\[ = C \int_{U_0} \frac{|\nabla u(x + z)|}{|x|^{n-1}} dz \]
\[ \leq C \left( \int_{U_0} |\nabla u(z)|^p dz \right)^{1/p} \left( \int_U |z|^{p'-np'} \right)^{1/p'} \]
\[ = C \left( \int_U |\nabla u(z)|^p dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \rho^{p'-np'} \rho^{n-1} d\rho d\sigma \right)^{(p-1)/p} \]
\[ = C \left( \int_U |\nabla u(z)|^p dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \frac{1}{\rho^{\frac{n-1}{p}}} d\rho d\sigma \right)^{(p-1)/p} \]
Suppose exceptional points being in a set of measure zero. Then

\[ u \text{ is differentiable at a.e. } x. \]

Similarly,

\[ \frac{1}{m(V)} \int_V |u(x) - u(z)| dz \leq C \left( \frac{p-1}{p-n} \right)^{(p-1)/p} \left( \int_U |\nabla u(z)|^p dz \right)^{1/p} |x - y|^{1-\frac{p}{n}} \]

Therefore,

\[ |u(x) - u(y)| \leq C \left( \frac{p-1}{p-n} \right)^{(p-1)/p} \left( \int_{B(x,2|x-y|)} |\nabla u(z)|^p dz \right)^{1/p} |x - y|^{1-\frac{p}{n}} \]

because \( B(x,2|x-y|) \supset V \cup U. \]

Here is Rademacher’s theorem.

**Theorem 24.5.3** Suppose \( u \) is Lipschitz with constant \( K \) then if \( x \) is a point where \( \nabla u(x) \) exists,

\[ |u(y) - u(x) - \nabla u(x) \cdot (y-x)| \]

\[ \leq C \left( \frac{1}{m(B(x,2|x-y|))} \right) \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p dz \right)^{1/p} |x - y|. \]

(24.5.11)

Also \( u \) is differentiable at a.e. \( x \) and also

\[ u(x+tv) - u(x) = \int_0^t Dv u(x+sv) ds \]  

(24.5.12)

**Proof:** This follows easily from letting \( g(y) \equiv u(y) - u(x) - \nabla u(x) \cdot (y-x). \)

As explained above, \( |\nabla u(x)| \leq \sqrt{n}K \) at every point where \( \nabla u \) exists, the exceptional points being in a set of measure zero. Then \( g(x) = 0, \) and \( \nabla g(y) = \nabla u(y) - \nabla u(x) \) at the points \( y \) where the gradient of \( g \) exists. From Lemma
Now this is no larger than
\[
C \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)| \left(2\sqrt{nK}\right)^{p-1} dz \right)^{1/p} |x-y|
\]

It follows that at Lebesgue points of \(\nabla u\), the above expression is \(o(|x-y|)\) and so at all such points \(u\) is differentiable. As to 24.5.12, this follows from Lemma 24.5.2.

In the above major theorem, the function \(u\) is defined on all of \(\mathbb{R}^n\). However, it is always the case that Lipschitz functions can be extended off a given set. Thus if a Lipschitz function is defined on some set \(\Omega\), then it can always be considered the restriction to \(\Omega\) of a Lipschitz map defined on all of \(\mathbb{R}^n\).

**Theorem 24.5.4** If \(h: \Omega \to \mathbb{R}^m\) is Lipschitz, then there exists \(\overline{h}: \mathbb{R}^n \to \mathbb{R}^m\) which extends \(h\) and is also Lipschitz.

**Proof:** It suffices to assume \(m = 1\) because if this is shown, it may be applied to the components of \(h\) to get the desired result. Suppose

\[
|h(x) - h(y)| \leq K|x-y|, \quad (24.5.13)
\]

Define

\[
\overline{h}(x) \equiv \inf\{h(w) + K|x-w| : w \in \Omega\}. \quad (24.5.14)
\]

If \(x \in \Omega\), then for all \(w \in \Omega\),

\[
h(w) + K|x-w| \geq h(x)
\]

by 24.5.13. This shows \(h(x) \leq \overline{h}(x)\). But also you could take \(w = x\) in 24.5.13 which yields \(\overline{h}(x) \leq h(x)\). Therefore \(\overline{h}(x) = h(x)\) if \(x \in \Omega\).

Now suppose \(x,y \in \mathbb{R}^n\) and consider \(|\overline{h}(x) - \overline{h}(y)|\). Without loss of generality assume \(\overline{h}(x) \geq \overline{h}(y)\). (If not, repeat the following argument with \(x\) and \(y\) interchanged.) Pick \(w \in \Omega\) such that

\[
h(w) + K|y-w| - \varepsilon < \overline{h}(y).
\]

Then

\[
|\overline{h}(x) - \overline{h}(y)| = \overline{h}(x) - \overline{h}(y) \leq h(w) + K|x-w| -
\]

\[
|h(w) + K|y-w| - \varepsilon| \leq K|x-y| + \varepsilon.
\]

Since \(\varepsilon\) is arbitrary,

\[
|\overline{h}(x) - \overline{h}(y)| \leq K|x-y| \quad \blacksquare
\]

### 24.6 Rademacher’s Theorem

It turns out that Lipschitz functions on \(\mathbb{R}^n\) can be differentiated a.e. This is called Rademacher’s theorem. It also can be shown to follow from the Lebesgue theory of differentiation.
24.6.1 Morrey’s Inequality

The following inequality will be called Morrey’s inequality. It relates an expression which is given pointwise to an integral of the \( p \)th power of the derivative.

**Lemma 24.6.1** Let \( u \in C^1(\mathbb{R}^n) \) and \( p > n \). Then there exists a constant, \( C \), depending only on \( n \) such that for any \( x, y \in \mathbb{R}^n \),

\[
|u(x) - u(y)| \leq C \left( \int_{B(x,2|x-y|)} |\nabla u(z)|^p dz \right)^{1/p} \left( |x - y|^{(1-n/p)} \right),
\]  

(24.6.15)

**Proof:** In the argument \( C \) will be a generic constant which depends on \( n \). Consider the following picture.

![Picture of two balls intersecting](image)

This is a picture of two balls of radius \( r \) in \( \mathbb{R}^n \), \( U \) and \( V \) having centers at \( x \) and \( y \) respectively, which intersect in the set, \( W \). The center of \( U \) is on the boundary of \( V \) and the center of \( V \) is on the boundary of \( U \) as shown in the picture. There exists a constant, \( C \), independent of \( r \) depending only on \( n \) such that

\[
\frac{m(W)}{m(U)} = \frac{m(W)}{m(V)} = C.
\]

You could compute this constant if you desired but it is not important here.

Define the average of a function over a set, \( E \subseteq \mathbb{R}^n \) as follows.

\[
\int_E f dx = \frac{1}{m(E)} \int_E f dx.
\]

Then

\[
|u(x) - u(y)| = \int_W |u(x) - u(y)| dz \\
\leq \int_W |u(x) - u(z)| dz + \int_W |u(z) - u(y)| dz \\
= \frac{C}{m(U)} \left[ \int_W |u(x) - u(z)| dz + \int_W |u(z) - u(y)| dz \right] \\
\leq C \left[ \int_U |u(x) - u(z)| dz + \int_V |u(y) - u(z)| dz \right].
\]
Now consider these two terms. Using spherical coordinates and letting \( U_0 \) denote the ball of the same radius as \( U \) but with center at \( 0 \),

\[
\int_U |u(x) - u(z)| \, dz = \frac{1}{m(U_0)} \int_{U_0} |u(x) - u(z + x)| \, dz
\]

\[
= \frac{1}{m(U_0)} \int_0^r \int_{S^{n-1}} |u(x) - u(\rho w + x)| \, d\sigma \, d\rho
\]

\[
\leq \frac{1}{m(U_0)} \int_0^r \int_{S^{n-1}} |\nabla u(x + tw)| \, dtd\rho
\]

\[
\leq C \int_0^r \int_{S^{n-1}} \int_0^\rho \frac{|\nabla u(x + tw)|}{t^{n-1}} \, dt \, d\sigma \, d\rho
\]

\[
= C \int_{S^{n-1}} \int_0^r \frac{|\nabla u(x + tw)|}{t^{n-1}} \, dt \, d\sigma
\]

\[
= C \int_{S^{n-1}} \int_0^r |\nabla u(x + z)| \, t^{n-1} \, dt \, d\sigma
\]

\[
\leq C \left( \int_{U_0} |\nabla u(x + z)|^p \, dz \right)^{1/p} \left( \int_U |z|^{p' - np'} \right)^{1/p'}
\]

\[
= C \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \frac{1}{\rho^{\frac{n'-1}{n}}} \, d\rho \, d\sigma \right)^{(p-1)/p}
\]

\[
= C \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \rho^{\frac{n'-1}{n}} \, d\rho \, d\sigma \right)^{(p-1)/p}
\]

\[
= C \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_{S^{n-1}} |x - y|^{1 - \frac{2}{p'}} \right)^{1/p}
\]

Similarly,

\[
\int_V |u(y) - u(z)| \, dz \leq C \left( \int_V |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_V |x - y|^{1 - \frac{2}{p}} \right)^{1/p}
\]
Therefore,
\[ |u(x) - u(y)| \leq C \left( \frac{p-1}{p-n} \right)^{\frac{1}{p-1/p}} \left( \int_{B(x,2|y-x|)} |\nabla u(z)|^p \, dz \right)^{1/p} |x - y|^{1-\frac{2}{p}} \]

because \( B(x,2|x-y|) \supseteq V \cup U \). This proves the lemma.

The following corollary is also interesting

**Corollary 24.6.2** Suppose \( u \in C^1(\mathbb{R}^n) \). Then

\[
|u(y) - u(x) - \nabla u(x) \cdot (y - x)| 
\leq C \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x - y|. 
\]

(24.6.16)

**Proof:** This follows easily from letting \( g(y) \equiv u(y) - u(x) - \nabla u(x) \cdot (y - x) \).
Then \( g \in C^1(\mathbb{R}^n) \), \( g(x) = 0 \), and \( \nabla g(z) = \nabla u(z) - \nabla u(x) \). From Lemma 24.6.1,

\[
|u(y) - u(x) - \nabla u(x) \cdot (y - x)| 
= |g(y)| = |g(y) - g(x)| 
\leq C \left( \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x - y|^{1-\frac{2}{p}} 
= C \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x - y|. 
\]

This proves the corollary.

It may be interesting at this point to recall the definition of differentiability on Page 446. If you knew the above inequality held for \( \nabla u \) having components in \( L^1_{loc}(\mathbb{R}^n) \), then at Lebesgue points of \( \nabla u \), the above would imply \( Du(x) \) exists.

### 24.6.2 Rademacher’s Theorem

**Lemma 24.6.3** Let \( u \) be a Lipschitz continuous function which vanishes outside some compact set. Then there exists a unique \( u_{i} \in L^\infty(\mathbb{R}^n) \) such that

\[
\lim_{h \to 0} \frac{u(\cdot + h) - u(\cdot)}{h} = u_{i} \text{ weak * in } L^\infty(\mathbb{R}^n). 
\]

**Proof:** By the Lipschitz condition, the above difference quotient is bounded in \( L^\infty \) by \( K \) the Lipschitz constant of \( u \). It follows from the Banach Aloglu theorem and Corollary 24.5.6 on Page 124 that there exists a subsequence \( h_k \to 0 \) and \( g \in L^\infty(\mathbb{R}^n) \) such that

\[
\frac{u(\cdot + h_k) - u(\cdot)}{h_k} \to g \text{ weak * in } L^\infty(\mathbb{R}^n) 
\]
Letting \( \phi \in C_c^\infty (\mathbb{R}^n) \), it follows
\[
\int g \phi dx = \lim_{k \to \infty} \int \frac{u (\cdot + h_k) - u (\cdot)}{h_k} \phi dx = - \int u \phi , dx
\]
This also shows that \( g \) must vanish outside some compact set because the integral on the right shows that if \( \text{spt} \phi \) does not intersect \( \text{spt} u \), then \( \int g \phi dx = 0 \). Thus \( g \in L^2 (\mathbb{R}^n) \). If \( g_1 \) is a weak \( * \) limit of another subsequence \( h_j \to 0 \), the same result follows. Thus for any \( \phi \in C_c^\infty (\mathbb{R}^n) \)
\[
\int (g - g_1) \phi dx = 0
\]
and since \( C_c^\infty (\mathbb{R}^n) \) is dense in \( L^2 (\mathbb{R}^n) \), this requires \( g = g_1 \) in \( L^2 \) and so they are equal a.e. Since every sequence of \( h \to 0 \) has a subsequence which when applied to the difference quotient, always converges to the same thing, it follows the claimed limit exists. This is called \( u \). This proves the lemma.

**Lemma 24.6.4** Let \( u \) be a Lipschitz continuous function which vanishes outside a compact set and let \( u_{\varepsilon,i} \) be described above. For \( \phi_z \) a mollifier and \( u_{\varepsilon} \equiv u * \phi_z \),
\[
u_{\varepsilon,i} = u_{\varepsilon,i} * \phi_z
\]
where the symbol \( u_{\varepsilon,i} \) means the usual partial derivative with respect to the \( i \)th variable. Also for any \( p > n \),
\[
u_{\varepsilon,i} \to u_{\varepsilon,i} \text{ in } L^p (\mathbb{R}^n).
\]

**Proof:** This follows from a computation and Lemma 24.6.3
\[
u_{\varepsilon,i} (x) = \lim_{h \to 0} \int \frac{u (x - y + he_i) - u (x - y)}{h} \phi_z (y) dy
\]
\[
= \lim_{h \to 0} \int \frac{u (z + he_i) - u (z)}{h} \phi_z (x - z) dz
\]
\[
= \int u_{\varepsilon} (z) \phi_z (x - z) dz = u_{\varepsilon,i} * \phi_z (x)
\]
It remains to verify the last assertion. Note that \( u_{\varepsilon,i} \in L^p (\mathbb{R}^n) \) for any \( p > 1 \) because it is bounded and vanishes outside some compact set. By the first part,
\[
\left( \int |u_{\varepsilon,i} - u_{\varepsilon,i}|^p dx \right)^{1/p} = \left( \int \left( \int (u_{\varepsilon,i} (x - y) - u_{\varepsilon,i} (x)) \phi_z (y) dy \right)^p dx \right)^{1/p}
\]
and by Minkowski's inequality,
\[
\leq \int \phi_z (y) \left( \int |(u_{\varepsilon,i} (x - y) - u_{\varepsilon,i} (x))|^p dy \right)^{1/p} dx
\]
\[
= \int_{B(0, \varepsilon)} \phi_z (y) \left( \int |u_{\varepsilon,i} - u_{\varepsilon,i}|^p dy \right)^{1/p} dx
\]
24.6. RADEMACHER’S THEOREM

which converges to 0 from continuity of translation. This proves the lemma.

Now from Corollary 24.6.2 applied to \( u \) just described and letting \( y - x = v \)

\[
|u(x + v) - u(x) - \nabla u(x) \cdot v|
\]

\[\leq C \left( \frac{1}{m(\mathcal{B}(x,2|v|))} \int_{\mathcal{B}(x,2|v|)} |\nabla u(z) - \nabla u(x)|^p dz \right)^{1/p} |v|.
\]

From Lemma 24.6.3, there is a subsequence, still denoted as \( \varepsilon \) such that for each
\( i, u_{\varepsilon,i} \to u_i \) pointwise a.e. and in \( L^p(\mathbb{R}^n) \) where \( p > n \) is given. Denote as \( \nabla u \) the vector \((u_1, u_2, \cdots, u_n)^T\). Then passing to the limit as \( \varepsilon \to 0 \), for a.e. \( x \),

\[
|u(x + v) - u(x) - \nabla u(x) \cdot v|
\]

\[\leq C \left( \frac{1}{m(\mathcal{B}(x,2|v|))} \int_{\mathcal{B}(x,2|v|)} |\nabla u(z) - \nabla u(x)|^p dz \right)^{1/p} |v|.
\]

At every Lebesgue point \( x \) of \( \nabla u; \)
the above shows \( u(x + v) - u(x) - \nabla u(x) \cdot v = o(v) \). Thus this has proved the following.

**Lemma 24.6.5** Let \( u \) be Lipschitz continuous and vanish outside some bounded set. Then \( Du(x) \) exists for a.e. \( x \).

This is a good result but it is easy to give an even easier to use result. First here is a theorem which says you can extend a Lipschitz map.

**Theorem 24.6.6** If \( h : \Omega \to \mathbb{R}^m \) is Lipschitz, then there exists \( \tilde{h} : \mathbb{R}^n \to \mathbb{R}^m \) which extends \( h \) and is also Lipschitz.

**Proof:** It suffices to assume \( m = 1 \) because if this is shown, it may be applied to the components of \( h \) to get the desired result. Suppose

\[
|h(x) - h(y)| \leq K |x - y|.
\]

Define

\[
\tilde{h}(x) \equiv \inf \{ h(w) + K |x - w| : w \in \Omega \}.
\]

If \( x \in \Omega \), then for all \( w \in \Omega \),

\[
h(w) + K |x - w| \geq h(x)
\]

by 24.6.14. This shows \( h(x) \leq \tilde{h}(x) \). But also you could take \( w = x \) in 24.6.14 which yields \( \tilde{h}(x) \leq h(x) \). Therefore \( \tilde{h}(x) = h(x) \) if \( x \in \Omega \).

Now suppose \( x, y \in \mathbb{R}^n \) and consider \( \tilde{h}(x) - \tilde{h}(y) \). Without loss of generality assume \( \tilde{h}(x) \geq \tilde{h}(y) \). (If not, repeat the following argument with \( x \) and \( y \) interchanged.) Pick \( w \in \Omega \) such that

\[
h(w) + K |y - w| - \varepsilon < \tilde{h}(y).
\]
CHAPTER 24. INTEGRALS AND DERIVATIVES

Then
\[ h(x) - h(y) = h(x) - h(y) \leq h(w) + K |x - w| - h(w) + K |y - w| - \varepsilon \leq K |x - y| + \varepsilon. \]

Since \( \varepsilon \) is arbitrary,
\[ |h(x) - h(y)| \leq K |x - y| \]
and this proves the theorem.

With this theorem, here is the main result called Rademacher’s theorem.

**Theorem 24.6.7** Let \( h : \Omega \to \mathbb{R}^m \) be Lipschitz on \( \Omega \) where \( \Omega \) is some nonempty measurable set in \( \mathbb{R}^n \). Then \( Dh(x) \) exists for a.e. \( x \in \Omega \). If \( \Omega = \mathbb{R}^n \), then for each \( e_i \),
\[ \lim_{h \to 0} \frac{h(\cdot + he_i) - h(\cdot)}{h} = h_i \text{ weak } \text{ in } L^\infty(\mathbb{R}^n) \]
and whenever \( \phi_\varepsilon \) is a mollifier,
\[ (h * \phi_\varepsilon)_i \to h_i \text{ in } L^p(\mathbb{R}^n; \mathbb{R}^m). \]

**Proof:** The last two claims follow from the above argument applied to the components of \( h \). By Theorem 24.6.6 the function can be extended to a Lipschitz function defined on all of \( \mathbb{R}^n \), still denoted as \( h \). Let \( \Omega_r = \Omega \cap B(0, r) \). Now let \( \psi \in C_0^\infty(B(0, 2r)) \) such that \( \psi = 1 \) on \( B(0, \frac{3}{2}r) \). Then \( \psi h \) is Lipschitz on \( \mathbb{R}^n \) and vanishes off a bounded set. It follows from Lemma 24.6.7 applied to the components of \( h \) that this function has a derivative off a set of measure zero \( N_r \). If \( x \in \Omega \setminus N_r \), it follows since \( \psi = 1 \) near \( x \) that \( Dh(x) \) exists. Letting \( N = \bigcup_{r=1}^\infty N_r \), it follows that if \( x \in \Omega \setminus N \), then \( Dh(x) \) exists. This proves the theorem.

For \( u \) Lipschitz as described above, the limit of the difference quotient \( u_i \) is called the weak partial derivative of \( u \). For \( p > n \) and an assertion that the difference quotients are bounded in \( L^p \) everything done above would work out the same way and one can therefore generalize parts of the above theorem. The extension is problematic but one can give the following results with essentially the same proof as the above.

**Lemma 24.6.8** Let \( u \in L^p(\mathbb{R}^n) \). There exists \( u_i \in L^p(\mathbb{R}^n) \) such that
\[ \lim_{h \to 0} \frac{u(\cdot + he_i) - u(\cdot)}{h} = u_i \text{ weakly in } L^p(\mathbb{R}^n) \]
if and only if the difference quotients \( \frac{u(\cdot + he_i) - u(\cdot)}{h} \) are bounded in \( L^p(\mathbb{R}^n) \) for all nonzero \( h \).

**Proof:** If the weak limit exists, then the difference quotients must be bounded. This follows from the uniform boundedness theorem, Theorem 15.1.8. Here is why. Denote the difference quotient by \( D_h \) to save space. Weak convergence requires \( \int D_h f \to \int u_i f \) for all \( f \in L^p \). Could there exist \( h_k \) such that \( ||D_{h_k}||_{L^p} \to \infty \)? Not unless a subsequence satisfies \( h_k \to 0 \) because if this sequence is bounded away from

944
0, the formula for \( D_h \) will yield the difference quotients are bounded. However, if \( h \to 0 \), then for each \( f \in L^{p'} \),

\[
\sup_k \int D_{h_k} f < \infty
\]

because in fact, \( \lim_{k \to \infty} \int D_{h_k} f \) exists so it must be bounded. Now \( D_{h_k} \) can be considered in \( (L^p)' \) and this shows it is pointwise bounded on \( L^{p'} \). Therefore, \( D_{h_k} \) is bounded in \( (L^p)' \) but the norm on this is the same as the norm in \( L^p \). Thus \( D_{h_k} \) is bounded after all.

Conversely, if the difference quotients are bounded, the same argument used earlier, involving convergence of a subsequence, this time coming from the Eberlein Smulian theorem, Theorem 15.5.12 and showing that every subsequence converges to the same thing, shows the difference quotients converge weakly in \( L^p(\mathbb{R}^n) \) to something we can call \( u_i \). This proves the lemma.

**Definition 24.6.9** A function \( f \in L^p(\mathbb{R}^n) \) is said to have weak partial derivatives in \( L^p(\mathbb{R}^n) \) if the difference quotients \( \frac{u_i(x + he_i) - u_i(x)}{h} \) for each \( i = 1, 2, \ldots, n \) are bounded for \( h \neq 0 \).

If \( f \in L^p(\mathbb{R}^n; \mathbb{R}^m) \), it has weak partial derivatives in \( L^p(\mathbb{R}^n; \mathbb{R}^m) \) if each component function has weak partial derivatives in \( L^p(\mathbb{R}^n) \).

This following theorem may also be referred to as Rademacher’s theorem.

**Theorem 24.6.10** Let \( h \) be in \( L^p(\mathbb{R}^n; \mathbb{R}^m) \), \( p > n \), and suppose it has weak derivatives \( h_i \in L^p(\mathbb{R}^n; \mathbb{R}^m) \) for \( i = 1, \ldots, n \). Then \( Dh(x) \) exists a.e. and \( h \) is almost everywhere equal to a continuous function. Also if \( \phi_\varepsilon \) is a mollifier, \( (h \ast \phi_\varepsilon)_i = h_i \ast \phi_\varepsilon \), \( (h \ast \phi_\varepsilon)_i \to h_i \) in \( L^p(\mathbb{R}^n; \mathbb{R}^m) \).

**Proof:** As before,

\[
(h \ast \phi_\varepsilon)_i(x) \equiv \lim_{h \to 0} \int \frac{h(x + he_i - y) - h(x - y)}{h} \phi_\varepsilon(y) dy = \lim_{h \to 0} \int \frac{h(z + he_i) - h(z)}{h} \phi_\varepsilon(x - z) dy \equiv \int h_i(z) \phi_\varepsilon(x - y) dy = h_i \ast \phi_\varepsilon(x)
\]

and now \( (h \ast \phi_\varepsilon)_i \to h_i \) follows as before from a use of Minkowski’s inequality. Letting \( u \) be one of the component functions of \( h \), Morrey’s inequality holds for \( u_\varepsilon \equiv u \ast \phi_\varepsilon \). Thus

\[
|u_\varepsilon(x) - u_\varepsilon(y)| \leq C \left( \int_{B(x, 2|x - y|)} |\nabla u_\varepsilon(z)|^p dz \right)^{1/p} \left( |x - y|^{1-n/p} \right)
\]
Now there exists a subsequence such that $u_\varepsilon \to u$ pointwise a.e. and also each $u_{\varepsilon,i} \to u,i$ pointwise a.e. as well as in $L^p$. Therefore, for $x,y$ not in a set of measure zero,

$$|u(x) - u(y)| \leq C \left( \int_{B(x,2|x-y|)} |\nabla u(z)|^p \, dz \right)^{1/p} \left( |x-y|^{1-n/p} \right)$$

which shows the claim about $u$ being equal to a continuous function off a set of measure zero. Thus $h$ is also continuous off a set of measure zero.

As before, letting $g(y) = u_\varepsilon(y) - u_\varepsilon(x) - \nabla u_\varepsilon(x) \cdot (y-x)$ and writing Morrey’s inequality,

$$|u_\varepsilon(y) - u_\varepsilon(x) - \nabla u_\varepsilon(x) \cdot (y-x)| \leq C \left( \int_{B(x,2|x-y|)} |\nabla u_\varepsilon(z) - \nabla u_\varepsilon(x)|^p \, dz \right)^{1/p} \left( |x-y|^{1-n/p} \right)$$

Then taking a suitable subsequence and passing to the limit while also letting $v = y - x$, it follows

$$|u(x + v) - u(x) - \nabla u(x) \cdot v| \leq C \left( \int_{B(x,2|v|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} \left( |v|^{1-n/p} \right)$$

$$= C \left( \frac{1}{|v|^n} \int_{B(x,2|v|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |v|$$

$$= C' \left( \frac{1}{B(x,2|v|)} \int_{B(x,2|v|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |v|$$

for all $x, x + v \notin N$, a set of measure zero. Defining $u, \nabla u$ at the points of $N$ so that the inequality continues to hold, $Du(x)$ exists at every Lebesgue point of $\nabla u$. Also $Dh$ exists a.e. because this is true of the component functions. This proves the theorem.

## 24.7 Differentiation Of Measures With Respect To Lebesgue Measure

Recall the Vitali covering theorem in Corollary 11.4.5 on Page 333.

**Corollary 24.7.1** Let $E \subseteq \mathbb{R}^n$ and let $\mathcal{F}$ be a collection of open balls of bounded radii such that $\mathcal{F}$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $\mathcal{F}$, $\{B_j\}_{j=1}^\infty$, such that $\overline{m}(E \setminus \bigcup_{j=1}^\infty B_j) = 0$. 

24.7. DIFFERENTIATION OF MEASURES WITH RESPECT TO LEBESGUE MEASURE

Definition 24.7.2 Let $\mu$ be a Radon measure defined on $\mathbb{R}^n$. Then

$$\frac{d\mu}{dm}(x) \equiv \lim_{r \to 0} \frac{\mu(B(x, r))}{m(B(x, r))}$$

whenever this limit exists.

It turns out this limit exists for $m$ a.e. $x$. To verify this here is another definition.

Definition 24.7.3 Let $f(r)$ be a function having values in $[-\infty, \infty]$. Then

$$\limsup_{r \to 0^+} f(r) = \lim_{r \to 0} (\sup \{ f(t) : t \in [0, r] \})$$

$$\liminf_{r \to 0^+} f(r) = \lim_{r \to 0} (\inf \{ f(t) : t \in [0, r] \})$$

This is well defined because the function $r \to \inf \{ f(t) : t \in [0, r] \}$ is increasing and $r \to \sup \{ f(t) : t \in [0, r] \}$ is decreasing. Also note that $\lim_{r \to 0^+} f(r)$ exists if and only if

$$\limsup_{r \to 0^+} f(r) = \liminf_{r \to 0^+} f(r)$$

and if this happens

$$\lim_{r \to 0^+} f(r) = \liminf_{r \to 0^+} f(r) = \limsup_{r \to 0^+} f(r).$$

The claims made in the above definition follow immediately from the definition of what is meant by a limit in $[-\infty, \infty]$ and are left for the reader.

Theorem 24.7.4 Let $\mu$ be a Borel measure on $\mathbb{R}^n$ then $\frac{d\mu}{dm}(x)$ exists in $[-\infty, \infty]$ $m$ a.e.

Proof: Let $p < q$ and let $p, q$ be rational numbers. Define

$$N_{pq}(M) = \left\{ x \in \mathbb{R}^n \text{ such that } \limsup_{r \to 0^+} \frac{\mu(B(x, r))}{m(B(x, r))} > q \right\}$$

$$N_{pq} = \left\{ x \in \mathbb{R}^n \text{ such that } \limsup_{r \to 0^+} \frac{\mu(B(x, r))}{m(B(x, r))} > q \right\}$$

$$N = \left\{ x \in \mathbb{R}^n \text{ such that } \limsup_{r \to 0^+} \frac{\mu(B(x, r))}{m(B(x, r))} > \right\}$$

$$\liminf_{r \to 0^+} \frac{\mu(B(x, r))}{m(B(x, r))} \right\}.$$
I will show $m(N_{pq}(M)) = 0$. Use outer regularity to obtain an open set, $V$ containing $N_{pq}(M)$ such that

$$m(N_{pq}(M)) + \varepsilon > m(V).$$

From the definition of $N_{pq}(M)$, it follows that for each $x \in N_{pq}(M)$ there exists arbitrarily small $r > 0$ such that

$$\frac{\mu(B(x,r))}{m(B(x,r))} < p.$$

Only consider those $r$ which are small enough to be contained in $B(0,M)$ so that the collection of such balls has bounded radii. This is a Vitali cover of $N_{pq}(M)$ and so by Corollary 24.7.1 there exists a sequence of disjoint balls of this sort, $\{B_i\}_{i=1}^\infty$ such that

$$\mu(B_i) < pm(B_i), \ m(N_{pq}(M) \setminus \bigcup_{i=1}^\infty B_i) = 0. \ (24.7.19)$$

Now for $x \in N_{pq}(M) \cap (\bigcup_{i=1}^\infty B_i)$ (most of $N_{pq}(M)$), there exist arbitrarily small balls, $B(x,r)$, such that $B(x,r)$ is contained in some set of $\{B_i\}_{i=1}^\infty$ and

$$\frac{\mu(B(x,r))}{m(B(x,r))} > q.$$

This is a Vitali cover of $N_{pq}(M) \cap (\bigcup_{i=1}^\infty B_i)$ and so there exists a sequence of disjoint balls of this sort, $\{B_j'\}_{j=1}^\infty$ such that

$$\bar{m}\left((N_{pq}(M) \cap (\bigcup_{i=1}^\infty B_i)) \setminus \bigcup_{j=1}^\infty B_j'\right) = 0, \ \mu(B_j') > qm(B_j'). \ (24.7.20)$$

It follows from 24.7.19 and 24.7.20 that

$$\bar{m}(N_{pq}(M)) \leq \bar{m}\left((N_{pq}(M) \cap (\bigcup_{i=1}^\infty B_i)) \setminus \bigcup_{j=1}^\infty B_j'\right) \leq m(\bigcup_{j=1}^\infty B_j') \ (24.7.21)$$

Therefore,

$$\sum_j \mu(B_j') > q \sum_j m(B_j') \geq q\bar{m}(N_{pq}(M) \cap (\bigcup_i B_i)) = q\bar{m}(N_{pq}(M))$$

$$\geq \ p\bar{m}(N_{pq}(M)) \geq p(m(V) - \varepsilon) \geq p \sum_i m(B_i) - p\varepsilon$$

$$\geq \ \sum_i \mu(B_i) - p\varepsilon \geq \sum_j \mu(B_j') - p\varepsilon.$$

It follows

$$p\varepsilon \geq (q - p)\bar{m}(N_{pq}(M))$$

Since $\varepsilon$ is arbitrary, $m(N_{pq}(M)) = 0$. Now $N_{pq} \subseteq \bigcup_{M=1}^\infty N_{pq}(M)$ and so $m(N_{pq}) = 0$. Now

$$N = \cup_{p,q \in Q} N_{pq}$$

and since this is a countable union of sets of measure zero, $m(N) = 0$ also. This proves the theorem.

From Theorem 24.7.1 on Page 586 it follows that if $\mu$ is a complex measure then $|\mu|$ is a finite measure. This makes possible the following definition.
24.7. DIFFERENTIATION OF MEASURES WITH RESPECT TO LEBESGUE MEASURE

Definition 24.7.5 Let \( \mu \) be a real measure. Define the following measures. For \( E \) a measurable set,

\[
\mu^+ (E) \equiv \frac{1}{2} (|\mu| + \mu)(E), \\
\mu^- (E) \equiv \frac{1}{2} (|\mu| - \mu)(E).
\]

These are measures thanks to Theorem 18.2.3 on Page 584 and \( \mu^+ - \mu^- = \mu \). These measures have values in \([0, \infty)\). They are called the positive and negative parts of \( \mu \) respectively. For a complex measure, define \( \text{Re} \mu \) and \( \text{Im} \mu \) by

\[
\text{Re} \mu (E) \equiv \frac{1}{2} \left( \mu (E) + \overline{\mu (E)} \right), \\
\text{Im} \mu (E) \equiv \frac{1}{2i} \left( \mu (E) - \overline{\mu (E)} \right).
\]

Then \( \text{Re} \mu \) and \( \text{Im} \mu \) are both real measures. Thus for a complex measure,

\[
\mu = \text{Re} \mu^+ - \text{Re} \mu^- + i (\text{Im} \mu^+ - \text{Im} \mu^-) = \nu_1 - \nu_1 + i (\nu_3 - \nu_4)
\]

where each \( \nu_i \) is a real measure having values in \([0, \infty)\).

Then there is an obvious corollary to Theorem 24.7.4.

Corollary 24.7.6 Let \( \mu \) be a complex Borel measure on \( \mathbb{R}^n \). Then \( \frac{d\mu}{dm} (x) \) exists a.e.

Proof: Letting \( \nu_i \) be defined in Definition 24.7.5. By Theorem 24.7.3, for \( m \) a.e. \( x \), \( \frac{d\nu_i}{dm} (x) \) exists. This proves the corollary because \( \mu \) is just a finite sum of these \( \nu_i \).

Theorem 18.1.2 on Page 577, the Radon Nikodym theorem, implies that if you have two finite measures, \( \mu \) and \( \lambda \), you can write \( \lambda \) as the sum of a measure absolutely continuous with respect to \( \mu \) and one which is singular to \( \mu \) in a unique way. The next topic is related to this. It has to do with the differentiation of a measure which is singular with respect to Lebesgue measure.

Theorem 24.7.7 Let \( \mu \) be a Radon measure on \( \mathbb{R}^n \) and suppose there exists a \( \mu \) measurable set, \( N \) such that for all Borel sets, \( E \), \( \mu (E) = \mu (E \cap N) \) where \( \text{m}(N) = 0 \). Then

\[
\frac{d\mu}{dm} (x) = 0 \; m \; \text{a.e.}
\]

Proof: For \( k \in \mathbb{N} \), let

\[
B_k (M) \equiv \left\{ x \in N^C : \lim_{r \to 0^+} \sup_{B(x,r)} \frac{\mu (B(x,r))}{m (B(x,r))} > \frac{1}{k} \right\} \cap B (0,M),
\]

\[
B_k = \left\{ x \in N^C : \lim_{r \to 0^+} \sup_{B(x,r)} \frac{\mu (B(x,r))}{m (B(x,r))} > \frac{1}{k} \right\},
\]

\[
B = \left\{ x \in N^C : \lim_{r \to 0^+} \sup_{B(x,r)} \frac{\mu (B(x,r))}{m (B(x,r))} > 0 \right\}.
\]
Let \( \varepsilon > 0 \). Since \( \mu \) is regular, there exists \( H \), a compact set such that \( H \subseteq N \cap B(0, M) \) and
\[
\mu (N \cap B(0, M) \setminus H) < \varepsilon.
\]

For each \( x \in B_k(M) \), there exist arbitrarily small \( r > 0 \) such that \( B(x, r) \subseteq B(0, M) \setminus H \) and
\[
\frac{\mu (B(x, r))}{m(B(x, r))} \geq \frac{1}{k}.
\]
(24.7.22)

Two such balls are illustrated in the above picture. This is a Vitali cover of \( B_k(M) \) and so there exists a sequence of disjoint balls of this sort, \( \{B_i\}_{i=1}^\infty \) such that \( m(B_k(M) \setminus \bigcup_i B_i) = 0 \). Therefore,
\[
\begin{align*}
\overline{m}(B_k(M)) &\leq \overline{m}(B_k(M) \cap (\bigcup_i B_i)) \\
&\leq \sum_i \overline{m}(B_i) \\
&\leq k \sum_i \mu(B_i) \\
&= k \sum_i \mu(B_i \cap N) \\
&= k \sum_i \mu(B_i \cap N \cap B(0, M)) \\
&\leq k \mu(N \cap B(0, M) \setminus H) < \varepsilon k
\end{align*}
\]

Since \( \varepsilon \) was arbitrary, this shows \( \overline{m}(B_k(M)) = 0 \).

Therefore,
\[
\overline{m}(B_k) \leq \sum_{M=1}^\infty \overline{m}(B_k(M)) = 0
\]
and \( \overline{m}(B) \leq \sum_k \overline{m}(B_k) = 0 \). Since \( \overline{m}(N) = 0 \), this proves the theorem.

It is easy to obtain a different version of the above theorem. This is done with the aid of the following lemma.

**Lemma 24.7.8** Suppose \( \mu \) is a Borel measure on \( \mathbb{R}^n \) having values in \([0, \infty)\). Then there exists a Radon measure, \( \mu_1 \) such that \( \mu_1 = \mu \) on all Borel sets.
Proof: By assumption, \( \mu(\mathbb{R}^n) < \infty \) and so it is possible to define a positive linear functional, \( L \) on \( C_c(\mathbb{R}^n) \) by
\[
Lf \equiv \int f \, d\mu.
\]
By the Riesz representation theorem for positive linear functionals of this sort, there exists a unique Radon measure, \( \mu_1 \) such that for all \( f \in C_c(\mathbb{R}^n) \),
\[
\int f \, d\mu_1 = Lf = \int f \, d\mu.
\]
Now let \( V \) be an open set and let \( K_k \equiv \{ x \in V : \text{dist} \, (x, V^C) \leq 1/k \} \cap \overline{B(0, k)} \). Then \( \{ K_k \} \) is an increasing sequence of compact sets whose union is \( V \). Let \( K_k \prec f_k \prec V \). Then \( f_k(x) \to \lambda_V(x) \) for every \( x \). Therefore,
\[
\mu_1(V) = \lim_{k \to \infty} \int f_k \, d\mu_1 = \lim_{k \to \infty} \int f_k \, d\mu = \mu(V)
\]
and so \( \mu = \mu_1 \) on open sets. Now if \( K \) is a compact set, let
\[
V_k \equiv \{ x \in \mathbb{R}^n : \text{dist} \, (x, K) < 1/k \}.
\]
Then \( V_k \) is an open set and \( \cap_k V_k = K \). Letting \( K_k \prec f_k \prec V_k \), it follows that \( f_k(x) \to \lambda_K(x) \) for all \( x \in \mathbb{R}^n \). Therefore, by the dominated convergence theorem with a dominating function, \( \lambda_{\mathbb{R}^n} \)
\[
\mu_1(K) = \lim_{k \to \infty} \int f_k \, d\mu_1 = \lim_{k \to \infty} \int f_k \, d\mu = \mu(K)
\]
and so \( \mu \) and \( \mu_1 \) are equal on all compact sets. It follows \( \mu = \mu_1 \) on all countable unions of compact sets and countable intersections of open sets.

Now let \( E \) be a Borel set. By regularity of \( \mu_1 \), there exist sets, \( H \) and \( G \) such that \( H \) is the countable union of an increasing sequence of compact sets, \( G \) is the countable intersection of a decreasing sequence of open sets, \( H \subseteq E \subseteq G \), and \( \mu_1(H) = \mu_1(G) = \mu_1(E) \). Therefore,
\[
\mu_1(H) = \mu_1(E) \leq \mu(G) = \mu_1(G) = \mu_1(E) = \mu_1(H).
\]
Therefore, \( \mu(E) = \mu_1(E) \) and this proves the lemma.

**Corollary 24.7.9** Suppose \( \mu \) is a complex Borel measure defined on \( \mathbb{R}^n \) for which there exists a \( \mu \) measurable set, \( N \) such that for all Borel sets, \( E \), \( \mu(E) = \mu(E \cap N) \) where \( m(N) = 0 \). Then
\[
\frac{d\mu}{dm}(x) = 0 \text{ m.a.e.}
\]

Proof: Each of \( \text{Re} \, \mu^+ \), \( \text{Re} \, \mu^- \), \( \text{Im} \, \mu^+ \), and \( \text{Im} \, \mu^- \) are real measures having values in \([0, \infty)\) and so by Lemma 24.7.8 each is a Radon measure having the same property that \( \mu \) has in terms of being supported on a set of \( m \) measure zero. Therefore, for \( \nu \) equal to any of these, \( \frac{d\nu}{dm}(x) = 0 \text{ m.a.e.} \) This proves the corollary.
CHAPTER 24. INTEGRALS AND DERIVATIVES

24.8 Exercises

1. Suppose \( A \) and \( B \) are sets of positive Lebesgue measure in \( \mathbb{R}^n \). Show that
\[ A - B = \{ a - b : a \in A \text{ and } b \in B \} \]
must contain \( B (c, \varepsilon) \) for some \( c \in \mathbb{R}^n \) and \( \varepsilon > 0 \).

**Hint:** First assume both sets are bounded. This creates no loss of generality. Next there exist \( a_0 \in A \), \( b_0 \in B \) and \( \delta > 0 \) such that
\[ \int_{B(a_0, \delta)} X_A (t) \, dt > \frac{3}{4} m (B (a_0, \delta)), \quad \int_{B(b_0, \delta)} X_B (t) \, dt > \frac{3}{4} m (B (b_0, \delta)). \]
Now explain why this implies
\[ m (A - a_0 \cap B (0, \delta)) > \frac{3}{4} m (B (0, \delta)) \]
and
\[ m (B - b_0 \cap B (0, \delta)) > \frac{3}{4} m (B (0, \delta)). \]
Explain why
\[ m ((A - a_0) \cap (B - b_0)) > \frac{1}{2} m (B (0, \delta)) > 0. \]
Let
\[ f (x) = \int X_{A-a_0} (x + t) X_{B-b_0} (t) \, dt. \]
Explain why \( f (0) > 0 \). Next explain why \( f (x) > 0 \) for all \( x \in B (0, \varepsilon) \) for some \( \varepsilon > 0 \). Thus if \( |x| < \varepsilon \), there exists \( t \) such that \( x + t \in A - a_0 \) and \( t \in B - b_0 \). Subtract these.

2. Show \( Mf \) is Borel measurable by verifying that \([Mf > \lambda] = E_\lambda\) is actually an open set. **Hint:** If \( x \in E_\lambda \) then for some \( r, \int_{B(x, r)} |f| \, dm > \lambda m (B (x, r)) \).
Then for \( \delta \) a small enough positive number, \( \int_{B(x, r)} |f| \, dm > \lambda m (B (x, r + 2\delta)) \).
Now pick \( y \in B (x, \delta) \) and argue that \( B (y, \delta + r) \supseteq B (x, r) \). Therefore show that,
\[ \int_{B(y, \delta + r)} |f| \, dm > \int_{B(x, r)} |f| \, dm > \lambda B (x, r + 2\delta) \geq \lambda m (B (y, r + \delta)). \]
Thus \( B (x, \delta) \subseteq E_\lambda \).

3. Consider the following nested sequence of compact sets, \( \{ P_n \} \). Let \( P_1 = [0, 1], \ P_2 = [0, \frac{1}{3}] \cup [\frac{2}{3}, 1], \) etc. To go from \( P_n \) to \( P_{n+1} \), delete the open interval which is the middle third of each closed interval in \( P_n \). Let \( P = \cap_{n=1}^\infty P_n \).
By the finite intersection property of compact sets, \( P \neq \emptyset \). Show \( m (P) = 0 \). If you feel ambitious also show there is a one to one onto mapping of \([0, 1]\)
24.8. EXERCISES

to $P$. The set $P$ is called the Cantor set. Thus, although $P$ has measure zero, it has the same number of points in it as $[0, 1]$ in the sense that there is a one to one and onto mapping from one to the other. **Hint:** There are various ways of doing this last part but the most enlightenment is obtained by exploiting the topological properties of the Cantor set rather than some silly representation in terms of sums of powers of two and three. All you need to do is use the Schroder Bernstein theorem and show there is an onto map from the Cantor set to $[0, 1]$. If you do this right and remember the theorems about characterizations of compact metric spaces, Proposition 6.2.5 on Page 146, you may get a pretty good idea why every compact metric space is the continuous image of the Cantor set.

4. Consider the sequence of functions defined in the following way. Let $f_1(x) = x$ on $[0, 1]$. To get from $f_n$ to $f_{n+1}$, let $f_{n+1} = f_n$ on all intervals where $f_n$ is constant. If $f_n$ is nonconstant on $[a, b]$, let $f_{n+1}(a) = f_n(a)$, $f_{n+1}(b) = f_n(b)$. $f_{n+1}$ is piecewise linear and equal to $\frac{1}{3}(f_n(a) + f_n(b))$ on the middle third of $[a, b]$. Sketch a few of these and you will see the pattern. The process of modifying a nonconstant section of the graph of this function is illustrated in the following picture.

Show $\{f_n\}$ converges uniformly on $[0, 1]$. If $f(x) = \lim_{n \to \infty} f_n(x)$, show that $f(0) = 0$, $f(1) = 1$, $f$ is continuous, and $f'(x) = 0$ for all $x \notin P$ where $P$ is the Cantor set of Problem 3. This function is called the Cantor function. It is a very important example to remember. Note it has derivative equal to zero a.e. and yet it succeeds in climbing from 0 to 1. Explain why this interesting function is not absolutely continuous although it is continuous. **Hint:** This isn't too hard if you focus on getting a careful estimate on the difference between two successive functions in the list considering only a typical small interval in which the change takes place. The above picture should be helpful.

5. A function, $f : [a, b] \to \mathbb{R}$ is Lipschitz if $|f(x) - f(y)| \leq K|x - y|$. Show that every Lipschitz function is absolutely continuous. Thus every Lipschitz function is differentiable a.e., $f' \in L^1$, and $f(y) - f(x) = \int_x^y f'(t) \, dt$.

6. Suppose $f, g$ are both absolutely continuous on $[a, b]$. Show the product of these functions is also absolutely continuous. Explain why $(fg)' = f'g + g'f$ and show the usual integration by parts formula

$$f(b)g(b) - f(a)g(a) - \int_a^b fg' \, dt = \int_a^b f'g \, dt.$$

7. In Problem 3, $f'$ failed to give the expected result for $\int_a^b f' \, dx$ but at least

---

1In this example, you only know that $f'$ exists a.e.
8. A sequence of sets, \( \{ E_i \} \) containing the point \( x \) is said to shrink to \( x \) nicely if there exists a sequence of positive numbers, \( \{ r_i \} \) and a positive constant, \( \alpha \) such that \( r_i \to 0 \) and

\[
m(E_i) \geq \alpha m(B(x, r_i)), \quad E_i \subseteq B(x, r_i).
\]

Show the above theorems about differentiation of measures with respect to Lebesgue measure all have a version valid for \( E_i \) replacing \( B(x, r) \).

9. Suppose \( F(x) = \int_a^x f(t) \, dt \). Using the concept of nicely shrinking sets in Problem 8 show \( F'(x) = f(x) \) a.e.

10. A random variable, \( X \) is a measurable real valued function defined on a measure space, \( (\Omega, S, P) \) where \( P \) is just a measure with \( P(\Omega) = 1 \) called a probability measure. The distribution function for \( X \) is the function, \( F(x) = P([X \leq x]) \) in words, \( F(x) \) is the probability that \( X \) has values no larger than \( x \). Show that \( F \) is a right continuous increasing function with the property that \( \lim_{x \to -\infty} F(x) = 0 \) and \( \lim_{x \to \infty} F(x) = 1 \).

11. Suppose \( F \) is an increasing right continuous function.
   (a) Show that \( Lf = \int_a^b f \, dF \) is a well defined positive linear functional on \( C_c(\mathbb{R}) \) where here \( [a, b] \) is a closed interval containing the support of \( f \in C_c(\mathbb{R}) \).
   (b) Using the Riesz representation theorem for positive linear functionals on \( C_c(\mathbb{R}) \), let \( \mu \) denote the Radon measure determined by \( L \). Show that \( \mu([a,b]) = F(b) - F(a) \) and \( \mu(\{b\}) = F(b) - F(b-) \) where \( F(b-) = \lim_{x \to b-} F(x) \).
   (c) Review Corollary on Page 954 at this point. Show that the conditions of this corollary hold for \( \mu \) and \( m \). Consider \( \mu_\perp = \mu_\perp \ll m \), the Lebesgue decomposition of \( \mu \) where \( \mu_\perp \ll m \) and there exists a set of \( m \) measure zero, \( N \) such that \( \mu_\perp(E) = \mu_\perp(E \cap N) \). Show \( \mu((0, x]) = \mu_\perp((0, x]) + \int_0^x h(t) \, dt \) for some \( h \in L^1(m) \). Using Theorem 24.7.6 show \( h(x) = F'(x) \) \( m \) a.e. Explain why \( F(x) = F(0) + S(x) + \int_0^x F'(t) \, dt \) for some function, \( S(x) \) which is increasing but has \( S'(x) = 0 \) \( m \) a.e. Note this shows in particular that a right continuous increasing function has a derivative \( m \) a.e.

12. Suppose now that \( G \) is just an increasing function defined on \( \mathbb{R} \). Show that \( G'(x) \) exists \( m \) a.e. \textbf{Hint:} You can mimic the proof of Theorem 24.7.3. The Dini derivatives are defined as

\[
D_- G(x) = \lim \inf_{h \to 0^+} \frac{G(x + h) - G(x)}{h},
\]

\[
D_+ G(x) = \lim \sup_{h \to 0^+} \frac{G(x + h) - G(x)}{h}.
\]
When \( D_+ G(x) = D^+ G(x) \) the derivative from the right exists and when \( D^- G(x) = D_- G(x) \), then the derivative from the left exists. Let \((a, b)\) be an open interval and let

\[
N_{pq} = \{ x \in (a, b) : D^+ G(x) > q > p > D_+ G(x) \}.
\]

Let \( V \subseteq (a, b) \) be an open set containing \( N_{pq} \) such that \( m(V) < m(N_{pq}) + \varepsilon \). Show using a Vitali covering theorem there is a disjoint sequence of intervals contained in \( V \), \( \{(x_i, x_i + h_i)\}_{i=1}^\infty \) such that

\[
\frac{G(x_i + h_i) - G(x_i)}{h_i} < p.
\]

Next show there is a disjoint sequence of intervals \( \{(x'_i, x'_i + h'_i)\}_{j=1}^\infty \) such that each of these is contained in one of the former intervals and

\[
\frac{G(x'_i + h'_i) - G(x'_i)}{h'_i} > q, \quad \sum_j h'_j \geq m(N_{pq}).
\]

Then

\[
qm(N_{pq}) \leq q \sum_j h'_j \leq \sum_j G(x'_j + h'_j) - G(x'_j) \leq \sum_i G(x_i + h_i) - G(x_i) \leq p \sum_i h_i \leq pm(V) \leq p(m(N_{pq}) + \varepsilon).
\]

Since \( \varepsilon \) was arbitrary, this shows \( m(N_{pq}) = 0 \). Taking a union of all \( N_{pq} \) for \( p, q \) rational, shows the derivative from the right exists a.e. Do a similar argument to show the derivative from the left exists a.e. and then show the derivative from the left equals the derivative from the right a.e. using a similar argument. Thus \( G'(x) \) exists on \((a, b)\) a.e. and so it exists a.e. on \( \mathbb{R} \) because \((a, b)\) was arbitrary.
Chapter 25

Orlitz Spaces

25.1 Basic Theory

All the theorems about the $L^p$ spaces have generalizations to something called an Orlitz space. Instead of the convex function, $A(t) = t^p/p$, one considers a more general convex increasing function called an $N$ function.

**Definition 25.1.1** $A : [0, \infty) \to [0, \infty)$ is an $N$ function if the following two conditions hold.

1. $A$ is convex and strictly increasing  
2. $\lim_{t \to 0^+} \frac{A(t)}{t} = 0$, $\lim_{t \to \infty} \frac{A(t)}{t} = \infty.$

For $A$ an $N$ function,

$$\widetilde{A}(s) \equiv \max \{st - A(t) : t \geq 0\}.$$  

As an example see the following picture of a typical $N$ function.

![Graph of A(t)](image)

Note that from the assumption, the maximum in the definition of $\widetilde{A}$ must exist. This is because for $t \neq 0$

$$(s - A(t)/t) \cdot t$$

is negative for all $t$ large enough. On the other hand, it equals 0 when $t = 0$ and so it suffices to consider only $t$ in a compact set.
Lemma 25.1.2 Let \( \phi : \mathbb{R} \to \mathbb{R} \) be a convex function. Then \( \phi \) is Lipschitz continuous on \([a, b]\).

Proof: Since it is convex, the difference quotients,
\[
\frac{\phi(t) - \phi(a)}{t - a}
\]
are increasing because by convexity, if \( a < t < x \)
\[
\frac{t - a}{x - a} \phi(x) + \left(1 - \frac{t - a}{x - a}\right) \phi(a) \geq \phi(t)
\]
and this reduces to
\[
\frac{\phi(t) - \phi(a)}{t - a} \leq \frac{\phi(x) - \phi(a)}{x - a}.
\]
Also these difference quotients are bounded below by
\[
\frac{\phi(a) - \phi(a - 1)}{1} = \phi(a) - \phi(a - 1).
\]
Let
\[
A = \inf \left\{ \frac{\phi(t) - \phi(a)}{t - a} : t \in (a, b) \right\}.
\]
Then \( A \) is some finite real number. Similarly there exists a real number \( B \) such that for all \( t \in (a, b) \),
\[
B \geq \frac{\phi(b) - \phi(t)}{b - t}.
\]
Now let \( a \leq s < t \leq b \). Then
\[
\frac{\phi(t) - \phi(s)}{t - s} \geq \frac{\phi(t) - \theta \phi(a) - (1 - \theta) \phi(t)}{t - s}
\]
where \( \theta \) is such that \( \theta a + (1 - \theta) t = s \). Thus
\[
\theta = \frac{t - s}{t - t_1}
\]
and so the above implies
\[
\frac{\phi(t) - \phi(s)}{t - s} \geq \frac{t - s}{t - t_1} \frac{\phi(t) - \phi(a)}{t - s} = \frac{\phi(t) - \phi(a)}{t - t_1} \geq A.
\]
Similarly,
\[
\frac{\phi(t) - \phi(s)}{t - s} \leq \frac{\theta \phi(b) + (1 - \theta) \phi(s) - \phi(s)}{t - s}
\]
\[
= \frac{t - s}{b - s} \frac{\phi(b) - \phi(s)}{t - s} \leq B.
\]
25.1. BASIC THEORY

It follows

$$|\phi(t) - \phi(s)| \leq (|A| + |B|)|t - s|$$

and this proves the lemma.

The following is like the inequality, $st \leq tp/p + sq/q$, important in the study of $L^p$ spaces.

**Proposition 25.1.3** If $A$ is an $N$ function, then so is $\tilde{A}$ and

$$A(t) = \max \left\{ ts - \tilde{A}(s) : s \geq 0 \right\},$$  \hspace{1cm} (25.1.4)

so $\tilde{A} = A$. Also

$$st \leq A(t) + \tilde{A}(s) \text{ for all } s, t \geq 0$$  \hspace{1cm} (25.1.5)

and for all $s > 0$,

$$A\left(\frac{\tilde{A}(s)}{s}\right) \leq \tilde{A}(s).$$  \hspace{1cm} (25.1.6)

**Proof:** First consider the claim $\tilde{A}$ is convex. Let $\lambda \in [0, 1]$.

$$\tilde{A}(\lambda s_1 + (1 - \lambda) s_2) = \max \{ [s_1 \lambda + (1 - \lambda) s_2] t - A(t) : t \geq 0 \}$$

$$\leq \lambda \max \{ s_1 t - A(t) : t \geq 0 \} + (1 - \lambda) \max \{ s_2 t - A(t) : t \geq 0 \}$$

$$= \lambda \tilde{A}(s_1) + (1 - \lambda) \tilde{A}(s_2).$$

It is obvious $\tilde{A}$ is strictly increasing because $st$ is strictly increasing in $s$. Next consider

For $s > 0$ let $t_s$ denote the number where the maximum is achieved. That is,

$$\tilde{A}(s) \equiv st_s - A(t_s).$$

Thus

$$\frac{\tilde{A}(s)}{s} = t_s - \frac{A(t_s)}{s} \geq 0.$$

(25.1.7)

It follows from this that

$$\lim_{s \to 0^+} t_s = 0$$

since otherwise, a contradiction results to the expression becoming negative for small enough $s$. Thus

$$t_s \geq \frac{\tilde{A}(s)}{s} \geq 0$$

and this shows

$$\lim_{s \to 0^+} \frac{\tilde{A}(s)}{s} = 0.$$
To verify the second part of 25.1.2, let $t$ be as just described. Then for any $t > 0$
\[
\frac{\bar{A}(s)}{s} = t_s - \frac{A(t)}{s} \geq t - \frac{A(t)}{s}
\]
It follows
\[
\lim_{s \to \infty} \inf \frac{\bar{A}(s)}{s} \geq t.
\]
Since $t$ is arbitrary, this proves the second part of 25.1.2.

The inequality 25.1.5 follows from the definition of $\bar{A}(s)$.

Next consider 25.1.4. It must be shown that
\[
A(t_0) = \max \left\{ t_0 s - \bar{A}(s) : s \geq 0 \right\}.
\]
To do so, first note
\[
\bar{A}(s) = \max \left\{ st - A(t) : t \geq 0 \right\} \geq st_0 - A(t_0).
\]
Hence
\[
\max \left\{ t_0 s - \bar{A}(s) : s \geq 0 \right\} \leq \max \left\{ t_0 s - [st_0 - A(t_0)] \right\} = A(t_0).
\]

Now let
\[
s_0 \equiv \inf \left\{ \frac{A(t) - A(t_0)}{t - t_0} : t > t_0 \right\}.
\]
By convexity, the above difference quotients are nondecreasing in $t$ and so
\[
s_0 (t - t_0) \leq A(t) - A(t_0)
\]
for all $t \neq t_0$. Hence for all $t$,
\[
s_0 t - A(t) \leq s_0 t_0 - A(t_0)
\]
and so
\[
\bar{A}(s_0) = s_0 t_0 - A(t_0)
\]
implying
\[
A(t_0) = s_0 t_0 - \bar{A}(s_0) \leq \max \left\{ st_0 - \bar{A}(s) : s \geq 0 \right\} \leq A(t_0).
\]
Therefore, 25.1.4 holds.

Consider 25.1.6 next. To do so, let $a = A'$ so that
\[
A(t) = \int_0^t a(r) \, dr, \ a \text{ increasing}.
\]
This is possible by Rademacher’s theorem, Corollary 24.4.3 and the fact that since $A$ is convex, it is locally Lipshitz found in Lemma 25.1.2 above. That $a$ is increasing follows from convexity of $A$. Here is why. For a.e. $s,t \geq 0$, and letting $\lambda \in [0,1]$, 
\[
\frac{A(s + \lambda(t-s)) - A(s)}{\lambda} \leq \frac{(1-\lambda)A(s) + \lambda A(t) - A(s)}{\lambda} = A(t) - A(s)
\]
Then passing to a limit as $\lambda \to 0+$,
\[a(s)(t-s) \leq A(t) - A(s) . \]
Similarly
\[a(t)(s-t) \leq A(s) - A(t)\]
and so
\[(a(t) - a(s))(t-s) \geq 0\]  
(If you like, you can simply assume from the beginning that $A(t)$ is given this way as an integral of a positive increasing function, $a$, and verify directly that such an $A$ is convex and satisfies the properties of an $N$ function. There is no loss of generality in doing so.) Thus geometrically, $A(t)$ equals the area under the curve defined by $a$ and above the $x$ axis from $x = 0$ to $x = t$. In the definition of $\tilde{A}(s)$ let $t_s$ be the point where the maximum is achieved. Then
\[\tilde{A}(s) = st_s - A(t_s)\]
and so at this point, $\tilde{A}(s) + A(t_s) = st_s$. This means that $\tilde{A}(s)$ is the area to the left of the graph of $a$ which is to the right of the $y$ axis for $y$ between 0 and $a(t_s)$ and that in fact $a(t_s) = s$. The following picture illustrates the reasoning which follows.

Therefore,
\[
\frac{\tilde{A}(s)}{s} = t_s - \frac{A(t_s)}{s} = t_s - \frac{1}{s} \int_0^{t_s} a(r) \, dr = \frac{1}{a(t_s)} \left( t_s s - \int_0^{t_s} a(r) \, dr \right)
\]
and so

\[
A \left( \frac{\tilde{A}(s)}{s} \right) = \int_0^\infty \frac{\tilde{A}(s)}{s} a(r) \, dr = \int_0^\infty \frac{s - a(r)}{s} a(r) \, dr \\
\leq \int_0^t s - a(r) \, dr = st - A(t_s) = \tilde{A}(s).
\]

The inequality results from replacing \( a(r) \) with \( a(t_s) \) in the last integral on the top line.

An example of an \( N \) function is \( A(t) = t^p \) for \( t \geq 0 \) and \( p > 1 \). For this example, \( \tilde{A}(s) = \frac{s^p}{p} \) where \( \frac{1}{p} + \frac{1}{p'} = 1 \).

**Definition 25.1.4** Let \( A \) be an \( N \) function and let \((\Omega, \mathcal{S}, \mu)\) be a measure space. Define

\[
K_A(\Omega) = \left\{ u \text{ measurable such that } \int_\Omega A(|u|) \, d\mu < \infty \right\}.
\]

This is called the Orlitz class. Also define

\[
L_A(\Omega) = \{ \lambda u : u \in K_A(\Omega) \text{ and } \lambda \in \mathbb{F} \}
\]

where \( \mathbb{F} \) is the field of scalars, assumed to be either \( \mathbb{R} \) or \( \mathbb{C} \).

The pair \((A, \Omega)\) is called \( \Delta \) regular if either of the following conditions hold.

\[
A(rx) \leq K_r A(x) \text{ for all } x \in [0, \infty)
\]

or \( \mu(\Omega) < \infty \) and for all \( r > 0 \), there exists \( M_r \) and \( K_r > 0 \) such that

\[
A(rx) \leq K_r A(x) \text{ for all } x \geq M_r.
\]

Note there are \( N \) functions which are not \( \Delta \) regular. For example, consider

\[
A(x) = e^{x^2} - 1.
\]

It can't be \( \Delta \) regular because

\[
\lim_{r \to \infty} \frac{e^{x^2} - 1}{e^{x^2} - x} = \infty.
\]

However, functions like \( x^p/p \) for \( p > 1 \) are \( \Delta \) regular.

Then the following proposition is important.

**Proposition 25.1.5** If \((A, \Omega)\) is \( \Delta \) regular, then \( K_A(\Omega) = L_A(\Omega) \). In any case, \( L_A(\Omega) \) is a vector space and \( K_A(\Omega) \subseteq L_A(\Omega) \).
Proof: Suppose \((A, \Omega)\) is \(\Delta\) regular. Then I claim \(K_A(\Omega)\) is a vector space. This will verify \(K_A(\Omega) = L_A(\Omega)\). Let \(f, g \in K_A(\Omega)\) and suppose \(25.1.10\). Then
\[
A(|f + g|) = A \left( 2 \left( \frac{|f + g|}{2} \right) \right) \leq K_2 A \left( \frac{|f + g|}{2} \right) \leq K_2 \frac{1}{2} \left[ A(|f|) + A(|g|) \right]
\]
so \(f + g \in K_A(\Omega)\) in this case. Now suppose \(25.1.11\).
\[
\int_\Omega A(|f + g|) \, d\mu = \int_{|f + g| \leq M_2} A(|f + g|) \, d\mu + \int_{|f + g| > M_2} A(|f + g|) \, d\mu
\]
\[
\leq A(M_2) \mu(\Omega) + \int_\Omega \frac{K_2}{2} (A(|f|) + A(|g|)) \, d\mu < \infty.
\]
Thus \(f + g \in K_A(\Omega)\) in this case also.

Next consider scalar multiplication. First consider the case of \(25.1.10\). If \(f \in K_A(\Omega)\) and \(\alpha \in \mathbb{F}\),
\[
\int_\Omega A(|\alpha| |f|) \, d\mu \leq K_{|\alpha|} \int_\Omega A(|f|) \, d\mu
\]
so in the case of \(25.1.10\) \(\alpha f \in K_A(\Omega)\) whenever \(f \in K_A(\Omega)\). In the case of \(25.1.11\),
\[
\int_\Omega A(|\alpha| |f|) \, d\mu = \int_{|\alpha||f| \leq M_{|\alpha|}} A(|\alpha| |f|) \, d\mu + \int_{|\alpha||f| > M_{|\alpha|}} A(|\alpha| |f|) \, d\mu
\]
\[
\leq A(M_{|\alpha|}) \mu(\Omega) + \int_\Omega K_{|\alpha|} A(|f|) \, d\mu < \infty.
\]
This establishes the first part of the proposition.

Next consider the claim that \(L_A(\Omega)\) is always a vector space. First note \(K_A(\Omega)\) is always convex due to convexity of \(A\). Let \(\lambda u, \alpha v \in L_A(\Omega)\) where \(u, v \in K_A(\Omega)\) and let \(a, b\) be scalars in \(\mathbb{F}\). Then
\[
a\lambda u + b\alpha v = |\alpha\lambda| \omega u + |b\alpha| \theta v
\]
where \(|\omega| = |\theta| = 1\). Then
\[
= (|\alpha\lambda| + |b\alpha|) \left( \frac{|\alpha\lambda| \omega u + |b\alpha| \theta v}{|\alpha\lambda| + |b\alpha|} \right)
\]
which exhibits \(a\lambda u + b\alpha v\) as a multiple of a convex combination of two elements of \(K_A(\Omega)\), \(\omega u\) and \(\theta v\). Thus \(L_A(\Omega)\) is closed with respect to linear combinations. This shows it is a vector space. This proves the proposition.

The following norm for \(L_A(\Omega)\) is due to Luxemburg \([37\). You might compare this to the definition of a Minkowski functional. The definition of \(L_A(\Omega)\) above was cooked up so that the following norm does make sense.

**Definition 25.1.6** Define
\[
\|u\|_A = \|u\|_{A, \Omega} = \inf \left\{ t > 0 : \int_\Omega A \left( \frac{|u(x)|}{t} \right) \, d\mu \leq 1 \right\}.
\]
If two functions of $L_A(\Omega)$ are equal a.e. they are considered to be the same in the usual way.

**Proposition 25.1.7** The number defined in Definition 25.1.6 is a norm on $L_A(\Omega)$.

Also, if $\Omega_1 \subseteq \Omega$, then $\|u\|_{A,\Omega_1} \leq \|u\|_{A,\Omega}$.

**Proof:** Clearly $\|u\|_A \geq 0$. Is $\|u\|_A$ finite for $u \in L_A(\Omega)$? Let $u \in L_A(\Omega)$ so $u = \lambda v$ where $v \in K_A(\Omega)$. Then for $s > 0$

$$
\int_{\Omega} A\left(\frac{|u|}{s}\right) \, d\mu = \int_{\Omega} A\left(\frac{|v|}{s}\right) \, d\mu < \infty
$$

whenever $s > 1$. Therefore, from the dominated convergence theorem, if $s$ is large enough,

$$
\int_{\Omega} A\left(\frac{|u|}{s}\right) \, d\mu \leq 1
$$

and this shows there are values of $t > 0$ such that

$$
\int_{\Omega} A\left(\frac{|u(x)|}{t}\right) \, d\mu \leq 1.
$$

Thus $\|u\|_A$ is finite as hoped.

Now suppose $\|u\|_A = 0$ and let

$$
E_n = \left\{ x : |u(x)| \geq \frac{1}{n} \right\}.
$$

Then for arbitrarily small values of $t$,

$$
\int_{E_n} A\left(\frac{1/n}{t}\right) \, d\mu \leq \int_{\Omega} A\left(\frac{|u(x)|}{t}\right) \, d\mu \leq 1
$$

and so for arbitrarily small values of $t$,

$$
A\left(\frac{1/n}{t}\right) \mu(E_n) \leq 1.
$$

Letting $t \to 0+$ yields a contradiction unless $\mu(E_n) = 0$. Now

$$
\mu(|u(x)| > 0) \leq \sum_{n=1}^{\infty} \mu(E_n) = 0.
$$

Thus $u = 0$ as claimed.

Consider the other axioms of a norm. Let $u, v \in L_A(\Omega)$ and let $\alpha, \beta$ be scalars. Then

$$
\|\alpha u + \beta v\|_A = \inf \left\{ t > 0 : \int_{\Omega} A\left(\frac{|u(x) + v(x)|}{t}\right) \, d\mu \leq 1 \right\}
$$
Without loss of generality \( ||u||_A \cdot ||v||_A < \infty \) since otherwise there is nothing to prove.

\[
||u + v||_A \equiv \inf \left\{ t > 0 : \int_{\Omega} A \left( \frac{|\alpha u(x) + \beta v(x)|}{t} \right) \, d\mu \leq 1 \right\}.
\]

\[
\leq \inf \left\{ t > 0 : \int_{\Omega} A \left( \frac{|\alpha| |u| + |\beta| |v|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\}
\]

\[
= \inf \left\{ t > 0 : \int_{\Omega} A \left( \frac{|\alpha| |u|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\}
\]

\[
\leq \inf \left\{ t > 0 : \frac{|\alpha|}{|\alpha| + |\beta|} \int_{\Omega} A \left( \frac{|u|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\}
\]

\[
+ \inf \left\{ t > 0 : \frac{|\beta|}{|\alpha| + |\beta|} \int_{\Omega} A \left( \frac{|v|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\}
\]

\[
= |\alpha| \inf \left\{ t/(|\alpha| + |\beta|) > 0 : \int_{\Omega} A \left( \frac{|u|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\}
\]

\[
+ |\beta| \inf \left\{ t/(|\alpha| + |\beta|) > 0 : \int_{\Omega} A \left( \frac{|v|}{t/|\alpha| + |\beta|} \right) \, d\mu \leq 1 \right\} = |\alpha| ||u||_A + |\beta| ||v||_A.
\]

Now let \( \Omega_1 \subseteq \Omega \).

\[
||u||_{A,\Omega_1} = \inf \left\{ t > 0 : \int_{\Omega_1} A \left( \frac{|u(x)|}{t} \right) \, d\mu \leq 1 \right\}
\]

\[
\leq \inf \left\{ t > 0 : \int_{\Omega} A \left( \frac{|u(x)|}{t} \right) \, d\mu \leq 1 \right\} \equiv ||u||_{A,\Omega}.
\]

This occurs because if \( t \) is in the second set, then it is in the first so the infimum of the second is no smaller than that of the first. This proves the proposition.

Next it is shown that \( L_A(\Omega) \) is a Banach space.

**Theorem 25.1.8** \( L_A(\Omega) \) is a Banach space and every Cauchy sequence has a subsequence which also converges pointwise a.e.

**Proof:** Let \( \{f_n\} \) be a Cauchy sequence in \( L_A(\Omega) \) and select a subsequence \( \{f_{n_k}\} \) such that

\[
||f_{n_{k+1}} - f_{n_k}||_A \leq 2^{-k}.
\]

Thus

\[
f_{n_m}(x) = f_{n_1}(x) + \sum_{k=1}^{m-1} f_{n_{k+1}}(x) - f_{n_k}(x).
\]
LET

\[ g_m (x) \equiv |f_{n_1} (x)| + \sum_{k=1}^{m-1} |f_{n_{k+1}} (x) - f_{n_k} (x)|. \]

Then

\[ ||g_m||_A \leq ||f_{n_1}||_A + \sum_{k=1}^{\infty} 2^{-k} \equiv K < \infty. \]

Let

\[ g(x) \equiv \lim_{m \to \infty} g_m (x) \equiv |f_{n_1} (x)| + \sum_{k=1}^{\infty} |f_{n_{k+1}} (x) - f_{n_k} (x)|. \]

Now \( K > ||g_m||_A \) so

\[ 1 \geq \int_{\Omega} A \left( \frac{|g_m (x)|}{K} \right) d\mu. \]

By the monotone convergence theorem,

\[ 1 \geq \int_{\Omega} A \left( \frac{|g (x)|}{K} \right) d\mu \]

showing \( g (x) < \infty \) a.e., say for all \( x \notin E \) where \( E \) is a measurable set having measure zero. Let

\[ f (x) \equiv X_{EC} (x) \left( f_{n_1} (x) + \sum_{k=1}^{\infty} (f_{n_{k+1}} (x) - f_{n_k} (x)) \right) \]

\[ = \lim_{m \to \infty} X_{EC} (x) f_{n_m} (x). \]

Thus \( f \) is measurable and \( f_{n_m} (x) \to f (x) \) a.e. as \( m \to \infty \).

For \( l > k \),

\[ ||f_{n_k} - f_{n_l}||_A < \frac{1}{2^{k-2}} \]

and so

\[ 1 \geq \int_{\Omega} A \left( \frac{|f_{n_l} (x) - f_{n_k} (x)|}{\frac{1}{2^{k-2}}} \right) d\mu. \]

By Fatou's lemma, let \( l \to \infty \) and obtain

\[ 1 \geq \int_{\Omega} A \left( \frac{|f (x) - f_{n_k} (x)|}{\frac{1}{2^{k-2}}} \right) d\mu \]

and so \((f - f_{n_k}) 2^{k-2} \in K_A (\Omega) \) and so \( f - f_{n_k} \in L_A (\Omega) \), \( f_{n_k} \in L_A (\Omega) \). Since \( L_A (\Omega) \) is a vector space, this shows \( f \in L_A (\Omega) \). Also

\[ ||f - f_{n_k}||_A \leq \frac{1}{2^{k-2}}, \]
25.1. BASIC THEORY

showing that \( f_{n_k} \to f \) in \( L_A(\Omega) \). Since a subsequence converges in \( L_A(\Omega) \), it follows the original Cauchy sequence also converges to \( f \) in \( L_A(\Omega) \). This proves the theorem.

Next consider the space, \( E_A(\Omega) \) which will be a subspace of the Orlitz class, \( K_A(\Omega) \) just as \( L_A(\Omega) \) is a vector space containing the Orlitz class.

**Definition 25.1.9** Let \( S \) denote the set of simple functions, \( s \), such that \( \mu(\{x : s(x) \neq 0\}) < \infty \).

Then define

\[
E_A(\Omega) \equiv \text{the closure in } L_A(\Omega) \text{ of } S.
\]

**Proposition 25.1.10** \( E_A(\Omega) \subseteq K_A(\Omega) \subseteq L_A(\Omega) \) and they are all equal if \((A, \Omega)\) is \( \Delta \) regular.

**Proof:** First note that \( S \subseteq K_A(\Omega) \cap E_A(\Omega) \). Let \( f \in E_A(\Omega) \). Then by the definition of \( E_A(\Omega) \), there exists \( s_n \in S \) such that

\[
\|s_n - f\|_A \to 0.
\]

Therefore, for \( n \) large enough,

\[
\|s_n - f\|_A < \frac{1}{2}
\]

and so

\[
\int_{\Omega} A\left(\frac{|f - s_n|}{\frac{1}{2}}\right) d\mu = \int_{\Omega} A(2|f - 2s_n|) d\mu < \infty.
\]

Since \( S \subseteq K_A(\Omega) \),

\[
\int_{\Omega} A(2|s_n|) d\mu < \infty.
\]

Therefore, \( 2f - 2s_n \in K_A(\Omega) \) and \( 2s_n \in K_A(\Omega) \) and so, since \( K_A(\Omega) \) is convex,

\[
\frac{2f - 2s_n}{2} + \frac{2s_n}{2} = f \in K_A(\Omega).
\]

This shows \( E_A(\Omega) \subseteq K_A(\Omega) \).

Next consider the claim these spaces are all equal in the case that \((A, \Omega)\) is \( \Delta \) regular. It was already shown in Proposition 25.1.5 that in this case,

\[
K_A(\Omega) = L_A(\Omega)
\]

so it remains to show \( E_A(\Omega) = K_A(\Omega) \). Is every \( f \in K_A(\Omega) \) the limit in \( L_A(\Omega) \) of functions from \( S \)? First suppose \( \mu(\Omega) = \infty \). Then \( A(r|f|) \leq K_rA(|f|) \) and so \( A(r|f|) \in L^1(\Omega) \) for any \( r \). Let \( \epsilon > 0 \) be given and let

\[
\Omega_{\delta} = \{x : |f(x)| \geq \delta\}
\]
Then by the dominated convergence theorem,
\[
\lim_{\delta \to 0+} \int_{\Omega \setminus \Omega_\delta} A \left( \frac{|f|}{\varepsilon} \right) d\mu = 0.
\]
Choose \( \delta \) such that
\[
\int_{\Omega \setminus \Omega_\delta} A \left( \frac{|f|}{\varepsilon} \right) d\mu < \frac{1}{2}
\]
and let \( s_n \to f \chi_{\Omega_\delta} \) pointwise with \( |s_n| \leq |f \chi_{\Omega_\delta}| \). Then \( s_n = 0 \) on \( \Omega \setminus \Omega_\delta \) and so
\[
\int_{\Omega} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu = \int_{\Omega_\delta} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu + \int_{\Omega \setminus \Omega_\delta} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu + \frac{1}{2}.
\]
By the dominated convergence theorem,
\[
\int_{\Omega_\delta} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu < \frac{1}{2}
\]
for all \( n \) large enough. Therefore, for such \( n \),
\[
\int_{\Omega} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu < 1
\]
and so \( \|f - s_n\|_A \leq \varepsilon \) showing that in this case \( E_A (\Omega) \supseteq K_A (\Omega) \) since \( \varepsilon > 0 \) is arbitrary.

