. Then for all \( x \),

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} g(y) \, dy = g(x).
\]

Proof: Note that

\[
g(x) = \frac{1}{m(B(x, r))} \int_{B(x, r)} g(y) \, dy
\]
and so

\[
\left| g(x) - \frac{1}{m(B(x, r))} \int_{B(x, r)} g(y) \, dy \right|
= \left| \frac{1}{m(B(x, r))} \int_{B(x, r)} (g(y) - g(x)) \, dy \right|
\leq \frac{1}{m(B(x, r))} \int_{B(x, r)} |g(y) - g(x)| \, dy.
\]

Now by continuity of \( g \) at \( x \), there exists \( r > 0 \) such that if \( |x - y| < r \), \( |g(y) - g(x)| < \varepsilon \). For such \( r \), the last expression is less than

\[
\frac{1}{m(B(x, r))} \int_{B(x, r)} \varepsilon \, dy < \varepsilon.
\]

This proves the lemma.

Definition 24.1.4 Let \( f \in L^1(\mathbb{R}^k, m) \). A point, \( x \in \mathbb{R}^k \) is said to be a Lebesgue point if

\[
\limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm = 0.
\]

Note that if \( x \) is a Lebesgue point, then

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} f(y) \, dm = f(x).
\]

and so the symmetric derivative exists at all Lebesgue points.

Theorem 24.1.5 (Fundamental Theorem of Calculus) Let \( f \in L^1(\mathbb{R}^k) \). Then there exists a set of measure 0, \( N \), such that if \( x \notin N \), then

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dy = 0.
\]
CHAPTER 24. INTEGRALS AND DERIVATIVES

Proof: Let $\lambda > 0$ and let $\varepsilon > 0$. By density of $C_c(\mathbb{R}^k)$ in $L^1(\mathbb{R}^k, m)$ there exists $g \in C_c(\mathbb{R}^k)$ such that $\|g - f\|_{L^1(\mathbb{R}^k)} < \varepsilon$. Now since $g$ is continuous,

$$
\limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm
\leq \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x) - g(y) - g(x)| \, dm
\leq \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |g(y) - g(x)| \, dm
\leq M(|f - g|)(x) + |f(x) - g(x)|.
$$

Therefore,

$$
\left[ x : \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm > \lambda \right]
\subseteq \left[ M(|f - g|) > \frac{\lambda}{2} \right] \cup \left[ |f - g| > \frac{\lambda}{2} \right].
$$

Now

$$
\varepsilon > \int |f - g| \, dm \geq \int_{[|f - g| > \frac{\lambda}{2}]} |f - g| \, dm
\geq \frac{\lambda}{2} m \left( \left[ |f - g| > \frac{\lambda}{2} \right] \right)
$$

This along with the weak estimate of Theorem 24.1.2 implies

$$
m \left( \left[ x : \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm > \lambda \right] \right)
\leq \left( \frac{2 \lambda^5 + \frac{2}{\lambda}}{2^5} \right) \|f - g\|_{L^1(\mathbb{R}^k)}
\leq \left( \frac{2 \lambda^5 + \frac{2}{\lambda}}{2^5} \right) \varepsilon.
$$
Since \( \varepsilon > 0 \) is arbitrary, it follows

\[
m_n \left( \left\{ x : \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm > \lambda \right\} \right) = 0.
\]

Now let

\[
N = \left\{ x : \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm > 0 \right\}
\]

and

\[
N_n = \left\{ x : \limsup_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm > \frac{1}{n} \right\}
\]

It was just shown that \( m(N_n) = 0 \). Also, \( N = \bigcup_{n=1}^{\infty} N_n \). Therefore, \( m(N) = 0 \) also.

It follows that for \( x \notin N \),

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dm = 0
\]

and this proves a.e. point is a Lebesgue point.

Of course it is sufficient to assume \( f \) is only in \( L^1_{\text{loc}}(\mathbb{R}^k) \).

**Corollary 24.1.6 (Fundamental Theorem of Calculus)** Let \( f \in L^1_{\text{loc}}(\mathbb{R}^k) \). Then there exists a set of measure 0, \( N \), such that if \( x \notin N \), then

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dy = 0.
\]

**Proof:** Consider \( B(0, n) \) where \( n \) is a positive integer. Then \( f_n \equiv f \chi_{B(0, n)} \in L^1(\mathbb{R}^k) \) and so there exists a set of measure 0, \( N_n \), such that if \( x \in B(0, n) \setminus N_n \), then

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f_n(y) - f_n(x)| \, dy
\]

\[
= \lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, dy = 0.
\]

Let \( N = \bigcup_{n=1}^{\infty} N_n \). Then if \( x \notin N \), the above equation holds.

**Corollary 24.1.7** If \( f \in L^1_{\text{loc}}(\mathbb{R}^n) \), then

\[
\lim_{r \to 0} \frac{1}{m(B(x, r))} \int_{B(x, r)} f(y) \, dy = f(x) \text{ a.e. } x. \quad (24.1.3)
\]
Proof:

\[
\left| \frac{1}{m(B(x,r))} \int_{B(x,r)} f(y) \, dy - f(x) \right| \\
\leq \frac{1}{m(B(x,r))} \int_{B(x,r)} |f(y) - f(x)| \, dy
\]

and the last integral converges to 0 a.e. \(x\).

**Definition 24.1.8** For \(N\) the set of Theorem 24.1.5 or Corollary 24.1.6, \(N^C\) is called the Lebesgue set or the set of Lebesgue points.

The next corollary is a one dimensional version of what was just presented.

**Corollary 24.1.9** Let \(f \in L^1(\mathbb{R})\) and let

\[
F(x) = \int_{-\infty}^{x} f(t) \, dt.
\]

Then for a.e. \(x\), \(F'(x) = f(x)\).

**Proof:** For \(h > 0\)

\[
\frac{1}{h} \int_{x}^{x+h} |f(y) - f(x)| \, dy \leq 2(\frac{1}{2h}) \int_{x-h}^{x+h} |f(y) - f(x)| \, dy
\]

By Theorem 24.1.5, this converges to 0 a.e. Similarly

\[
\frac{1}{h} \int_{x-h}^{x} |f(y) - f(x)| \, dy
\]

converges to 0 a.e. \(x\).

\[
\left| \frac{F(x + h) - F(x)}{h} - f(x) \right| \leq \frac{1}{h} \int_{x}^{x+h} |f(y) - f(x)| \, dy \quad (24.1.4)
\]

and

\[
\left| \frac{F(x) - F(x - h)}{h} - f(x) \right| \leq \frac{1}{h} \int_{x-h}^{x} |f(y) - f(x)| \, dy. \quad (24.1.5)
\]

Now the expression on the right in (24.1.4) and (24.1.5) converges to zero for a.e. \(x\). Therefore, by (24.1.4) for a.e. \(x\) the derivative from the right exists and equals \(f(x)\) while from (24.1.5) the derivative from the left exists and equals \(f(x)\) a.e. It follows

\[
\lim_{h \to 0} \frac{F(x + h) - F(x)}{h} = f(x) \quad \text{a.e. } x
\]

This proves the corollary.
24.2 Absolutely Continuous Functions

Definition 24.2.1 Let \([a, b]\) be a closed and bounded interval and let \(F : [a, b] \to \mathbb{R}\). Then \(F\) is said to be absolutely continuous if for every \(\varepsilon > 0\) there exists \(\delta > 0\) such that if \(\sum_{i=1}^{m} |y_i - x_i| < \delta\) where the intervals \((x_i, y_i)\) are non-overlapping, then \(\sum_{i=1}^{m} |F(y_i) - F(x_i)| < \varepsilon\).

Definition 24.2.2 A finite subset, \(P\) of \([a, b]\) is called a partition of \([x, y] \subseteq [a, b]\) if \(P = \{x_0, x_1, \cdots, x_n\}\) where

\[x = x_0 < x_1 < \cdots < x_n = y.\]

For \(f : [a, b] \to \mathbb{R}\) and \(P = \{x_0, x_1, \cdots, x_n\}\) define

\[V_P [x, y] = \sum_{i=1}^{n} |f(x_i) - f(x_{i-1})| .\]

Denoting by \(P[x, y]\) the set of all partitions of \([x, y]\) define

\[V [x, y] = \sup_{P \in P[x, y]} V_P [x, y] .\]

For simplicity, \(V[a, x]\) will be denoted by \(V(x)\). It is called the total variation of the function, \(f\).

There are some simple facts about the total variation of an absolutely continuous function, \(f\) which are contained in the next lemma.

Lemma 24.2.3 Let \(f\) be an absolutely continuous function defined on \([a, b]\) and let \(V\) be its total variation function as described above. Then \(V\) is an increasing bounded function. Also if \(P\) and \(Q\) are two partitions of \([x, y]\) with \(P \subseteq Q\), then \(V_P [x, y] \leq V_Q [x, y]\) and if \([x, y] \subseteq [z, w]\),

\[V [x, y] \leq V [z, w] \quad (24.2.6)\]

If \(P = \{x_0, x_1, \cdots, x_n\}\) is a partition of \([x, y]\), then

\[V [x, y] = \sum_{i=1}^{n} V [x_i, x_{i-1}] .\]

(24.2.7)

Also if \(y > x\),

\[V (y) - V (x) \geq |f (y) - f (x)| \quad (24.2.8)\]

and the function, \(x \to V (x) - f (x)\) is increasing. The total variation function, \(V\) is absolutely continuous.
Proof: The claim that $V$ is increasing is obvious as is the next claim about $P \subseteq Q$ leading to $V_P [x, y] \leq V_Q [x, y]$. To verify this, simply add in one point at a time and verify that from the triangle inequality, the sum involved gets no smaller. The claim that $V$ is increasing consistent with set inclusion of intervals is also clearly true and follows directly from the definition.

Now let $t < V [x, y]$ where $P_0 = \{x_0, x_1, \ldots, x_n\}$ is a partition of $[x, y]$. There exists a partition, $P$ of $[x, y]$ such that $t < V_P [x, y]$. Without loss of generality it can be assumed that $\{x_0, x_1, \ldots, x_n\} \subseteq P$ since if not, you can simply add in the points of $P_0$ and the resulting sum for the total variation will get no smaller. Let $P_i$ be those points of $P$ which are contained in $[x_{i-1}, x_i]$. Then

$$t < V_P [x, y] = \sum_{i=1}^{n} V_{P_i} [x_{i-1}, x_i] \leq \sum_{i=1}^{n} V [x_{i-1}, x_i].$$

Since $t < V [x, y]$ is arbitrary,

$$V [x, y] \leq \sum_{i=1}^{n} V [x_i, x_{i-1}] \quad (24.2.9)$$

Note that (24.2.9) does not depend on $f$ being absolutely continuous. Suppose now that $f$ is absolutely continuous. Let $\delta$ correspond to $\varepsilon = 1$. Then if $[x, y]$ is an interval of length no larger than $\delta$, the definition of absolute continuity implies

$$V [x, y] < 1.$$

Then from (24.2.9)

$$V [a, n\delta] \leq \sum_{i=1}^{n} V [a + (i - 1) \delta, a + i\delta] < \sum_{i=1}^{n} 1 = n.$$

Thus $V$ is bounded on $[a, b]$. Now let $P_i$ be a partition of $[x_{i-1}, x_i]$ such that

$$V_{P_i} [x_{i-1}, x_i] > V [x_{i-1}, x_i] - \frac{\varepsilon}{n}$$

Then letting $P = \cup P_i$,

$$-\varepsilon + \sum_{i=1}^{n} V [x_{i-1}, x_i] < \sum_{i=1}^{n} V_{P_i} [x_{i-1}, x_i] = V_P [x, y] = \sum_{i=1}^{n} V [x_{i-1}, x_i].$$

Since $\varepsilon$ is arbitrary, (24.2.7) follows from this and (24.2.9).