Now suppose \( \mu (\Omega) < \infty \). In this case, only assume \( A (rt) \leq K_A (t) \) for \( t \) large enough, say for \( t \geq M_r \). However, this is enough to conclude \( A (r |f|) \in L^1 (\Omega) \) for any \( r > 0 \) because \( \mu (\Omega) < \infty \) and \( f \in K_A (\Omega) \). Let \( s_n \to f \) pointwise with \( |s_n| \leq |f| \), and \( s \) simple. Then
\[
A \left( \frac{|f - s_n|}{\varepsilon} \right) \leq A \left( \frac{2}{\varepsilon} |f| \right) \in L^1 (\Omega)
\]
and so the dominated convergence theorem implies
\[
\lim_{n \to \infty} \int_{\Omega} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu = 0.
\]
Hence
\[
\int_{\Omega} A \left( \frac{|f - s_n|}{\varepsilon} \right) d\mu < 1
\]
for all \( n \) large enough and so for such \( n \),
\[
\|f - s_n\|_A \leq \varepsilon
\]
which proves the proposition.

It turns out \( E_A (\Omega) \) is the largest linear subspace of \( K_A (\Omega) \).
Proposition 25.1.11 \( E_A(\Omega) \) is the maximal linear subspace of \( K_A(\Omega) \).

**Proof:** Let \( M \) be a subspace of \( K_A(\Omega) \). Is \( M \subseteq E_A(\Omega) \)? For \( f \in M, f/\varepsilon \in K_A(\Omega) \) for all \( \varepsilon > 0 \) because of the fact that \( M \) is a subspace and \( f \in M \). Thus \( A(|f|/\varepsilon) \) is in \( L^1(\Omega) \). Let \( \varepsilon > 0 \) be given, choose \( \delta > 0 \) and let

\[
F_\delta \equiv \{x : |f(x)| \leq \delta\}
\]

By the dominated convergence theorem there exists \( \delta \) small enough that

\[
\int_{F_\delta} A\left(\frac{|f|}{\varepsilon}\right) \, d\mu < \frac{1}{2}.
\]

Let \( |s_n| \leq |f| \chi_{F_\delta^C} \) and \( s_n \to f \chi_{F_\delta^C} \) pointwise for \( s_n \) a simple function. Thus \( s_n = 0 \) on \( F_\delta \) and so \( s_n \in \mathcal{S} \) because \( \mu(F_\delta^C) < \infty \). Now

\[
\int_{\Omega} A\left(\frac{|f-s_n|}{\varepsilon}\right) \, d\mu = \int_{F_\delta} A\left(\frac{|f|}{\varepsilon}\right) \, d\mu + \int_{F_\delta^C} A\left(\frac{|f-s_n|}{\varepsilon}\right) \, d\mu
\]

\[
< \frac{1}{2} + \int_{F_\delta^C} A\left(\frac{|f-s_n|}{\varepsilon}\right) \, d\mu.
\]

The integrand in the last integral is no larger than \( \frac{2|f|}{\varepsilon} \) and so by the dominated convergence theorem, this integral converges to 0 as \( n \to \infty \). In particular, it is eventually less than \( \frac{1}{2} \). Therefore, for such \( n \),

\[
||f-s_n||_A \leq r.
\]

Since \( r \) is arbitrary, this shows that \( f \in E_A(\Omega) \) which proves the proposition.

Next is a comparison of these function spaces for different choices of the \( N \) function. The notation \( X \leftrightarrow Y \) for two normed linear spaces means \( X \) is a subset of \( Y \) and the identity map is continuous.

**Proposition 25.1.12** \( L_B(\Omega) \leftrightarrow L_A(\Omega) \) if either

\[
B(t) \geq A(t) \text{ for all } t \geq 0 \quad (25.1.12)
\]

or if

\[
B(t) \geq A(t) \text{ for all } t > M \quad (25.1.13)
\]

and \( \mu(\Omega) < \infty \).

**Proof:** Let \( f \in L_B(\Omega) \) and let

\[
\int_{\Omega} B\left(\frac{|f|}{t}\right) \, d\mu \leq 1.
\]

Then if \( 25.1.12 \) holds, it follows

\[
\int_{\Omega} A\left(\frac{|f|}{t}\right) \, d\mu \leq 1.
\]
Thus if \( t \geq ||f||_B \) then \( t \geq ||f||_A \) which implies \( ||f||_B \geq ||f||_A \).

Now suppose Corollary 25.1.13 holds and \( \mu (\Omega) < \infty \). Then \( \max (A, B) \) is an \( N \) function dominating both \( A \) and \( B \) for all \( t \). By what was just shown \( L_{\max(A,B)} (\Omega) \hookrightarrow L_B (\Omega) \). Then let \( f \in L_B (\Omega) \) and let

\[
\int_\Omega B \left( \frac{|f|}{t} \right) d\mu < 1.
\]

Then

\[
\int_\Omega \max (A, B) \left( \frac{|f|}{t} \right) d\mu = \int_{|\frac{|f|}{\mu} > M} B \left( \frac{|f|}{t} \right) d\mu
\]

\[
+ \int_{|\frac{|f|}{\mu} \leq M} \max (A, B) \left( \frac{|f|}{t} \right) d\mu
\]

\[
\leq \int_\Omega B \left( \frac{|f|}{t} \right) d\mu + \mu (\Omega) \max (A, B) (M) < \infty.
\]

It follows \( \frac{|f|}{\mu} \in K_{\max(A,B)} (\Omega) \) and so \( f \in L_{\max(A,B)} (\Omega) \). Hence \( L_B (\Omega) = L_{\max(A,B)} (\Omega) \) and the identity map from \( L_{\max(A,B)} (\Omega) \) to \( L_B (\Omega) \) is continuous. Therefore, by the open mapping theorem, the norms \( || ||_B \) and \( || ||_{\max(A,B)} \) are equivalent. Hence

\[
||f||_A \leq ||f||_{\max(A,B)} \leq C ||f||_B.
\]

This proves the proposition.

**Corollary 25.1.13** Suppose there exists \( C > 0 \), a constant such that either

\[
CB (t) \geq A (t)
\]

for all \( t \geq 0 \) or

\[
CB (t) \geq A (t)
\]

for all \( t > M \) and \( \mu (\Omega) < \infty \). Then

\[
L_B (\Omega) \hookrightarrow L_A (\Omega).
\]

**Proof:** If \( f \in L_B (\Omega) \) then \( f = \lambda u \) where \( u \in K_B (\Omega) = K_{CB} (\Omega) \). Hence \( L_{CB} (\Omega) = L_B (\Omega) \) and the two norms on \( L_B (\Omega) \),

\[
|| ||_{CB} \quad \text{and} \quad || ||_B,
\]

are equivalent norms by the open mapping theorem. Hence by the Proposition 25.1.12, if \( f \in L_B (\Omega) \),

\[
||f||_A \leq C_1 ||f||_{CB} \leq C_2 ||f||_B
\]

which proves the corollary.
\textbf{Definition 25.1.14} A increases essentially more slowly than B if for all \( a > 0 \),

\[
\lim_{t \to \infty} \frac{A(at)}{B(t)} = 0
\]

The next theorem gives added information on how these spaces are related in case that one \( N \) function increases essentially more slowly than the other.

\textbf{Theorem 25.1.15} Suppose \( \mu(\Omega) < \infty \) and \( A \) increases essentially more slowly than \( B \). Then

\[ L_B(\Omega) \hookrightarrow E_A(\Omega) \]

\textbf{Proof:} Let \( f \in L_B(\Omega) \). Then there exists \( \lambda > 0 \) such that

\[
\int_{\Omega} B\left(\frac{|f|}{\lambda}\right) d\mu \leq 1.
\]

Let \( r \) be such that for \( t \geq r \),

\[ A(|\lambda| t) \leq B(t). \]

Then

\[
\int_{\Omega} A(|f|) d\mu = \int_{|f| \geq r} A(|f|) d\mu + \int_{|f| < r} A(|f|) d\mu
\]

\[ \leq \int_{\Omega} B\left(\frac{|f|}{|\lambda|}\right) d\mu + A(r) \mu(\Omega)
\]

\[ < 1 + A(r) \mu(\Omega). \]

Therefore, \( L_B(\Omega) \) is a linear space contained in \( K_A(\Omega) \). It follows from Proposition \( 25.1.11 \) that \( L_B(\Omega) \subseteq E_A(\Omega) \). This proves the theorem.

The norm of \( E_A(\Omega) \) is the same as the norm on \( L_A(\Omega) \) so this shows \( L_B(\Omega) \hookrightarrow L_A(\Omega) \).

Note that for \( 1 < p < q \) and \( A(t) = t^p/p, B(t) = t^q/q, \)

\[ A(rt) = r^p t^p \]

and

\[ \lim_{t \to \infty} \frac{A(rt)}{B(t)} = 0 \]

showing this case is covered by the above theorem.

If \( A \) is increasing essentially more slowly than \( B \) and \( \mu(\Omega) < \infty \), this has shown the following inclusions

\[ E_B(\Omega) \subseteq K_B(\Omega) \subseteq L_B(\Omega) \hookrightarrow E_A(\Omega) \subseteq K_A(\Omega) \subseteq L_A(\Omega). \]

In the case of \( A(t) = t^p/p, B(t) = t^q/q \) both \( (A, \Omega) \) and \( (B, \Omega) \) are \( \Delta \) regular and so in this case or any other case where the \( N \) functions are \( \Delta \) regular, the above sequence of inclusions reduces to

\[ E_B(\Omega) = K_B(\Omega) = L_B(\Omega) \hookrightarrow E_A(\Omega) = K_A(\Omega) = L_A(\Omega). \]
25.2 Dual Spaces In Orlicz Space

Recall that for $s, t \geq 0$,

$$st \leq A(t) + \tilde{A}(s).$$

Let $v \in L_{\tilde{A}}(\Omega)$ and $u \in L_A(\Omega)$. Then there is a version of Holder’s inequality as follows. For $\varepsilon > 0$,

$$\frac{|v|}{||v||_{\tilde{A}} + \varepsilon} \in K_{\tilde{A}}(\Omega), \quad \frac{|u|}{||u||_A + \varepsilon} \in K_A(\Omega).$$

Therefore,

$$\int_{\Omega} \left( \frac{|u|}{||u||_A + \varepsilon} \right) \left( \frac{|v|}{||v||_{\tilde{A}} + \varepsilon} \right) d\mu \leq \int_{\Omega} A \left( \frac{|u|}{||u||_A + \varepsilon} \right) d\mu$$

$$+ \int_{\Omega} \tilde{A} \left( \frac{|v|}{||v||_{\tilde{A}} + \varepsilon} \right) d\mu \leq 2$$

and so $uv \in L^1(\Omega)$ and

$$\left| \int_{\Omega} uv d\mu \right| \leq \int_{\Omega} |u| |v| d\mu \leq 2 (||v||_{\tilde{A}} + \varepsilon) (||u||_A + \varepsilon).$$

Since $\varepsilon$ is arbitrary this shows

$$\left| \int_{\Omega} uv d\mu \right| \leq \int_{\Omega} |u| |v| d\mu \leq 2 ||v||_{\tilde{A}} ||u||_A. \quad (25.2.14)$$

Defining $L_v$ for $v \in \tilde{A}$ by

$$L_v(u) \equiv \int_{\Omega} uv d\mu,$$

it follows $L_v \in L_A(\Omega)^\prime$. From now on assume the measure space is $\sigma$ finite. That is, there exist measurable sets, $\Omega_k$ satisfying the following:

$$\Omega = \bigcup_{k=1}^\infty \Omega_k, \quad \mu(\Omega_k) < \infty, \quad \Omega_k \subseteq \Omega_{k+1}.$$

Then

**Proposition 25.2.1** For $v \in L_{\tilde{A}}(\Omega)$, the following inequality holds.

$$||v||_{\tilde{A}} \leq ||L_v|| \leq 2 ||v||_{\tilde{A}}.$$

Here $L_v$ is considered as either an element of $E_A(\Omega)^\prime$ or $L_A(\Omega)^\prime$ and $||L_v||$ refers to the operator norm in either dual space.
25.2. Dual Spaces in Orlicz Space

**Proof:** The inequality (25.2.14) implies \( ||L_v|| \leq 2 ||v||_A \). It remains to show the other half of the inequality. If \( L_v = 0 \) there is nothing to show because this would imply that \( v = 0 \) so assume \( ||L_v|| > 0 \). Define a measurable function, \( u \), as follows. Letting \( r \in (0, 1) \),

\[
u(x) = \begin{cases} 
\tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) / \frac{r v(x)}{||L_v||} & \text{if } v(x) \neq 0 \\
0 & \text{if } v(x) = 0.
\end{cases}
\] (25.2.15)

Now let

\[ F_n \equiv \{ x : |u(x)| \leq n \} \cap \Omega_n \cap \{ x : v(x) \neq 0 \} \] (25.2.16)

and define

\[ u_n(x) \equiv u(x) \chi_{F_n}(x) . \] (25.2.17)

Thus \( u_n \) is bounded and equals zero off a set which has finite measure. It follows that

\[ A \left( \frac{|u_n|}{A} \right) \in L^1(\Omega) \]

for all \( \alpha > 0 \). I claim that \( ||u_n||_A \leq 1 \). If not, there exists \( \varepsilon > 0 \) such that \( ||u_n||_A - \varepsilon > 1 \). Then since \( A \) is convex,

\[
1 < \int_\Omega A \left( \frac{|u_n|}{||u_n||_A - \varepsilon} \right) d\mu \leq \frac{1}{||u_n||_A - \varepsilon} \int_\Omega A (|u_n|) d\mu.
\]

Taking \( \varepsilon \to 0^+ \), using (25.2.14) and convexity of \( A \) along with (25.2.15) and (25.2.16),

\[
||u_n||_A \leq \int_\Omega A (|u_n|) d\mu = \int_{F_n} A \left( r \tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) \right) d\mu \\
\leq r \int_{F_n} A \left( \tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) \right) d\mu \\
= r \frac{1}{||L_v||} \int_{F_n} u_n(x) v(x) d\mu \\
\leq r \frac{1}{||L_v||} ||u_n||_A ||L_v|| = r ||u_n||_A ,
\]

a contradiction since \( r < 1 \). Therefore, from (25.2.15),

\[
||L_v|| \geq |L_v(u_n)| = \int_{F_n} v(x) u(x) d\mu = ||L_v|| \int_{F_n} \tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) d\mu
\]

and so

\[
1 \geq \int_{F_n} \tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) d\mu
\]

By the monotone convergence theorem, letting \( n \to \infty \),

\[
1 \geq \int_\Omega \tilde{A} \left( \frac{r |v(x)|}{||L_v||} \right) d\mu
\]

showing that

\[
||v||_A \leq \frac{||L_v||}{r} .
\]
Since this holds for all $r \in (0,1)$, it follows $\|L_v\| \geq \|v\|_{\tilde{A}}$ as claimed. This proves the proposition.

Now what follows is the Riesz representation theorem for the dual space of $E_A(\Omega)$.

**Theorem 25.2.2** Suppose $\mu(\Omega) < \infty$ and suppose $L \in E_A(\Omega)'$. Then the map $v \mapsto L_v$ from $L_{\tilde{A}}(\Omega)$ to $E_A(\Omega)'$ is one to one continuous, linear, and onto. If $(\Omega, A)$ is $\Delta$ regular then $v \mapsto L_v$ is one to one, linear, onto and continuous as a map from $L_{\tilde{A}}(\Omega)$ to $L_A(\Omega)'$.

**Proof:** It is obvious this map is linear. From Proposition 25.2.1 it is continuous and one-to-one. It remains only to verify that it is onto. Let $L \in E_A(\Omega)'$ and define a complex valued function, $\lambda$, mapping the measurable sets to $\mathbb{C}$ as follows.

$$\lambda(F) \equiv L(\chi_F).$$

In case $\mu(F) \neq 0$,

$$\int_{\Omega} A \left( \chi_F(x) A^{-1} \left( \frac{1}{\mu(F)} \right) \right) d\mu = \int_F A \left( A^{-1} \left( \frac{1}{\mu(F)} \right) \right) d\mu = \frac{1}{\mu(F)} d\mu = 1$$

and so

$$\|\chi_F\|_A \leq \frac{1}{A^{-1} \left( \frac{1}{\mu(F)} \right)}.$$  \hspace{1cm} (25.2.18)

In fact, $\lambda$ is actually a complex measure. To see this, suppose $F_i \uparrow F$. Then from the formula just derived,

$$\|\chi_{F_i} - \chi_F\|_A = \|\chi_{F_i \setminus F}\|_A \leq \frac{1}{A^{-1} \left( \frac{1}{\mu(F_i \setminus F)} \right)}$$

which converges to zero as $i \to \infty$. Therefore, if the $F_i$ are disjoint and $F = \cup_{i=1}^{\infty} F_i$, let $S_m = \cup_{i=1}^{m} F_i$ so that $S_m \uparrow F$. Then since $\chi_{S_m} \to \chi_F$ in $E_A(\Omega)$ and $L$ is continuous,

$$\lambda(F) = \lim_{m \to \infty} L(\chi_{S_m}) = \lim_{m \to \infty} \sum_{i=1}^{m} L(\chi_{F_i}) = \sum_{i=1}^{\infty} \lambda(F_i).$$

Next observe that $\lambda$ is absolutely continuous with respect to $\mu$. To see this, suppose $\mu(F) = 0$. Then if $t > 0$,

$$\int_{\Omega} A \left( \frac{\chi_F(x)}{t} \right) d\mu = 0 < 1$$
for all \( t > 0 \) and so \( \| \mathcal{X}_F \|_A = 0 \). Therefore, \( \lambda(F) \equiv L(\mathcal{X}_F) = 0 \).

It follows by the Radon Nikodym theorem there exists \( v \in L^1(\Omega) \) such that

\[
L(\mathcal{X}_F) = \lambda(F) = \int_F v d\mu.
\]

Therefore, for all \( s \in S \),

\[
L(s) = \int_F s v d\mu. \quad (25.2.19)
\]

I need to show that \( v \) is actually in \( L^1_1(\Omega) \). If \( v = 0 \) a.e., there is nothing to prove so assume this is not so. Let \( u \) be defined by.

\[
u(x) \equiv \begin{cases} \tilde{A} \left( \frac{r |v(x)|}{||L||} \right) / \frac{v(x)}{||L||} & \text{if } v(x) \neq 0 \\ 0 & \text{if } v(x) = 0. \end{cases} \quad (25.2.20)
\]

for \( r \in (0,1) \). Now let

\[
F_n \equiv \{ x : |u(x)| \leq n \} \cap \{ x : v(x) \neq 0 \} \quad (25.2.21)
\]

and define

\[
u_n(x) \equiv u(x) \mathcal{X}_{F_n}(x). \quad (25.2.22)
\]

I claim \( \| u_n \|_A \leq 1 \). It is clear that since \( \mu(\Omega) < \infty \), \( u_n \in E_A(\Omega) \). If \( \| u_n \|_A > 1 \), then for \( \varepsilon \) small enough,

\[
\| u_n \|_A - \varepsilon > 1
\]

and so, by convexity of \( A \) and the fact that \( A(0) = 0 \),

\[
1 \leq \int_\Omega A \left( \frac{|u_n(x)|}{||u_n||_A - \varepsilon} \right) d\mu \leq \frac{1}{||u_n||_A - \varepsilon} \int_\Omega A(|u_n(x)|) d\mu
\]

and so, letting \( \varepsilon \to 0^+ \) and using \( 25.1.6 \) and convexity of \( A \) as in the proof of the preceding proposition,

\[
\| u_n \|_A \leq \int_\Omega A(|u_n(x)|) d\mu \leq \int_{F_n} A \left( \frac{r |v(x)|}{||L||} \right) / \frac{r |v(x)|}{||L||} d\mu \leq r \int_{F_n} \tilde{A} \left( \frac{r |v(x)|}{||L||} \right) d\mu \leq r \int_{F_n} u(x) v(x) d\mu = \frac{1}{||L||} \int_{F_n} u(x) v(x) d\mu = \frac{r}{||L||} \int_\Omega u_n v d\mu. \quad (25.2.23)
\]

Now by Theorem 4.6.6 applied to the positive and negative parts of real and imaginary parts, there exists a uniformly bounded sequence of simple functions, \( \{ s_k \} \) converging uniformly to \( u_n \), implying convergence in \( E_A(\Omega) \), and so

\[
Lu_n = \lim_{k \to \infty} Ls_k = \lim_{k \to \infty} \int s_k v d\mu = \int u_n v d\mu. \quad (25.2.24)
\]
therefore, from \(25.2.23\),
\[
\|u_n\|_A \leq \frac{r}{\|L\|} \int_{\Omega} u_n v d\mu = \frac{r}{\|L\|} L(u_n) \leq \frac{r}{\|L\|} \|L\| \|u_n\|_A,
\]
which is a contradiction since \(r < 1\). Therefore, \(\|u_n\|_A \leq 1\) and from \(25.2.23\),
\[
\|L\| \geq \|L\| \|u_n\|_A \geq |Lu_n| = \int_{\Omega} u_n v d\mu
\]
\[
\geq \|L\| \int_{F_n} \tilde{A} \left( \frac{r |v(x)|}{\|L\|} \right) d\mu.
\]
Letting \(n \to \infty\) the monotone convergence theorem and the above imply
\[
\int_{\Omega} \tilde{A} \left( \frac{r |v(x)|}{\|L\|} \right) d\mu \leq 1
\]
which shows that \(v \in L_{\tilde{A}}(\Omega)\) and \(\|v\|_{L_{\tilde{A}}} \leq \frac{\|L\|}{r}\) for all \(r \in (0,1)\). Therefore, \(\|v\|_{L_{\tilde{A}}} \leq \|L\|\).

Since \(v \in L_{\tilde{A}}(\Omega)\) it follows \(L_v = L\) on \(S\) and so \(L_v = L\) because \(S\) is dense in \(E_A(\Omega)\). The last assertion follows from Proposition \(25.1.10\). This completes the proof.
Chapter 26

Hausdorff Measure

26.1 Definition Of Hausdorff Measures

This chapter is on Hausdorff measures. First I will discuss some outer measures. In all that is done here, \( \alpha(n) \) will be the volume of the ball in \( \mathbb{R}^n \) which has radius 1.

**Definition 26.1.1** For a set \( E \), denote by \( r(E) \) the number which is half the diameter of \( E \). Thus

\[
r(E) = \frac{1}{2} \sup \{|x - y| : x, y \in E\} = \frac{1}{2} \text{diam}(E)
\]

Let \( E \subseteq \mathbb{R}^n \).

\[
\mathcal{H}_s^\delta(E) = \inf \{ \sum_{j=1}^{\infty} \beta(s)(r(C_j))^s : E \subseteq \bigcup_{j=1}^{\infty} C_j, \text{diam}(C_j) \leq \delta \}
\]

\[
\mathcal{H}^s(E) = \lim_{\delta \to 0^+} \mathcal{H}_s^\delta(E).
\]

Note that \( \mathcal{H}_s^\delta(E) \) is increasing as \( \delta \to 0^+ \) so the limit clearly exists.

In the above definition, \( \beta(s) \) is an appropriate positive constant depending on \( s \). It will turn out that for \( n \) an integer, \( \beta(n) = \alpha(n) \) where \( \alpha(n) \) is the Lebesgue measure of the unit ball, \( B(0,1) \) where the usual norm is used to determine this ball.

**Lemma 26.1.2** \( \mathcal{H}^s \) and \( \mathcal{H}_s^\delta \) are outer measures.

**Proof:** It is clear that \( \mathcal{H}^s(\emptyset) = 0 \) and if \( A \subseteq B \), then \( \mathcal{H}^s(A) \leq \mathcal{H}^s(B) \) with similar assertions valid for \( \mathcal{H}_s^\delta \). Suppose \( E = \bigcup_{i=1}^{\infty} E_i \) and \( \mathcal{H}_s^\delta(E_i) < \infty \) for each \( i \). Let \( \{C_j^i\}_{j=1}^{\infty} \) be a covering of \( E_i \) with

\[
\sum_{j=1}^{\infty} \beta(s)(r(C_j^i))^s - \varepsilon/2^i < \mathcal{H}_s^\delta(E_i)
\]
and \( \text{diam}(C_j^i) \leq \delta \). Then
\[
\mathcal{H}_s^\delta (E) \leq \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \beta(s)(r(C_j^i))^s \\
\leq \sum_{i=1}^{\infty} \mathcal{H}_s^\delta (E_i) + \varepsilon/2^i \\
\leq \varepsilon + \sum_{i=1}^{\infty} \mathcal{H}_s^\delta (E_i).
\]
It follows that since \( \varepsilon > 0 \) is arbitrary,
\[
\mathcal{H}_s^\delta (E) \leq \sum_{i=1}^{\infty} \mathcal{H}_s^\delta (E_i)
\]
which shows \( \mathcal{H}_s^\delta \) is an outer measure. Now notice that \( \mathcal{H}_s^\delta (E) \) is increasing as \( \delta \to 0 \). Picking a sequence \( \delta_k \) decreasing to 0, the monotone convergence theorem implies
\[
\mathcal{H}^s (E) \leq \sum_{i=1}^{\infty} \mathcal{H}^s (E_i) .
\]
The outer measure \( \mathcal{H}^s \) is called \( s \) dimensional Hausdorff measure when restricted to the \( \sigma \) algebra of \( \mathcal{H}^s \) measurable sets.

Next I will show the \( \sigma \) algebra of \( \mathcal{H}^s \) measurable sets includes the Borel sets. This is done by the following very interesting condition known as Caratheodory’s criterion.

26.1.1 Properties Of Hausdorff Measure

**Definition 26.1.3** For two sets, \( A, B \) in a metric space, we define
\[
\text{dist} (A, B) \equiv \inf \{d(x, y) : x \in A, y \in B \}.
\]

**Theorem 26.1.4** Let \( \mu \) be an outer measure on the subsets of \( (X, d) \), a metric space. If
\[
\mu(A \cup B) = \mu(A) + \mu(B)
\]
whenever \( \text{dist}(A, B) > 0 \), then the \( \sigma \) algebra of measurable sets contains the Borel sets.

**Proof:** It suffices to show that closed sets are in \( \mathcal{S} \), the \( \sigma \)-algebra of measurable sets, because then the open sets are also in \( \mathcal{S} \) and consequently \( \mathcal{S} \) contains the Borel sets. Let \( K \) be closed and let \( S \) be a subset of \( \Omega \). Is \( \mu(S) \geq \mu(S \cap K) + \mu(S \setminus K) \)? It suffices to assume \( \mu(S) < \infty \). Let
\[
K_n \equiv \{ x : \text{dist}(x, K) \leq \frac{1}{n} \}
\]
26.1. DEFINITION OF HAUSDORFF MEASURES

By Lemma 6.1.7 on Page 145, \( x \to \text{dist}(x, K) \) is continuous and so \( K_n \) is closed. By the assumption of the theorem,

\[
\mu(S) \geq \mu((S \cap K) \cup (S \setminus K_n)) = \mu(S \cap K) + \mu(S \setminus K_n)
\]

since \( S \cap K \) and \( S \setminus K_n \) are a positive distance apart. Now

\[
\mu(S \setminus K_n) \leq \mu(S \setminus K) \leq \mu(S \setminus K_n) + \mu((K_n \setminus K) \cap S).
\]

If \( \lim_{n \to \infty} \mu((K_n \setminus K) \cap S) = 0 \) then the theorem will be proved because this limit along with (26.1.2) implies \( \lim_{n \to \infty} \mu(S \setminus K_n) = \mu(S \setminus K) \) and then taking a limit in (26.1.1), \( \mu(S) \geq \mu(S \cap K) + \mu(S \setminus K) \) as desired. Therefore, it suffices to establish this limit.

Since \( K \) is closed, a point, \( x \notin K \) must be at a positive distance from \( K \) and so

\[
K_n \setminus K = \bigcup_{k=n}^{\infty} K_k \setminus K_{k+1}.
\]

Therefore

\[
\mu(S \cap (K_n \setminus K)) \leq \sum_{k=n}^{\infty} \mu(S \cap (K_k \setminus K_{k+1})).
\]

If

\[
\sum_{k=1}^{\infty} \mu(S \cap (K_k \setminus K_{k+1})) < \infty,
\]

then \( \mu(S \cap (K_n \setminus K)) \to 0 \) because it is dominated by the tail of a convergent series so it suffices to show (26.1.4).

\[
\sum_{k=1}^{M} \mu(S \cap (K_k \setminus K_{k+1})) =
\]

\[
\sum_{k \text{ even}, k \leq M} \mu(S \cap (K_k \setminus K_{k+1})) + \sum_{k \text{ odd}, k \leq M} \mu(S \cap (K_k \setminus K_{k+1})).
\]

By the construction, the distance between any pair of sets, \( S \cap (K_k \setminus K_{k+1}) \) for different even values of \( k \) is positive and the distance between any pair of sets, \( S \cap (K_k \setminus K_{k+1}) \) for different odd values of \( k \) is positive. Therefore,

\[
\sum_{k \text{ even}, k \leq M} \mu(S \cap (K_k \setminus K_{k+1})) + \sum_{k \text{ odd}, k \leq M} \mu(S \cap (K_k \setminus K_{k+1})) \leq
\]

\[
\mu( \bigcup_{k \text{ even}} S \cap (K_k \setminus K_{k+1})) + \mu( \bigcup_{k \text{ odd}} S \cap (K_k \setminus K_{k+1})) \leq 2\mu(S) < \infty
\]

and so for all \( M, \sum_{k=1}^{M} \mu(S \cap (K_k \setminus K_{k+1})) \leq 2\mu(S) \) showing (26.1.4).

With the above theorem, the following theorem is easy to obtain.

**Theorem 26.1.5** The \( \sigma \)-algebra of \( \mathcal{H}^a \) measurable sets contains the Borel sets and \( \mathcal{H}^a \) has the property that for all \( E \subseteq \mathbb{R}^n \), there exists a Borel set \( F \supseteq E \) such that \( \mathcal{H}^a(F) = \mathcal{H}^a(E) \).
**Proof:** Let \( \text{dist}(A, B) = 2\delta_0 > 0 \). Is it the case that
\[
\mathcal{H}^s(A) + \mathcal{H}^s(B) = \mathcal{H}^s(A \cup B)?
\]
This is what is needed to use Caratheodory’s criterion.

Let \( \{C_j\}_{j=1}^{\infty} \) be a covering of \( A \cup B \) such that \( \text{diam}(C_j) \leq \delta < \delta_0 \) for each \( j \) and
\[
\mathcal{H}^s_\delta(A \cup B) + \varepsilon > \sum_{j=1}^{\infty} \beta(s)(r(C_j))^s.
\]
Thus
\[
\mathcal{H}^s_\delta(A \cup B) + \varepsilon > \sum_{j \in J_1} \beta(s)(r(C_j))^s + \sum_{j \in J_2} \beta(s)(r(C_j))^s
\]
where
\[
J_1 = \{j : C_j \cap A \neq \emptyset\}, \quad J_2 = \{j : C_j \cap B \neq \emptyset\}.
\]
Recall \( \text{dist}(A, B) = 2\delta_0 \), \( J_1 \cap J_2 = \emptyset \). It follows
\[
\mathcal{H}^s_\delta(A \cup B) + \varepsilon > \mathcal{H}^s_\delta(A) + \mathcal{H}^s_\delta(B).
\]
Letting \( \delta \to 0 \), and noting \( \varepsilon > 0 \) was arbitrary, yields
\[
\mathcal{H}^s(A \cup B) \geq \mathcal{H}^s(A) + \mathcal{H}^s(B).
\]
Equality holds because \( \mathcal{H}^s \) is an outer measure. By Caratheodory’s criterion, \( \mathcal{H}^s \) is a Borel measure.

To verify the second assertion, note first there is no loss of generality in letting \( \mathcal{H}^s(E) < \infty \). Let
\[
E \subseteq \bigcup_{j=1}^{\infty} C_j, \quad r(C_j) < \delta,
\]
and
\[
\mathcal{H}^s_\delta(E) + \varepsilon > \sum_{j=1}^{\infty} \beta(s)(r(C_j))^s.
\]
Let
\[
F_\delta = \bigcup_{j=1}^{\infty} \overline{C_j}.
\]
Thus \( F_\delta \supseteq E \) and
\[
\mathcal{H}^s_\delta(E) \leq \mathcal{H}^s_\delta(F_\delta) \leq \sum_{j=1}^{\infty} \beta(s)(r(C_j))^s = \sum_{j=1}^{\infty} \beta(s)(r(C_j))^s < \mathcal{H}^s_\delta(E).
\]
Let \( \delta_k \to 0 \) and let \( F = \bigcap_{k=1}^{\infty} F_{\delta_k} \). Then \( F \supseteq E \) and
\[
\mathcal{H}^s_{\delta_k}(E) \leq \mathcal{H}^s_{\delta_k}(F) \leq \mathcal{H}^s_{\delta_k}(F_\delta) \leq \delta_k + \mathcal{H}^s_{\delta_k}(E).
\]
Letting \( k \to \infty \),
\[
\mathcal{H}^s(E) \leq \mathcal{H}^s(F) \leq \mathcal{H}^s(E).
\]
A measure satisfying the conclusion of Theorem 26.1.5 is called a Borel regular measure.
26.2 \( \mathcal{H}^n \) And \( m_n \)

Next I will compare \( \mathcal{H}^n \) and \( m_n \). To do this, recall the following covering theorem which is a summary of Corollaries 26.2.1 and 26.2.2 found on Page 981.

**Theorem 26.2.1** Let \( E \subseteq \mathbb{R}^n \) and let \( \mathcal{F} \) be a collection of balls of bounded radii such that \( \mathcal{F} \) covers \( E \) in the sense of Vitali. Then there exists a countable collection of disjoint balls from \( \mathcal{F} \), \( \{B_j\}_{j=1}^\infty \), such that \( \mathcal{H}_n(E \setminus \bigcup_{j=1}^\infty B_j) = 0 \).

In the next lemma, the balls are the usual balls taken with respect to the usual distance in \( \mathbb{R}^n \).

**Lemma 26.2.2** If \( m_n(S) = 0 \) then \( \mathcal{H}^n(S) = \mathcal{H}_2^n(S) = 0 \). Also, there exists a constant, \( k \) such that \( \mathcal{H}^n(E) \leq km_n(E) \) for all \( E \) Borel. Also, if \( Q_0 = [0,1]^n \), the unit cube, then \( \mathcal{H}^n([0,1]^n) > 0 \).

**Proof:** Suppose first \( m_n(S) = 0 \). Without loss of generality, \( S \) is bounded. Then by outer regularity, there exists a bounded open \( V \) containing \( S \) and \( m_n(V) < \varepsilon \). For each \( x \in S \), there exists a ball \( B_x \) such that \( \widetilde{B}_x \subseteq V \) and \( \delta > r(\widetilde{B}_x) \). By the Vitali covering theorem there is a sequence of disjoint balls \( \{B_k\} \) such that \( \{\widetilde{B}_k\} \) covers \( S \). Here \( \widetilde{B}_k \) has the same center as \( B_k \) but 5 times the radius. Then letting \( \alpha(n) \) be the Lebesgue measure of the unit ball in \( \mathbb{R}^n \)

\[
\mathcal{H}_2^n(S) \leq \sum_k \beta(n) r(\widetilde{B}_k)^n = \frac{\beta(n)}{\alpha(n)} 5^n \sum_k \alpha(n) r(B_k)^n \\
\leq \frac{\beta(n)}{\alpha(n)} 5^n m_n(V) < \frac{\beta(n)}{\alpha(n)} 5^n \varepsilon
\]

Since \( \varepsilon \) is arbitrary, this shows \( \mathcal{H}_2^n(S) = 0 \) and now it follows \( \mathcal{H}^n(S) = 0 \).

Letting \( U \) be an open set and \( \delta > 0 \), consider all balls \( B \) contained in \( U \) which have diameters less than \( \delta \). This is a Vitali covering of \( U \) and therefore by Theorem 26.2.1, there exists \( \{B_i\} \), a sequence of disjoint balls of radii less than \( \delta \) contained in \( U \) such that \( \bigcup_{i=1}^\infty B_i \) differs from \( U \) by a set of Lebesgue measure zero. Let \( \alpha(n) \) be the Lebesgue measure of the unit ball in \( \mathbb{R}^n \). Then from what was just shown,

\[
\mathcal{H}_2^n(U) = \mathcal{H}_2^n(\bigcup_i B_i) \leq \sum_{i=1}^\infty \beta(n) r(B_i)^n = \frac{\beta(n)}{\alpha(n)} \sum_{i=1}^\infty \alpha(n) r(B_i)^n \\
= \frac{\beta(n)}{\alpha(n)} \sum_{i=1}^\infty m_n(B_i) = \frac{\beta(n)}{\alpha(n)} m_n(U) = km_n(U), \ k = \frac{\beta(n)}{\alpha(n)}
\]

Now letting \( E \) be Borel, it follows from the outer regularity of \( m_n \) there exists a decreasing sequence of open sets, \( \{V_i\} \) containing \( E \) such that \( m_n(V_i) \to m_n(E) \). Then from the above,

\[
\mathcal{H}_2^n(E) \leq \lim_{i \to \infty} \mathcal{H}_2^n(V_i) \leq \lim_{i \to \infty} km_n(V_i) = km_n(E).
\]
Since \( \delta > 0 \) is arbitrary, it follows that also

\[
\mathcal{H}^n (E) \leq km_n (E).
\]

This proves the first part of the lemma.

To verify the second part, note that it is obvious \( \mathcal{H}^n \) and \( \mathcal{H}^n \) are translation invariant because diameters of sets do not change when translated. Therefore, if \( \mathcal{H}^n (0, 1)^n) = 0 \), it follows \( \mathcal{H}^n (\mathbb{R}^n) = 0 \) because \( \mathbb{R}^n \) is the countable union of translates of \( Q_0 \equiv (0, 1)^n \). Since each \( \mathcal{H}^n \) is no larger than \( \mathcal{H}^n \), the same must hold for \( \mathcal{H}^n \). Therefore, there exists a sequence of sets, \( \{C_i\} \) each having diameter less than \( \delta \) such that the union of these sets equals \( \mathbb{R}^n \) but

\[
1 > \sum_{i=1}^{\infty} \beta (n) r (C_i)^n.
\]

Now let \( B_i \) be a ball having radius equal to \( \text{diam} (C_i) = 2r (C_i) \) which contains \( C_i \). It follows

\[
m_n (B_i) = \alpha (n) 2^n r (C_i)^n = \frac{\alpha (n) 2^n}{\beta (n)} \beta (n) r (C_i)^n
\]

which implies

\[
1 > \sum_{i=1}^{\infty} \beta (n) r (C_i)^n = \sum_{i=1}^{\infty} \frac{\beta (n)}{\alpha (n)} 2^n m_n (B_i) = \infty,
\]

a contradiction. \( \blacksquare \)

**Theorem 26.2.3** By choosing \( \beta (n) \) properly, one can obtain \( \mathcal{H}^n = m_n \) on all Lebesgue measurable sets.

**Proof:** I will show \( \mathcal{H}^n \) is a positive multiple of \( m_n \) for any choice of \( \beta (n) \). Define

\[
k = \frac{m_n (Q_0)}{\mathcal{H}^n (Q_0)}
\]

where \( Q_0 = [0, 1)^n \) is the half open unit cube in \( \mathbb{R}^n \). I will show \( k\mathcal{H}^n (E) = m_n (E) \) for any Lebesgue measurable set. When this is done, it will follow that by adjusting \( \beta (n) \) the multiple can be taken to be 1.

Let \( Q = \prod_{i=1}^{n} (a_i, a_i + 2^{-k}) \) be a half open box where \( a_i = l2^{-k} \). Thus \( Q_0 \) is the union of \( (2^k)^n \) of these identical half open boxes. By translation invariance, of \( \mathcal{H}^n \) and \( m_n \)

\[
(2^k)^n \mathcal{H}^n \ (Q) = \mathcal{H}^n (Q_0) = \frac{1}{k} m_n (Q_0) = \frac{1}{k} (2^k)^n m_n (Q).
\]

Therefore, \( k\mathcal{H}^n (Q) = m_n (Q) \) for any such half open box and by translation invariance, for the translation of any such half open box. It follows from Lemma that \( k\mathcal{H}^n (U) = m_n (U) \) for all open sets. It follows immediately, since every compact set is the countable intersection of open sets that \( k\mathcal{H}^n = m_n \) on compact
sets. Therefore, they are also equal on all closed sets because every closed set is the countable union of compact sets. Now let $F$ be an arbitrary Lebesgue measurable set. I will show that $F$ is $\mathcal{H}^n$ measurable and that $k\mathcal{H}^n (F) = m_n (F)$. Let $F_l = B(0, l) \cap F$. Then there exists $H$ a countable union of compact sets and $G$ a countable intersection of open sets such that

$$H \subseteq F_l \subseteq G$$

and $m_n (G \setminus H) = 0$ which implies by Lemma 26.2.6

$$m_n (G \setminus H) = k\mathcal{H}^n (G \setminus H) = 0.$$  \hspace{1cm} (26.2.7)

To do this, let $\{G_i\}$ be a decreasing sequence of bounded open sets containing $F_l$ and let $\{H_i\}$ be an increasing sequence of compact sets contained in $F_l$ such that

$$k\mathcal{H}^n (G_i \setminus H_i) = m_n (G_i \setminus H_i) < 2^{-i}$$

Then letting $G = \cap_i G_i$ and $H = \cup_i H_i$ this establishes $\mathcal{H}^n$ and $\mathcal{H}^n M$. Then by completeness of $\mathcal{H}^n$ it follows $F_l$ is $\mathcal{H}^n$ measurable and

$$k\mathcal{H}^n (F_l) = k\mathcal{H}^n (H) = m_n (H) = m_n (F_l).$$

Now taking $l \to \infty$, it follows $F$ is $\mathcal{H}^n$ measurable and $k\mathcal{H}^n (F) = m_n (F)$. Therefore, adjusting $\beta (n)$ it can be assumed the constant, $k$ is 1. \hspace{1cm} \blacksquare

The exact determination of $\beta (n)$ is more technical.

26.3  Technical Considerations

Let $\alpha (n)$ be the volume of the unit ball in $\mathbb{R}^n$. Thus the volume of $B(0, r)$ in $\mathbb{R}^n$ is $\alpha (n) r^n$ from the change of variables formula. There is a very important and interesting inequality known as the isodiametric inequality which says that if $A$ is any set in $\mathbb{R}^n$, then

$$\overline{m} (A) \leq \alpha (n) (2^{-1} \text{diam}(A))^n = \alpha (n) r (A)^n.$$

This inequality may seem obvious at first but it is not really. The reason it is not is that there are sets which are not subsets of any sphere having the same diameter as the set. For example, consider an equilateral triangle.

Lemma 26.3.1  Let $f : \mathbb{R}^{n-1} \to [0, \infty)$ be Borel measurable and let

$$S = \{(x, y) : |y| < f(x)\}.$$

Then $S$ is a Borel set in $\mathbb{R}^n$.

Proof: Set $s_k$ be an increasing sequence of Borel measurable functions converging pointwise to $f$.

$$s_k (x) = \sum_{m=1}^{N_k} c_m^k \mathcal{N}_m^k (x).$$
Let 
\[ S_k = \bigcup_{m=1}^{N_k} E_m^k \times (-c_m^k, c_m^k). \]
Then \((x,y) \in S_k\) if and only if \(f(x) > 0\) and \(|y| < s_k(x) \leq f(x)\). It follows that 
\[ S_k \subseteq S_{k+1} \text{ and } S = \bigcup_{k=1}^\infty S_k. \]
But each \(S_k\) is a Borel set and so \(S\) is also a Borel set. This proves the lemma.

Let \(P_i\) be the projection onto 
\[ \text{span} (e_1, \ldots, e_{i-1}, e_{i+1}, \ldots, e_n) \]
where the \(e_k\) are the standard basis vectors in \(\mathbb{R}^n\), \(e_k\) being the vector having a 1 in the \(k\)th slot and a 0 elsewhere. Thus \(P_i(x) = \sum_{j \neq i} x_j e_j\). Also let 
\[ A_{P_i,x} = \{ x_i : (x_1, \ldots, x_i, \ldots, x_n) \in A \} \]

**Lemma 26.3.2** Let \(A \subseteq \mathbb{R}^n\) be a Borel set. Then \(P_i(x) \rightarrow m(A_{P_i,x})\) is a Borel measurable function defined on \(P_i(\mathbb{R}^n)\).

**Proof:** Let \(K\) be the \(\pi\) system consisting of sets of the form \(\prod_{i=1}^n A_j\) where \(A_i\) is Borel. Also let \(G\) denote those Borel sets of \(\mathbb{R}^n\) such that if \(A \in G\) then 
\[ P_i(x) \rightarrow m((A \cap R_k)_{P_i,x}) \]
is Borel measurable because it is of the form 
\[ m((R_k)_{P_i,x}) - m((A \cap R_k)_{P_i,x}) \]
and these are Borel measurable functions of \(P_i(x)\). Also, if \(\{A_i\}\) is a disjoint sequence of sets in \(G\) then 
\[ m((\cup_i A_i \cap R_k)_{P_i,x}) = \sum_i m((A_i \cap R_k)_{P_i,x}) \]
and each function of \(P_i(x)\) is Borel measurable. Thus by the lemma on \(\pi\) systems, Lemma 10.12.3, \(G = B(\mathbb{R}^n)\) and this proves the lemma.

Now let \(A \subseteq \mathbb{R}^n\) be Borel. Let \(P_i\) be the projection onto 
\[ \text{span} (e_1, \ldots, e_{i-1}, e_{i+1}, \ldots, e_n) \]
and as just described, 
\[ A_{P_i,x} = \{ y \in \mathbb{R} : P_i(x) + ye_i \in A \} \]
Thus for $x = (x_1, \cdots, x_n)$,

$$A_{P_i x} = \{ y \in \mathbb{R} : (x_1, \cdots, x_{i-1}, y, x_{i+1}, \cdots, x_n) \in A \}.$$

Since $A$ is Borel, it follows from Lemma 26.3.1 that

$$P_i x \rightarrow m(A_{P_i x})$$

is a Borel measurable function on $P_i \mathbb{R}^n = \mathbb{R}^{n-1}$.

### 26.3.1 Steiner Symmetrization

Define

$$S(A, e_i) \equiv \{ x = P_i x + ye_i : |y| < 2^{-1}m(A_{P_i x}) \}$$

**Lemma 26.3.3** Let $A$ be a Borel subset of $\mathbb{R}^n$. Then $S(A, e_i)$ satisfies

- $P_i x + ye_i \in S(A, e_i)$ if and only if $P_i x - ye_i \in S(A, e_i)$,
- $S(A, e_i)$ is a Borel set in $\mathbb{R}^n$,
- $m_n(S(A, e_i)) = m_n(A),$ \hspace{1cm} (26.3.8)
- $diam(S(A, e_i)) \leq diam(A).$ \hspace{1cm} (26.3.9)

**Proof:** The first assertion is obvious from the definition. The Borel measurability of $S(A, e_i)$ follows from the definition and Lemmas 26.3.2 and 26.3.1. To show Formula (26.3.8),

$$m_n(S(A, e_i)) = \int_{P_i \mathbb{R}^n} \int_{-2^{-1}m(A_{P_i x})}^{2^{-1}m(A_{P_i x})} dx_i dx_1 \cdots dx_{i-1} dx_{i+1} \cdots dx_n$$

$$= \int_{P_i \mathbb{R}^n} m(A_{P_i x}) dx_1 \cdots dx_{i-1} dx_{i+1} \cdots dx_n$$

$$= m(A).$$

Now suppose $x_1$ and $x_2 \in S(A, e_i)$

$$x_1 = P_i x_1 + y_1 e_i, \quad x_2 = P_i x_2 + y_2 e_i.$$

For $x \in A$ define

$$l(x) = \sup \{ y : P_i x + ye_i \in A \},$$

$$g(x) = \inf \{ y : P_i x + ye_i \in A \}.$$

Then it is clear that

$$l(x_1) - g(x_1) \geq m(A_{P_i x_1}) \geq 2|y_1|,$$ \hspace{1cm} (26.3.10)

$$l(x_2) - g(x_2) \geq m(A_{P_i x_2}) \geq 2|y_2|.$$ \hspace{1cm} (26.3.11)
Claim: \(|y_1 - y_2| \leq |l(x_1) - g(x_2)|\) or \(|y_1 - y_2| \leq |l(x_2) - g(x_1)|\).

Proof of Claim: If not,

\[2|y_1 - y_2| > |l(x_1) - g(x_2)| + |l(x_2) - g(x_1)| \geq |l(x_1) - g(x_1) + l(x_2) - g(x_2)| = l(x_1) - g(x_1) + l(x_2) - g(x_2).\]

\[\geq 2|y_1| + 2|y_2|\]

by Lemma 26.3.10 and Lemma 26.3.11 contradicting the triangle inequality.

Now suppose \(|y_1 - y_2| \leq |l(x_1) - g(x_2)|\). From the claim,

\[\|x_1 - x_2\| = (|P_1x_1 - P_1x_2|^2 + |y_1 - y_2|^2)^{1/2} \leq (|P_1x_1 - P_1x_2|^2 + |l(x_1) - g(x_2)|^2)^{1/2} \leq (|P_1x_1 - P_1x_2|^2 + |z_1 - z_2|^2 + 2\varepsilon)^{1/2} \leq \text{diam}(A) + O(\sqrt{\varepsilon})\]

where \(z_1\) and \(z_2\) are such that \(P_i(x_1 + z_1e_i) \in A\), \(P_i(x_2 + z_2e_i) \in A\), and \(|z_1 - l(x_1)| < \varepsilon\) and \(|z_2 - g(x_2)| < \varepsilon\).

If \(|y_1 - y_2| \leq |l(x_2) - g(x_1)|\), then we use the same argument but let \(|z_1 - g(x_1)| < \varepsilon\) and \(|z_2 - l(x_2)| < \varepsilon\).

Since \(x_1, x_2\) are arbitrary elements of \(S(A, e_i)\) and \(\varepsilon\) is arbitrary, this proves Lemma 26.3.4.

The next lemma says that if \(A\) is already symmetric with respect to the \(j^{th}\) direction, then this symmetry is not destroyed by taking \(S(A, e_i)\).

Lemma 26.3.4 Suppose \(A\) is a Borel set in \(\mathbb{R}^n\) such that \(P_jx + e_jx_j \in A\) if and only if \(P_jx + (-x_j)e_j \in A\). Then if \(i \neq j\), \(P_jx + e_jx_j \in S(A, e_i)\) if and only if \(P_jx + (-x_j)e_j \in S(A, e_i)\).

Proof: By definition,

\[P_jx + e_jx_j \in S(A, e_i)\]

if and only if \(|x_i| < 2^{-1}m(A_{P_i(P_jx + e_jx_j)})\).

Now \(x_i \in A_{P_i(P_jx + e_jx_j)}\) if and only if \(x_i \in A_{P_i(P_jx + (-x_j)e_j)}\) by the assumption on \(A\) which says that \(A\) is symmetric in the \(e_j\) direction. Hence \(P_jx + e_jx_j \in S(A, e_i)\) if and only if \(|x_i| < 2^{-1}m(A_{P_i(P_jx + (-x_j)e_j)})\)

if and only if \(P_jx + (-x_j)e_j \in S(A, e_i)\).

This proves the lemma.
26.3.2 The Isodiametric Inequality

The next theorem is called the isodiametric inequality. It is the key result used to compare Lebesgue and Hausdorff measures.

**Theorem 26.3.5** Let \( A \) be any Lebesgue measurable set in \( \mathbb{R}^n \). Then

\[
m_n(A) \leq \alpha(n)(r(A))^n.
\]

**Proof:** Suppose first that \( A \) is Borel. Let \( A_1 = S(A, e_1) \) and let \( A_k = S(A_{k-1}, e_k) \). Then by the preceding lemmas, \( A_n \) is a Borel set, \( \text{diam}(A_n) \leq \text{diam}(A) \), \( m_n(A_n) = m_n(A) \), and \( A_n \) is symmetric. Thus \( x \in A_n \) if and only if \( -x \in A_n \). It follows that

\[
A_n \subseteq B(0, r(A_n)).
\]

(If \( x \in A_n \setminus B(0, r(A_n)) \), then \( -x \in A_n \setminus B(0, r(A_n)) \) and so \( \text{diam}(A_n) \geq 2|x| > \text{diam}(A_n) \).) Therefore,

\[
m_n(A_n) \leq \alpha(n)(r(A_n))^n \leq \alpha(n)(r(A))^n.
\]

It remains to establish this inequality for arbitrary measurable sets. Letting \( A \) be such a set, let \( \{K_n\} \) be an increasing sequence of compact subsets of \( A \) such that

\[
m(A) = \lim_{k \to \infty} m(K_k).
\]

Then

\[
m(A) = \lim_{k \to \infty} m(K_k) \leq \lim_{k \to \infty} \alpha(n)(r(K_k))^n
\]

\[
\leq \alpha(n)(r(A))^n.
\]

This proves the theorem.

26.4 The Proper Value Of \( \beta(n) \)

I will show that the proper determination of \( \beta(n) \) is \( \alpha(n) \), the volume of the unit ball. Since \( \beta(n) \) has been adjusted such that \( k = 1 \), \( m_n(B(0, 1)) = \mathcal{H}^n(B(0, 1)) \). There exists a covering of \( B(0, 1) \) of sets of radii less than \( \delta \), \( \{C_i\}_{i=1}^\infty \) such that

\[
\mathcal{H}^n_\delta(B(0, 1)) + \varepsilon > \sum_i \beta(n) r(C_i)^n
\]

Then by Theorem [20.3.3], the isodiametric inequality,

\[
\mathcal{H}^n_\delta(B(0, 1)) + \varepsilon > \sum_i \beta(n) r(C_i)^n = \frac{\beta(n)}{\alpha(n)} \sum_i \alpha(n) r(C_i)^n
\]

\[
\geq \frac{\beta(n)}{\alpha(n)} \sum_i m_n(C_i) \geq \frac{\beta(n)}{\alpha(n)} m_n(B(0, 1)) = \frac{\beta(n)}{\alpha(n)} \mathcal{H}^n(B(0, 1))
\]
Now taking the limit as $\delta \to 0$,

$$\mathcal{H}^n (B(0,1)) + \varepsilon \geq \frac{\beta(n)}{\alpha(n)} \mathcal{H}^n(B(0,1))$$

and since $\varepsilon > 0$ is arbitrary, this shows $\alpha(n) \geq \beta(n)$.

By the Vitali covering theorem, there exists a sequence of disjoint balls, $\{B_i\}$ such that

$$B(0,1) = (\cup_{i=1}^{\infty} B_i) \cup N$$

where $m_n(N) = 0$. Then $\mathcal{H}_n^\delta (N) = 0$ can be concluded because $\mathcal{H}_n^\delta \leq \mathcal{H}^n$ and Lemma 26.2.2. Using $m_n(B(0,1)) = \mathcal{H}^n(B(0,1))$ again,

$$\mathcal{H}_n^\delta(B(0,1)) = \mathcal{H}_n^\delta(\cup_i B_i) \leq \sum_{i=1}^{\infty} \beta(n) r(B_i)^n$$

$$= \frac{\beta(n)}{\alpha(n)} \sum_{i=1}^{\infty} \alpha(n) r(B_i)^n = \frac{\beta(n)}{\alpha(n)} \sum_{i=1}^{\infty} m_n(B_i)$$

$$= \frac{\beta(n)}{\alpha(n)} m_n(\cup_i B_i) = \frac{\beta(n)}{\alpha(n)} m_n(B(0,1)) = \frac{\beta(n)}{\alpha(n)} \mathcal{H}^n(B(0,1))$$

which implies $\alpha(n) \leq \beta(n)$ and so the two are equal. This proves that if $\alpha(n) = \beta(n)$, then the $\mathcal{H}^\alpha = m_n$ on the measurable sets of $\mathbb{R}^n$.

This gives another way to think of Lebesgue measure which is a particularly nice way because it is coordinate free, depending only on the notion of distance.

For $s < n$, note that $\mathcal{H}^s$ is not a Radon measure because it will not generally be finite on compact sets. For example, let $n = 2$ and consider $\mathcal{H}^1(L)$ where $L$ is a line segment joining $(0,0)$ to $(1,0)$. Then $\mathcal{H}^1(L)$ is no smaller than $\mathcal{H}^1(L)$ when $L$ is considered a subset of $\mathbb{R}^1$, $n = 1$. Thus by what was just shown, $\mathcal{H}^1(L) \geq 1$. Hence $\mathcal{H}^1([0,1] \times [0,1]) = \infty$. The situation is this: $L$ is a one-dimensional object inside $\mathbb{R}^2$ and $\mathcal{H}^1$ is giving a one-dimensional measure of this object. In fact, Hausdorff measures can make such heuristic remarks as these precise. Define the Hausdorff dimension of a set, $A$, as

$$\dim(A) = \inf\{s : \mathcal{H}^s(A) = 0\}$$

### 26.4.1 A Formula For $\alpha(n)$

What is $\alpha(n)$? Recall the gamma function which makes sense for all $p > 0$.

$$\Gamma(p) = \int_0^{\infty} e^{-t} t^{p-1} dt.$$ 

**Lemma 26.4.1** The following identities hold.

$$p \Gamma(p) = \Gamma(p + 1),$$
26.4. THE PROPER VALUE OF $\beta(N)$

$$\Gamma(p)\Gamma(q) = \left( \int_0^1 x^{p-1}(1-x)^{q-1} dx \right) \Gamma(p+q),$$

$$\Gamma \left( \frac{1}{2} \right) = \sqrt{\pi}$$

**Proof:** Using integration by parts,

$$\Gamma(p+1) = \int_0^\infty e^{-t} t^p dt = -e^{-t} t^p|_0^\infty + \int_0^\infty e^{-t} t^p dt$$

Next

$$\Gamma(p)\Gamma(q) = \int_0^\infty e^{-t} t^{p-1} dt \int_0^\infty e^{-s} s^{q-1} ds$$

$$= \int_0^\infty \int_0^\infty e^{-(t+s)} t^{p-1} s^{q-1} dtds$$

$$= \int_0^\infty \int_s^\infty e^{-u} (u-s)^{p-1} s^{q-1} du ds$$

$$= \int_0^\infty \int_0^u e^{-u} (u-s)^{p-1} s^{q-1} ds du$$

$$= \int_0^\infty \int_0^1 e^{-u} (u-u_1)^{p-1} (u_1)^{q-1} u_1 dudu$$

$$= \int_0^\infty \int_0^1 e^{-u} u^{p+q-1} (1-x)^{p-1} x^{q-1} dx du$$

$$= \Gamma(p+q) \left( \int_0^1 x^{p-1}(1-x)^{q-1} dx \right).$$

It remains to find $\Gamma \left( \frac{1}{2} \right)$.

$$\Gamma \left( \frac{1}{2} \right) = \int_0^\infty e^{-t} t^{-1/2} dt = \int_0^\infty e^{-u^2/2} u^{-1/2} du = 2 \int_0^\infty e^{-u^2} du$$

Now

$$\left( \int_0^\infty e^{-x^2} dx \right)^2 = \int_0^\infty e^{-x^2} dx \int_0^\infty e^{-y^2} dy = \int_0^\infty \int_0^\infty e^{-(x^2+y^2)} dx dy$$

$$= \int_0^{\pi/2} \int_0^\infty e^{-r^2} r \theta dr d\theta = \frac{1}{4}\pi$$

and so

$$\Gamma \left( \frac{1}{2} \right) = 2 \int_0^\infty e^{-u^2} du = \sqrt{\pi}$$

This proves the lemma.

Next let $n$ be a positive integer.

**Theorem 26.4.2** \( \alpha(n) = \pi^{n/2}(\Gamma(n/2 + 1))^{-1} \) where \( \Gamma(s) \) is the gamma function

\[
\Gamma(s) = \int_0^\infty e^{-t^{s-1}}dt.
\]

**Proof:** First let \( n = 1 \).

\[
\Gamma\left(\frac{3}{2}\right) = \frac{1}{2} \Gamma\left(\frac{1}{2}\right) = \frac{\sqrt{\pi}}{2}.
\]

Thus

\[
\pi^{1/2}(\Gamma(1/2 + 1))^{-1} = \frac{2}{\sqrt{\pi}}\sqrt{\pi} = 2 = \alpha(1).
\]

and this shows the theorem is true if \( n = 1 \).

Assume the theorem is true for \( n \) and let \( B_{n+1} \) be the unit ball in \( \mathbb{R}^{n+1} \). Then by the result in \( \mathbb{R}^n \),

\[
m_{n+1}(B_{n+1}) = \int_0^1 \alpha(n)(1 - x_{n+1}^2)^{n/2}dx_{n+1}
\]

\[
= 2\alpha(n) \int_0^1 (1 - t^2)^{n/2}dt.
\]

Doing an integration by parts and using Lemma 26.4.1

\[
= 2\alpha(n)n \int_0^1 t^2(1 - t^2)^{(n-2)/2}dt
\]

\[
= 2\alpha(n)n \frac{1}{2} \int_0^1 u^{1/2}(1 - u)^{n/2-1}du
\]

\[
= n\alpha(n) \int_0^1 u^{3/2-1}(1 - u)^{n/2-1}du
\]

\[
= n\alpha(n)\Gamma(3/2)\Gamma(n/2)(\Gamma((n + 3)/2))^{-1}
\]

\[
= n\pi^{n/2}(\Gamma(n/2 + 1))^{-1}\Gamma((n + 3)/2))^{-1}\Gamma(3/2)\Gamma(n/2)
\]

\[
= n\pi^{n/2}(\Gamma(n/2)(n/2))^{-1}(\Gamma((n + 1)/2 + 1))^{-1}\Gamma(3/2)\Gamma(n/2)
\]

\[
= 2\pi^{n/2}\Gamma(3/2)(\Gamma((n + 1)/2 + 1))^{-1}
\]

\[
= \pi^{(n+1)/2}(\Gamma((n + 1)/2 + 1))^{-1}.
\]

This proves the theorem.

From now on, in the definition of Hausdorff measure, it will always be the case that \( \beta(s) = \alpha(s) \). As shown above, this is the right thing to have \( \beta(s) \) to equal if \( s \) is a positive integer because this yields the important result that Hausdorff measure is the same as Lebesgue measure. Note the formula, \( \pi^{s/2}(\Gamma(s/2 + 1))^{-1} \) makes sense for any \( s \geq 0 \).
26.4. THE PROPER VALUE OF $\beta(N)$

26.4.2 Hausdorff Measure And Linear Transformations

Hausdorff measure makes possible a unified development of $n$ dimensional area. As in the case of Lebesgue measure, the first step in this is to understand basic considerations related to linear transformations. Recall that for $L \in \mathcal{L}(\mathbb{R}^k,\mathbb{R}^l), L^*$ is defined by

$$(Lu,v) = (u,L^*v).$$

Also recall Theorem 4.13.6 on Page 99 which is stated here for convenience. This theorem says you can write a linear transformation as the composition of two linear transformations, one which preserves length and the other which distorts, the right polar decomposition. The one which distorts is the one which will have a nontrivial interaction with Hausdorff measure while the one which preserves lengths does not change Hausdorff measure. These ideas are behind the following theorems and lemmas.

**Theorem 26.4.3** Let $F$ be an $n \times m$ matrix where $m \geq n$. Then there exists an $m \times n$ matrix $R$ and a $n \times n$ matrix $U$ such that

$$F = RU, \quad U = U^*,$$

all eigenvalues of $U$ are non-negative,

$$U^2 = F^*F, \quad R^*R = I,$$

and $|Rx| = |x|$.

**Lemma 26.4.4** Let $R \in \mathcal{L}(\mathbb{R}^n,\mathbb{R}^m), n \leq m$, and $R^*R = I$. Then if $A \subseteq \mathbb{R}^n$,

$$\mathcal{H}^n(RA) = \mathcal{H}^n(A).$$

In fact, if $P : \mathbb{R}^n \to \mathbb{R}^m$ satisfies $|P(x) - P(y)| = |x - y|$, then

$$\mathcal{H}^n(PA) = \mathcal{H}^n(A).$$

**Proof:** Note that

$$|R(x - y)|^2 = (R(x - y)\cdot R(x - y)) = (R^*R(x - y)\cdot x - y) = |x - y|^2$$

Thus $R$ preserves lengths.

Now let $P$ be an arbitrary mapping which preserves lengths and let $A$ be bounded, $P(A) \subseteq \bigcup_{j=1}^{\infty} C_j$, $r(C_j) < \delta$, and

$$\mathcal{H}_3^n(PA) + \varepsilon > \sum_{j=1}^{\infty} \alpha(n)(r(C_j))^n.$$
Since $P$ preserves lengths, it follows $P$ is one to one on $P(\mathbb{R}^n)$ and $P^{-1}$ also preserves lengths on $P(\mathbb{R}^n)$. Replacing each $C_j$ with $C_j \setminus (PA)$,

$$H^n_\delta(PA) + \varepsilon > \sum_{j=1}^{\infty} \alpha(n)r(C_j \setminus (PA))^n$$

$$= \sum_{j=1}^{\infty} \alpha(n)r(P^{-1}(C_j \setminus (PA)))^n$$

$$\geq H^n_\delta(A).$$

Thus $H^n_\delta(PA) \geq H^n_\delta(A)$.

Now let $A \subseteq \bigcup_{j=1}^{\infty} C_j$, $\text{diam}(C_j) \leq \delta$, and

$$H^n_\delta(A) + \varepsilon \geq \sum_{j=1}^{\infty} \alpha(n)(r(C_j))^n$$

Then

$$H^n_\delta(A) + \varepsilon \geq \sum_{j=1}^{\infty} \alpha(n)(r(C_j))^n$$

$$= \sum_{j=1}^{\infty} \alpha(n)(r(PC_j))^n$$

$$\geq H^n_\delta(PA).$$

Hence $H^n_\delta(PA) = H^n_\delta(A)$. Letting $\delta \to 0$ yields the desired conclusion in the case where $A$ is bounded. For the general case, let $A_r = A \cap B(0, r)$. Then $H^n(PA_r) = H^n(A_r)$. Now let $r \to \infty$. ■

**Lemma 26.4.5** Let $F \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^m), n \leq m$, and let $F = RU$ where $R$ and $U$ are described in Theorem 11.5.7 on Page 337. Then if $A \subseteq \mathbb{R}^n$ is Lebesgue measurable,

$$H^n(FA) = \det(U)m_n(A).$$

**Proof:** Using Theorem 11.5.7 on Page 337 and Theorem 26.2.3.

$$H^n(FA) = H^n(RUA)$$

$$= H^n(UA) = m_n(UA) = \det(U)m_n(A).$$

**Definition 26.4.6** Define $J$ to equal $\det(U)$. Thus

$$J = \det((F^*F)^{1/2}) = (\det(F^*F))^{1/2}.$$
26.5 The Area Formula

I am very grateful to those who have found errors in earlier versions of this material, some which were quite egregious. I was unlikely to find these mistakes because I never teach this material and do not use it in my research. If there are still errors, it is my fault.

26.5.1 Preliminary Results

It was shown in Lemma 26.4.5 that

$$\mathcal{H}^n(FA) = \det(U)m_n(A)$$

where $F = RU$ with $R$ preserving distances and $U$ a symmetric matrix having all positive eigenvalues. The area formula gives a generalization of this simple relationship to the case where $F$ is replaced by a nonlinear mapping, $h$. It contains as a special case the earlier change of variables formula. There are two parts to this development. The first part is to generalize Lemma 26.4.5 to the case of nonlinear maps. When this is done, the area formula can be presented.

In the first part of this, $h$ will be a Lipschitz function,

$$|h(x) - h(y)| \leq K|x - y|$$

defined on $\mathbb{R}^n$ which is one to one on $\mathcal{G}$, a measurable subset of $\mathbb{R}^n$. This is no loss of generality because of Theorem 24.5.4.

The following lemma states that Lipschitz maps take sets of measure zero to sets of measure zero.

**Lemma 26.5.1** If $h$ is Lipschitz and $m_n(T) = 0$, then

$$\mathcal{H}^n(h(T)) = 0$$

**Proof:** Let $\varepsilon > 0$ be given. By outer regularity, there exists an open set $V$ containing $T$ such that $m_n(V) < \frac{\varepsilon}{5Kr_1}$. For $x \in T$ it follows there exists $r_x < 1$ such that the ball centered at $x$ with radius $5r_x$ is contained in $V$ and $5Kr_x < \delta$ for $\delta > 0$. Here $K$ is the Lipschitz constant of $h$. Then by the Vitali covering theorem, there are disjoint balls $\{B(x_i, r_i)\}$ such that the enlarged balls $\tilde{B}_i$ having five times the radius cover $T$, each being contained in $V$. Then

$$\mathcal{H}^n(h(T)) \leq \mathcal{H}^n_h(\bigcup_{i=1}^{\infty} \tilde{B}_i) \leq \mathcal{H}^n_h\left(\bigcup_{i=1}^{\infty} h\left(\tilde{B}_i\right)\right)$$

$$\leq \sum_{i=1}^{\infty} \mathcal{H}^n_h\left(h\left(\tilde{B}_i\right)\right) \leq \sum_{i=1}^{\infty} \mathcal{H}^n_h\left(B(x_i, 5Kr_x)\right)$$
\[ \leq \sum_{i=1}^{\infty} a(n) (5Kr_x)^n = (5K)^n \sum_{i=1}^{\infty} a(n) r_x^n \]
\[ = (5K)^n \sum_{i=1}^{\infty} m_n(B(x_i, r_x)) \]
\[ \leq (5K)^n m_n(V) \leq (5K)^n \frac{\varepsilon}{K^n 6^n} < \varepsilon \]

Since \( \varepsilon > 0 \) is arbitrary, this shows \( \mathcal{H}^n_\varepsilon (\mathbf{h}(T)) = 0 \). \( \square \)

Recall the following theorem on Vitali covers. It is Corollary 26.5.1 on Page 633.

**Corollary 26.5.2** Let \( F \subseteq \mathbb{R}^n \) be a set and let \( \mathcal{F} \) be a collection of balls which come from some norm, open or not, but having bounded radii such that \( \mathcal{F} \) covers \( F \) in the sense of Vitali. Then there exists a countable collection of balls from \( \mathcal{F} \) having disjoint closures, denoted by \( \{B_j\}_{j=1}^{\infty} \), such that \( m_n(F \setminus \bigcup_{j=1}^{\infty} B_j) = 0 \).

**Lemma 26.5.3** If \( S \) is a Lebesgue measurable set and \( \mathbf{h} \) is Lipschitz then \( \mathbf{h}(S) \) is \( \mathcal{H}^n \) measurable. Also, if \( \mathbf{h} \) is Lipschitz with constant \( K \),

\[ \mathcal{H}^n(\mathbf{h}(S)) \leq K^n m_n(S) \]

**Proof:** Let \( S_k = S \cap B(0, k) \), \( k \in \mathbb{N} \). By inner regularity of Lebesgue measure, there exists a set \( F \), which is the countable union of compact sets and a set \( T \) with \( m_n(T) = 0 \) such that

\[ F \cup T = S_k. \]

Then \( \mathbf{h}(F) \subseteq \mathbf{h}(S_k) \subseteq \mathbf{h}(F) \cup \mathbf{h}(T) \). By continuity of \( \mathbf{h} \), \( \mathbf{h}(F) \) is a countable union of compact sets and so it is Borel. By Lemma 26.5.1, \( \mathcal{H}^n(\mathbf{h}(T)) = 0 \) and so \( \mathbf{h}(S_k) \) is \( \mathcal{H}^n \) measurable because of completeness of Hausdorff measure, which comes from \( \mathcal{H}^n \) being obtained from an outer measure. Now \( \mathbf{h}(S) = \bigcup_{k=1}^{\infty} \mathbf{h}(S_k) \) and so it is also true that \( \mathbf{h}(S) \) is \( \mathcal{H}^n \) measurable.

Consider the estimate. Assume first that \( S \subseteq B(0, R) \). Let \( V \) be an open set containing \( S \) which is contained in \( B(0, R) \) such that \( m_n(V \setminus S) < \varepsilon \). Then each point of \( S \) is contained in an open ball which is contained in \( V \). Considering all such open balls having radius less than \( \frac{\delta}{K} \), this forms a Vitali cover of \( S \). Therefore, there are disjoint balls \( \{B_i\} \) centered at points of \( S \) such that \( m_n(S \setminus \bigcup_i B_i) = 0 \). Lemma 26.5.1 says that \( \mathcal{H}^n(\mathbf{h}(S \setminus \bigcup_i B_i)) = 0 \). Thus \( \mathbf{h}(B_i) \) is a set of radius no larger than \( \delta \). Also,

\[ \mathbf{h}(S) = \mathbf{h}(S \setminus \bigcup_i B_i) + \mathbf{h}(\bigcup_i B_i) \]

Hence,

\[ \mathcal{H}^\beta_\delta(\mathbf{h}(S)) \leq \mathcal{H}^\beta_\delta(\mathbf{h}(S \setminus \bigcup_i B_i)) + \sum_i \beta(n) r(\mathbf{h}(B_i))^n \]
\[ \leq \mathcal{H}^\beta_\delta(\mathbf{h}(S \setminus \bigcup_i B_i)) + \sum_i \beta(n) K^n r(B_i)^n \]
\[ \leq \mathcal{H}^\beta_\delta(\mathbf{h}(S \setminus \bigcup_i B_i)) + K^n m_n(V) \]
Then take the limit as $\delta \to 0$ to obtain
\[
\mathcal{H}^n (h(S)) \leq K^n m_n (V) \leq K^n (m_n (S) + \varepsilon)
\]

Since $\varepsilon$ is arbitrary, this verifies the inequality. For the general case,
\[
\mathcal{H}^n (h(S)) = \lim_{m \to \infty} \mathcal{H}^n (h(S \cap B(0, m))) \leq \lim \inf_{m \to \infty} K^n m_n (S \cap B(0, m)) = K^n m_n (S)
\]

By Theorem 4.13.6 on Page 99, when $Dh(x)$ exists,
\[
Dh(x) = R(x) U(x)
\]

where $(U(x) u, v) = (U(x) v, u), (U(x) u, u) \geq 0$ and $R^* R = I$ so $R$ preserves lengths. This convention will be used in what follows.

**Lemma 26.5.4** In this situation, $|R^* u| \leq |u|$.

**Proof:** First note that
\[
(u - RR^* u, RR^* u) = (u, RR^* u) - |RR^* u|^2
\]
and so
\[
|u|^2 = |u - RR^* u + RR^* u|^2
\]
\[
= |u - RR^* u|^2 + |RR^* u|^2
\]
\[
= |u - RR^* u|^2 + |R^* u|^2.
\]

As discussed earlier, there is a convenient estimate involving Lipschitz maps.

**Lemma 26.5.5** If $|P x - P y| \leq L |x - y|$, then for $E$ a set in $\mathbb{R}^n$,
\[
\mathcal{H}^n (PE) \leq L^n \mathcal{H}^n (E).
\]

**Proof:** Without loss of generality, assume $\mathcal{H}^n (E) < \infty$. Let $\delta > 0$ and let $\{C_i\}_{i=1}^\infty$ be a covering of $E$ such that $r(C_i) \leq \delta$ for each $i$ and
\[
\sum_{i=1}^\infty \alpha(n) r(C_i)^n \leq \mathcal{H}^n_\delta (E) + \varepsilon.
\]

Then $\{PC_i\}_{i=1}^\infty$ is a covering of $PE$ such that $r(PC_i) \leq L \delta$. Therefore,
\[
\mathcal{H}^n_{L\delta} (PE) \leq \sum_{i=1}^\infty \alpha(n) r(PC_i)^n
\]
\[
\leq L^n \sum_{i=1}^\infty \alpha(n) r(C_i)^n \leq L^n \mathcal{H}^n_\delta (E) + L^n \varepsilon
\]
\[
\leq L^n \mathcal{H}^n (E) + L^n \varepsilon.
\]
Letting $\delta \to 0$,
\[ \mathcal{H}^n(PE) \leq L^n \mathcal{H}^n(E) + L^n \varepsilon \]
and since $\varepsilon > 0$ is arbitrary, this proves the Lemma. \hfill $\blacksquare$

Then the following corollary follows from Lemma 26.5.4.

**Corollary 26.5.6** Let $T \subseteq \mathbb{R}^m$. Then
\[ \mathcal{H}^n(T) \geq \mathcal{H}^n(R^n T). \]

A decomposition

First is a simple lemma which is fairly interesting.

**Lemma 26.5.7** Let $S, T$ be $n \times n$ matrices which are invertible. Then
\[ o(Tv) = o(Sv) = o(v) \]
and if $L$ is a continuous linear transformation such that for $a < b$,
\[ \sup_{v \neq 0} \frac{|Lv|}{|Sv|} < b, \quad \inf_{v \neq 0} \frac{|Lv|}{|Sv|} > a \]

If $\|S - T\|$ is small enough, it follows that the same inequalities hold with $S$ replaced with $T$. Here $\|\cdot\|$ denotes the operator norm.

**Proof:** Consider the first claim. For
\[ |v| = |T^{-1}Tv| \leq \|T^{-1}\| \|Tv\|, \]
\[ |Tv| \leq \|T\| \|v\| \]
and so
\[ \frac{1}{\|T\|} |Tv| \leq |v| \leq \|T^{-1}\| |Tv| \]
so $|v| \to 0$ is the same as saying that $|Tv| \to 0$. Similar considerations apply to $S$. Thus the first claim is clearly true.

Consider the second claim. To say that $\|S - T\|$ is small is the same as saying that $\|S - T\|_F$ is small where this refers to the Frobenius norm in which the $n \times n$ matrix is regarded as an element of $\mathbb{R}^{n^2}$, with the Euclidean norm, since all norms are equivalent. Then
\[ |Sv| = |ST^{-1}Tv| \leq \|ST^{-1}\| |Tv| \]
\[ |Tv| = |TS^{-1}Sv| \leq \|TS^{-1}\| |Sv| \]
Hence
\[ \frac{1}{\|TS^{-1}\|} |Tv| \leq |Sv| \leq \|ST^{-1}\| |Tv| \]
Thus the second result follows if it is the case that for $\|T - S\|$ sufficiently small, both $\|TS^{-1}\|$, $\|ST^{-1}\|$ close to 1. This is because there is $\hat{a} > a$ such that

$$\inf_{v \neq 0} \frac{|Lv|}{|Sv|} > \hat{a} > a$$

provided $\|TS^{-1}\|$ is close enough to 1. The other inequality is similar.

From the formula for the inverse in terms of the determinant, the entries of $T^{-1}$ are close to the corresponding entries of $S^{-1}$ provided $\|T - S\|$ is small enough. Thus by continuity,

$$\|ST^{-1} - I\|_F, \|TS^{-1} - I\|_F$$

are close to the corresponding entries of $I$ provided $\|T - S\|$ is small enough. This is because being close to $I$ in the Frobenius norm is equivalent to being close to $I$ in the operator norm.