Now let $x < y$

$$V (y) - f (y) - (V (x) - f (x)) = V (y) - V (x) - (f (y) - f (x)) \geq V (y) - V (x) - |f (y) - f (x)| \geq 0.$$

It only remains to verify that $V$ is absolutely continuous.
Let \( \varepsilon > 0 \) be given and let \( \delta \) correspond to \( \varepsilon / 2 \) in the definition of absolute continuity applied to \( f \). Suppose \( \sum_{i=1}^{n} |y_i - x_i| < \delta \) and consider \( \sum_{i=1}^{n} |V(y_i) - V(x_i)| \). By the definition of absolute continuity, this last is no larger than \( \sum_{i=1}^{n} V(x_i, y_i) \). Now let \( P_i \) be a partition of \([x_i, y_i]\) such that \( V_{P_i} + \varepsilon / 2n > V[x_i, y_i] \). Then by the definition of absolute continuity,

\[
\sum_{i=1}^{n} |V(y_i) - V(x_i)| = \sum_{i=1}^{n} V[x_i, y_i] \\
\leq \sum_{i=1}^{n} V_{P_i} [x_i, y_i] + \varepsilon < \varepsilon / 2 + \varepsilon / 2 = \varepsilon.
\]

and shows \( V \) is absolutely continuous as claimed.

**Lemma 24.2.4** Suppose \( f : [a, b] \to \mathbb{R} \) is absolutely continuous and increasing. Then \( f' \) exists a.e., is in \( L^1 ([a, b]) \), and

\[
f(x) = f(a) + \int_{a}^{x} f'(t) \, dt.
\]

**Proof:** Define \( L \), a positive linear functional on \( C ([a, b]) \) by

\[
Lg = \int_{a}^{b} gdf
\]

where this integral is the Riemann-Stieltjes integral with respect to the integrating function, \( f \). By the Riesz representation theorem for positive linear functionals, there exists a unique Radon measure, \( \mu \) such that \( Lg = \int gd\mu \). Now consider the following picture for \( g_n \in C ([a, b]) \) in which \( g_n \) equals 1 for \( x \) between \( x + 1/n \) and \( y \).

Then \( g_n (t) \to \mathcal{X}_{(x,y)} (t) \) pointwise. Therefore, by the dominated convergence theorem,

\[
\mu ((x, y]) = \lim_{n \to \infty} \int g_n d\mu.
\]
However,

\[
\left( f(y) - f\left( x + \frac{1}{n} \right) \right) \\
\leq \int_a^b g_n \, d\mu = \int_a^b g_n \, df \leq \left( f\left( y + \frac{1}{n} \right) - f(y) \right) \\
+ \left( f(y) - f\left( x + \frac{1}{n} \right) \right) + \left( f\left( x + \frac{1}{n} \right) - f(x) \right)
\]

and so as \( n \to \infty \) the continuity of \( f \) implies

\[
\mu((x, y]) = f(y) - f(x).
\]

Similarly, \( \mu((x, y]) = f(y) - f(y) \) and \( \mu([x, y]) = f(y) - f(x) \), the argument used to establish this being very similar to the above. It follows in particular that

\[
f(x) - f(a) = \int_{[a, x]} d\mu.
\]

Note that up till now, no reference has been made to the absolute continuity of \( f \). Any increasing continuous function would be fine.

Now if \( E \) is a Borel set such that \( m(E) = 0 \), then the outer regularity of \( m \) implies there exists an open set, \( V \) containing \( E \) such that \( m(V) < \delta \) where \( \delta \) corresponds to \( \varepsilon \) in the definition of absolute continuity of \( f \). Then letting \( \{I_k\} \) be the connected components of \( V \) it follows \( E \subseteq \bigcup_{k=1}^\infty I_k \) with \( \sum_k m(I_k) = m(V) < \delta \). Therefore, from absolute continuity of \( f \), it follows that for \( I_k = (a_k, b_k) \) and each \( n \)

\[
\mu(\bigcup_{k=1}^n I_k) = \sum_{k=1}^n \mu(I_k) = \sum_{k=1}^n |f(b_k) - f(a_k)| < \varepsilon
\]

and so letting \( n \to \infty \),

\[
\mu(E) \leq \mu(V) = \sum_{k=1}^\infty |f(b_k) - f(a_k)| \leq \varepsilon.
\]

Since \( \varepsilon \) is arbitrary, it follows \( \mu(E) = 0 \). Therefore, \( \mu \ll m \) and so by the Radon Nikodym theorem there exists a unique \( h \in L^1([a, b]) \) such that

\[
\mu(E) = \int_E h \, dm.
\]

In particular,

\[
\mu([a, x]) = f(x) - f(a) = \int_{[a, x]} h \, dm.
\]

From the fundamental theorem of calculus \( f''(x) = h(x) \) at every Lebesgue point of \( h \). Therefore, writing in usual notation,

\[
f(x) = f(a) + \int_a^x f'(t) \, dt
\]
as claimed. This proves the lemma.

With the above lemmas, the following is the main theorem about absolutely continuous functions.

**Theorem 24.2.5** Let \( f : [a, b] \to \mathbb{R} \) be absolutely continuous if and only if \( f'(x) \) exists a.e., \( f' \in L^1([a, b]) \) and

\[
f(x) = f(a) + \int_a^x f'(t) \, dt.
\]

**Proof:** Suppose first that \( f \) is absolutely continuous. By Lemma 24.2.3 the total variation function, \( V \) is absolutely continuous and \( f(x) = V(x) - (V(a) - V(a)) \) where both \( V \) and \( V - f \) are increasing and absolutely continuous. By Lemma 24.2.4

\[
f(x) - f(a) = \int_a^x V'(t) \, dt - \int_a^x (V - f)'(t) \, dt.
\]

Now \( f' \) exists and is in \( L^1 \) because \( f = V - (V - f) \) and \( V \) and \( V - f \) have derivatives in \( L^1 \). Therefore, \( (V - f)' = V' - f' \) and so the above reduces to

\[
f(x) - f(a) = \int_a^x f'(t) \, dt.
\]

This proves one half of the theorem.

Now suppose \( f' \in L^1 \) and \( f(x) = f(a) + \int_a^x f'(t) \, dt \). It is necessary to verify that \( f \) is absolutely continuous. But this follows easily from Lemma 24.2.4 on Page 923 which implies that a single function, \( f' \) is uniformly integrable. This lemma implies that if \( \sum_i |y_i - x_i| \) is sufficiently small then

\[
\sum_i \left| \int_{x_i}^{y_i} f'(t) \, dt \right| = \sum_i |f(y_i) - f(x_i)| < \varepsilon.
\]

The following simple corollary is a case of Rademacher’s theorem.

**Corollary 24.2.6** Suppose \( f : [a, b] \to \mathbb{R} \) is Lipschitz continuous,

\[
|f(x) - f(y)| \leq K |x - y|.
\]

Then \( f'(x) \) exists a.e. and

\[
f(x) = f(a) + \int_a^x f'(t) \, dt.
\]

**Proof:** It is easy to see that \( f \) is absolutely continuous. Therefore, Theorem 24.2.5 applies.
24.3 Weak Derivatives

A related concept is that of weak derivatives. Let $\Omega \subseteq \mathbb{R}^n$. A distribution on $\Omega$ is defined to be a linear functional on $C^\infty_c(\Omega)$, called the space of test functions. The space of all such linear functionals will be denoted by $\mathcal{D}'(\Omega)$. Actually, more is sometimes done here. One imposes a topology on $C^\infty_c(\Omega)$ making it into a topological vector space, and when this has been done, $\mathcal{D}'(\Omega)$ is defined as the dual space of this topological vector space. To see this, consult the book by Yosida [115] or the book by Rudin [103].

**Example:** The space $L^1_{loc}(\Omega)$ may be considered as a subset of $\mathcal{D}'(\Omega)$ as follows.

$$f(\phi) \equiv \int_{\Omega} f(x) \phi(x) \, dx$$

for all $\phi \in C^\infty_c(\Omega)$. Recall that $f \in L^1_{loc}(\Omega)$ if $f \mathcal{X}_K \in L^1(\Omega)$ whenever $K$ is compact.

The following lemma is the main result which makes this identification possible.

**Lemma 24.3.1** Suppose $f \in L^1_{loc}(\mathbb{R}^n)$ and suppose

$$\int f \phi \, dx = 0$$

for all $\phi \in C^\infty_c(\mathbb{R}^n)$. Then $f(x) = 0$ a.e. $x$.

**Proof:** Without loss of generality $f$ is real-valued. Let

$$E \equiv \{ x : f(x) > \epsilon \}$$

and let

$$E_m = E \cap B(0, m).$$

We show that $m(E_m) = 0$. If not, there exists an open set, $V$, and a compact set $K$ satisfying

$$K \subseteq E_m \subseteq V \subseteq B(0, m), \quad m(V \setminus K) < 4^{-1} m(E_m),$$

$$\int_{V \setminus K} |f| \, dx < \epsilon 4^{-1} m(E_m).$$

Let $H$ and $W$ be open sets satisfying

$$K \subseteq H \subseteq \overline{H} \subseteq W \subseteq \overline{W} \subseteq V$$

and let

$$\overline{H} \prec g \prec W$$

where the symbol, $\prec$, has the same meaning as it does in Chapter 10. Then let $\phi_\delta$ be a mollifier and let $h \equiv g * \phi_\delta$ for $\delta$ small enough that

$$K \prec h \prec V.$$
Thus

\[ 0 = \int fh \, dx = \int_K f \, dx + \int_{V \setminus K} fh \, dx \]

\[ \geq \epsilon m(K) - \epsilon 4^{-1} m(E_m) \]

\[ \geq \epsilon (m(E_m) - 4^{-1} m(E_m)) - \epsilon 4^{-1} m(E_m) \]

\[ \geq 2^{-1} \epsilon m(E_m). \]

Therefore, \( m(E_m) = 0 \), a contradiction. Thus

\[ m \left( E \right) = \sum_{m=1}^{\infty} m(E_m) = 0 \]

and so, since \( \epsilon > 0 \) is arbitrary,

\[ m \left( \{ x : f(x) > 0 \} \right) = 0. \]

Similarly \( m \left( \{ x : f(x) < 0 \} \right) = 0 \). This proves the lemma.

**Example:** \( \delta_x \in \mathcal{D}^* (\Omega) \) where \( \delta_x (\phi) \equiv \phi (x) \).

It will be observed from the above two examples and a little thought that \( \mathcal{D}^* (\Omega) \) is truly enormous. We shall define the derivative of a distribution in such a way that it agrees with the usual notion of a derivative on those distributions which are also continuously differentiable functions. With this in mind, let \( f \) be the restriction to \( \Omega \) of a smooth function defined on \( \mathbb{R}^n \). Then \( D_x f \) makes sense and for \( \phi \in C^1_c(\Omega) \)

\[ D_x f (\phi) = \int_{\Omega} D_x f (x) \phi (x) \, dx = - \int_{\Omega} f D_x \phi \, dx = - f (D_x \phi). \]

Motivated by this, here is the definition of a weak derivative.

**Definition 24.3.2** For \( T \in \mathcal{D}^* (\Omega) \)

\[ D_x T (\phi) = - T (D_x \phi). \]

Of course one can continue taking derivatives indefinitely. Thus,

\[ D_{x_1 x_2} T = D_{x_1} (D_{x_2} T) \]

and it is clear that all mixed partial derivatives are equal because this holds for the functions in \( C^\infty_c(\Omega) \). Thus one can differentiate virtually anything, even functions that may be discontinuous everywhere. However the notion of "derivative" is very weak, hence the name, "weak derivatives".