The following is a simplified version of an argument in [13]. In what follows, it is assumed also that $h$ is one to one. In particular, we assume the following:

$$h$$ is one to one on $G$ a measurable subset of $\mathbb{R}^n$  \hspace{1cm} (26.5.12)

$$Dh(x)$$ exists at a.e. $x \in G$ say at all $x \in A \subseteq G$  \hspace{1cm} (26.5.13)

By Rademacher’s theorem, these conditions are satisfied if $h : \mathbb{R}^n \to \mathbb{R}^m$ is Lipschitz and this situation is the one of main interest here. The conditions 26.5.12 - 26.5.13 could likely be obtained in other situations also.

For $x \in A$, let $Dh(x) \equiv R(x)U(x)$ where $R(x)$ preserves lengths and $U(x) \equiv (Dh(x)^\dagger Dh(x))^{1/2}$. Let $A^+$ denote those points of $A$ for which $U(x)^{-1}$ exists. Thus this is a measurable subset of $A$.

Let $B$ be a Lebesgue measurable subset of $A^+$ and let $b \in B$. Let $S$ be a countable dense subset of the space of symmetric invertible matrices and let $C$ be a countable dense subset of $B$. Let $t > 1$ and let $\varepsilon$ be so small that

$$\frac{1}{t} + \varepsilon < 1 < t - \varepsilon$$

Now since $U(b)$ is invertible, Lemma 26.5.7 implies $o(a - b) = o(U(b)(a - b))$ and so

$$|h(a) - h(b) - Dh(b)(a - b)| < \varepsilon |U(b)(a - b)|$$

provided that $a \in B(b, \frac{2}{t})$ assuming $i$ is sufficiently large. In addition to this,

$$\sup_{v \neq 0} \frac{|Dh(b)v|}{|U(b)v|} = \sup_{v \neq 0} \frac{|R(b)U(b)v|}{|U(b)v|} = \sup_{v \neq 0} \frac{|U(b)v|}{|U(b)v|} < (t - \varepsilon)$$

$$\inf_{v \neq 0} \frac{|Dh(b)v|}{|U(b)v|} = \inf_{v \neq 0} \frac{|R(b)U(b)v|}{|U(b)v|} = \inf_{v \neq 0} \frac{|U(b)v|}{|U(b)v|} > \frac{1}{t} + \varepsilon$$
By Lemma 26.5.7, the inequalities 26.5.15 continue to hold if $U(b)$ is replaced by another linear one to one and onto symmetric mapping $T$ provided $T$ is sufficiently close to $U(b)$. Let $T \in S$ be such a linear transformation. Also let $i$ be large enough that for all $a \in B(b, \frac{2}{i})$,

$$|h(a) - h(b) - Dh(b)(a-b)| < \varepsilon |T(a-b)| \quad (26.5.16)$$

Now let $c \in C$ be close enough to $b$ that $b \in B(c, \frac{1}{T})$. Thus $b \in E(T,c,i)$ where for $i \in N, c \in C, T \in S, E(T,c,i)$ consists of those $b \in B(c, \frac{1}{T})$ such that for all $a \in B(b, \frac{2}{i})$, 26.5.16 holds and also

$$\inf_{v \neq 0} \frac{|Dh(b)v|}{|Tv|} > \frac{1}{t} + \varepsilon, \quad \sup_{v \neq 0} \frac{|Dh(b)v|}{|Tv|} < (t-\varepsilon) \quad (26.5.17)$$

Thus there are countably many of these sets $E(T,c,i)$, some may be empty but as just shown, their union includes all of $B$. They are Borel measurable sets because $b \rightarrow Dh(b)$ is Borel measurable.

For $a, b \in E(T, c, i)$ it follows from 26.5.16,

$$|h(a) - h(b)| < |Dh(b)(a-b)| + \varepsilon |T(a-b)| < |T(a-b)|$$

and also

$$\left(\frac{1}{t} + \varepsilon\right) |T(a-b)| < |Dh(b)(a-b)| < |h(a) - h(b)| + \varepsilon |T(a-b)|$$

and so

$$t |T(a-b)| > |h(a) - h(b)| > \frac{1}{t} |T(a-b)|$$

It follows from this that

$$|h(T^{-1}(x)) - h(T^{-1}(y))| \leq t |x - y| \quad (26.5.18)$$

$$\frac{1}{t} |T(h^{-1}(x)) - T(h^{-1}(y))| \leq |x - y| \quad (26.5.19)$$

Here the functions are defined on the appropriate sets, $T(E(T,c,i))$ in the first inequality and $h(E(T,c,i))$ in the second.

Now let $(E_k, T_k)$ result from a disjoint union of measurable subsets of the countably many $E(T,c,i)$ such that $B = \cup_k E_k$. Thus the above Lipschitz conditions hold for $T_k$ in place of $T$. This proves most of the following lemma.
26.5. THE AREA FORMULA

Lemma 26.5.8 There are disjoint measurable sets $E_k$ whose union equals $B$ and symmetric linear transformations $T_k$ such that

$$|\mathbf{h}(T_k^{-1}(x)) - \mathbf{h}(T_k^{-1}(y))| \leq t|x - y|$$

(26.5.20)

$$|T_k(h^{-1}(x)) - T_k(h^{-1}(y))| \leq t|x - y|$$

(26.5.21)

on $T_k(E_k)$ and $h(E_k)$ respectively. Also, for $b \in E_k$

$$\left(\frac{1}{t} + \varepsilon\right)|T_k v| < |D\mathbf{h}(b) v| = |U(b)v| < (t - \varepsilon)|T_k v|$$

(26.5.22)

One can also conclude that for $b \in E_k$,

$$t^{-n} |\det(T_k)| \leq \det(U(b)) \leq t^n |\det(T_k)|$$

(26.5.23)

Proof: It only remains to verify the last claim. However, this follows right away from 26.5.22. This formula implies that

$$\frac{1}{t} |v| < |U(b)T_k^{-1}v| < t|v|$$

and so

$$B\left(0, \frac{1}{t}\right) \subseteq U(b)T_k^{-1}B(0,1) \subseteq B(0, t)$$

This implies

$$\alpha(n) \frac{1}{t^n} \leq \det(U(b)T_k^{-1}) \alpha(n) \leq \alpha(n) t^n$$

and so

$$\frac{1}{t^n} |\det(T_k)| \leq \det(U(b)) \leq t^n |\det(T_k)|$$

This lemma, along with Lemma 26.5.3 about the relationship between Hausdorff measure and Lipschitz mappings, implies the following.

$$\mathcal{H}^n(\mathbf{h}(E_k)) = \mathcal{H}^n(h \circ T_k^{-1}(T_k(E_k))) \leq t^n \mathcal{H}^n(T_k(E_k)) = t^n m_n(T_k(E_k))$$

$$m_n(T_k(E_k)) = m_n((T_k \circ h^{-1}(h(E_k)))) \leq t^n \mathcal{H}^n(h(E_k))$$

Summarizing,

$$t^n \mathcal{H}^n(h(E_k)) \geq m_n(T_k(E_k)) \geq t^{-n} \mathcal{H}^n(h(E_k))$$

Then the above inequality and 46.5.46 implies the following.

$$t^{-2n} \mathcal{H}^n(h(E_k)) \leq t^{-n} m_n(T_k(E_k)) \leq t^{-n} |\det(T_k)| m_n(E_k)$$

$$\leq \int_{E_k} \det(U(x)) \, dm_n \leq t^n |\det(T_k)| m_n(E_k) = t^n m_n(T_kE_k) \leq t^{2n} \mathcal{H}^n(h(E_k))$$
Summing over all \( E_k \) yields the following thanks to the assumption that \( h \) is one to one.

\[
t^{-2n} \mathcal{H}^n (h (B)) \leq \int_B \det (U (x)) \, dx \leq t^{2n} \mathcal{H}^n (h (B))
\]

Now \( B \) was completely arbitrary. Let it equal \( B (x, r) \cap A^+ \) where \( x \in A^+ \). Then

\[
t^{-2n} \mathcal{H}^n (h (B (x, r) \cap A^+)) \leq \int_{B(x,r)} X_{A^+} (y) \det (U (y)) \, dm_n (y)
\]

\[
\leq t^{2n} \mathcal{H}^n (h (B (x, r) \cap A^+))
\]

Divide by \( m_n (B (x, r)) \) and use the fundamental theorem of calculus. This yields that for \( x \) off a set of measure zero,

\[
t^{-2n} \limsup_{r \to 0^+} \frac{\mathcal{H}^n (h (B (x, r) \cap A^+))}{m_n (B (x, r))} \leq \mathcal{X}_{A^+} (x) \det (U (x))
\]

However, \( t > 1 \) was completely arbitrary and this shows that off a set of measure zero,

\[
\lim_{r \to 0^+} \frac{\mathcal{H}^n (h (B (x, r) \cap A^+))}{m_n (B (x, r))} = \mathcal{X}_{A^+} (x) \det (U (x))
\]

This has proved the following lemma.

**Lemma 26.5.9** There is a set of measure zero \( N \) such that for \( x \in A^+ \setminus N \),

\[
\lim_{r \to 0^+} \frac{\mathcal{H}^n (h (B (x, r) \cap A^+))}{m_n (B (x, r))} = \det (U (x))
\]

The next theorem removes the assumption that \( U (x)^{-1} \) exists. From now on \( J_* (x) \equiv \det (U (x)) \).

**Theorem 26.5.10** Let \( h : U \to \mathbb{R}^m \) for \( n \leq m, U \) an open set in \( \mathbb{R}^n \), and suppose \( h \) Lipschitz. Then for a.e. \( x \in A \), the set in \( G \) where \( Dh (x) \) exists,

\[
J_* (x) = \lim_{r \to 0} \frac{\mathcal{H}^n (h (B (x, r) \cap A))}{m_n (B (x, r))},
\]

(26.5.24)

where \( J_* (x) \equiv \det (U (x)) = \det \left( Dh (x)^* Dh (x) \right)^{1/2} \).

**Proof:** The above argument shows that the conclusion of the theorem holds when \( J_* (x) \neq 0 \) at least with \( A \) replaced with \( A^+ \). I will apply this to a modified function in which the corresponding \( U (x) \) always has an inverse. Let \( k : \mathbb{R}^n \to \mathbb{R}^m \times \mathbb{R}^n \).
be defined as

\[ k(x) = \begin{pmatrix} h(x) \\ \varepsilon x \end{pmatrix}. \]

Then

\[ Dk(x)^* Dk(x) = Dh(x)^* Dh(x) + \varepsilon^2 I_n \]

and so

\[
J, k(x)^2 = \det (Dh(x)^* Dh(x) + \varepsilon^2 I_n) = \det (Q^* DQ + \varepsilon^2 I_n) > 0
\]

where \( D \) is a diagonal matrix having the nonnegative eigenvalues of \( Dh(x)^* Dh(x) \) down the main diagonal, \( Q \) an orthogonal matrix.

Therefore, what was just shown applies to \( k \). Let

\[
T \equiv \left\{ (h(w), 0)^T : w \in B(x, r) \cap A \right\},
\]

\[
T_\varepsilon \equiv \left\{ (h(w), \varepsilon w)^T : w \in B(x, r) \cap A \right\} = k(B(x, r) \cap A),
\]

then

\[
T = PT_\varepsilon
\]

where \( P \) is the projection map defined by

\[
P \begin{pmatrix} x \\ y \end{pmatrix} \equiv \begin{pmatrix} x \\ 0 \end{pmatrix}.
\]

Since \( P \) decreases distances, it follows from Lemma 26.5.5

\[
H^n (h(B(x, r) \cap A)) = H^n (T) = H^n (PT_\varepsilon) \leq H^n (T_\varepsilon) = H^n (k(B(x, r) \cap A)).
\]

Now from what was shown earlier,

\[
\det (Dk(x)^* Dk(x))^{1/2} = \lim_{r \to 0} \frac{H^n (k(B(x, r) \cap A))}{m_n (B(x, r))}
\]

for a.e. \( x \in A \). This is because

\[
\{ x : Dk(x) \text{ exists} \} = A
\]

and there is no exceptional set where \( Dk(x)^* Dk(x) \) fails to have an inverse. Thus for a.e. \( x \),

\[
\det (Dk(x)^* Dk(x))^{1/2} = \lim_{r \to 0} \frac{H^n (k(B(x, r) \cap A))}{m_n (B(x, r))} \geq \limsup_{r \to 0} \frac{H^n (h(B(x, r) \cap A))}{m_n (B(x, r))}
\]
Now let \( \varepsilon_n \to 0^+ \) and pass to a limit. This yields that for a.e. \( x \), those not in the union of the exceptional sets corresponding to the exceptional sets which correspond to each \( \varepsilon_n \) in the sequence \( \varepsilon_n \),

\[
\det \left( D_h(x) \right) \geq \lim \sup_{r \to 0} \frac{H^n(h(B(x,r) \cap A))}{m_n(B(x,r))}.
\]

If \( x \in A^+ \), then it was shown above, that

\[
\det \left( D_h(x) \right) = \lim_{r \to 0} \frac{H^n(h(B(x,r) \cap A))}{m_n(B(x,r))} \geq 0
\]

and if \( x \notin A^+ \), the above shows that

\[
\det \left( D_h(x) \right) = 0 = \lim_{r \to 0} \frac{H^n(h(B(x,r) \cap A))}{m_n(B(x,r))} \geq 0
\]

and so this has shown that for a.e. \( x \),

\[
\lim_{r \to 0} \frac{H^n(h(B(x,r) \cap A))}{m_n(B(x,r))} = J_*(x)
\]

Define the following set for future reference.

\[
S = \{ x \in A, D_h(x) \text{ exists and } U(x)^{-1} \text{ does not exist} \} \quad (26.5.25)
\]

### 26.5.2 The Area Formula

Since \( h \) is one to one on \( G \), and Lipschitz on \( G \), Lemma 26.5.3 implies one can define a measure \( \nu \), on the \( \sigma \)– algebra of Lebesgue measurable subsets of \( G \) as follows.

\[
\nu(E) = H^n(h(E \cap A)).
\]

Recall that \( A \) is the set in \( G \) on which \( D_h(x) \) exists. This is all except a set of measure zero and so one could actually replace the right side with \( H^n(h(E)) \) because the new material has \( H^n \) measure zero. By Lemma 26.5.3, this is a measure and \( \nu \ll m \). If \( m_n(E) = 0 \), then by Lemma 26.5.3, \( H^n(h(E \cap A)) = 0 \). In fact, by this lemma, \( H^n(h(E \cap A)) \leq K^n m_n(E) \) so it is also clear that \( \nu \) is \( \sigma \) finite.

Therefore by the corollary to the Radon Nikodym theorem, Corollary 18.1.3 on Page 581, there exists \( f \geq 0, f(x) = 0 \) if \( x \notin A \), and

\[
\nu(E) = \int_E f \, dm = \int_{A \cap E} f \, dm_n.
\]

In fact,

\[
f \in L^1_{loc}(\mathbb{R}^n)
\]

Indeed, for a ball \( B \),

\[
\infty > K^n m_n(B) \geq H^n(h(B \cap A)) \equiv \nu(B) = \int_B f \, dm_n
\]
What is $f$? I will show that $f(x) = J_*(x) = \det(U(x))$ a.e. Here $U(x) \equiv (Dh(x)Dh(x))^1/2$. Theorem [26.5.10] and the fundamental theorem of calculus implies that for a.e. $x \in G$, 

$$f(x) = \lim_{r \to 0} \frac{1}{m_n(B(x,r))} \int_{B(x,r)} f(y) \, dm$$ 

$$= \lim_{r \to 0} \frac{\mathcal{H}^n(h(B(x,r) \cap A))}{m_n(B(x,r))} = J_*(x).$$ 

Therefore, $f(x) = J_*(x)$ a.e.

Note that one could define a measure $\nu_R$ as $\mathcal{H}^n(h(E \cap A \cap B(0,R)))$ and it would still be the case that $\nu_R \ll m_n$ and the Radon Nikodym derivative would still be $J_*(x)$ for $x \in A \cap B(0,R)$. You would just apply the above Theorem [26.5.10] for $G = A \cap B(0,R)$ and the new $A$ would be $A \cap B(0,R)$.

Now let $F$ be a Borel set in $\mathbb{R}^m$. Recall this implies $F$ is $\mathcal{H}^n$ measurable. Then

$$\int_{h(A)} X_F(y) \, d\mathcal{H}^n = \int_{h(A)^{-1}(F)} (y) \, d\mathcal{H}^n$$ 

$$= \mathcal{H}^n(h^{-1}(F \cap A))$$ 

$$= \nu(h^{-1}(F)) = \int_{A \cap h^{-1}(F)} (x) J_*(x) \, dm$$ 

$$= \int_{A \cap h^{-1}(F)} (x) J_*(x) \, dm. \quad (26.5.26)$$ 

Similarly, if $A_R \equiv A \cap B(0,R)$, 

$$\int_{h(A_R)} X_F(y) \, d\mathcal{H}^n = \int_{h(A_R)} X_F(y) \, d\mathcal{H}^n = \int_{A_R} X_F(h(x)) J_*(x) \, dm. \quad (26.5.26)$$ 

Note there are no measurability questions in the above formula because $h^{-1}(F)$ is a Borel set due to the continuity of $h$. The Borel measurability of $J_*(x)$ also follows from the observation that $h$ is continuous and therefore, the partial derivatives are Borel measurable, being the limit of continuous functions. Then $J_*(x)$ is just a continuous function of these partial derivatives. However, things are not so clear if $F$ is only assumed $\mathcal{H}^n$ measurable. Is there a similar formula for $F$ only $\mathcal{H}^n$ measurable?

First consider the case where $E$ is only $\mathcal{H}^n$ measurable but 

$$\mathcal{H}^n(E \cap h(A)) = 0.$$ 

By Theorem [26.3.30] on Page 1739, there exists a Borel set $F \supset E \cap h(A)$ such that 

$$\mathcal{H}^n(F) = \mathcal{H}^n(E \cap h(A)) = 0.$$ 

Then from [26.5.20] 

$$X_{A \cap h^{-1}(F)} (x) J_*(x) = 0 \text{ a.e.}$$
But
\[ 0 \leq \mathcal{X}_{A \cap h^{-1}(E)}(x) J_*(x) \leq \mathcal{X}_{A \cap h^{-1}(F)}(x) J_*(x) \]  
which shows the two functions in (26.5.27) are equal a.e. Therefore by completeness of Lebesgue measure, \( \mathcal{X}_{A \cap h^{-1}(E)}(x) J_*(x) \) is Lebesgue measurable and so from (26.5.29)
\[
0 = \int \mathcal{X}_{E \cap h(A)}(y) \, d\mathcal{H}^n = \int \mathcal{X}_{F \cap h(A)}(y) \, d\mathcal{H}^n.
\]
\[
= \int \mathcal{X}_{A \cap h^{-1}(F)}(x) J_*(x) \, dm_n = \int \mathcal{X}_{A \cap h^{-1}(E)}(x) J_*(x) \, dm_n,
\]  
which shows (26.5.28) holds in this case where \( E \) is \( \mathcal{H}^n \) measurable and
\[
\mathcal{H}^n (E \cap h(A)) = 0.
\]

Now let \( A_R \equiv A \cap B(0, R) \) for large \( R \) and let \( E \) be \( \mathcal{H}^n \) measurable. By Theorem 26.4, there exists \( F \supseteq E \cap h(A_R) \) such that \( F \) is Borel and
\[
\mathcal{H}^n (F \setminus (E \cap h(A_R))) = 0.
\]  
Then
\[
(E \cap h(A_R)) \cup (F \setminus (E \cap h(A_R)) \cap h(A_R)) = F \cap h(A_R)
\]
and so
\[
\mathcal{X}_{A_R \cap h^{-1}(F)}(x) J_*(x) = \mathcal{X}_{A_R \cap h^{-1}(E)}(x) J_*(x) + \mathcal{X}_{A_R \cap h^{-1}(F \setminus (E \cap h(A_R))))(x) J_*(x),
\]  
where from (26.5.28) and (26.5.29) the second function on the right of the equal sign is Lebesgue measurable and equals zero a.e. Therefore, the first function on the right of the equal sign is also Lebesgue measurable and equals the function on the left a.e. Thus,
\[
\int \mathcal{X}_{E \cap h(A_R)}(y) \, d\mathcal{H}^n = \int \mathcal{X}_{F \cap h(A_R)}(y) \, d\mathcal{H}^n = \int_{A_R} \mathcal{X}_F(h(x)) \, J_*(x) \, dm
\]
\[
= \int \mathcal{X}_{A_R \cap h^{-1}(F)}(x) J_*(x) \, dm_n = \int \mathcal{X}_{A_R \cap h^{-1}(E)}(x) J_*(x) \, dm_n.
\]  
Since this holds for any \( R \), it holds for (26.5.30) with \( A \) replacing \( A_R \) and the function
\[
x \to \mathcal{X}_{A \cap h^{-1}(E)}(x) J_*(x)
\]
is Lebesgue measurable. Writing this in a more familiar form yields
\[
\int_{h(A)} \mathcal{X}_E(y) \, d\mathcal{H}^n = \int_A \mathcal{X}_E(h(x)) \, J_*(x) \, dm_n.
\]  
From this, it follows that if \( s \) is a nonnegative, \( \mathcal{H}^n \) measurable simple function, (26.5.31) continues to be valid with \( s \) in place of \( \mathcal{X}_E \). Then approximating an arbitrary nonnegative \( \mathcal{H}^n \) measurable function \( g \) by an increasing sequence of simple functions, it follows that (26.5.31) holds with \( g \) in place of \( \mathcal{X}_E \) and there are no measurability problems because \( x \to g(h(x)) J_*(x) \) is Lebesgue measurable. This proves the following theorem which is the area formula.
Theorem 26.5.11 Let $h : \mathbb{R}^n \to \mathbb{R}^m$ be Lipschitz continuous. Also let $h$ be one to one on a measurable set $G \subseteq \mathbb{R}^n$ and let $m \geq n$. Let $A \subseteq G$ be the set of $x \in G$ on which $D_h(x)$ exists which is all but a set of measure zero, and let $g : h(A) \to [0, \infty]$ be $\mathcal{H}^n$ measurable. Then

$$\mathbf{x} \mapsto (g \circ h)(\mathbf{x}) J_* (\mathbf{x})$$

is Lebesgue measurable and

$$\int_{h(A)} g(y) \, d\mathcal{H}^n = \int_A g(h(\mathbf{x})) J_* (\mathbf{x}) \, d\mathcal{M}$$

where $J_* (\mathbf{x}) = \det (U(\mathbf{x})) = \det \left( D_h(\mathbf{x}) \right)^{1/2}$.}

Since $\mathcal{H}^n = m_n$ on $\mathbb{R}^n$, this is just a generalization of the usual change of variables formula except that here, one does not even need to know that $h$ is $C^1$ so this is much better and in addition it is not limited to $h$ having values in $\mathbb{R}^n$. Also note that you could replace $A$ with $G$ since they differ by a set of measure zero.

Note that if you assume that $h$ is Lipschitz on $G$ then it has a Lipschitz extension to $\mathbb{R}^n$. The conclusion has to do with integrals over $G$. It is not really necessary to have $h$ be Lipschitz continuous on $\mathbb{R}^n$, but you might as well assume this because of the existence of the Lipschitz extension. However, it can all be generalized to a situation in which $h$ is not known to be Lipschitz on $G$. An assumption of locally Lipschitz is sufficient. The definition follows.

**Definition 26.5.12** Let $h : \mathbb{R}^n \to \mathbb{R}^m$. This function is said to be locally Lipschitz if for every $x \in \mathbb{R}^n$, there exists a ball $B_x$ containing $x$ and a constant $K_x$ such that for all $y, z \in B_x$,

$$|h(z) - h(y)| \leq K_x |z - y|$$

The proof uses a little generalization of Lemma 26.5.1.

**Lemma 26.5.13** If $h$ is locally Lipschitz and $m_n (T) = 0$, then

$$\mathcal{H}^n (h(T)) = 0$$

**Proof:** Let

$$T_k \equiv \{ x \in T : h \text{ has Lipschitz constant } k \text{ near } x \}.$$ 

Thus $T = \bigcup_k T_k$. I will show $h(T_k)$ has $\mathcal{H}^n$ measure zero and then it will follow that

$$h(T) = \bigcup_{k=1}^\infty h(T_k), \text{ the } h(T_k) \text{ increasing in } k,$$

must also have measure zero.

Let $\varepsilon > 0$ be given. By outer regularity, there exists an open set $V$ containing $T_k$ such that $m_n (V) < \frac{\varepsilon}{4^k \delta}$. For $x \in T_k$ it follows there exists $r_x < 1$ such that the ball centered at $x$ with radius $5r_x$ is contained in $V$ and in this ball, $h$ has Lipschitz constant $k$ and $5kr_x < \delta$ for $\delta > 0$. Then by the Vitali covering theorem, there
are disjoint balls \( \{ B(\mathbf{x}_i, r_i) \} \) such that the enlarged balls \( \hat{B}_i \) having five times the radius cover \( T_k \), each being contained in \( V \). Then

\[
\mathcal{H}_\delta^n (h(T_k)) \leq \mathcal{H}_\delta^n \left( h \left( \bigcup_{i=1}^{\infty} \hat{B}_i \right) \right) \leq \mathcal{H}_\delta^n \left( \bigcup_{i=1}^{\infty} h \left( \hat{B}_i \right) \right)
\]

\[
\leq \sum_{i=1}^{\infty} \mathcal{H}_\delta^n \left( h \left( \hat{B}_i \right) \right) \leq \sum_{i=1}^{\infty} \mathcal{H}_\delta^n \left( B(h(\mathbf{x}_i), 5kr_{\mathbf{x}_i}) \right)
\]

\[
\leq \sum_{i=1}^{\infty} \alpha(n)(5kr_{\mathbf{x}_i})^n = (5k)^n \sum_{i=1}^{\infty} \alpha(n)r_{\mathbf{x}_i}^n.
\]

\[
= (5k)^n \sum_{i=1}^{\infty} m_n \left( B(\mathbf{x}_i, r_{\mathbf{x}_i}) \right)
\]

\[
\leq (5k)^n m_n (V) \leq (5k)^n \frac{\varepsilon}{k^n 6^n} \leq \varepsilon.
\]

Since \( \varepsilon > 0 \) is arbitrary, this shows \( \mathcal{H}_\delta^n (h(T_k)) = 0 \). Since \( \delta \) is arbitrary, this implies \( \mathcal{H}^n (h(T_k)) = 0 \). Now

\[
\mathcal{H}^n (h(T)) = \lim_{k \to \infty} \mathcal{H}^n (h(T_k)) = 0. \]

Then an easy generalization of the above formula is the following.

**Theorem 26.5.14** Let \( h : \mathbb{R}^n \to \mathbb{R}^m \) be locally Lipschitz. Also suppose that \( h \) is one to one on \( G \), a measurable subset of \( \mathbb{R}^n \). Then let \( g : h(G) \to [0, \infty] \) be \( \mathcal{H}^n \) measurable. It follows that

\[
\mathbf{x} \to (g \circ h)(\mathbf{x}) \ J_\ast (\mathbf{x})
\]

is Lebesgue measurable and

\[
\int_{h(G)} g(y) \, d\mathcal{H}^n = \int_{G} g(h(\mathbf{x})) \ J_\ast (\mathbf{x}) \, dm
\]

where \( J_\ast (\mathbf{x}) = \det (U(\mathbf{x})) = \det (Dh(\mathbf{x})^tDh(\mathbf{x}))^{1/2} \).

**Proof:** Let \( \mathcal{C} \) consist of balls of radius less than 1 covering \( G \) such that for \( B \in \mathcal{C} \), \( h \) is Lipschitz continuous on \( B \). By the Vitali covering theorem, there exists a sequence of these balls \( \{\hat{B}_i\} \) such that they are disjoint and \( G \setminus \bigcup_i \hat{B}_i \) has measure zero. Then, using Theorem 26.5.11 and the above Lemma 26.5.13

\[
\int_{h(G)} g(y) \, d\mathcal{H}^n = \int_{h(\bigcup_i \hat{B}_i)} g(y) \, d\mathcal{H}^n = \sum_i \int_{h(\hat{B}_i)} g(y) \, d\mathcal{H}^n
\]

\[
= \sum_i \int_{\hat{B}_i} g(h(\mathbf{x})) \ J_\ast (\mathbf{x}) \, dm
\]

\[
= \int_{\bigcup_i \hat{B}_i} g(h(\mathbf{x})) \ J_\ast (\mathbf{x}) \, dm = \int_{G} g(h(\mathbf{x})) \ J_\ast (\mathbf{x}) \, dm. \]
26.5. THE AREA FORMULA

26.5.3 Mappings That Are Not One To One

Let \( h : \mathbb{R}^n \to \mathbb{R}^m \) be Lipschitz. We drop the requirement that \( h \) be one to one. This follows [70]. See also [13] which is where I read it originally. This reference considers this case originally instead of splitting it into a case where \( h \) is one to one and a case where it is not. Again, let \( A \) be the set on which \( Dh (x) \) exists.

Thus \( m_n (N) = 0 \) where \( N \) is the set where \( Dh (x) \) does not exist and \( H^n (h (S)) = 0 \) and so by Lemma 26.5.3

\[
H^n (h (S \cup N)) \leq H^n (h (S)) + H^n (h (N)) = 0. \tag{26.5.32}
\]

Let \( B = \mathbb{R}^n \backslash (S \cup N) \).

A similar lemma to the following was proved in the section on the change of variables formula for a \( C^1 \) map. There the proof was based on the inverse function theorem. However, this is no longer possible so a slightly more technical argument is required.

Let \( S \) be given by

\[
S = \{ x \in A, \text{ such that } U (x)^{-1} \text{ does not exist} \}
\]

Recall that \( Dh (x) = R (x) U (x) \) where \( R \) preserves distances.

**Lemma 26.5.15** For \( S \) defined above, \( H^n (h (S)) = 0 \).

**Proof:** From Theorem 26.5.10 for a.e. \( x \in S \) and \( r \) is small enough,

\[
\frac{H^n (h (B (x,r) \cap A))}{m_n (B (x,r))} = \frac{H^n (h (B (x,r)))}{m_n (B (x,r))} < \varepsilon.
\]

Therefore, whenever \( x \in S \) and \( r \) small enough,

\[
H^n (h (B (x,r))) \leq \varepsilon \alpha (n) r^n. \tag{26.5.33}
\]

Let \( S_k = S \cap B (0,k) \) and for each \( x \in S_k \), let \( r_x \) be such that 26.5.33 holds with \( r \) replaced by \( 5r_x \) and

\[
B (x,r_x) \subseteq B (0,k).
\]

By the Vitali covering theorem, there is a disjoint subsequence of these balls, \( \{B (x_i, r_i)\} \), with the property that \( \{B (x_i, 5r_i)\} \) covers \( S_k \). Then by the way these balls were defined, with 26.5.33 holding for \( r = 5r_i \),

\[
H^n (h (S_k)) \leq \sum_{i=1}^{\infty} H^n (h (\tilde{B}_i)) \leq 5^n \varepsilon \sum_{i=1}^{\infty} \alpha (n) r_i^n
\]

\[
= 5^n \varepsilon \sum_{i=1}^{\infty} m_n (B (x_i, r_i)) \leq 5^n \varepsilon m_n (B (0,k)).
\]

Since \( \varepsilon \) is arbitrary, this shows \( H^n (h (S_k)) = 0 \). Now letting \( k \to \infty \), this shows \( H^n (h (S)) = 0 \).
Lemma 26.5.16 There exists a sequence of disjoint measurable sets, \( \{F_i\} \), such that
\[
\bigcup_{i=1}^{\infty} F_i = B
\]
and \( h \) is one to one on \( F_i \).

Proof: \( \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \) is a finite dimensional normed linear space. Let \( \mathcal{I} \) be the elements of \( \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n) \) which are invertible and let \( \mathcal{F} \) be a countable dense subset of \( \mathcal{I} \). Also let \( C \) be a countable dense subset of \( B \equiv \mathbb{R}^n \setminus (S \cup N) \). For \( c \in C \) and \( T \in \mathcal{F} \),
\[
E(c, T, i) \equiv \{ b \in B(c, i^{-1}) \cap B \text{ such that (a.) and (b.) hold} \}
\]
where the conditions (a.) and (b.) are as follows.

\[
\frac{1}{1 + \varepsilon} |Tv| \leq |U(b)v| \quad \text{for all } v \tag{a.}
\]
\[
|h(a) - h(b) - D_h(b)(a - b)| \leq \varepsilon |T(a - b)| \tag{b.}
\]
for all \( a \in B(b, 2i^{-1}) \). Here \( 0 < \varepsilon < 1/2 \).

![Diagram](B(b, \frac{2}{i}) \circ \bullet b \circ \bullet c \circ \circ \bullet \circ \circ B(c, \frac{4}{i}))

Obviously, there are countably many \( E(c, T, i) \). Now suppose \( a, b \in E(c, T, i) \) and \( h(a) = h(b) \). Then
\[
|a - b| \leq |a - c| + |c - b| < \frac{2}{i}.
\]
Therefore, from (a.) and (b.),
\[
\frac{1}{1 + \varepsilon} |T(a - b)| \leq |U(b)(a - b)| = |D_h(b)(a - b)| = |h(a) - h(b) - D_h(b)(a - b)| \leq \varepsilon |T(a - b)|.
\]
Since \( T \) is one to one, this shows that \( a = b \). Thus \( h \) is one to one on \( E(c, T, i) \).

Now let \( b \in B \). Choose \( T \in \mathcal{F} \) such that
\[
\|U(b) - T\| < \varepsilon \left\|U(b)^{-1}\right\|^{-1}.
\]
Then for all \( v \in \mathbb{R}^n \),
\[
|Tv - U(b)v| \leq \varepsilon \left\|U(b)^{-1}\right\|^{-1} |v| \leq \varepsilon |U(b)v|
\]
and so
\[ |Tv| \leq (1 + \varepsilon) |U(b)v| \]
which yields (a). Now choose \(i\) large enough that for \(|a - b| < 2i^{-1}\),
\[
|h(a) - h(b) - Dh(b)(a - b)| < \frac{\varepsilon}{\|T^{-1}\|}|a - b|
\]
\[ \leq \varepsilon |T(a - b)|\]
and pick \(c \in C \cap B(b,i^{-1})\). Then \(b \in E(c,T,i)\) and this shows that \(B\) equals the union of these sets.

Let \(\{E_i\}\) be an enumeration of these sets and define \(F_1 \equiv E_1\), and if \(F_1, \ldots, F_{n}\) have been chosen, \(F_{n+1} \equiv E_{n+1} \setminus \bigcup_{i=1}^{n} F_i\). Then \(\{F_i\}\) satisfies the conditions of the lemma and this proves the lemma. \(\blacksquare\)

The following corollary will not be needed right away but it is of interest.

**Corollary 26.5.17** For each \(E_i\) in Lemma 26.5.16, \(h^{-1}\) is Lipschitz on \(h(E_i)\).

**Proof:** Pick \(a, b \in E_i\). Then by condition \(a.\) and \(b.\),
\[
|h(a) - h(b)| \geq |Dh(b)(a - b)| - \varepsilon |T(a - b)|
\]
\[ \geq \left( \frac{1}{1 + \varepsilon} - \varepsilon \right) |T(a - b)| \geq r |a - b|\]
for some \(r > 0\) by the equivalence of all norms on a finite dimensional space. Therefore,
\[
|h^{-1}(h(a)) - h^{-1}(h(b))| \leq \frac{1}{r} |h(a) - h(b)|
\]
and this proves the corollary. \(\blacksquare\)

Now let \(g : h(\mathbb{R}^n) \to [0, \infty]\) be \(\mathcal{H}^n\) measurable. By Theorem 26.5.11,
\[
\int_{h(A)} X_{h(F_i)}(y) g(y) d\mathcal{H}^n = \int_{F_i} g(h(x)) J_*(x) dm. \tag{26.5.34}
\]
Now define
\[
n(y) = \sum_{i=1}^{\infty} X_{h(F_i)}(y).
\]
By Lemma 26.5.9, \(h(F_i)\) is \(\mathcal{H}^n\) measurable and so \(n\) is a \(\mathcal{H}^n\) measurable function. For each \(y \in B\), \(n(y)\) gives the number of elements in \(h^{-1}(y) \cap B\). From 26.5.35,
\[
\int_{h(\mathbb{R}^n)} n(y) g(y) d\mathcal{H}^n = \int_B g(h(x)) J_*(x) dm. \tag{26.5.35}
\]
Now define
\[
\#(y) \equiv \text{number of elements in } h^{-1}(y).
\]
Theorem 26.5.18 Let \( h : \mathbb{R}^n \to \mathbb{R}^m \) be Lipschitz. Then the function \( y \to \#(y) \) is \( \mathcal{H}^n \) measurable and if
\[
g : h(\mathbb{R}^n) \to [0, \infty]
\]
is \( \mathcal{H}^n \) measurable, then
\[
\int_{h(\mathbb{R}^n)} g(y) \#(y) \, d\mathcal{H}^n = \int_{\mathbb{R}^n} g(h(x)) J_* (x) \, dm.
\]

**Proof:** If \( y \notin h(S \cup N) \), then \( n(y) = \#(y) \). By 26.5.32
\[
\mathcal{H}^n (h(S \cup N)) = 0
\]
and so \( n(y) = \#(y) \) a.e. Since \( \mathcal{H}^n \) is a complete measure, \( \#(\cdot) \) is \( \mathcal{H}^n \) measurable. Letting
\[
G \equiv h(\mathbb{R}^n) \setminus h(S \cup N),
\]
26.5.35 implies
\[
\int_{h(\mathbb{R}^n)} g(y) \#(y) \, d\mathcal{H}^n = \int_{G} g(y) n(y) \, d\mathcal{H}^n
\]
\[
= \int_{B} g(h(x)) J_* (x) \, dm
\]
\[
= \int_{\mathbb{R}^n} g(h(x)) J_* (x) \, dm. \quad \blacksquare
\]

As in Theorem 26.5.14, there is an easy generalization based on the Vitali covering theorem to the case where \( h \) is only locally Lipschitz on \( \mathbb{R}^n \).

Theorem 26.5.19 Let \( h : \mathbb{R}^n \to \mathbb{R}^m \) be locally Lipschitz. Then the function \( y \to \#(y) \) is \( \mathcal{H}^n \) measurable and if
\[
g : h(\mathbb{R}^n) \to [0, \infty]
\]
is \( \mathcal{H}^n \) measurable, then
\[
\int_{h(\mathbb{R}^n)} g(y) \#(y) \, d\mathcal{H}^n = \int_{\mathbb{R}^n} g(h(x)) J_* (x) \, dm.
\]

### 26.6 The Divergence Theorem

As an important application of the area formula I will give a general version of the divergence theorem. It will always be assumed \( n \geq 2 \). Actually it is not necessary to make this assumption but what results in the case where \( n = 1 \) is nothing more than the fundamental theorem of calculus and the considerations necessary to draw this conclusion seem unnecessarily tedious. You have to consider \( \mathcal{H}^0 \), zero dimensional Hausdorff measure. It is left as an exercise but I will not present it.

It will be convenient to have some lemmas and theorems in hand before beginning the proof. First recall the Tietze extension theorem on Page 161. It is stated next for convenience.
Theorem 26.6.1 Let $M$ be a closed nonempty subset of a metric space $(X, d)$ and let $f : M \to [a, b]$ be continuous at every point of $M$. Then there exists a function, $g$ continuous on all of $X$ which coincides with $f$ on $M$ such that $g(X) \subseteq [a, b]$.

The next topic needed is the concept of an infinitely differentiable partition of unity.

Definition 26.6.2 Let $\mathcal{C}$ be a set whose elements are subsets of $\mathbb{R}^n$. Then $\mathcal{C}$ is said to be locally finite if for every $x \in \mathbb{R}^n$, there exists an open set, $U_x$ containing $x$ such that $U_x$ has nonempty intersection with only finitely many sets of $\mathcal{C}$.

Lemma 26.6.3 Let $\mathcal{C}$ be a set whose elements are open subsets of $\mathbb{R}^n$ and suppose $\cup \mathcal{C} \supseteq H$, a closed set. Then there exists a countable list of open sets, $\{U_i\}_{i=1}^{\infty}$ such that each $U_i$ is bounded, each $U_i$ is a subset of some set of $\mathcal{C}$, and $\cup_{i=1}^{\infty} U_i \supseteq H$.

Proof: Let $W_k = B(0, k), W_0 = W_{-1} = \emptyset$. For each $x \in H \cap \overline{W}_k$ there exists an open set, $U_x$ such that $U_x$ is a subset of some set of $\mathcal{C}$ and $U_x \subseteq W_{k+1} \setminus \overline{W}_k$. Then since $H \cap \overline{W}_k$ is compact, there exist finitely many of these sets, $\{U^i_k\}_{i=1}^{m(k)}$ whose union contains $H \cap \overline{W}_k$. If $H \cap \overline{W}_k = \emptyset$, let $m(k) = 0$ and there are no such sets obtained. The desired countable list of open sets is $\cup_{k=1}^{\infty} \{U^i_k\}_{i=1}^{m(k)}$. Each open set in this list is bounded. Furthermore, if $x \in \mathbb{R}^n$, then $x \in W_k$ where $k$ is the first positive integer with $x \in W_k$. Then $W_k \setminus \overline{W}_{k-1}$ is an open set containing $x$ and this open set can have nonempty intersection only with with a set of $\{U^i_k\}_{i=1}^{m(k)} \cup \{U^i_{k-1}\}_{i=1}^{m(k-1)}$, a finite list of sets. Therefore, $\cup_{k=1}^{\infty} \{U^i_k\}_{i=1}^{m(k)}$ is locally finite.

The set, $\{U_i\}_{i=1}^{\infty}$ is said to be a locally finite cover of $H$. The following lemma gives some important reasons why a locally finite list of sets is so significant. First of all consider the rational numbers, $\{r_i\}_{i=1}^{\infty}$ each rational number is a closed set.

$$
\mathbb{Q} = \{r_i\}_{i=1}^{\infty} = \cup_{i=1}^{\infty} \{r_i\} \neq \cup_{i=1}^{\infty} \{r_i\} = \mathbb{R}
$$

The set of rational numbers is definitely not locally finite.

Lemma 26.6.4 Let $\mathcal{C}$ be locally finite. Then

$$
\overline{\mathcal{C}} = \cup \{H : H \in \mathcal{C}\}.
$$

Next suppose the elements of $\mathcal{C}$ are open sets and that for each $U \in \mathcal{C}$, there exists a differentiable function, $\psi_U$, having spt($\psi_U$) $\subseteq U$. Then you can define the following finite sum for each $x \in \mathbb{R}^n$

$$
f(x) = \sum \{\psi_U(x) : x \in U \in \mathcal{C}\}.
$$

Furthermore, $f$ is also a differentiable function$^1$ and

$$
Df(x) = \sum \{D\psi_U(x) : x \in U \in \mathcal{C}\}.
$$

$^1$The definition applies with no change to a general topological space in place of $\mathbb{R}^n$.

$^2$If each $\psi_U$ were only continuous, one could conclude $f$ is continuous. Here the main interest is differentiable.
**Proof:** Let $p$ be a limit point of $\cup \mathcal{C}$ and let $W$ be an open set which intersects only finitely many sets of $\mathcal{C}$. Then $p$ must be a limit point of one of these sets. It follows $p \in \cup \{H : H \in \mathcal{C}\}$ and so $\cup \mathcal{C} \subseteq \cup \{H : H \in \mathcal{C}\}$. The inclusion in the other direction is obvious.

Now consider the second assertion. Letting $x \in \mathbb{R}^n$, there exists an open set, $W$ intersecting only finitely many open sets of $\mathcal{C}, U_1, U_2, \cdots, U_m$. Then for all $y \in W$,

$$f(y) = \sum_{i=1}^{m} \psi_{U_i}(y)$$

and so the desired result is obvious. It merely says that a finite sum of differentiable functions is differentiable. Recall the following definition.

**Definition 26.6.5** Let $K$ be a closed subset of an open set, $U$. $K \prec f \prec U$ if $f$ is continuous, has values in $[0, 1]$, equals 1 on $K$, and has compact support contained in $U$.

**Lemma 26.6.6** Let $U$ be a bounded open set and let $K$ be a closed subset of $U$. Then there exist an open set, $W$, such that $W \subseteq W \subseteq U$ and a function, $f \in C^\infty_c(U)$ such that $K \prec f \prec U$.

**Proof:** The set, $K$ is compact so is at a positive distance from $U^C$. Let

$$W \equiv \{x : \text{dist} (x, K) < 3^{-1} \text{dist} (K, U^C)\}.$$  

Also let

$$W_1 \equiv \{x : \text{dist} (x, K) < 2^{-1} \text{dist} (K, U^C)\}$$

Then it is clear

$$K \subseteq W \subseteq \overline{W} \subseteq W_1 \subseteq W_1 \subseteq U$$

Now consider the function,

$$h(x) \equiv \frac{\text{dist} (x, W_1^C)}{\text{dist} (x, W_1^C) + \text{dist} (x, \overline{W})}$$

Since $\overline{W}$ is compact it is at a positive distance from $W_1^C$ and so $h$ is a well defined continuous function which has compact support contained in $W_1$, equals 1 on $W$, and has values in $[0, 1]$. Now let $\phi_k$ be a mollifier. Letting

$$k^{-1} < \min \{\text{dist} (K, W^C), 2^{-1} \text{dist} (W_1, U^C)\},$$

it follows that for such $k$, the function, $h \ast \phi_k \in C^\infty_c(U)$, has values in $[0, 1]$, and equals 1 on $K$. Let $f = h \ast \phi_k$.

The above lemma is used repeatedly in the following.
Lemma 26.6.7 Let $K$ be a closed set and let $\{V_i\}_{i=1}^\infty$ be a locally finite list of bounded open sets whose union contains $K$. Then there exist functions, $\psi_i \in C_0^\infty(V_i)$ such that for all $x \in K$,

$$1 = \sum_{i=1}^\infty \psi_i(x)$$

and the function $f(x)$ given by

$$f(x) = \sum_{i=1}^\infty \psi_i(x)$$

is in $C^\infty(\mathbb{R}^n)$.

Proof: Let $K_1 = K \setminus \bigcup_{i=2}^\infty V_i$. Thus $K_1$ is compact because $K_1 \subseteq V_1$. Let $W_1$ be an open set having compact closure which satisfies

$$K_1 \subseteq W_1 \subseteq \overline{W}_1 \subseteq V_1$$

Thus $W_1, V_2, \ldots, V_n$ covers $K$ and $\overline{W}_1 \subseteq V_1$. Suppose $W_1, \ldots, W_r$ have been defined such that $\overline{W}_i \subseteq V_i$ for each $i$, and $W_1, \ldots, W_r, V_{r+1}, \ldots, V_n$ covers $K$. Then let

$$K_{r+1} = K \setminus \left( (\bigcup_{i=r+2}^\infty V_i) \cup \left( \bigcup_{j=1}^r W_j \right) \right).$$

It follows $K_{r+1}$ is compact because $K_{r+1} \subseteq V_{r+1}$. Let $W_{r+1}$ satisfy

$$K_{r+1} \subseteq W_{r+1} \subseteq \overline{W}_{r+1} \subseteq V_{r+1}, \quad \overline{W}_{r+1} \text{ is compact}$$

Continuing this way defines a sequence of open sets, $\{W_i\}_{i=1}^\infty$ having compact closures with the property

$$\overline{W}_i \subseteq V_i, \quad K \subseteq \bigcup_{i=1}^\infty W_i.$$  

Note $\{W_i\}_{i=1}^\infty$ is locally finite because the original list, $\{V_i\}_{i=1}^\infty$ was locally finite.

Now let $U_i$ be open sets which satisfy

$$\overline{W}_i \subseteq U_i \subseteq \overline{U}_i \subseteq V_i, \quad \overline{U}_i \text{ is compact}.$$  

Similarly, $\{U_i\}_{i=1}^\infty$ is locally finite.

Since the sets, $\{W_i\}_{i=1}^\infty$ are locally finite, it follows $\bigcup_{i=1}^\infty W_i = \bigcup_{i=1}^\infty \overline{W}_i$ and so it is possible to define $\phi_i$ and $\gamma_i$, infinitely differentiable functions having compact support such that

$$\overline{U}_i \preceq \phi_i \preceq V_i, \quad \overline{W}_i \preceq \gamma_i \preceq U_i.$$
Now define
\[ \psi_i(x) = \begin{cases} \gamma_i(x)\psi_i(x) / \sum_{j=1}^{\infty} \phi_j(x) & \text{if } \sum_{j=1}^{\infty} \phi_j(x) \neq 0, \\ 0 & \text{if } \sum_{j=1}^{\infty} \phi_j(x) = 0. \end{cases} \]

Note how the sum makes sense because of local finiteness. If \( x \) is such that \( \sum_{j=1}^{\infty} \phi_j(x) = 0 \), then \( x \notin \bigcup_{i=1}^{\infty} \overline{U_i} \) because \( \phi_i \) equals one on \( U_i \). Consequently, for each \( i \), \( \gamma_i(y) = 0 \) for all \( y \) near \( x \) thanks to the fact that \( \overline{U_i} \) is closed and so \( \psi_i(y) = 0 \) for all \( y \) near \( x \). Hence \( \psi_i \) is infinitely differentiable at such \( x \). If \( \sum_{j=1}^{\infty} \phi_j(x) \neq 0 \), this situation persists near \( x \) because each \( \phi_j \) is continuous and by local finiteness, so is the sum. So \( \psi_i \) is infinitely differentiable at such points also thanks to Lemma 26.6.4. Therefore \( \psi_i \) is infinitely differentiable. If \( x \in K \), then \( \gamma_i(x) = 1 \) for each \( i \) and so \( \sum_{j=1}^{\infty} \psi_j(x) = 1 \). Clearly \( 0 \leq \psi_i(x) \leq 1 \) and \( \text{spt}(\psi_j) \subseteq V_j \). This proves the theorem.

The functions, \( \{\psi_i\} \) are called a \( C^\infty \) partition of unity.

The method of proof of this lemma easily implies the following useful corollary.

**Corollary 26.6.8** If \( H \) is a compact subset of \( V_i \) for some \( V_i \) there exists a partition of unity such that \( \psi_i(x) = 1 \) for all \( x \in H \) in addition to the conclusion of Lemma 26.6.7.

**Proof:** Keep \( V_i \) the same but replace \( V_j \) with \( \widetilde{V_j} \equiv V_j \setminus H \). Now in the proof above, applied to this modified collection of open sets, if \( j \neq i, \phi_j(x) = 0 \) whenever \( x \in H \). Therefore, \( \psi_i(x) = 1 \) on \( H \).

**Lemma 26.6.9** Let \( \Omega \) be a metric space with the closed balls compact and suppose \( \mu \) is a measure defined on the Borel sets of \( \Omega \) which is finite on compact sets. Then there exists a unique Radon measure, \( \overline{\mu} \) which equals \( \mu \) on the Borel sets. In particular \( \mu \) must be both inner and outer regular on all Borel sets.

**Proof:** Define a positive linear functional, \( \Lambda(f) = \int fd\mu \). Let \( \overline{\mu} \) be the Radon measure which comes from the Riesz representation theorem for positive linear functionals. Thus for all \( f \) continuous,
\[ \int fd\mu = \int fd\overline{\mu}. \]

If \( V \) is an open set, let \( \{f_n\} \) be a sequence of continuous functions which is increasing and converges to \( \mathcal{X}_V \) pointwise. Then applying the monotone convergence theorem,
\[ \int \mathcal{X}_V d\mu = \mu(V) = \int \mathcal{X}_V d\overline{\mu} = \overline{\mu}(V) \]
and so the two measures coincide on all open sets. Every compact set is a countable intersection of open sets and so the two measures coincide on all compact sets. Now let \( B(a,n) \) be a ball of radius \( n \) and let \( E \) be a Borel set contained in this ball. Then by regularity of \( \overline{\mu} \) there exist sets \( F, G \) such that \( G \) is a countable intersection
of open sets and $F$ is a countable union of compact sets such that $F \subseteq E \subseteq G$ and $\mu(G \setminus F) = 0$. Now $\mu(G) = \overline{\mu}(G)$ and $\mu(F) = \overline{\mu}(F)$. Thus

$$\overline{\mu}(G \setminus F) + \overline{\mu}(F) = \overline{\mu}(G) = \mu(G) = \mu(G \setminus F) + \mu(F)$$

and so $\mu(G \setminus F) = \overline{\mu}(G \setminus F)$. Thus

$$\mu(E) = \mu(F) = \overline{\mu}(F) = \overline{\mu}(G) = \overline{\mu}(E).$$

If $E$ is an arbitrary Borel set, then

$$\mu(E \cap B(a,n)) = \overline{\mu}(E \cap B(a,n))$$

and letting $n \to \infty$, this yields $\mu(E) = \overline{\mu}(E)$.

One more lemma will be useful.

**Lemma 26.6.10** Let $V$ be a bounded open set and let $X$ be the closed subspace of $C(V)$, the space of continuous functions defined on $\overline{V}$, which is given by the following.

$$X = \{u \in C(V) : u(x) = 0 \text{ on } \partial V\}.$$ 

Then $C_c^\infty(V)$ is dense in $X$ with respect to the norm given by

$$\|u\| = \max\{|u(x)| : x \in \overline{V}\}$$

**Proof:** Let $O \subseteq \overline{O} \subseteq W \subseteq \overline{W} \subseteq V$ be such that $\text{dist}(\overline{O}, V^C) < \eta$ and let $\psi_\delta(\cdot)$ be a mollifier. Let $u \in X$ and consider $X_W u * \psi_\delta$. Let $\varepsilon > 0$ be given and let $\eta$ be small enough that $|u(x)| < \varepsilon/2$ whenever $x \in V \setminus \overline{O}$. Then if $\delta$ is small enough $|X_W u * \psi_\delta(x) - u(x)| < \varepsilon$ for all $x \in \overline{O}$ and $X_W u * \psi_\delta$ is in $C_c^\infty(V)$. For $x \in V \setminus \overline{O}$, $|X_W u * \psi_\delta(x)| \leq \varepsilon/2$ and so for such $x$,

$$|X_W u * \psi_\delta(x) - u(x)| \leq \varepsilon.$$

This proves the lemma since $\varepsilon$ was arbitrary.

**Definition 26.6.11** A bounded open set, $U \subseteq \mathbb{R}^n$ is said to have a Lipschitz boundary and to lie on one side of its boundary if the following conditions hold. There exist open boxes, $Q_1, \ldots, Q_N$,

$$Q_i = \prod_{j=1}^n (a_j^i, b_j^i)$$

such that $\partial U \equiv \overline{U} \setminus U$ is contained in their union. Also, for each $Q_i$, there exists $k$ and a Lipschitz function, $g_i$ such that $U \cap Q_i$ is of the form

$$\left\{x : (x_1, \ldots, x_{k-1}, x_{k+1}, \ldots, x_n) \in \prod_{j=1}^{k-1} (a_j^i, b_j^i) \times \prod_{j=k+1}^n (a_j^i, b_j^i) \text{ and } a_k^i < x_k < g_i(x_1, \ldots, x_{k-1}, x_{k+1}, \ldots, x_n)\right\}$$

(26.6.36)
or else of the form
\[
\left\{ x : (x_1, \cdots, x_{k-1}, x_{k+1}, \cdots, x_n) \in \prod_{j=1}^{k-1} (a_j^i, b_j^i) \times \prod_{j=k+1}^{n} (a_j^i, b_j^i) \leq x < b_j^i \right\}
\]

and
\[
g_i(x_1, \cdots, x_{k-1}, x_{k+1}, \cdots, x_n) < x < b_j^i \quad (26.6.37)
\]

The function, \( g_i \), has a derivative on \( A_i \subseteq \prod_{j=1}^{k-1} (a_j^i, b_j^i) \times \prod_{j=k+1}^{n} (a_j^i, b_j^i) \) where
\[
m_{n-1} \left( \prod_{j=1}^{k-1} (a_j^i, b_j^i) \times \prod_{j=k+1}^{n} (a_j^i, b_j^i) \setminus A_i \right) = 0.
\]

Also, there exists an open set, \( Q_0 \) such that \( Q_0 \subseteq \overline{Q_0} \subseteq U \) and \( \overline{U} \subseteq Q_0 \cup Q_1 \cup \cdots \cup Q_N \).

Note that since there are only finitely many \( Q_i \) and each \( g_i \) is Lipschitz, it follows from an application of Lemma 26.5.5 that \( H^{n-1}(\partial U) < \infty \). Also from Lemma 26.6.9 \( H^{n-1} \) is inner and outer regular on \( \partial U \).

**Lemma 26.6.12** Suppose \( U \) is a bounded open set as described above. Then there exists a unique function in \( L^1(\partial U, H^{n-1}) \) \( n(y) \) for \( y \in \partial U \) such that \( |n(y)| = 1, n \) is \( H^{n-1} \) measurable, (meaning each component of \( n \) is \( H^{n-1} \) measurable) and for every \( w \in \mathbb{R}^n \) satisfying \( |w| = 1 \), and for every \( f \in C^1_c(\mathbb{R}^n) \),
\[
\lim_{t \to 0} \int_U f(x + tw) - f(x) \frac{dx}{t} = \int_{\partial U} f(n \cdot w) dH^{n-1}
\]

**Proof:** Let \( \mathcal{U} \subseteq V \subseteq \mathcal{V} \subseteq \bigcup_{i=0}^{N} Q_i \), and let \( \{\psi_i\}_{i=0}^{N} \) be a \( C^\infty \) partition of unity on \( \mathcal{V} \) such that \( \text{spt}(\psi_i) \subseteq Q_i \). Then for all \( t \) small enough and \( x \in U \),
\[
\frac{f(x + tw) - f(x)}{t} = \frac{1}{t} \sum_{i=0}^{N} \psi_i f(x + tw) - \psi_i f(x)
\]

Thus using the dominated convergence theorem,
\[
\lim_{t \to 0} \int_U \frac{f(x + tw) - f(x)}{t} dx = \lim_{t \to 0} \int_U \left( \frac{1}{t} \sum_{i=0}^{N} \psi_i f(x + tw) - \psi_i f(x) \right) dx
\]
\[
= \int_U \sum_{i=0}^{N} \sum_{j=1}^{n} D_j(\psi_i f)(x) w_j dx
\]
26.6. THE DIVERGENCE THEOREM

\[ \int_U \sum_{j=1}^n D_j (\psi_i f) (x) \, w_j \, dx + \sum_{i=1}^N \int_U \sum_{j=1}^n D_j (\psi_j f) (x) \, w_j \, dx \quad (26.6.38) \]

Since \( \text{spt} (\psi_0) \subseteq Q_0 \), it follows the first term in the above equals zero. In the second term, fix \( i \). Without loss of generality, suppose the \( k \) in the above definition equals \( n \) and \( 26.6.37 \) holds. This just makes things a little easier to write. Thus \( g_i \) is a function of \( (x_1, \ldots, x_{n-1}) \in \prod_{j=1}^{n-1} (a_j^i, b_j^i) \equiv B_i \)

Then

\[ \int_U \sum_{j=1}^n D_j (\psi_i f) (x) \, w_j \, dx \]

\[ = \int_{B_i} \int_{a_i^j}^0 \sum_{j=1}^n D_j (\psi_i f) (x) \, w_j \, dx_n \, dx_1 \cdots dx_{n-1} \]

\[ = \int_{A_i} \int_{-\infty}^0 \sum_{j=1}^n D_j (\psi_i f) (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1})) \cdot \]

\[ w_j \, dy \, dx_1 \cdots dx_{n-1} \]

\[ = \int_{A_i} \int_{-\infty}^0 \sum_{j=1}^n D_j (\psi_i f) (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1})) \cdot \]

\[ w_j \, dy \, dx_1 \cdots dx_{n-1} \]

Recall \( D_j \) refers to the partial derivative taken with respect to the entry in the \( j \)th slot. In the \( n \)th slot is found not just \( x_n \) but \( y + g_i (x_1, \ldots, x_{n-1}) \) so a differentiation with respect to \( x_j \) will not be the same as \( D_j \). In fact, it will introduce another term involving \( g_{i,j} \). Thus from the chain rule,

\[ = \int_{A_i} \int_{-\infty}^0 \sum_{j=1}^{n-1} \frac{\partial}{\partial x_j} (\psi_i f (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1}))) \, w_j - \]

\[ D_n (\psi_i f) (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1})) \cdot \]

\[ g_{i,j} (x_1, \ldots, x_{n-1}) \, w_j \, dy \, dx_1 \cdots dx_{n-1} \]

\[ + \int_{A_i} \int_{-\infty}^0 D_n (\psi_i f) (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1})) \cdot \]

\[ w_n \, dy \, dx_1 \cdots dx_{n-1} \]

(26.6.39)
Consider the term
\[
\int_{A_i} \int_{-\infty}^0 \sum_{j=1}^{n-1} \frac{\partial}{\partial x_j} (\psi_i f (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1}))) \cdot w_j dy dx_1 \cdots dx_{n-1}.
\]
This equals
\[
\int_{B_i} \int_{-\infty}^0 \sum_{j=1}^{n-1} \frac{\partial}{\partial x_j} (\psi_i f (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1}))) \cdot w_j dy dx_1 \cdots dx_{n-1},
\]
and now interchanging the order of integration and using the fact that \(\text{spt} (\psi_i) \subseteq Q_i\), it follows this term equals zero. (The reason this is valid is that \(x_j \rightarrow \psi_i f (x_1, \ldots, x_{n-1}, y + g_i (x_1, \ldots, x_{n-1}))\) is the composition of Lipschitz functions and is therefore Lipschitz. Therefore, this function is absolutely continuous and can be recovered by integrating its derivative.)

Then, changing the variable back to \(x_n\) it follows \(26.6.39\) reduces to
\[
= -\int_{A_i} \int_{-\infty}^{g_i(x_1, \ldots, x_{n-1})} \left(\sum_{j=1}^{n-1} D_n (\psi_i f) (x_1, \ldots, x_{n-1}, x_n) \right) \cdot g_{i,j} (x_1, \ldots, x_{n-1}) w_j dx_n dx_1 \cdots dx_{n-1}
\]
\[
+ \int_{A_i} \int_{-\infty}^{g_i(x_1, \ldots, x_{n-1})} D_n (\psi_i f) (x_1, \ldots, x_{n-1}, x_n) w_n dx_n dx_1 \cdots dx_{n-1}
\]
Doing the integrals using the observation that \(g_{i,j} (x_1, \ldots, x_{n-1})\) does not depend on \(x_n\), this reduces further to
\[
\int_{A_i} (\psi_i f) (x_1, \ldots, x_{n-1}, x_n) \mathbf{N}_i (x_1, \ldots, x_{n-1}, g_i (x_1, \ldots, x_{n-1})) \cdot \mathbf{w} dm_{n-1}
\]
(26.6.40)
where \(\mathbf{N}_i (x_1, \ldots, x_{n-1}, g_i (x_1, \ldots, x_{n-1}))\) is given by
\[
(-g_{i,1} (x_1, \ldots, x_{n-1}), -g_{i,2} (x_1, \ldots, x_{n-1}), \ldots, -g_{i,n-1} (x_1, \ldots, x_{n-1}), 1).
\]
(26.6.41)
At this point I need a technical lemma which will allow the use of the area formula. The part of the boundary of \(U\) which is contained in \(Q_i\) is the image of the map, \(h_i (x_1, \ldots, x_{n-1})\) given by \((x_1, \ldots, x_{n-1}, g_i (x_1, \ldots, x_{n-1}))\) for \((x_1, \ldots, x_{n-1}) \in A_i\).
I need a formula for
\[
\text{det} (Dh_i (x_1, \ldots, x_{n-1})^* Dh_i (x_1, \ldots, x_{n-1}))^{1/2}.
\]
To avoid interrupting the argument, I will state the lemma here and prove it later.
Lemma 26.6.13

\[ \det \left( D h_i (x_1, \cdots, x_{n-1})^T D h_i (x_1, \cdots, x_{n-1}) \right)^{1/2} = \sqrt{1 + \sum_{j=1}^{n-1} g_{i,j} (x_1, \cdots, x_{n-1})^2} \equiv J_i (x_1, \cdots, x_{n-1}). \]

For \( y = (x_1, \cdots, x_{n-1}, g_i (x_1, \cdots, x_{n-1})) \in \partial U \cap Q_i \) and \( n \) defined by

\[ n_i (y) = \frac{1}{J_i (x_1, \cdots, x_{n-1})} N_i (y) \]

it follows from the description of \( J_i (x_1, \cdots, x_{n-1}) \) given in the above lemma, that \( n_i \) is a unit vector. All components of \( n_i \) are continuous functions of limits of continuous functions. Therefore, \( n_i \) is Borel measurable and so it is \( \mathcal{H}^{n-1} \) measurable.

Now 26.6.38 reduces to

\[ \int_{A_i} (\psi, f) (x_1, \cdots, x_{n-1}, g_i (x_1, \cdots, x_{n-1})) \times n_i (x_1, \cdots, x_{n-1}, g_i (x_1, \cdots, x_{n-1})) \cdot w J_i (x_1, \cdots, x_{n-1}) \, dm_{n-1}. \]

By the area formula this equals

\[ \int_{h(A_i)} \psi f(y) n_i (y) \cdot w d\mathcal{H}^{n-1}. \]

Now by Lemma 26.5.5 and the equality of \( m_{n-1} \) and \( \mathcal{H}^{n-1} \) on \( \mathbb{R}^{n-1} \), the above integral equals

\[ \int_{\partial U \cap Q_i} \psi f(y) n_i (y) \cdot w d\mathcal{H}^{n-1} = \int_{\partial U} \psi f(y) n_i (y) \cdot w d\mathcal{H}^{n-1}. \]

Returning to 26.6.42 similar arguments apply to the other terms and therefore,

\[ \lim_{t \to 0} \int_U f(x + tw) - f(x) t \, dm_n \]

\[ = \sum_{i=1}^{N} \int_{\partial U} \psi_i f(y) n_i (y) \cdot w d\mathcal{H}^{n-1} \]

\[ = \int_{\partial U} f(y) \sum_{i=1}^{N} \psi_i (y) n_i (y) \cdot w d\mathcal{H}^{n-1} \]

\[ = \int_{\partial U} f(y) n (y) \cdot w d\mathcal{H}^{n-1} \]

(26.6.42)

Then let \( n (y) = \sum_{i=1}^{N} \psi_i (y) n_i (y) \).

---

**26.6. THE DIVERGENCE THEOREM**
I need to show first there is no other \( \mathbf{n} \) which satisfies (26.6.34) and then I need to show that \( |\mathbf{n}(y)| = 1 \). Note that it is clear \( |\mathbf{n}(y)| \leq 1 \) because each \( \mathbf{n}_i \) is a unit vector and this is just a convex combination of these. Suppose then that \( \mathbf{n}_1 \in L^\infty (\partial U, \mathcal{H}^{n-1}) \) also works in (26.6.32). Then for all \( f \in C^1_c(\mathbb{R}^n) \),

\[
\int_{\partial U} f(y) \mathbf{n}(y) \cdot \mathbf{w} \mathcal{H}^{n-1} = \int_{\partial U} f(y) \mathbf{n}_1(y) \cdot \mathbf{w} \mathcal{H}^{n-1}.
\]

Suppose \( h \in C(\partial U) \). Then by the Tietze extension theorem, there exists \( f \in C^c(\mathbb{R}^n) \) such that the restriction of \( f \) to \( \partial U \) equals \( h \). Now by Lemma 40.6.11 applied to a bounded open set containing the support of \( f \), there exists a sequence \( \{f_m\} \) of functions in \( C^c(\mathbb{R}^n) \) converging uniformly to \( f \). Therefore,

\[
\int_{\partial U} h(y) \mathbf{n}(y) \cdot \mathbf{w} \mathcal{H}^{n-1} = \lim_{m \to \infty} \int_{\partial U} f_m(y) \mathbf{n}(y) \cdot \mathbf{w} \mathcal{H}^{n-1} = \lim_{m \to \infty} \int_{\partial U} f_m(y) \mathbf{n}_1(y) \cdot \mathbf{w} \mathcal{H}^{n-1} = \int_{\partial U} h(y) \mathbf{n}_1(y) \cdot \mathbf{w} \mathcal{H}^{n-1}.
\]

Now \( \mathcal{H}^{n-1} \) is a Radon measure on \( \partial U \) and so the continuous functions on \( \partial U \) are dense in \( L^1 (\partial U, \mathcal{H}^{n-1}) \). It follows \( \mathbf{n} \cdot \mathbf{w} = \mathbf{n}_1 \cdot \mathbf{w} \) a.e. Now let \( \{\mathbf{w}_m\}_{m=1}^\infty \) be a countable dense subset of the unit sphere. From what was just shown, \( \mathbf{n} \cdot \mathbf{w}_m = \mathbf{n}_1 \cdot \mathbf{w}_m \) except for a set of measure zero, \( N_m \). Letting \( N = \cup_m N_m \), it follows that for \( y \notin N, \mathbf{n}(y) \cdot \mathbf{w}_m = \mathbf{n}_1(y) \cdot \mathbf{w}_m \) for all \( m \). Since the set is dense, it follows \( \mathbf{n}(y) \cdot \mathbf{w} = \mathbf{n}_1(y) \cdot \mathbf{w} \) for all \( y \notin N \) and for all \( \mathbf{w} \) a unit vector. Therefore, \( \mathbf{n}(y) = \mathbf{n}_1(y) \) for all \( y \notin N \) and this shows \( \mathbf{n} \) is unique. In particular, although it appears to depend on the partition of unity \( \{\psi_i\} \) from its definition, this is not the case.

It only remains to verify \( |\mathbf{n}(y)| = 1 \) a.e. I will do this by showing how to compute \( \mathbf{n} \). In particular, I will show that \( \mathbf{n} = \mathbf{n}_1 \) a.e. on \( \partial U \cap Q_i \). Let \( W \subseteq \overline{W} \subseteq Q_i \cap \partial U \) where \( W \) is open in \( \partial U \). Let \( O \) be an open set such that \( O \cap \partial U = W \) and \( \overline{O} \subseteq Q_i \). Using Corollary 40.6.5 there exists a \( C^\infty \) partition of unity \( \{\psi_m\} \) such that \( \psi_i = 1 \) on \( \overline{O} \). Therefore, if \( m \neq i, \psi_m = 0 \) on \( \overline{O} \). Then if \( f \in C^1_c(O) \),

\[
\int_W f \mathbf{w} \cdot \mathbf{n} \mathcal{H}^{n-1} = \int_{\partial U} f \mathbf{w} \cdot \mathbf{n} \mathcal{H}^{n-1} = \int_U \nabla f \cdot \mathbf{w} dm_n
\]

\[
= \int_U \nabla (\psi_i f) \cdot \mathbf{w} dm_n
\]

which by the first part of the argument given above equals

\[
\int_W \psi_i f \mathbf{n}_i \cdot \mathbf{w} \mathcal{H}^{n-1} = \int_W f \mathbf{w} \cdot \mathbf{n}_i \mathcal{H}^{n-1}.
\]
Thus for all $f \in C^1_c(O)$,
\begin{equation}
\int_W f w \cdot n dH^{n-1} = \int_W f w \cdot n_i dH^{n-1}
\end{equation}

(26.6.43)

Since $C^1_c(O)$ is dense in $C_c(O)$, the above equation is also true for all $f \in C_c(O)$. Now letting $h \in C_c(W)$, the Tietze extension theorem implies there exists $f_1 \in C(\overline{U})$ whose restriction to $W$ equals $h$. Let $f$ be defined by

\[ f_1(x) = \frac{\text{dist}(x, O^C)}{\text{dist}(x, \text{spt}(h)) + \text{dist}(x, O^C)} = f(x). \]

Then $f = h$ on $W$ and so this has shown that for all $h \in C_c(W)$, (26.6.43) holds for $h$ in place of $f$. But as observed earlier, $H^{n-1}$ is outer and inner regular on $\partial U$ and so $C_c(W)$ is dense in $L^1(W, H^{n-1})$ which implies $w \cdot n(y) = w \cdot n_i(y)$ for a.e. $y$. Considering a countable dense subset of the unit sphere as above, this implies $n(y) = n_i(y)$ a.e. $y$. This proves $|n(y)| = 1$ a.e. and in fact $n(y)$ can be computed by using the formula for $n_i(y)$. This proves the lemma.

It remains to prove Lemma 26.6.13.

Proof of Lemma 26.6.13: Let $h(x) = (x_1, \ldots, x_n, g(x_1, \ldots, x_n))^T$.
\[ Dh(x) = \begin{pmatrix} 1 & 0 \\ \vdots & \ddots & \vdots \\ 0 & 1 \\ g_{x_1} & \cdots & g_{x_n} \end{pmatrix} \]

Therefore,
\[ J(x) = (\det(Dh(x)^* Dh(x)))^{1/2}. \]

Therefore, $J(x)$ is the square root of the determinant of the following $(n-1) \times (n-1)$ matrix.
\[ \begin{pmatrix} 1 + (g_{x_1})^2 & g_{x_1} g_{x_2} & \cdots & g_{x_1} g_{x_{n-1}} \\ g_{x_2} g_{x_1} & 1 + (g_{x_2})^2 & \cdots & g_{x_2} g_{x_{n-1}} \\ \vdots & \ddots & \ddots & \vdots \\ g_{x_{n-1}} g_{x_1} & g_{x_{n-1}} g_{x_2} & \cdots & 1 + (g_{x_{n-1}})^2 \end{pmatrix}. \]

(26.6.44)

I need to show the determinant of the above matrix equals
\[ 1 + \sum_{i=1}^{n-1} (g_{x_i}(x))^2. \]

This is implied by the following claim. To simplify the notation I will replace $n-1$ with $n$. 

**Claim:** Let $a_1, \ldots, a_n$ be real numbers and let $A(a_1, \ldots, a_n)$ be the matrix which has $1 + a_i^2$ in the $i^\text{th}$ slot and $a_i a_j$ in the $ij^\text{th}$ slot when $i \neq j$. Then

$$
\det A = 1 + \sum_{i=1}^n a_i^2.
$$

**Proof of the claim:** The matrix, $A(a_1, \ldots, a_n)$ is of the form

$$
A(a_1, \ldots, a_n) = \begin{pmatrix}
1 + a_1^2 & a_1 a_2 & \cdots & a_1 a_n \\
a_1 a_2 & 1 + a_2^2 & \cdots & a_2 a_n \\
\vdots & \vdots & \ddots & \vdots \\
a_1 a_n & a_2 a_n & \cdots & 1 + a_n^2
\end{pmatrix}
$$

Now consider the product of a matrix and its transpose, $B^T B$ below.

\[
\begin{pmatrix}
1 & 0 & \cdots & 0 & a_1 \\
0 & 1 & 0 & a_2 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & a_n \\
-a_1 & -a_2 & \cdots & -a_n & 1
\end{pmatrix}
\begin{pmatrix}
1 & 0 & \cdots & 0 & -a_1 \\
0 & 1 & 0 & -a_2 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & -a_n \\
a_1 & a_2 & \cdots & a_n & 1
\end{pmatrix}
\]

(26.6.45)

This product equals a matrix of the form

\[
\begin{pmatrix}
A(a_1, \ldots, a_n) & 0 \\
0 & 1 + \sum_{i=1}^n a_i^2
\end{pmatrix}
\]

Therefore, $(1 + \sum_{i=1}^n a_i^2) \det (A(a_1, \ldots, a_n)) = \det (B)^2 = \det (B^T)^2$. However, using row operations,

\[
\det B^T = \det \begin{pmatrix}
1 & 0 & \cdots & 0 & a_1 \\
0 & 1 & 0 & a_2 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 1 & a_n \\
0 & 0 & \cdots & 0 & 1 + \sum_{i=1}^n a_i^2
\end{pmatrix}
\]

\[
= 1 + \sum_{i=1}^n a_i^2
\]

and therefore,

\[
\left(1 + \sum_{i=1}^n a_i^2\right) \det (A(a_1, \ldots, a_n)) = \left(1 + \sum_{i=1}^n a_i^2\right)^2
\]

which shows $\det (A(a_1, \ldots, a_n)) = \left(1 + \sum_{i=1}^n a_i^2\right)$. This proves the claim.

Now the above lemma implies the divergence theorem.
Theorem 26.6.14 Let $U$ be a bounded open set with a Lipschitz boundary which lies on one side of its boundary. Then if $f \in C^1_c(\mathbb{R}^n)$,

$$\int_U f_{,k}(x) \ dm_n = \int_{\partial U} f_n k d\mathcal{H}^{n-1}$$

(26.6.46)

where $n = (n_1, \cdots, n_n)$ is the $\mathcal{H}^{n-1}$ measurable unit vector of Lemma 26.6.12. Also, if $F$ is a vector field such that each component is in $C^1_c(\mathbb{R}^n)$, then

$$\int_U \nabla \cdot F(x) \ dm_n = \int_{\partial U} F \cdot n d\mathcal{H}^{n-1}.$$  

(26.6.47)

Proof: To obtain (26.6.46) apply Lemma 26.6.12 to $w = e_k$. Then to obtain (26.6.47) from this,

$$\int_U \nabla \cdot F(x) \ dm_n = \sum_{j=1}^n \int_U F_{j,j} \ dm_n = \sum_{j=1}^n \int_{\partial U} F_{j,n_j} d\mathcal{H}^{n-1} = \int_{\partial U} \sum_{j=1}^n F_{j,n_j} d\mathcal{H}^{n-1} = \int_{\partial U} F \cdot n d\mathcal{H}^{n-1}.$$  

This proves the theorem.

What is the geometric significance of the vector, $n$? Recall that in the part of the boundary contained in $Q_i$, this vector points in the same direction as the vector

$$N_1(x_1, \cdots, x_{n-1}, g_i(x_1, \cdots, x_{n-1}))$$

given by

$$(-g_{i,1}(x_1, \cdots, x_{n-1}), -g_{i,2}(x_1, \cdots, x_{n-1}), \cdots, -g_{i,n-1}(x_1, \cdots, x_{n-1}), 1)$$

(26.6.48)

in the case where $k = n$. This vector is the gradient of the function,

$$x_n - g_i(x_1, \cdots, x_{n-1})$$

and so is perpendicular to the level surface given by

$$x_n - g_i(x_1, \cdots, x_{n-1}) = 0$$

in the case where $g_i$ is $C^1$. It also points away from $U$ so the vector $n$ is the unit outer normal. The other cases work similarly.