**Example:** Let \( \Omega = \mathbb{R} \) and let

\[ H(x) \equiv \begin{cases} 1 & \text{if } x \geq 0, \\ 0 & \text{if } x < 0. \end{cases} \]

Then

\[ D H (\phi) = - \int H(x) \phi' (x) \, dx = \phi (0) = \delta_0(\phi). \]

Note that in this example, \( D H \) is not a function.

What happens when \( D f \) is a function?
Theorem 24.3.3 Let \( \Omega = (a, b) \) and suppose that \( f \) and \( Df \) are both in \( L^1 (a, b) \). Then \( f \) is equal to a continuous function a.e., still denoted by \( f \) and
\[
f (x) = f (a) + \int_a^x Df (t) \, dt.
\]

The proof of Theorem 24.3.3 depends on the following lemma.

Lemma 24.3.4 Let \( T \in \mathcal{D}^* (a, b) \) and suppose \( DT = 0 \). Then there exists a constant \( C \) such that
\[
T (\phi) = \int_a^b C \phi \, dx.
\]

Proof: \( T (D\phi) = 0 \) for all \( \phi \in C_c^\infty (a, b) \) from the definition of \( DT = 0 \). Let
\[
\phi_0 \in C_c^\infty (a, b), \quad \int_a^b \phi_0 (x) \, dx = 1,
\]
and let
\[
\psi_\phi (x) = \int_a^x [\phi (t) - \left( \int_a^b \phi (y) \, dy \right) \phi_0 (t)] \, dt
\]
for \( \phi \in C_c^\infty (a, b) \). Thus \( \psi_\phi \in C_c^\infty (a, b) \) and
\[
D \psi_\phi = \phi - \left( \int_a^b \phi (y) \, dy \right) \phi_0.
\]
Therefore,
\[
\phi = D \psi_\phi + \left( \int_a^b \phi (y) \, dy \right) \phi_0
\]
and so
\[
T (\phi) = T (D \psi_\phi) + \left( \int_a^b \phi (y) \, dy \right) T (\phi_0) = \int_a^b T (\phi_0) \phi (y) \, dy.
\]
Let \( C = T \phi_0 \). This proves the lemma.

Proof of Theorem 24.3.3 Since \( f \) and \( Df \) are both in \( L^1 (a, b) \),
\[
D f (\phi) - \int_a^b D f (x) \phi (x) \, dx = 0.
\]
Consider
\[
f (\cdot) - \int_a^{(\cdot)} D f (t) \, dt
\]
and let \( \phi \in C_c^\infty (a, b) \).
\[
D \left( f (\cdot) - \int_a^{(\cdot)} D f (t) \, dt \right) (\phi)
\]
24.3. WEAK DERIVATIVES

\[- \int_a^b f(x) \phi'(x) \, dx + \int_a^b \left( \int_a^x Df(t) \, dt \right) \phi'(x) \, dx \]

\[= Df(\phi) + \int_a^b \int_t^b Df(t) \phi'(x) \, dx \, dt \]

\[= Df(\phi) - \int_a^b Df(t) \phi(t) \, dt = 0. \]

By Lemma 24.3.1, there exists a constant, $C$, such that

\[
\left( f(\cdot) - \int_a^x Df(t) \, dt \right)(\phi) = \int_a^b C\phi(x) \, dx
\]

for all $\phi \in C^\infty_c(a,b)$. Thus

\[
\int_a^b \left\{ \left( f(x) - \int_a^x Df(t) \, dt \right) - C \right\} \phi(x) \, dx = 0
\]

for all $\phi \in C^\infty_c(a,b)$. It follows from Lemma 24.3.1 in the next section that

\[f(x) - \int_a^x Df(t) \, dt - C = 0 \text{ a.e. } x.\]

Thus we let $f(a) = C$ and write

\[f(x) = f(a) + \int_a^x Df(t) \, dt.\]

This proves Theorem 33.2.2.

Theorem 33.2.2 says that

\[f(x) = f(a) + \int_a^x Df(t) \, dt\]

whenever it makes sense to write $\int_a^x Df(t) \, dt$, if $Df$ is interpreted as a weak derivative. Somehow, this is the way it ought to be. It follows from the fundamental theorem of calculus that $f'(x)$ exists for a.e. $x$ in the classical sense where the derivative is taken in the sense of a limit of difference quotients and $f'(x) = Df(x)$. This raises an interesting question. Suppose $f$ is continuous on $[a,b]$ and $f'(x)$ exists in the classical sense for a.e. $x$. Does it follow that

\[f(x) = f(a) + \int_a^x f'(t) \, dt?\]

The answer is no. You can build such an example from the Cantor function which is increasing and has a derivative a.e. which equals 0 a.e. and yet climbs from 0 to 1. Thus this function is not recovered from integrating its classical derivative. Thus, in a sense weak derivatives are more agreeable than the classical ones.
### 24.4 Lipschitz Functions

**Definition 24.4.1** A function \( f : [a, b] \to \mathbb{R} \) is Lipschitz if there is a constant \( K \) such that for all \( x, y \),
\[
|f(x) - f(y)| \leq K |x - y|.
\]

More generally, \( f \) is Lipschitz on a subset of \( \mathbb{R}^n \) if for all \( x, y \) in this set,
\[
|f(x) - f(y)| \leq K |x - y|.
\]

**Lemma 24.4.2** Suppose \( f : [a, b] \to \mathbb{R} \) is Lipschitz continuous and increasing. Then \( f' \) exists a.e., is in \( L^1([a, b]) \), and
\[
f(x) = f(a) + \int_a^x f'(t) \, dt.
\]

If \( f : \mathbb{R} \to \mathbb{R} \) is Lipschitz, then it is in \( L^1_{loc}(\mathbb{R}) \).

**Proof:** The Dini derivatives are defined as follows.
\[
D^+ f(x) = \lim_{h \to 0^+} \frac{f(x+h) - f(x)}{h}, \quad D^- f(x) = \lim_{h \to 0^+} \frac{f(x) - f(x-h)}{h},
\]
\[
D_+ f(x) = \lim_{h \to 0^+} \frac{f(x) - f(x-h)}{h}, \quad D_- f(x) = \lim_{h \to 0^+} \frac{f(x+h) - f(x)}{h}.
\]

For convenience, just let \( f \) equal \( f(a) \) for \( x < a \) and equal \( f(b) \) for \( x > b \). Let \( (a, b) \)
be an open interval and let
\[
N_{ab} = \{ x \in (a, b) : D^+ f(x) > q > p > D_- f(x) \}
\]

Let \( V \subseteq (a, b) \) be an open set containing \( N_{pq} \) such that \( m(V) < m(N_{pq}) + \varepsilon \). By assumption, if \( x \in N_{pq} \), there exist arbitrarily small \( h \) such that
\[
\frac{f(x+h) - f(x)}{h} < p.
\]

These intervals \([x, x+h]\) are then a Vitali covering of \( N_{pq} \). It follows from Corollary \ref{cor:disjoint} that there is a disjoint union of countably many, \( \{ [x_i, x_i+h_i] \}_{i=1}^\infty \) which cover all of \( N_{pq} \) except for a set of measure zero. Thus also the open intervals \( \{ (x_i, x_i+h_i) \}_{i=1}^\infty \) also cover all of \( N_{pq} \) except for a set of measure zero. Now for points \( x' \) of \( N_{pq} \) so covered, there are arbitrarily small \( h \) such that
\[
\frac{f(x'+h') - f(x')}{h'} > q
\]

and \([x', x'+h']\) is contained in one of these original open intervals \((x_i, x_i+h_i)\). By the Vitali covering theorem again, Corollary \ref{cor:disjoint} it follows that there exists a countable disjoint sequence \( \{ [x'_j, x'_j+h'_j] \}_{j=1}^\infty \) which covers all of \( N_{pq} \) except for a
set of measure zero, each of these \([x'_j, x'_j + h'_j]\) being contained in some \((x_i, x_i + h_i)\).

Then it follows that

\[
qm\left(N_{pq}\right) \leq q \sum_{j} h'_j \leq \sum_{j} f\left(x'_j + h'_j\right) - f\left(x'_j\right) \leq \sum_{i} f\left(x_i + h_i\right) - f\left(x_i\right)
\]

\[
\leq p \sum_{i} h_i \leq pm\left(V\right) \leq p\left(m\left(N_{pq}\right) + \varepsilon\right)
\]

Since \(\varepsilon > 0\) is arbitrary, this shows that \(qm\left(N_{pq}\right) \leq pm\left(N_{pq}\right)\) and so \(m\left(N_{pq}\right) = 0\).

Now taking the union of all \(N_{pq}\) for \(p, q \in \mathbb{Q}\), it follows that for a.e. \(x, D^+f\left(x\right) = D_+f\left(x\right)\) and so the derivative from the right exists. Similar reasoning shows that off a set of measure zero the derivative from the left also exists. You just do the same argument using \(D^-f\left(x\right)\) and \(D_-f\left(x\right)\) to obtain the existence of a derivative from the left. Next you can use the same argument to verify that \(D^-f\left(x\right) = D_+f\left(x\right)\) off a set of measure zero. This is outlined next. Define a new \(N_{pq}\):

\[
N_{pq} = \{x \in (a, b) : D_+f\left(x\right) > q > p > D^-f\left(x\right)\}
\]

Let \(V\) be an open set containing \(N_{pq}\) such that \(m\left(V\right) < m\left(N_{pq}\right) + \varepsilon\). For each \(x \in N_{pq}\) there are arbitrarily small \(h\) such that

\[
\frac{f\left(x\right) - f\left(x - h\right)}{h} < p
\]

Then as before, there is a countable disjoint sequence of closed intervals contained in \(V, \{[x_i - h_i, x_i]\}_{i=1}^{\infty}\) such that their union includes all of \(N_{pq}\) except a set of measure zero. Thus this is also true of the open intervals \(\{[x_i - h_i, x_i]\}_{i=1}^{\infty}\). Then for the points of \(N_{pq}\) covered by these open intervals \(x'\), there are arbitrarily small \(h'\) such that

\[
\frac{f\left(x' + h'\right) - f\left(x'\right)}{h'} > q.
\]

and each \([x', x' + h']\) is contained in an interval \((x_i - h_i, x_i)\). Then by the Vitali covering theorem again, Corollary 24.4.4.2.4.3 there are countably many disjoint closed intervals \(\{[x'_j, x'_j + h'_j]\}_{j=1}^{\infty}\) whose union includes all of \(N_{pq}\) except for a set of measure zero such that each of these is contained in some \((x_i - h_i, x_i)\) described earlier. Then as before,

\[
qm\left(N_{pq}\right) \leq q \sum_{j} h'_j \leq \sum_{j} f\left(x'_j + h'_j\right) - f\left(x'_j\right) \leq \sum_{i} f\left(x_i + h_i\right) - f\left(x_i - h_i\right)
\]

\[
\leq p \sum_{i} h_i \leq pm\left(V\right) \leq p\left(m\left(N_{pq}\right) + \varepsilon\right)
\]

Then as before, this shows that \(qm\left(N_{pq}\right) \leq pm\left(N_{pq}\right)\) and so \(m\left(N_{pq}\right) = 0\). Then taking the union of all such for \(p, q \in \mathbb{Q}\) yields \(D_+f\left(x\right) = D^-f\left(x\right)\) for a.e. \(x\).

Taking the union of all these sets of measure zero and considering points not in this union, it follows that \(f'\left(x\right)\) exists for a.e. \(x\). Thus \(f'\left(t\right) \geq 0\) and is a limit of
measurable even continuous functions for a.e. \( x \) so \( f' \) is clearly measurable. The issue is whether \( f (y) - f (x) = \int X_{[x,y]} (t) f' (t) \, dm \). Up to now, the only thing used has been that \( f \) is increasing.