The divergence theorem is valid in situations more general than for Lipschitz boundaries. What you need is essentially the ability to say that the functions, $g_i$ above can be differentiated a.e. and more importantly that these functions can be recovered by integrating their partial derivatives. In other words, you need absolute continuity in each variable. Later in the chapter on weak derivatives, examples of such functions which are more general than Lipschitz functions will be discussed. However, the Lipschitz functions are pretty general and will suffice for now.
26.7 Integration And The Degree

There is a very interesting application of the degree to integration \[1\]. Recall Lemma 21.3.5. I want to generalize this to the case where \( h : \mathbb{R}^n \to \mathbb{R}^n \) is only Lipschitz continuous, vanishing outside a bounded set. In the following proposition, let \( \phi_\varepsilon \) be a symmetric nonnegative mollifier,

\[
\phi_\varepsilon (x) \equiv \frac{1}{\varepsilon^n} \phi \left( \frac{x}{\varepsilon} \right), \text{spt } \phi \subseteq B(0,1).
\]

\( \Omega \) will be a bounded open set. By Theorem 24.6.7, \( h \) satisfies

\[
Dh(x) \text{ exists a.e.,} \quad (26.7.49)
\]

For any \( p > n \),

\[
\lim_{m \to \infty} D(h \ast \psi_m) = Dh \text{ in } L^p(\mathbb{R}^n; \mathbb{R}^{n \times n}) \quad (26.7.50)
\]

where \( \psi_m \) is a mollifier.

**Proposition 26.7.1** Let \( S \subseteq h(\partial \Omega)^C \) such that

\[
\text{dist} (S, h(\partial \Omega)) > 0
\]

where \( \Omega \) is a bounded open set and also let \( h \) be Lipschitz continuous, vanishing outside some bounded set. Then whenever \( \varepsilon > 0 \) is small enough,

\[
d (h, \Omega, y) = \int_{\Omega} \phi_\varepsilon (h(x) - y) \det Dh(x) \, dx
\]

for all \( y \in S \).

**Proof:** Let \( \varepsilon_0 > 0 \) be small enough that for all \( y \in S \),

\[
B(y, 5\varepsilon_0) \cap h(\partial \Omega) = \emptyset.
\]

Now let \( \psi_m \) be a mollifier as \( m \to \infty \) with support in \( B(0, m^{-1}) \) and let

\[
h_m \equiv h \ast \psi_m.
\]

Thus \( h_m \in C^\infty(\overline{\Omega}; \mathbb{R}^n) \) and for any \( p > n \),

\[
\|h_m - h\|_{L^\infty(\Omega)}, \|Dh_m - Dh\|_{L^p(\Omega)} \to 0 \quad (26.7.51)
\]

as \( m \to \infty \). The first claim above is obvious and the second follows by 26.7.50. Choose \( M \) such that for \( m \geq M \),

\[
\|h_m - h\|_{\infty} < \varepsilon_0. \quad (26.7.52)
\]

Thus \( h_m \in \mathcal{U}_y \cap C^2(\overline{\Omega}; \mathbb{R}^n) \) for all \( y \in S \).
For \( y \in S \), let \( z \in B(y, \varepsilon) \) where \( \varepsilon < \varepsilon_0 \) and suppose \( x \in \partial \Omega \), and \( k, m \geq M \). Then for \( t \in [0, 1] \),

\[
| (1 - t) h_m(x) + h_k(x) t - z | \geq | h_m(x) - z | - t | h_k(x) - h_m(x) | \\
> 2\varepsilon_0 - t 2 \varepsilon_0 \geq 0
\]

showing that for each \( y \in S \), \( B(y, \varepsilon) \cap ((1 - t) h_m + t h_k)(\partial \Omega) = \emptyset \). By Lemma 26.7.5, for all \( y \in S \),

\[
\int_{\Omega} \phi_{\varepsilon}(h_m(x) - y) \det(D h_m(x)) \, dx = \\
\int_{\Omega} \phi_{\varepsilon}(h_k(x) - y) \det(D h_k(x)) \, dx
\]

(26.7.53)

for all \( k, m \geq M \). By this lemma again, which says that for small enough \( \varepsilon \) the integral is constant and the definition of the degree in Definition 21.2.6, \( d(y, \Omega, h_m) = \int_{\Omega} \phi_{\varepsilon}(h_m(x) - y) \det(D h_m(x)) \, dx \)

(26.7.54)

for all \( \varepsilon \) small enough. For \( x \in \partial \Omega \), \( y \in S \), and \( t \in [0, 1] \),

\[
| (1 - t) h(x) + h_m(x) t - y | \geq | h(x) - y | - t | h(x) - h_m(x) | \\
> 3\varepsilon_0 - t 3 \varepsilon_0 \geq 0
\]

and so by Theorem 26.7.6, the part about homotopy, for each \( y \in S \),

\[
d(y, \Omega, h) = d(y, \Omega, h_m) = \\
\int_{\Omega} \phi_{\varepsilon}(h_m(x) - y) \det(D h_m(x)) \, dx
\]

whenever \( \varepsilon \) is small enough. Fix such an \( \varepsilon < \varepsilon_0 \) and use 26.7.5 to conclude the right side of the above equation is independent of \( m > M \).

By 26.7.7, there exists a subsequence still denoted by \( m \) such that \( D h_m(x) \rightarrow D h(x) \) a.e. Since \( p > n \), \( \det(D h_m) \) is bounded in \( L^r(\Omega) \) for some \( r > 1 \) and so the integrands in the following are uniformly integrable. By the Vitali convergence theorem, one can pass to the limit as follows.

\[
d(y, \Omega, h) = \lim_{m \rightarrow \infty} \int_{\Omega} \phi_{\varepsilon}(h_m(x) - y) \det(D h_m(x)) \, dx \\
= \int_{\Omega} \phi_{\varepsilon}(h(x) - y) \det(D h(x)) \, dx.
\]

This proves the proposition.

Next is an interesting change of variables theorem. Let \( \Omega \) be a bounded open set with the property that \( \partial \Omega \) has measure zero and let \( h \) be Lipschitz continuous on \( \mathbb{R}^n \). Then from Lemma 26.5.1, \( h(\partial \Omega) \) also has measure zero.
Now suppose \( f \in C_c \left( h(\partial \Omega)^c \right) \). There are finitely many components of \( h(\partial \Omega)^c \) which have nonempty intersection with \( \text{spt}(f) \). From the Proposition above,

\[
\int f(y) d(y, \Omega, h) dy = \int f(y) \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(h(x) - y) \det D h(x) dx dy
\]

Actually, there exists an \( \varepsilon \) small enough that for all \( y \in \text{spt}(f) \),

\[
\lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(h(x) - y) dx = \int_{\Omega} \phi_\varepsilon(h(x) - y) dx = d(y, \Omega, h)
\]

This is because \( \text{spt}(f) \) is at a positive distance from the compact set \( h(\partial \Omega)^c \). Therefore, for all \( \varepsilon \) small enough,

\[
\int f(y) d(y, \Omega, h) dy = \int_{\Omega} \int f(y) \phi_\varepsilon(h(x) - y) dx dy = \int_{\Omega} \det D h(x) \int f(y) \phi_\varepsilon(h(x) - y) dy dx
\]

Using the uniform continuity of \( f \), you can now pass to a limit and obtain using the fact that \( \det D h(x) \) is in \( L^r(\mathbb{R}^n) \) for some \( r > 1 \),

\[
\int f(y) d(y, \Omega, h) dy = \int_{\Omega} f(h(x)) \det D h(x) dx
\]

This has proved the following interesting lemma.

**Lemma 26.7.2** Let \( f \in C_c \left( h(\partial \Omega)^c \right) \) for \( \Omega \) a bounded open set and let \( h \) be Lipschitz on \( \mathbb{R}^n \). Say \( \partial \Omega \) has measure zero so that \( h(\partial \Omega) \) has measure zero. Then everything is measurable which needs to be and

\[
\int f(y) d(y, \Omega, h) dy = \int_{\Omega} \det (D h(x)) f(h(x)) dx.
\]

Note that \( h \) is not necessarily one to one. Next is a simple corollary which replaces \( C_c(\mathbb{R}^n) \) with \( L^1_{loc}(\mathbb{R}^n) \) in the case that \( h \) is one to one. Also another assumption is made on there being finitely many components.

**Corollary 26.7.3** Let \( f \in L^1_{loc}(\mathbb{R}^n) \) and let \( h \) be one to one and satisfy 26.7.49 - 26.7.50, \( \partial \Omega \) has measure zero for \( \Omega \) a bounded open set and \( h(\partial \Omega)^c \) has finitely many components. Then everything is measurable which needs to be and

\[
\int f(y) d(y, \Omega, h) dy = \int_{\Omega} \det D h(x) f(h(x)) dx.
\]
Proof: Since \( d(y, \Omega, h) = 0 \) for all \(|y| \) large enough due to \( y \notin h(\Omega) \) for large \( y \), there is no loss of generality in assuming \( f \) is in \( L^1 (\mathbb{R}^n) \). For all \( y \notin h(\partial\Omega) \), a set of measure zero, \( d(y, \Omega, h) \) is bounded by some constant, depending on the maximum of the degree on the various components of \( h \). Then from Proposition 26.7.11

\[
\int f(y) d(y, \Omega, h) \, dy = \int f(y) \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon (h(x) - y) \, dy 
\]

This time, use the area formula to write

\[
\left| \int_{\Omega} \phi_\varepsilon (h(x) - y) \, dy \right| \leq \int_{\mathbb{R}^n} \phi_\varepsilon (h(x) - y) |\det Dh(x)| \, dx
\]

and so using the dominated convergence theorem in 26.7.55, it equals

\[
\lim_{\varepsilon \to 0} \int \det Dh(x) \int f(y) \phi_\varepsilon (h(x) - y) \, dy dx
\]

\[
= \lim_{\varepsilon \to 0} \int \det Dh(x) \int f(h(x) - y) \, dy dx
\]

Now

\[
\left| \int \det Dh(x) \int_{B(0,1)} f(h(x) - \varepsilon u) \, dudx - \int \det Dh(x) \right| \leq \int_{B(0,1)} \int_{\Omega} |\det Dh(x)| |f(h(x) - \varepsilon u) - f(h(x))| \, dxd\phi(u)
\]

which needs to converge to 0 as \( \varepsilon \to 0 \). However, from the area formula, Theorem 26.5.11 applied to the inside integral, the above equals

\[
\int f(y) d(y, \Omega, h) \, dy = \lim_{\varepsilon \to 0} \int f(y) \phi_\varepsilon (h(x) - y) \, dy dx dy
\]

and this proves the corollary.

Note that in this corollary \( h \) is one to one.
26.8 The Case Of $W^{1,p}$

There is a very interesting application of the degree to integration \[49\]. Recall Lemma 21.3.5. I want to generalize this to the case where $h : \mathbb{R}^n \to \mathbb{R}^n$ has the property that its weak partial derivatives and $h$ are in $L^p(\mathbb{R}^n; \mathbb{R}^n)$, $p > n$. This is denoted by saying

$$h \in W^{1,p}(\mathbb{R}^n; \mathbb{R}^n).$$

In the following proposition, let $\phi_\varepsilon$ be a symmetric nonnegative mollifier,

$$\phi_\varepsilon (x) = \frac{1}{\varepsilon^n} \phi \left( \frac{x}{\varepsilon} \right), \text{spt } \phi \subseteq B(0, 1).$$

$\Omega$ will be a bounded open set. By Theorem 21.6.11, $h$ may be considered continuous and it satisfies

$$Dh(x) \text{ exists a.e.,} \quad (26.8.56)$$

For any $p > n$,

$$\lim_{m \to \infty} D(h \ast \psi_m) = Dh \text{ in } L^p(\mathbb{R}^n; \mathbb{R}^{n \times n}) \quad (26.8.57)$$

where $\psi_m$ is a mollifier. Here $\mathbb{R}^{n \times n}$ denotes the $n \times n$ matrices with any norm you like.

**Proposition 26.8.1** Let $S \subseteq h(\partial \Omega)^C$ such that

$$\text{dist}(S, h(\partial \Omega)) > 0$$

where $\Omega$ is a bounded open set and also let $h$ be in $W^{1,p}(\mathbb{R}^n; \mathbb{R}^n)$. Then whenever $\varepsilon > 0$ is small enough,

$$d(h, \Omega, y) = \int_{\Omega} \phi_\varepsilon (h(x) - y) \det Dh(x) \, dx$$

for all $y \in S$.

**Proof:** Let $\varepsilon_0 > 0$ be small enough that for all $y \in S$,

$$B(y, 3\varepsilon_0) \cap h(\partial \Omega) = \emptyset.$$  

Now let $\psi_m$ be a mollifier as $m \to \infty$ with support in $B(0, m^{-1})$ and let

$$h_m = h \ast \psi_m.$$  

Thus $h_m \in C^\infty(\overline{\Omega}; \mathbb{R}^n)$ and,

$$\|h_m - h\|_{L^\infty(\Omega)}, \|Dh_m - Dh\|_{L^p(\Omega)} \to 0 \quad (26.8.58)$$

as $m \to \infty$. The first claim above follows from the definition of convolution and the uniform continuity of $h$ on the compact set $\overline{\Omega}$ and the second follows by 26.8.57. Choose $M$ such that for $m \geq M$,

$$\|h_m - h\|_{L^\infty(\Omega)} < \varepsilon_0. \quad (26.8.59)$$
26.8. THE CASE OF \( W^{1,p} \)

Thus \( h_m \in \mathcal{U}_p \cap C^2 (\Omega; \mathbb{R}^n) \) for all \( y \in S \).

For \( y \in S \), let \( z \in B(y, \varepsilon) \) where \( \varepsilon < \varepsilon_0 \) and suppose \( x \in \partial \Omega \), and \( k, m \geq M \).

Then for \( t \in [0, 1] \),

\[
|(1 - t) h_m (x) + h_k (x) t - z| \geq |h_m (x) - z| - t |h_k (x) - h_m (x)| \\
> 2\varepsilon_0 - t2\varepsilon_0 \geq 0
\]

showing that for each \( y \in S \), \( B(y, \varepsilon) \cap ((1 - t) h_m + t h_k)(\partial \Omega) = \emptyset \). By Lemma 26.8.60, for all \( y \in S \),

\[
\int_{\Omega} \phi \varepsilon (h_m (x) - y) \det (Dh_m (x)) \, dx = \\
\int_{\Omega} \phi \varepsilon (h_k (x) - y) \det (Dh_k (x)) \, dx
\]

(26.8.60)

for all \( k, m \geq M \). By this lemma again, which says that for small enough \( \varepsilon \) the integral is constant and the definition of the degree in Definition 21.2.6,

\[
d(y, \Omega, h_m) = \int_{\Omega} \phi \varepsilon (h_m (x) - y) \det (Dh_m (x)) \, dx
\]

(26.8.61)

for all \( \varepsilon \) small enough. For \( x \in \partial \Omega \), \( y \in S \), and \( t \in [0, 1] \),

\[
|(1 - t) h (x) + h_m (x) t - y| \geq |h (x) - y| - t |h (x) - h_m (x)| \\
> 3\varepsilon_0 - t2\varepsilon_0 > 0
\]

and so by Theorem 26.8.58, the part about homotopy, for each \( y \in S \),

\[
d(y, \Omega, h) = d(y, \Omega, h_m) = \\
\int_{\Omega} \phi \varepsilon (h_m (x) - y) \det (Dh_m (x)) \, dx
\]

whenever \( \varepsilon \) is small enough. Fix such an \( \varepsilon < \varepsilon_0 \) and use 26.8.60 to conclude the right side of the above equation is independent of \( m > M \).

By 26.8.65, there exists a subsequence still denoted by \( m \) such that \( Dh_m (x) \rightarrow Dh (x) \) a.e. Since \( p > n \), \( \det (Dh_m) \) is bounded in \( L^r (\Omega) \) for some \( r > 1 \) and so the integrands in the following are uniformly integrable. By the Vitali convergence theorem, one can pass to the limit as follows.

\[
d(y, \Omega, h) = \lim_{m \rightarrow \infty} \int_{\Omega} \phi \varepsilon (h_m (x) - y) \det (Dh_m (x)) \, dx
\]

\[
= \int_{\Omega} \phi \varepsilon (h (x) - y) \det (Dh (x)) \, dx.
\]

This proves the proposition.

Next is an interesting change of variables theorem. Let \( \Omega \) be a bounded open set and let \( h \in W^{1,p} (\mathbb{R}^n) \). Also assume

\[
m(h (\partial \Omega)) = 0.
\]
From Proposition 26.8.1, for \( y \notin h(\partial \Omega) \),

\[
d(y, \Omega, h) = \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(h(x) - y) \det Dh(x) \, dx,
\]

showing that \( y \to d(y, \Omega, h) \) is a measurable function since it is the limit of continuous functions off the set of measure zero \( h(\partial \Omega) \).

Now suppose \( f \in C_c \left( h(\partial \Omega)^C \right) \). There are finitely many components of \( h(\partial \Omega)^C \) which have nonempty intersection with \( \text{spt}(f) \). From the Proposition above,

\[
\int f(y) \, d(y, \Omega, h) \, dy = \int f(y) \lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(h(x) - y) \det Dh(x) \, dxdy
\]

Actually, from Proposition 26.8.1 there exists an \( \varepsilon \) small enough that for all \( y \in \text{spt}(f) \),

\[
\lim_{\varepsilon \to 0} \int_{\Omega} \phi_\varepsilon(h(x) - y) \det Dh(x) \, dx = \int_{\Omega} \phi_\varepsilon(h(x) - y) \det Dh(x) \, dx = d(y, \Omega, h)
\]

This is because \( \text{spt}(f) \) is at a positive distance from \( h(\partial \Omega)^C \). Therefore, for all \( \varepsilon \) small enough,

\[
\int f(y) \, d(y, \Omega, h) \, dy = \int \int_{\Omega} f(y) \phi_\varepsilon(h(x) - y) \det Dh(x) \, dxdy
\]

\[
= \int \det Dh(x) \int f(y) \phi_\varepsilon(h(x) - y) \, dydx
\]

\[
= \int \det Dh(x) \int f(h(x) - \varepsilon u) \phi(u) \, du \, dx
\]

Using the uniform continuity of \( f \), you can now pass to a limit as \( \varepsilon \to 0 \) and obtain, using the fact that \( \det Dh(x) \) is in \( L^r(\mathbb{R}^n) \) for some \( r > 1 \),

\[
\int f(y) \, d(y, \Omega, h) \, dy = \int_{\Omega} f(h(x)) \det Dh(x) \, dx
\]

This has proved the following interesting lemma.

**Lemma 26.8.2** Let \( f \in C_c \left( h(\partial \Omega)^C \right) \) and let \( h \in W^{1,p}(\mathbb{R}^n; \mathbb{R}^n), p > n, h(\partial \Omega) \) has measure zero for \( \Omega \) a bounded open set. Then everything is measurable which needs to be and

\[
\int f(y) \, d(y, \Omega, h) \, dy = \int_{\Omega} \det (Dh(x)) \, f(h(x)) \, dx.
\]

Note that \( h \) is not necessarily one to one. The difficult issue is handling \( d(y, \Omega, h) \) which has integer values constant on each component of \( h(\partial \Omega)^C \) and
the difficulty arrises in not knowing how many components there are. What if there are infinitely many, for example, and what if the degree changes sign. If this happens, it is hard to exploit convergence theorems to get generalizations of \( f \in C_c\left(\mathfrak{h}(\partial \Omega)^C\right) \). One way around this is to insist \( \mathfrak{h} \) be one to one and that \( \Omega \) be connected having a boundary which separates \( \mathbb{R}^n \) into two components, three if \( n = 1 \). That way, you can use the Jordan separation theorem and assert \( \mathfrak{h}(\partial \Omega) \) also separates \( \mathbb{R}^n \) into the same number of components with \( \mathfrak{h}(\Omega) \) being the only one on which the degree is nonzero.

First recall the following proposition.

**Proposition 26.8.3** Let \( \Omega \) be an open connected bounded set in \( \mathbb{R}^n, n \geq 1 \) such that \( \mathbb{R}^n \setminus \partial \Omega \) consists of two, three if \( n = 1 \), connected components. Let \( f \in C(\overline{\Omega}; \mathbb{R}^n) \) be continuous and one to one. Then \( f(\Omega) \) is the bounded component of \( \mathbb{R}^n \setminus f(\partial \Omega) \) and for \( y \in f(\Omega), d(f, \Omega, y) \) either equals 1 or \(-1\).

**Proof:** First suppose \( n \geq 2 \). By the Jordan separation theorem, \( \mathbb{R}^n \setminus f(\partial \Omega) \) consists of two components, a bounded component \( B \) and an unbounded component \( U \). Using the Tietze extension theorem, there exists \( g \) defined on \( \mathbb{R}^n \) such that \( g = f^{-1} \) on \( f(\Omega) \). Thus on \( \partial \Omega, g \circ f = id \). It follows from this and the product formula that

\[
1 \quad = \quad d(id, \Omega, g(y)) = d(g \circ f, \Omega, g(y)) \\
= \quad d(g, B, g(y)) d(f, \Omega, B) + d(f, \Omega, U) d(g, U, g(y)) \\
= \quad d(g, B, g(y)) d(f, \Omega, B)
\]

Therefore, \( d(f, \Omega, B) \neq 0 \) and so for every \( z \in B \), it follows \( z \in f(\Omega) \). Thus \( B \subseteq f(\Omega) \). On the other hand, \( f(\Omega) \) cannot have points in both \( U \) and \( B \) because it is a connected set. Therefore \( f(\Omega) \subset B \) and this shows \( B = f(\Omega) \). Thus \( d(f, \Omega, B) = d(f, \Omega, y) \) for each \( y \in B \) and the above formula shows this equals either 1 or \(-1\) because the degree is an integer. In the case where \( n = 1 \), the argument is similar but here you have 3 components in \( \mathbb{R}^1 \setminus f(\partial \Omega) \) so there are more terms in the above sum although two of them give 0. This proves the proposition.

The following is a version of the area formula.

**Lemma 26.8.4** Let \( h \in W^{1,p}(\mathbb{R}^n; \mathbb{R}^n), p > n \) where \( h \) is one to one, \( h(\partial \Omega) \) have measure zero for \( \Omega \) a bounded open connected set in \( \mathbb{R}^n \). Then \( h(\partial \Omega)^C \) has two components, three if \( n = 1 \), and for \( y \in h(\Omega), f \in C_c(\mathbb{R}^n) \).

\[
\int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det(Dh(x))| f(h(x)) \, dx
\]

If \( O \) is an open set, it is also true that

\[
\int_{h(\Omega)} \chi_O(y) \, dy = \int_{\Omega} |\det(Dh(x))| \chi_O(h(x)) \, dx
\]
Also if $f$ is any nonnegative Borel measurable function

$$\int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det (Dh(x))| f(h(x)) \, dx$$

Proof: Consider the first claim. Let $\delta$ be such that $B(x_1, \delta) \subset \Omega$ and let $\{f_j(y)\}_{j=1}^{\infty}$ be nonnegative, increasing in $j$ and converging pointwise to $\chi_{h(B(x_1, \delta))}(y)$. This can be done because $h(B(x_1, \delta))$ is an open bounded set thanks to invariance of domain, Theorem 26.5.3. By Proposition 26.5.3, $d(y, \Omega, h)$ either equals 1 or $-1$. Suppose it equals $-1$. Then from Lemma 26.7.2

$$\int_{h(\Omega)} f_j(y) \, dy = -\int_{\Omega} \det (Dh(x)) f_j(h(x)) \, dx$$

The integrand on the right is uniformly integrable thanks to the fact the $f_j$ are bounded and $\det (Dh(x))$ is in $L^r(\Omega)$ for some $r > 1$. Therefore, by the Vitali convergence theorem and the monotone convergence theorem,

$$\int_{h(\Omega)} \chi_{h(B(x_1, \delta))}(y) \, dy = -\int_{\Omega} \det (Dh(x)) \chi_{B(x_1, \delta)}(x) \, dx$$

so

$$m(h(B(x_1, \delta))) \frac{1}{m(B(x_1, \delta))} = -\frac{1}{m(B(x_1, \delta))} \int_{B(x_1, \delta)} \det (Dh(x)) \, dx$$

If $x_1$ is a Lebesgue point of $\det (Dh(x))$, then you can pass to the limit as $\delta \to 0$ and conclude

$$-\det (Dh(x_1)) \geq 0$$

Since a.e. point is a Lebesgue point, it follows that in the case where $d(y, \Omega, h) = -1$,

$$-\det (Dh(x)) = |\det (Dh(x))| \text{ a.e. } x \in \Omega$$

The case where the degree equals 1 is similar. Thus $\det (Dh(x))$ has the same sign on $h(\Omega)$.

Now let $O$ be an open set. Then by invariance of domain, $h(O)$ is also an open set. Let $V_k$ denote a decreasing sequence of open sets, $V_k \supseteq V_{k+1}$ whose intersection is the compact set $h(\partial \Omega)$ such that $m(V_k) < 1/k$. Then if $f \prec h(O) \setminus V_k$, it follows since $h(O) \setminus V_k$ is an open set which is at a positive distance from $h(\partial \Omega)$, Lemma 26.6.4 implies

$$\int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det (Dh(x))| f(h(x)) \, dx$$

Taking a sequence of such $f$ increasing to $\chi_{h(O) \setminus V_k}$, it follows from monotone convergence theorem in the above that

$$\int_{h(\Omega)} \chi_{h(O) \setminus V_k}(y) \, dy = \int_{\Omega} |\det (Dh(x))| \chi_{h(O) \setminus V_k}(h(x)) \, dx$$

$$= \int_{\Omega} |\det (Dh(x))| \chi_{h^{-1}(V_k)}(x) \, dx$$
26.8. THE CASE OF $W^{1,p}$

Now letting $k \to \infty$, it follows from the monotone convergence theorem that

$$\int_{h(\Omega)}^{X_{h(O)}} (y) dy = \int_{h(\partial \Omega)} |\det (Dh(x))| X_{O \setminus \partial \Omega}(x) dx$$

Since both $\partial \Omega$ and $h(\partial \Omega)$ have measure zero, this implies

$$\int_{h(\Omega)}^{X_{h(O)}} (y) dy = \int_{\Omega} |\det (Dh(x))| X_O(x) dx$$

Now let $\mathcal{G}$ denote the Borel sets $E$ with the property that

$$\int_{h(\Omega)}^{X_{h(E)}} (y) dy = \int_{\Omega} |\det (Dh(x))| X_E(x) dx$$

It follows easily that if $E \in \mathcal{G}$ then so does $E^C$. This is because $h(\Omega)$ has finite measure and $|\det (Dh(x))|$ is in $L^1(\Omega)$. If $E_i$ is a sequence of disjoint sets of $\mathcal{G}$ then the monotone convergence theorem implies $\cup E_i$ is also in $\mathcal{G}$. It was shown above that the $\pi$ system of open sets is contained in $\mathcal{G}$. Therefore, it follows from the lemma on $\pi$ systems, Lemma 10.12.3 on Page 311, $\mathcal{G}$ equals the Borel sets. Now the desired result follows from approximating $f \geq 0$ and Borel measurable with a sequence of Borel simple functions which converge pointwise to $f$. This proves the theorem.

The following corollary follows right away by splitting $f$ into positive and negative parts of real and imaginary parts.

**Corollary 26.8.5** Let $h$ be one to one and in $W^{1,p}(\mathbb{R}^n; \mathbb{R}^n)$, $p > n$. Let $\Omega$ be a bounded, open, connected set in $\mathbb{R}^n$ and suppose $\partial \Omega, h(\partial \Omega)$ have measure zero. Let $f \in L^1(h(\Omega))$ where $f$ is also Borel measurable. Then

$$\int_{h(\Omega)} f(y) dy = \int_{\Omega} |\det (Dh(x))| f(h(x)) dx$$

It can also be written in the form

$$\int f(y) d(y, \Omega, h) dy = \int_{\Omega} \det (Dh(x)) f(h(x)) dx$$

Note this is a general area formula under somewhat more restrictive hypotheses than the usual area formula because it involves an assumption that $\Omega$ is connected and a troublesome condition on the measure of $h(\partial \Omega), \partial \Omega$ being zero, but it does not require $h$ to be Lipschitz. It looks like a strange result because $|\det Dh(x)|$ is not in $L^\infty$ and so it is not clear why the integral on the right should even be finite just because $f$ is in $L^1$. If the result is correct, it is surprising.

The condition on the measure of $\partial \Omega$ and $h(\partial \Omega)$ is not necessary. Neither is it necessary to assume $\Omega$ is connected. This is shown next.
Theorem 26.8.6 Let \( h \) be one to one on \( \Omega \) and in \( W^{1,p}(\mathbb{R}^n;\mathbb{R}^n), p > n \). Let \( \Omega \) be a bounded, open set in \( \mathbb{R}^n \). Let \( f \in L^1(h(\Omega)) \) where \( f \) is also Borel measurable.

Then
\[
\int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det (Dh(x))| f(h(x)) \, dx
\]

It can also be written in the form
\[
\int f(y) \, d(y,\Omega,h) \, dy = \int_{\Omega} \det (Dh(x)) f(h(x)) \, dx
\]

**Proof:** Let \( \Omega \subseteq [-R,R]^n \equiv Q \). Let \( p_i(x) \equiv x_i \) where \( x = (x_1, \ldots, x_n)^T \). Then here is a claim.

**Claim:** Let \( b \) be given. There exists \( a; |a - b| \leq 4^{-k} \) such that
\[
m(h([p_i x = a] \cap Q)) = 0.
\]

Here \([p_i x = a]\) is short for \( \{x : p_i x = a\} \).

**Proof of claim:** If this is not so, then for every \( a \) in an interval centered at \( b \),
\[
m(h([p_i x = a] \cap Q)) > 0
\]

However,
\[
m\left(\bigcup_{a \in [-4^{-k},4^{-k}]} h([p_i x = a] \cap Q)\right) = m\left( h\left(\prod_j A_j\right)\right)
\]

where \( A_j = [-R,R] \) if \( j \neq i \) and \( A_i = [b - 4^{-k}, b + 4^{-k}] \). This is finite because \( h\left(\prod_j A_j\right) \) is a compact set, being the continuous image of such a set. Since \( h \) is one to one, this compact set would then be the union of uncountably many disjoint sets, each having positive measure. Thus for some \( 1/l > 0 \) there must be infinitely many of these disjoint sets having measure larger than \( 1/l, l \in \mathbb{N} \) a contradiction to the set having finite measure. This proves the claim.

Now from the claim, consider \( b_k, k \in \mathbb{Z} \) given by \( b_k = k2^{-(m+1)} \) and for each \( i = 1, \ldots, n \), let \( a_{ik} \) denote a value of the claim, \( |a_{ik} - b_k| \leq 4^{-m} \). Thus
\[
m(h([p_i x = a_{ik}] \cap Q)) = 0, i = 1, \ldots, n
\]

Thus also
\[
|a_{ik} - a_{i(k+1)}| \leq |a_{ik} - b_k| + |b_{k+1} - a_{i(k+1)}| + |b_{k+1} - b_k| \\
\leq 4^{-m} + 4^{-m} + 2^{-(m+1)} < 2^{-m}
\]

Consider boxes of the form \( \prod_{i=1}^n [a_{ik}, a_{i(k+1)}] \). Denote these boxes as \( \mathcal{B}_m \). Thus they are non overlapping boxes the sides of which are of length less than \( 2^{-m} \). Let \( \Omega_1 \) denote the union of the finitely many boxes of \( \mathcal{B}_1 \) which are contained in \( \Omega \).
Next let $\Omega_2$ denote the union of the boxes of $B_2 \cup B_1$ which are contained in $\Omega$ and so forth. Then $\bigcup_{k=1}^{\infty} \Omega_k \subseteq \Omega$. Suppose now that $p \in \Omega$. Then it is at positive distance from $\partial \Omega$. Let $k$ be the first such that $p$ is contained in a box of $B_k$ which is contained in $\Omega$. Then $p \in \Omega_k$. Therefore, this has shown that $\Omega$ is a countable union of non overlapping closed boxes $B$ which have the property that $\partial B, h(\partial B)$ have measure zero. Denote these boxes as $\{B_k\}$.

First assume $f$ is nonnegative and Borel measurable. Then from Corollary 26.8.5,

$$\int_{h(B_k)} f(y) \, dy = \int_{B_k} |\det(Dh(x))| f(h(x)) \, dx$$

Since $h(\partial B_k)$ has measure zero,

$$\int_{h(\bigcup_{k=1}^{m} B_k)} f(y) \, dy = \sum_{k=1}^{m} \int_{h(B_k)} f(y) \, dy = \sum_{k=1}^{m} \int_{B_k} |\det(Dh(x))| f(h(x)) \, dx = \int_{\bigcup_{k=1}^{m} B_k} |\det(Dh(x))| f(h(x)) \, dx$$

and now letting $m \to \infty$ and using the monotone convergence theorem,

$$\int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det(Dh(x))| f(h(x)) \, dx \quad (26.8.62)$$

Next assume in addition that $f$ is also in $L^1(h(\Omega))$. Recall that from properties of the degree, $d(y, U, h)$ is constant on $h(U)$ for $U$ a component of $\Omega$. Since $h$ is one to one, Proposition 21.6.4 implies this constant is either $-1$ or $1$. Let the components of $\Omega$ be $\{U_i\}_{i=1}^{\infty}$. Also from Theorem 21.3.7 and the assumption that $h$ is one to one, if $y \in h(U_i)$, then $y \not\in h(\bigcup_{j \neq i} U_j)$ and

$$d(y, U_i, h) + d(y, \bigcup_{j \neq i} U_j, h) = d(y, \Omega, h)$$

Since $y \not\in h(\bigcup_{j \neq i} U_j)$ the second term on the left is 0 and so $d(y, U_i, h) = d(y, \Omega, h)$. Therefore, by Corollary 26.8.8,

$$\int_{h(\Omega)} f(y) \, dy = \sum_{i=1}^{\infty} \int_{h(U_i)} f(y, \Omega, h) \, dy = \sum_{i=1}^{\infty} \int_{U_i} f(y, h(x)) \det(Dh(x)) \, dx \quad (26.8.63)$$
From (26.8.62)

\[ \sum_{i=1}^{\infty} \int X_{U_i}(x) f(h(x)) |\det(Dh(x))| \, dx \]

\[ = \int \sum_{i=1}^{\infty} X_{U_i}(x) f(h(x)) |\det(Dh(x))| \, dx \]

\[ = \int X_{\Omega} f(h(x)) |\det(Dh(x))| \, dx < \infty \]

and so by Fubini’s theorem, the sum and the integral may be interchanged in (26.8.63) to obtain from the dominated convergence theorem,

\[ \int \sum_{i=1}^{\infty} X_{U_i}(x) f(h(x)) \det(Dh(x)) \, dx \]

\[ = \int X_{\Omega} f(h(x)) \det(Dh(x)) \, dx \]

which shows

\[ \int_{h(\Omega)} f(y) \, dy = \int_{\Omega} f(h(x)) \det(Dh(x)) \, dx \quad (26.8.64) \]

Now if \( f \) is Borel measurable and in \( L^1(\Omega) \), the above may be applied to the positive parts of the real and imaginary parts of \( f \) to obtain (26.8.64) for such \( f \). This proves the theorem.

Not surprisingly, it is not necessary to assume \( f \) is Borel measurable.

**Corollary 26.8.7** Let \( h \) be one to one on \( \overline{\Omega} \) and in \( W^{1,p}(\mathbb{R}^n;\mathbb{R}^n), p > n \). Let \( \Omega \) be a bounded, open set in \( \mathbb{R}^n \). Let \( f \in L^1(h(\Omega)) \) where \( f \) is Lebesgue measurable. Then \( x \to |\det(Dh(x))| f(h(x)) \) is Lebesgue measurable and

\[ \int_{h(\Omega)} f(y) \, dy = \int_{\Omega} |\det(Dh(x))| f(h(x)) \, dx \quad (26.8.65) \]

It can also be written in the form

\[ \int f(y) \, dy \, dy = \int \det(Dh(x)) f(h(x)) \, dx \quad (26.8.66) \]

**Proof:** Let \( E \) be a Lebesgue measurable subset of \( h(\Omega) \). By regularity of the measure, there exist Borel sets \( F \subseteq E \subseteq G \) such that \( F \) and \( G \) are both Borel measurable sets contained in \( h(\Omega) \) with \( m(G \setminus F) = 0 \). Then by Theorem 26.8.6

\[ \int_{\Omega} |\det(Dh(x))| \chi_F(h(x)) \, dx = \int_{h(\Omega)} \chi_F(y) \, dy \]

\[ = \int_{h(\Omega)} \chi_E(y) \, dy = \int_{h(\Omega)} \chi_G(y) \, dy \]

\[ = \int_{\Omega} |\det(Dh(x))| \chi_G(h(x)) \, dx \quad (26.8.67) \]
which shows that

\[
|\det (Dh(x))| \mathcal{X}_E(h(x)) = |\det (Dh(x))| \mathcal{X}_G(h(x)) = |\det (Dh(x))| \mathcal{X}_E(h(x))
\]

ea.e. and so, by completeness, it follows \(x \to |\det (Dh(x))| \mathcal{X}_E(h(x))\) must be Lebesgue measurable. This is because the function \(x \to |\det (Dh(x))| \mathcal{X}_G(h(x))\) is Borel measurable due to the continuity of \(h\) which forces \(x \to \det (Dh(x))\) to be Borel measurable, and the other function in the product is of the form \(X_{h^{-1}(G)}(x)\) and since \(G\) is Borel, so is \(h^{-1}(G)\). Now the desired result follows because

\[
\int_{\Omega} |\det (Dh(x))| \mathcal{X}_E(h(x)) \, dx
\]

is between the ends of 26.8.67. The rest of the argument involves the usual technique of approximating a nonnegative function with an increasing sequence of simple functions followed by consideration of the positive and negative parts of the real and imaginary parts of an arbitrary function in \(L^1(\Omega)\). The other version of the formula follows as in the proof of Theorem 26.8.6. This proves the corollary.
Chapter 27
Integration Of Differential Forms

27.1 Manifolds

Manifolds are sets which resemble $\mathbb{R}^n$ locally. To make the concept of a manifold more precise, here is a definition.

Definition 27.1.1 Let $\Omega \subseteq \mathbb{R}^m$. A set, $U$, is open in $\Omega$ if it is the intersection of an open set from $\mathbb{R}^m$ with $\Omega$. Equivalently, a set, $U$ is open in $\Omega$ if for every point, $x \in U$, there exists $\delta > 0$ such that if $|x - y| < \delta$ and $y \in \Omega$, then $y \in U$. A set, $H$, is closed in $\Omega$ if it is the intersection of a closed set from $\mathbb{R}^m$ with $\Omega$. Equivalently, a set, $H$, is closed in $\Omega$ if whenever, $y$ is a limit point of $H$ and $y \in \Omega$, it follows $y \in H$.

Recall the following definition.

Definition 27.1.2 Let $V \subseteq \mathbb{R}^n$. $C^k(V; \mathbb{R}^m)$ is the set of functions which are restrictions to $V$ of some function defined on $\mathbb{R}^n$ which has $k$ continuous derivatives and compact support. When $k = 0$, it means the restriction to $V$ of continuous functions with compact support.

Definition 27.1.3 A closed and bounded subset of $\mathbb{R}^m$, $\Omega$, will be called an $n$-dimensional manifold with boundary, $n \geq 1$, if there are finitely many sets, $U_i$, open in $\Omega$ and continuous one to one functions, $R_i \in C^0(U_i, \mathbb{R}^n)$ such that $R_iU_i$ is relatively open in $\mathbb{R}^n_\leq \equiv \{u \in \mathbb{R}^n : u_1 \leq 0\}$, $R_i^{-1}$ is continuous. These mappings, $R_i$, together with their domains, $U_i$, are called charts and the totality of all the charts, $(U_i, R_i)$ just described is called an atlas for the manifold. Define

$$\text{int}(\Omega) \equiv \{x \in \Omega : \text{for some } i, R_i x \in \mathbb{R}^n_\leq\}$$
where $\mathbb{R}^n_\leq \equiv \{ u \in \mathbb{R}^n : u_1 < 0 \}$. Also define

$$\partial \Omega \equiv \{ x \in \Omega : \text{for some } i, R_i x \in \mathbb{R}^n_0 \}$$

where

$$\mathbb{R}^n_0 \equiv \{ u \in \mathbb{R}^n : u_1 = 0 \}$$

and $\partial \Omega$ is called the boundary of $\Omega$. Note that if $n = 1$, $\mathbb{R}^n_0$ is just the single point 0. By convention, we will consider the boundary of such a 0 dimensional manifold to be empty.

This definition is a little too restrictive. In general the collection of sets, $U_i$, is not finite. However, in the case where $\Omega$ is closed and bounded, compactness of $\Omega$ can be used to get a finite covering and since this is the case of most interest here, the assumption that the collection of sets, $U_i$, is finite is made. However, most of what is presented here can be generalized to the case of a locally finite atlas.

**Theorem 27.1.4** Let $\partial \Omega$ and $\text{int} \ (\Omega)$ be as defined above. Then $\text{int} \ (\Omega)$ is open in $\Omega$ and $\partial \Omega$ is closed in $\Omega$. Furthermore, $\partial \Omega \cap \text{int} \ (\Omega) = \emptyset$, $\Omega = \partial \Omega \cup \text{int} \ (\Omega)$, and for $n \geq 2$, $\partial \Omega$ is an $n - 1$ dimensional manifold for which $\partial (\partial \Omega) = \emptyset$. The property of being in $\text{int} \ (\Omega)$ or $\partial \Omega$ does not depend on the choice of atlas.

**Proof:** It is clear that $\Omega = \partial \Omega \cup \text{int} \ (\Omega)$. First consider the claim that $\partial \Omega \cap \text{int} \ (\Omega) = \emptyset$. Suppose this does not happen. Then there would exist $x \in \partial \Omega \cap \text{int} \ (\Omega)$. Therefore, there would exist two mappings $R_i$ and $R_j$ such that $R_j x \in \mathbb{R}^n_0$ and $R_i x \in \mathbb{R}^n_\leq$ with $x \in U_i \cap U_j$. Now consider the map, $R_j \circ R_i^{-1}$, a continuous one to one map from $\mathbb{R}^n_\leq$ to $\mathbb{R}^n_\leq$ having a continuous inverse. By continuity, there exists $r > 0$ small enough that,

$$R_i^{-1} B (R_i x, r) \subseteq U_i \cap U_j.$$  

Therefore, $R_j \circ R_i^{-1} (B (R_i x, r)) \subseteq \mathbb{R}^n_0$ and contains a point on $\mathbb{R}^n_0, R_j x$. However, this cannot occur because it contradicts the theorem on invariance of domain, Theorem 24.1, which requires that $R_j \circ R_i^{-1} (B (R_i x, r))$ must be an open subset of $\mathbb{R}^n$ and this one isn’t because of the point on $\mathbb{R}^n_0$. Therefore, $\partial \Omega \cap \text{int} \ (\Omega) = \emptyset$ as claimed. This same argument shows that the property of being in $\text{int} \ (\Omega)$ or $\partial \Omega$ does not depend on the choice of the atlas.

To verify that $\partial (\partial \Omega) = \emptyset$, let $S_i$ be the restriction of $R_i$ to $\partial \Omega \cap U_i$. Thus

$$S_i (x) = (0, (R_i x)_2, \cdots, (R_i x)_n)$$

and the collection of such points for $x \in \partial \Omega \cap U_i$ is an open bounded subset of

$$\{ u \in \mathbb{R}^n : u_1 = 0 \},$$

identified with $\mathbb{R}^{n-1}$. $S_i (\partial \Omega \cap U_i)$ is bounded because $S_i$ is the restriction of a continuous function defined on $\mathbb{R}^m$ and $\partial \Omega \cap U_i \equiv V_i$ is contained in the compact set $\Omega$. Thus if $S_i$ is modified slightly, to be of the form

$$S_i' (x) = ((R_i x)_2 - k_i, \cdots, (R_i x)_n)$$

where $k_i = \frac{1}{2}(R_i x)_1$. By convention, we will consider the boundary of such a 0 dimensional manifold to be empty.
where \( k_i \) is chosen sufficiently large enough that \((R_i(V_i))_2 - k_i < 0\), it follows that \( \{(V_i, S_i')\} \) is an atlas for \( \partial \Omega \) as an \( n - 1 \) dimensional manifold such that every point of \( \partial \Omega \) is sent to to \( \mathbb{R}^{n-1}_{<0} \) and none gets sent to \( \mathbb{R}^{n-1}_{>0} \). It follows \( \partial \Omega \) is an \( n - 1 \) dimensional manifold with empty boundary. In case \( n = 1 \), the result follows by definition of the boundary of a 0 dimensional manifold.

Next consider the claim that \( \text{int} (\Omega) \) is open in \( \Omega \). If \( x \in \text{int} (\Omega) \), are all points of \( \Omega \) which are sufficiently close to \( x \) also in \( \text{int} (\Omega) \)? If this were not true, there would exist \( \{x_n\} \) such that \( x_n \in \partial \Omega \) and \( x_n \to x \). Since there are only finitely many charts of interest, this would imply the existence of a subsequence, still denoted by \( x_n \) and a single map, \( R_i \) such that \( R_i(x_n) \in \mathbb{R}^n_0 \). But then \( R_i(x_n) \to R_i(x) \) and so \( R_i(x) \in \mathbb{R}^n_0 \) showing \( x \in \partial \Omega \), a contradiction to \( \text{int} (\Omega) \cap \partial \Omega = \emptyset \). Now it follows that \( \partial \Omega \) is closed in \( \Omega \) because \( \partial \Omega = \Omega \setminus \text{int} (\Omega) \). This proves the Theorem.

**Definition 27.1.5** An \( n \) dimensional manifold with boundary, \( \Omega \) is a \( C^k \) manifold with boundary for some \( k \geq 1 \) if

\[
R_j \circ R_i^{-1} \in C^k \left( \mathbb{R}^n; \mathbb{R}^n \right)
\]

and \( R_i^{-1} \in C^k \left( \mathbb{R}^n; \mathbb{R}^n \right) \). It is called a continuous or Lipschitz manifold with boundary if the mappings, \( R_j \circ R_i^{-1} \), \( R_i^{-1} \), \( R_j \) are respectively continuous or Lipschitz continuous. In the case where \( \Omega \) is a \( C^k \), \( k \geq 1 \) manifold, it is called orientable if in addition to this there exists an atlas, \( (U_r, R_r) \), such that whenever \( U_i \cap U_j \neq \emptyset \),

\[
\det \left( D \left( R_j \circ R_i^{-1} \right) \right) (u) > 0 \quad \text{for all} \quad u \in R_i(U_i \cap U_j)
\]

(27.1.1)

The mappings, \( R_i \circ R_i^{-1} \) are called the overlap maps. In the case where \( k = 0 \), the \( R_i \) are only assumed continuous so there is no differentiability available and in this case, the manifold is oriented if whenever \( A \) is an open connected subset of \( \text{int} (R_i(U_i \cap U_j)) \) whose boundary has measure zero and separates \( \mathbb{R}^n \) into two components,

\[
d (y, A, R_j \circ R_i^{-1}) \in \{1, 0\}
\]

(27.1.2)

depending on whether \( y \in R_j \circ R_i^{-1}(A) \). An atlas satisfying 27.1.1 or more generally 27.1.4 is called an oriented atlas.

It follows from Proposition 24.6.3 the degree in 27.1.2 is either undefined if \( y \in R_j \circ R_i^{-1} \partial A \) or it is 1, -1, or 0.

The study of manifolds is really a generalization of something with which everyone who has taken a normal calculus course is familiar. We think of a point in three dimensional space in two ways. There is a geometric point and there are coordinates associated with this point. There are many different coordinate systems which describe a point. There are spherical coordinates, cylindrical coordinates and rectangular coordinates to name the three most popular coordinate systems. These coordinates are like the vector \( u \). The point, \( x \) is like the geometric point although it is always assumed \( x \) has rectangular coordinates in \( \mathbb{R}^m \) for some \( m \). Under fairly general conditions, it can be shown there is no loss of generality in making such an assumption. Next is some algebra.
27.2 The Binet Cauchy Formula

The Binet Cauchy formula is a generalization of the theorem which says the determinant of a product is the product of the determinants. The situation is illustrated in the following picture.

\[
\begin{bmatrix} B & A \end{bmatrix}
\]

**Theorem 27.2.1** Let \( A \) be an \( n \times m \) matrix with \( n \geq m \) and let \( B \) be a \( m \times n \) matrix. Also let \( A_i \)

\[
i = 1, \ldots , C \left( n, m \right)
\]

be the \( m \times m \) submatrices of \( A \) which are obtained by deleting \( n - m \) rows and let \( B_i \)

be the \( m \times m \) submatrices of \( B \) which are obtained by deleting corresponding \( n - m \) columns. Then

\[
\det (BA) = \sum_{k=1}^{C(n,m)} \det (B_k) \det (A_k)
\]

**Proof:** This follows from a computation. By Corollary on Page 76,
\[
\det (BA) = \frac{1}{m!} \sum_{(i_1 \cdots i_m)} \sum_{(j_1 \cdots j_m)} \text{sgn} (i_1 \cdots i_m) \text{sgn} (j_1 \cdots j_m) (BA)_{i_1j_1} (BA)_{i_2j_2} \cdots (BA)_{i_mj_m}
\]

\[
= \frac{1}{m!} \sum_{(i_1 \cdots i_m)} \sum_{(j_1 \cdots j_m)} \text{sgn} (i_1 \cdots i_m) \text{sgn} (j_1 \cdots j_m) \cdot \sum_{r_1=1}^{n} B_{i_1r_1} A_{r_1j_1} \sum_{r_2=1}^{n} B_{i_2r_2} A_{r_2j_2} \cdots \sum_{r_m=1}^{n} B_{i_mr_m} A_{r_mj_m}
\]

Now denote by \( I_k \) one subsets of \( \{ 1, \cdots , n \} \) having \( m \) elements. Thus there are \( C (n, m) \) of these. Then the above equals

\[
= \sum_{k=1}^{C(n,m)} \sum_{\{ r_1, \cdots , r_m \} = I_k} \frac{1}{m!} \sum_{(i_1 \cdots i_m)} \sum_{(j_1 \cdots j_m)} \text{sgn} (i_1 \cdots i_m) \text{sgn} (j_1 \cdots j_m) \cdot B_{i_1r_1} A_{r_1j_1} B_{i_2r_2} A_{r_2j_2} \cdots B_{i_mr_m} A_{r_mj_m}
\]

\[
= \sum_{k=1}^{C(n,m)} \sum_{\{ r_1, \cdots , r_m \} = I_k} \frac{1}{m!} \sum_{(i_1 \cdots i_m)} \text{sgn} (i_1 \cdots i_m) B_{i_1r_1} B_{i_2r_2} \cdots B_{i_mr_m} \cdot \sum_{(j_1 \cdots j_m)} \text{sgn} (j_1 \cdots j_m) A_{r_1j_1} A_{r_2j_2} \cdots A_{r_mj_m}
\]
27.3. INTEGRATION OF DIFFERENTIAL FORMS ON MANIFOLDS

\[ C(n,m) \sum_{k=1}^{m!} \sum_{(r_1, \ldots, r_m) = I_k} \frac{1}{m!} \text{sgn} (r_1 \cdots r_m)^2 \det (B_k) \det (A_k) \]

\[ = \sum_{k=1}^{C(n,m)} \det (B_k) \det (A_k) \]

since there are \( m! \) ways of arranging the indices \( \{r_1, \ldots, r_m\} \).

27.3 Integration Of Differential Forms On Manifolds

This section presents the integration of differential forms on manifolds. This topic is a higher dimensional version of what is done in calculus in finding the work done by a force field on an object which moves over some path. There you evaluated line integrals. Differential forms are just a higher dimensional version of this idea and it turns out they are what it makes sense to integrate on manifolds. The following lemma, on Page 411 used in establishing the definition of the degree and in giving a proof of the Brouwer fixed point theorem is also a fundamental result in discussing the integration of differential forms.

Lemma 27.3.1 Let \( g : U \to V \) be \( C^2 \) where \( U \) and \( V \) are open subsets of \( \mathbb{R}^n \). Then

\[ \sum_{j=1}^{n} (\text{cof}(Dg))_{ij,j} = 0, \]

where here \( (Dg)_{ij} \equiv g_{ij} = \frac{\partial g_i}{\partial x_j} \).

Also recall the interesting relation of the degree to integration in Corollary 26.7.1.

Corollary 27.3.2 Let \( f \in L^p_{\text{loc}}(\mathbb{R}^n) \) for \( p \geq 1 \) and let \( h \) be Lipschitz where \( \partial U \) has measure zero for \( U \) a bounded open set and \( h(\partial U)^C \) has finitely many components. Then everything is measurable which needs to be and

\[ \int f(y) \, d(y, U, h) \, dy = \int_U \det Dg(x) f(h(x)) \, dx. \]

(Recall that if \( y \notin h(U) \), then \( d(y, U, h) = 0 \).)

Recall Proposition 21.6.9.

Proposition 27.3.3 Let \( \Omega \) be an open connected bounded set in \( \mathbb{R}^n \) such that \( \mathbb{R}^n \setminus \partial \Omega \) consists of two, three if \( n = 1 \), connected components. Let \( f \in C(\overline{\Omega}, \mathbb{R}^n) \) be continuous and one to one. Then \( f(\Omega) \) is the bounded component of \( \mathbb{R}^n \setminus f(\partial \Omega) \) and for \( y \in f(\Omega) \), \( d(f, \Omega, y) \) either equals 1 or −1.
Also recall the following fundamental lemma on partitions of unity in Corollary 13.5.9.

**Lemma 27.3.4** Let $K$ be a compact set in $\mathbb{R}^n$ and let $\{U_i\}_{i=1}^\infty$ be an open cover of $K$. Then there exist functions, $\psi_k \in C_c^\infty(U_i)$ such that $\psi_i \prec U_i$ and for all $x \in K$,

$$\sum_{i=1}^\infty \psi_i(x) = 1.$$  

If $K$ is a compact subset of $U_1 \cup U_i$ there exist such functions such that also $\psi_1(x) = 1$ ($\psi_i(x) = 1$) for all $x \in K$.

With the above, what follows is the definition of what a differential form is and how to integrate one.

**Definition 27.3.5** Let $I$ denote an ordered list of $n$ indices taken from the set, $\{1, \ldots, m\}$. Thus $I = \{i_1, \ldots, i_n\}$. It is an ordered list because the order matters. A differential form of order $n$ in $\mathbb{R}^m$ is a formal expression,

$$\omega = \sum_I a_I(x) \, dx^I$$

where $a_I$ is at least Borel measurable $dx^I$ is short for the expression

$$dx_{i_1} \wedge \cdots \wedge dx_{i_n},$$

and the sum is taken over all ordered lists of indices taken from the set, $\{1, \ldots, m\}$. For $\Omega$ an orientable $n$ dimensional manifold with boundary, define

$$\int_\Omega \omega$$

according to the following procedure in which it is assumed the integrals which occur make sense. Let $\{(U_i, R_i)\}$ be an oriented atlas for $\Omega$. Each $U_i$ is the intersection of an open set in $\mathbb{R}^m$, $O_i$, with $\Omega$ and so there exists a $C^\infty$ partition of unity subordinate to the open cover, $\{O_i\}$ which sums to 1 on $\Omega$. Thus $\psi_i \in C_c^\infty(O_i)$, has values in $[0,1]$ and satisfies $\sum_i \psi_i(x) = 1$ for all $x \in \Omega$. Then define $\int_\Omega \omega$ by

$$\int_\Omega \omega \equiv \sum_{i=1}^P \sum_I \int_{R_i U_i} \psi_i(R_i^{-1}(u)) a_I(R_i^{-1}(u)) \frac{\partial (x_{i_1} \cdots x_{i_n})}{\partial (u_1 \cdots u_n)} \, du$$

where that symbol at the end denotes

$$\det \begin{pmatrix} x_{i_1,u_1} & x_{i_1,u_2} & \cdots & x_{i_1,u_n} \\ x_{i_2,u_1} & x_{i_2,u_2} & \cdots & x_{i_2,u_n} \\ \vdots & \vdots & \ddots & \vdots \\ x_{i_n,u_1} & x_{i_n,u_2} & \cdots & x_{i_n,u_n} \end{pmatrix}(u)$$

for $(x_1, x_2, \ldots, x_n) = R_i^{-1}(u)$.  

27.3. INTEGRATION OF DIFFERENTIAL FORMS ON MANIFOLDS

Of course there are all sorts of questions related to whether this definition is well defined. The formula [Equation 27.3.6] makes no mention of partitions of unity or a particular atlas. What if you had a different atlas and a different partition of unity? Would \( \int_{\Omega} \omega \) change? In general, the answer is yes. However, there is a sense in which [Equation 27.3.6] is well defined. This involves the concept of orientation. This looks a lot like the concept of an oriented manifold.

**Definition 27.3.6** Suppose \( \Omega \) is an \( n \) dimensional orientable manifold with boundary and let \((U_i, R_i)\) and \((V_i, S_i)\) be two oriented atlases of \( \Omega \). They have the same orientation if for all open connected sets \( A \subseteq S_j (V_j \cap U_i) \) with \( \partial A \) having measure zero and separating \( \mathbb{R}^n \) into two components,

\[
\int_{U_i} d\left( u, R_i \circ S_j^{-1}, A \right) \in \{0, 1\}
\]

depending on whether \( u \in R_i \circ S_j^{-1}(A) \).

The above definition of \( \int_{\Omega} \omega \) is well defined in the sense that any two atlases which have the same orientation deliver the same value for this symbol.

**Theorem 27.3.7** Suppose \( \Omega \) is an \( n \) dimensional Lipschitz orientable manifold with boundary and let \((U_i, R_i)\) and \((V_i, S_i)\) be two oriented atlases of \( \Omega \). Suppose the two atlases have the same orientation. Then if \( \int_{\Omega} \omega \) is computed with respect to the two atlases the same number is obtained.

**Proof:** Let \( \{ \psi_i \} \) be a partition of unity as described in Lemma 27.3.4 which is associated with the atlas \((U_i, R_i)\) and let \( \{ \eta_i \} \) be a partition of unity associated in the same manner with the atlas \((V_i, S_i)\). First note the following.

\[
\sum_I \int_{R_i U_i} \psi_i (R_i^{-1}(u)) a_I (R_i^{-1}(u)) \frac{\partial (x_{i_1} \cdots x_{i_n})}{\partial (u_1 \cdots u_n)} du
\]

(27.3.5)

\[
= \sum_{j=1}^q \sum_I \int_{R_i (U_i \cap V_j)} \eta_j (R_i^{-1}(u)) \psi_i (R_i^{-1}(u)) a_I (R_i^{-1}(u)) \frac{\partial (x_{i_1} \cdots x_{i_n})}{\partial (u_1 \cdots u_n)} du
\]

\[
= \sum_{j=1}^q \sum_I \int_{R_i (U_i \cap V_j)} \eta_j (R_i^{-1}(u)) \psi_i (R_i^{-1}(u)) a_I (R_i^{-1}(u)) \frac{\partial (x_{i_1} \cdots x_{i_n})}{\partial (u_1 \cdots u_n)} du
\]

The reason this can be done is that points not on the interior of \( R_i (U_i \cap V_j) \) are on the plane \( u_1 = 0 \) which is a set of measure zero.

Now let \( A \) be an open connected set contained in \( S_j (U_j \cap V_j) \) whose boundary \( \partial A \) separates \( \mathbb{R}^n \) into two components. Then by assumption,

\[
\int_{R_i \circ S_j^{-1}(A)} \eta_j (R_i^{-1}(u)) \psi_i (R_i^{-1}(u)) a_I (R_i^{-1}(u)) \frac{\partial (x_{i_1} \cdots x_{i_n})}{\partial (u_1 \cdots u_n)} du
\]

(27.3.6)
27.3.2 was the goal. With this, the definition of \( \int_{\mathbb{R}^n} \eta_j (R_i^{-1}(u)) \psi_i (R_i^{-1}(u)) \alpha_I \left( R_i^{-1}(u) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (u_1 \cdot \cdot \cdot u_n)} du \)

due to that degree is given to be 1. (Unless \( u \in R_i \circ S_j^{-1}(A) \), the above degree equals 0.) By Corollary 24.6.7, this equals

\[
\int_A \eta_j \left( S_j^{-1}(v) \right) \psi_i \left( S_j^{-1}(v) \right) \alpha_I \left( S_j^{-1}(v) \right) \cdot \frac{\partial (x_i, \ldots, x_n)}{\partial (u_1 \cdot \cdot \cdot u_n)} \left( R_i \circ S_j^{-1}(v) \right) \det \left( D \left( R_i \circ S_j^{-1}(v) \right) \right) dv
\]

and by the chain rule and Rademacher’s theorem, Theorem 24.6.7, this equals

\[
\int_A \eta_j \left( S_j^{-1}(v) \right) \psi_i \left( S_j^{-1}(v) \right) \alpha_I \left( S_j^{-1}(v) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (v_1 \cdot \cdot \cdot v_n)} dv \quad (27.3.7)
\]

Thus for every open \( A \) of the sort described \( 27.3.4 = 27.3.8 \). By the Vitali covering theorem, there exists a sequence of disjoint open balls \( \{B_k\} \) whose union fills \( \text{int}(S_j(U_i \cap V_j)) \) except for a set of measure zero \( N \). Since \( R_i \circ S_j^{-1} \) is Lipschitz, it follows \( R_i \circ S_j^{-1}(N) \) also has measure zero. Therefore,

\[
\int_{\mathbb{R}^n} \eta_j \left( R_i^{-1}(u) \right) \psi_i \left( R_i^{-1}(u) \right) \alpha_I \left( R_i^{-1}(u) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (u_1 \cdot \cdot \cdot u_n)} du \quad (27.3.8)
\]

\[
= \int_{\text{int} R_i(U_i \cap V_j)} \eta_j \left( R_i^{-1}(u) \right) \psi_i \left( R_i^{-1}(u) \right) \alpha_I \left( R_i^{-1}(u) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (u_1 \cdot \cdot \cdot u_n)} du
\]

\[
= \sum_{k=1}^{\infty} \int_{B_k} \eta_j \left( S_j^{-1}(v) \right) \psi_i \left( S_j^{-1}(v) \right) \alpha_I \left( S_j^{-1}(v) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (v_1 \cdot \cdot \cdot v_n)} dv
\]

\[
= \int_{\text{int} S_j(U_i \cap V_j)} \eta_j \left( S_j^{-1}(v) \right) \psi_i \left( S_j^{-1}(v) \right) \alpha_I \left( S_j^{-1}(v) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (v_1 \cdot \cdot \cdot v_n)} dv \quad (27.3.9)
\]

The equality of \( 27.3.8 \) and \( 27.3.9 \) was the goal. With this, the definition of \( \int \omega \) using the atlas \( (U_i, R_i) \) and partition of unity \( \{\psi_i\}_{i=1}^p \) given in \( 27.3.4 \) is

\[
\sum_{i=1}^{p} \sum_{j} \int_{R_j U_i} \psi_j \left( R_j^{-1}(u) \right) \alpha_I \left( R_j^{-1}(u) \right) \frac{\partial (x_i, \ldots, x_n)}{\partial (u_1 \cdot \cdot \cdot u_n)} du
\]
27.4 STOKES THEOREM AND THE ORIENTATION OF \( \partial \Omega \)

\[
= \sum_{j=1}^{q} \sum_{i=1}^{p} \int_{S_j(U_i \cap V_j)} \eta_j (S_{j}^{-1} (v)) \psi_i (S_{j}^{-1} (v)) a_I (S_{j}^{-1} (v)) \frac{\partial (x_i \cdots x_{n})}{\partial (v_1 \cdots v_n)} dv
\]

and from 27.3.8 - 27.3.9, this equals

\[
= \sum_{j=1}^{q} \sum_{i=1}^{p} \int_{S_j(U_i \cap V_j)} \eta_j (S_{j}^{-1} (v)) \psi_i (S_{j}^{-1} (v)) a_I (S_{j}^{-1} (v)) \frac{\partial (x_i \cdots x_{n})}{\partial (v_1 \cdots v_n)} dv
\]

which is the definition of \( \int \omega \) using the other atlas and partition of unity. This proves the theorem.

27.3.1 The Derivative Of A Differential Form

The derivative of a differential form is defined next.

**Definition 27.3.8** Let \( \omega = \sum_I a_I (x) dx_i \wedge \cdots \wedge dx_{n-1} \) be a differential form of order \( n-1 \) where \( a_I \) has weak partial derivatives. Then define \( d\omega \), a differential form of order \( n \) by replacing \( a_I (x) \) with

\[
da_I (x) = \sum_{k=1}^{m} \frac{\partial a_I (x)}{\partial x_k} dx_k
\]

and putting a wedge after the \( dx_k \). Therefore,

\[
d\omega = \sum_{I} \sum_{k=1}^{m} \frac{\partial a_I (x)}{\partial x_k} dx_k \wedge dx_i \wedge \cdots \wedge dx_{n-1}.
\]

27.4 Stoke’s Theorem And The Orientation Of \( \partial \Omega \)

Here \( \Omega \) will be an \( n \) dimensional orientable Lipschitz manifold with boundary in \( \mathbb{R}^m \). Let an oriented manifold for it be \( \{U_i, R_i\}_{i=1}^{p} \) and let a \( C^\infty \) partition of unity be \( \{\psi_i\}_{i=1}^{p} \). Also let

\[
\omega = \sum_I a_I (x) dx_i \wedge \cdots \wedge dx_{n-1}
\]

be a differential form such that \( a_I \) is \( C^1 (\overline{\Omega}) \). Since \( \sum \psi_i (x) = 1 \) on \( \Omega \),

\[
d\omega = \sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \frac{\partial (\psi_j a_I)}{\partial x_k} (x) dx_k \wedge dx_i \wedge \cdots \wedge dx_{n-1}
\]

It follows

\[
\int d\omega = \sum_{I} \sum_{k=1}^{m} \sum_{j=1}^{p} \int_{R_j(U_j)} \frac{\partial (\psi_j a_I)}{\partial x_k} (R_j^{-1} (u)) \frac{\partial (x_k, x_i \cdots x_{n-1})}{\partial (u_1, \cdots, u_n)} du
\]
27.4.12 equals (27.4.13)
term vanishes because of $e$
can be applied to each of the integrals in the above sum and obtain that for a
The integrands are also uniformly integrable. Thus the Vitali convergence theorem

\[ \sum_{l=1}^{m} \sum_{j=1}^{p} \int_{R_{j}(U_{j})} \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \frac{\partial (x_{k}, x_{j}, \ldots, x_{i_{n}-1}, \varepsilon)}{\partial (u_{1}, \ldots, u_{n})} \, du + \]

\[ - \sum_{l=1}^{m} \sum_{j=1}^{p} \int_{R_{j}(U_{j})} \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \frac{\partial (x_{k}, x_{j}, \ldots, x_{i_{n}-1}, \varepsilon)}{\partial (u_{1}, \ldots, u_{n})} \, du \]  

(27.4.12)

where those last two expressions sum to $e(\varepsilon)$ which converges to 0 as $\varepsilon \to 0$ for a
suitable subsequence. Here is why.

\[ \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \to \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \]

because of the uniform convergence of $R_{j}^{-1}$ to $R_{j}^{-1}$. In addition to this,

\[ \frac{\partial (x_{k}, x_{j}, \ldots, x_{i_{n}-1}, \varepsilon)}{\partial (u_{1}, \ldots, u_{n})} \to \frac{\partial (x_{k}, x_{j}, \ldots, x_{i_{n}-1}, \varepsilon)}{\partial (u_{1}, \ldots, u_{n})} \]

in $L^{r} (R_{j}(U_{j}))$ for any $r > 0$ and so a suitable subsequence converges pointwise.
The integrands are also uniformly integrable. Thus the Vitali convergence theorem
can be applied to each of the integrals in the above sum and obtain that for a
suitable subsequence, $e(\varepsilon) \to 0$.

Then (27.4.13) equals

\[ = \sum_{l=1}^{m} \sum_{j=1}^{p} \int_{R_{j}(U_{j})} \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \sum_{l=1}^{m} \frac{\partial x_{k}}{\partial u_{l}} A_{i_{l}} \, du + e(\varepsilon) \]

where $A_{i_{l}}$ is the $l^{th}$ cofactor for the determinant

\[ \frac{\partial (x_{k}, x_{j}, \ldots, x_{i_{n}-1}, \varepsilon)}{\partial (u_{1}, \ldots, u_{n})} \]

which is determined by a particular $I$. I am suppressing the $\varepsilon$ for the sake of notation. Then the above reduces to

\[ = \sum_{l=1}^{m} \sum_{j=1}^{p} \int_{R_{j}(U_{j})} \sum_{l=1}^{n} A_{i_{l}} \sum_{k=1}^{m} \frac{\partial (\psi_{j} a_{l})}{\partial x_{k}} \left( R_{j}^{-1} (u) \right) \frac{\partial x_{k}}{\partial u_{l}} \, du + e(\varepsilon) \]

\[ = \sum_{l=1}^{m} \sum_{j=1}^{p} \int_{R_{j}(U_{j})} \sum_{l=1}^{n} A_{i_{l}} \frac{\partial (\psi_{j} a_{l} \circ R_{j}^{-1})}{\partial u_{l}} (u) \, du + e(\varepsilon) \]

(27.4.13)

(Note $l$ goes up to $n$ not $m$.) Recall $R_{j}(U_{j})$ is relatively open in $\mathbb{R}_{\leq}^{n}$. Consider the
integral where $l > 1$. Integrate first with respect to $u_{l}$. In this case the boundary
term vanishes because of $\psi_{j}$ and you get

\[ - \int_{U_{j}(x_{j})} A_{i_{l}} \frac{\partial (\psi_{j} a_{l} \circ R_{j}^{-1})}{\partial u_{l}} (u) \, du \]

(27.4.14)
Next consider the case where \( l = 1 \). Integrating first with respect to \( u_1 \), the term reduces to
\[
\int_{\mathbb{R}^1_{V_j}} \psi_j a_I \circ R_j^{-1} (0, u_2, \ldots, u_n) A_{11} du_1 - \int_{\mathbb{R}^1_{U_j}} A_{11,1} \left( \psi_j a_I \circ R_j^{-1} \right) (u) du
\]  
(27.4.15)
where \( \mathbb{R}^1_{V_j} \) is an open set in \( \mathbb{R}^{n-1} \) consisting of
\[
\{(u_2, \ldots, u_n) \in \mathbb{R}^{n-1} : (0, u_2, \ldots, u_n) \in \mathbb{R}_j (U_j) \}
\]
and \( du_1 \) represents \( du_2 du_3 \cdots du_n \) on \( \mathbb{R}^1_{V_j} \) for short. Thus \( V_j \) is just the part of \( \partial \Omega \) which is in \( U_j \) and the mappings \( S_j^{-1} \) given on \( \mathbb{R}^1_{V_j} = \mathbb{R}^1_{j} (U_j \cap \partial \Omega) \) by
\[
S_j^{-1} (u_2, \ldots, u_n) \equiv R_j^{-1} (0, u_2, \ldots, u_n)
\]
are such that \( \{(S_j, V_j)\} \) is an atlas for \( \partial \Omega \). Then if \( \mathbb{R}^{n-1}_{\Omega} \) and \( \mathbb{R}^{n-1}_{\partial \Omega} \) are placed in \( \mathbb{R}^{n-1}_{\Omega} \), then it follows from Lemma [lemma reference] that this reduces to
\[
\sum_j \sum_{l=1}^p \int_{\mathbb{R}^1_{V_j}} \psi_j a_I \circ R_j^{-1} (0, u_2, \ldots, u_n) A_{11} du_1 + \varepsilon (\varepsilon)
\]
Now as before, there exists a subsequence, still denoted as \( \varepsilon \) such that each \( \partial x_1 / \partial u_r \) converges pointwise to \( \partial x_1 / \partial u_r \) and then using that these are bounded in every \( L^p \), one can use the Vitali convergence theorem to pass to a limit obtaining finally
\[
\sum_j \sum_{l=1}^p \int_{\mathbb{R}^1_{V_j}} \psi_j a_I \circ R_j^{-1} (0, u_2, \ldots, u_n) A_{11} du_1 = \sum_j \sum_{l=1}^p \int_{S_j V_j} \psi_j a_I \circ S_j^{-1} (u_2, \ldots, u_n) A_{11} du_1
\]
\[
= \sum_j \sum_{l=1}^p \int_{S_j V_j} \psi_j a_I \circ S_j^{-1} (u_2, \ldots, u_n) \partial \left( \frac{x_1 \cdots x_{n-1}}{\partial (u_2, \ldots, u_n)} \right) (0, u_2, \ldots, u_n) du_1
\]  
(27.4.16)
This of course is the definition of \( \int_{\partial \Omega} \omega \) provided \( \partial \Omega \) is orientable. This is shown next.

What if \( \text{spt } a_I \subseteq K \subseteq U_i \cap U_j \) for each \( I \)? Then using Lemma [lemma reference] it can be shown that \( \int d\omega = \)
\[
\sum_I \int_{S_I (V_j \cap V_j)} a_I \circ S_j^{-1} (u_2, \ldots, u_n) \partial \left( \frac{x_1 \cdots x_{n-1}}{\partial (u_2, \ldots, u_n)} \right) (0, u_2, \ldots, u_n) du_1
\]
This is done by using a partition of unity which has the property that \( \psi_j \) equals 1 on \( K \) which forces all the other \( \psi_k \) to equal zero there. Using the same trick involving a judicious choice of the partition of unity, \( \int d\omega \) is also equal to
\[
\sum_I \int_{S_I (V_j \cap V_j)} a_I \circ S_i^{-1} (v_2, \ldots, v_n) \partial \left( \frac{x_1 \cdots x_{n-1}}{\partial (v_2, \ldots, v_n)} \right) (0, v_2, \ldots, v_n) dv_1
\]
Similarly if \( A \) is an open connected subset of \( S_i \) \((V_j \cap V_j)\) whose measure zero boundary separates \( \mathbb{R}^n \) into two components, and \( K \) is a compact subset of \( S_i^{-1} (A) \), containing \( \text{spt} \ a_I \) for all \( I, \int d\omega \) equals each of \( \text{Cor. 27.21} \) and \( \text{Cor. 27.20} \) below.

\[
\sum_I \int_A a_I \circ S_i^{-1} (v_1, \ldots, v_n) \frac{\partial (x_i, \ldots, x_{i-1})}{\partial (v_2, \ldots, v_n)} (0, v_2, \ldots, v_n) d\nu_1 \tag{27.4.17}
\]

\[
\sum_I \int_{S_j \circ S_i^{-1} (A)} a_I \circ S_j^{-1} (u_2, \ldots, u_n) \frac{\partial (x_i, \ldots, x_{i-1})}{\partial (u_2, \ldots, u_n)} du_1 \tag{27.4.18}
\]

By Corollary \text{Cor. 27.22} applied to \( S_j \circ S_i^{-1} (v_1) = u_1 \), the expression in \text{Cor. 27.21} equals

\[
\sum_I \int_{S_j \circ S_i^{-1} (A)} a_I \circ S_j^{-1} (u_2, \ldots, u_n) \frac{\partial (x_i, \ldots, x_{i-1})}{\partial (u_2, \ldots, u_n)} du_1
\]

and so, subtracting \text{Cor. 27.21} and the above,

\[
\sum_I \int_{S_j \circ S_i^{-1} (A)} a_I \circ S_j^{-1} (u_2, \ldots, u_n) \frac{\partial (x_i, \ldots, x_{i-1})}{\partial (u_2, \ldots, u_n)} du_1 = 0
\]

Now by invariance of domain, it follows \( S_j \circ S_i^{-1} (A) \) is an open connected set contained in a single component of \( (S_j \circ S_i^{-1} (A))^{\complement} \) and so the above degree is constant on \( S_j \circ S_i^{-1} (A) \). If this degree is not 1 then it follows that for any choice of the \( a_I \) having compact support in \( S_i^{-1} (A) \),

\[
\sum_I \int_{S_j \circ S_i^{-1} (A)} a_I \circ S_j^{-1} (u_2, \ldots, u_n) \frac{\partial (x_i, \ldots, x_{i-1})}{\partial (u_2, \ldots, u_n)} du_1 = 0 \tag{27.4.19}
\]

Next let \( I \) always denote an increasing list of indices. Note that \( S_j \circ S_i^{-1} \) maps the open set \( A \) to an open set which therefore has positive Lebesgue measure. It follows from the area formula that

\[
\det (D (S_j \circ S_i^{-1})) = \det \left( \frac{n \times m}{\det (D (S_j \circ S_i^{-1} (u)) D (S_i^{-1} (u))} \right) \tag{27.4.20}
\]

must be nonzero on a set of positive measure. It follows that at least some

\[
\frac{\partial (x_i, \ldots, x_{i-1})}{\partial (u_2, \ldots, u_n)}
\]

must be nonzero since by the Binet Cauchy theorem, the above determinant in \text{Cor. 27.21} is the sum of products of these multiplied by other determinants which
come from deleting corresponding columns in the matrix for \(D \left( S_j \left( S_i^{-1}(u) \right) \right)\). It follows that
\[
\sum_I \left( \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_2, \cdots, u_n)} \right)^2
\]
is positive on a set of positive measure. Let \(\lim_{p \to \infty} a_{tp} \circ S_i^{-1} = \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_2, \cdots, u_n)}\) in \(L^2 (S_j \circ S_i^{-1}(A))\) for each \(I = (i_1, \cdots, i_{n-1})\). Replacing \(a_I \circ S_i^{-1}\) with \(a_{tp} \circ S_i^{-1}\) in \(\text{Grads} \) and passing to the limit, it follows
\[
0 = \lim_{p \to \infty} \int_{S_j \circ S_i^{-1}(A)} \sum_I a_{tp} \circ S_i^{-1} (u_I) \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_2, \cdots, u_n)} \, du_I
= \int_{S_j \circ S_i^{-1}(A)} \left( \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_2, \cdots, u_n)} \right)^2 \, du_I > 0
\]
a contradiction. Therefore, \(d (u_1, A, S_j \circ S_i^{-1}) = 1\) and this shows the atlas is an oriented atlas for \(\partial \Omega\). This has proved a general Stokes theorem.