Let \( h > 0 \).

\[
\int_a^x \frac{f (t) - f (t - h)}{h} \, dt = \frac{1}{h} \int_a^x f (t) \, dt - \frac{1}{h} \int_a^x f (t - h) \, dt
\]

\[
= \frac{1}{h} \int_a^x f (t) \, dt - \frac{1}{h} \int_{a-h}^x f (t) \, dt
\]

\[
= \frac{1}{h} \int_{x-h}^x f (t) \, dt - \frac{1}{h} \int_{a-h}^a f (t) \, dt
\]

\[
= \frac{1}{h} \int_{x-h}^x f (t) \, dt - f (a)
\]

Therefore, by continuity of \( f \) it follows from Fatou’s lemma that

\[
\int_a^x D_- f (t) \, dt = \int_a^x f' (t) \, dt \leq \lim_{h \to 0^+} \inf \int_a^x \frac{f (t) - f (t - h)}{h} \, dt = f (x) - f (a)
\]

and this shows that \( f' \) is in \( L^1 \). This part only used the fact that \( f \) is increasing and continuous. That \( f \) is Lipschitz has not been used.

If it were known that there is a dominating function for \( t \to \frac{f(t) - f(t-h)}{h} \), then you could simply apply the dominated convergence theorem in the above inequality instead of Fatou’s lemma and get the desired result. But from Lipschitz continuity, you have

\[
\left| \frac{f (t) - f (t - h)}{h} \right| \leq K
\]

and so one can indeed apply the dominated convergence theorem and conclude that

\[
\int_a^x f' (t) \, dt = f (x) - f (a)
\]

The last claim follows right away from consideration of intervals since the restriction of a Lipschitz function is Lipschitz.

With the above lemmas, the following is the main theorem about absolutely continuous functions.

The following simple corollary is a case of Rademacher’s theorem.

**Corollary 24.4.3** Suppose \( f : [a, b] \to \mathbb{R} \) is Lipschitz continuous,

\[
|f (x) - f (y)| \leq K |x - y|.
\]

Then \( f' (x) \) exists a.e. and

\[
f (x) = f (a) + \int_a^x f' (t) \, dt.
\]
Proof: If $f$ were increasing, this would follow from the above lemma. Let $g(x) = 2Kx - f(x)$. Then $g$ is Lipschitz with a different Lipschitz constant and also if $x < y$,

$$g(y) - g(x) = 2Ky - f(y) - (2Kx - f(x))$$

$$\geq 2K(y - x) - K|y - x| = k|y - x| \geq 0$$

and so Lemma 24.4.2 applies to $g$ and this shows that $f'(t)$ exists for a.e. $t$ and $g'(x) = 2K - f'(x)$. Also

$$2K(x - a) - (f(x) - f(a))$$

$$= g(x) - g(a) = 2Kx - f(x) - (2Ka - f(a)) = \int_a^x (2K - f'(t)) dt$$

$$= 2K(x - a) - \int_a^x f'(t) dt$$

showing that $f(x) - f(a) = \int_a^x f'(t) dt$. □

24.5 Rademacher’s Theorem First Version

It turns out that Lipschitz functions on $\mathbb{R}^n$ can be differentiated a.e. This is called Rademacher’s theorem. It also can be shown to follow from the Lebesgue theory of differentiation. We denote $D_v f(x)$ the directional derivative of $f$ in the direction $v$. Here $v$ is a unit vector. In the following lemma, notation is abused slightly. The symbol $f(x+tv)$ will mean $t \to f(x+tv)$ and $\frac{d}{dt} f(x+tv)$ will refer to the derivative of this function of $t$.

**Lemma 24.5.1** Let $f: \mathbb{R}^n \to \mathbb{R}$ be a Lipschitz function with constant $K$ and let $v$ be a unit vector. Then the following hold.

1. $D_v f(x)$ exists for a.e. $x$. Also off a set of measure zero, $|D_v f(x)| \leq K$.

2. For every $x$,

$$f(x+tv) - f(x) = \int_0^t D_v f(x + sv) ds$$

3. $D_v f(x) = \nabla f(x) \cdot v$.

4. For a given $x$ and for $\sigma$ the measure on $S^{n-1}$ of Section 11.8 and for $w \in S^{n-1}$,

$$D_v f(x+tw) = \nabla f(x+tw) \cdot w$$

for a.e. $t$ for $\sigma$ a.e. $w$. Thus

$$\int_{S^{n-1}} \int_0^r t^{n-1} D_w f(x+tw) dt d\sigma(w)$$

$$= \int_{S^{n-1}} \int_0^r t^{n-1} \nabla f(x+tw) \cdot wdtd\sigma(w)$$
**Proof:** Let $h(t) \equiv f(x + tv)$. Then from Corollary 24.4.3,

$$f(x + tv) - f(x) = h(t) - h(0) = \int_0^t h'(s) \, ds = \int_0^t D_v f(x + sv) \, ds$$

This verifies 2. To verify 1., let $Q$ be an orthogonal matrix such that $Qe_n = v$ and $Q(\text{span}(e_1, \ldots, e_{n-1})) = v^\perp$ where this denotes the orthogonal complement of $v$, meaning all vectors perpendicular to $v$. Now let

$$g(x) \equiv f(Qx)$$

Then from Corollary 24.4.3 for an arbitrary $y = (y_1, \ldots, y_{n-1}, 0)$

$$\frac{d}{dt} g(y + te_n) \equiv D_{e_n} g(y + te_n)$$

exists for a.e. $t$. By the definition of product measure, this shows that $D_{e_n} g(x)$ exists for $x$ off some set of measure zero $N$. Now

$$D_v f(Qy + tv) = D_v f(Q(y + te_n)) \equiv \frac{d}{dt} f(Qy + tv)$$

$$= \frac{d}{dt} g(y + te_n) = D_{e_n} g(y + te_n)$$

Since every point of $\mathbb{R}^n$ is of the form $y + te_n$ for suitable $t$, it follows that for $x \notin Q(N)$, a set of measure zero, $D_v f(x)$ exists. The estimate for $D_v f(x)$ wherever the limit exists is obvious from the Lipschitz condition. This proves part 1.