**Theorem 27.4.1** Let \(\Omega\) be an oriented Lipschitz manifold and let
\[
\omega = \sum_I a_I \left( x_1 \right) \, dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}},
\]
where each \(a_I\) is \(C^1(\overline{\Omega})\). For \(\{U_j, R_j\}_{j=0}^p\) an oriented atlas for \(\Omega\) where \(R_j \left( U_j \right)\) is a relatively open set in \(\{u \in \mathbb{R}^n : u_1 \leq 0\}\), define an atlas for \(\partial \Omega\), \(\{V_j, S_j\}\) where \(V_j \equiv \partial \Omega \cap U_j\) and \(S_j\) is just the restriction of \(R_j\) to \(V_j\). Then this is an oriented atlas for \(\partial \Omega\) and
\[
\int_{\partial \Omega} \omega = \int_{\Omega} d\omega
\]
where the two integrals are taken with respect to the given oriented atlas.

What if \(a_I\) is only the restriction to \(\Omega\) of a function in \(W^{1,p}(\mathbb{R}^m)\), \(p > 1\)? Would the same formula still hold? Let \(\phi_\varepsilon\) be a mollifier and let \(a_{I_\varepsilon} \equiv a_I * \phi_\varepsilon\). Then Stoke’s theorem applies to the mollified situation and it follows
\[
\int_{\Omega} d\omega_\varepsilon
= \sum_I \sum_{k=1}^m \sum_{j=1}^p \int_{R_j(U_j)} \frac{\partial (\psi_j a_{I_\varepsilon})}{\partial x_k} \left( R_j^{-1}(u) \right) \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_1, \cdots, u_n)} \, du
= \sum_{j=1}^p \sum_{j=1}^p \int_{S_j \circ V_j} \psi_j a_{I_\varepsilon} \circ S_j^{-1} (u_2, \cdots, u_n) \frac{\partial (x_{i_1} \cdots x_{i_{n-1}})}{\partial (u_2, \cdots, u_n)} \left( 0, u_2, \cdots, u_n \right) \, du_1
= \int_{\partial \Omega} \omega_\varepsilon
\]
CHAPTER 27. INTEGRATION OF DIFFERENTIAL FORMS

Now if you let $\varepsilon \rightarrow 0$, it follows from the definition of convolution that

$$\frac{\partial (\psi_j a_{1\varepsilon})}{\partial x_k} \rightarrow \frac{\partial (\psi_j a_I)}{\partial x_k} \text{ in } L^p(\mathbb{R}^m)$$

and so there is a subsequence such that for each $k$,

$$\frac{\partial (\psi_j a_{1\varepsilon})}{\partial x_k}(x) \rightarrow \frac{\partial (\psi_j a_I)}{\partial x_k}(x)$$

pointwise a.e. Since $R_j^{-1}, R_j$ are Lipschitz, they take sets of measure zero to sets of measure zero. Hence

$$\frac{\partial (\psi_j a_{1\varepsilon})}{\partial x_k} \circ R_j^{-1} \rightarrow \frac{\partial (\psi_j a_I)}{\partial x_k} \circ R_j^{-1}$$

pointwise a.e. on $R_j(U_j)$. Similar considerations apply to $a_{1\varepsilon}$. Using the Vitali convergence theorem in $\int_\Omega \omega_\varepsilon, \int_\Omega \omega$, it is possible to pass to the limit. This is because the integrands are bounded in $L^p$ and so they are uniformly integrable. This proves the following corollary.

**Corollary 27.4.2** Let $\Omega$ be an oriented Lipschitz manifold and let

$$\omega = \sum_I a_I(x) \, dx_1 \wedge \cdots \wedge dx_{n-1},$$

where each $a_I$ is in $W^{1,p}(\mathbb{R}^m)$ where $p > 1$. For $\{U_j, R_j\}_{j=0}^p$ an oriented atlas for $\Omega$ where $R_j(U_j)$ is a relatively open set in

$$\{u \in \mathbb{R}^n : u_1 \leq 0\},$$

define an atlas for $\partial \Omega, \{V_j, S_j\}$ where $V_j \equiv \partial \Omega \cap U_j$ and $S_j$ is just the restriction of $R_j$ to $V_j$. Then this is an oriented atlas for $\partial \Omega$ and

$$\int_{\partial \Omega} \omega = \int_\Omega d\omega$$

where the two integrals are taken with respect to the given oriented atlas.

### 27.5 Green’s Theorem

Green’s theorem is a well known result in calculus and it pertains to a region in the plane. I am going to generalize to an open set in $\mathbb{R}^n$ with sufficiently smooth boundary using the methods of differential forms described above.
27.5.1 An Oriented Manifold

A bounded open subset, $\Omega$, of $\mathbb{R}^n$, $n \geq 2$ has Lipschitz boundary and lies locally on one side of its boundary if it satisfies the following conditions.

For each $p \in \partial \Omega \equiv \overline{\Omega} \setminus \Omega$, there exists an open set, $Q$, containing $p$, an open interval $(a, b)$, a bounded open set $B \subseteq \mathbb{R}^{n-1}$, and an orthogonal transformation $R$ such that $\det R = 1$,

$$B \times (a, b) = RQ,$$

and letting $W = Q \cap \Omega$, $R$ is Lipschitz continuous on $\mathbb{R}^{n-1}$. $g$ vanishing outside some compact set in $\mathbb{R}^{n-1}$.

$$R (\partial \Omega \cap Q) = \{u \in \mathbb{R}^n : u_1 = g(u_2, \cdots, u_n), (u_2, \cdots, u_n) \in B\}.$$

Note that finitely many of these sets $Q$ cover $\partial \Omega$ because $\partial \Omega$ is compact. The following picture describes the situation.

Define $P_1 : \mathbb{R}^n \to \mathbb{R}^{n-1}$ by

$$P_1 u \equiv (u_2, \cdots, u_n)$$

and $\Sigma : \mathbb{R}^n \to \mathbb{R}^n$ given by

$$\Sigma u \equiv u - g(P_1 u) e_1$$

$$\equiv (u_1 - g(u_2, \cdots, u_n), u_2, \cdots, u_n)$$

Thus $\Sigma$ is invertible and

$$\Sigma^{-1} u = u + g(P_1 u) e_1$$

$$\equiv (u_1 + g(u_2, \cdots, u_n), u_2, \cdots, u_n)$$

For $x \in \partial \Omega \cap Q$, it follows the first component of $Rx$ is $g(P_1 (Rx))$. Now define $R : W \to \mathbb{R}^n_\leq$ as

$$u \equiv Rx \equiv Rx - g(P_1 (Rx)) e_1 \equiv \Sigma Rx$$
and so it follows

$$R^{-1} = R^* \Sigma^{-1}.$$ 

These mappings $R$ involve first a rotation followed by a variable shear in the direction of the $u_1$ axis.

Since $\partial \Omega$ is compact, there are finitely many of these open sets, $Q_1, \ldots, Q_p$ which cover $\partial \Omega$. Let the orthogonal transformations and other quantities described above also be indexed by $k$ for $k = 1, \ldots, p$. Also let $Q_0$ be an open set with $Q_0 \subseteq \Omega$ and $\Omega$ is covered by $Q_0, Q_1, \ldots, Q_p$. Let $u \equiv R_0 x \equiv x - k e_1$ where $k$ is large enough that $R_0 Q_0 \subseteq \mathbb{R}^n_\epsilon$. Thus in this case, the orthogonal transformation $R_0$ equals $I$ and $\Sigma_0 x = x - k e_1$. I claim $\Omega$ is an oriented manifold with boundary and the charts are $(W_i, R_i)$.

Letting $A$ be an open set contained in $R_i (W_i \cap W_j)$ such that $\partial A$ has measure 0 and $\partial A$ separates $\mathbb{R}^n$ into two components, consider

$$d \left( u, A, R_j \circ R_i^{-1} \right), \ u \notin R_j \circ R_i^{-1} (\partial A)$$

By convolving $g$ with a mollifier, there exists a sequence of infinitely differentiable functions $g_\epsilon$ which converge uniformly to $g$ on all of $\mathbb{R}^{n-1}$ as $\epsilon \to 0$. Therefore, letting $\Sigma_\epsilon$ be the corresponding functions defined above with $g$ replaced with $g_\epsilon$, it follows the $\Sigma_\epsilon$ will converge uniformly to $\Sigma$ and $\Sigma_\epsilon^{-1}$ will converge uniformly to $\Sigma^{-1}$. Thus from the above descriptions of $R_j^{-1}$, it follows $R_j^{-1}$ converges uniformly to $R_j^{-1}$ for each $j$. Therefore, if $\epsilon$ is small enough, $u \notin (\partial R_\epsilon \circ R_i^{-1} + (1 - t) R_j \circ R_i^{-1}) (\partial A)$ and so from properties of the degree, the mappings $R_j$ and $R_i^{-1}$ can be replaced with smooth ones in computing the degree. To save on notation, I will drop the $\epsilon$.

The mapping involved is

$$\Sigma_j R_j R_i^* \Sigma_i^{-1}$$

and it is a one to one mapping. What is the determinant of its derivative? By the chain rule,

$$D \left( \Sigma_j R_j R_i^* \Sigma_i^{-1} \right) = D \Sigma_j \left( R_j R_i^* \Sigma_i^{-1} \right) D R_j \left( R_i^* \Sigma_i^{-1} \right) D R_i \left( \Sigma_i^{-1} \right) D \Sigma_i^{-1}$$

However,

$$\det \left( D \Sigma_j \right) = 1 = \det \left( D \Sigma_i^{-1} \right)$$

and $\det (R_i) = \det (R_i^*) = 1$ by assumption. Therefore, if $u \in (R_j \circ R_i^{-1}) (A)$, the above degree is 1 and if $u$ is not in this set, the above degree is 0 or undefined if $u$ is on $(R_j \circ R_i^{-1}) (\partial A)$. By Definition 27.1.5, $\Omega$ is indeed an oriented manifold.

### 27.5.2 Green’s Theorem

The general Green’s theorem is the following. It follows from Corollary 27.4.2.

**Theorem 27.5.1** Let $\Omega$ be a bounded open set having Lipschitz boundary as described above. Also let

$$\omega = \sum_I a_I (x) \, dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}}$$
be a differential form where \( a_1 \) is assumed to be the restriction to \( \Omega \) of a function in \( W^{1,p}(\mathbb{R}^n) \), \( p > 1 \). Then

\[
\int_{\partial \Omega} \omega = \int_{\Omega} d\omega
\]

It can be shown that, since the boundary is Lipschitz, it would have sufficed to assume \( u \in W^{1,p}(\Omega) \) and then it is automatically the restriction of one in \( W^{1,p}(\mathbb{R}^n) \). However, these terms have not all been defined and the necessary results are not proved till the topic of Sobolev spaces is discussed.

Another thing to notice is that, while the above result is pretty general, including the usual calculus result in the plane as a special case, it does not have the generality of the best results in the plane which involve only a rectifiable simple closed curve. The issue whether \( \partial \Omega \) is an oriented manifold was dealt with in the general Stokes theorem described above.

Next is a general version of the divergence theorem which comes from choosing the differential form in an auspicious manner.

### 27.6 The Divergence Theorem

From Green’s theorem, one can quickly obtain a general Divergence theorem for \( \Omega \) as described above in Section 27.5.1. First note that from the above description of the \( R_j \),

\[
\frac{\partial (x_k, x_{i_1}, \cdots x_{i_{n-1}})}{\partial (u_1, \cdots, u_n)} = \text{sgn} (k, i_1, \cdots, i_{n-1})
\]

So let \( F(x) \) be a Lipschitz vector field. Say \( F = (F_1, \cdots, F_n) \). Consider the differential form

\[
\omega(x) = \sum_{k=1}^{n} F_k(x) (-1)^{k-1} \ dx_1 \wedge \cdots \wedge \widehat{dx_k} \wedge \cdots \wedge dx_n
\]

where the hat means \( dx_k \) is being left out. Here it is assumed \( F_k \) is the restriction to \( \Omega \) of a function in \( W^{1,p}(\mathbb{R}^n) \) where \( p > 1 \). Then

\[
d\omega(x) = \sum_{k=1}^{n} \sum_{j=1}^{n} \frac{\partial F_k}{\partial x_j} (-1)^{k-1} \ dx_j \wedge dx_1 \wedge \cdots \wedge \widehat{dx_k} \wedge \cdots \wedge dx_n
\]

\[
= \sum_{k=1}^{n} \frac{\partial F_k}{\partial x_k} dx_1 \wedge \cdots \wedge dx_k \wedge \cdots \wedge dx_n
\]

\[
= \text{div} (F) dx_1 \wedge \cdots \wedge dx_k \wedge \cdots \wedge dx_n
\]

The assertion between the first and second lines follows right away from properties of determinants and the definition of the integral of the above wedge products in terms of determinants. From Green’s theorem and the change of variables formula applied to the individual terms in the description of \( \int_{\Omega} d\omega \)

\[
\int_{\Omega} \text{div} (F) \ dx =
\]
\[
\sum_{j=1}^{p} \int_{B_j} \sum_{k=1}^{n} (-1)^{k-1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} \left( \psi_j F_k \right) \circ R_j^{-1} (0, u_2, \cdots, u_n) \, du_1,
\]

\(du_1\) short for \(du_2 du_3 \cdots du_n\). Also, this shows the result on the right of the equal sign does not depend on the choice of partition of unity or on the atlas.

I want to write this in a more attractive manner which will give more insight in terms of the Hausdorff measure on \(\partial \Omega\). The above involves a particular partition of unity, the functions being the \(\psi_j\). Replace \(F\) in the above with \(\psi_j F\). Next let \(\{\eta_j\}\) be a partition of unity \(\eta_j \prec O_j\) such that \(\eta_n = 1\) on \(spt \psi_s\). This partition of unity exists by Lemma 27.6.23. Then

\[
\int_{\Omega} \text{div} (\psi_s F) \, dx =
\]

\[
\sum_{j=1}^{p} \int_{B_j} \sum_{k=1}^{n} (-1)^{k-1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} (\eta_j \psi_s F_k) \circ R_j^{-1} (0, u_2, \cdots, u_n) \, du_1
\]

\[
= \int_{B_j} \sum_{k=1}^{n} (-1)^{k-1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} (\psi_s F_k) \circ R_s^{-1} (0, u_2, \cdots, u_n) \, du_1 \quad (27.6.21)
\]

because since \(\eta_n = 1\) on \(spt \psi_s\), it follows all the other \(\eta_j\) equal zero there. Consider the vector defined for \(u_1 \in R_s (W_s) \cap R^n\) whose \(k\)th component is

\[
(-1)^{k-1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} = (-1)^{k+1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} \quad (27.6.22)
\]

Suppose you dot this vector with a “tangent” vector \(\partial R_s^{-1} / \partial u_i\). For each \(j\) this yields

\[
\sum_{j} (-1)^{k+1} \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} \frac{\partial x_k}{\partial u_i} = 0
\]

because it is the expansion of

\[
\begin{bmatrix}
  x_{1,i} & x_{1,2} & \cdots & x_{1,n} \\
  x_{2,i} & x_{2,2} & \cdots & x_{2,n} \\
  \vdots & \vdots & \ddots & \vdots \\
  x_{n,i} & x_{n,2} & \cdots & x_{n,n}
\end{bmatrix}
\]

a determinant with two equal columns. Thus this vector is at least in some sense normal to \(\Omega\). Since it works in the divergence theorem, it is called the exterior normal.

One could normalize the vector of (27.6.22) by dividing by its magnitude. Then it would be the unit exterior normal \(\mathbf{n}\). Letting \(J(u_1)\) be its usual Euclidean norm, this equals

\[
J(u_1)^2 = \sum_{k=1}^{n} \left( \frac{\partial (x_1, \cdots, \tilde{x}_k \cdots, x_n)}{\partial (u_2, \cdots, u_n)} \right)^2
\]
and by the Binet Cauchy theorem this equals
\[
\det\left(DR_s^{-1}(u)^T DR_s^{-1}(u)\right)^{1/2}
\]
Thus the expression in (27.6.21) reduces to
\[
\int_{B_s} (\psi_s F \circ R_s^{-1}(u_1)) \cdot n(R_s^{-1}(u_1)) J(u_1) \, du_1.
\]
By the area formula, Theorem 26.5.11, this reduces to
\[
\int_{\partial\Omega \cap W_s} \psi_s F \cdot n d\mathcal{H}^{n-1} = \int_{\partial\Omega} \psi_s F \cdot n d\mathcal{H}^{n-1}.
\]
It follows upon summing over \(s\) and using that the \(\psi_s\) add to 1,
\[
\int_{\partial\Omega} F \cdot n d\mathcal{H}^{n-1} = \int_{\Omega} \sum_{s=1}^p \text{div} (\psi_s F) \, dx
\]
\[
= \int_{\Omega} \sum_{s=1}^p \psi_{s,k} F_k + \psi_s \text{div} (F) \, dx = \int_{\Omega} F_k \left(\sum_{s=1}^p \psi_s\right)_{,k} + \psi_s \text{div} (F) \, dx
\]
\[
= \int_{\Omega} \text{div} (F) \, dx
\]
This proves the following general divergence theorem.

**Theorem 27.6.1** Let \(\Omega\) be a bounded open set having Lipschitz boundary as described above. Also let \(F\) be a vector field with the property that for each component function of \(F\), \(F_k\) is the restriction to \(\Omega\) of a function in \(W^{1,p}(\mathbb{R}^n)\), \(p > 1\). Then there exists a normal vector \(n\) which is defined a.e. on \(\partial\Omega\) such that
\[
\int_{\partial\Omega} F \cdot n d\mathcal{H}^{n-1} = \int_{\Omega} \text{div} (F) \, dx
\]
It is clear \(n\) is unique \(\mathcal{H}^{n-1}\) a.e. since if there were two, then a simple manipulation shows for all such \(F\),
\[
\int_{\partial\Omega} F \cdot (n - n_1) \, d\mathcal{H}^{n-1} = 0
\]
Thus \(n - n_1 = 0\) a.e.
CHAPTER 27. INTEGRATION OF DIFFERENTIAL FORMS
Chapter 28

Differentiation Of Radon Measures

This is a brief chapter on certain important topics on the differentiation theory for general Radon measures. For different proofs and some results which are not discussed here, a good source is [44] which is where I first read some of these things. The Besicovitch covering theorem is one of the most amazing and insightful ideas that I have ever encountered. It is simultaneously elegant, elementary and profound. The next section is an attempt to present this wonderful result.

28.1 Besicovitch Covering Theorem

When dealing with probability distribution functions or some other Radon measure, it is necessary to have a better covering theorem than the Vitali covering theorem which works well for Lebesgue measure. However, for a Radon measure, if you enlarge the ball by making the radius larger, you don’t know what happens to the measure of the enlarged ball except that its measure does not get smaller. Thus the thing required is a covering theorem which does not depend on enlarging balls.

The first fundamental observation is found in the following lemma which holds for the context illustrated by the following picture. This picture is drawn such that the balls come from the usual Euclidean norm, but the norm could be any norm on $\mathbb{R}^n$.

![Diagram of Besicovitch Covering Theorem](image-url)
The idea is to consider balls $B_i$ which intersect a given ball $B$ such that $B$ contains no center of any $B_i$ and no $B_i$ contains the center of another $B_j$. There are two cases to consider, the case where the balls have large radii and the case where the balls have small radii.

Intersections with big balls

**Lemma 28.1.1** Let the balls $B_a, B_x, B_y$ be as shown having radii $r, r_x, r_y$ respectively. Suppose the centers of $B_x$ and $B_y$ are not both in any of the balls shown, and suppose $r_y \geq r_x \geq 0$ where $\alpha$ is a number larger than 1. Also let $P_x \equiv a + r \frac{x-a}{|x-a|}$ with $P_y$ being defined similarly. Then it follows that $|P_x - P_y| \geq \frac{\alpha - 1}{\alpha + 1} r$. There exists a constant $L(n, \alpha)$ depending on $\alpha$ and the dimension, such that if $B_1, \cdots, B_m$ are all balls such that any pair are in the same situation relative to $B_a$ as $B_x$ and $B_y$, then $m \leq L(n, \alpha)$.

**Proof:** From the definition,

$$
|P_x - P_y| = r \left| \frac{x-a}{|x-a|} - \frac{y-a}{|y-a|} \right|
= r \left| \frac{(x-a)||y-a| - (y-a)||x-a|}{|x-a||y-a|} \right|
\geq r \left| \frac{|x-y|}{|x-a|} - r \frac{|y-a|}{|x-a||y-a|} \right|
= r \left| \frac{|x-y|}{|x-a|} - \frac{r}{|x-a|} |y-a| - |x-a| \right|. \quad (28.1.1)
$$

There are two cases. First suppose that $|y-a| - |x-a| \geq 0$. Then the above

$$
= r \left| \frac{|x-y|}{|x-a|} - \frac{r}{|x-a|} |y-a| + r. 
$$

From the assumptions, $|x-y| \geq r_y$ and also $|y-a| \leq r + r_y$. Hence the above

$$
\geq r \left( \frac{r_y}{|x-a|} - \frac{r + r_y}{|x-a|} + 1 \right) \geq r \left( 1 - \frac{r}{|x-a|} \right)
\geq r \left( 1 - \frac{r}{r_x} \right) \geq r \left( 1 - \frac{1}{\alpha} \right) = r \left( \frac{\alpha - 1}{\alpha} \right) \geq \frac{\alpha - 1}{\alpha + 1}.
$$

The other case is that $|y-a| - |x-a| < 0$ in (28.1.1). Then in this case (28.1.1) reduces to

$$
= r \left( \frac{|x-y|}{|x-a|} - \frac{1}{|x-a|} (|x-a| - |y-a|) \right)
= r \left( \frac{|x-y|}{|x-a|} - 1 + \frac{|y-a|}{|x-a|} \right)
= r \left( \frac{|x-y|}{|x-a|} - 1 + \frac{|y-a|}{|x-a|} \right)
$$
28.1. BESICOVITCH COVERING THEOREM

\[ \frac{r}{||x-a||} (||x-y|| + ||y-a||) \]

equals

\[ r \left( \frac{||x-y||}{||x-a||} - \frac{1}{||x-a||} \right) \left( \frac{||y-a||}{||x-a||} - \frac{1}{||x-a||} \right) \]

Then since \( ||x-a|| \leq r + r_x, ||x-y|| \geq r_y, ||y-a|| \leq r + r_x, ||y-a|| \geq r_y, \)

\[ \geq \frac{r}{r_x + r} (r_y - (r + r_x) + r_y) \geq \frac{r}{r_x + r} \left( r_y - (r + r_y) + r_y \right) \]

\[ \geq \frac{r}{r_x + r} (r_y - r) \geq \frac{r}{r_x + r} \left( r_x - r \right) \geq \frac{r}{r_x + r} \left( r_x - \frac{1}{\alpha} r_x \right) \]

\[ = \frac{r}{1 + (1/\alpha)} \left( (1 - 1/\alpha) \right) = \frac{\alpha - 1}{\alpha + 1} \]

This proves the estimate between \( P_x \) and \( P_y \).

Finally, in the case of the balls \( B_i \) having centers at \( x_i \), then as above, let \( P_{x_i} = a + r_{x_i - a} \). Then \( (P_{x_i} - a) r^{-1} \) is on the unit sphere having center \( 0 \). Furthermore,

\[ ||(P_{x_i} - a) r^{-1} - (P_{y_i} - a) r^{-1}|| = r^{-1} ||P_{x_i} - P_{y_i}|| \geq r^{-1} \frac{\alpha - 1}{\alpha + 1} \]

How many points on the unit sphere can be pairwise this far apart? This set is compact and so there exists a \( \frac{1}{4} \left( \frac{\alpha - 1}{\alpha + 1} \right) \) net having \( L(n, \alpha) \) points. Thus \( m \) cannot be any larger than \( L(n, \alpha) \) because if it were, then by the pigeon hole principal, two of the points \( (P_{x_i} - a) r^{-1} \) would lie in a single ball \( B \left( p, \frac{1}{4} \left( \frac{\alpha - 1}{\alpha + 1} \right) \right) \) so they could not be \( \frac{\alpha - 1}{\alpha + 1} \) apart.

The above lemma has to do with balls which are relatively large intersecting a given ball. Next is a lemma which has to do with relatively small balls intersecting a given ball. Note that in the statement of this lemma, the radii are smaller than \( \alpha r \) in contrast to the above lemma in which the radii of the balls are larger than \( \alpha r \). In the application of this lemma, we will have \( \gamma = 4/3 \) and \( \beta = 1/3 \). These constants will come from a construction, while \( \alpha \) is just something larger than 1 which we will take here to equal 10.

**Intersections with small but comparable balls**

**Lemma 28.1.2** Let \( B \) be a ball having radius \( r \) and suppose \( B \) has nonempty intersection with the balls \( B_1, \ldots, B_m \) having radii \( r_1, \ldots, r_m \) respectively, and as before, no \( B_i \) has the center of any other and the centers of the \( B_i \) are not contained in \( B \). Suppose \( \alpha, \gamma > 1 \) and the \( r_i \) are comparable with \( r \) in the sense that

\[ \frac{1}{\gamma} r \leq r_i \leq \alpha r. \]
Let \( B'_i \) have the same center as \( B_i \) with radius equal to \( r'_i = \beta r_i \) for some \( \beta < 1 \). If the \( B'_i \) are disjoint, then there exists a constant \( M(n, \alpha, \beta, \gamma) \) such that \( m \leq M(n, \alpha, \beta, \gamma) \). Letting \( \alpha = 10, \beta = 1/3, \gamma = 4/3 \), it follows that \( m \leq 60^n \).

**Proof:** Let the volume of a ball of radius \( r \) be given by \( \alpha(n) r^n \) where \( \alpha(n) \) depends on the norm used and on the dimension \( n \) as indicated. The idea is to enlarge \( B \), till it swallows all the \( B'_i \). Then, since they are disjoint and their radii are not too small, there can’t be too many of them.

This can be done for a single \( B'_i \) by enlarging the radius of \( B \) to \( r + r_i + r'_i \).

Then to get all the \( B_i \), you would just enlarge the radius of \( B \) to \( r + \alpha r + \beta \alpha r = (1 + \alpha + \alpha \beta) r \). Then, using the inequality which makes \( r_i \) comparable to \( r \), it follows that

\[
\sum_{i=1}^{m} \alpha(n) \left( \frac{\beta}{\gamma} r \right)^n \leq \sum_{i=1}^{m} \alpha(n) (\beta r_i)^n \leq \alpha(n) (1 + \alpha + \alpha \beta)^n r^n
\]

Therefore,

\[
m \left( \frac{\beta}{\gamma} \right)^n \leq (1 + \alpha + \alpha \beta)^n
\]

and so \( m \leq (1 + \alpha + \alpha \beta)^n \left( \frac{\beta}{\gamma} \right)^n \equiv M(n, \alpha, \beta, \gamma) \).

From now on, let \( \alpha = 10 \) and let \( \beta = 1/3 \) and \( \gamma = 4/3 \). Then

\[
M(n, \alpha, \beta, \gamma) \leq \left( \frac{172}{3} \right)^n \leq 60^n
\]

Thus \( m \leq 60^n \).

The next lemma gives a construction which yields balls which are comparable as described in the above lemma. \( r(B) \) will denote the radius of the ball \( B \).

**A construction of a sequence of balls**

**Lemma 28.1.3** Let \( \mathcal{F} \) be a nonempty set of nonempty balls in \( \mathbb{R}^n \) with

\[
\sup \{ \text{diam} (B) : B \in \mathcal{F} \} \leq D < \infty
\]

and let \( A \) denote the set of centers of these balls. Suppose \( A \) is bounded. Define a sequence of balls from \( \mathcal{F} \), \{\( B_j \)\}_{j=1}^{J} \) where \( J \leq \infty \) such that

\[
r(B_1) \geq \frac{3}{4} \sup \{ r(B) : B \in \mathcal{F} \}
\]

(28.1.2)
and if
\[ A_m \equiv A \setminus (\bigcup_{i=1}^m B_i) \neq \emptyset, \] (28.1.3)
then \( B_{m+1} \in \mathcal{F} \) is chosen with center in \( A_m \) such that
\[ r_{m+1} \equiv r(B_{m+1}) \geq \frac{3}{4} \sup \{ r : B(a,r) \in \mathcal{F}, a \in A_m \}. \] (28.1.4)

Then letting \( B_j = B(a_j, r_j) \), this sequence satisfies
\[ r(B_k) \leq \frac{4}{3} r(B_j) \text{ for } j < k, \] (28.1.5)
\[ \{B(a_j, r_j/3)\}_{j=1}^J \text{ are disjoint}, \] (28.1.6)
\[ A \subseteq \bigcup_{i=1}^J B_i. \] (28.1.7)

**Proof:** Consider (28.1.3). First note the sets \( A_m \) form a decreasing sequence. Thus from the definition of \( B_j \), for \( j < k \),
\[ r(B_k) \leq \sup \{ r : B(a,r) \in \mathcal{F}, a \in A_{k-1} \} \]
\[ \leq \sup \{ r : B(a,r) \in \mathcal{F}, a \in A_{j-1} \} \leq \frac{4}{3} r(B_j) \]
because the construction gave
\[ r(B_j) \geq \frac{3}{4} \sup \{ r : B(a,r) \in \mathcal{F}, a \in A_{j-1} \}. \]

Next consider (28.1.6). If \( x \in B(a_j, r_j/3) \cap B(a_i, r_i/3) \) where these balls are two which are chosen by the above scheme such that \( j > i \), then from what was just shown
\[ ||a_j - a_i|| \leq ||a_j - x|| + ||x - a_i|| \leq \frac{r_j}{3} + \frac{r_i}{3} \leq \left( \frac{4}{9} + \frac{1}{3} \right) r_i = \frac{7}{9} r_i < r_i \]
and this contradicts the construction because \( a_j \) is not covered by \( B(a_i, r_i) \).

Finally consider the claim that \( A \subseteq \bigcup_{i=1}^J B_i \). Pick \( B_1 \) satisfying (28.1.2). If \( B_1, \ldots, B_m \) have been chosen, and \( A_m \) is given in (28.1.3) then if it equals \( \emptyset \), it follows \( A \subseteq \bigcup_{i=1}^m B_i \). Set \( J = m \). Now let \( a \) be the center of \( B_a \in \mathcal{F} \). If \( a \in A_m \) for all \( m \). (That is \( a \) does not get covered by the \( B_i \)) then \( r_{m+1} \geq \frac{3}{4} r(B_a) \) for all \( m \), a contradiction since the balls \( B(a_j, \frac{r_j}{3}) \) are disjoint and \( A \) is bounded, implying that \( r_j \to 0 \). Thus \( a \) must fail to be in some \( A_m \) which means it got covered by some ball in the sequence. □

As explained above, in this sequence of balls from the above lemma, if \( j < k \)
\[ \frac{3}{4} r(B_k) \leq r(B_j) \]
Then there are two cases to consider,
\[ r(B_j) \geq 10r(B_k), \] \[ r(B_j) \leq 10r(B_k) \]
In the first case, we use Lemma 28.1.1 to estimate the number of intersections of $B_k$ with $B_j$ for $j < k$. In the second case, we use Lemma 28.1.2 to estimate the number of intersections of $B_k$ with $B_j$ for $j < k$.

Now here is the Besicovitch covering theorem.

**Theorem 28.1.4** There exists a constant $N_n$, depending only on $n$ with the following property. If $F$ is any collection of nonempty balls in $\mathbb{R}^n$ with

$$\sup \{\text{diam}(B) : B \in F\} < D < \infty$$

and if $A$ is the set of centers of the balls in $F$, then there exist subsets of $F$, $H_1, \ldots, H_{N_n}$, such that each $H_i$ is a countable collection of disjoint balls from $F$ (possibly empty) and

$$A \subseteq \bigcup_{i=1}^{N_n} \{B : B \in H_i\}.$$  

**Proof:** To begin with, suppose $A$ is bounded. Let $L(n, 10)$ be the constant of Lemma 28.1.1 and let $M_n = L(n, 10) + 60^n + 1$. Define the following sequence of subsets of $F$, $G_1, G_2, \ldots, G_{M_n}$. Referring to the sequence $\{B_k\}$ just considered, let $B_1 \in G_1$ and if $B_1, \ldots, B_{m-1}$ have been assigned, each to a $G_i$, place $B_m$ in the first $G_j$ such that $B_m$ intersects no set already in $G_j$. The existence of such a $j$ follows from Lemmas 28.1.1 and 28.1.2. Here is why. $B_m$ can intersect at most $L(n, 10)$ sets of $\{B_1, \ldots, B_m\}$ which have radii at least as large as $10B_{m+1}$ thanks to Lemma 28.1.1. It can intersect at most $60^n$ sets of $\{B_1, \ldots, B_m\}$ which have radii smaller than $10B_{m+1}$ thanks to Lemma 28.1.2. Thus each $G_j$ consists of disjoint sets of $F$ and the set of centers is covered by the union of these $G_j$. This proves the theorem in case the set of centers is bounded.

Now let $R_1 = B(0, 5D)$ and if $R_m$ has been chosen, let

$$R_{m+1} = B(0, (m+1)5D) \setminus R_m.$$  

Thus, if $|k - m| \geq 2$, no ball from $F$ having nonempty intersection with $R_m$ can intersect any ball from $F$ which has nonempty intersection with $R_k$. This is because all these balls have radius less than $D$. Now let $A_m = A \cap R_m$ and apply the above result for a bounded set of centers to those balls of $F$ which intersect $R_m$ to obtain sets of disjoint balls $G_1(R_m), G_2(R_m), \ldots, G_{M_n}(R_m)$ covering $A_m$. Then simply define $G'_j = \bigcup_{i=1}^{M_n} G_j(R_{2k})$, $G_j \equiv \bigcup_{i=1}^{M_n} G_j(R_{2k-1})$. Let $N_n = 2M_n$ and

$$\{H_1, \ldots, H_{N_n}\} \equiv \{G'_1, \ldots, G'_{M_n}, G_1, \ldots, G_{M_n}\}.$$  

Note that the balls in $G'_j$ are disjoint. This is because those in $G_j(R_{2k})$ are disjoint and if you consider any ball in $G_j(R_{2k})$, it cannot intersect a ball of $G_j(R_{2m})$ for $m \neq k$ because $|2k - 2m| \geq 2$. Similar considerations apply to the balls of $G_j$.

### 28.2 Fundamental Theorem Of Calculus For Radon Measures

In this section the Besicovitch covering theorem will be used to give a generalization of the Lebesgue differentiation theorem to general Radon measures. In what follows,
28.2. FUNDAMENTAL THEOREM OF CALCULUS FOR RADON MEASURES

\( \mu \) will be a Radon measure,

\[ Z \equiv \{ x \in \mathbb{R}^n : \mu (B(x,r)) = 0 \text{ for some } r > 0 \} , \]

Lemma 28.2.1 \( Z \) is measurable and \( \mu (Z) = 0 \).

**Proof:** For each \( x \in Z \), there exists a ball \( B(x,r) \) with \( \mu (B(x,r)) = 0 \). Let \( \mathcal{C} \) be the collection of these balls. Since \( \mathbb{R}^n \) has a countable basis, a countable subset, \( \tilde{\mathcal{C}} \), of \( \mathcal{C} \) also covers \( Z \). Let

\[ \tilde{\mathcal{C}} = \{ B_i \}_{i=1}^\infty . \]

Then letting \( \overline{\mu} \) denote the outer measure determined by \( \mu \),

\[ \overline{\mu}(Z) \leq \sum_{i=1}^\infty \overline{\mu}(B_i) = \sum_{i=1}^\infty \mu(B_i) = 0 \]

Therefore, \( Z \) is measurable and has measure zero as claimed. \( \blacksquare \)

Let \( Mf : \mathbb{R}^n \rightarrow [0, \infty] \) by

\[ Mf(x) \equiv \begin{cases} \sup_{r \leq 1} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |f| \, d\mu \text{ if } x \notin Z, \\ 0 \text{ if } x \in Z \end{cases} . \]

Theorem 28.2.2 Let \( \mu \) be a Radon measure and let \( f \in L^1(\mathbb{R}^n, \mu) \). Then for a.e.\( x \),

\[ \lim_{r \to 0} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |f(y) - f(x)| \, d\mu(y) = 0 \]

**Proof:** First consider the following claim which is a weak type estimate of the same sort used when differentiating with respect to Lebesgue measure.

**Claim 1:** The following inequality holds for \( N_n \) the constant of the Besicovitch covering theorem.

\[ \overline{\mu}([Mf > \varepsilon]) \leq N_n \varepsilon^{-1} ||f||_1 \]

**Proof:** First note \( [Mf > \varepsilon] \cap Z = \emptyset \) and without loss of generality, you can assume \( \overline{\mu}([Mf > \varepsilon]) > 0 \). Next, for each \( x \in [Mf > \varepsilon] \) there exists a ball \( B_x = B(x,r_x) \) with \( r_x \leq 1 \) and

\[ \mu(B_x)^{-1} \int_{B(x,r_x)} |f| \, d\mu > \varepsilon. \]

Let \( \mathcal{F} \) be this collection of balls so that \( [Mf > \varepsilon] \) is the set of centers of balls of \( \mathcal{F} \).

By the Besicovitch covering theorem,

\[ [Mf > \varepsilon] \subseteq \bigcup_{i=1}^{N_n} \{ B : B \in \mathcal{G}_i \} \]

where \( \mathcal{G}_i \) is a collection of disjoint balls of \( \mathcal{F} \). Now for some \( i \),

\[ \overline{\mu}([Mf > \varepsilon]) / N_n \leq \mu(\bigcup \{ B : B \in \mathcal{G}_i \}) \]
CHAPTER 28. DIFFERENTIATION OF RADON MEASURES

because if this is not so, then

\[ \mu \left( \left[ Mf > \varepsilon \right] \right) \leq \sum_{i=1}^{N_n} \mu \left( \cup \{ B : B \in \mathcal{G}_i \} \right) \]
\[ < \sum_{i=1}^{N_n} \frac{\mu \left( \left[ Mf > \varepsilon \right] \right)}{N_n} = \mu \left( [Mf > \varepsilon] \right), \]

a contradiction. Therefore for this \( i \),

\[ \frac{\mu \left( \left[ Mf > \varepsilon \right] \right)}{N_n} \leq \mu \left( \cup \{ B : B \in \mathcal{G}_i \} \right) = \sum_{B \in \mathcal{G}_i} \mu (B) \leq \sum_{B \in \mathcal{G}_i} \varepsilon^{-1} \int_B |f| d\mu \]
\[ \leq \varepsilon^{-1} \int_{\mathbb{R}^n} |f| d\mu = \varepsilon^{-1} ||f||_1. \]

This shows Claim 1.

**Claim 2:** If \( g \) is any continuous function defined on \( \mathbb{R}^n \), then for \( x \notin Z \),

\[ \lim_{r \to 0} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |g(y) - g(x)| d\mu(y) = 0 \]

and

\[ \lim_{r \to 0} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} g(y) d\mu(y) = g(x). \] (28.2.8)

**Proof:** Since \( g \) is continuous at \( x \), whenever \( r \) is small enough,

\[ \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |g(y) - g(x)| d\mu(y) \leq \frac{1}{\mu(B(x,r))} \int_{B(x,r)} \varepsilon d\mu(y) = \varepsilon. \]

follows from the above and the triangle inequality. This proves the claim.

Now let \( g \in C_c(\mathbb{R}^n) \) and \( x \notin Z \). Then from the above observations about continuous functions,

\[ \mu \left( \left[ x \notin Z : \lim \sup_{r \to 0} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |f(y) - f(x)| d\mu(y) > \varepsilon \right] \right) \] (28.2.9)

\[ \leq \mu \left( \left[ x \notin Z : \lim \sup_{r \to 0} \frac{1}{\mu(B(x,r))} \int_{B(x,r)} |f(y) - g(y)| d\mu(y) > \frac{\varepsilon}{2} \right] \right) \]
\[ + \mu \left( \left[ x \notin Z : |g(x) - f(x)| > \frac{\varepsilon}{2} \right] \right) \]
\[ \leq \mu \left( [M(f-g) > \frac{\varepsilon}{2}] \right) + \mu \left( [||f-g|| > \frac{\varepsilon}{2}] \right) \] (28.2.10)

Now

\[ \int_{||f-g|| > \frac{\varepsilon}{2}} |f-g| d\mu \geq \frac{\varepsilon}{2} \mu \left( [||f-g|| > \frac{\varepsilon}{2}] \right) \]
and so from Claim 1 and hence is dominated by
\[ \left( \frac{2}{\varepsilon} + \frac{N_n}{\varepsilon} \right) \| f - g \|_{L^1(\mathbb{R}^n, \mu)}. \]

But by regularity of Radon measures, \( C_c(\mathbb{R}^n) \) is dense in \( L^1(\mathbb{R}^n, \mu) \), and so since \( g \) in the above is arbitrary, this shows equals 0. Now
\[ \left( x \in \mathbb{Z} : \limsup_{r \to 0} \frac{1}{\mu(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, d\mu(y) > \frac{1}{k} \right) = 0 \]
By completeness of \( \mu \) this implies
\[ \left( x \in \mathbb{Z} : \limsup_{r \to 0} \frac{1}{\mu(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, d\mu(y) > 0 \right) \]
is a set of \( \mu \) measure zero. ■

The following corollary is the main result referred to as the Lebesgue Besicovitch Differentiation theorem.

**Corollary 28.2.3** If \( f \in L^1_{\text{loc}}(\mathbb{R}^n, \mu) \), then for a.e. \( x \notin Z \),
\[ \lim_{r \to 0} \frac{1}{\mu(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, d\mu(y) = 0. \] (28.2.11)

**Proof:** If \( f \) is replaced by \( f\chi_{B_0(0,k)} \) then the conclusion holds for all \( x \in \mathbb{Z} \setminus F_k \) where \( F_k \) is a set of \( \mu \) measure 0. Letting \( k = 1, 2, \ldots \), and \( F \equiv \cup_{k=1} F_k \), it follows that \( F \) is a set of measure zero and for any \( x \notin F \), and \( k \in \{1, 2, \ldots\} \), holds if \( f \) is replaced by \( f\chi_{B_0(0,k)} \). Picking any such \( x \), and letting \( k > |x| + 1 \), this shows
\[ \lim_{r \to 0} \frac{1}{\mu(B(x, r))} \int_{B(x, r)} |f(y) - f(x)| \, d\mu(y) \]
\[ = \lim_{r \to 0} \frac{1}{\mu(B(x, r))} \int_{B(x, r)} |f\chi_{B_0(0,k)}(y) - f\chi_{B_0(0,k)}(x)| \, d\mu(y) = 0. \] ■

### 28.3 Slicing Measures

Let \( \mu \) be a finite Radon measure. I will show here that a formula of the following form holds.
\[ \mu(F) = \int_F d\mu = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} \chi_F(x, y) \, d\nu_x(y) \, d\alpha(x) \]
where \( \alpha(E) = \mu(E \times \mathbb{R}^m) \). When this is done, the measures, \( \nu_x \), are called slicing measures and this shows that an integral with respect to \( \mu \) can be written as an
iterated integral in terms of the measure $\alpha$ and the slicing measures, $\nu_x$. This is like going backwards in the construction of product measure. One starts with a measure $\mu$, defined on the Cartesian product and produces $\alpha$ and an infinite family of slicing measures from it whereas in the construction of product measure, one starts with two measures and obtains a new measure on a $\sigma$ algebra of subsets of the Cartesian product of two spaces. These slicing measures are dependent on $x$. Later, this will be tied to the concept of independence or not of random variables. First here are two technical lemmas.

**Lemma 28.3.1** The space $C_c(\mathbb{R}^m)$ with the norm

$$||f|| \equiv \sup \{|f(y)| : y \in \mathbb{R}^m\}$$

is separable.

**Proof:** Let $D_l$ consist of all functions which are of the form

$$\sum_{|\alpha| \leq N} a_\alpha y^\alpha \left(\text{dist}(y,B(0,l+1)^C)\right)^n$$

where $a_\alpha \in \mathbb{Q}$, $\alpha$ is a multi-index, and $a_\alpha$ is a positive integer. Consider $D \equiv \bigcup_l D_l$. Then $D$ is countable. If $f \in C_c(\mathbb{R}^n)$, then choose $l$ large enough that $\text{spt}(f) \subseteq B(0,l+1)$, a locally compact space, $f \in C_0(B(0,l+1))$. Then since $D_l$ separates the points of $B(0,l+1)$ is closed with respect to conjugates, and annihilates no point, it is dense in $C_0(B(0,l+1))$ by the Stone Weierstrass theorem. Alternatively, $D$ is dense in $C_0(\mathbb{R}^n)$ by Stone Weierstrass and $C_c(\mathbb{R}^n)$ is a subspace so it is also separable. So is $C_c(\mathbb{R}^n)^+$, the nonnegative functions in $C_c(\mathbb{R}^n)$. $\blacksquare$

From the regularity of Radon measures, the following lemma follows.

**Lemma 28.3.2** If $\mu$ and $\nu$ are two Radon measures defined on $\sigma$ algebras, $S_\mu$ and $S_\nu$, of subsets of $\mathbb{R}^n$ and if $\mu(V) = \nu(V)$ for all $V$ open, then $\mu = \nu$ and $S_\mu = S_\nu$.

**Proof:** Every compact set is a countable intersection of open sets so the two measures agree on every compact set. Hence it is routine that the two measures agree on every $G_\delta$ and $F_\sigma$ set. (Recall $G_\delta$ sets are countable intersections of open sets and $F_\sigma$ sets are countable unions of closed sets.) Now suppose $E \in S_\nu$ is a bounded set. Then by regularity of $\nu$ there exists $G$ a $G_\delta$ set and $F$ an $F_\sigma$ set such that $F \subseteq E \subseteq G$ and $\nu(G \setminus F) = 0$. Then it is also true that $\mu(G \setminus F) = 0$. Hence $E = F \cup (E \setminus F)$ and $E \setminus F$ is a subset of $G \setminus F$, a set of $\mu$ measure zero. By completeness of $\mu$, it follows $E \in S_\mu$ and

$$\mu(E) = \mu(F) = \nu(F) = \nu(E).$$

If $E \in S_\nu$ not necessarily bounded, let $E_m = E \cap B(0,m)$ and then $E_m \in S_\mu$ and $\mu(E_m) = \nu(E_m)$. Letting $m \to \infty$, $E \in S_\mu$ and $\mu(E) = \nu(E)$. Similarly, $S_\mu \subseteq S_\nu$ and the two measures are equal on $S_\mu$.

The main result in the section is the following theorem.
Theorem 28.3.3 Let \( \nu \) be a finite Radon measure on \( \mathbb{R}^{n+m} \) defined on a \( \sigma \) algebra, \( \mathcal{F} \). Then there exists a unique finite Radon measure \( \alpha \), defined on a \( \sigma \) algebra \( \mathcal{S} \), of sets of \( \mathbb{R}^n \) which satisfies
\[
\alpha (E) = \mu (E \times \mathbb{R}^m) \tag{28.3.12}
\]
for all \( E \) Borel. There also exists a Borel set of \( \alpha \) measure zero \( N \), such that for each \( x \notin N \), there exists a Radon probability measure \( \nu_x \) such that if \( f \) is a nonnegative \( \mu \) measurable function or a \( \mu \) measurable function in \( L^1 (\mu) \),
\[
y \rightarrow f(x,y) \text{ is } \nu_x \text{ measurable } \alpha \text{ a.e.}
\]
\[
x \rightarrow \int_{\mathbb{R}^m} f(x,y) \, d\nu_x(y) \text{ is } \alpha \text{ measurable} \tag{28.3.13}
\]
and
\[
\int_{\mathbb{R}^{n+m}} f(x,y) \, d\mu = \int_{\mathbb{R}^n} \left( \int_{\mathbb{R}^m} f(x,y) \, d\nu_x(y) \right) \, d\alpha (x). \tag{28.3.14}
\]
If \( \tilde{\nu}_x \) is any other collection of Radon measures satisfying 28.3.12 and 28.3.14, then \( \tilde{\nu}_x = \nu_x \) for \( \alpha \) a.e. \( x \).

**Proof:**

**Existence and uniqueness of \( \alpha \)**

First consider the uniqueness of \( \alpha \). Suppose \( \alpha_1 \) is another Radon measure satisfying 28.3.12. Then in particular, \( \alpha_1 \) and \( \alpha \) agree on open sets and so the two measures are the same by Lemma 28.3.2.

To establish the existence of \( \alpha \), define \( \alpha_0 \) on Borel sets by
\[
\alpha_0 (E) = \mu (E \times \mathbb{R}^m).
\]
Thus \( \alpha_0 \) is a finite Borel measure and so it is finite on compact sets. Lemma 12.2.3 on Page 365 implies the existence of the Radon measure \( \alpha \) extending \( \alpha_0 \).

**Uniqueness of \( \nu_x \)**

Next consider the uniqueness of \( \nu_x \). Suppose \( \nu_x \) and \( \tilde{\nu}_x \) satisfy all conclusions of the theorem with exceptional sets denoted by \( N \) and \( \tilde{N} \) respectively. Then, enlarging \( N \) and \( \tilde{N} \), one may also assume, using Lemma 28.2.1, that for \( x \notin N \cup \tilde{N} \),
\[
\alpha (B(x,r)) > 0 \text{ whenever } r > 0.
\]
Now let
\[
A = \prod_{i=1}^m (a_i, b_i)
\]
where \( a_i \) and \( b_i \) are rational. Thus there are countably many such sets. Then from the conclusion of the theorem, if \( x_0 \notin N \cup \tilde{N} \),
\[
\frac{1}{\alpha (B(x_0,r))} \int_{B(x_0,r)} \int_{\mathbb{R}^m} x_A(y) \, d\nu_x(y) \, d\alpha.
\]
and by the Lebesgue Besicovitch Differentiation theorem, there exists a set of \( \alpha \) measure zero, \( E_A \), such that if \( x_0 \notin E_A \cup N \cup \bar{N} \), then the limit in the above exists as \( r \to 0 \) and yields

\[
\nu_{x_0}(A) = \hat{\nu}_{x_0}(A).
\]

Letting \( E \) denote the union of all the sets \( E_A \) for \( A \) as described above, it follows that \( E \) is a set of measure zero and if \( x_0 \notin E \cup N \cup \bar{N} \) then \( \nu_{x_0}(A) = \hat{\nu}_{x_0}(A) \) for all such sets \( A \). But every open set can be written as a disjoint union of sets of this form and so for all such \( x_0 \), \( \nu_{x_0}(V) = \hat{\nu}_{x_0}(V) \) for all \( V \) open. By Lemma 28.3.2 this shows the two measures are equal and proves the uniqueness assertion for \( \nu_\times \).

It remains to show the existence of the measures \( \nu_\times \).

**Existence of \( \nu_\times \)**

For \( f \geq 0, f, g \in C_c(\mathbb{R}^m) \) and \( C_c(\mathbb{R}^n) \) respectively, define

\[
g \to \int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu
\]

Since \( f \geq 0 \), this is a positive linear functional on \( C_c(\mathbb{R}^n) \). Therefore, there exists a unique Radon measure \( \nu_f \) such that for all \( g \in C_c(\mathbb{R}^n) \),

\[
\int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu = \int_{\mathbb{R}^n} g(x) \, d\nu_f.
\]

I claim that \( \nu_f \ll \alpha \), the two being considered as measures on \( B(\mathbb{R}^n) \). Suppose then that \( K \) is a compact set and \( \alpha(K) = 0 \). Then let \( K \prec g \prec V \) where \( V \) is open.

\[
\nu_f(K) = \int_{\mathbb{R}^n} \mathcal{X}_K(x) \, d\nu_f(x) \leq \int_{\mathbb{R}^n} g(x) \, d\nu_f(x) = \int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu
\]

\[
\leq \int_{\mathbb{R}^{n+m}} \mathcal{X}_V \times \mathbb{R}^m(x, y) f(y) \, d\mu \leq \|f\|_\infty \mu(V \times \mathbb{R}^m) = \|f\|_\infty \alpha(V)
\]

Then for any \( \varepsilon > 0 \), one can choose \( V \) such that the right side is less than \( \varepsilon \). Therefore, \( \nu_f(K) = 0 \) also. By regularity considerations, \( \nu_f \ll \alpha \) as claimed.

It follows from the Radon Nikodým theorem the existence of a function \( h_f \in L^1(\alpha) \) such that for all \( g \in C_c(\mathbb{R}^n) \),

\[
\int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu = \int_{\mathbb{R}^n} g(x) \, d\nu_f = \int_{\mathbb{R}^n} g(x) h_f(x) \, d\alpha. \tag{28.3.15}
\]

It is obvious from the formula that the map from \( f \in C_c(\mathbb{R}^m) \) to \( L^1(\alpha) \) given by \( f \to h_f \) is linear. However, this is not sufficiently specific because functions in \( L^1(\alpha) \) are only determined a.e. However, for \( h_f \in L^1(\alpha) \), you can specify a particular representative \( \alpha \) a.e. By the fundamental theorem of calculus,

\[
\hat{h}_f(x) \equiv \lim_{r \to 0} \frac{1}{\alpha(B(x, r))} \int_{B(x, r)} h_f(z) \, d\alpha(z) \tag{28.3.16}
\]
exists off some set of measure zero $Z_f$. Note that since this involves the integral over a ball, it does not matter which representative of $h_f$ is placed in the formula. Therefore, $\widehat{h_f}(x)$ is well defined pointwise for all $x$ not in some set of measure zero $Z_f$. Since $\widehat{h_f} = h_f \ a.e.$ it follows that $\widehat{h_f}$ is well defined and will work in the formula

Let

$$Z = \{ f \in D \}$$

where $D$ is a countable dense subset of $C_c(\mathbb{R}^m)$. Of course it is desired to have the limit hold for all $f$, not just $f \in D$. We will show that this limit holds for all $x \notin Z$. Thus, we will have $x \to \widehat{h_f}(x)$ defined by the above limit off $Z$ and so, since $\widehat{h_f}(x) = h_f(x) \ a.e.$, it follows that

$$\int_{\mathbb{R}^{n+m}} g(x)f(y) \, d\mu = \int_{\mathbb{R}^n} g(x) \, d\nu_f = \int_{\mathbb{R}^n} g(x) \, d\widehat{h_f} \, d\alpha$$

One could then take $\widehat{h_f}(x)$ to be defined as 0 for $x \notin Z$.

For $f$ an arbitrary function in $C_c(\mathbb{R}^m)$ and $f' \in D$, a dense countable subset of $C_c(\mathbb{R}^n)$, it follows from

$$\left| \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \right| \leq ||f - f'||_\infty \int_{B(z,r) \times \mathbb{R}^n} |g(x)| \, d\mu$$

Let $g_k(x) \uparrow \chi_{B(z,r)}(x)$ where $z \notin Z$. Then by the dominated convergence theorem, the above implies

$$\int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha = \int_{B(z,r) \times \mathbb{R}^n} d\mu = \int_{B(z,r) \times \mathbb{R}^n} d\mu = ||f - f'||_\infty \alpha(B(z,r))$$

Dividing by $\alpha(B(z,r))$, it follows that if $\alpha(B(z,r)) > 0$ for all $r > 0$, then for all $r > 0$,

$$\left| \frac{1}{\alpha(B(z,r))} \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \right| \leq ||f - f'||_\infty$$

It follows that for $f \in C_c(\mathbb{R}^m)$ arbitrary and $z \notin Z$,

$$\limsup_{r \to 0} \frac{1}{\alpha(B(z,r))} \int_{B(z,r)} h_f(x) \, d\alpha = \liminf_{r \to 0} \frac{1}{\alpha(B(z,r))} \int_{B(z,r)} h_f(x) \, d\alpha$$

$$= \limsup_{r \to 0} \alpha(B(z,r)) \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \, dx$$

$$- \liminf_{r \to 0} \alpha(B(z,r)) \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \, dx$$

$$\leq \left| \frac{1}{\alpha(B(z,r))} \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \right|$$

$$+ \liminf_{r \to 0} \frac{1}{\alpha(B(z,r))} \int_{B(z,r)} (h_f(x) - h_{f'}(x)) \, d\alpha \, dx$$

$$\leq 2 ||f - f'||_\infty$$
and since \( f' \) is arbitrary, it follows that the limit of (28.3.16) holds for all \( f \in C_c (\mathbb{R}^m)^+ \) whenever \( z \notin Z \), the above set of measure zero.

Now for \( f \) an arbitrary real valued function of \( C_c (\mathbb{R}^n) \), simply apply the above result to positive and negative parts to obtain \( h_f = h_{f^+} - h_{f^-} \) and \( \hat{h}_f = \hat{h}_{f^+} - \hat{h}_{f^-} \). Then it follows that for all \( f \in C_c (\mathbb{R}^m) \) and \( g \in C_c (\mathbb{R}^m) \)

\[
\int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu = \int_{\mathbb{R}^n} g(x) \hat{h}_f(x) \, d\alpha.
\]

It is obvious from the description given above that for each \( x \notin Z \), the set of measure zero given above, that \( f \to \hat{h}_f (x) \) is a positive linear functional. It is clear that it acts like a linear map for nonnegative \( f \) and so the usual trick just described above is well defined and delivers a positive linear functional. Hence by the Riesz representation theorem, there exists a unique \( \nu_x \) such that for all \( x \)

\[
\hat{h}_f (x) = \int_{\mathbb{R}^m} f(y) \, d\nu_x (y).
\]

It follows that

\[
\int_{\mathbb{R}^{n+m}} g(x) f(y) \, d\mu = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} g(x) f(y) \, d\nu_x (y) \, d\alpha (x) \quad (28.3.17)
\]

and \( x \to \int_{\mathbb{R}^n} f(y) \, d\nu_x \) is \( \alpha \) measurable and \( \nu_x \) is a Radon measure.

Now let \( f_k \uparrow \chi_{\mathbb{R}^n} \) and \( g \geq 0 \). Then by monotone convergence theorem,

\[
\int_{\mathbb{R}^{n+m}} g(x) \, d\mu = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} g(x) \, d\nu_x \, d\alpha
\]

If \( g_k \uparrow \chi_{\mathbb{R}^n} \), the monotone convergence theorem shows that \( x \to \int_{\mathbb{R}^n} d\nu_x \) is \( L^1 (\alpha) \).

Next let \( g_k \uparrow \chi_{B(x,r)} \) and use monotone convergence theorem to write

\[
\alpha (B (x,r)) = \int_{B(x,r) \times \mathbb{R}^m} \, d\mu = \int_{B(x,r)} \int_{\mathbb{R}^m} d\nu_x \, d\alpha
\]

Then dividing by \( \alpha (B (x,r)) \) and taking a limit as \( r \to 0 \), it follows that for \( \alpha \) a.e. \( x, 1 = \nu_x (\mathbb{R}^m) \), so these \( \nu_x \) are probability measures off a set of \( \alpha \) measure zero.

Letting \( g_k (x) \uparrow \chi_A (x), f_k (y) \uparrow \chi_B (y) \) for \( A, B \) open, it follows that (28.3.17) is valid for \( g(x) \) replaced with \( \chi_A (x) \) and \( f(y) \) replaced with \( \chi_B (y) \).

Now let \( \mathcal{G} \) denote the Borel sets \( F \) of \( \mathbb{R}^{n+m} \) such that

\[
\int_{\mathbb{R}^{n+m}} \chi_F (x, y) \, d\mu (x, y) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} \chi_F (x, y) \, d\nu_x (y) \, d\alpha (x)
\]

and that all the integrals make sense. As just explained, this includes all Borel sets of the form \( F = A \times B \) where \( A, B \) are open. It is clear that \( \mathcal{G} \) is closed with respect to countable disjoint unions and complements, while sets of the form \( A \times B \) for \( A, B \) open form a \( \pi \) system. Therefore, by Lemma 10.1.1, \( \mathcal{G} \) contains the Borel
sets which is the smallest $\sigma$ algebra which contains such products of open sets. It follows from the usual approximation with simple functions that if $f \geq 0$ and is Borel measurable, then

$$\int_{\mathbb{R}^{n+m}} f(x, y) \, d\mu(x, y) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} f(x, y) \, d\nu_\alpha(y) \, d\alpha(x)$$

with all the integrals making sense.

This proves the theorem in the case where $f$ is Borel measurable and nonnegative. It just remains to extend this to the case where $f$ is only measurable. However, from regularity of $\mu$ there exist Borel measurable functions $g, h, g \leq f \leq h$ such that

$$\int_{\mathbb{R}^{n+m}} f(x, y) \, d\mu(x, y) = \int_{\mathbb{R}^{n+m}} g(x, y) \, d\mu(x, y) = \int_{\mathbb{R}^{n+m}} h(x, y) \, d\mu(x, y)$$

It follows

$$\int_{\mathbb{R}^n} \int_{\mathbb{R}^m} g(x, y) \, d\nu_\alpha(y) \, d\alpha(x) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} h(x, y) \, d\nu_\alpha(y) \, d\alpha(x)$$

and so, since for $\alpha$ a.e. $x, y \to g(x, y)$ and $y \to h(x, y)$ are $\nu_\alpha$ measurable with

$$0 = \int_{\mathbb{R}^m} (h(x, y) - g(x, y)) \, d\nu_\alpha(y)$$

and $\nu_\alpha$ is a Radon measure, hence complete, it follows for $\alpha$ a.e. $x, y \to f(x, y)$ must be $\nu_\alpha$ measurable because it is equal to $y \to g(x, y) - h(x, y)$ a.e. Therefore, for $\alpha$ a.e. $x$, it makes sense to write

$$\int_{\mathbb{R}^m} f(x, y) \, d\nu_\alpha(y).$$

Similar reasoning applies to the above function of $x$ being $\alpha$ measurable due to $\alpha$ being complete. It follows

$$\int_{\mathbb{R}^{n+m}} f(x, y) \, d\mu(x, y) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^m} f(x, y) \, d\nu_\alpha(y) \, d\alpha(x)$$

with everything making sense. ■
28.4 Vitali Coverings

There is another covering theorem which may also be referred to as the Besicovitch covering theorem. As before, the balls can be taken with respect to any norm on $\mathbb{R}^n$. At first, the balls will be closed but this assumption will be removed.

**Definition 28.4.1** A collection of balls, $\mathcal{F}$ covers a set, $E$ in the sense of Vitali if whenever $x \in E$ and $\varepsilon > 0$, there exists a ball $B \in \mathcal{F}$ whose center is $x$ having diameter less than $\varepsilon$.

I will give a proof of the following theorem.

**Theorem 28.4.2** Let $\mu$ be a Radon measure on $\mathbb{R}^n$ and let $E$ be a set with $\overline{\mu}(E) < \infty$. Where $\overline{\mu}$ is the outer measure determined by $\mu$. Suppose $\mathcal{F}$ is a collection of closed balls which cover $E$ in the sense of Vitali. Then there exists a sequence of disjoint balls, $\{B_i\} \subseteq \mathcal{F}$ such that

$$\overline{\mu}(E \setminus \bigcup_{j=1}^{\infty} B_j) = 0.$$  

**Proof:** Let $N_n$ be the constant of the Besicovitch covering theorem. Choose $r > 0$ such that

$$(1 - r)^{-1} \left(1 - \frac{1}{2N_n + 2}\right) \equiv \lambda < 1.$$  

If $\overline{\mu}(E) = 0$, there is nothing to prove so assume $\overline{\mu}(E) > 0$. Let $U_1$ be an open set containing $E$ with $(1 - r) \mu(U_1) < \overline{\mu}(E)$ and $2\overline{\mu}(E) > \mu(U_1)$, and let $\mathcal{F}_1$ be those sets of $\mathcal{F}$ which are contained in $U_1$ whose centers are in $E$. Thus $\mathcal{F}_1$ is also a Vitali cover of $E$. Now by the Besicovitch covering theorem proved earlier, there exist balls, $B$, of $\mathcal{F}_1$ such that

$$E \subseteq \bigcup_{i=1}^{N_n} \{B : B \in \mathcal{G}_i\}$$  

where $\mathcal{G}_i$ consists of a collection of disjoint balls of $\mathcal{F}_1$. Therefore,

$$\overline{\mu}(E) \leq \sum_{i=1}^{N_n} \sum_{B \in \mathcal{G}_i} \mu(B)$$  

and so, for some $i \leq N_n$,

$$(N_n + 1) \sum_{B \in \mathcal{G}_i} \mu(B) > \overline{\mu}(E).$$  

It follows there exists a finite set of balls of $\mathcal{G}_i$, $\{B_1, \cdots, B_{m_1}\}$ such that

$$(N_n + 1) \sum_{i=1}^{m_1} \mu(B_i) > \overline{\mu}(E)$$  

(28.4.18)
and so
\[(2N_n + 2) \sum_{i=1}^{m_1} \mu(B_i) > 2\pi(E) > \mu(U_1).\]

Since \(2\pi(E) \geq \mu(U_1)\), \(28.4\) implies
\[\frac{\mu(U_1)}{2N_2 + 2} \leq \frac{2\pi(E)}{2N_2 + 2} = \pi(E) \cdot \frac{N_2 + 1}{N_2 + 1} < \sum_{i=1}^{m_1} \mu(B_i).\]

Also \(U_1\) was chosen such that \((1-r) \mu(U_1) < \pi(E)\), and so
\[\lambda \pi(E) \geq \lambda (1-r) \mu(U_1) = \left(1 - \frac{1}{2N_n + 2}\right) \mu(U_1)\]
\[\geq \mu(U_1) - \sum_{i=1}^{m_1} \mu(B_i) = \mu(U_1) - \mu(\bigcup_{j=1}^{m_1} B_j)\]
\[= \mu(U_1 \setminus \bigcup_{j=1}^{m_1} B_j) \geq \pi(E \setminus \bigcup_{j=1}^{m_1} B_j).\]

Since the balls are closed, you can consider the sets of \(\mathcal{F}\) which have empty intersection with \(\bigcup_{j=1}^{m_1} B_j\) and this new collection of sets will be a Vitali cover of \(E \setminus \bigcup_{j=1}^{m_1} B_j\). Letting this collection of balls play the role of \(\mathcal{F}\) in the above argument and letting \(E \setminus \bigcup_{j=1}^{m_1} B_j\) play the role of \(E\), repeat the above argument and obtain disjoint sets of \(\mathcal{F}\),
\[\{B_{m_1+1}, \ldots, B_{m_2}\},\]
such that
\[\lambda \pi(E \setminus \bigcup_{j=1}^{m_1} B_j) > \pi\left((E \setminus \bigcup_{j=1}^{m_1} B_j) \setminus \bigcup_{j=m_1+1}^{m_2} B_j\right) = \pi\left(E \setminus \bigcup_{j=1}^{m_2} B_j\right),\]
and so
\[\lambda^2 \pi(E) > \pi\left(E \setminus \bigcup_{j=1}^{m_2} B_j\right).\]
Continuing in this way, yields a sequence of disjoint balls \(\{B_i\}\) contained in \(\mathcal{F}\) and
\[\pi\left(E \setminus \bigcup_{j=1}^{m_k} B_j\right) \leq \pi\left(E \setminus \bigcup_{j=1}^{m_{k+1}} B_j\right) < \lambda^k \pi(E)\]
for all \(k\). Therefore, \(\pi\left(E \setminus \bigcup_{j=1}^{\infty} B_j\right) = 0\) and this proves the Theorem.

It is not necessary to assume \(\pi(E) < \infty\).

Corollary 28.4.3 Let \(\mu\) be a Radon measure on \(\mathbb{R}^n\). Letting \(\overline{\mu}\) be the outer measure determined by \(\mu\), suppose \(\mathcal{F}\) is a collection of closed balls which cover \(E\) in the sense of Vitali. Then there exists a sequence of disjoint balls, \(\{B_i\} \subset \mathcal{F}\) such that
\[\overline{\mu}\left(E \setminus \bigcup_{j=1}^{\infty} B_j\right) = 0.\]
CHAPTER 28. DIFFERENTIATION OF RADON MEASURES

Proof: Since \( \mu \) is a Radon measure it is finite on compact sets. Therefore, there are at most countably many numbers, \( \{b_i\}_{i=1}^{\infty} \) such that \( \mu(\partial B(0,b_i)) > 0 \). It follows there exists an increasing sequence of positive numbers, \( \{r_i\}_{i=1}^{\infty} \) such that \( \lim_{i \to \infty} r_i = \infty \) and \( \mu(\partial B(0,r_i)) = 0 \). Now let

\[
D_1 = \{x: ||x|| < r_1\}, D_2 = \{x: r_1 < ||x|| < r_2\}, \\
\cdots, D_m = \{x: r_{m-1} < ||x|| < r_m\}, \cdots
\]

Let \( F_m \) denote those closed balls of \( F \) which are contained in \( D_m \). Then letting \( E_m \) denote \( E \cap D_m \), \( F_m \) is a Vitali cover of \( E_m, \overline{\mu}(E_m) < \infty \), and so by Theorem 28.4.3 there exists a countable sequence of balls from \( F_m \) \( \{B^m_j\}_{j=1}^{\infty} \), such that \( \overline{\mu}(E_m \setminus \cup_{j=1}^{\infty} B^m_j) = 0 \). Then consider the countable collection of balls, \( \{B^m_j\}_{j,m=1}^{\infty} \).

\[
\overline{\mu}(E \setminus \cup_{m=1}^{\infty} \cup_{j=1}^{\infty} B^m_j) \leq \overline{\mu}(\cup_{j=1}^{\infty} \partial B(0,r_i)) + \\
+ \sum_{m=1}^{\infty} \overline{\mu}(E_m \setminus \cup_{j=1}^{\infty} B^m_j) = 0
\]

This proves the corollary.

You don’t need to assume the balls are closed. In fact, the balls can be open closed or anything in between and the same conclusion can be drawn.

Corollary 28.4.4 Let \( \mu \) be a Radon measure on \( \mathbb{R}^n \). Letting \( \overline{\mu} \) be the outer measure determined by \( \mu \), suppose \( F \) is a collection of balls which cover \( E \) in the sense of Vitali, open closed or neither. Then there exists a sequence of disjoint balls, \( \{B_i\} \subseteq F \) such that

\[
\overline{\mu}(E \setminus \cup_{j=1}^{\infty} B_j) = 0.
\]

Proof: Let \( x \in E \). Thus \( x \) is the center of arbitrarily small balls from \( F \). Since \( \mu \) is a Radon measure, at most countably many radii, \( r \) of these balls can have the property that \( \mu(\partial B(x,r)) = 0 \). Let \( F' \) denote the closures of the balls of \( F \), \( \overline{B}(x,r) \) with the property that \( \mu(\partial B(x,r)) = 0 \). Since for each \( x \in E \) there are only countably many exceptions, \( F' \) is still a Vitali cover of \( E \). Therefore, by Corollary 28.4.3 there is a disjoint sequence of these balls of \( F' \), \( \{\overline{B}_j\}_{i=1}^{\infty} \) for which

\[
\overline{\mu}(E \setminus \cup_{j=1}^{\infty} \overline{B}_j) = 0
\]

However, since their boundaries have \( \mu \) measure zero, it follows

\[
\overline{\mu}(E \setminus \cup_{j=1}^{\infty} B_j) = 0.
\]

This proves the corollary.

28.5 Differentiation Of Radon Measures

This section is a generalization of earlier material in which a measure was differentiated with respect to Lebesgue measure. Here an arbitrary Radon measure will
be differentiated with respect to another arbitrary Radon measure. In this section, $B(x, r)$ will denote a ball with center $x$ and radius $r$. Also, let $\lambda$ and $\mu$ be Radon measures and as above, $Z$ will denote a $\mu$ measure zero set off of which $\mu(B(x, r)) > 0$ for all $r > 0$.

**Definition 28.5.1** For $x \notin Z$, define the upper and lower symmetric derivatives as

$$D_{\mu}^+ \lambda(x) \equiv \limsup_{r \to 0} \frac{\lambda(B(x, r))}{\mu(B(x, r))}, \quad D_{\mu}^- \lambda(x) \equiv \liminf_{r \to 0} \frac{\lambda(B(x, r))}{\mu(B(x, r))}.$$

respectively. Also define

$$D_{\mu} \lambda(x) \equiv D_{\mu}^+ \lambda(x) = D_{\mu}^- \lambda(x)$$

in the case when both the upper and lower derivatives are equal.

**Lemma 28.5.2** Let $\lambda$ and $\mu$ be Radon measures. If $A$ is a bounded subset of $\{x \notin Z : D_{\mu}^+ \lambda(x) \geq a\}$, then

$$\lambda(A) \geq a\overline{\mu}(A)$$

and if $A$ is a bounded subset of $\{x \notin Z : D_{\mu}^- \lambda(x) \leq a\}$, then

$$\lambda(A) \leq a\overline{\mu}(A)$$

**Proof**: Suppose first that $A$ is a bounded subset of $\{x \notin Z : D_{\mu}^+ \lambda(x) \geq a\}$, let $\varepsilon > 0$, and let $V$ be a bounded open set with $V \supseteq A$ and $\lambda(V) - \varepsilon < \lambda(A), \mu(V) - \varepsilon < \overline{\mu}(A)$. Then if $x \in A$,

$$\frac{\lambda(B(x, r))}{\mu(B(x, r))} > a - \varepsilon, \quad B(x, r) \subseteq V,$$

for infinitely many values of $r$ which are arbitrarily small. Thus the collection of such balls constitutes a Vitali cover for $A$. By Corollary 28.4.4 there is a disjoint sequence of these balls $\{B_i\}$ such that

$$\overline{\mu}(A \setminus \bigcup_{i=1}^{\infty} B_i) = 0. \quad (28.5.19)$$

Therefore,

$$(a - \varepsilon) \sum_{i=1}^{\infty} \mu(B_i) < \sum_{i=1}^{\infty} \lambda(B_i) \leq \lambda(V) < \varepsilon + \lambda(A)$$

and so

$$a \sum_{i=1}^{\infty} \mu(B_i) \leq \varepsilon + \varepsilon \mu(V) + \lambda(A)$$

$$\leq \varepsilon + \varepsilon (\overline{\mu}(A) + \varepsilon) + \lambda(A) \quad (28.5.20)$$

Now

$$\overline{\mu}(A \setminus \bigcup_{i=1}^{\infty} B_i) + \overline{\mu}(\bigcup_{i=1}^{\infty} B_i) \geq \overline{\mu}(A)$$
and so by Corollary 28.5.14 and the fact the $B_i$ are disjoint,

$$a\Pi(A) \leq a\Pi(\bigcup_{i=1}^{\infty} B_i) = a \sum_{i=1}^{\infty} \mu(B_i)$$

$$\leq \varepsilon + \varepsilon (\Pi(A) + \varepsilon) + \bar{\lambda}(A). \quad (28.5.21)$$

Hence $a\Pi(A) \leq \bar{\lambda}(A)$ since $\varepsilon > 0$ was arbitrary.

Now suppose $A$ is a bounded subset of $\{x \in \mathbb{Z} : D_\mu \lambda(x) \leq a\}$ and let $V$ be a bounded open set containing $A$ with $\mu(V) - \varepsilon < a\Pi(A)$. Then if $x \in A$,

$$\frac{\lambda(B(x,r))}{\mu(B(x,r))} < a + \varepsilon, \quad B(x,r) \subseteq V$$

for values of $r$ which are arbitrarily small. Therefore, by Corollary 28.5.10 again, there exists a disjoint sequence of these balls, $\{B_i\}$ satisfying this time,

$$\bar{\lambda}(A \setminus \bigcup_{i=1}^{\infty} B_i) = 0.$$

Then by arguments similar to the above,

$$\bar{\lambda}(A) \leq \sum_{i=1}^{\infty} \lambda(B_i) < (a + \varepsilon) \mu(V) < (a + \varepsilon) (\Pi(A) + \varepsilon).$$

Since $\varepsilon$ was arbitrary, this proves the lemma.

**Theorem 28.5.3** There exists a set of measure zero, $N$ containing $Z$ such that for $x \not\in N$, $D_\mu \lambda(x)$ exists and also $X_{Nc}(\cdot) D_\mu \lambda(\cdot)$ is a $\mu$ measurable function. Furthermore, $D_\mu \lambda(x) < \infty \mu$ a.e.

**Proof:** First I show $D_\mu \lambda(x)$ exists a.e. Let $0 \leq a < b < \infty$ and let $A$ be any bounded subset of

$$N(a,b) \equiv \{x \in Z : D_\mu \lambda(x) > b > a > D_\mu \lambda(x)\}.$$

By Lemma 28.5.14,

$$a\Pi(A) \geq \bar{\lambda}(A) \geq b\Pi(A)$$

and so $\mu(A) = 0$ and $A$ is $\mu$ measurable. It follows $\mu(N(a,b)) = 0$ because

$$\mu(N(a,b)) \leq \sum_{m=1}^{\infty} \mu(N(a,b) \cap B(0,m)) = 0.$$

Define

$$N_0 \equiv \{x \notin Z : D_\mu \lambda(x) > D_\mu \lambda(x)\}.$$

Thus $\mu(N_0) = 0$ because

$$N_0 \subseteq \bigcup \{N(a,b) : 0 \leq a < b, \text{ and } a,b \in \mathbb{Q}\}$$
Therefore, \( N_0 \) is also \( \mu \) measurable and has \( \mu \) measure zero. Letting \( N \equiv N_0 \cup Z \), it follows \( D_\mu \lambda (x) \) exists on \( N^C \). It remains to verify \( X_{N^C} (\cdot) D_\mu \lambda (\cdot) \) is finite a.e. and is \( \mu \) measurable.

Let

\[
I = \{ x : D_\mu \lambda (x) = \infty \}.
\]

Then by Lemma 28.3.2

\[
\overline{\lambda} (I \cap B (0, m)) \geq \alpha (I \cap B (0, m))
\]

for all \( \alpha \) and since \( \lambda \) is finite on bounded sets, the above implies \( \overline{\lambda} (I \cap B (0, m)) = 0 \) for each \( m \) which implies that \( I \) is \( \mu \) measurable and has \( \mu \) measure zero since

\[
I = \bigcup_{m=1}^{\infty} I_m.
\]

Letting \( \eta \) be an arbitrary Radon measure, let \( r > 0 \), and suppose \( \eta (\partial B (x, r)) = 0 \). (Since \( \eta \) is finite on every ball, there are only countably many \( r \) such that \( \eta (\partial B (x, r)) > 0 \)) and let \( V \) be an open set containing \( B (x, r) \). Then whenever \( y \) is close enough to \( x \), it follows that \( B (y, r) \) is also a subset of \( V \). Since \( V \) is an arbitrary open set containing \( B (x, r) \), it follows

\[
\eta (B (x, r)) = \eta \left( \overline{B (x, r)} \right) \geq \lim \sup_{y \to x} \eta (B (y, r))
\]

and so \( y \to \eta (B (y, r)) \) an upper semicontinuous real valued function of \( x \), one which satisfies

\[
f (x) \geq \lim \sup_{n \to \infty} f (x_n)
\]

whenever \( x_n \to x \). Now it is routine to verify that a function \( f \) is upper semicontinuous if and only if \( f^{-1} (\left[ -\infty, a \right]) \) is open for all \( a \in \mathbb{R} \). Therefore, \( f^{-1} (\left[ -\infty, a \right]) \) is a Borel set for all \( a \in \mathbb{R} \) and so \( f \) is Borel measurable by Lemma 9.1.6. Now the measurability of \( X_{N^C} (\cdot) D_\mu \lambda (\cdot) \) follows from

\[
X_{N^C} (x) D_\mu \lambda (x) = \lim_{r_i \to 0} \frac{\lambda (B (x, r_i))}{\mu (B (x, r_i))} X_{N^C} (x)
\]

where \( r_i \) is such that \( \partial B (x, r_i) \) has \( \mu \) and \( \lambda \) measure zero.