Finally, consider part 3. Let $\phi \in C^\infty_c(\mathbb{R}^n)$.

$$\int_{\mathbb{R}^n} \frac{f(x + tv) - f(x)}{t} \phi(x) \, dx = \int_{\mathbb{R}^n} \frac{\phi(x - tv) - \phi(x)}{t} f(x) \, dx$$

Then passing to the limit using the dominated convergence theorem,

$$\int_{\mathbb{R}^n} D_v f(x) \phi(x) \, dx = -\int_{\mathbb{R}^n} f(x) \nabla \phi \cdot v \, dx \equiv -\int_{\mathbb{R}^n} f(x) \sum_i \partial_i \phi(x) v_i \, dx$$

$$= \lim_{h \to 0} -\int_{\mathbb{R}^n} f(x) \sum_i \frac{\phi(x + he_i) - \phi(x)}{h} v_i \, dx$$

$$= \lim_{h \to 0} \int_{\mathbb{R}^n} \sum_i \frac{f(x) - f(x - he_i)}{h} v_i \phi(x) \, dx$$

Using the dominated convergence theorem and what was just shown about existence of directional derivatives a.e.,

$$\int_{\mathbb{R}^n} D_v f(x) \phi(x) \, dx = \int_{\mathbb{R}^n} (\nabla f(x) \cdot v) \phi(x) \, dx$$
By Lemma 24.3.1 this implies that $D_v f(x) = \nabla f(x) \cdot v$ a.e.

For $|w| = 1$, denote the measure of Section 11.9 defined on the unit sphere $S^{n-1}$ as $\sigma$. Let $N_w$ be defined as those $t \in [0, \infty)$ for which $D_w f(x + tw) \neq \nabla f(x + tw) \cdot w$.

$$B \equiv \{ w \in S^{n-1} : N_w \text{ has positive measure} \}$$

The set of points of $\mathbb{R}^n$ for which $D_w f(x) \neq \nabla f(x) \cdot w$ consists of all points $x + tw$ where $t \in N_w$ and $w \in S^{n-1}$. Thus from Section 11.9 the measure of this set is

$$\int_B \int_{N_w} \rho^{n-1} d\rho d\sigma(w)$$

This must equal zero from what was just shown and so $\sigma(B) = 0$. The claimed formula follows from this.

The following lemma gives an interesting inequality due to Morrey.

**Lemma 24.5.2** Let $u$ be Lipschitz continuous on $\mathbb{R}^n$. Then there exists a constant $C$, depending only on $n$ such that for any $x, y \in \mathbb{R}^n$,

$$|u(x) - u(y)| \leq C \left( \int_{B(x, 2|x-y|)} |\nabla u(z)|^p dz \right)^{1/p} \left( |x - y|^{(1-n/p)} \right). \quad (24.5.10)$$

Here $p > n$.

**Proof:** In the argument $C$ will be a generic constant which depends on $n$. Consider the following picture.

```
  U   V
 x y
```

This is a picture of two balls of radius $r$ in $\mathbb{R}^n$, $U$ and $V$ having centers at $x$ and $y$ respectively, which intersect in the set $W$. The center of $U$ is on the boundary of $V$ and the center of $V$ is on the boundary of $U$ as shown in the picture. There exists a constant, $C$, independent of $r$ depending only on $n$ such that

$$\frac{m(W)}{m(U)} = \frac{m(W)}{m(V)} = \frac{1}{C}.$$

You could compute this constant if you desired but it is not important here.
Then
\[ |u(x) - u(y)| = \frac{1}{m(W)} \int_W |u(x) - u(y)| dz \]
\[ \leq \frac{1}{m(W)} \int_W |u(x) - u(z)| dz + \frac{1}{m(W)} \int_W |u(z) - u(y)| dz \]
\[ = \frac{C}{m(U)} \left[ \int_W |u(x) - u(z)| dz + \int_W |u(z) - u(y)| dz \right] \]
\[ \leq \frac{C}{m(U)} \left[ \int_W |u(x) - u(z)| dz + \int_W |u(y) - u(z)| dz \right] \]

Now consider these two terms. Using spherical coordinates and letting \( U_0 \) denote the ball of the same radius as \( U \) but with center at \( 0 \),
\[ = \frac{1}{m(U)} \int_{U_0} |u(x) - u(z)| dz \]
\[ \leq \frac{1}{m(U_0)} \int_{U_0} |u(x) - u(z + x)| dz \]

Now using spherical coordinates, Section 11.9, and letting \( C \) denote a generic constant which depends on \( n \) and also using Lemma 24.5.1,
\[ = \frac{1}{m(U_0)} \int_{U_0} \rho^{n-1} \int_{S^{n-1}} |u(\rho w + x) - u(\rho w + x)| d\sigma(w) d\rho \]
\[ \leq \frac{1}{m(U_0)} \int_{U_0} \rho^{n-1} \int_{S^{n-1}} \int_0^\rho |D_w u(x + tw)| dt d\sigma(w) d\rho \]
\[ = \frac{1}{m(U_0)} \int_{U_0} \rho^{n-1} \int_{S^{n-1}} \int_0^\rho |\nabla u(x + tw) \cdot w| dtd\sigma(w) d\rho \]
\[ \leq \frac{C}{r} \int_{S^{n-1}} \int_0^r \int_0^\rho |\nabla u(x + tw)| dtd\sigma(w) d\rho \]
\[ = C \int_{S^{n-1}} \int_0^r |\nabla u(x + tw)| t^{n-1} \frac{1}{t^{n-1}} dt d\sigma(w) \]