28.6 The Radon Nikodym Theorem For Radon Measures

The above theory can be used to give an alternative treatment of the Radon Nikodym theorem for Radon measures. Recall first the definition of absolute continuity.

**Definition 28.6.1** Let \( \lambda, \mu \) be two Radon measures defined on \( F \). Then \( \lambda \ll \mu \) means that whenever \( \mu (E) = 0 \), it follows that \( \lambda (E) = 0 \).
Theorem 28.6.2 Let $\lambda$ and $\mu$ be Radon measures and suppose $\lambda \ll \mu$. Then for all $E$ a $\mu$ measurable set,

$$\lambda(E) = \int_E (D_\mu \lambda) \, d\mu.$$

**Proof:** Let $t > 1$ and let $E$ be a $\mu$ measurable set which is bounded and a subset of $N^C$ where $N$ is the exceptional set of $\mu$ measure zero in Theorem 28.5.3 off of which $\mu(B(x,r)) > 0$ for all $r > 0$ and $D_\mu \lambda(x)$ exists. Consider

$$E_m = E \cap \{x \in N^C : t^m \leq D_\mu \lambda(x) < t^{m+1}\}$$

for $m \geq 0$ and let

$$E_m = E \cap \{x \in N^C : t^{m+1} < D_\mu \lambda(x) \leq t^m\}$$

for $m < 0$. Here $m$ is an integer. First note that

$$E \cap \{x \in N^C : D_\mu \lambda(x) = 0\}$$

has $\lambda$ measure zero because by Lemma 28.5.2,

$$\lambda(E \cap \{x \in N^C : D_\mu \lambda(x) = 0\}) \leq a\mu(E)$$

for all $a > 0$ and $\mu(E)$ is finite due to the assumption that $E$ is bounded and $\mu$ is a Radon measure. Therefore, by Lemma 28.5.3,

$$\lambda(E) = \sum_{m=0}^{\infty} \lambda(E_m) + \sum_{h=-\infty}^{-1} \lambda(E_m)$$

$$\leq \sum_{m=0}^{\infty} t^{m+1} \mu(E_m) + \sum_{h=-\infty}^{-1} t^m \mu(E_m) = t \sum_{m=0}^{\infty} t^m \mu(E_m) + \sum_{h=-\infty}^{-1} t^m \mu(E_m)$$

$$= t \sum_{m=0}^{\infty} t^m \mu(E_m) + t^{-1} \sum_{h=-\infty}^{-1} t^{m+1} \mu(E_m)$$

$$\leq t \sum_{m=0}^{\infty} \int_{E_m} D_\mu \lambda(x) \, d\mu + t^{-1} \sum_{h=-\infty}^{-1} \int_{E_m} D_\mu \lambda(x) \, d\mu$$

$$= t \int_{E_+} D_\mu \lambda(x) \, d\mu + t^{-1} \int_{E_-} D_\mu \lambda(x) \, d\mu$$

where $E_-$ is the union of the $E_m$ for $m < 0$. Thus $E_-$ is the set of $x$ in $E$ such that $D_\mu \lambda(x) < 1$ and $E_+$ is the union of the $E_m$ for $m \geq 0$ so it is the set of $x$ in $E$ out of the exceptional set where $D_\mu \lambda(x) \geq 1$. Hence $E_-$ and $E_+$ do not depend on $m$. Also by this same lemma,

$$\lambda(E) = \sum_{m=0}^{\infty} \lambda(E_m) + \sum_{m=0}^{-1} \lambda(E_m) \geq \sum_{m=0}^{\infty} t^m \mu(E_m) + \sum_{m=0}^{-1} t^{m+1} \mu(E_m)$$
28.6. **THE RADON NIKODYM THEOREM FOR RADON MEASURES**

\[
\begin{align*}
\geq t^{-1} \sum_{m=0}^{\infty} t^{m+1} \mu(E_m) + t \sum_{m=-\infty}^{-1} t^m \mu(E_m)
\geq t^{-1} \sum_{m=0}^{\infty} \int_{E_m} D_\mu \lambda(x) \, d\mu + t \sum_{m=-\infty}^{-1} \int_{E_m} D_\mu \lambda(x) \, d\mu
= t^{-1} \int_{E_+} D_\mu \lambda(x) \, d\mu + t \int_{E_-} D_\mu \lambda(x) \, d\mu
\end{align*}
\]

Thus,

\[
t \int_{E_+} D_\mu \lambda(x) \, d\mu + t^{-1} \int_{E_-} D_\mu \lambda(x) \, d\mu 
\geq \lambda(E) \geq t^{-1} \int_{E_+} D_\mu \lambda(x) \, d\mu + t \int_{E_-} D_\mu \lambda(x) \, d\mu
\]

and letting \( t \to 1 \), it follows

\[
\lambda(E) = \int_E D_\mu \lambda(x) \, d\mu. \tag{28.6.22}
\]

Now if \( E \) is an arbitrary measurable set, contained in \( N^C \), this formula holds with \( E \) replaced with \( E \cap B(0,k) \). Letting \( k \to \infty \) and using the monotone convergence theorem, the above formula holds for all \( E \subseteq N^C \). Since \( N \) is a set of \( \mu \) measure zero, it follows \( N \) is also a set of \( \lambda \) measure zero due to the assumption of absolute continuity. Therefore 28.6.22 continues to hold for arbitrary \( \mu \) measurable sets, \( E \) even if they are not contained in \( N^C \). This is where the \( \lambda \ll \mu \) was used.

What if \( \lambda \) and \( \mu \) are just two arbitrary Radon measures defined on \( \mathcal{F} \)? What then? It was shown above that \( D_\mu \lambda(x) \) exists for \( \mu \) a.e. \( x \). Also, it was shown above in the proof that if \( E \subseteq N^C \), then

\[
\lambda(E) = \int_E D_\mu \lambda(x) \, d\mu
\]

Define for arbitrary \( E \in \mathcal{F} \),

\[
\lambda_\mu(E) \equiv \int_E D_\mu \lambda(x) \, d\mu
\]

Then you could let

\[
\lambda_\perp(E) \equiv \lambda(E) - \lambda_\mu(E)
\]

Letting \( N \) be the set on which the derivative \( D_\mu \lambda(x) \) does not exist, it was shown above that \( \mu(N) = 0 \). Then

\[
\lambda(E) = \lambda(E \cap N) + \lambda(E \cap N^C)
\]
\[ \lambda_{\perp} (E) + \lambda_{\mu} (E) = \lambda (E) = \lambda (E \cap N) + \lambda \left( E \cap N^C \right) \]
\[ = \lambda (E \cap N) + \int_{E \cap N^C} D_{\mu} \lambda (x) \, d\mu \]
\[ = \lambda (E \cap N) + \int_{E} D_{\mu} \lambda (x) \, d\mu = \lambda (E \cap N) + \lambda_{\mu} (E) \]

and this shows that \( \lambda_{\perp} (E) = \lambda (E \cap N) \). This shows most of the following corollary.

**Corollary 28.6.3**  Let \( \mu, \lambda \) be two Radon measures. Then there exist two measures, \( \lambda_{\mu}, \lambda_{\perp} \) such that

\[ \lambda_{\mu} \ll \mu, \quad \lambda = \lambda_{\mu} + \lambda_{\perp} \]

and a set of \( \mu \) measure zero \( N \) such that

\[ \lambda_{\perp} (E) = \lambda (E \cap N) \]

Also \( \lambda_{\mu} \) is given by the formula

\[ \lambda_{\mu} (E) = \int_{E} D_{\mu} \lambda (x) \, d\mu \]

**Proof:** It only remains to verify that \( \lambda_{\mu} \) given above satisfies \( \lambda_{\mu} \ll \mu \). However, this is obvious because if \( \mu (E) = 0 \), then clearly \( \int_{E} D_{\mu} \lambda (x) \, d\mu = 0 \).
Chapter 29

Fourier Transforms

29.1 An Algebra Of Special Functions

First recall the following definition of a polynomial.

Definition 29.1.1 \( \alpha = (\alpha_1, \ldots, \alpha_n) \) for \( \alpha_1 \cdots \alpha_n \) positive integers is called a multi-index. For \( \alpha \) a multi-index, \( |\alpha| = \alpha_1 + \cdots + \alpha_n \) and if \( x \in \mathbb{R}^n \),

\[
x = (x_1, \ldots, x_n),
\]

and \( f \) a function, define

\[
x^\alpha \equiv x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n}.
\]

A polynomial in \( n \) variables of degree \( m \) is a function of the form

\[
p(x) = \sum_{|\alpha| \leq m} a_\alpha x^\alpha.
\]

Here \( \alpha \) is a multi-index as just described and \( a_\alpha \in \mathbb{C} \). Also define for \( \alpha = (\alpha_1, \ldots, \alpha_n) \) a multi-index

\[
D^\alpha f(x) \equiv \frac{\partial^{|\alpha|} f}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2} \cdots \partial x_n^{\alpha_n}}.
\]

Definition 29.1.2 Define \( \mathcal{G}_1 \) to be the functions of the form \( p(x) e^{-\alpha|x|^2} \) where \( \alpha > 0 \) and \( p(x) \) is a polynomial. Let \( \mathcal{G} \) be all finite sums of functions in \( \mathcal{G}_1 \). Thus \( \mathcal{G} \) is an algebra of functions which has the property that if \( f \in \mathcal{G} \) then \( \overline{f} \in \mathcal{G} \).

It is always assumed, unless stated otherwise that the measure will be Lebesgue measure.

Lemma 29.1.3 \( \mathcal{G} \) is dense in \( C_0(\mathbb{R}^n) \) with respect to the norm,

\[
\|f\|_\infty \equiv \sup \{|f(x)| : x \in \mathbb{R}^n}\]

1083
Proof: By the Weierstrass approximation theorem, it suffices to show \( G \) separates the points and annihilates no point. It was already observed in the above definition that if \( f \in G \) whenever \( y_1 \neq y_2 \). Then in this case, you can let \( f(x) \equiv e^{-|x|^2} \) and \( f \in G \) and \( f(y_1) \neq f(y_2) \). If \( |y_1| = |y_2| \), then suppose \( y_{1k} \neq y_{2k} \). This must happen for some \( k \) because \( y_1 \neq y_2 \). Then let \( f(x) \equiv x_k e^{-|x|^2} \). Thus \( G \) separates points. Now \( e^{-|x|^2} \) is never equal to zero and so \( G \) annihilates no point of \( \mathbb{R}^n \). This proves the lemma.

These functions are clearly quite specialized. Therefore, the following theorem is somewhat surprising.

Theorem 29.1.4 For each \( p \geq 1, p < \infty \), \( G \) is dense in \( L^p(\mathbb{R}^n) \).

Proof: Let \( f \in L^p(\mathbb{R}^n) \). Then there exists \( g \in C_c(\mathbb{R}^n) \) such that \( ||f - g||_p < \epsilon \). Now let \( b > 0 \) be large enough that
\[
\int_{\mathbb{R}^n} \left( e^{-|b|^2} \right)^p dx < \epsilon^p.
\]
Then \( x \to g(x)e^{b|x|^2} \) is in \( C_c(\mathbb{R}^n) \subseteq C_0(\mathbb{R}^n) \). Therefore, from Lemma 29.1.3 there exists \( \psi \in G \) such that
\[
\left| \left| ge^{b|x|^2} - \psi \right| \right|_\infty < 1
\]
Therefore, letting \( \phi(x) \equiv e^{-b|x|^2}\psi(x) \) it follows that \( \phi \in G \) and for all \( x \in \mathbb{R}^n \),
\[
|g(x) - \phi(x)| < e^{-b|x|^2}
\]
Therefore,
\[
\left( \int_{\mathbb{R}^n} |g(x) - \phi(x)|^p dx \right)^{1/p} \leq \left( \int_{\mathbb{R}^n} \left( e^{-b|x|^2} \right)^p dx \right)^{1/p} < \epsilon.
\]
It follows
\[
||f - \phi||_p \leq ||f - g||_p + ||g - \phi||_p < 2\epsilon.
\]
Since \( \epsilon > 0 \) is arbitrary, this proves the theorem.

The following lemma is also interesting even if it is obvious.

Lemma 29.1.5 For \( \psi \in G \), \( p \) a polynomial, and \( \alpha, \beta \) multiindices, \( D^\alpha \psi \in G \) and \( p\psi \in G \). Also
\[
\sup\{|x^\beta D^\alpha \psi(x)| : x \in \mathbb{R}^n \} < \infty
\]

29.2 Fourier Transforms Of Functions In \( G \)

Definition 29.2.1 For \( \psi \in G \) Define the Fourier transform, \( F \) and the inverse Fourier transform, \( F^{-1} \) by
\[
F\psi(t) \equiv (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} \psi(x) dx,
\]
29.2. FOURIER TRANSFORMS OF FUNCTIONS IN $\mathcal{G}$

$$F^{-1} \psi(t) \equiv (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{it \cdot x} \psi(x) dx.$$  

where $t \cdot x \equiv \sum_{i=1}^{n} t_i x_i$. Note there is no problem with this definition because $\psi$ is in $L^1(\mathbb{R}^n)$ and therefore,

$$|e^{it \cdot x} \psi(x)| \leq |\psi(x)|,$$

an integrable function.

One reason for using the functions, $\mathcal{G}$ is that it is very easy to compute the Fourier transform of these functions. The first thing to do is to verify $F$ and $F^{-1}$ map $\mathcal{G}$ to $\mathcal{G}$ and that $F^{-1} \circ F(\psi) = \psi$.

**Lemma 29.2.2** The following formulas are true. ($c > 0$)

$$\int_{\mathbb{R}} e^{-ct^2} e^{-ist} dt = \int_{\mathbb{R}} e^{-ct^2} e^{ist} dt = e^{-\frac{s^2 \sqrt{\pi}}{c}}. \quad (29.2.1)$$

$$\int_{\mathbb{R}^n} e^{-|t|^2} e^{-i|s|t} dt = \int_{\mathbb{R}^n} e^{-|t|^2} e^{i|s|t} dt = e^{-\frac{|s|^2 \pi}{4c}} \left( \frac{\sqrt{\pi}}{\sqrt{c}} \right)^n. \quad (29.2.2)$$

**Proof:** Consider the first one. Let $h(s)$ be given by the left side. Then

$$H(s) \equiv \int_{\mathbb{R}} e^{-ct^2} e^{-ist} dt = \int_{\mathbb{R}} e^{-ct^2} \cos(st) dt$$

Then using the dominated convergence theorem to differentiate,

$$H'(s) = \int_{\mathbb{R}} -ce^{-ct^2} t \sin(st) dt = \frac{e^{-ct^2}}{2c} \sin(st) \bigg|_{-\infty}^{\infty} - \frac{s}{2c} \int_{\mathbb{R}} e^{-ct^2} \cos(st) dt = -\frac{s}{2c} H(s).$$

Also $H(0) = \int_{\mathbb{R}} e^{-ct^2} dt$. Thus $H(0) = \int_{\mathbb{R}} e^{-cx^2} dx \equiv I$ and so

$$I^2 = \int_{\mathbb{R}^2} e^{-r(x^2+y^2)} drdy = \int_{0}^{\infty} \int_{0}^{2\pi} e^{-cr^2} r dr d\theta = \frac{\pi}{c}.$$  

Hence

$$H'(s) + \frac{s}{2c} H(s) = 0, \quad H(0) = \sqrt{\frac{\pi}{c}}.$$  

It follows that $H(s) = e^{-\frac{s^2 \sqrt{\pi}}{\sqrt{c}}}$. The second formula follows right away from Fubini’s theorem. ■

With these formulas, it is easy to verify $F, F^{-1}$ map $\mathcal{G}$ to $\mathcal{G}$ and $F \circ F^{-1} = F^{-1} \circ F = \text{id}$.

**Theorem 29.2.3** Each of $F$ and $F^{-1}$ map $\mathcal{G}$ to $\mathcal{G}$. Also $F^{-1} \circ F(\psi) = \psi$ and $F \circ F^{-1}(\psi) = \psi$. 

**Proof:** The first claim will be shown if it is shown that $F \phi \in \mathcal{G}$ for $\phi (x) = x^\alpha e^{-b|\chi|^2}$ because an arbitrary function of $\mathcal{G}$ is a finite sum of scalar multiples of functions such as $\phi$. Using Lemma 29.2.2,

$$F \phi (t) = \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{-it \cdot \chi} \chi^\alpha e^{-b|\chi|^2} d\chi$$

$$= \left( \frac{1}{2\pi} \right)^{n/2} (i)^{-|\alpha|} D^\alpha_t \left( \int_{\mathbb{R}^n} e^{-it \cdot \chi} e^{-b|\chi|^2} d\chi \right)$$

$$= \left( \frac{1}{2\pi} \right)^{n/2} (i)^{-|\alpha|} D^\alpha_t \left( e^{-\frac{t^2}{4b}} \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \right)$$

and this is clearly in $\mathcal{G}$ because it equals a polynomial times $e^{-\frac{t^2}{4b}}$.

It remains to verify the other assertion. As in the first case, it suffices to consider $\psi (x) = x^\alpha e^{-b|\chi|^2}$.

$$F^{-1} \circ F (\psi) (s) = \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{is \cdot t} F (\psi) (t) dt$$

$$= \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{is \cdot t} \left( \frac{1}{2\pi} \right)^{n/2} (i)^{-|\alpha|} D^\alpha_t \left( e^{-\frac{t^2}{4b}} \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \right) dt$$

$$= \left( \frac{1}{2\pi} \right)^n (i)^{-|\alpha|} \int_{\mathbb{R}^n} e^{is \cdot t} D^\alpha_t \left( e^{-\frac{t^2}{4b}} \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \right) dt$$

$$= \left( \frac{1}{2\pi} \right)^n (i)^{-|\alpha|} \int_{\mathbb{R}^n} (i)^{|\alpha|} s^\alpha e^{is \cdot t} \left( e^{-\frac{t^2}{4b}} \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \right) dt$$

and by Lemma 29.2.2,

$$= \left( \frac{1}{2\pi} \right)^n \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \int_{\mathbb{R}^n} s^\alpha e^{is \cdot t} \left( e^{-\frac{t^2}{4b}} \right) dt$$

$$= \left( \frac{1}{2\pi} \right)^n \left( \frac{\sqrt{\pi}}{\sqrt{b}} \right)^n \left( \frac{\sqrt{\pi}}{\sqrt{1/4b}} \right)^n s^\alpha e^{-b|s|^2} = \psi (s) \blacksquare$$

### 29.3 Fourier Transforms Of Just About Anything

#### 29.3.1 Fourier Transforms Of $\mathcal{G}^*$

**Definition 29.3.1** Let $\mathcal{G}^*$ denote the vector space of linear functions defined on $\mathcal{G}$ which have values in $\mathbb{C}$. Thus $T \in \mathcal{G}^*$ means $T : \mathcal{G} \to \mathbb{C}$ and $T$ is linear,

$$T (a \psi + b \phi) = aT (\psi) + bT (\phi)$$

for all $a, b \in \mathbb{C}, \ \psi, \phi \in \mathcal{G}$.
Let $\psi \in \mathcal{G}$. Then we can regard $\psi$ as an element of $\mathcal{G}^*$ by defining

$$\psi(\phi) \equiv \int_{\mathbb{R}^n} \psi(x) \phi(x) \, dx.$$ 

Then we have the following important lemma.

**Lemma 29.3.2** The following is obtained for all $\phi, \psi \in \mathcal{G}$.

$$F\psi(\phi) = \psi(F\phi), \quad F^{-1}\psi(\phi) = \psi(F^{-1}\phi)$$

Also if $\psi \in \mathcal{G}$ and $\psi = 0$ in $\mathcal{G}^*$ so that $\psi(\phi) = 0$ for all $\phi \in \mathcal{G}$, then $\psi = 0$ as a function.

**Proof:**

$$F\psi(\phi) = \int_{\mathbb{R}^n} F\psi(t) \phi(t) \, dt$$

$$= \int_{\mathbb{R}^n} \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{-i t \cdot x} \psi(x) \phi(t) \, dx \, dt$$

$$= \int_{\mathbb{R}^n} \psi(x) \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{-i t \cdot x} \phi(t) \, dt \, dx$$

$$= \int_{\mathbb{R}^n} \psi(x) F\phi(x) \, dx \equiv \psi(F\phi)$$

The other claim is similar.

Suppose now $\psi(\phi) = 0$ for all $\phi \in \mathcal{G}$. Then

$$\int_{\mathbb{R}^n} \psi \phi \, dx = 0$$

for all $\phi \in \mathcal{G}$. Therefore, this is true for $\phi = \psi$ and so $\psi = 0$. ■

This lemma suggests a way to define the Fourier transform of something in $\mathcal{G}^*$.

**Definition 29.3.3** For $T \in \mathcal{G}^*$, define $FT, F^{-1}T \in \mathcal{G}^*$ by

$$FT(\phi) \equiv T(F\phi), \quad F^{-1}T(\phi) \equiv T(F^{-1}\phi)$$

**Lemma 29.3.4** $F$ and $F^{-1}$ are both one to one, onto, and are inverses of each other.

**Proof:** First note $F$ and $F^{-1}$ are both linear. This follows directly from the definition. Suppose now $FT = 0$. Then $FT(\phi) = T(F\phi) = 0$ for all $\phi \in \mathcal{G}$. But $F$ and $F^{-1}$ map $\mathcal{G}$ onto $\mathcal{G}$ because if $\psi \in \mathcal{G}$, then as shown above, $\psi = F\left(F^{-1}(\psi)\right)$.

Therefore, $T = 0$ and so $F$ is one to one. Similarly $F^{-1}$ is one to one. Now

$$F^{-1}(FT)(\phi) \equiv (FT)(F^{-1}\phi) \equiv T\left(F\left(F^{-1}(\phi)\right)\right) = T\phi.$$ 

Therefore, $F^{-1} \circ F(T) = T$. Similarly, $F \circ F^{-1}(T) = T$. Thus both $F$ and $F^{-1}$ are one to one and onto and are inverses of each other as suggested by the notation. ■

Probably the most interesting things in $\mathcal{G}^*$ are functions of various kinds. The following lemma will be useful in considering this situation.
Lemma 29.3.5 If \( f \in L^1_{\text{loc}}(\mathbb{R}^n) \) and \( \int_{\mathbb{R}^n} f \phi dx = 0 \) for all \( \phi \in C_c(\mathbb{R}^n) \), then \( f = 0 \) a.e.

**Proof:** For \( r > 0 \), let \( E \equiv \{ x : f(x) \geq r \} \), \( E_R \equiv E \cap B(0,R) \).

Let \( K_m \) be an increasing sequence of compact sets, and let \( V_m \) be a decreasing sequence of open sets satisfying

\[
K_m \subseteq E_r \subseteq V_m, \ m_n(V_m) \leq m_n(K_m) + 2^{-m}, V_1 \subseteq B(0,R) .
\]

Therefore,

\[
m_n(V_m \setminus K_m) \leq 2^{-m}.
\]

Let

\( \phi_m \in C_c(V_m), K_m \prec \phi_m \prec V_m \).

The statement \( K_m \prec \phi_m \prec V_m \) means that \( \phi_m \) equals 1 on \( K_m \), has compact support in \( V_m \), maps into \([0,1]\), and is continuous. Then \( \phi_m(x) \to \mathcal{X}_{E_R}(x) \) a.e. because the set where \( \phi_m(x) \) fails to converge to this set is contained in the set of all \( x \) which are in infinitely many of the sets \( V_m \setminus K_m \). This set has measure zero because

\[
\sum_{m=1}^{\infty} m_n(V_m \setminus K_m) < \infty
\]

Thus \( \phi_m \) converges pointwise a.e to \( \mathcal{X}_{E_R} \) and so, by the dominated convergence theorem,

\[
0 = \lim_{m \to \infty} \int_{\mathbb{R}^n} f \phi_m dx = \lim_{m \to \infty} \int_{V_1} f \phi_m dx = \int_{E_R} f dx \geq rm(E_R).
\]

Thus, \( m_n(E_R) = 0 \) and therefore \( m_n(E) = \lim_{R \to \infty} m_n(E_R) = 0 \). Since \( r > 0 \) is arbitrary, it follows

\[
m_n([f > 0]) = \bigcup_{k=1}^{\infty} m_n([f > k^{-1}]) = \bigcup_{k=1}^{\infty} m_n([f^+ > k^{-1}]) = m_n([f^+ > 0]) = 0.
\]

Hence \( f^+ = 0 \) a.e. It follows that \( \int f^- \phi dx = 0 \) for all \( \phi \in C_c(\mathbb{R}^n) \) because

\[
\int f^- \phi dx = \int f^+ \phi - \int f \phi = 0.
\]

Thus from what was just shown, with \( f^- \) taking the place of \( f \), it follows \( \frac{|f^-| + f^-}{2} = 0 \) and so \( f^- = 0 \) a.e. also.

**Corollary 29.3.6** Let \( f \in L^1(\mathbb{R}^n) \) and suppose

\[
\int_{\mathbb{R}^n} f(x) \phi(x) dx = 0
\]

for all \( \phi \in \mathcal{G} \). Then \( f = 0 \) a.e.
29.3. FOURIER TRANSFORMS OF JUST ABOUT ANYTHING

Proof: Let \( \psi \in C_c(\mathbb{R}^n) \). Then by the Stone Weierstrass approximation theorem, there exists a sequence of functions, \( \{ \phi_k \} \subseteq \mathcal{G} \) such that \( \phi_k \rightarrow \psi \) uniformly. Then by the dominated convergence theorem,

\[
\int f \psi dx = \lim_{k \to \infty} \int f \phi_k dx = 0.
\]

By Lemma \( \ref{lem:fourier-transforms-of-just-about-anything} \), \( f = 0 \).

The next theorem is the main result of this sort.

**Theorem 29.3.7** Let \( f \in L^p(\mathbb{R}^n) \), \( p \geq 1 \), or suppose \( f \) is measurable and has polynomial growth,

\[
|f(x)| \leq K \left( 1 + |x|^2 \right)^m
\]

for some \( m \in \mathbb{N} \). Then if

\[
\int f \psi dx = 0
\]

for all \( \psi \in \mathcal{G} \), then it follows \( f = 0 \).

Proof: First note that if \( f \in L^p(\mathbb{R}^n) \) or has polynomial growth, then it makes sense to write the integral \( \int f \psi dx \) described above. This is obvious in the case of polynomial growth. In the case where \( f \in L^p(\mathbb{R}^n) \) it also makes sense because

\[
\int |f| \psi dx \leq \left( \int |f|^p dx \right)^{1/p} \left( \int |\psi|^{p'} dx \right)^{1/p'} < \infty
\]

due to the fact mentioned above that all these functions in \( \mathcal{G} \) are in \( L^p(\mathbb{R}^n) \) for every \( p \geq 1 \). Suppose now that \( f \in L^p, p \geq 1 \). The case where \( f \in L^1(\mathbb{R}^n) \) was dealt with in Corollary \( \ref{cor:fourier-transforms-of-just-about-anything} \). Suppose \( f \in L^p(\mathbb{R}^n) \) for \( p > 1 \). Then

\[
|f|^{p-2} \mathcal{F} \in L^{p'}(\mathbb{R}^n), \quad \left( p' = q, \frac{1}{p} + \frac{1}{q} = 1 \right)
\]

and by density of \( \mathcal{G} \) in \( L^{p'}(\mathbb{R}^n) \) (Theorem \( \ref{thm:fourier-transforms-of-just-about-anything} \)), there exists a sequence \( \{g_k\} \subseteq \mathcal{G} \) such that

\[
\left\| g_k - |f|^{p-2} \mathcal{F} \right\|_{p'} 
\rightarrow 0.
\]

Then

\[
\int_{\mathbb{R}^n} |f|^p dx = \int_{\mathbb{R}^n} f \left( |f|^{p-2} \mathcal{F} - g_k \right) dx + \int_{\mathbb{R}^n} fg_k dx 
\]

\[
= \int_{\mathbb{R}^n} f \left( |f|^{p-2} \mathcal{F} - g_k \right) dx 
\]

\[
\leq \||f||_{L^p} \left\| g_k - |f|^{p-2} \mathcal{F} \right\|_{p'}
\]

which converges to 0. Hence \( f = 0 \).
CHAPTER 29. FOURIER TRANSFORMS

It remains to consider the case where \( f \) has polynomial growth. Thus \( x \rightarrow f(x)e^{-|x|^2} \in L^1(\mathbb{R}^n) \). Therefore, for all \( \psi \in \mathcal{G} \),

\[
0 = \int f(x)e^{-|x|^2}\psi(x)\,dx
\]
because \( e^{-|x|^2}\psi(x) \in \mathcal{G} \). Therefore, by the first part, \( f(x)e^{-|x|^2} = 0 \) a.e. \( \blacksquare \)

The following theorem shows that you can consider most functions you are likely to encounter as elements of \( \mathcal{G}^* \).

**Theorem 29.3.8** Let \( f \) be a measurable function with polynomial growth,

\[
|f(x)| \leq C\left(1 + |x|^2\right)^N \text{ for some } N,
\]
or let \( f \in L^p(\mathbb{R}^n) \) for some \( p \in [1,\infty] \). Then \( f \in \mathcal{G}^* \) if

\[
f(\phi) = \int f\phi\,dx.
\]

**Proof:** Let \( f \) have polynomial growth first. Then the above integral is clearly well defined and so in this case, \( f \in \mathcal{G}^* \).

Next suppose \( f \in L^p(\mathbb{R}^n) \) with \( \infty > p \geq 1 \). Then it is clear again that the above integral is well defined because of the fact that \( \phi \) is a sum of polynomials times exponentials of the form \( e^{-|x|^2} \) and these are in \( L^p(\mathbb{R}^n) \). Also \( \phi \rightarrow f(\phi) \) is clearly linear in both cases. \( \blacksquare \)

This has shown that for nearly any reasonable function, you can define its Fourier transform as described above. You could also define the Fourier transform of a finite Borel measure \( \mu \) because for such a measure

\[
\psi \rightarrow \int_{\mathbb{R}^n} \psi\,d\mu
\]
is a linear functional on \( \mathcal{G} \). This includes the very important case of probability distribution measures. The theoretical basis for this assertion will be given a little later.

**29.3.2 Fourier Transforms Of Functions In \( L^1(\mathbb{R}^n) \)**

First suppose \( f \in L^1(\mathbb{R}^n) \).

**Theorem 29.3.9** Let \( f \in L^1(\mathbb{R}^n) \). Then \( Ff(\phi) = \int_{\mathbb{R}^n} g\phi\,dt \) where

\[
g(t) = \left(\frac{1}{2\pi}\right)^{n/2} \int_{\mathbb{R}^n} e^{-it\cdot x}f(x)\,dx
\]

and \( F^{-1}f(\phi) = \int_{\mathbb{R}^n} g\phi\,dt \) where \( g(t) = \left(\frac{1}{2\pi}\right)^{n/2} \int_{\mathbb{R}^n} e^{it\cdot x}f(x)\,dx \). In short,

\[
Ff(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it\cdot x}f(x)\,dx,
\]
29.3. FOURIER TRANSFORMS OF JUST ABOUT ANYTHING

\[ F^{-1}f(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{it \cdot x} f(x) dx. \]

**Proof:** From the definition and Fubini’s theorem,

\[ F f (\phi) = \int_{\mathbb{R}^n} f(t) \phi(t) dt = \int_{\mathbb{R}^n} f(t) \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} \phi(x) dx dt = \int_{\mathbb{R}^n} \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} f(t) e^{-it \cdot x} dx \phi(x) dx. \]

Since \( \phi \in \mathcal{G} \) is arbitrary, it follows from Theorem 29.3.7 that \( F f (x) \) is given by the claimed formula. The case of \( F^{-1} \) is identical.

Here are interesting properties of these Fourier transforms of functions in \( L^1 \).

**Theorem 29.3.10** If \( f \in L^1(\mathbb{R}^n) \) and \( \|f_k - f\|_1 \rightarrow 0 \), then \( F f_k \) and \( F^{-1} f_k \) converge uniformly to \( F f \) and \( F^{-1} f \) respectively. If \( f \in L^1(\mathbb{R}^n) \), then \( F^{-1} f \) and \( F f \) are both continuous and bounded. Also,

\[ \lim_{|x| \rightarrow \infty} F^{-1} f(x) = \lim_{|x| \rightarrow \infty} F f(x) = 0. \] (29.3.3)

Furthermore, for \( f \in L^1(\mathbb{R}^n) \) both \( F f \) and \( F^{-1} f \) are uniformly continuous.

**Proof:** The first claim follows from the following inequality.

\[ |F f_k(t) - F f(t)| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} |e^{-it \cdot x} f_k(x) - e^{-it \cdot x} f(x)| dx = (2\pi)^{-n/2} \int_{\mathbb{R}^n} |f_k(x) - f(x)| dx = (2\pi)^{-n/2} \|f - f_k\|_1. \]

which a similar argument holding for \( F^{-1} \).

Now consider the second claim of the theorem.

\[ |F f(t) - F f(t')| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} \left| e^{-it \cdot x} - e^{-it' \cdot x} \right| |f(x)| dx \]

The integrand is bounded by \( 2|f(x)| \), a function in \( L^1(\mathbb{R}^n) \) and converges to 0 as \( t' \rightarrow t \) and so the dominated convergence theorem implies \( F f \) is continuous. To see \( F f(t) \) is uniformly bounded,

\[ |F f(t)| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} |f(x)| dx < \infty. \]

A similar argument gives the same conclusions for \( F^{-1} \).

It remains to verify that \( F f \) and \( F^{-1} f \) are uniformly continuous.

\[ |F f(t)| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} f(x) dx \]

\[ |F^{-1} f(t)| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} f(x) dx \]
Now let \( \varepsilon > 0 \) be given and let \( g \in C_\infty^c (\mathbb{R}^n) \) such that \((2\pi)^{-n/2} \|g - f\|_1 < \varepsilon / 2 \). Then

\[
|Ff(t)| \leq (2\pi)^{-n/2} \int_{\mathbb{R}^n} |f(x) - g(x)| \, dx + \left| (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} g(x) \, dx \right| \leq \varepsilon / 2 + (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} g(x) \, dx.
\]

Now integrating by parts, it follows that for \( ||t||_\infty \equiv \max \{|t_j| : j = 1, \ldots, n\} > 0 \)

\[
|Ff(t)| \leq \varepsilon / 2 + (2\pi)^{-n/2} \left| \frac{1}{||t||_\infty} \int_{\mathbb{R}^n} \sum_{j=1}^n \frac{\partial g(x)}{\partial x_j} \, dx \right| \quad (29.3.4)
\]

and this last expression converges to zero as \( ||t||_\infty \to \infty \). The reason for this is that if \( t_j \neq 0 \), integration by parts with respect to \( x_j \) gives

\[
(2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot x} g(x) \, dx = (2\pi)^{-n/2} \frac{1}{-it_j} \int_{\mathbb{R}^n} e^{-it \cdot x} \frac{\partial g(x)}{\partial x_j} \, dx.
\]

Therefore, choose the \( j \) for which \( ||t||_\infty = |t_j| \) and the result of \( 29.3.4 \) holds. Therefore, from \( 29.3.4 \), if \( ||t||_\infty \) is large enough, \( |Ff(t)| < \varepsilon \). Similarly, \( \lim_{||t||_\infty \to \infty} F^{-1}(t) = 0 \). Consider the claim about uniform continuity. Let \( \varepsilon > 0 \) be given. Then there exists \( R \) such that if \( ||t||_\infty > R \), then \( |Ff(t)| < \varepsilon / 2 \). Since \( Ff \) is continuous, it is uniformly continuous on the compact set \( [-R - 1, R + 1]^n \). Therefore, there exists \( \delta_1 \) such that if \( ||t - t'|_\infty < \delta_1 \) for \( t, t' \in [-R - 1, R + 1]^n \), then

\[
|Ff(t) - Ff(t')| < \varepsilon / 2. \quad (29.3.5)
\]

Now let \( 0 < \delta < \min (\delta_1, 1) \) and suppose \( ||t - t'||_\infty < \delta \). If both \( t, t' \) are contained in \( [-R, R]^n \), then \( 29.3.5 \) holds. If \( t \in [-R, R]^n \) and \( t' \notin [-R, R]^n \), then both are contained in \( [-R - 1, R + 1]^n \) and so this verifies \( 29.3.5 \) in this case. The other case is that neither point is in \( [-R, R]^n \) and in this case,

\[
|Ff(t) - Ff(t')| \leq |Ff(t)| + |Ff(t')| < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
\]

There is a very interesting relation between the Fourier transform and convolutions.

**Theorem 29.3.11** Let \( f, g \in L^1(\mathbb{R}^n) \). Then \( f \ast g \in L^1 \) and \( F(f \ast g) = (2\pi)^{n/2} FfFg \).

**Proof:** Consider

\[
\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} |f(x - y)g(y)| \, dy \, dx.
\]
The function, \((x, y) \rightarrow |f(x - y)g(y)|\) is Lebesgue measurable and so by Fubini’s theorem,
\[
\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} |f(x - y)g(y)| \, dy \, dx = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} |f(x - y)g(y)| \, dx \, dy = \|f\|_1 \|g\|_1 < \infty.
\]
It follows that for a.e. \(x\), \(\int_{\mathbb{R}^n} |f(x - y)g(y)| \, dy < \infty\) and for each of these values of \(x\), it follows that \(\int_{\mathbb{R}^n} f(x - y)g(y) \, dy\) exists and equals a function of \(x\) which is in \(L^1(\mathbb{R}^n)\), \(f \ast g(x)\). Now
\[
F(f \ast g)(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} \overline{e^{-it \cdot x}} f \ast g(x) \, dx
\]
\[
= (2\pi)^{-n/2} \int_{\mathbb{R}^n} \overline{e^{-it \cdot x}} \int_{\mathbb{R}^n} f(x - y)g(y) \, dy \, dx
\]
\[
= (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-it \cdot y} g(y) \int_{\mathbb{R}^n} e^{-it(x-y)} f(x - y) \, dx \, dy
\]
\[
= (2\pi)^{n/2} Ff(t) Fg(t). \quad \blacksquare
\]
There are many other considerations involving Fourier transforms of functions in \(L^1(\mathbb{R}^n)\).

### 29.3.3 Fourier Transforms Of Functions In \(L^2(\mathbb{R}^n)\)

Consider \(Ff\) and \(F^{-1}f\) for \(f \in L^2(\mathbb{R}^n)\). First note that the formula given for \(Ff\) and \(F^{-1}f\) when \(f \in L^1(\mathbb{R}^n)\) will not work for \(f \in L^2(\mathbb{R}^n)\) unless \(f\) is also in \(L^1(\mathbb{R}^n)\).

**Theorem 29.3.12** For \(\phi \in \mathcal{G}\), \(||F\phi||_2 = ||F^{-1}\phi||_2 = ||\phi||_2\).

**Proof:** First note that for \(\psi \in \mathcal{G}\),
\[
F(\overline{\psi}) = \overline{F^{-1}(\psi)}, \quad F^{-1}(\overline{\psi}) = \overline{F(\psi)}.
\]
This follows from the definition. For example,
\[
F(\overline{\psi})(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} \overline{e^{-it \cdot x}} \overline{\psi(x)} \, dx
\]
\[
= (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{it \cdot x} \psi(x) \, dx
\]
Let \(\phi, \psi \in \mathcal{G}\). It was shown above that
\[
\int_{\mathbb{R}^n} (F\phi)\psi(t) \, dt = \int_{\mathbb{R}^n} \phi(F\psi) \, dx.
\]
Similarly,
\[
\int_{\mathbb{R}^n} \phi(F^{-1}\psi) \, dx = \int_{\mathbb{R}^n} (F^{-1}\phi)\psi(t) \, dt. \quad (29.3.7)
\]
CHAPTER 29. FOURIER TRANSFORMS

Now, \( 29.3.6 - 29.3.7 \) imply

\[
\int_{\mathbb{R}^n} |\phi|^2 \, dx = \int_{\mathbb{R}^n} \phi F^{-1}(F\phi) \, dx = \int_{\mathbb{R}^n} \phi F(\overline{F\phi}) \, dx
\]

\[
= \int_{\mathbb{R}^n} F\phi F(\overline{F\phi}) \, dx = \int_{\mathbb{R}^n} |F\phi|^2 \, dx.
\]

Similarly

\[
\|\phi\|_2 = \|F^{-1}\phi\|_2. \quad \blacksquare
\]

**Lemma 29.3.13** Let \( f \in L^2(\mathbb{R}^n) \) and let \( \phi_k \to f \) in \( L^2(\mathbb{R}^n) \) where \( \phi_k \in \mathcal{G} \). (Such a sequence exists because of density of \( \mathcal{G} \) in \( L^2(\mathbb{R}^n) \).) Then \( Ff \) and \( F^{-1}f \) are both in \( L^2(\mathbb{R}^n) \) and the following limits take place in \( L^2 \).

\[
\lim_{k \to \infty} F(\phi_k) = F(f), \quad \lim_{k \to \infty} F^{-1}(\phi_k) = F^{-1}(f).
\]

**Proof:** Let \( \psi \in \mathcal{G} \) be given. Then

\[
Ff(\psi) = f(F\psi) = \int_{\mathbb{R}^n} f(x) F\psi(x) \, dx
\]

\[
= \lim_{k \to \infty} \int_{\mathbb{R}^n} \phi_k(x) F\psi(x) \, dx = \lim_{k \to \infty} \int_{\mathbb{R}^n} F\phi_k(x) \psi(x) \, dx.
\]

Also by Theorem 29.3.12 \( \{F\phi_k\}_{k=1}^\infty \) is Cauchy in \( L^2(\mathbb{R}^n) \) and so it converges to some \( h \in L^2(\mathbb{R}^n) \). Therefore, from the above,

\[
Ff(\psi) = \int_{\mathbb{R}^n} h(x) \, \psi(x)
\]

which shows that \( F(f) \in L^2(\mathbb{R}^n) \) and \( h = F(f) \). The case of \( F^{-1} \) is entirely similar. \( \blacksquare \)

Since \( Ff \) and \( F^{-1}f \) are in \( L^2(\mathbb{R}^n) \), this also proves the following theorem.

**Theorem 29.3.14** If \( f \in L^2(\mathbb{R}^n) \), \( Ff \) and \( F^{-1}f \) are the unique elements of \( L^2(\mathbb{R}^n) \) such that for all \( \phi \in \mathcal{G} \),

\[
\int_{\mathbb{R}^n} Ff(x)\phi(x) \, dx = \int_{\mathbb{R}^n} f(x)F\phi(x) \, dx, \quad (29.3.8)
\]

\[
\int_{\mathbb{R}^n} F^{-1}f(x)\phi(x) \, dx = \int_{\mathbb{R}^n} f(x)F^{-1}\phi(x) \, dx. \quad (29.3.9)
\]

**Theorem 29.3.15** (Plancherel)

\[
\|f\|_2 = \|Ff\|_2 = \|F^{-1}f\|_2. \quad (29.3.10)
\]
29.3. FOURIER TRANSFORMS OF JUST ABOUT ANYTHING

**Proof:** Use the density of $\mathcal{G}$ in $L^2(\mathbb{R}^n)$ to obtain a sequence, $\{\phi_k\}$ converging to $f$ in $L^2(\mathbb{R}^n)$. Then by Lemma 29.3.13

$$||Ff||^2 = \lim_{k \to \infty} ||F\phi_k||^2 = \lim_{k \to \infty} ||\hat{\phi}_k||_2 = ||f||_2.$$

Similarly,

$$||f||_2 = ||F^{-1}f||_2.$$ 

The following corollary is a simple generalization of this. To prove this corollary, use the following simple lemma which comes as a consequence of the Cauchy Schwarz inequality.

**Lemma 29.3.16** Suppose $f_k \to f$ in $L^2(\mathbb{R}^n)$ and $g_k \to g$ in $L^2(\mathbb{R}^n)$. Then

$$\lim_{k \to \infty} \int_{\mathbb{R}^n} f_k g_k dx = \int_{\mathbb{R}^n} f g dx$$

**Proof:**

$$\left| \int_{\mathbb{R}^n} f_k g_k dx - \int_{\mathbb{R}^n} f g dx \right| \leq \left| \int_{\mathbb{R}^n} f_k g_k dx - \int_{\mathbb{R}^n} f_k g dx \right| +$$

$$\left| \int_{\mathbb{R}^n} f_k g dx - \int_{\mathbb{R}^n} f g dx \right|$$

$$\leq ||f_k||_2 ||g - g_k||_2 + ||g||_2 ||f_k - f||_2.$$ 

Now $||f_k||_2$ is a Cauchy sequence and so it is bounded independent of $k$. Therefore, the above expression is smaller than $\varepsilon$ whenever $k$ is large enough. 

**Corollary 29.3.17** For $f, g \in L^2(\mathbb{R}^n)$,

$$\int_{\mathbb{R}^n} f \overline{g} dx = \int_{\mathbb{R}^n} Ff \overline{Fg} dx = \int_{\mathbb{R}^n} F^{-1}f \overline{F^{-1}g} dx.$$ 

**Proof:** First note the above formula is obvious if $f, g \in \mathcal{G}$. To see this, note

$$\int_{\mathbb{R}^n} Ff \overline{Fg} dx = \int_{\mathbb{R}^n} Ff(x) \frac{1}{(2\pi)^n/2} \int_{\mathbb{R}^n} e^{-ix \cdot t} \overline{g(t)} dt dx$$

$$= \frac{1}{(2\pi)^n/2} \int_{\mathbb{R}^n} e^{ix \cdot t} Ff(x) dx \overline{g(t)} dt = \int_{\mathbb{R}^n} (F^{-1} \circ F) f(t) \overline{g(t)} dt$$

$$= \int_{\mathbb{R}^n} f(t) \overline{g(t)} dt.$$ 

The formula with $F^{-1}$ is exactly similar.

Now to verify the corollary, let $\phi_k \to f$ in $L^2(\mathbb{R}^n)$ and let $\psi_k \to g$ in $L^2(\mathbb{R}^n)$. Then by Lemma 29.3.13

$$\int_{\mathbb{R}^n} Ff \overline{g} dx = \lim_{k \to \infty} \int_{\mathbb{R}^n} F\phi_k \overline{F\psi_k} dx = \lim_{k \to \infty} \int_{\mathbb{R}^n} \phi_k \overline{\psi_k} dx = \int_{\mathbb{R}^n} f \overline{g} dx$$

A similar argument holds for $F^{-1}$. 

**How does one compute $Ff$ and $F^{-1}f$?**
Theorem 29.3.18 For \( f \in L^2(\mathbb{R}^n) \), let \( f_r = f 1_{E_r} \) where \( E_r \) is a bounded measurable set with \( E_r \uparrow \mathbb{R}^n \). Then the following limits hold in \( L^2(\mathbb{R}^n) \). 

\[
Ff = \lim_{r \to \infty} Ff_r, \quad F^{-1}f = \lim_{r \to \infty} F^{-1}f_r.
\]

Proof: \( \|f - f_r\|_2 \to 0 \) and so \( \|Ff - Ff_r\|_2 \to 0 \) and \( \|F^{-1}f - F^{-1}f_r\|_2 \to 0 \) by Plancherel’s Theorem.

What are \( Ff_r \) and \( F^{-1}f_r \)? Let \( \phi \in \mathcal{G} \)

\[
\int_{\mathbb{R}^n} Ff_r \phi dx = \int_{\mathbb{R}^n} f_r \phi dx = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f_r(x)e^{-ixy}\phi(y)dydx = \int_{\mathbb{R}^n} [(2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} f_r(x)e^{-ixy}dy]\phi(y)dy.
\]

Since this holds for all \( \phi \in \mathcal{G} \), a dense subset of \( L^2(\mathbb{R}^n) \), it follows that

\[
Ff_r(y) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} f_r(x)e^{-ixy}dx.
\]

Similarly

\[
F^{-1}f_r(y) = (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} f_r(x)e^{ixy}dx.
\]

This shows that to take the Fourier transform of a function in \( L^2(\mathbb{R}^n) \), it suffices to take the limit as \( r \to \infty \) in \( L^2(\mathbb{R}^n) \) of \( (2\pi)^{-\frac{n}{2}} \int_{\mathbb{R}^n} f_r(x)e^{-ixy}dx \). A similar procedure works for the inverse Fourier transform.

Note this reduces to the earlier definition in case \( f \in L^1(\mathbb{R}^n) \). Now consider the convolution of a function in \( L^2 \) with one in \( L^1 \).

Theorem 29.3.19 Let \( h \in L^2(\mathbb{R}^n) \) and let \( f \in L^1(\mathbb{R}^n) \). Then \( h * f \in L^2(\mathbb{R}^n) \),

\[
F^{-1}(h * f) = (2\pi)^{n/2} F^{-1}h F^{-1}f,
\]

\[
F(h * f) = (2\pi)^{n/2} Fh Ff,
\]

and

\[
\|h * f\|_2 \leq \|h\|_2 \|f\|_1. \quad (29.3.11)
\]

Proof: An application of Minkowski’s inequality yields

\[
\left( \int_{\mathbb{R}^n} \left( \int_{\mathbb{R}^n} |h(x - y)||f(y)|dy \right)^2 dx \right)^{1/2} \leq \|f\|_1 \|h\|_2. \quad (29.3.12)
\]

Hence \( \int |h(x - y)||f(y)|dy < \infty \) a.e. \( x \) and

\[
x \to \int h(x - y) f(y) dy
\]
is in $L^2(\mathbb{R}^n)$. Let $E_r \uparrow \mathbb{R}^n$, $m(E_r) < \infty$. Thus,

$$h_r \equiv \mathcal{X}_{E_r} h \in L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n),$$

and letting $\phi \in \mathcal{G}$,

$$\int F(h_r * f)(\phi) \, dx$$

$$= \int (h_r * f)(F\phi) \, dx$$

$$= (2\pi)^{-n/2} \int \int h_r(x - y) f(y) e^{-ix\cdot t} \phi(t) \, dtdydx$$

$$= (2\pi)^{-n/2} \int \left( \int h_r(x - y) e^{-i(x-y)\cdot t} dx \right) f(y) e^{-iy\cdot t} dy \phi(t) \, dt$$

$$= \int (2\pi)^{n/2} Fh_r(t) Ff(t) \, t \phi(t) \, dt.$$ 

Since $\phi$ is arbitrary and $\mathcal{G}$ is dense in $L^2(\mathbb{R}^n)$,

$$F(h_r * f) = (2\pi)^{n/2} Fh_r Ff.$$ 

Now by Minkowski’s Inequality, $h_r * f \rightarrow h * f$ in $L^2(\mathbb{R}^n)$ and also it is clear that $h_r \rightarrow h$ in $L^2(\mathbb{R}^n)$; so, by Plancherel’s theorem, you may take the limit in the above and conclude

$$F(h * f) = (2\pi)^{n/2} Fh Ff.$$ 

The assertion for $F^{-1}$ is similar and follows from 29.3.11.

### 29.3.4 The Schwartz Class

The problem with $\mathcal{G}$ is that it does not contain $C_c^\infty(\mathbb{R}^n)$. I have used it in presenting the Fourier transform because the functions in $\mathcal{G}$ have a very specific form which made some technical details work out easier than in any other approach I have seen. The Schwartz class is a larger class of functions which does contain $C_c^\infty(\mathbb{R}^n)$ and also has the same nice properties as $\mathcal{G}$. The functions in the Schwartz class are infinitely differentiable and they vanish very rapidly as $|x| \rightarrow \infty$ along with all their partial derivatives. This is the description of these functions, not a specific form involving polynomials times $e^{-\alpha |x|^2}$. To describe this precisely requires some notation.

**Definition 29.3.20** $f \in \mathcal{G}$, the Schwartz class, if $f \in C^\infty(\mathbb{R}^n)$ and for all positive integers $N$,

$$\rho_N(f) < \infty$$

where

$$\rho_N(f) = \sup \{|1 + |x|^2|^N |D^\alpha f(x)| : x \in \mathbb{R}^n, |\alpha| \leq N\}.$$
Thus \( f \in \mathcal{S} \) if and only if \( f \in C^\infty(\mathbb{R}^n) \) and

\[
\sup\{|x^\alpha D^\beta f(x)| : x \in \mathbb{R}^n\} < \infty
\]

(29.3.13)

for all multi indices \( \alpha \) and \( \beta \).

Also note that if \( f \in \mathcal{S} \), then \( p(f) \in \mathcal{S} \) for any polynomial, \( p \) with \( p(0) = 0 \) and that

\[
\mathcal{S} \subseteq L^p(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n)
\]

for any \( p \geq 1 \). To see this assertion about the \( p(f) \), it suffices to consider the case of the product of two elements of the Schwartz class. If \( f, g \in \mathcal{S} \), then \( D^\alpha(fg) \) is a finite sum of derivatives of \( f \) times derivatives of \( g \). Therefore, \( \rho_N(fg) < \infty \) for all \( N \). You may wonder about examples of things in \( \mathcal{S} \). Clearly any function in \( C^1_c(\mathbb{R}^n) \) is in \( \mathcal{S} \). However there are other functions in \( \mathcal{S} \). For example \( e^{jx_j} \) is in \( \mathcal{S} \) as you can verify for yourself and so is any function from \( \mathcal{G} \). Note also that the density of \( C^1_c(\mathbb{R}^n) \) in \( L^p(\mathbb{R}^n) \) shows that \( \mathcal{S} \) is dense in \( L^p(\mathbb{R}^n) \) for every \( p \).

Recall the Fourier transform of a function in \( L^1(\mathbb{R}^n) \) is given by

\[
Ff(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-ix \cdot f(x)} dx.
\]

Therefore, this gives the Fourier transform for \( f \in \mathcal{S} \). The nice property which \( \mathcal{S} \) has in common with \( \mathcal{G} \) is that the Fourier transform and its inverse map \( \mathcal{S} \) one to one onto \( \mathcal{S} \). This means I could have presented the whole of the above theory in terms of \( \mathcal{S} \) rather than in terms of \( \mathcal{G} \). However, it is more technical.

**Theorem 29.3.21** If \( f \in \mathcal{S} \), then \( Ff \) and \( F^{-1}f \) are also in \( \mathcal{S} \).

**Proof:** To begin with, let \( \alpha = e_j = (0,0,\cdots,1,0,\cdots,0) \), the 1 in the \( j^{th} \) slot.

\[
\frac{F^{-1}f(t + he_j) - F^{-1}f(t)}{h} = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{i\mathbf{x} \cdot f(x)} (\frac{e^{ihx_j} - 1}{h}) dx.
\]

(29.3.14)

Consider the integrand in (29.3.14)

\[
\left| e^{i\mathbf{x} \cdot f(x)} (\frac{e^{ihx_j} - 1}{h}) \right| = \left| f(x) \right| \left| \frac{e^{i(h/2)x_j} - e^{-i(h/2)x_j}}{h} \right|
\]

\[
= \left| f(x) \right| \left| \frac{i \sin \left( (h/2)x_j \right)}{(h/2)} \right| \leq \left| f(x) \right| |x_j|
\]

and this is a function in \( L^1(\mathbb{R}^n) \) because \( f \in \mathcal{S} \). Therefore by the Dominated Convergence Theorem,

\[
\frac{\partial F^{-1}f(t)}{\partial t_j} = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{i\mathbf{x} \cdot tx_j} f(x) dx
\]

\[
= i(2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{i\mathbf{x} \cdot e_j} f(x) dx.
\]
Now \( x^\alpha f(x) \in \mathcal{S} \) and so one can continue in this way and take derivatives indefinitely. Thus \( F^{-1} f \in C^\infty (\mathbb{R}^n) \) and from the above argument,

\[
D^\alpha F^{-1} f(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{it \cdot x} (ix)^\alpha f(x) dx.
\]

To complete showing \( F^{-1} f \in \mathcal{S} \),

\[
t^\beta D^\alpha F^{-1} f(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{it \cdot t^\beta (ix)^\alpha f(x)} dx.
\]

Integrate this integral by parts to get

\[
t^\beta D^\alpha F^{-1} f(t) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} i |\beta| e^{it \cdot D^\beta ((ix)^\alpha f(x))} dx.
\]

(29.3.15)

Here is how this is done.

\[
\int e^{it_j x_j} t_j^\beta (ix)^\alpha f(x) dx_j = e^{it_j x_j} \frac{t_j^\beta (ix)^\alpha f(x) |_{-\infty}^\infty}{it_j^\beta (ix)^\alpha f(x)} + 
\]

\[
i \int e^{it_j x_j} t_j^\beta (ix)^\alpha f(x) D^\beta ((ix)^\alpha f(x)) dx_j
\]

where the boundary term vanishes because \( f \in \mathcal{S} \). Returning to (29.3.15), use the fact that \( |e^{it_j^\alpha}| = 1 \) to conclude

\[
|t^\beta D^\alpha F^{-1} f(t)| \leq C \int_{\mathbb{R}^n} |D^\beta ((ix)^\alpha f(x))| dx < \infty.
\]

It follows \( F^{-1} f \in \mathcal{S} \). Similarly \( F f \in \mathcal{S} \) whenever \( f \in \mathcal{S} \). ■

Of course \( \mathcal{S} \) can be considered a subset of \( \mathcal{G}^* \) as follows. For \( \psi \in \mathcal{S} \),

\[
\psi (\phi) = \int_{\mathbb{R}^n} \psi \phi dx
\]

**Theorem 29.3.22** Let \( \psi \in \mathcal{S} \). Then \( (F \circ F^{-1})(\psi) = \psi \) and \( (F^{-1} \circ F)(\psi) = \psi \) whenever \( \psi \in \mathcal{S} \). Also \( F \) and \( F^{-1} \) map \( \mathcal{S} \) one to one and onto \( \mathcal{S} \).

**Proof:** The first claim follows from the fact that \( F \) and \( F^{-1} \) are inverses of each other on \( \mathcal{G}^* \) which was established above. For the second, let \( \psi \in \mathcal{S} \). Then \( \psi = F (F^{-1} \psi) \). Thus \( F \) maps \( \mathcal{S} \) onto \( \mathcal{S} \). If \( F \psi = 0 \), then do \( F^{-1} \) to both sides to conclude \( \psi = 0 \). Thus \( F \) is one to one and onto. Similarly, \( F^{-1} \) is one to one and onto. ■

### 29.3.5 Convolution

To begin with it is necessary to discuss the meaning of \( \phi f \) where \( f \in \mathcal{G}^* \) and \( \phi \in \mathcal{G} \). What should it mean? First suppose \( f \in L^p (\mathbb{R}^n) \) or measurable with polynomial growth. Then \( \phi f \) also has these properties. Hence, it should be the case that \( \phi f (\psi) = \int_{\mathbb{R}^n} \phi f \psi dx = \int_{\mathbb{R}^n} f (\phi \psi) dx \). This motivates the following definition.
Definition 29.3.23 Let $T \in \mathcal{G}^*$ and let $\phi \in \mathcal{G}$. Then $\phi T \equiv T \phi \in \mathcal{G}^*$ will be defined by

$$\phi T (\psi) \equiv T (\phi \psi).$$

The next topic is that of convolution. It was just shown that

$$F (f * \phi) = (2\pi)^{n/2} F \phi F f, \quad F^{-1} (f * \phi) = (2\pi)^{n/2} F^{-1} \phi F^{-1} f$$

whenever $f \in L^2(\mathbb{R}^n)$ and $\phi \in \mathcal{G}$ so the same definition is retained in the general case because it makes perfect sense and agrees with the earlier definition.

Definition 29.3.24 Let $f \in \mathcal{G}^*$ and let $\phi \in \mathcal{G}$. Then define the convolution of $f$ with an element of $\mathcal{G}$ as follows.

$$f * \phi \equiv (2\pi)^{n/2} F^{-1} (F \phi F f) \in \mathcal{G}^*$$

There is an obvious question. With this definition, is it true that $F^{-1} (f * \phi) = (2\pi)^{n/2} F^{-1} \phi F^{-1} f$ as it was earlier?

Theorem 29.3.25 Let $f \in \mathcal{G}^*$ and let $\phi \in \mathcal{G}$.

$$F (f * \phi) = (2\pi)^{n/2} F \phi F f,$$

$$F^{-1} (f * \phi) = (2\pi)^{n/2} F^{-1} \phi F^{-1} f.$$  \hspace{1cm} (29.3.16) \hspace{1cm} (29.3.17)

Proof: Note that \hspace{1cm} (29.3.16) follows from Definition \hspace{1cm} (29.3.17) and both assertions hold for $f \in \mathcal{G}$. Consider \hspace{1cm} (29.3.18). Here is a simple formula involving a pair of functions in $\mathcal{G}$.

$$(\psi * F^{-1} F^{-1} \phi) (x)$$

$$= \left( \int \int \int \psi(x - y) e^{iy_1 \cdot y_1} e^{iy_1 \cdot z} \phi(z) dz dy_1 dy \right) (2\pi)^n$$

$$= \left( \int \int \int \psi(x - y) e^{-iy_1 \cdot y_1} e^{-iy_1 \cdot z} \phi(z) dz dy_1 dy \right) (2\pi)^n$$

$$= (\psi * FF \phi) (x).$$

Now for $\psi \in \mathcal{G}$,

$$(2\pi)^{n/2} F (F^{-1} \phi F^{-1} f) (\psi) \equiv (2\pi)^{n/2} (F^{-1} \phi F^{-1} f) (F \psi) \equiv$$

$$(2\pi)^{n/2} F^{-1} f (F^{-1} \phi F \psi) \equiv (2\pi)^{n/2} f \left( F^{-1} \left(F^{-1} \phi F \psi \right) \right) =$$

$$f \left( (2\pi)^{n/2} F^{-1} \left((FF^{-1} \phi) (F \psi) \right) \right) \equiv$$

$$f \left( \psi * F^{-1} F^{-1} \phi \right) = f (\psi * FF \phi)$$  \hspace{1cm} (29.3.18)
Also

\[(2\pi)^{n/2} F^{-1} (F\phi Ff) (\psi) \equiv (2\pi)^{n/2} (F\phi Ff) (F^{-1} \psi) \equiv \]

\[(2\pi)^{n/2} f (F\phi F^{-1} \psi) \equiv (2\pi)^{n/2} f (F (F\phi F^{-1} \psi)) = \]

\[= f \left( F \left( (2\pi)^{n/2} (F\phi F^{-1} \psi) \right) \right) \]

\[f (FF\phi * \psi) = f (\psi * FF\phi). \quad (29.3.19)\]

The last line follows from the following.

\[\int FF\phi (x - y) \psi (y) dy = \int F\phi (x - y) F\psi (y) dy \]

\[= \int F\psi (x - y) F\phi (y) dy \]

\[= \int \psi (x - y) FF\phi (y) dy. \]

From 29.3.18 and 29.3.19, since \( \psi \) was arbitrary,

\[(2\pi)^{n/2} F (F^{-1} \phi F^{-1} f) = (2\pi)^{n/2} F^{-1} (F\phi Ff) \equiv f \phi\]

which shows 29.3.17.

### 29.4 Exercises

1. For \( f \in L^1 (\mathbb{R}^n) \), show that if \( F^{-1} f \in L^1 \) or \( Ff \in L^1 \), then \( f \) equals a continuous bounded function a.e.

2. Suppose \( f, g \in L^1 (\mathbb{R}) \) and \( Ff = Fg \). Show \( f = g \) a.e.

3. Show that if \( f \in L^1 (\mathbb{R}^n) \), then \( \lim_{|x|\to\infty} Ff (x) = 0 \).

4. Suppose \( f \ast f = f \) or \( f \ast f = 0 \) and \( f \in L^1 (\mathbb{R}) \). Show \( f = 0 \).

5. For this problem define \( \int_a^\infty f (t) dt \equiv \lim_{r \to \infty} \int_a^r f (t) dt \). Note this coincides with the Lebesgue integral when \( f \in L^1 (a, \infty) \). Show

   \[(a) \quad \int_0^\infty \frac{\sin(u)}{u} du = \frac{\pi}{2}\]

   \[(b) \quad \lim_{r \to \infty} \int_0^r \frac{\sin(u)}{u} du = 0 \text{ whenever } \delta > 0.\]

   \[(c) \quad \text{If } f \in L^1 (\mathbb{R}), \text{ then } \lim_{r \to \infty} \int_{\mathbb{R}} \sin (ru) f (u) du = 0.\]

**Hint:** For the first two, use \( \int_0^\infty e^{-ut} dt \) and apply Fubini’s theorem to \( \int_0^R \sin u \int_R e^{-ut} dt du \). For the last part, first establish it for \( f \in C_c^\infty (\mathbb{R}) \) and then use the density of this set in \( L^1 (\mathbb{R}) \) to obtain the result. This is sometimes called the Riemann Lebesgue lemma.
6. Suppose that $g \in L^1(\mathbb{R})$ and that at some $x > 0$, $g$ is locally Holder continuous from the right and from the left. This means

$$\lim_{r \to 0^+} g(x + r) \equiv g(x+)$$

exists,

$$\lim_{r \to 0^+} g(x - r) \equiv g(x-)$$

exists and there exist constants $K, \delta > 0$ and $r \in (0, 1]$ such that for $|x - y| < \delta$,

$$|g(x+) - g(y)| < K |x - y|$$

for $y > x$ and

$$|g(x-) - g(y)| < K |x - y|$$

for $y < x$. Show that under these conditions,

$$\lim_{r \to 1} \frac{1}{2} \int_0^\infty \sin(ur) u \left( \frac{g(x - u) + g(x + u)}{2} \right) du = \frac{g(x+) + g(x-)}{2}.$$

7. Let $g \in L^1(\mathbb{R})$ and suppose $g$ is locally Holder continuous from the right and from the left at $x$. Show that then

$$\lim_{R \to \infty} \frac{1}{2\pi} \int_{-R}^{R} e^{ixt} \int_{-\infty}^{\infty} e^{-ity} g(y) dy dt = \frac{g(x+) + g(x-)}{2}.$$

This is very interesting. If $g \in L^2(\mathbb{R})$, this shows $F^{-1}(Fg)(x) = \frac{g(x+) + g(x-)}{2}$, the midpoint of the jump in $g$ at the point, $x$. In particular, if $g \in \mathcal{G}$, $F^{-1}(Fg) = g$. Hint: Show the left side of the above equation reduces to

$$\frac{2}{\pi} \int_0^\infty \sin(ur) u \left( \frac{g(x - u) + g(x + u)}{2} \right) du$$

and then use Problem 6 to obtain the result.

8. A measurable function $g$ defined on $(0, \infty)$ has exponential growth if $|g(t)| \leq Ce^{\eta t}$ for some $\eta$. For $\Re(s) > \eta$, define the Laplace Transform by

$$Lg(s) = \int_0^\infty e^{-su} g(u) du.$$ 

Assume that $g$ has exponential growth as above and is Holder continuous from the right and from the left at $t$. Pick $\gamma > \eta$. Show that

$$\lim_{R \to \infty} \frac{1}{2\pi} \int_{-R}^{R} e^{\gamma t} e^{iyt} Lg(\gamma + iy) dy = \frac{g(t+) + g(t-)}{2}.$$
This formula is sometimes written in the form
\[
\frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} e^{st} Lg(s) \, ds
\]
and is called the complex inversion integral for Laplace transforms. It can be used to find inverse Laplace transforms. Hint:
\[
\frac{1}{2\pi} \int_{-R}^{R} e^{\gamma t} e^{iyt} Lg(\gamma + iy) \, dy =
\]
\[
\frac{1}{2\pi} \int_{-R}^{R} e^{\gamma t} e^{iyt} \int_{0}^{\infty} e^{-(\gamma + iy)u} g(u) \, du dy.
\]
Now use Fubini’s theorem and do the integral from $-R$ to $R$ to get this equal to
\[
\frac{e^{\gamma t}}{\pi} \int_{-\infty}^{\infty} e^{-\gamma u} g(u) \frac{\sin(R(t-u))}{t-u} \, du
\]
where $\overline{g}$ is the zero extension of $g$ off $[0, \infty)$. Then this equals
\[
\frac{e^{\gamma t}}{\pi} \int_{-\infty}^{\infty} e^{-\gamma(t-u)} g(t-u) \frac{\sin(Ru)}{u} \, du
\]
which equals
\[
\frac{2e^{\gamma t}}{\pi} \int_{0}^{\infty} \frac{\overline{g}(t-u) e^{-\gamma(t-u)} + \overline{g}(t+u) e^{-\gamma(t+u)} \sin(Ru)}{u} \, du
\]
and then apply the result of Problem 6.

9. Suppose $f \in \mathcal{S}$. Show $F(f_{x_j})(t) = it_j Ff(t)$.

10. Let $f \in \mathcal{S}$ and let $k$ be a positive integer.
\[
\|f\|_{k,2} \equiv (\|f\|_2^2 + \sum_{|\alpha| \leq k} \|D^\alpha f\|_2^2)^{1/2}
\]
One could also define
\[
\|f\|_{k,2} \equiv (\int_{\mathbb{R}^n} |Ff(x)|^2(1 + |x|^2)^k \, dx)^{1/2}
\]
Show both $\| \|_{k,2}$ and $\| \|_{k,2}$ are norms on $\mathcal{S}$ and that they are equivalent. These are Sobolev space norms. For which values of $k$ does the second norm make sense? How about the first norm?

11. Define $H^k(\mathbb{R}^n), k \geq 0$ by $f \in L^2(\mathbb{R}^n)$ such that
\[
(\int |Ff(x)|^2(1 + |x|^2)^k \, dx)^{1/2} < \infty,
\]
Show $H^k(\mathbb{R}^n)$ is a Banach space, and that if $k$ is a positive integer, $H^k(\mathbb{R}^n)$ $= \{ f \in L^2(\mathbb{R}^n) : \text{there exists } \{u_j\} \subseteq \mathcal{G} \text{ with } ||u_j - f||_2 \to 0 \text{ and } \{u_j\} \text{ is a Cauchy sequence in } || \cdot ||_{k,2} \text{ of Problem 11} \}$ This is one way to define Sobolev Spaces. **Hint:** One way to do the second part of this is to define a new measure, $\mu$ by

$$\mu(E) \equiv \int_E \left(1 + |x|^2\right)^k dx.$$  

Then show $\mu$ is a Radon measure and show there exists $\{g_m\}$ such that $g_m \in \mathcal{G}$ and $g_m \to Ff$ in $L^2(\mu)$. Thus $g_m = Ff_m$, $f_m \in \mathcal{G}$ because $F$ maps $\mathcal{G}$ onto $\mathcal{G}$.  

Then by Problem 11, $\{f_m\}$ is Cauchy in the norm $|| \cdot ||_{k,2}$.

12. If $2k > n$, show that if $f \in H^k(\mathbb{R}^n)$, then $f$ equals a bounded continuous function a.e.  

**Hint:** Show that for $k$ this large, $Ff \in L^1(\mathbb{R}^n)$, and then use Problem 1. To do this, write

$$|Ff(x)| = |Ff(x)|(1 + |x|^2)^{\frac{k}{2}}(1 + |x|^2)^{-\frac{k}{2}}.$$  

So

$$\int |Ff(x)| dx = \int |Ff(x)|(1 + |x|^2)^{\frac{k}{2}}(1 + |x|^2)^{-\frac{k}{2}} dx.$$  

Use the Cauchy Schwarz inequality. This is an example of a Sobolev imbedding Theorem.

13. Let $u \in \mathcal{G}$. Then $Fu \in \mathcal{G}$ and so, in particular, it makes sense to form the integral,

$$\int_{\mathbb{R}} Fu(x', x_n) dx_n$$  

where $(x', x_n) = x \in \mathbb{R}^n$. For $u \in \mathcal{G}$, define $\gamma u(x') \equiv u(x', 0)$. Find a constant such that $F(\gamma u)(x')$ equals this constant times the above integral.  

**Hint:** By the dominated convergence theorem

$$\int_{\mathbb{R}} Fu(x', x_n) dx_n = \lim_{\varepsilon \to 0} \int_{\mathbb{R}} e^{-(xx - \varepsilon)^2} Fu(x', x_n) dx_n.$$  

Now use the definition of the Fourier transform and Fubini’s theorem as required in order to obtain the desired relationship.

14. Recall the Fourier series of a function in $L^2(-\pi, \pi)$ converges to the function in $L^2(-\pi, \pi)$. Prove a similar theorem with $L^2(-\pi, \pi)$ replaced by $L^2(-m\pi, m\pi)$ and the functions

$$\left\{ \frac{(2\pi)^{-1/2}}{2^{n/2}} e^{inx} \right\}_{n \in \mathbb{Z}}$$  

used in the Fourier series replaced with

$$\left\{ \frac{(2m\pi)^{-1/2}}{2^{n/2}} e^{inx} \right\}_{n \in \mathbb{Z}}$$
29.4. EXERCISES

Now suppose $f$ is a function in $L^2(\mathbb{R})$ satisfying $Ff(t) = 0$ if $|t| > m\pi$. Show that if this is so, then

$$f(x) = \frac{1}{\pi} \sum_{n \in \mathbb{Z}} f\left( \frac{-n}{m} \right) \frac{\sin(\pi(mx + n))}{mx + n}.$$  

Here $m$ is a positive integer. This is sometimes called the Shannon sampling theorem. **Hint:** First note that since $Ff \in L^2$ and is zero off a finite interval, it follows $Ff \in L^1$. Also

$$f(t) = \frac{1}{\sqrt{2\pi}} \int_{-m\pi}^{m\pi} e^{itz} Ff(x) \, dx$$

and you can conclude from this that $f$ has all derivatives and they are all bounded. Thus $f$ is a very nice function. You can replace $Ff$ with its Fourier series. Then consider carefully the Fourier coefficient of $Ff$. Argue it equals $f\left( \frac{-n}{m} \right)$ or at least an appropriate constant times this. When you get this the rest will fall quickly into place if you use $Ff$ is zero off $[-m\pi, m\pi]$. 
Chapter 30

Fourier Analysis In $\mathbb{R}^n$ An Introduction

The purpose of this chapter is to present some of the most important theorems on Fourier analysis in $\mathbb{R}^n$. These theorems are the Marcinkiewicz interpolation theorem, the Calderon Zygmund decomposition, and Mihlin’s theorem. They are all fundamental results whose proofs depend on the methods of real analysis.

30.1 The Marcinkiewicz Interpolation Theorem

Let $(\Omega, \mu, S)$ be a measure space.

Definition 30.1.1 $L^p(\Omega) + L^1(\Omega)$ will denote the space of measurable functions, $f$, such that $f$ is the sum of a function in $L^p(\Omega)$ and $L^1(\Omega)$. Also, if $T : L^p(\Omega) + L^1(\Omega) \to$ space of measurable functions, $T$ is subadditive if

$$|T(f + g)(x)| \leq |Tf(x)| + |Tg(x)|.$$

$T$ is of type $(p,p)$ if there exists a constant independent of $f \in L^p(\Omega)$ such that

$$\|Tf\|_p \leq A\|f\|_p, \ f \in L^p(\Omega).$$

$T$ is weak type $(p,p)$ if there exists a constant $A$ independent of $f$ such that

$$\mu \left( \{x : |Tf(x)| > \alpha \} \right) \leq \left( \frac{A}{\alpha} \|f\|_p \right)^p, \ f \in L^p(\Omega).$$

The following lemma involves writing a function as a sum of a functions whose values are small and one whose values are large.

Lemma 30.1.2 If $p \in [1, r)$, then $L^p(\Omega) \subseteq L^1(\Omega) + L^r(\Omega)$. 

1107
CHAPTER 30. FOURIER ANALYSIS IN \( \mathbb{R}^N \) AN INTRODUCTION

**Proof:** Let \( \lambda > 0 \) and let \( f \in L^p(\Omega) \)

\[
 f_1(x) = \begin{cases} f(x) & \text{if } |f(x)| \leq \lambda \\ 0 & \text{if } |f(x)| > \lambda \end{cases}, \quad f_2(x) = \begin{cases} f(x) & \text{if } |f(x)| > \lambda \\ 0 & \text{if } |f(x)| \leq \lambda \end{cases}.
\]

Thus \( f(x) = f_1(x) + f_2(x) \).

\[
 \int |f_1(x)|^r \, d\mu = \int_{[|f| \leq \lambda]} |f(x)|^r \, d\mu \leq \lambda^{r-p} \int_{[|f| \leq \lambda]} |f(x)|^p \, d\mu < \infty.
\]

Therefore, \( f_1 \in L^r(\Omega) \).

\[
 \int |f_2(x)| \, d\mu = \int_{[|f| > \lambda]} |f(x)| \, d\mu \leq \mu([|f| > \lambda])^{1/p'} \left( \int_{[|f| > \lambda]} |f(x)|^p \, d\mu \right)^{1/p} < \infty.
\]

This proves the lemma since \( f = f_1 + f_2, f_1 \in L^r \) and \( f_2 \in L^1 \).

For \( f \) a function having nonnegative real values, \( \alpha \to \mu([f > \alpha]) \) is called the distribution function.

**Lemma 30.1.3** Let \( \phi(0) = 0, \phi \) is strictly increasing, and \( C^1 \). Let \( f: \Omega \to [0, \infty) \) be measurable. Then

\[
 \int_{\Omega} (\phi \circ f) \, d\mu = \int_{0}^{\infty} \phi'(\alpha) \mu([f > \alpha]) \, d\alpha. \tag{30.1.1}
\]

**Proof:** First suppose

\[
 f = \sum_{i=1}^{m} a_i \chi_{E_i}
\]

where \( a_i > 0 \) and the \( a_i \) are all distinct nonzero values of \( f \), the sets, \( E_i \) being disjoint. Thus,

\[
 \int_{\Omega} (\phi \circ f) \, d\mu = \sum_{i=1}^{m} \phi(a_i) \mu(E_i).
\]

Suppose without loss of generality \( a_1 < a_2 < \cdots < a_m \). Observe

\[
 \alpha \to \mu([f > \alpha])
\]

is constant on the intervals \([0, a_1], [a_1, a_2], \ldots \). For example, on \([a_i, a_{i+1})\), this function has the value

\[
 \sum_{j=i+1}^{m} \mu(E_j).
\]

The function equals zero on \([a_m, \infty)\). Therefore,

\[
 \alpha \to \phi'(\alpha) \mu([|f| > \alpha])
\]
30.1. THE MARCINKIEWICZ INTERPOLATION THEOREM

is Lebesgue measurable and letting $a_0 = 0$, the second integral in (30.1.1) equals

$$\int_0^\infty \phi' (\alpha) \mu ([f > \alpha]) \, d\alpha = \sum_{i=1}^{m} \int_{a_{i-1}}^{a_i} \phi' (\alpha) \mu ([f > \alpha]) \, d\alpha$$

$$= \sum_{i=1}^{m} \sum_{j=1}^{m} \mu (E_j) \int_{a_{i-1}}^{a_i} \phi' (\alpha) \, d\alpha$$

$$= \sum_{j=1}^{m} \sum_{i=1}^{m} \mu (E_j) (\phi (a_i) - \phi (a_{i-1}))$$

$$= \sum_{j=1}^{m} \mu (E_j) \phi (a_j) = \int_\Omega (\phi \circ f) \, d\mu$$

and so this establishes (30.1.1) in the case when $f$ is a nonnegative simple function.

Since every measurable nonnegative function may be written as the pointwise limit of such simple functions, the desired result will follow by the Monotone convergence theorem and the next claim.

**Claim:** If $f_n \uparrow f$, then for each $\alpha > 0$,

$$\mu ([f > \alpha]) = \lim_{n \to \infty} \mu ([f_n > \alpha]).$$

**Proof of the claim:** $[f_n > \alpha] \uparrow [f > \alpha]$ because if $f (x) > \alpha$ then for large enough $n$, $f_n (x) > \alpha$ and so

$$\mu ([f_n > \alpha]) \uparrow \mu ([f > \alpha]).$$

This proves the lemma. (Note the importance of the strict inequality in $[f > \alpha]$ in proving the claim.)

The next theorem is the main result in this section. It is called the Marcinkiewicz interpolation theorem.

**Theorem 30.1.4** Let $(\Omega, \mu, \mathcal{S})$ be a $\sigma$ finite measure space, $1 < r < \infty$, and let

$$T : L^1 (\Omega) \rightarrow L^r (\Omega) \rightarrow \text{space of measurable functions}$$

be subadditive, weak $(r, r)$, and weak $(1, 1)$. Then $T$ is of type $(p, p)$ for every $p \in (1, r)$ and

$$\|Tf\|_p \leq A_p \|f\|_p$$

where the constant $A_p$ depends only on $p$ and the constants in the definition of weak $(1, 1)$ and weak $(r, r)$.

**Proof:** Let $\alpha > 0$ and let $f_1$ and $f_2$ be defined as in Lemma 30.1.2.

$$f_1 (x) = \begin{cases} f (x) & \text{if } |f (x)| \leq \alpha \\ 0 & \text{if } |f (x)| > \alpha \end{cases}, \quad f_2 (x) = \begin{cases} f (x) & \text{if } |f (x)| > \alpha \\ 0 & \text{if } |f (x)| \leq \alpha \end{cases}$$
Thus \( f = f_1 + f_2 \) where \( f_1 \in L^r \) and \( f_2 \in L^1 \). Since \( T \) is subadditive, 
\[
\|Tf\| > \alpha \subseteq \|Tf_1\| > \alpha/2 \cup \|Tf_2\| > \alpha/2 .
\]

Let \( p \in (1, r) \). By Lemma 30.1.3
\[
\int |Tf|^p \, d\mu \leq p \int_0^\infty \alpha^{p-1} \mu (\|Tf_1\| > \alpha/2) \, d\alpha + p \int_0^\infty \alpha^{p-1} \mu (\|Tf_2\| > \alpha/2) \, d\alpha .
\]

Therefore, since \( T \) is weak \((1, 1)\) and weak \((r, r)\),
\[
\int |Tf|^p \, d\mu \leq p \int_0^\infty \alpha^{p-1} \left( \frac{2A_r}{\alpha} \|f_1\|_r \right)^r \, d\alpha + p \int_0^\infty \alpha^{p-1} \frac{2A_1}{\alpha} \|f_2\|_1 \, d\alpha . \tag{30.1.2}
\]

Therefore, the right side of (30.1.2) equals
\[
p(2A_r)^r \int_0^\infty \alpha^{p-1-r} \left( \int_{\Omega} |f_1|^{r} \, d\alpha \right) \, d\alpha + 2A_p \int_0^\infty \alpha^{p-2} \left( \int_{\Omega} |f_2| \, d\mu \right) \, d\alpha =
\]
\[
p(2A_r)^r \int_0^\infty \alpha^{p-1-r} \left( \int_{\Omega} |f_1|^{r} \, d\alpha \right) \, d\alpha + 2A_p \int_0^\infty \alpha^{p-2} \left( \int_{\Omega} |f_2| \, d\alpha \right) \, d\mu .
\]

Now \( f_1(x) = 0 \) unless \( |f_1(x)| \leq \alpha \) and \( f_2(x) = 0 \) unless \( |f_2(x)| > \alpha \) so this equals
\[
p(2A_r)^r \int_{\Omega} |f(x)|^r \left( \int_{|f(x)|} \alpha^{p-1-r} \, d\alpha \right) \, d\mu + 2A_p \int_{\Omega} |f(x)| \left( \int_{|f(x)|} \alpha^{p-2} \, d\alpha \right) \, d\mu
\]
which equals
\[
\frac{2^r A_r^r p}{r-p} \int_{\Omega} |f(x)|^p \, d\mu + \frac{2pA_1}{p-1} \int_{\Omega} |f(x)|^p \, d\mu
\]
\[
\leq \max \left( \frac{2^r A_r^r p}{r-p}, \frac{2pA_1}{p-1} \right) \|f\|_{L^p(\Omega)}^p
\]
and this proves the theorem.

### 30.2 The Calderon Zygmund Decomposition

For a given nonnegative integrable function, \( \mathbb{R}^n \) can be decomposed into a set where the function is small and a set which is the union of disjoint cubes on which the average of the function is under some control. The measure in this section will always be Lebesgue measure on \( \mathbb{R}^n \). This theorem depends on the Lebesgue theory of differentiation.
### Theorem 30.2.1

Let \( f \geq 0, \int f \, dx < \infty \), and let \( \alpha \) be a positive constant. Then there exist sets \( F \) and \( \Omega \) such that

\[
\mathbb{R}^n = F \cup \Omega, \quad F \cap \Omega = \emptyset
\]  

(30.2.3)

\[
f(x) \leq \alpha \text{ a.e. on } F
\]

(30.2.4)

\[
\Omega = \cup_{k=1}^{\infty} Q_k \text{ where the interiors of the cubes are disjoint and for each cube, } Q_k,
\]

\[
\alpha < \frac{1}{m(Q_k)} \int_{Q_k} f(x) \, dx \leq 2^n \alpha.
\]  

(30.2.5)

**Proof:** Let \( S_0 \) be a tiling of \( \mathbb{R}^n \) into cubes having sides of length \( M \) where \( M \) is chosen large enough that if \( Q \) is one of these cubes, then

\[
\frac{1}{m(Q)} \int_Q f \, dm \leq \alpha.
\]  

(30.2.6)

Suppose \( S_0, \ldots, S_m \) have been chosen. To get \( S_{m+1} \), replace each cube of \( S_m \) by the \( 2^n \) cubes obtained by bisecting the sides. Then \( S_{m+1} \) consists of exactly those cubes of \( S_m \) for which \( 30.2.6 \) holds and let \( T_{m+1} \) consist of the bisected cubes from \( S_m \) for which \( 30.2.6 \) does not hold. Now define

\[
F = \{ x : x \text{ is contained in some cube from } S_m \text{ for all } m \},
\]

\[
\Omega = \mathbb{R}^n \setminus F = \cup_{m=1}^{\infty} \{ Q : Q \in T_m \}
\]

Note that the cubes from \( T_m \) have pair wise disjoint interiors and also the interiors of cubes from \( T_m \) have empty intersections with the interiors of cubes of \( T_k \) if \( k \neq m \).

Let \( x \) be a point of \( \Omega \) and let \( x \) be in a cube of \( T_m \) such that \( m \) is the first index for which this happens. Let \( Q \) be the cube in \( S_{m-1} \) containing \( x \) and let \( Q^* \) be the cube in the bisection of \( Q \) which contains \( x \). Therefore \( 30.2.6 \) does not hold for \( Q^* \). Thus

\[
\alpha < \frac{1}{m(Q^*)} \int_{Q^*} f \, dx \leq \frac{m(Q)}{m(Q^*)} \left( \frac{1}{m(Q)} \int_Q f \, dx \right) \leq 2^n \alpha
\]

which shows \( \Omega \) is the union of cubes having disjoint interiors for which \( 30.2.6 \) holds.

Now a.e. point of \( F \) is a Lebesgue point of \( f \). Let \( x \) be such a point of \( F \) and suppose \( x \in Q_k \) for \( Q_k \in S_k \). Let \( d_k \equiv \text{diameter of } Q_k \). Thus \( d_k \to 0 \).

\[
\frac{1}{m(Q_k)} \int_{Q_k} |f(y) - f(x)| \, dy \leq \frac{1}{m(Q_k)} \int_{B(x,d_k)} |f(y) - f(x)| \, dy
\]

\[
= \frac{m(B(x,d_k))}{m(Q_k)} \frac{1}{m(B(x,d_k))} \int_{B(x,d_k)} |f(y) - f(x)| \, dy
\]

\[
\leq K_n \frac{1}{m(B(x,d_k))} \int_{B(x,d_k)} |f(x) - f(y)| \, dy
\]
where $K_n$ is a constant which depends on $n$ and measures the ratio of the volume of a ball with diameter $2d$ and a cube with diameter $d$. The last expression converges to 0 because $x$ is a Lebesgue point. Hence

$$ f(x) = \lim_{k \to \infty} \frac{1}{m(Q_k)} \int_{Q_k} f(y) \, dy \leq \alpha $$

and this shows $f(x) \leq \alpha$ a.e. on $F$. This proves the theorem.

### 30.3 Mihlin’s Theorem

In this section, the Marcinkiewicz interpolation theorem and Calderon Zygmund decomposition will be used to establish a remarkable theorem of Mihlin, a generalization of Plancherel’s theorem to the $L^p$ spaces. It is of fundamental importance in the study of elliptic partial differential equations and can also be used to give proofs for the theory of singular integrals. Mihlin’s theorem involves a conclusion which is of the form

$$ F_{1 \phi} (x) \lesssim A_p \| \phi \|_p $$

for $p > 1$ and $\phi \in \mathcal{G}$. Thus $F_{1 \phi}$ extends to a continuous linear map defined on $L^p$ because of the density of $\mathcal{G}$. It is proved by showing various weak type estimates and then applying the Marcinkiewicz Interpolation Theorem to get an estimate like the above.

Recall that by Corollary 29.3.19, if $f \in L^2(\mathbb{R}^n)$ and if $\phi \in \mathcal{G}$, then $f * \phi \in L^2(\mathbb{R}^n)$ and

$$ F(f * \phi)(x) = (2\pi)^{n/2} F\phi(x) Ff(x). $$

The next lemma is essentially a weak $(1,1)$ estimate. The inequality is established under the condition, and then it is shown there exist conditions which are easier to verify which imply condition. I think the approach used here is due to Hormander and is found in Berg and Lofstrom. For many more references and generalizations, you might look in Triebel. Functions, $\rho$ which yield an inequality of the sort in are called $L^p$ multipliers.

**Lemma 30.3.1** Suppose $\rho \in L^\infty(\mathbb{R}^n) \cap L^2(\mathbb{R}^n)$ and suppose also there exists a constant $C_1$ such that

$$ \int_{|x| \geq 2|y|} |F^{-1} \rho(x - y) - F^{-1} \rho(x)| \, dx \leq C_1. $$

Then there exists a constant $A$ depending only on $C_1, \| \rho \|_\infty$, and $n$ such that

$$ m \left( \left\{ x : |F^{-1} \rho * \phi(x)| > \alpha \right\} \right) \leq \frac{A}{\alpha} \| \phi \|_1 $$

for all $\phi \in \mathcal{G}$. 

Proof: Let \( \phi \in \mathcal{G} \) and use the Calderon decomposition to write \( \mathbb{R}^n = E \cup \Omega \) where \( \Omega \) is a union of cubes, \( \{Q_i\} \) with disjoint interiors such that

\[
\alpha m(Q_i) \leq \int_{Q_i} |\phi(x)| \, dx \leq 2^n \alpha m(Q_i), \quad |\phi(x)| \leq \alpha \text{ a.e. on } E. \tag{30.3.9}
\]

The proof is accomplished by writing \( \phi \) as the sum of a good function and a bad function and establishing a similar weak inequality for these two functions separately. Then this information is used to obtain the desired conclusion.

\[
g(x) = \begin{cases} 
\phi(x) & \text{if } x \in E \\
\frac{1}{m(Q_i)} \int_{Q_i} \phi(x) \, dx & \text{if } x \in Q_i \subseteq \Omega 
\end{cases}, \quad g(x) + b(x) = \phi(x). \tag{30.3.10}
\]

Thus

\[
\begin{align*}
\int_{Q_i} b(x) \, dx &= \int_{Q_i} (\phi(x) - g(x)) \, dx = \int_{Q_i} \phi(x) \, dx - \int_{Q_i} \phi(x) \, dx \\
b(x) &= 0 \text{ if } x \notin \Omega. \tag{30.3.11}
\end{align*}
\]

Claim:

\[
||g||_2^2 \leq \alpha (1 + 4^n) ||\phi||_1, \quad ||g||_1 \leq ||\phi||_1. \tag{30.3.13}
\]

Proof of claim:

\[
||g||_2^2 = ||g||_{L^2(E)}^2 + ||g||_{L^2(\Omega)}^2.
\]

Thus

\[
||g||_{L^2(\Omega)}^2 = \sum_i \int_{Q_i} |g(x)|^2 \, dx \leq \sum_i \left( \frac{1}{m(Q_i)} \right) \left( \int_{Q_i} |\phi(y)| \, dy \right)^2 \, dx \leq \sum_i \int_{Q_i} (2^n \alpha)^2 \, dx \leq 4^n \alpha^2 \sum_i m(Q_i) \leq 4^n \alpha^2 \sum_i \int_{Q_i} |\phi(x)| \, dx \leq 4^n \alpha \, ||\phi||_1.
\]

\[
||g||_{L^2(E)}^2 = \int_E |\phi(x)|^2 \, dx \leq \alpha \int_E |\phi(x)| \, dx = \alpha \, ||\phi||_1.
\]

Now consider the second of the inequalities in (30.3.13):

\[
||g||_1 = \int_E |g(x)| \, dx + \int_{\Omega} |g(x)| \, dx = \int_E |\phi(x)| \, dx + \sum_i \int_{Q_i} |g| \, dx \leq \int_E |\phi(x)| \, dx + \sum_i \frac{1}{m(Q_i)} \int_{Q_i} |\phi(x)| \, dm \, dx = \int_E |\phi(x)| \, dx + \sum_i \int_{Q_i} |\phi(x)| \, dm \, dx = ||\phi||_1
\]
This proves the claim. From the claim, it follows that $b \in L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n)$.

Because of \ref{30.3.13}, $g \in L^1(\mathbb{R}^n)$ and so $F^{-1}\rho \ast g \in L^2(\mathbb{R}^n)$. (Since $\rho \in L^2$, it follows $F^{-1}\rho \in L^2$ and so this convolution is indeed in $L^2$. ) By Plancherel’s theorem,

$$||F^{-1}\rho \ast g||_2 = ||F(F^{-1}\rho \ast g)||_2.$$  

By Corollary \ref{30.3.13} on Page \ref{1096}, the expression on the right equals

$$(2\pi)^{n/2} ||\rho Fg||_2$$

and so

$$||F^{-1}\rho \ast g||_2 = (2\pi)^{n/2} ||\rho Fg||_2 \leq C_n ||\rho||_\infty ||g||_2.$$  

From this and \ref{30.3.13},

$$m\left(\left|\left|F^{-1}\rho \ast b\right|\right| \geq \alpha/2\right)$$

$$\leq \frac{C_n ||\rho||_\infty^2}{\alpha^2} (1 + 4^n) ||\phi||_1 = C_n \alpha^{-1} ||\phi||_1. \quad (30.3.14)$$

This is what is wanted so far as $g$ is concerned. Next it is required to estimate $m\left(\left|\left|F^{-1}\rho \ast b\right|\right| \geq \alpha/2\right)$.

If $Q$ is one of the cubes whose union is $\Omega$, let $Q^*$ be the cube with the same center as $Q$ but whose sides are $2\sqrt{n}$ times as long.

$$Q^*_i$$

$$Q_i$$

$$y_i$$

Let

$$\Omega^* \equiv \bigcup_{i=1}^\infty Q^*_i$$

and let

$$E^* \equiv \mathbb{R}^n \setminus \Omega^*.$$  

Thus $E^* \subseteq E$. Let $x \in E^*$. Then because of \ref{30.3.13},

$$\int_{Q_i} F^{-1}\rho (x - y) b(y) dy$$

$$= \int_{Q_i} \left[F^{-1}\rho (x - y) - F^{-1}\rho (x - y_i)\right] b(y) dy, \quad (30.3.15)$$

where $y_i$ is the center of $Q_i$. Consequently if the sides of $Q_i$ have length $2t/\sqrt{n}$, \ref{30.3.13} implies

$$\int_{E^*} \left|\int_{Q_i} F^{-1}\rho (x - y) b(y) dy\right| dx \leq \quad (30.3.16)$$
\[ \int_{E_{i}} \int_{Q_{i}} \left| F^{-1} \rho(x - y) - F^{-1} \rho(x - y_{i}) \right| |b(y)| \, dy \, dx \]

\[ = \int_{Q_{i}} \int_{E_{i}} \left| F^{-1} \rho(x - y) - F^{-1} \rho(x - y_{i}) \right| |b(y)| \, dy \, dx \quad (30.3.17) \]

\[ \leq \int_{Q_{i}} \int_{|x - y| \geq 2t} \left| F^{-1} \rho(x - y) - F^{-1} \rho(x - y_{i}) \right| |b(y)| \, dy \, dx \quad (30.3.18) \]

since if \( x \in E^{*} \), then \( |x - y_{i}| \geq 2t \). Now for \( y \in Q_{i} \),

\[ |y - y_{i}| \leq \left( \sum_{j=1}^{n} \left( \frac{t}{\sqrt{n}} \right)^{2} \right)^{1/2} = t. \]

From 30.3.8 and the change of variables \( u = x - y_{i} \). \( 30.3.9 \) and \( 30.3.16 \) imply

\[ \int_{E_{i}} \int_{Q_{i}} F^{-1} \rho(x - y) b(y) \, dy \, dx \leq C_{1} \int_{Q_{i}} |b(y)| \, dy. \quad (30.3.19) \]

Now from 30.3.10, and the fact that \( b = 0 \) off \( \Omega \),

\[ \int_{E_{i}} \left| F^{-1} \rho \ast b(x) \right| \, dx = \int_{E_{i}} \left| \int_{\mathbb{R}^{n}} F^{-1} \rho(x - y) b(y) \, dy \right| \, dx \]

\[ = \int_{E_{i}} \sum_{i=1}^{\infty} \int_{Q_{i}} F^{-1} \rho(x - y) b(y) \, dy \, dx \]

\[ \leq \int_{E_{i}} \sum_{i=1}^{\infty} \int_{Q_{i}} F^{-1} \rho(x - y) b(y) \, dy \, dx \]

\[ = \sum_{i=1}^{\infty} \int_{E_{i}} \int_{Q_{i}} F^{-1} \rho(x - y) b(y) \, dy \, dx \]

\[ \leq \sum_{i=1}^{\infty} C_{1} \int_{Q_{i}} |b(y)| \, dy = C_{1} ||b||_{1}. \]

Thus, by 30.3.14,

\[ \int_{E_{i}} \left| F^{-1} \rho \ast b(x) \right| \, dx \leq C_{1} ||b||_{1} \]

\[ \leq C_{1} \left( ||\phi||_{1} + ||g||_{1} \right) \]

\[ \leq C_{1} \left( ||\phi||_{1} + ||\psi||_{1} \right) \]

\[ \leq 2C_{1} ||\phi||_{1}. \]

Consequently,

\[ m \left( \left\{ \left| F^{-1} \rho \ast b \right| \geq \frac{\alpha}{2} \right\} \cap E^{*} \right) \leq \frac{4C_{1}}{\alpha} ||\phi||_{1}. \]
From 30.3.10, 30.3.14, and 30.3.9,
\[ m \left[ \left| F^{-1} \rho * \phi \right| > \alpha \right] \leq m \left[ \left| F^{-1} \rho * g \right| \geq \frac{\alpha}{2} \right] + m \left[ \left| F^{-1} \rho * b \right| \geq \frac{\alpha}{2} \right] \]
\[ \leq C_n \frac{\alpha}{\alpha} \| \phi \|_1 + m \left( \left[ \left| F^{-1} \rho * b \right| \geq \frac{\alpha}{2} \right] \cap E^* \right) + m (\Omega^*) \]
\[ \leq C_n \frac{\alpha}{\alpha} \| \phi \|_1 + 4C_1 \frac{\alpha}{\alpha} \| \phi \|_1 + C_n m (\Omega) \leq \frac{A}{\alpha} \| \phi \|_1 \]
because
\[ m (\Omega) \leq \alpha^{-1} \| \phi \|_1 \]
by 30.3.9. This proves the lemma.

The next lemma extends this lemma by giving a weak (2, 2) estimate and a (2, 2) estimate.

**Lemma 30.3.2** Suppose \( \rho \in L^\infty (\mathbb{R}^n) \cap L^2 (\mathbb{R}^n) \) and suppose also that there exists a constant \( C_1 \) such that
\[ \int_{|x| > 2|y|} |F^{-1} \rho (x - y) - F^{-1} \rho (x)| \ dx \leq C_1. \] (30.3.20)

Then \( F^{-1} \rho * \) maps \( L^1 (\mathbb{R}^n) + L^2 (\mathbb{R}^n) \) to measurable functions and there exists a constant \( A \) depending only on \( C_1, n, ||\rho||_\infty \) such that
\[ m \left( \left[ \left| F^{-1} \rho * f \right| > \alpha \right] \right) \leq A \frac{\| f \|_1}{\alpha} \text{ if } f \in L^1 (\mathbb{R}^n), \] (30.3.21)
\[ m \left( \left[ \left| F^{-1} \rho * f \right| > \alpha \right] \right) \leq \left( A \frac{\| f \|_2}{\alpha} \right)^2 \text{ if } f \in L^2 (\mathbb{R}^n). \] (30.3.22)

Thus, \( F^{-1} \rho * \) is weak type \((1, 1)\) and weak type \((2, 2)\). Also
\[ \left\| F^{-1} \rho * f \right\|_2 \leq A \left\| f \right\|_2 \text{ if } f \in L^2 (\mathbb{R}^n). \] (30.3.23)

**Proof:** By Plancherel's theorem \( F^{-1} \rho \) is in \( L^2 (\mathbb{R}^n) \). If \( f \in L^1 (\mathbb{R}^n) \), then by Minkowski's inequality,
\[ F^{-1} \rho * f \in L^2 (\mathbb{R}^n). \]

Now let \( g \in L^2 (\mathbb{R}^n) \). By Holder's inequality,
\[ \int |F^{-1} \rho (x - y)| |g (y)| \ dy \leq \left( \int |F^{-1} \rho (x - y)|^2 \ dy \right)^{1/2} \left( \int |g (y)|^2 \ dy \right)^{1/2} < \infty \]
and so the following is well defined a.e.
\[ F^{-1} \rho * g (x) \equiv \int F^{-1} \rho (x - y) g (y) \ dy \]
also,

$$\left| F^{-1} \rho \ast g (x) - F^{-1} \rho \ast g (x') \right| \leq \int \left| F^{-1} \rho (x - y) - F^{-1} \rho (x' - y) \right| |g(y)| \, dy$$

and by continuity of translation in $L^2 (\mathbb{R}^n)$, this shows $x \rightarrow F^{-1} \rho \ast g (x)$ is continuous. Therefore, $F^{-1} \rho \ast$ maps $L^1 (\mathbb{R}^n) + L^2 (\mathbb{R}^n)$ to the space of measurable functions. (Continuous functions are measurable.) It is clear that $F^{-1} \rho \ast$ is subadditive.

If $\phi \in \mathcal{G}$, Plancherel’s theorem implies as before,

$$\left\| F^{-1} \rho \ast \phi \right\|_2 = \left\| F (F^{-1} \rho \ast \phi) \right\|_2 = (2\pi)^{n/2} \left\| \rho \phi \right\|_2 \leq (2\pi)^{n/2} \left\| \rho \right\|_\infty \left\| \phi \right\|_2.$$  \hfill (30.3.24)

Now let $f \in L^2 (\mathbb{R}^n)$ and let $\phi_k \in \mathcal{G}$, with

$$\left\| \phi_k - f \right\|_2 \rightarrow 0.$$

Then by Holder’s inequality,

$$\int F^{-1} \rho (x - y) f (y) \, dy = \lim_{k \rightarrow \infty} \int F^{-1} \rho (x - y) \phi_k (y) \, dy$$

and so by Fatou’s lemma, Plancherel’s theorem, and (30.3.24),

$$\left\| F^{-1} \rho \ast f \right\|_2 = \left( \int \left( \int F^{-1} \rho (x - y) f (y) \, dy \right)^2 \, dx \right)^{1/2} \leq \lim \inf_{k \rightarrow \infty} \left( \int \left( \int F^{-1} \rho (x - y) \phi_k (y) \, dy \right)^2 \, dx \right)^{1/2} = \lim \inf_{k \rightarrow \infty} \left\| F^{-1} \rho \ast \phi_k \right\|_2 \leq \left\| \rho \right\|_\infty (2\pi)^{n/2} \lim \inf_{k \rightarrow \infty} \left\| \phi_k \right\|_2 = \left\| \rho \right\|_\infty (2\pi)^{n/2} \left\| f \right\|_2.$$

Thus, (30.3.24) holds with $A = \left\| \rho \right\|_\infty (2\pi)^{n/2}$. Consequently,

$$A \left\| f \right\|_2 \geq \left( \int_{\left\{ \left| F^{-1} \rho \ast f \right| > \alpha \right\}} \left| F^{-1} \rho \ast f (x) \right|^2 \, dx \right)^{1/2} \geq \alpha m \left( \left\{ \left| F^{-1} \rho \ast f \right| > \alpha \right\} \right)^{1/2}$$

and so (30.3.22) follows.

It remains to prove (30.3.21) which holds for all $f \in \mathcal{G}$ by Lemma (30.3.1). Let $f \in L^1 (\mathbb{R}^n)$ and let $\phi_k \rightarrow f$ in $L^1 (\mathbb{R}^n), \phi_k \in \mathcal{G}$. Without loss of generality, assume that both $f$ and $F^{-1} \rho$ are Borel measurable. Therefore, by Minkowski’s inequality, and Plancherel’s theorem,

$$\left\| F^{-1} \rho \ast \phi_k - F^{-1} \rho \ast f \right\|_2$$
which shows that $F^{-1} \rho * \phi_k$ converges to $F^{-1} \rho * f$ in $L^2(\mathbb{R}^n)$. Therefore, there exists a subsequence such that the convergence is pointwise a.e. Then, denoting the subsequence by $k$,

$$X_{[|F^{-1} \rho * f| > \alpha]}(x) \leq \liminf_{k \to \infty} X_{[|F^{-1} \rho * \phi_k| > \alpha]}(x) \text{ a.e. } x.$$ 

Thus by Lemma 30.3.2 and Fatou’s lemma, there exists a constant, $A$, depending on $C_1, n$, and $\|\rho\|_\infty$ such that

$$m\left([|F^{-1} \rho * f| > \alpha]\right) \leq \liminf_{k \to \infty} m\left([|F^{-1} \rho * \phi_k| > \alpha]\right) \leq \liminf_{k \to \infty} A \frac{\|\phi_k\|_1}{\alpha} = A \frac{\|f\|_1}{\alpha}.$$ 

This shows 30.3.21 and proves the lemma.

**Theorem 30.3.3** Let $\rho \in L^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n)$ and suppose

$$\int_{|x| \geq 2|y|} |F^{-1} \rho (x - y) - F^{-1} \rho (x)| \, dx \leq C_1.$$ 

Then for each $p \in (1, \infty)$, there exists a constant, $A_p$, depending only on $p, n, \|\rho\|_\infty$, and $C_1$ such that for all $\phi \in \mathcal{G}$,

$$\|F^{-1} \rho * \phi\|_p \leq A_p \|\phi\|_p.$$ 

**Proof:** From Lemma 30.3.2, $F^{-1} \rho *$ is weak $(1,1)$, weak $(2,2)$, and maps

$$L^1(\mathbb{R}^n) + L^2(\mathbb{R}^n)$$

to measurable functions. Therefore, by the Marcinkiewicz interpolation theorem, there exists a constant $A_p$ depending only on $p, C_1, n$, and $\|\rho\|_\infty$ for $p \in (1, 2]$, such that for $f \in L^p(\mathbb{R}^n)$, and $p \in (1, 2]$,

$$\|F^{-1} \rho * f\|_p \leq A_p \|f\|_p.$$ 

Thus the theorem is proved for these values of $p$. Now suppose $p > 2$. Then $p' < 2$ where

$$\frac{1}{p} + \frac{1}{p'} = 1.$$
By Plancherel's theorem and Theorem 29.3.25,
\[ \int F^{-1} \rho \ast \phi(x) \psi(x) \, dx = (2\pi)^{n/2} \int \rho(x) F\phi(x) F\psi(x) \, dx \]
\[ = \int F (F^{-1} \rho \ast \psi) F\phi \, dx \]
\[ = \int (F^{-1} \rho \ast \psi)(\phi) \, dx. \]

Thus by the case for \( p \in (1, 2) \) and Holder's inequality,
\[ \left| \int F^{-1} \rho \ast \phi(x) \psi(x) \, dx \right| = \left| \int (F^{-1} \rho \ast \psi)(\phi) \, dx \right| \leq \| F^{-1} \rho \ast \psi \|_p \| \phi \|_p \]
\[ \leq A_p \| \psi \|_p \| \phi \|_p. \]

Letting \( L \psi \equiv \int F^{-1} \rho \ast \phi(x) \psi(x) \, dx \), this shows \( L \in L^{p'}(\mathbb{R}^n) \) and \( \| L \|_{(L^{p'})'} \leq A_{p'} \| \phi \|_p \), which implies by the Riesz representation theorem that \( F^{-1} \rho \ast \phi \) represents \( L \) and
\[ \| L \|_{(L^{p'})'} = \| F^{-1} \rho \ast \phi \|_{L^p} \leq A_{p'} \| \phi \|_p. \]

Since \( p' = p/(p - 1) \), this proves the theorem.

It is possible to give verifiable conditions on \( \rho \) which imply (30.3.25). The condition on \( \rho \) which is presented here is the existence of a constant, \( C_0 \) such that

\[ C_0 \geq \sup \{ |x|^{\alpha} |D^\alpha \rho(x)| : |\alpha| \leq L, x \in \mathbb{R}^n \setminus \{0\}, \, L > n/2. \]  
(30.3.25)

\[ \rho \in C^L(\mathbb{R}^n \setminus \{0\}) \] where \( L \) is an integer.

Here \( \alpha \) is a multi-index and \( |\alpha| = \sum_{i=1}^n \alpha_i \). The condition says roughly that \( \rho \) is pretty smooth away from \( 0 \) and all the partial derivatives vanish pretty fast as \( |x| \to \infty \). Also recall the notation
\[ x^\alpha \equiv x_1^{\alpha_1} \cdots x_n^{\alpha_n} \]
where \( \alpha = (\alpha_1 \cdots \alpha_n) \). For more general conditions, see [12].

**Lemma 30.3.4** Let (30.3.25) hold and suppose \( \psi \in C^\infty(\mathbb{R}^n \setminus \{0\}) \). Then for each \( \alpha, \, |\alpha| \leq L \), there exists a constant \( C \equiv C(\alpha, n, \psi) \) independent of \( k \) such that
\[ \sup_{x \in \mathbb{R}^n} |x|^{\alpha} |D^\alpha (\rho(x) \psi(2^k x))| \leq C C_0. \]

**Proof:**
\[ |x|^{\alpha} |D^\alpha (\rho(x) \psi(2^k x))| \leq |x|^{\alpha} \sum_{\beta + \gamma = \alpha} |D^\beta \rho(x)| 2^{k|\gamma|} |D^\gamma \psi(2^k x)| \]
\[ = \sum_{\beta + \gamma = \alpha} |x|^{2|\beta|} |D^\beta \rho(x)| \left|2^k x\right|^{\gamma} \left|D^\gamma \psi(2^k x)\right| \]
\[ \leq C_0 C(\alpha, n) \sum_{|\gamma| \leq \alpha} \sup\{|z|^{\gamma} |D^\gamma \psi(z)| : z \in \mathbb{R}^n\} = C_0 C(\alpha, n, \psi) \]

and this proves the lemma.

**Lemma 30.3.5** There exists 
\[ \phi \in C_c^\infty\left(\left[x : 4^{-1} < |x| < 4\right]\right), \quad \phi(x) \geq 0 \]

and
\[ \sum_{k = -\infty}^{\infty} \phi(2^k x) = 1 \]

for each \(x \neq 0\).

**Proof:** Let 
\[ \psi \geq 0, \quad \psi = 1 \text{ on } [2^{-1} \leq |x| \leq 2], \]
\[ \text{spt} (\psi) \subseteq [4^{-1} < |x| < 4]. \]

Consider
\[ g(x) = \sum_{k = -\infty}^{\infty} \psi(2^k x). \]

Then for each \(x\), only finitely many terms are not equal to 0. Also, \(g(x) > 0\) for all \(x \neq 0\). To verify this last claim, note that for some \(k\) an integer, \(|x| \in [2^l, 2^{l+2}]\).

Therefore, choose \(k\) an integer such that \(2^k |x| \in [2^{-l}, 2]\). For example, let \(k = -l - 1\). This works because \(2^k |x| \in [2^l 2^k, 2^{l+2} 2^k] = [2^{l-1}, 2^{l+2-l-1}] = [2^{-1}, 2].\)

Therefore, for this value of \(k\), \(\psi(2^k x) = 1\) so \(g(x) > 0\).

Now notice that
\[ g(2^r x) = \sum_{k = -\infty}^{\infty} \psi(2^k 2^r x) = \sum_{k = -\infty}^{\infty} \psi(2^k x) = g(x). \]

Let \(\phi(x) \equiv \psi(x) g(x)^{-1}\). Then
\[ \sum_{k = -\infty}^{\infty} \phi(2^k x) = \sum_{k = -\infty}^{\infty} \frac{\psi(2^k x)}{g(2^k x)} = g(x)^{-1} \sum_{k = -\infty}^{\infty} \psi(2^k x) = 1 \]

for each \(x \neq 0\). This proves the lemma.

Now define
\[ \rho_m(x) \equiv \sum_{k = -m}^{m} \rho(x) \phi(2^k x), \quad \gamma_k(x) \equiv \rho(x) \phi(2^k x). \]
Let \( t > 0 \) and let \( |y| \leq t \). Consider the problem of estimating
\[
\int_{|x| \geq 2t} |F^{-1} \gamma_k (x - y) - F^{-1} \gamma_k (x)| \, dx. 
\] (30.3.26)

In the following estimates, \( C(a, b, \ldots, d) \) will denote a generic constant depending only on the indicated objects, \( a, b, \ldots, d \). For the first estimate, note that since \( |y| \leq t \), (30.3.26) is no larger than
\[
2 \int_{|x| \geq t} |F^{-1} \gamma_k (x)| \, dx = 2 \int_{|x| \geq t} |F^{-1} \gamma_k (x)| \, |x|^{-L} \, |x|^L \, dx
\]
\[
\leq 2 \left( \int_{|x| \geq t} |x|^{-2L} \, dx \right)^{1/2} \left( \int_{|x| \geq t} |x|^{2L} |F^{-1} \gamma_k (x)|^2 \, dx \right)^{1/2}
\]
Using spherical coordinates and Plancherel’s theorem,
\[
\leq C(n, L) t^{n/2 - L} \left( \int |x|^{2L} |F^{-1} \gamma_k (x)|^2 \, dx \right)^{1/2}
\]
\[
\leq C(n, L) t^{n/2 - L} \left( \sum_{j=1}^n |x_j|^{2L} |F^{-1} \gamma_k (x)|^2 \, dx \right)^{1/2}
\]
\[
= C(n, L) t^{n/2 - L} \left( \sum_{j=1}^n \int_{S_k} |D_j^L \gamma_k (x)|^2 \, dx \right)^{1/2}
\] (30.3.27)

where
\[
S_k \equiv \{ x : 2^{-2-k} < |x| < 2^{2-k} \},
\] (30.3.28)
a set containing the support of \( \gamma_k \). Now from the definition of \( \gamma_k \),
\[
|D_j^L \gamma_k (z)| = |D_j^L (\rho (x) \phi (2^k z))|.
\]

By Lemma 30.3.24, this is no larger than
\[
C(L, n, \phi) C_0 |z|^{-L}.
\] (30.3.29)

It follows, using polar coordinates, that the last expression in (30.3.27) is no larger than
\[
C(n, L, \phi, C_0) t^{n/2 - L} \left( \int_{S_k} |z|^{-2L} \, dz \right)^{1/2} \leq C(n, L, \phi, C_0) t^{n/2 - L}.
\] (30.3.30)
\[
\left( \int_{2^{-2-k}}^{2^{2-k}} \rho^{n/2 - 2L} \, d\rho \right)^{1/2} \leq C(n, L, \phi, C_0) t^{n/2 - L} 2^{k(L-n/2)}.
\]

Now estimate (30.3.26) in another way. The support of \( \gamma_k \) is in \( S_k \), a bounded set, and so \( F^{-1} \gamma_k \) is differentiable. Therefore,
\[
\int_{|x| \geq 2t} |F^{-1} \gamma_k (x - y) - F^{-1} \gamma_k (x)| \, dx =
\]
\[
\int_{|x| \geq 2t} \left| \int_0^1 \sum_{j=1}^n D_j F^{-1} \gamma_k(x - sy) y_j ds \right| dx \\
\leq t \int_{|x| \geq 2t} \left| \int_0^1 \sum_{j=1}^n |D_j F^{-1} \gamma_k(x - sy)| ds dx \right|
\]
\[
\leq t \int \sum_{j=1}^n |D_j F^{-1} \gamma_k(x)| dx
\]
\[
\leq t \sum_{j=1}^n \left( \int \left( 1 + |2^{-k}x|^2 \right)^L |D_j F^{-1} \gamma_k(x)|^2 dx \right)^{1/2}
\cdot \left( \int \left( 1 + |2^{-k}x|^2 \right)^L \left| D_j F^{-1} \gamma_k(x) \right|^2 dx \right)^{1/2}
\leq C(n, L) t 2^{kn/2} \sum_{j=1}^n \left( \int \left( 1 + |2^{-k}x|^2 \right)^L \left| D_j F^{-1} \gamma_k(x) \right|^2 dx \right)^{1/2}.
\]

(30.3.31)

Now consider the \(j\)th term in the last sum in (30.3.31).
\[
\int \left( 1 + |2^{-k}x|^2 \right)^L \left| D_j F^{-1} \gamma_k(x) \right|^2 dx \leq C(n, L) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int x^{2\alpha} \left| D_j F^{-1} \gamma_k(x) \right|^2 dx \tag{30.3.32}
\]
\[
= C(n, L) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int x^{2\alpha} \left| F^{-1} (\pi_j \gamma_k)(x) \right|^2 dx
\]

where \(\pi_j(z) \equiv z_j\). This last assertion follows from
\[
D_j \int e^{-ix\cdot y} \gamma_k(y) dy = \int (-i) e^{-ix\cdot y} y_j \gamma_k(y) dy.
\]

Therefore, a similar computation and Plancherel’s theorem implies (30.3.32) equals
\[
\int \left( 1 + |2^{-k}x|^2 \right)^L \left| F^{-1} (\pi_j \gamma_k)(x) \right|^2 dx \leq C(n, L) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int x^{2\alpha} \left| F^{-1} (\pi_j \gamma_k)(x) \right|^2 dx
\]
\[
= C(n, L) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int \left| D^\alpha (\pi_j \gamma_k)(x) \right|^2 dx
\]
\[
= C(n, L) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int_{S_k} \left| D^\alpha (z_j \gamma_k(z)) \right|^2 dz \tag{30.3.33}
\]

where \(S_k\) is given in (30.3.28).

Now
\[
|D^\alpha (z_j \gamma_k(z))| = 2^{-k} \left| D^\alpha (\rho(z) z_j 2^k \phi(2^k z)) \right|
\]
\[
= 2^{-k} \left| D^\alpha (\rho(z) \psi_j(2^k z)) \right|
\]
where $\psi_j(z) \equiv z_j \phi(z)$. By Lemma 30.3.4, this is dominated by

$$2^{-k} C(\alpha, n, \phi, j, C_0) |z|^{-|\alpha|}.$$ 

Therefore, 30.3.3 is dominated by

$$C(L, n, \phi, j, C_0) \sum_{|\alpha| \leq L} 2^{-2k|\alpha|} \int_{S_k} 2^{-2k} |z|^{-2|\alpha|} dz \leq C(L, n, \phi, j, C_0) \sum_{|\alpha| \leq L} 2^{-2k(2-2-k)} (2^{-k})^n \leq C(L, n, \phi, j, C_0) \sum_{|\alpha| \leq L} 2^{-kn-2k} \leq C(L, n, \phi, j, C_0) 2^{-kn} 2^{-2k}.$$

It follows that 30.3.3 is no larger than

$$C(L, n, \phi, C_0) t 2^{kn/2} 2^{-kn/2} 2^{-k} = C(L, n, \phi, C_0) t 2^{-k}. \quad (30.3.34)$$

It follows from 30.3.3 and 30.3.4 that if $|y| \leq t$,

$$\int_{|x| \geq 2t} \left| F^{-1} \gamma_k(x - y) - F^{-1} \gamma_k(x) \right| dx \leq C(L, n, \phi, C_0) \min \left( t 2^{-k}, (2^{-k} t)^n / L \right).$$

With this inequality, the next lemma which is the desired result can be obtained.

**Lemma 30.3.6** There exists a constant depending only on the indicated objects, $C_1 = C(L, n, \phi, C_0)$ such that when $|y| \leq t$,

$$\int_{|x| \geq 2t} \left| F^{-1} \rho(x - y) - F^{-1} \rho(x) \right| dx \leq C_1 \int_{|x| \geq 2t} \left| F^{-1} \rho_m(x - y) - F^{-1} \rho_m(x) \right| dx \leq C_1. \quad (30.3.35)$$

**Proof:** $F^{-1} \rho = \lim_{m \to \infty} F^{-1} \rho_m$ in $L^2(\mathbb{R}^n)$. Let $m_k \to \infty$ be such that convergence is pointwise a.e. Then if $|y| \leq t$, Fatou’s lemma implies

$$\int_{|x| \geq 2t} \left| F^{-1} \rho(x - y) - F^{-1} \rho(x) \right| dx \leq \lim \inf_{l \to \infty} \int_{|x| \geq 2t} \left| F^{-1} \rho_{m_l}(x - y) - F^{-1} \rho_{m_l}(x) \right| dx$$
\[ \lim \inf_{l \to \infty} \sum_{k=-m_l}^{m_l} \int_{|x| \geq 2t} \left| F^{-1} \gamma_k(x - y) - F^{-1} \gamma_k(x) \right| \, dx \]

\[ \leq C(L, n, \phi, C_0) \sum_{k=-\infty}^{\infty} \min \left( t^{2^{-k}}, (2^{-k}t)^{n/2-L} \right). \quad (30.3.36) \]

Now consider the sum in (30.3.36):

\[ \sum_{k=-\infty}^{\infty} \min \left( t^{2^{-k}}, (2^{-k}t)^{n/2-L} \right). \quad (30.3.37) \]

\[ t^{2^j} = \min \left( t^{2^j}, (2^jt)^{n/2-L} \right) \text{ exactly when } t^{2^j} \leq 1. \] This occurs if and only if \( j \leq -\log(t)/\log(2) \). Therefore (30.3.37) is no larger than

\[ \sum_{j \leq -\log(t)/\log(2)} 2^j + \sum_{j \geq -\log(t)/\log(2)} (2^jt)^{n/2-L}. \]

Letting \( a = L - n/2 \), this equals

\[ t \sum_{k \geq \log(t)/\log(2)} 2^{-k} + t^{-a} \sum_{j \geq -\log(t)/\log(2)} (2^{-a})^j \]

\[ \leq 2t \left( \frac{1}{2} \right)^{\log_2(t)} + t^{-a} \left( \frac{1}{2^a} \right)^{-\log_2(t)} \]

\[ = 2t \left( \frac{1}{2} \right)^{\log_2(t)} + t^{-a} \left( \frac{1}{2^a} \right)^{-\log_2(t)} \]

\[ = 2 + 1 = 3. \]

Similarly, (30.3.35) holds. This proves the lemma.

Now it is possible to prove Mihlin’s theorem.

**Theorem 30.3.7 (Mihlin’s theorem)** Suppose \( \rho \) satisfies

\[ C_0 \geq \sup \{|x|^\alpha |D^\alpha \rho(x)| : |\alpha| \leq L, \ x \in \mathbb{R}^n \setminus \{0\} \}, \]

where \( L \) is an integer greater than \( n/2 \) and \( \rho \in C^L(\mathbb{R}^n \setminus \{0\}) \). Then for every \( p > 1 \), there exists a constant \( A_p \) depending only on \( p, C_0, \phi, n, \) and \( L \), such that for all \( \psi \in \mathcal{G} \),

\[ \|F^{-1} \rho * \psi\|_p \leq A_p \|\psi\|_p. \]

**Proof:** Since \( \rho_m \) satisfies (30.3.35) and is obviously in \( L^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n) \), Theorem [30.3.5] implies there exists a constant \( A_p \) depending only on \( p, n, \|\rho_m\|_\infty \), and \( C_1 \) such that for all \( \psi \in \mathcal{G} \) and \( p \in (1, \infty) \),

\[ \|F^{-1} \rho_m * \psi\|_p \leq A_p \|\psi\|_p. \]
Now \( \| \rho_m \|_\infty \leq \| \rho \|_\infty \) because
\[
\| \rho_m (x) \| \leq \| \rho (x) \| \sum_{k=-m}^{m} \phi (2^k x) \leq \| \rho (x) \|. \tag{30.3.38}
\]

Therefore, since \( C_1 = C_1 (L, n, \phi, C_0) \) and \( C_0 \geq \| \rho \|_\infty \),
\[
\| F^{-1} \rho_m * \psi \|_p \leq A_p (L, n, \phi, C_0, p) \| \psi \|_p .
\]

In particular, \( A_p \) does not depend on \( m \). Now, by \( \| \rho_m \|_\infty \), the observation that \( \rho \in L^\infty (\mathbb{R}^n) \), \( \lim_{m \to \infty} \rho_m (y) = \rho (y) \) and the dominated convergence theorem, it follows that for \( \theta \in \mathcal{G} \).
\[
\left| (F^{-1} \rho * \psi) (\theta) \right| = \left| (2\pi)^{n/2} \int \rho (x) F\psi (x) \ F^{-1} \theta (x) \ dx \right|
\]
\[
= \lim_{m \to \infty} \left| (F^{-1} \rho_m * \psi) (\theta) \right| \leq \lim_{m \to \infty} \sup \left| (F^{-1} \rho_m * \psi) \right|_p \| \theta \|_{p'}
\]
\[
\leq A_p (L, n, \phi, C_0, p) \| \psi \|_p \| \theta \|_{p'} .
\]

Hence \( F^{-1} \rho * \psi \in L^p (\mathbb{R}^n) \) and \( \| F^{-1} \rho * \psi \|_p \leq A_p \| \psi \|_p \). This proves the theorem.

## 30.4 Singular Integrals

If \( K \in L^1 (\mathbb{R}^n) \) then when \( p > 1 \),
\[
\| K * f \|_p \leq \| f \|_p .
\]

It turns out that some meaning can be assigned to \( K * f \) for some functions \( K \) which are not in \( L^1 \). This involves assuming a certain form for \( K \) and exploiting cancellation. The resulting theory of singular integrals is very useful. To illustrate, an application will be given to the Helmholtz decomposition of vector fields in the next section. Like Mihlin’s theorem, the theory presented here rests on Theorem \( \| \rho_m \|_\infty \), restated here for convenience.

**Theorem 30.4.1** Let \( \rho \in L^2 (\mathbb{R}^n) \cap L^\infty (\mathbb{R}^n) \) and suppose
\[
\int_{|x| \geq 2|y|} \left| F^{-1} \rho (x-y) - F^{-1} \rho (x) \right| dx \leq C_1 .
\]

Then for each \( p \in (1, \infty) \), there exists a constant, \( A_p \), depending only on
\[
p, n, \| \rho \|_\infty ,
\]
and \( C_1 \) such that for all \( \phi \in \mathcal{G} \),
\[
\| F^{-1} \rho * \phi \|_p \leq A_p \| \phi \|_p .
\]
Lemma 30.4.2 Suppose

\[ K \in L^2(\mathbb{R}^n), \|FK\|_\infty \leq B < \infty, \]  

and

\[ \int_{|x| > |y|} |K(x - y) - K(x)| \, dx \leq B. \]  

Then for all \( p > 1 \), there exists a constant, \( A(p, n, B) \), depending only on the indicated quantities such that

\[ \|K * f\|_p \leq A(p, n, B) \|f\|_p \]

for all \( f \in \mathcal{G} \).

Proof: Let \( FK = \rho \) so \( F^{-1} \rho = K \). Then from Lemma 30.4.39, \( \rho \in L^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n) \) and \( K = F^{-1} \rho \). By Theorem 30.3.3 listed above,

\[ \|K * f\|_p = \|F^{-1} \rho * f\|_p \leq A(p, n, B) \|f\|_p \]

for all \( f \in \mathcal{G} \). This proves the lemma.

The next lemma provides a situation in which the above conditions hold.

Lemma 30.4.3 Suppose

\[ |K(x)| \leq B |x|^{-n}, \]  

\[ \int_{a < |x| < b} K(x) \, dx = 0, \]  

\[ \int_{|x| > 2|y|} |K(x - y) - K(x)| \, dx \leq B. \]

Define

\[ K_{\varepsilon}(x) = \begin{cases} K(x) & \text{if } |x| \geq \varepsilon, \\ 0 & \text{if } |x| < \varepsilon. \end{cases} \]

Then there exists a constant \( C(n) \) such that

\[ \int_{|x| > 2|y|} |K_{\varepsilon}(x - y) - K_{\varepsilon}(x)| \, dx \leq C(n) B \]

and

\[ \|FK_{\varepsilon}\|_\infty \leq C(n) B. \]

Proof: In the argument, \( C(n) \) will denote a generic constant depending only on \( n \). Consider first. The integral is broken up according to whether \( |x|, |x - y| \geq \varepsilon \) or not.

| \( |x| \) | \( > \varepsilon \) | \( > \varepsilon \) | \( < \varepsilon \) | \( < \varepsilon \) \\
| \( |x - y| \) | \( > \varepsilon \) | \( < \varepsilon \) | \( < \varepsilon \) | \( > \varepsilon \) |
\[ \int_{|x| \geq 2|y|} |K_\varepsilon(x - y) - K_\varepsilon(x)| \, dx = \]

\[ \int_{|x| \geq 2|y|, |x - y| > \varepsilon, |x| < \varepsilon} |K_\varepsilon(x - y) - K_\varepsilon(x)| \, dx + \]

\[ \int_{|x| \geq 2|y|, |x - y| < \varepsilon, |x| > \varepsilon} |K_\varepsilon(x - y) - K_\varepsilon(x)| \, dx \]

\[ \int_{|x| \geq 2|y|, |x - y| > \varepsilon, |x| > \varepsilon} |K_\varepsilon(x - y) - K_\varepsilon(x)| \, dx + \]

\[ \int_{|x| \geq 2|y|, |x - y| < \varepsilon, |x| < \varepsilon} |K_\varepsilon(x - y) - K_\varepsilon(x)| \, dx. \]

(30.4.46)

Now consider the terms in the above expression. The last integral in (30.4.46) equals 0 from the definition of \( K_\varepsilon \). The third integral on the right is no larger than \( B \) by the definition of \( K_\varepsilon \) and (30.4.39). Consider the second integral on the right. This integral is no larger than

\[ \int_{|x| \geq 2|y|, |x - y| < \varepsilon} B |x|^{-n} \, dx. \]

Now \( |x| \leq |y| + \varepsilon \leq |x|/2 + \varepsilon \) and so \( |x| < 2\varepsilon \). Thus this is no larger than

\[ \int_{\varepsilon \leq |x| \leq 2\varepsilon} B |x|^{-n} \, dx = B \int_{\delta_{n-1}} \int_{\varepsilon}^{2\varepsilon} \rho^{n-1} \frac{1}{\rho^n} \, d\rho \, d\sigma \leq BC(n) \ln 2 = C(n) B. \]

It remains to estimate the first integral on the right in (30.4.46). This integral is bounded by

\[ \int_{|x| \geq 2|y|, |x - y| > \varepsilon, |x| < \varepsilon} B |x - y|^{-n} \, dx. \]

In the integral above, \( |x| < \varepsilon \) and so \( |x - y| - |y| < \varepsilon \). Therefore, \( |x - y| < \varepsilon + |y| < \varepsilon + |x|/2 < \varepsilon + \varepsilon/2 = (3/2) \varepsilon \). Hence \( \varepsilon \leq |x - y| \leq (3/2) |x - y| \). Therefore, the above integral is no larger than

\[ \int_{\varepsilon}^{(3/2)\varepsilon} B |z|^{-n} \, dz = B \int_{\delta_{n-1}} \int_{\varepsilon}^{(3/2)\varepsilon} \rho^{n-1} \, d\rho \, d\sigma = BC(n) \ln (3/2). \]

This establishes (30.4.46).

Now it remains to show a statement about the Fourier transforms of \( K_\varepsilon \). Fix \( \varepsilon \) and let \( y \neq 0 \) also be given.

\[ K_{\varepsilon R}(y) \equiv \begin{cases} K_\varepsilon(y) & \text{if } |y| < R, \\ 0 & \text{if } |y| \geq R \end{cases} \]

where \( R > \frac{3\pi}{|y|} \). (The 3 here isn’t important. It just needs to be larger than 1.) Then

\[ |FK_{\varepsilon R}(y)| \leq \left| \int_{0 < |x| < 3\pi|y|^{-1}} K_\varepsilon(x) e^{-ix \cdot y} \, dx \right| + \left| \int_{3\pi|y|^{-1} < |x| \leq R} K_\varepsilon(x) e^{-ix \cdot y} \, dx \right|. \]
Consider \( A \). By (30.4.41)
\[
\int_{\varepsilon<|x|<3\pi|y|^{-1}} K_\varepsilon (x) \, dx = 0
\]
and so
\[
A = \left| \int_{\varepsilon<|x|<3\pi|y|^{-1}} K_\varepsilon (x) \left( e^{-ix \cdot y} - 1 \right) \, dx \right|
\]
Now
\[
|e^{-ix \cdot y} - 1| = |2 - 2 \cos (x \cdot y)|^{1/2} \leq 2 |x \cdot y| \leq 2 |x| |y|
\]
so, using polar coordinates, this expression is no larger than
\[
2B \int_{\varepsilon<|x|<3\pi|y|^{-1}} |x|^{-n} |x| |y| \, dx \leq C(n) B |y| \int_{\varepsilon}^{3\pi/|y|} d\rho \leq BC(n).
\]

Next, consider \( B \). This estimate is based on the trick which follows. Let
\[
z \equiv y \pi / |y|^2
\]
so that
\[
|z| = \pi / |y|, \quad z \cdot y = \pi.
\]
Then
\[
\int_{3\pi|y|^{-1}<|x|\leq R} K_\varepsilon (x) e^{-ix \cdot y} \, dx = \frac{1}{2} \int_{3\pi|y|^{-1}<|x|\leq R} K_\varepsilon (x) e^{-ix \cdot y} \, dx
\]
\[
= \frac{1}{2} \int_{3\pi|y|^{-1}<|x|\leq R} K_\varepsilon (x) e^{-i(x+z) \cdot y} \, dx.
\]
Then changing the variables in (30.4.48),

\[
\int_{3\pi|y|^{-1} < |x| \leq R} K_e(x) e^{-ix \cdot y} dx = \frac{1}{2} \int_{3\pi|y|^{-1} < |x| \leq R} K_e(x) e^{-ix \cdot y} dx - \frac{1}{2} \int_{|x - z| < R} K_e(x - z) e^{-ix \cdot y} dx.
\]

Thus

\[
\int K_e(x) e^{-ix \cdot y} dx = \frac{1}{2} \int_{|x| \leq R} K_e(x) e^{-ix \cdot y} dx - \frac{1}{2} \int_{|x - z| \leq R} K_e(x - z) e^{-ix \cdot y} dx - \frac{1}{2} \int_{|x| \leq 3\pi|y|^{-1}} K_e(x) e^{-ix \cdot y} dx.
\]

Since \(|z| = \pi / |y|\), it follows \(|z| = \frac{\pi}{|y|} < \frac{3\pi}{|y|} < R\) and so the following picture describes the situation. In this picture, the radius of each ball equals either \(R\) or \(3\pi|y|^{-1}\) and each integral above is taken over one of the two balls in the picture, either the one centered at \(0\) or the one centered at \(z\).

To begin with, consider the integrals which involve \(K_e(x - z)\).

\[
\frac{1}{2} \int_{|x - z| \leq R} K_e(x - z) e^{-ix \cdot y} dx - \frac{1}{2} \int_{|x - z| > R, |x| < R} K_e(x - z) e^{-ix \cdot y} dx + \int_{|x - z| < R, |x| > R} K_e(x - z) e^{-ix \cdot y} dx.
\]
Look at the picture. Similarly,

\[
\int_{|x-z| \leq 3\pi |y|^{-1}} K_e(x-z) e^{-ixy} dx \\
= \int_{|x| \leq 3\pi |y|^{-1}} K_e(x-z) e^{-ixy} dx \\
- \int_{|x-z| > 3\pi |y|^{-1}} K_e(x-z) e^{-ixy} dx + \int_{|x-z| < 3\pi |y|^{-1}, |x| > 3\pi |y|^{-1}} K_e(x-z) e^{-ixy} dx.
\]

(30.4.51)

The last integral in (30.4.50) is taken over a set that is contained in

\[ B(0,R + |z|) \setminus B(0,R) \]

illustrated in the following picture as the region between the small ball centered at 0 and the big ball which surrounds the two small balls

\[ 0 \quad z \]

and so this integral is dominated by

\[ B \left( \frac{1}{(R - |z|)^n} \right) \alpha(n) \left((R + |z|)^n - R^n\right), \]

an expression which converges to 0 as \( R \to \infty \). Similarly, the second integral on the right in (30.4.51) converges to zero as \( R \to \infty \). Now consider the last two integrals in (30.4.51) Letting \( 3\pi |y|^{-1} \) play the role of \( R \) and using \( |z| = \pi/|y| \), these are each dominated by an expression of the form

\[
B \left( \frac{1}{(3\pi |y|^{-1} - |z|)^n} \right) \alpha(n) \left((3\pi |y|^{-1} + |z|)^n - (3\pi |y|^{-1})^n\right)
\]

\[
= B \left( \frac{1}{(3\pi |y|^{-1} - \pi |y|^{-1})^n} \right) \alpha(n) \cdot \left((3\pi |y|^{-1} + \pi |y|^{-1})^n - (3\pi |y|^{-1})^n\right)
\]
\[ B = \left| \int_{3\pi|y|^{-1} < |x| \leq R} K_\varepsilon (x) e^{-ix\cdot y} dx \right| \]
\[ B \leq \frac{1}{2} \int_{|x| < R} K_\varepsilon (x) e^{-ix\cdot y} dx - \int_{|x| < R} K_\varepsilon (x - z) e^{-ix\cdot y} dx \]
\[ + \int_{|x| < 3\pi|y|^{-1}} K_\varepsilon (x - z) e^{-ix\cdot y} dx - \int_{|x| < 3\pi|y|^{-1}} K_\varepsilon (x) e^{-ix\cdot y} dx \]
\[ + C(n) B + g(R) \]
where \( g(R) \to 0 \) as \( R \to \infty \). Using \( |z| = \pi / |y| \) again,
\[ B \leq \frac{1}{2} \int_{3|z| < |x| < R} |K_\varepsilon (x) - K_\varepsilon (x - z)| dx + C(n) B + g(R). \]
But the integral in the above is dominated by \( C(n) B \) by (30.4.44) which was established earlier. Therefore, from (30.4.47),
\[ |FK_\varepsilon R| \leq C(n) B + g(R) \]
where \( g(R) \to 0 \).
Now \( K_\varepsilon R \to K_\varepsilon \) in \( L^2 (\mathbb{R}^n) \) because
\[ ||K_\varepsilon R - K_\varepsilon||_{L^2(\mathbb{R}^n)} \leq B \int_{|x| > R} \frac{1}{|x|^{n+1}} dx \]
\[ = B \int_{S^{n-1}} \int_{R}^{\infty} \frac{1}{\rho^{n+1}} d\rho d\sigma, \]
which converges to 0 as \( R \to \infty \) and so \( FK_\varepsilon R \to FK_\varepsilon \) in \( L^2 (\mathbb{R}^n) \) by Plancherel’s theorem. Therefore, by taking a subsequence, still denoted by \( R \), \( FK_\varepsilon R (y) \to FK_\varepsilon (y) \) a.e. which shows
\[ |FK_\varepsilon (y)| \leq C(n) B \text{ a.e.} \]
This proves the lemma.

**Corollary 30.4.4** Suppose (30.4.40) - (30.4.42) hold. Then if \( g \in C_c^1 (\mathbb{R}^n) \), \( K_\varepsilon * g \) converges uniformly and in \( L^p (\mathbb{R}^n) \) as \( \varepsilon \to 0 \).
Proof:

\[ K_\varepsilon * g (x) = \int K_\varepsilon (y) \, g (x - y) \, dy. \]

Let \( 0 < \eta < \varepsilon \). Then since \( g \in C^1_c (\mathbb{R}^n) \), there exists a constant, \( K \) such that \( K |u - v| \geq |g (u) - g (v)| \) for all \( u, v \in \mathbb{R}^n \).

\[
|K_\varepsilon * g (x) - K_\eta * g (x)| \leq BK \int_{|y| < \varepsilon} \frac{1}{|y|} \, |y| \, dy
\]

\[
= BK \int_{S^{n-1}} \int_\eta^\varepsilon d\sigma \, = C_n |\varepsilon - \eta|.
\]

This proves the corollary.

**Theorem 30.4.5** Suppose \( 30.4.40 \) - \( 30.4.42 \). Then for \( K_\varepsilon \) given by \( 30.4.43 \) and \( p > 1 \), there exists a constant \( A (p, n, B) \) such that for all \( f \in L^p (\mathbb{R}^n) \),

\[
||K_\varepsilon * f||_p \leq A (p, n, B) ||f||_p.
\]

(30.4.52)

Also, for each \( f \in L^p (\mathbb{R}^n) \),

\[
Tf \equiv \lim_{\varepsilon \to 0} K_\varepsilon * f
\]

exists in \( L^p (\mathbb{R}^n) \) and for all \( f \in L^p (\mathbb{R}^n) \),

\[
||Tf||_p \leq A (p, n, B) ||f||_p.
\]

(30.4.53)

(30.4.54)

Thus \( T \) is a linear and continuous map defined on \( L^p (\mathbb{R}^n) \) for each \( p > 1 \).

**Proof:** From \( 30.4.40 \) it follows \( K_\varepsilon \in L^p (\mathbb{R}^n) \cap L^2 (\mathbb{R}^n) \) where, as usual, \( 1/p + 1/p' = 1 \). By continuity of translation in \( L^p (\mathbb{R}^n) \), \( x \to K_\varepsilon * f (x) \) is a continuous function. By Lemma \( 30.4.3 \), \( ||FK_\varepsilon ||_\infty \leq C (n) B \) for all \( \varepsilon \). Therefore, by Lemma \( 30.4.4 \),

\[
||K_\varepsilon * g||_p \leq A (p, n, B) ||g||_p
\]

for all \( g \in \mathcal{G} \). Now let \( f \in L^p (\mathbb{R}^n) \) and \( g_k \to f \) in \( L^p (\mathbb{R}^n) \) where \( g_k \in \mathcal{G} \). Then

\[
|K_\varepsilon * f (x) - K_\varepsilon * g_k (x)| \leq \int |K_\varepsilon (x - y)| \, |g_k (y) - f (y)| \, dy
\]

\[
\leq ||K_\varepsilon ||_{p'} ||g_k - f||_p
\]

which shows that \( K_\varepsilon * g_k (x) \to K_\varepsilon * f (x) \) pointwise and so by Fatou’s lemma,

\[
||K_\varepsilon * f||_p \leq \liminf_{k \to \infty} ||K_\varepsilon * g_k||_p \leq \liminf_{k \to \infty} A (p, n, B) ||g_k||_p
\]

\[
= A (p, n, B) ||f||_p.
\]

This verifies \( 30.4.52 \).

To verify \( 30.4.53 \), let \( \delta > 0 \) be given and let

\[
f \in L^p (\mathbb{R}^n), g \in C^\infty_c (\mathbb{R}^n).
\]
30.4. SINGULAR INTEGRALS

\[ ||K_\varepsilon * f - K_\eta * f||_p \leq ||K_\varepsilon * (f - g)||_p + ||K_\varepsilon * g - K_\eta * g||_p \]
\[ + ||K_\eta * (f - g)||_p \leq 2A(p, n, B) ||f - g||_p + ||K_\varepsilon * g - K_\eta * g||_p. \]

Choose \( g \) such that \( 2A(p, n, B) ||f - g||_p \leq \delta/2 \). Then if \( \varepsilon, \eta \) are small enough, Corollary 30.4.3 implies the last term is also less than \( \delta/2 \). Thus, \( \lim_{\varepsilon \to 0} K_\varepsilon * f \) exists in \( L^p(\mathbb{R}^n) \). Let \( Tf \) be the element of \( L^p(\mathbb{R}^n) \) to which it converges. Then 30.4.5 follows and \( T \) is obviously linear because

\[ T(af + bg) = \lim_{\varepsilon \to 0} K_\varepsilon * (af + bg) = \lim_{\varepsilon \to 0} (aK_\varepsilon * f + bK_\varepsilon * g) = aTf + bTg. \]

This proves the theorem.

When do conditions 30.4.4 - 30.4.5 hold? It turns out this happens for \( K \) given by the following.

\[ K(x) = \frac{\Omega(x)}{|x|^n}, \quad (30.4.55) \]

where

\[ \Omega(\lambda x) = \Omega(x) \text{ for all } \lambda > 0, \]
\[ \Omega \text{ is Lipschitz on } S^{n-1}, \]
\[ \int_{S^{n-1}} \Omega(x) d\sigma = 0. \quad (30.4.57) \]

**Theorem 30.4.6** For \( K \) given by 30.4.55 - 30.4.57, it follows there exists a constant \( B \) such that

\[ |K(x)| \leq B |x|^{-n}, \quad (30.4.58) \]
\[ \int_{a<|x|<b} K(x) dx = 0, \quad (30.4.59) \]
\[ \int_{|x|>2|y|} |K(x - y) - K(x)| dx \leq B. \quad (30.4.60) \]

Consequently, the conclusions of Theorem 30.4.5 hold also.

**Proof:** 30.4.58 is obvious. To verify 30.4.59,

\[
\int_{a<|x|<b} K(x) dx = \int_a^b \int_{S^{n-1}} \frac{\Omega(\rho w)}{\rho^{n+1}} d\sigma d\rho
= \int_a^b \frac{1}{\rho} \int_{S^{n-1}} \Omega(w) d\sigma d\rho = 0.
\]

It remains to show

\[ K(x - y) - K(x) = |x - y|^{-n} \left( \Omega \left( \frac{x - y}{|x - y|} \right) - \Omega \left( \frac{x}{|x|} \right) \right) + \Omega(x) \left( \frac{1}{|x - y|^n} - \frac{1}{|x|^n} \right). \quad (30.4.61) \]
where \( \text{strcut} \) was used to write \( \Omega \left( \frac{z}{|z|} \right) = \Omega \left( \frac{x}{|x|} \right) \). The first group of terms in (30.4.61) is dominated by
\[
|x - y|^{-n} \text{Lip} (\Omega) \left| \frac{x - y}{|x|} - \frac{x}{|x|} \right|
\]
and an estimate is required for \( |x| > 2|y| \). Since \( |x| > 2|y| \),
\[
|x - y|^{-n} \leq (|x| - |y|)^{-n} \leq \frac{2^n}{|x|^n}.
\]
Also
\[
\left| \frac{x - y}{|x|} - \frac{x}{|x|} \right| = \left| \frac{(x - y)|x| - x|x - y|}{|x|(x - |y|)} \right| \leq \left| \frac{(x - y)|x| - x|x - y|}{|x|(|x|/2)} \right|
\]
\[
= \frac{2}{|x|^2} |x||x| - y|x| - x|x - y| \leq \frac{2}{|x|^2} |x|(|x| - |x - y|) - y|x|\n\]
\[
\leq \frac{2}{|x|^2} |x||x - |x - y|| + |y| |x| \leq \frac{2}{|x|^2} (|x||x - (x - y)| + |y||x|)
\]
\[
\leq \frac{4}{|x|^2} |x||y| = \frac{4|y|}{|x|}.
\]
Therefore,
\[
\int_{|x| > 2|y|} |x - y|^{-n} \left| \Omega \left( \frac{x - y}{|x - y|} \right) - \Omega \left( \frac{x}{|x|} \right) \right| \, dx
\]
\[
\leq 4 \left( 2^n \right) \int_{|x| > 2|y|} \frac{1}{|x|^n} |y| \, dx \text{Lip} (\Omega)
\]
\[
= C (n, \text{Lip} \Omega) \int_{|x| > 2|y|} \frac{|y|}{|x|^{n+1}} \, dx
\]
\[
= C (n, \text{Lip} \Omega) \int_{|u| > 2} \frac{1}{|u|^{n+1}} \, du. \quad (30.4.62)
\]
It remains to consider the second group of terms in (30.4.61) when \( |x| > 2|y| \).
\[
\left| \frac{1}{|x - y|^n} - \frac{1}{|x|^n} \right| = \left| \frac{|x|^n - |x - y|^n}{|x - y|^n |x|^n} \right|
\]
\[
\leq \frac{2^n}{|x|^{2n}} ||x|^n - |x - y|^n|
\]
\[
\leq \frac{2^n}{|x|^{2n}} |y| \left[ |x|^{n-1} + |x|^{n-2}|x - y| + \cdots + |x||x - y|^{n-2} + |x - y|^{n-1} \right]
\]
30.5. HELMHOLTZ DECOMPOSITIONS

Thus

\[ \int_{|x| > 2|y|} |\nabla (x)| \left( \frac{1}{|x - y|^{n}} - \frac{1}{|x|^{n}} \right) \, dx \]

\[ \leq C(n) \int_{|x| > 2|y|} \frac{|y|}{|x|^{n+1}} \, dx \]

\[ \leq C(n) \int_{|u| > 2} \frac{1}{|u|^{n+1}} \, du. \]  (30.4.63)

From (30.4.62) and (30.4.63),

\[ \int_{|x| > 2|y|} |K(x - y) - K(x)| \, dx \leq C(n, \text{Lip } \Omega). \]

This proves the theorem.

30.5 Helmholtz Decompositions

It turns out that every vector field which has its components in \( L^p \) can be written as a sum of a gradient and a vector field which has zero divergence. This is a very remarkable result, especially when applied to vector fields which are only in \( L^p \).

Recall that for \( u \) a function of \( n \) variables, \( \Delta u = \sum_{i=1}^{n} \frac{\partial^2 u}{\partial x^2_i} \).

**Definition 30.5.1** Define

\[ \Phi(y) = \begin{cases} -\frac{1}{a_2} \ln |y|, & \text{if } n = 2, \\ \frac{1}{(n-2)a_{n-1}} |y|^{2-n}, & \text{if } n > 2. \end{cases} \]

where \( a_k \) denotes the area of the unit sphere, \( S^k \).

Then it is routine to verify \( \Delta \Phi = 0 \) away from 0. In fact, if \( n > 2 \),

\[ \Phi_{,ii}(y) = C_n \left[ \frac{1}{|y|^n} - n \frac{y_i^2}{|y|^{n+2}} \right], \quad \Phi_{,ij}(y) = C_n \frac{y_i y_j}{|y|^{n+2}}, \]  (30.5.64)

while if \( n = 2 \),

\[ \Phi_{,22}(y) = C_2 \frac{y_1^2 - y_2^2}{(y_1^2 + y_2^2)^2}, \quad \Phi_{,11}(y) = C_2 \frac{y_2^2 - y_1^2}{(y_1^2 + y_2^2)^2}, \]

\[ \Phi_{,ij}(y) = C_2 \frac{y_i y_j}{(y_1^2 + y_2^2)^2}. \]

Also,

\[ \nabla \Phi(y) = \frac{-y}{a_{n-1}|y|^n}. \]  (30.5.65)

In the above the subscripts following a comma denote partial derivatives.
Lemma 30.5.2 For $n \geq 2$

$$
\Phi_{ij}(y) = \frac{\Omega_{ij}(y)}{|y|^n}
$$

where

$$
\Omega_{ij} \text{ is Lipschitz continuous on } S^{n-1},
$$
(30.5.66)

$$
\Omega_{ij}(\lambda y) = \Omega_{ij}(y),
$$
(30.5.67)

for all $\lambda > 0$, and

$$
\int_{S^{n-1}} \Omega_{ij}(y) \, d\sigma = 0.
$$
(30.5.68)

Proof:

The case $n = 2$ is left to the reader. (30.5.66) and (30.5.67) are obvious from the above descriptions. It remains to verify (30.5.68). If $n \geq 3$ and $i \neq j$, then this formula is also clear from (30.5.64). Thus consider the case when $n \geq 3$ and $i = j$. By symmetry,

$$
I \equiv \int_{S^{n-1}} 1 - ny_i^2 \, d\sigma = \int_{S^{n-1}} 1 - ny_j^2 \, d\sigma.
$$

Hence

$$
nI = \sum_{i=1}^{n} \int_{S^{n-1}} 1 - ny_i^2 \, d\sigma = \int_{S^{n-1}} \left(n - n \sum_{i=1}^{n} y_i^2\right) \, d\sigma
$$

$$
= \int_{S^{n-1}} (n - n) \, d\sigma = 0.
$$

This proves the lemma.

Let $U$ be a bounded open set locally on one side of its boundary having Lipschitz boundary so the divergence theorem holds and let $B = B(0,R)$ where

$$
B \supseteq U \equiv \{x - y : x \in U, y \in U\}
$$

Let $f \in C^\infty_c(U)$ and define for $x \in U$,

$$
u(x) \equiv \int_{B} \Phi(y) f(x-y) \, dy = \int_{U} \Phi(x-y) f(y) \, dy.
$$

Let $h(y) = f(x-y)$. Then since $\Phi$ is in $L^1(B)$,

$$
\Delta u(x) = \int_{B} \Phi(y) \Delta f(x-y) \, dy = \int_{B} \Phi(y) \Delta h(y) \, dy
$$

$$
= \int_{B \setminus B(0,\varepsilon)} \nabla \cdot (\nabla \Phi(y) f(y)) - \nabla \Phi(y) \cdot \nabla h(y) \, dy
$$

$$
+ \int_{B(0,\varepsilon)} \Phi(y) \Delta h(y) \, dy.
$$
The last term converges to 0 as $\varepsilon \to 0$ because $\Phi$ is in $L^1$ and $\Delta h$ is bounded. Since $\text{spt}(h) \subseteq B$, the divergence theorem implies

$$
\Delta u(x) = -\int_{\partial B(0,\varepsilon)} \Phi(y) \nabla h(y) \cdot n d\sigma - \int_{B \setminus B(0,\varepsilon)} \nabla \Phi(y) \cdot \nabla h(y) dy + e(\varepsilon) \tag{30.5.69}
$$

where here and below, $e(\varepsilon) \to 0$ as $\varepsilon \to 0$. The first term in $30.5.69$ converges to 0 as $\varepsilon \to 0$ because

$$
\int_{\partial B(0,\varepsilon)} \Phi(y) \nabla h(y) \cdot n d\sigma \leq \left\{ \begin{array}{cl} C_{nh} \varepsilon^{n-1} & \text{if } n > 2 \\ C_h (\ln \varepsilon) \varepsilon & \text{if } n = 2 \end{array} \right.
$$

and since $\Delta \Phi(y) = 0$,

$$
\nabla \Phi(y) \cdot \nabla h(y) = \nabla \cdot (\nabla \Phi(y) h(y)).
$$

Consequently

$$
\Delta u(x) = -\int_{B \setminus B(0,\varepsilon)} \nabla \cdot (\nabla \Phi(y) h(y)) dy + e(\varepsilon).
$$

Thus, by the divergence theorem, and the definition of $h$ above,

$$
\Delta u(x) = \int_{\partial B(0,\varepsilon)} f(x - y) \nabla \Phi(y) \cdot n d\sigma + e(\varepsilon)
$$

$$
= \int_{\partial B(0,\varepsilon)} f(x - y) \left( -\frac{y}{|y|^{n-1}} \right) \cdot \left( -\frac{y}{|y|} \right) d\sigma + e(\varepsilon)
$$

$$
= -\left( \int_{\partial B(0,\varepsilon)} f(x - y) d\sigma(y) \right) \frac{1}{a_{n-1} \varepsilon^{n-1}} + e(\varepsilon).
$$

Letting $\varepsilon \to 0$,

$$
-\Delta u(x) = f(x).
$$

This proves the following lemma.

**Lemma 30.5.3** Let $U$ be a bounded open set in $\mathbb{R}^n$ with Lipschitz boundary and let $B \supseteq U - U$ where $B = B(0,R)$. Let $f \in C_0^\infty(U)$. Then for $x \in U$,

$$
\int_B \Phi(y) f(x - y) dy = \int_U \Phi(x - y) f(y) dy,
$$

and it follows that if $u$ is given by one of the above formulas, then for all $x \in U$,

$$
-\Delta u(x) = f(x).
$$

**Theorem 30.5.4** Let $f \in L^p(U)$. Then there exists $u \in L^p(U)$ whose weak derivatives are also in $L^p(U)$ such that in the sense of weak derivatives,

$$
-\Delta u = f.
$$
It is given by
\[
u(x) = \int_B \Phi(y) \tilde{f}(x-y) \, dy = \int_U \Phi(x-y) f(y) \, dy\] (30.5.70)

where \(\tilde{f}\) denotes the zero extension of \(f\) off of \(U\).

**Proof:** Let \(f \in L^p(U)\) and let \(f_k \in C_c^\infty(U), \|f_k - f\|_{L^p(U)} \to 0\), and let \(u_k\) be given by (30.5.70) with \(f_k\) in place of \(f\). Then by Minkowski's inequality,
\[
\|u - u_k\|_{L^p(U)} = \left( \int_U \left( \int_B \Phi(y) \left| \tilde{f}(x-y) - f_k(x-y) \right| \, dy \right)^p \, dx \right)^{1/p} 
\leq \left( \int_B |\Phi(y)| \left( \int_U \left| \tilde{f}(x-y) - f_k(x-y) \right|^p \, dx \right)^{1/p} \, dy \right) 
\leq \int_B |\Phi(y)| \|f - f_k\|_{L^p(U)} = C(B) \|f - f_k\|_{L^p(U)}
\]
and so \(u_k \to u\) in \(L^p(U)\). Also
\[
u_{k,i}(x) = \int_U \Phi_{i}(x-y) f_k(y) \, dy = \int_B f_k(x-y) \Phi_{i}(y) \, dy.
\]

Now let
\[
w_i = \int_B f(x-y) \Phi_{i}(y) \, dy.
\] (30.5.71)

and since \(\Phi_{i} \in L^1(B)\), it follows from Minkowski's inequality that
\[
\|u_{k,i} - w_i\|_{L^p(U)} 
\leq \int_B |\Phi_{i}(y)| \left( \int_U \left| f_k(x-y) - \tilde{f}(x-y) \right|^p \, dx \right)^{1/p} \, dy 
\leq \int_B |\Phi_{i}(y)| \|f - f_k\|_{L^p(U)} = C(B) \|f - f_k\|_{L^p(U)}
\]
and so \(u_{k,i} \to w_i\) in \(L^p(U)\).

Now let \(\phi \in C_c^\infty(U)\). Then
\[
\int_U w_i \phi \, dx = - \lim_{k \to \infty} \int_U u_{k,i} \phi \, dx = - \int_U u \phi \, dx.
\]

Thus \(u_{i} = w_i \in L^p(\mathbb{R}^n)\) and so if \(\phi \in C_c^\infty(U)\),
\[
\int_U f \phi \, dx = \lim_{k \to \infty} \int_U f_k \phi \, dx = \lim_{k \to \infty} \int_U \nabla u_k : \nabla \phi \, dx = \int_U \nabla u : \nabla \phi \, dx
\]
and so \(- \Delta u = f\) as claimed. This proves the theorem.
One could also ask whether the second weak partial derivatives of \( u \) are in \( L^p ( U ) \). This is where the theory singular integrals is used. Recall from 30.5.70 and 30.5.71 along with the argument of the above lemma, that if \( u \) is given by \( 30.5.70 \), then \( u_i \) is given by \( 30.5.71 \) which equals
\[
\int_U \Phi_i ( x - y ) f ( y ) \, dy.
\]

**Lemma 30.5.5** Let \( f \in L^p ( U ) \) and let
\[
w_i ( x ) = \int_U \Phi_i ( x - y ) f ( y ) \, dy.
\]
Then \( w_{i,j} \in L^p ( U ) \) for each \( j = 1 \cdots n \) and the map \( f \to w_{i,j} \) is continuous and linear on \( L^p ( U ) \).

**Proof:** First let \( f \in C^\infty_c ( U ) \). For such \( f \),
\[
w_i ( x ) = \int_U \Phi_i ( x - y ) f ( y ) \, dy = \int_{\mathbb{R}^n} \Phi_i ( x - y ) f ( y ) \, dy = \int_{\mathbb{R}^n} \Phi_i ( y ) f ( x - y ) \, dy.
\]
and
\[
w_{i,j} ( x ) = \int_B \Phi_i ( y ) f_{,j} ( x - y ) \, dy = \int_{B \setminus B ( 0, \varepsilon )} \Phi_i ( y ) f_{,j} ( x - y ) \, dy + \int_{B ( 0, \varepsilon )} \Phi_i ( y ) f_{,j} ( x - y ) \, dy.
\]
The second term converges to 0 because \( f_{,j} \) is bounded and by 30.5.92, \( \Phi_i \in L_1^1 \). Thus
\[
w_{i,j} ( x ) = \int_{B \setminus B ( 0, \varepsilon )} \Phi_i ( y ) f_{,j} ( x - y ) \, dy + e ( \varepsilon )
\]
\[
= \int_{B \setminus B ( 0, \varepsilon )} ( \Phi_i ( y ) f ( x - y ) )_{,j} + \Phi_i ( y ) f_{,j} ( x - y ) \, dy + e ( \varepsilon )
\]
where \( e ( \varepsilon ) \to 0 \) as \( \varepsilon \to 0 \). Using the divergence theorem, this yields
\[
w_{i,j} ( x ) = \int_{\partial B ( 0, \varepsilon )} \Phi_{,i} ( y ) f ( x - y ) n_j d\sigma + \int_{B \setminus B ( 0, \varepsilon )} \Phi_{,ij} ( y ) f ( x - y ) \, dy + e ( \varepsilon ).
\]
Consider the first term on the right. This term equals, after letting \( y = \varepsilon z \),
\[
\varepsilon^{n-1} \int_{\partial B ( 0, 1 )} \Phi_{,i} ( \varepsilon z ) f ( x - \varepsilon z ) n_j d\sigma = C_n \varepsilon^{n-1} \int_{\partial B ( 0, 1 )} \varepsilon^{1-n} z_i z_j f ( x - \varepsilon z ) d\sigma ( z )
\]
\[
= C_n \int_{\partial B ( 0, 1 )} z_i z_j f ( x - \varepsilon z ) d\sigma ( z )
\]
and this converges to 0 if $i \neq j$ and it converges to
\[ C_n f(x) \int_{\partial B(0,1)} z_i^2 d\sigma(z) \]
if $i = j$. Thus
\[ w_{i,j}(x) = C_n \delta_{ij} f(x) + \int_{B \setminus B(0,\varepsilon)} \Phi_{ij}(y) f(x - y) dy + e(\varepsilon). \]

Letting
\[ \Phi_{ij}^\varepsilon = \begin{cases} 0 & \text{if } |y| < \varepsilon, \\ \Phi_{ij}(y) & \text{if } |y| \geq \varepsilon, \end{cases} \]
it follows
\[ w_{i,j}(x) = C_n \delta_{ij} f(x) + \Phi_{ij}^\varepsilon f(x) + e(\varepsilon). \]

By the theory of singular integrals, there exists a continuous linear map, $K_{ij} \in \mathcal{L}(L^p(\mathbb{R}^n), L^p(\mathbb{R}^n))$ such that
\[ K_{ij} f = \lim_{\varepsilon \to 0} \Phi_{ij}^\varepsilon f. \]

Therefore, letting $\varepsilon \to 0$,
\[ w_{i,j} = C_n \delta_{ij} f + K_{ij} \tilde{f} \]
whenever $f \in C_0^\infty(U)$.

Now let $f \in L^p(U)$, let
\[ \|f_k - f\|_{L^p(U)} \to 0, \]
where $f_k \in C_0^\infty(U)$, and let
\[ w_{i,j}^k(x) = \int_U \Phi_{ij}(x - y) f_k(y) dy. \]

Then it follows as before that $w_{i,j}^k \to w_{i,j}$ in $L^p(U)$ and
\[ w_{i,j}^k = C_n \delta_{ij} f_k + K_{ij} \tilde{f}_k. \]

Now let $\phi \in C_0^\infty(U)$.
\[ w_{i,j}(\phi) = -\int_U w_i \phi_j dx = -\lim_{k \to \infty} \int_U w_{i,j}^k \phi dx = \lim_{k \to \infty} \int_U w_{i,j}^k \phi dx = \lim_{k \to \infty} \int_U \left( C_n \delta_{ij} \tilde{f}_k + K_{ij} \tilde{f}_k \right) \phi dx \]
\[ = \int_U \left( C_n \delta_{ij} \tilde{f} + K_{ij} \tilde{f} \right) \phi dx. \]

It follows
\[ w_{i,j} = C_n \delta_{ij} \tilde{f} + K_{ij} \tilde{f} \]
and this proves the lemma.
30.5. HELMHOLTZ DECOMPOSITIONS

Corollary 30.5.6 In the situation of Theorem 30.5.4, all weak derivatives of \( u \) of order 2 are in \( L^p(U) \) and also \( f \to u_{ij} \) is a continuous map.

Proof:

\[ u_{ij}(x) = \int_U \Phi_i(x-y) f(y) \, dy \]

and so \( u_{ij} \in L^p(U) \) and \( f \to u_{ij} \) is continuous by Lemma 30.5.5.

With this preparation, it is possible to consider the Helmholtz decomposition. Let \( F \in L^p(U; \mathbb{R}^n) \) and define

\[ \phi(x) = \int_U \nabla \Phi(x-y) \cdot F(y) \, dy. \]  

(30.5.72)

Then by Lemma 30.5.5,

\[ \phi_{ij} = C_n \tilde{F}_j + \sum_i K_{ij} \tilde{F}_i \in L^p(\mathbb{R}^n) \]

and the mapping \( F \to \nabla \phi \) is continuous from \( L^p(U; \mathbb{R}^n) \) to \( L^p(U; \mathbb{R}^n) \).

Now suppose \( F \in C^\infty_c(U; \mathbb{R}^n) \). Then

\[ \phi(x) = \int_U \sum_{i=1}^n -\frac{\partial}{\partial y^i} (\Phi(x-y) F_i(y)) + \Phi(x-y) \nabla \cdot F(y) \, dy \]

\[ = \int_U \Phi(x-y) \nabla \cdot F(y) \, dy \]

and so by Lemma 30.5.3,

\[ \nabla \cdot \nabla \phi = \Delta \phi = -\nabla \cdot F. \]

This continues to hold in the sense of weak derivatives if \( F \) is only in \( L^p(U; \mathbb{R}^n) \) because by Minkowski’s inequality and 30.5.72 the map \( F \to \phi \) is continuous. Also note that for \( F \in C^\infty_c(U; \mathbb{R}^n) \),

\[ \phi(x) = \int_B \Phi(y) \nabla \cdot F(x-y) \, dy. \]

Next define \( \pi : L^p(U; \mathbb{R}^n) \to L^p(U; \mathbb{R}^n) \) by

\[ \pi F = -\nabla \phi, \quad \phi(x) = \int_U \nabla \Phi(x-y) \cdot F(y) \, dy. \]

It was already shown that \( \pi \) is continuous, linear, and \( \nabla \cdot \pi F = \nabla \cdot F \). It is also true that \( \pi \) is a projection. To see this, let \( F \in C^\infty_c(U; \mathbb{R}^n) \). Then for \( B \) large enough,

\[ \pi^2 F(x) = -\nabla \int_B \Phi(z) \nabla \cdot \pi F(x-z) \, dz \]

\[ = -\nabla \int_B \Phi(z) \nabla \int_B \Phi(w) \nabla \cdot F(x-z-w) \, dw \, dz \]

\[ = -\nabla \int_B \Phi(z) \nabla \cdot F(x-z) \, dz = \pi F(x). \]
Since $\pi$ is continuous and $C^\infty_c (U; \mathbb{R}^n)$ is dense in $L^p (U; \mathbb{R}^n)$, $\pi^2 \mathbf{F} = \pi \mathbf{F}$ for all $\mathbf{F} \in L^p (U; \mathbb{R}^n)$. This proves the following theorem which is the Helmholtz decomposition.

**Theorem 30.5.7** There exists a continuous projection

$$\pi : L^p (U; \mathbb{R}^n) \to L^p (U; \mathbb{R}^n)$$

such that $\pi \mathbf{F}$ is a gradient and

$$\nabla \cdot (\mathbf{F} - \pi \mathbf{F}) = 0$$

in the sense of weak derivatives.

Note this theorem shows that any $L^p$ vector field is the sum of a gradient and a part which is divergence free, $\mathbf{F} = \mathbf{F} - \pi \mathbf{F} + \pi \mathbf{F}$. 
Chapter 31

Gelfand Triples And Related Stuff

Let $H$ be a separable real Hilbert space and let $V \subseteq H$ be a separable Banach space which is embedded continuously into $H$ and which is also dense in $H$. Then identifying $H$ and $H'$ you can write

$$V \subseteq H = H' \subseteq V'.$$

This is called a Gelfand triple. If $V$ is reflexive, you could conclude separability of $V$ from the separability of $H$. However, if $V$ is not reflexive, this might not happen. For example, you could take $V = L^1(0,1)$ and $H = L^2(0,1)$.

**Proposition 31.0.1** Suppose $V$ is reflexive and a subset of $H$ a separable Hilbert space with the inclusion map continuous. Suppose also that $V$ is dense in $H$. Then identifying $H$ and $H'$, it follows that $H$ is dense in $V'$ and $V$ is separable.

**Proof:** If $H$ is not dense in $V'$, then by the Hahn Banach theorem, there exists $\phi^{**} \in V''$ such that $\phi^{**}(H) = 0$ but $\phi^{**}(\phi^*) \neq 0$ for some $\phi^* \in V' \setminus H$. Since $V$ is reflexive there exists $v \in V$ such that $\phi^{**} = Jv$ for $J$ the standard mapping from $V$ to $V''$. Thus

$$\phi^{**}(h) \equiv \langle h, v \rangle \equiv (v, h)_H = 0$$

for all $h \in H$. Therefore, $v = 0$ and so $Jv = 0 = \phi^{**}$ which contradicts $\phi^{**}(\phi^*) \neq 0$. Therefore, $H$ is dense in $V'$. Now by Theorem 19.1.13 which says separability of the dual space implies separability of the space, it follows $V$ is separable as claimed. This proves the proposition.

From now on, it is assumed $V$ and $V'$ are both separable and that $H$ is dense in $V'$. This is summarized in the following definition.

**Definition 31.0.2** $V, H, V'$ will be called a Gelfand triple if $V$, $V'$ are separable, $V \subseteq H$ with the inclusion map continuous, $H = H'$, and $H = H'$ is dense in $V'$. 
What about the Borel sets on $V$ and $H$?

**Proposition 31.0.3** Denote by $\mathcal{B}(X)$ the Borel sets of $X$ where $X$ is any separable Banach space. Then

$$\mathcal{B}(X) = \sigma(X').$$

Here $\sigma(X')$ is the smallest $\sigma$ algebra such that each $\phi \in X'$ is measurable. Also in the context of the above definition, $\mathcal{B}(V) = \sigma(i^*H')$ because $H'$ is dense in $V'$. Here $i^*$ is the restriction to $V$ so that $i^*h(v) \equiv h(v) \equiv (h,v)_H$ for all $v \in V$ and $\sigma(i^*H')$ denotes the smallest $\sigma$ algebra such that $i^*h$ is measurable for each $h \in H'$.

**Proof:** By Lemma 19.1.4 there exists a countable subset of the unit ball in $X'$

$$\{\phi_n\}_{n=1}^\infty = D'$$

such that

$$||v||_X = \sup \{||\phi(v)|| : \phi \in D'\}.$$ 

Consider a closed ball $B(v_0,r)$ in $X$. This equals

$$\left\{v \in X : \sup_n |\phi_n(v) - \phi_n(v_0)| \leq r\right\} = \cap_{n=1}^\infty \phi_n^{-1}(B^{(\phi_n(v_0),r)})$$

and this last set is in $\sigma(D')$. Therefore, every closed ball is in $\sigma(D')$ which implies every open ball is also in $\sigma(D')$ since open balls are the countable union of closed balls. Since $X$ is separable, it follows every open set is the countable union of balls and so every open set is in $\sigma(D')$. It follows $\mathcal{B}(X) \subseteq \sigma(D') \subseteq \sigma(X')$. On the other hand, every $\phi \in X'$ is continuous and so it is Borel measurable. Hence $\sigma(X') \subseteq \mathcal{B}(X)$.

Now consider the last claim. From Lemma 19.1.4 and density of $H' = H$ in $V'$, it can be assumed $D' \subseteq H = H'$. Therefore, from the first part of the argument

$$\mathcal{B}(V) \subseteq \sigma(D') \subseteq \sigma(i^*H')$$

Also each $i^*h$ is continuous on $V$ so in fact, equality holds in the above because $\sigma(i^*H') \subseteq \mathcal{B}(V)$. This proves the proposition.

Next I want to verify that $V$ is in $\mathcal{B}(H)$. This will be true if $V$ is reflexive. More generally, here is an interesting result.

**Proposition 31.0.4** Let $X \subseteq Y$, $X$ dense in $Y$ and suppose $X$, $Y$ are Banach spaces and that $X$ is reflexive. Then $X \in \mathcal{B}(Y)$.

**Proof:** Define the functional

$$\phi(x) = \begin{cases} ||x||_X & \text{if } x \in X \\ \infty & \text{if } x \in Y \setminus X \end{cases}$$

Then $\phi$ is lower semicontinuous on $Y$. Here is why. Suppose $(x,a) \notin \text{epi}(\phi)$ so that $a < \phi(x)$. I need to verify this situation persists for $(x,b)$ near $(x,a)$. If this is not so,
there exists $x_n \to x$ and $a_n \to a$ such that $a_n \geq \phi(x_n)$. If $\liminf_{n \to \infty} \phi(x_n) < \infty$, then there exists a subsequence still denoted by $n$ such that $\|x_n\|_X$ is bounded. Then by the Eberlein Smulian theorem, there exists a further subsequence such that $x_n$ converges weakly in $X$ to some $z$. Now since $X$ is dense in $Y$ it follows $Y'$ can be considered a subspace of $X'$ and so for $f \in Y'$

$$f(x_n) \to f(z), \ f(x_n) \to f(x)$$

and so $f(z-x) = 0$ for all $f \in Y'$ which requires $z = x$. Now $x \to \|x\|_X$ is convex and lower semicontinuous on $X$ so it follows from Corollary 16.2.12

$$a = \liminf_{n \to \infty} a_n \geq \liminf_{n \to \infty} \phi(x_n) \geq \phi(x) > a$$

which is a contradiction. If $\liminf_{n \to \infty} \phi(x_n) = \infty$, then

$$\infty > a = \liminf_{n \to \infty} a_n = \infty$$

another contradiction. Therefore, $\text{epi} (\phi)$ is closed and so $\phi$ is lower semicontinuous as claimed. Therefore,

$$X = Y \setminus (\cap_{n=1}^{\infty} \phi^{-1} ((n, \infty)))$$

and since $\phi$ is lower semicontinuous, each $\phi^{-1} ((n, \infty))$ is open. Hence $X$ is a Borel subset of $Y$. This proves the proposition.

### 31.1 An Unnatural Example

Recall Gelfand triples are of the form

$$V \subseteq H \subseteq V'$$

where $H$ is a Hilbert space and $V$ is a Banach space contained in $H$ and each of the above inclusions is continuous and each space is dense in the next one. The standard example of a Gelfand triple is $H^1_0(D) \subseteq L^2(D) \subseteq (H^1_0(D))'$ with the convention that $L^2(D)$ is identified with its dual space. Thus for $f \in L^2(D)$, $f$ is considered as something in $(H^1_0(D))^\prime$ according to the rule

$$\langle f, \phi \rangle \equiv (f, \phi)_{L^2(D)}$$

This is a very pleasant thing to contemplate and it is natural and transparent. However, there are other ways to come up with a Gelfand triple which are much more perverse. The following is an example of such a thing along with an application. See [RS] and references given there. I think this idea is due to Lions.

First consider the following situation.

$$X \not\to Y$$
where \( \theta \) is continuous, linear and one to one and \( X \) is a Banach space. Then 
\[ \theta(X) \subseteq Y \text{ and you could define} \]
\[ \|\theta x\|_{\theta(X)} \equiv \|x\|_X. \]
Then \( \theta(X) \) can be considered the same thing as \( X \) because \( \theta \) preserves distances and all algebraic properties. Thus people write \( X \subseteq Y \) to save space. In the above simple example, it is obvious what \( \theta \) is. This is because the things in \( H^1_0 \) and things in \( L^2 \) are both functions defined on \( D \) and we can simply take \( \theta \) to be the identity map. However, you might have \( H \) be the dual space of something. Thus it consists of bounded linear transformations defined on some Banach space. Then it becomes necessary to specify the manner in which vectors in \( V \) can be considered as vectors of \( H \).

Let \( \infty > p \geq 2 \). Then letting \( D \) be a bounded open set, \( H^1_0(D) \) embeds continuously into \( L^p(D) \). That is
\[ \|\phi\|_{L^p} \leq C \|\phi\|_{H^1_0}. \] (31.1.1)
Here \( \frac{1}{p} + \frac{1}{p'} = 1. \) Also note that an equivalent inner product on \( H^1_0(D) \) is
\[ (f,g)_{H^1_0} \equiv \int_D \nabla f \cdot \nabla g dx \]
Then with respect to this inner product, the Riesz map is given by \( -\Delta \).
\[ -\Delta : H^1_0(D) \to (H^1_0(D))' \]
Thus a typical vector of \( (H^1_0(D))' \) is of the form \( -\Delta \phi \) where \( \phi \in H^1_0(D) \) and the following hold.
\[ (\phi,\psi)_{H^1_0} \equiv (-\Delta \phi,\psi), \quad (-\Delta \phi,-\Delta \psi)_{(H^1_0)^'} \equiv (\phi,\psi)_{H^1_0} = \langle -\Delta \psi,\phi \rangle \]
The following is about the Gelfand triple
\[ V = L^p(D) \subseteq (H^1_0)^' \subseteq (L^p(D))' \]

**Lemma 31.1.1** It is possible to consider \( L^p(D) \equiv V \) as a dense subspace of \( (H^1_0)^' \equiv H \) as follows. For \( f \in L^p(D) \) and \( \phi \in H^1_0(D) \),
\[ \langle f,\phi \rangle \equiv \int_D f(x)\phi(x) dx \]
One can also consider \( H \equiv (H^1_0)^' \) as a dense subspace of \( (L^p(D))' \equiv V' \) as follows. For \( -\Delta \phi \in H \) and \( f \in L^p(D) \),
\[ \langle -\Delta \phi,f \rangle \equiv (-\Delta \phi,f)_H \equiv \langle f,\phi \rangle \]
\( -\Delta \) maps \( H^1_0(D) \) to \( H \equiv (H^1_0)^' \subseteq V' \). \( -\Delta \) can be extended to yield a map \( -\Delta_1 \) from \( L^p(D) \) to \( V' \).
\begin{align*}
H_0^1(D) & \hookrightarrow (H_0^1)' \\
L^p'(D) & = V' \\
\text{Proof:} & \text{ First of all, note that by } \text{\S 31.1.1} \\
|\langle f, \phi \rangle| \leq ||f||_{L^p} ||\phi||_{L^p'} \leq C ||f||_{L^p} ||\phi||_{H_0^1} \\
\text{and so it is certainly possible to consider } L^p \subseteq H \equiv (H_0^1)' \text{ as just claimed. Now why can } L^p(D) \text{ be considered dense in } H \equiv (H_0^1)'? \text{ If it isn’t dense, then there exists } \psi \in H_0^1(D), \psi \neq 0 \text{ such that} \\
(-\Delta \psi, f)_H = 0 \\
\text{for all } f \in L^p(D). \text{ However, the above would say that for all } f \in L^p, \\
(-\Delta \psi, f)_H & = \langle f, \psi \rangle \equiv \int_D f\psi = 0 \\
\text{But } \psi \in L^p'(D) \text{ because } H_0^1(D) \text{ embeds continuously into } L^p'(D) \text{ and so the above holding for all } f \in L^p(D) \text{ implies by the usual Riesz representation theorem that } \psi = 0 \text{ contrary to the way } \psi \text{ was chosen.} \\
\text{Now consider the next claim. For } -\Delta \phi \in H \equiv (H_0^1)' \text{ and } f \in L^p(D) \text{ and from the first part} \\
|\langle -\Delta \phi, f \rangle| & = |(-\Delta \phi, f)_H| = |\langle f, \phi \rangle| \leq C ||f||_{L^p} ||\phi||_{H_0^1(D)} \\
\text{Thus } -\Delta \phi \in H \text{ can be considered in } (L^p(D))'. \text{ Why should } H \text{ be dense in } (L^p(D))'? \text{ If it is not dense, then there exists } g^* \in (L^p(D))' \text{ which is not the limit of vectors of } H. \text{ Then since } L^p(D) \text{ is reflexive, an application of the Hahn Banach theorem shows there exists } f \in L^p(D) \text{ such that} \\
\langle g^*, f \rangle_{(L^p(D))',L^p(D)} & \neq 0, \langle -\Delta \phi, f \rangle_{(L^p(D))',L^p(D)} = 0 \quad (31.1.2) \\
\text{for all } -\Delta \phi \in H. \text{ However, it was just shown } H \text{ could be considered a subset of } (L^p(D))' \text{ in the manner described above. Therefore, the last equation in the above is of the form} \\
0 & = (-\Delta \phi, f)_H = \langle f, \phi \rangle = \int_D f\phi dx \\
\text{and since this holds for all } \phi \in H_0^1(D), \text{ it follows by density of } H_0^1(D) \text{ in } L^p'(D), \text{ that } f = 0 \text{ and now this contradicts the inequality in } \text{\S 31.1.1.} \\
\text{Now } \Delta \text{ is defined on } H_0^1(D) \text{ and it delivers something in } (H_0^1)' = H. \text{ Of course } H_0^1(D) \text{ is dense in } L^p'(D). \text{ Can } \Delta \text{ be extended to all of } L^p'(D)? \text{ The answer is yes}
and it is more of the same given above. For $\phi \in H^1_0(D)$, $-\Delta \phi \in H \subseteq (L^p(D))'$, then by the above, for $\phi \in H^1_0(D)$ and $f \in L^p(D)$,

$$\langle -\Delta \phi, f \rangle \equiv \langle f, \phi \rangle \equiv \int_D f \phi dx$$

$$\|\langle -\Delta \phi, f \rangle\| \equiv \|\langle f, \phi \rangle\| \equiv \left| \int_D f \phi dx \right| \leq \|\phi\|_{L^p(D)} \|f\|_{L^p(D)}$$

and so $-\Delta$ is a continuous linear mapping defined on a dense subspace $H^1_0(D)$ of $L^p(D)$ and so this does indeed extend to a continuous linear map defined on all of $L^p(D)$ given by the formula

$$\langle -\Delta g, f \rangle \equiv \int_D f g dx$$

This proves the lemma.

Thus letting $V \equiv L^p(D)$, and $H \equiv (H^1_0(D))'$, it follows $V \subseteq H \subseteq V'$ is a Gelfand triple with the understanding of what it means for one space to be included in another described above. To emphasize the above, for $-\Delta \phi \in H, f \in L^p$,

$$\langle -\Delta \phi, f \rangle \equiv (-\Delta \phi, f) \equiv \int_D f \phi dx$$

More generally, for $g \in L^{p'}(D)$, $-\Delta g \in (L^p(D))'$ according to the rule

$$\langle -\Delta g, f \rangle \equiv \int_D f g dx.$$

With this example of a Gelfand triple, one can define a “porous medium operator” $A : V \to V'$. Let $\Psi$ be a real valued function defined on $\mathbb{R}$ which satisfies

$$\Psi \text{ is continuous} \quad (31.1.3)$$

$$(t - s) (\Psi(t) - \Psi(s)) \geq 0 \quad (31.1.4)$$

There exists $p \geq 2, p < \infty$ and $\alpha \in (0, \infty)$ such that for all $s \in \mathbb{R}$

$$s \Psi(s) \geq \alpha |s|^p - c \quad (31.1.5)$$

There exist $c_3, c_4 \in (0, \infty)$ such that for all $s \in \mathbb{R}$

$$|\Psi(s)| \leq c_4 + c_3 |s|^{p-1} \quad (31.1.6)$$

Note that (31.1.6) implies that if $v \in L^p(D)$, then

$$\int_D |\Psi(v)|^{p'} dx \leq C \int_D \left(1 + |v|^{p\prime(p-1)}\right) dx = C \int_D (1 + |v|^p) dx < \infty.$$
Thus for \( v \in L^p(D) \), \( \Psi(v) \) is something you can do \( \Delta \) to and obtain something in \( V' \). The porous medium operator \( A:V \to V' \) is given as follows.

\[
\langle Av, w \rangle_{V',V} \equiv \langle \Delta \Psi(v), w \rangle_{V',V} \equiv -\int_D \Psi(v) \, w \, dx
\]

What are the properties of \( A \)?

\[
\langle A(u + \lambda v), w \rangle \equiv -\int_D \Psi(u + \lambda v) \, w \, dx
\]

and this is easily seen to be a continuous function of \( \lambda \) Thus \( A \) is Hemicontinuous.

\[
\langle A(u) - A(v), u - v \rangle \equiv -\int_D \Psi(u) (u - v) \, dx + \int_D \Psi(v) (u - v) \, dx \leq 0
\]

Thus \(-A\) is monotone. Also there is a coercivity estimate which is routine.

\[
\langle A(v), v \rangle \equiv -\int_D \Psi(v) \, v \, dx \leq \int_D c - \alpha |v|^p \, dx = C - \alpha \|v\|_V^p
\]

This operator also has a boundedness estimate.

\[
\|A(v)\|_{V'} \equiv \sup_{\|w\|_V \leq 1} |\langle A(v), w \rangle| \equiv \sup_{\|w\|_V \leq 1} \left|\int_D \Psi(v) \, w \, dx\right|
\]

\[
\leq \sup_{\|w\|_V \leq 1} \left( \int_D (c_4 + c_3 |v|^{p-1}) \, w \, dx \right)
\]

\[
\leq \left( \int_D C (1 + |v|^p) \, dx \right)^{1/p'} \leq C + C \left( \int_D |v|^p \, dx \right)^{1/p'}
\]

\[
= C + C \|v\|_V^{p/p'} = C + C \|v\|_V^{p-1}.
\]

Since \( \Psi \) is continuous, it will also follow that \( A \) is \( \mathcal{B}(V) \) measurable. Consider

\[
u \to \langle Au, w \rangle \equiv -\int_D \Psi(u) \, w \, dx
\]

for fixed \( w \in V \). Suppose \( u_n \to u \) in \( V \) and fix \( w \in L^\infty(D) \subseteq V \). Then it follows from an easy argument using the Vitali convergence theorem and the fact that from the estimates above

\[
\Psi(u_n) \, w
\]

is uniformly integrable that

\[
u \to -\int_D \Psi(u) \, w \, dx
\]
is continuous. For general $w \in L^p(D)$, let $w_n \to w$ in $L^p(D)$ where each $w_n$ is in $L^\infty(D)$. Then the function

$$u \to -\int_D \Psi(u) \, w \, dx \equiv \langle Au, w \rangle$$

(31.1.7)

is the limit of the continuous functions

$$u \to -\int_D \Psi(u) \, w_n \, dx$$

and so the function (31.1.7) is Borel measurable. Now by the Pettis theorem this shows $A: V \to V'$ is $B(V)$ measurable. This shows $A$ is an example of an operator which satisfies some conditions which will be considered later.

### 31.2 Standard Techniques In Evolution Equations

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

**Lemma 31.2.1** Suppose $g \in L^1([a,b];X)$ where $X$ is a Banach space. Then if $\int_a^b g(t) \phi(t) \, dt = 0$ for all $\phi \in C^\infty_c(a,b)$, then $g(t) = 0$ a.e.

**Proof:** Let $S$ be a measurable subset of $(a,b)$ and let $K \subseteq S \subseteq V \subseteq (a,b)$ where $K$ is compact, $V$ is open and $m(V \setminus K) < \varepsilon$. Let $K \prec h \prec V$ as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging $K$ slightly and convolving with a mollifier, it can be assumed $h \in C^\infty_c(a,b)$. Then

$$\left| \int_a^b X_S(t) g(t) \, dt \right| = \left| \int_a^b (X_S(t) - h(t)) g(t) \, dt \right| \leq \int_a^b |X_S(t) - h(t)| \|g(t)\| \, dt \leq \int_{V \setminus K} \|g(t)\| \, dt.$$

Now let $K_n \subseteq S \subseteq V_n$ with $m(V_n \setminus K_n) < 2^{-n}$. Then from the above,

$$\left| \int_a^b X_S(t) g(t) \, dt \right| \leq \int_a^b X_{V_n \setminus K_n}(t) \|g(t)\| \, dt$$

and the integrand of the last integral converges to 0 a.e. as $n \to \infty$ because $\sum_n m(V_n \setminus K_n) < \infty$. By the dominated convergence theorem, this last integral converges to 0. Therefore, whenever $S \subseteq (a,b)$,

$$\int_a^b X_S(t) g(t) \, dt = 0.$$
Since the endpoints have measure zero, it also follows that for any measurable \( S \), the above equation holds.

Now \( g \in L^1 ([a, b] ; X) \) and so it is measurable. Therefore, \( g ([a, b]) \) is separable. Let \( D \) be a countable dense subset and let \( E \) denote the set of linear combinations of the form \( \sum_i a_i d_i \), where \( a_i \) is a rational point of \( \mathbb{F} \) and \( d_i \in D \). Thus \( E \) is countable. Denote by \( Y \) the closure of \( E \) in \( X \). Thus \( Y \) is a separable closed subspace of \( X \) which contains all the values of \( g \).

Now let \( S_n \equiv g^{-1} (B (y_n, ||y_n|| / 2)) \) where \( E = \{ y_n \}_{n=1}^\infty \). Therefore, \( \cup_n S_n = g^{-1} (X \setminus \{0\}) \). This follows because if \( x \in Y \) and \( x \neq 0 \), then in \( B (x, ||x|| / 4) \) there is a point of \( E, y_n \). Therefore, \( ||y_n|| > \frac{3}{4} ||x|| \) and so \( ||y_n|| > \frac{3||x||}{4} > \frac{||x||}{4} \) so \( x \in B (y_n, ||y_n|| / 2) \). It follows that if each \( S_n \) has measure zero, then \( g (t) = 0 \) for a.e. \( t \). Suppose then that for some \( n \), the set, \( S_n \), has positive measure. Then from what was shown above,

\[
||y_n|| = \left| \left| \frac{1}{m (S_n)} \int_{S_n} g (t) \, dt - y_n \right| \right| = \left| \left| \frac{1}{m (S_n)} \int_{S_n} g (t) \, dt - y_n dt \right| \right|
\leq \frac{1}{m (S_n)} \int_{S_n} ||g (t) - y_n|| \, dt \leq \frac{1}{m (S_n)} \int_{S_n} ||y_n|| / 2 dt = ||y_n|| / 2
\]

and so \( y_n = 0 \) which implies \( S_n = \emptyset \), a contradiction to \( m (S_n) > 0 \). This contradiction shows each \( S_n \) has measure zero and so as just explained, \( g (t) = 0 \) a.e.

**Definition 31.2.2** For \( f \in L^1 (a, b; X) \), define an extension, \( \overline{f} \) defined on

\[
[2a - b, 2b - a] = [a - (b - a), b + (b - a)]
\]

as follows.

\[
\overline{f} (t) \equiv \begin{cases} f (t) & \text{if } t \in [a, b] \\ f (2a - t) & \text{if } t \in [2a - b, a] \\ f (2b - t) & \text{if } t \in [b, 2b - a] \end{cases}
\]

**Definition 31.2.3** Also if \( f \in L^p (a, b; X) \) and \( h > 0 \), define for \( t \in [a, b] \), \( f_h (t) \equiv \overline{f} (t - h) \) for all \( h < b - a \). Thus the map \( f \to f_h \) is continuous and linear on \( L^p (a, b; X) \). It is continuous because

\[
\int_a^b ||f_h (t)||^p \, dt = \int_a^{a+h} ||f (2a - t + h)||^p \, dt + \int_a^{b-h} ||f (t)||^p \, dt
\]

The following lemma is on continuity of translation in \( L^p (a, b; X) \).

**Lemma 31.2.4** Let \( \overline{f} \) be as defined in Definition 31.2.2. Then for \( f \in L^p (a, b; X) \) for \( p \in [1, \infty) \),

\[
\lim_{\delta \to 0} \int_a^b ||\overline{f} (t - \delta) - f (t)||_X^p \, dt = 0.
\]
Proof: Regarding the measure space as \((a, b)\) with Lebesgue measure, by regularity of the measure, there exists \(g \in C_c(a, b; X)\) such that \(\|f - g\|_p < \varepsilon\). Here the norm is the norm in \(L^p(a, b; X)\). Therefore,

\[
\|fh - f\|_p \leq \|fh - gh\|_p + \|gh - g\|_p + \|g - f\|_p \\
\leq (2^{1/p} + 1) \|f - g\|_p + \|gh - g\|_p \\
< (2^{1/p} + 1) \varepsilon + \varepsilon
\]

whenever \(h\) is sufficiently small. This is because of the uniform continuity of \(g\). Therefore, since \(\varepsilon > 0\) is arbitrary, this proves the lemma.

**Definition 31.2.5** Let \(f \in L^1(a, b; X)\). Then the distributional derivative in the sense of \(X\) valued distributions is given by

\[
f'(\phi) \equiv - \int_a^b f(t) \phi'(t) \, dt
\]

Then \(f' \in L^1(a, b; X)\) if there exists \(h \in L^1(a, b; X)\) such that for all \(\phi \in C_c^\infty(a, b)\),

\[
f'(\phi) = \int_a^b h(t) \phi(t) \, dt.
\]

Then \(f'\) is defined to equal \(h\). Here \(f\) and \(f'\) are considered as vector valued distributions in the same way as was done for scalar valued functions.

**Lemma 31.2.6** The above definition is well defined.

Proof: Suppose both \(h\) and \(g\) work in the definition for \(f'\). Then for all \(\phi \in C_c^\infty(a, b)\),

\[
\int_a^b (h(t) - g(t)) \phi(t) \, dt = 0.
\]

Therefore, by Lemma [??], \(h(t) - g(t) = 0\) a.e. 

The other thing to notice about this is the following lemma. It follows immediately from the definition.

**Lemma 31.2.7** Suppose \(f, f' \in L^1(a, b; X)\). Then if \([c, d] \subseteq [a, b]\), it follows that \((f|_{[c, d]})' = f'|_{[c, d]}\). This notation means the restriction to \([c, d]\).

Recall that in the case of scalar valued functions, if you had both \(f\) and its weak derivative, \(f'\) in \(L^1(a, b)\), then you were able to conclude that \(f\) is almost everywhere equal to a continuous function, still denoted by \(f\) and

\[
f(t) = f(a) + \int_a^t f'(s) \, ds.
\]
In particular, you can define $f(a)$ to be the initial value of this continuous function. It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if $f' = 0$ where the derivative is taken in the sense of $X$ valued distributions, then $f$ equals a constant.

**Lemma 31.2.8** Suppose $f \in L^1(a, b; X)$ and for all $\phi \in C^\infty_c(a, b)$,

$$\int_a^b f(t) \phi'(t) \, dt = 0.$$ 

Then there exists a constant, $a \in X$ such that $f(t) = a$ a.e.

**Proof:** Let $\phi_0 \in C^\infty_c(a, b)$, $\int_a^b \phi_0(x) \, dx = 1$ and define for $\phi \in C^\infty_c(a, b)$

$$\psi_\phi(x) = \int_a^x [\phi(t) - \left( \int_a^b \phi(y) \, dy \right) \phi_0(t)] \, dt$$

Then $\psi_\phi \in C^\infty_c(a, b)$ and $\psi_\phi' = \phi - \left( \int_a^b \phi(y) \, dy \right) \phi_0$. Then

$$\int_a^b f(t) (\psi_\phi(t)) \, dt = \int_a^b f(t) \left( \psi_\phi'(t) + \left( \int_a^b \phi(y) \, dy \right) \phi_0(t) \right) \, dt$$

$$= \int_a^b f(t) \, dt = 0 \text{ by assumption}$$

$$= \int_a^b f(t) \psi_\phi'(t) \, dt + \left( \int_a^b \phi(y) \, dy \right) \int_a^b f(t) \phi_0(t) \, dt$$

$$= \left( \int_a^b f(t) \phi_0(t) \, dt \right) \left( \int_a^b \phi(y) \, dy \right).$$

It follows that for all $\phi \in C^\infty_c(a, b)$,

$$\int_a^b \left( f(y) - \left( \int_a^b f(t) \phi_0(t) \, dt \right) \phi(y) \, dy = 0$$

and so by Lemma 31.2.7.4.

$$f(y) - \left( \int_a^b f(t) \phi_0(t) \, dt \right) = 0 \text{ a.e. } y$$

**Theorem 31.2.9** Suppose $f, f'$ both are in $L^1(a, b; X)$ where the derivative is taken in the sense of $X$ valued distributions. Then there exists a unique point of $X$, denoted by $f(a)$ such that the following formula holds a.e. $t$.

$$f(t) = f(a) + \int_a^t f'(s) \, ds$$
Proof:

\[
\int_a^b \left( f(t) - \int_a^t f'(s) \, ds \right) \phi'(t) \, dt = \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt.
\]

Now consider \( \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt \). Let \( \Lambda \in X' \). Then it is routine from approximating \( f' \) with simple functions to verify

\[
\Lambda \left( \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt \right) = \int_a^b \int_a^b \Lambda (f'(s)) \phi'(t) \, ds \, dt.
\]

Now the ordinary Fubini theorem can be applied to obtain

\[
\int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt = \int_a^b \int_a^b \left( f'(s) \phi'(t) \right) \, ds \, dt.
\]

Since \( X' \) separates the points of \( X \), it follows

\[
\int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt = \int_a^b \int_s^b f'(s) \phi'(t) \, ds \, dt.
\]

Therefore,

\[
\int_a^b \left( f(t) - \int_a^t f'(s) \, ds \right) \phi'(t) \, dt = \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_a^b f'(s) \phi'(t) \, ds \, dt
\]

\[
= \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_a^b f'(s) \phi'(t) \, ds \, dt
\]

\[
= \int_a^b f(t) \phi'(t) \, dt - \int_a^b f'(s) \int_a^b \phi'(t) \, ds \, dt
\]

\[
= \int_a^b f(t) \phi'(t) \, dt + \int_a^b f'(s) \phi(s) \, ds = 0.
\]

Therefore, by Lemma 31.2.8, there exists a constant, denoted as \( f(a) \) such that

\[ f(t) - \int_a^t f'(s) \, ds = f(a) \]

There is also a useful theorem about continuity of pointwise evaluation.

Corollary 31.2.10 Let \( f, f' \in L^1(a, b; X) \) so that

\[ f(t) = f(0) + \int_0^t f'(s) \, ds \quad (31.2.8) \]

where in this formula, \( t \to f(t) \) is the continuous representative of \( f \). Then there exists a constant \( C \) such that for each \( t \in [a, b] \),

\[ \|f(t)\|_X \leq C \left( \|f\|_{L^1(a, b; X)} + \|f'\|_{L^1(a, b; X)} \right) \]
Proof: From the integral equation

\[ f(t) = f(s) + \int_s^t f'(r) \, dr \]

\[ \|f(t)\|_X \leq \|f(s)\|_X + \left| \int_s^t \|f'(r)\|_X \, dr \right| \]

\[ \leq \|f(s)\|_X + \int_a^b \|f'(r)\|_X \, dr \]

and so, integrating both sides with respect to \(s\)

\[(b - a) \|f(t)\|_X \leq \|f\|_{L^1(a,b;X)} + (b - a) \|f'\|_{L^1(a,b;X)} \]

and so

\[ \|f(t)\|_X \leq \left( \frac{1}{b - a} + 1 \right) \left( \|f\|_{L^1(a,b;X)} + \|f'\|_{L^1(a,b;X)} \right) \]

Let \(X\) be the space of functions \(f \in L^1(a,b;X)\) such that their weak derivatives \(f'\) are also in \(L^1(a,b;X)\). Then \(X\) is a Banach space with norm given by

\[ \|f\|_X \equiv \|f\|_{L^1(a,b;X)} + \|f'\|_{L^1(a,b;X)} \]

This is because the map \(f \to f'\) is a closed map. If \(f_n \to f\) in \(L^1(a,b;X)\) and \(f'_n \to \xi\) in \(L^1(a,b;X)\), then for \(\phi \in C_c^\infty(a,b)\),

\[ \int_a^b \xi \phi dt = \lim_{n \to \infty} \int_a^b f'_n \phi dt = \lim_{n \to \infty} \int_a^b f_n \phi' dt = - \int_a^b f \phi' dt \]

showing that \(\xi = f'\). Thus if you have a Cauchy sequence in \(X\), \(\{f_n\}\), then \(f_n \to f\) in \(L^1(a,b;X)\) and \(f'_n \to \xi\) in \(L^1(a,b;X)\) for some \(\xi\). Hence \(f' = \xi\).

Then the above corollary says that pointwise evaluation is continuous as a map from \(X\) to \(X\). This is clearly a linear map. Also the formula obtained shows that in fact, this is continuous into \(C([a,b];X)\).

\[ \|f\|_{C([a,b];X)} = \sup_{t \in [a,b]} \|f(t)\|_X \leq C \left( \|f\|_{L^1(a,b;X)} + \|f'\|_{L^1(a,b;X)} \right) = C \|f\|_X. \]

Now let \(\theta : X \to C([a,b];X)\) be given by \(\theta f(t) \equiv f(t)\) where \(f(t) = f(0) + \int_0^t f'(s) \, ds\), \(f\) being the continuous representative of \(f\). Then \(\theta\) is continuous and linear. If \(\theta f \equiv f(t)\) so that it is pointwise evaluation at \(t\), then this \(\theta_t\) is also continuous and linear. Suppose \(X\) is also reflexive. It follows that if you have a sequence in \(X\) \(\{f_n\}\) which is converging weakly to \(f \in X\), then you would also have \(\theta_t f_n \to f_n(t) \to \theta_t f \equiv f(t)\) weakly in \(X\). If this is not so, then since \(X\) is reflexive, there is a subsequence, still denoted as \(f_n\) such that \(f_n(t) \to \xi \neq f(t)\). However, this says that \((f,\xi)\) is in the weak closure of the graph of \(\theta_t\). Since this graph is strongly closed and convex, it is also weakly closed and hence \(\xi = \theta_t f \equiv f(t)\), a contradiction. This proves the following nice corollary.
Corollary 31.2.11 Suppose \( f_n \to f \) weakly in \( X \) where we assume also that \( X \) is reflexive. Then \( f_n(t) \to f(t) \) weakly in \( X \).

The integration by parts formula is also important.

Corollary 31.2.12 Suppose \( f, f' \in L^1(a, b; X) \) and suppose \( \phi \in C^1([a, b]) \). Then the following integration by parts formula holds.

\[
\int_a^b f(t) \phi'(t) \, dt = f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(t) \phi(t) \, dt.
\]

Proof: From Theorem 31.2.9

\[
\int_a^b f(t) \phi'(t) \, dt \\
= \int_a^b \left( f(a) + \int_a^t f'(s) \, ds \right) \phi'(t) \, dt \\
= f(a) (\phi(b) - \phi(a)) + \int_a^b \int_a^t f'(s) \, ds \phi'(t) \, dt \\
= f(a) (\phi(b) - \phi(a)) + \int_a^b \int_a^b f'(s) \phi'(t) \, dt \, ds \\
= f(a) (\phi(b) - \phi(a)) - \int_a^b f'(s) (\phi(b) - \phi(s)) \, ds \\
= f(a) (\phi(b) - \phi(a)) - \int_a^b f'(s) \phi(s) \, ds + (f(b) - f(a)) \phi(b) \\
= f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(s) \phi(s) \, ds.
\]

The interchange in order of integration is justified as in the proof of Theorem 31.2.9.

With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define \( \mathcal{F} \) as in Definition 31.2.2.

Lemma 31.2.13 Let \( \mathcal{F} \) be given in Definition 31.2.2 and suppose \( f, f' \in L^1(a, b; X) \). Then \( \mathcal{F}, \mathcal{F}' \in L^1(2a - b, 2b - a; X) \) also and

\[
\mathcal{F}'(t) \equiv \begin{cases} 
  f'(t) & \text{if } t \in [a, b] \\
  -f'(2a - t) & \text{if } t \in [2a - b, a] \\
  -f'(2b - t) & \text{if } t \in [b, 2b - a]
\end{cases}
\] (31.2.9)

Proof: It is clear from the definition of \( \mathcal{F} \) that \( \mathcal{F} \in L^1(2a - b, 2b - a; X) \) and that in fact

\[
||\mathcal{F}||_{L^1(2a - b, 2b - a; X)} \leq 3 ||f||_{L^1(a, b; X)}. \tag{31.2.10}
\]
Let $\phi \in C_c^\infty(2a - b, 2b - a)$. Then from the integration by parts formula,
\[
\int_{2a-b}^{2b-a} f(t) \phi'(t) \, dt \\
= \int_a^b f(t) \phi'(t) \, dt + \int_{2a-b}^{2b-a} f(2b-t) \phi'(t) \, dt + \int_{2a-b}^a f(2a-t) \phi'(t) \, dt \\
= \int_a^b f(t) \phi'(t) \, dt + \int_a^b f(u) \phi'(2b-u) \, du + \int_a^b f(u) \phi'(2a-u) \, du \\
= f(b) \phi(b) - f(a) \phi(a) - \int_a^b f(t) \phi(t) \, dt - f(b) \phi(b) + f(a) \phi(2b-a) \\
+ \int_a^b f'(u) \phi(2b-u) \, du - f(b) \phi(2a-b) \\
+ f(a) \phi(a) + \int_a^b f'(u) \phi(2a-u) \, du \\
= - \int_a^b f'(t) \phi(t) \, dt + \int_a^b f'(u) \phi(2b-u) \, du + \int_a^b f'(u) \phi(2a-u) \, du \\
= - \int_a^b f'(t) \phi(t) \, dt - \int_b^{2b-a} f'(2b-t) \phi(t) \, dt - \int_{2a-b}^a -f'(2a-t) \phi(t) \, dt \\
= - \int_{2a-b}^{2b-a} f'(t) \phi(t) \, dt
\]
where $f'(t)$ is given in [112.4A].

**Definition 31.2.14** Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H = L^2(\Omega)$) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write
\[
V \subseteq H = H' \subseteq V'
\]
When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g \rangle$ to denote $f(g)$ for $f \in V'$ and $g \in V$. This may also be written as $\langle f, g \rangle_{V',V}$. Another term is that $V \subseteq H = H' \subseteq V'$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^p(0,T;V)$ while $f' \in L^p(0,T;V')$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

**Theorem 31.2.15** Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 31.2.14. Suppose $f \in L^p(0,T;V)$ and $f' \in L^p(0,T;V')$. Then $f$ is
a.e. equal to a continuous function mapping \([0, T]\) to \(H\). Furthermore, there exists \(f(0) \in H\) such that

\[
\frac{1}{2} |f(t)|_H^2 - \frac{1}{2} |f(0)|_H^2 = \int_0^t \langle f'(s), f(s) \rangle \, ds,
\]

(31.2.11)

and for all \(t \in [0, T]\),

\[
\int_0^t f'(s) \, ds \in H,
\]

(31.2.12)

and for a.e. \(t \in [0, T]\),

\[
f(t) = f(0) + \int_0^t f'(s) \, ds \text{ in } H,
\]

(31.2.13)

Here \(f'\) is being taken in the sense of \(V'\) valued distributions and \(\frac{1}{p} + \frac{1}{p'} = 1\) and \(p \geq 2\).

**Proof:** Let \(\Psi \in C_c^\infty (-T, 2T)\) satisfy \(\Psi(t) = 1\) if \(t \in [-T/2, 3T/2]\) and \(\Psi(t) \geq 0\). For \(t \in \mathbb{R}\), define

\[
\tilde{f}(t) = \begin{cases} f(t) \Psi(t) & \text{if } t \in [-T, 2T] \\ 0 & \text{if } t \notin [-T, 2T] \end{cases}
\]

and

\[
f_n(t) = \int_{-1/n}^{1/n} \tilde{f}(t-s) \phi_n(s) \, ds
\]

(31.2.14)

where \(\phi_n\) is a mollifier having support in \((-1/n, 1/n)\). Then by Minkowski’s inequality

\[
\left\|f_n - \tilde{f}\right\|_{L^p(\mathbb{R}; V)} = \left(\int_{\mathbb{R}} \left\| t \int_{-1/n}^{1/n} \tilde{f}(t-s) \phi_n(s) \, ds \right\|_V^p \, dt \right)^{1/p}
\]

\[
= \left(\int_{\mathbb{R}} \left\| \int_{-1/n}^{1/n} \tilde{f}(t-s) \phi_n(s) \, ds \right\|_V^p \, dt \right)^{1/p}
\]

\[
\leq \left(\int_{\mathbb{R}} \left(\int_{-1/n}^{1/n} \left\| \tilde{f}(t) - \tilde{f}(t-s) \right\|_V \phi_n(s) \, ds \right\|_V^p \, dt \right)^{1/p}
\]

\[
\leq \int_{-1/n}^{1/n} \phi_n(s) \left(\int_{\mathbb{R}} \left\| \tilde{f}(t) - \tilde{f}(t-s) \right\|_V^p \, dt \right)^{1/p} \, ds
\]

\[
\leq \int_{-1/n}^{1/n} \phi_n(s) \varepsilon \, ds = \varepsilon
\]

provided \(n\) is large enough. This follows from continuity of translation in \(L^p\) with Lebesgue measure. Since \(\varepsilon > 0\) is arbitrary, it follows \(f_n \to f\) in \(L^p(\mathbb{R}; V)\). Similarly,
31.2. STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

\( f_n \to f \) in \( L^2(\mathbb{R}; H) \). This follows because \( p \geq 2 \) and the norm in \( V \) and norm in \( H \) are related by \( |x|_H \leq C |x|_V \) for some constant, \( C \). Now

\[
\hat{f}(t) = \begin{cases} 
\Psi(t) f(t) & \text{if } t \in [0, T], \\
\Psi(t) f(2T - t) & \text{if } t \in [T, 2T], \\
\Psi(t) f(-t) & \text{if } t \in [0, T], \\
0 & \text{if } t \notin [-T, 2T].
\end{cases}
\]

An easy modification of the argument of Lemma \( \varphi \implies \psi \) yields

\[
\hat{f}'(t) = \begin{cases} 
\Psi'(t) f(t) + \Psi(y) f'(t) & \text{if } t \in [0, T], \\
\Psi'(t) f(2T - t) - \Psi(t) f'(2T - t) & \text{if } t \in [T, 2T], \\
\Psi'(t) f(-t) - \Psi(t) f'(-t) & \text{if } t \in [-T, 0], \\
0 & \text{if } t \notin [-T, 2T].
\end{cases}
\]

Recall

\[
f_n(t) = \int_{-1/n}^{1/n} \hat{f}(t-s) \phi_n(s) \, ds = \int_{\mathbb{R}} \hat{f}(t-s) \phi_n(s) \, ds
= \int_{\mathbb{R}} \hat{f}(s) \phi_n(t-s) \, ds.
\]

Therefore,

\[
f'_n(t) = \int_{\mathbb{R}} \hat{f}'(s) \phi'_n(t-s) \, ds = \int_{-T-\frac{1}{n}}^{2T+\frac{1}{n}} \hat{f}'(s) \phi'_n(t-s) \, ds
= \int_{-T-\frac{1}{n}}^{2T+\frac{1}{n}} \hat{f}'(s) \phi_n(t-s) \, ds = \int_{\mathbb{R}} \hat{f}'(s) \phi_n(t-s) \, ds
= \int_{-1/n}^{1/n} \hat{f}'(t-s) \phi_n(s) \, ds.
\]

and it follows from the first line above that \( f'_n \) is continuous with values in \( V \) for all \( t \in \mathbb{R} \). Also note that both \( f'_n \) and \( f_n \) equal zero if \( t \notin [-T, 2T] \) whenever \( n \) is large enough. Exactly similar reasoning to the above shows that \( f'_n \to f' \) in \( L^{p'}(\mathbb{R}; V') \).

Now let \( \phi \in C^\infty_c(0,T) \).

\[
\int_{\mathbb{R}} |f_n(t)|^2_H \phi'(t) \, dt = \int_{\mathbb{R}} (f_n(t), f_n(t))_H \phi'(t) \, dt \quad (31.2.15)
= -\int_{\mathbb{R}} 2 \langle f'_n(t), f_n(t) \rangle \phi(t) \, dt = -\int_{\mathbb{R}} 2 \langle f'_n(t), f_n(t) \rangle \phi(t) \, dt
\]

Now

\[
\left| \int_{\mathbb{R}} \langle f'_n(t), f_n(t) \rangle \phi(t) \, dt - \int_{\mathbb{R}} \langle f'(t), f(t) \rangle \phi(t) \, dt \right|
\leq \int_{\mathbb{R}} (|f'_n(t) - f'(t), f_n(t)| + |f'(t), f_n(t) - f(t)|) \phi(t) \, dt.
\]
From the first part of this proof which showed that \( f_n \to \hat{f} \) in \( L^p (\mathbb{R}; V) \) and \( f'_n \to \hat{f}' \) in \( L^{p'} (\mathbb{R}; V') \), an application of Holder’s inequality shows the above converges to 0 as \( n \to \infty \). Therefore, passing to the limit as \( n \to \infty \) in the limit
\[
\int_{\mathbb{R}} \left| \hat{f} (t) \right|^2_H \phi' (t) \, dt = - \int_{\mathbb{R}} 2 \left\langle \hat{f}' (t), \hat{f} (t) \right\rangle \phi (t) \, dt
\]
which shows \( t \to \left| \hat{f} (t) \right|^2_H \) equals a continuous function a.e. and it also has a weak derivative equal to \( 2 \left\langle \hat{f}', \hat{f} \right\rangle \).

It remains to verify that \( \hat{f} \) is continuous on \([0,T]\). Of course \( \hat{f} = f \) on this interval. Let \( N \) be large enough that \( f_n (-T) = 0 \) for all \( n > N \). Then for \( m, n > N \) and \( t \in [-T, 2T] \)
\[
|f_n (t) - f_m (t)|^2_H = 2 \int_{-T}^{t} (f'_n (s) - f'_m (s), f_n (s) - f_m (s)) \, ds
\]
\[
= 2 \int_{-T}^{t} \langle f'_n (s), f_n (s) - f_m (s) \rangle_{V', V} \, ds
\]
\[
\leq 2 \int \|f'_n (s) - f'_m (s)\|_{V'} \|f_n (s) - f_m (s)\|_V \, ds
\]
\[
\leq 2 \|f_n - f_m\|_{L^{p'}(\mathbb{R}; V')} \|f_n - f_m\|_{L^p(\mathbb{R}; V)}
\]
which shows from the above that \( \{f_n\} \) is uniformly Cauchy on \([-T, 2T]\) with values in \( H \). Therefore, there exists \( g \) a continuous function defined on \([-T, 2T]\) having values in \( H \) such that
\[
\lim_{n \to \infty} \max \{ |f_n (t) - g (t)|_H ; t \in [-T, 2T] \} = 0.
\]
However, \( g = \hat{f} \) a.e. because \( f_n \) converges to \( f \) in \( L^p (0, T; V) \). Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that \( V \subseteq H = H' \subseteq V' \) and Theorem 31.2.9, there exists \( f (0) \in V' \) such that for a.e. \( t \),
\[
f (t) = f (0) + \int_0^t f' (s) \, ds \text{ in } V'
\]
Now \( g = f \) a.e. and \( g \) is continuous with values in \( H \) hence continuous with values in \( V' \) and so
\[
g (t) = f (0) + \int_0^t f' (s) \, ds \text{ in } V'
\]
for all \( t \). Since \( g \) is continuous with values in \( H \) it is continuous with values in \( V' \). Taking the limit as \( t \downarrow 0 \) in the above, \( g (a) = \lim_{t \to 0^+} g (t) = f (0) \), showing that \( f (0) \in H \). Therefore, for a.e. \( t \),
\[
f (t) = f (0) + \int_0^t f' (s) \, ds \text{ in } H, \int_0^t f' (s) \, ds \in H. \]
31.3. AN IMPORTANT FORMULA

Note that if $f \in L^p (0, T; V)$ and $f' \in L^{p'} (0, T; V')$, then you can consider the initial value of $f$ and it will be in $H$. What if you start with something in $H$? Is it an initial condition for a function $f \in L^p (0, T; V)$ such that $f' \in L^{p'} (0, T; V')$? This is worth thinking about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if $V$ is a closed subspace of the Sobolev space, $W^{1,p} (\Omega)$ which contains $W^{1,0} (\Omega)$ for $p \geq 2$ and $H = L^2 (\Omega)$ the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

31.3 An Important Formula

It is not necessary to have $p > 2$ in order to do the sort of thing just described. First is an approximation theorem which says that a given function in $L^p ([0, T]; E)$ can be approximated by step functions.

Lemma 31.3.1 Let $\Phi : [0, T] \to E$, be Lebesgue measurable and suppose

$$\Phi \in K \equiv L^p ([0, T]; E), \ p \geq 1$$

Then there exists a sequence of nested partitions, $\mathcal{P}_k \subseteq \mathcal{P}_{k+1}$,

$$\mathcal{P}_k \equiv \{ t^k_0, \ldots , t^k_{m_k} \}$$

such that the step functions given by

$$\Phi^k_n (t) = \sum_{j=1}^{m_k} \Phi (t^k_j) \chi_{[t^k_{j-1}, t^k_j)} (t)$$

$$\Phi^k_n (t) = \sum_{j=1}^{m_k} \Phi (t^k_j) \chi_{[t^k_{j-1}, t^k_j)} (t)$$

both converge to $\Phi$ in $K$ as $k \to \infty$ and

$$\lim_{k \to \infty} \max \{ |t^k_j - t^k_{j+1}| : j \in \{0, \ldots , m_k\} \} = 0.$$ 

In the formulas, define $\Phi (0) = 0$. The mesh points $\{ t^k_j \}_{j=0}^{m_k}$ can be chosen to miss a given set of measure zero.

Note that it would make no difference in terms of the conclusion of this lemma if you defined

$$\Phi^k_n (t) = \sum_{j=1}^{m_k} \Phi (t^k_{j-1}) \chi_{[t^k_{j-1}, t^k_j)} (t)$$

because the modified function equals the one given above off a countable subset of $[0, T]$, the union of the mesh points.
CHAPTER 31. GELFAND TRIPLES AND RELATED STUFF

Proof: For \( t \in \mathbb{R} \) let \( \gamma_n(t) \equiv k/2^n, \delta_n(t) \equiv (k + 1)/2^n \), where
\[
t \in \left( k/2^n, (k + 1)/2^n \right],
\]
and \( 2^{-n} < T/4 \). Also suppose \( \Phi \) is defined to equal 0 on \([0, T]^C \times \Omega\). There exists a set of measure zero \( N \) such that for \( \omega \notin N, t \rightarrow \|\Phi(t, \omega)\| \) is in \( L^p(\mathbb{R}) \). Therefore by continuity of translation, as \( n \rightarrow \infty \) it follows that for \( \omega \notin N \), and \( t \in [0, T] \),
\[
\int_{\mathbb{R}} \|\Phi(\gamma_n(t) + s) - \Phi(t + s)\|_E^p ds \rightarrow 0
\]
The above is dominated by
\[
\int_{\mathbb{R}} 2^{p-1} (\|\Phi(s)\|^p + \|\Phi(t)\|^p) \mathcal{X}_{[-2T,2T]}(s) ds
\]
\[
= \int_{-2T}^{2T} 2^{p-1} (\|\Phi(s)\|^p + \|\Phi(t)\|^p) ds < \infty
\]
Consider
\[
\int_{-2T}^{2T} \left( \int_{\mathbb{R}} \|\Phi(\gamma_n(t) + s) - \Phi(t + s)\|_E^p ds \right) dt
\]
By the dominated convergence theorem, this converges to 0 as \( n \rightarrow \infty \). Now Fubini. This yields
\[
\int_{\mathbb{R}} \int_{-2T}^{2T} \|\Phi(\gamma_n(t) + s) - \Phi(t + s)\|_E^p dt ds
\]
Change the variables on the inside.
\[
\int_{\mathbb{R}} \int_{-2T+s}^{2T+s} \|\Phi(\gamma_n(t-s) + s) - \Phi(t)\|_E^p dt ds
\]
Now by definition, \( \Phi(t) \) vanishes if \( t \notin [0, T] \), thus the above reduces to
\[
\int_{\mathbb{R}} \int_{0}^{T} \|\Phi(\gamma_n(t-s) + s) - \Phi(t)\|_E^p dt ds
\]
\[\quad + \int_{\mathbb{R}} \int_{-2T+s}^{2T+s} \mathcal{X}_{[0,T]^C} \|\Phi(\gamma_n(t-s) + s)\|_E^p dt ds
\]
\[= \int_{\mathbb{R}} \int_{0}^{T} \|\Phi(\gamma_n(t-s) + s) - \Phi(t)\|_E^p dt ds
\]
\[\quad + \int_{\mathbb{R}} \int_{-2T+s}^{2T+s} \mathcal{X}_{[0,T]^C} \|\Phi(\gamma_n(t-s) + s) - \Phi(t)\|_E^p dt ds
\]
Also by definition, \( \gamma_n(t-s) + s \) is within \( 2^{-n} \) of \( t \) and so the integrand in the integral on the right equals 0 unless \( t \in [-2^{-n} - T, T + 2^{-n}] \subseteq [-2T, 2T] \). Thus the above reduces to
\[
\int_{\mathbb{R}} \int_{-2T}^{2T} \|\Phi(\gamma_n(t-s) + s) - \Phi(t)\|_E^p dt ds.
\]
This converges to 0 as \( n \to \infty \) as was shown above. Therefore,
\[
\int_0^T \int_0^T |\Phi (\gamma_n (t-s) + s) - \Phi (t)|^p dt ds
\]
also converges to 0 as \( n \to \infty \). The only problem is that \( \gamma_n (t-s) + s \geq t - 2^{-n} \) and so \( \gamma_n (t-s) + s \) could be less than 0 for \( t \in [0, 2^{-n}] \). Since this is an interval whose measure converges to 0 it follows
\[
\int_0^T \int_0^T |\Phi (\gamma_n (t-s) + s) + s) - \Phi (t)|^p dt ds
\]
converges to 0 as \( n \to \infty \). Let
\[
m_n (s) = \int_0^T |\Phi (\gamma_n (t-s) + s))^+ - \Phi (t)|^p dt
\]
Then letting \( \mu \) denote Lebesgue measure,
\[
\mu ([m_n (s) > \lambda]) \leq \frac{1}{\lambda} \int_0^T m_n (s) ds.
\]
It follows there exists a subsequence \( n_k \) such that
\[
\mu \left( \left[ m_{n_k} (s) > \frac{1}{k} \right] \right) < 2^{-k}
\]
Hence by the Borel Cantelli lemma, there exists a set of measure zero \( N \) such that for \( s \notin N \),
\[
m_{n_k} (s) \leq 1/k
\]
for all \( k \) sufficiently large. Pick such an \( s \). Then consider \( t \to \Phi (\gamma_{n_k} (t-s) + s)^+ \).
For \( n_k \), \( t \to (\gamma_{n_k} (t-s) + s)^+ \) has jumps at points of the form \( 0, s + l2^{-n_k} \) where \( l \) is an integer. Thus \( P_{n_k} \) consists of points of \([0, T]\) which are of this form and these partitions are nested. Define \( \Phi_{n_k}^l (0) \equiv 0, \Phi_{n_k}^l (t) \equiv \Phi (\gamma_{n_k} (t-s) + s)^+ \). Now suppose \( N_1 \) is a set of measure zero. Can \( s \) be chosen such that all jumps for all partitions occur off \( N_1 \)? Let \( (a, b) \) be an interval contained in \([0, T]\). Let \( S_j \) be the points of \((a, b)\) which are translations of the measure zero set \( N_1 \) by \( t_j^l \) for some \( j \). Thus \( S_j \) has measure 0. Now pick \( s \in (a, b) \setminus \cup_j S_j \). To get the other sequence of step functions, the right step functions, just use a similar argument with \( \delta_n \) in place of \( \gamma_n \). Just apply the argument to a subsequence of \( n_k \) so that the same \( s \) can hold for both. \( \blacksquare \)

**Theorem 31.3.2** Let \( V \subseteq H = H' \subseteq V' \) be a Gelfand triple and suppose \( Y \in L^p (0, T; V') \equiv K' \) and
\[
X (t) = X_0 + \int_0^t Y (s) ds \text{ in } V'
\]
(31.3.16)
where \( X_0 \in H \), and it is known that \( X \in L^p (0, T, V) \equiv K \) for \( p > 1 \). Then \( t \to X (t) \) is in \( C ([0, T], H \) and also

\[
\frac{1}{2} |X (t)|_H^2 = \frac{1}{2} |X_0|_H^2 + \int_0^t \langle Y (s), X (s) \rangle \, ds
\]

**Proof:** By Lemma 31.3.1 there exists a sequence of uniform partitions \( \{ t_n^k \}_{k=0}^{m_n} = P_n, P_n \subseteq P_{n+1} \), of \([0, T] \) such that the step functions

\[
\sum_{k=0}^{m_n-1} X (t_k^n) \mathcal{X} [t_k^n, t_{k+1}^n] (t) = X^l (t)
\]

\[
\sum_{k=0}^{m_n-1} X (t_{k+1}^n) \mathcal{X} [t_k^n, t_{k+1}^n] (t) = X^r (t)
\]

converge to \( X \) in \( K \) and in \( L^2 ([0, T], H) \).

**Lemma 31.3.3** Let \( s < t \). Then for \( X, Y \) satisfying

\[
|X (t)|^2 = |X (s)|^2 + 2 \int_s^t \langle Y (u), X (t) \rangle \, du - |X (t) - X (s)|^2 \tag{31.3.17}
\]

**Proof:** It follows from the following computations

\[
X (t) - X (s) = \int_s^t Y (u) \, du
\]

\[
- |X (t) - X (s)|^2 = - |X (t)|^2 + 2 \langle X (t), X (s) \rangle - |X (s)|^2
\]

\[
= - |X (t)|^2 + 2 \left( \langle X (t), X (t) - \int_s^t Y (u) \, du \rangle - |X (s)|^2 \right)
\]

\[
= - |X (t)|^2 + 2 |X (t)|^2 - 2 \left( \int_s^t \langle Y (u), X (t) \rangle - |X (s)|^2 \right)
\]

Hence

\[
|X (t)|^2 = |X (s)|^2 + 2 \int_s^t \langle Y (u), X (t) \rangle \, du - |X (t) - X (s)|^2 \]

**Lemma 31.3.4** In the above situation,

\[
\sup_{t \in [0, T]} |X (t)|_H \leq C (\|Y\|_{K'}, \|X\|_K)
\]

Also, \( t \to X (t) \) is weakly continuous with values in \( H \).
31.3. AN IMPORTANT FORMULA

Proof: From the above formula applied to the \(k^{th}\) partition of \([0,T]\) described above,

\[
|X(t_m)|^2 - |X_0|^2 = \sum_{j=0}^{m-1} |X(t_{j+1})|^2 - |X(t_j)|^2
\]

\[
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} (Y(u), X(t_{j+1})) \, du - |X(t_{j+1}) - X(t_j)|_H^2
\]

\[
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} (Y(u), X_k^+(u)) \, du - |X(t_{j+1}) - X(t_j)|_H^2
\]

Thus, discarding the negative terms and denoting by \(\mathcal{P}_k\) the \(k^{th}\) of these partitions,

\[
\sup_{t_j \in \mathcal{P}_k} |X(t_j)|_H^2 \leq |X_0|^2 + 2 \int_0^T \|Y(u)\|_V \|X_k^+(u)\|_V \, du
\]

\[
\leq |X_0|^2 + 2 \left( \int_0^T \|Y(u)\|_V^{p'} \, du \right)^{1/p'} \left( \int_0^T \|X_k^+(u)\|_V^p \, du \right)^{1/p} \leq C (\|Y\|_{K'}, \|X\|_K)
\]

because these partitions are chosen such that

\[
\lim_{k \to \infty} \left( \int_0^T \|X_k^+(u)\|_V^p \right)^{1/p} = \left( \int_0^T \|X(u)\|_V^p \right)^{1/p}
\]

and so these are bounded. This has shown that for the dense subset of \([0,T]\), \(D \equiv \cup_k \mathcal{P}_k\),

\[
\sup_{t \in D} |X(t)| < C (\|Y\|_{K'}, \|X\|_K)
\]

Now let \(\{g_k\}_{k=1}^{\infty}\) be linearly independent vectors of \(V\) whose span is dense in \(V\). This is possible because \(V\) is separable. Then let \(\{e_j\}_{j=1}^{\infty}\) be an orthonormal basis for \(H\) such that \(e_k \in \text{span} (g_1, \ldots, g_k)\) and each \(g_k \in \text{span} (e_1, \ldots, e_k)\). This is done with the Gram Schmidt process. Then it follows that \(\text{span} (\{e_k\}_{k=1}^{\infty})\) is dense in \(V\).

I claim

\[
|y|^2_H = \sum_{j=1}^{\infty} |(y, e_j)|_H^2.
\]

This is certainly true if \(y \in H\) because

\[
(y, e_j) = (y, e_j)_H
\]
If \( y \notin H \), then the series must diverge since otherwise, you could consider the infinite sum

\[
\sum_{j=1}^{\infty} \langle y, e_j \rangle e_j \in H
\]

because

\[
\left| \sum_{j=p}^{q} \langle y, e_j \rangle e_j \right|^2 = \sum_{j=p}^{q} |\langle y, e_j \rangle|^2 \to 0 \text{ as } p, q \to \infty.
\]

Letting \( z = \sum_{j=1}^{\infty} \langle y, e_j \rangle e_j \), it follows that \( \langle y, e_j \rangle \) is the \( j^{th} \) Fourier coefficient of \( z \) and that

\[
\langle z - y, v \rangle = 0
\]

for all \( v \in \text{span} (\{e_k\}_{k=1}^{\infty}) \) which is dense in \( V \). Therefore, \( z = y \) in \( V' \) and so \( y \in H \).

It follows

\[
|X(t)|^2 = \sup_n \sum_{j=1}^{n} |\langle X(t), e_j \rangle|^2
\]

which is just the sup of continuous functions of \( t \). Therefore, \( t \to |X(t)|^2 \) is lower semicontinuous. It follows that for any \( t \), letting \( t_j \to t \) for \( t_j \in D \),

\[
|X(t)|^2 \leq \liminf_{j \to \infty} |X(t_j)|^2 \leq C (\|Y\|_{K'}, \|X\|_K)
\]

This proves the first claim of the lemma.

Consider now the claim that \( t \to X(t) \) is weakly continuous. Letting \( v \in V \),

\[
\lim_{t \to s} \langle X(t), v \rangle = \lim_{t \to s} \langle X(s), v \rangle = \langle X(s), v \rangle = \langle X(s), v \rangle
\]

Since it was shown that \( |X(t)| \) is bounded independent of \( t \), and since \( V \) is dense in \( H \), the claim follows. \( \blacksquare \)

Now

\[
- \sum_{j=0}^{m-1} |X(t_{j+1}) - X(t_j)|^2_H = |X(t_m)|^2 - |X_0|^2 - \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(u), X_k(u) \rangle \, du
\]

\[
= |X(t_m)|^2 - |X_0|^2 - 2 \int_0^{t_m} \langle Y(u), X_k(u) \rangle \, du
\]

Thus, since the partitions are nested, eventually \( |X(t_m)|^2 \) is constant for all \( k \) large enough and the integral term converges to

\[
\int_0^{t_m} \langle Y(u), X(u) \rangle \, du
\]

It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by \( X \),

\[
X(t_{j+1}) - X(t_j) = \int_{t_j}^{t_{j+1}} Y(u) \, du
\]
Therefore, this term is dominated by an expression of the form

\[
\sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) - X(t_j) \rangle \, du
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} (Y(u), X(t_{j+1}) - X(t_j)) \, du
\]

\[
= \int_0^T (Y(u), X^r(u)) \, du - \int_0^T (Y(u), X^l(u)) \, du
\]

However, both \(X^r\) and \(X^l\) converge to \(X\) in \(K = L^p(0, T, V)\). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \(t \in D\), the desired formula holds. Thus, for such \(t\),

\[
|X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(u), X(u) \rangle \, du
\]

It remains to verify that this holds for all \(t\). Let \(t \notin D\) and let \(t(k) \in \mathcal{P}_k\) be the largest point of \(\mathcal{P}_k\) which is less than \(t\). Suppose \(t(m) \leq t(k)\) so that \(m \leq k\). Then

\[
X(t(m)) = X_0 + \int_0^{t(m)} Y(s) \, ds,
\]

a similar formula for \(X(t(k))\). Thus for \(t > t(m)\),

\[
X(t) - X(t(m)) = \int_{t(m)}^{t} Y(s) \, ds
\]

which is the same sort of thing already looked at except that it starts at \(t(m)\) rather than at 0 and \(X_0 = 0\). Therefore,

\[
|X(t(k)) - X(t(m))|^2 = 2 \int_{t(m)}^{t(k)} \langle Y(s), X(s) - X(t(m)) \rangle \, ds
\]

Thus, for \(m \leq k\)

\[
\lim_{m,k \to \infty} |X(t(k)) - X(t(m))|^2 = 0
\]

Hence \(\{X(t(k))\}_{k=1}^{\infty}\) is a convergent sequence in \(H\). Does it converge to \(X(t)\)? Let \(\xi(t) \in H\) be what it does converge to. Let \(v \in V\). Then

\[
(\xi(t), v) = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \langle X(t), v \rangle = \langle X(t), v \rangle
\]
because it is known that \( t \to X(t) \) is continuous into \( V' \) and it is also known that \( X(t) \in H \) and that the \( X(t) \) for \( t \in [0, T] \) are uniformly bounded. Therefore, since \( V \) is dense in \( H \), it follows that \( \xi(t) = X(t) \).

Now for every \( t \in D \), it was shown above that

\[
|X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds
\]

Thus, using what was just shown, if \( t \notin D \) and \( t_k \to t \),

\[
|X(t)|^2 = \lim_{k \to \infty} |X(t_k)|^2 = \lim_{k \to \infty} \left( |X_0|^2 + 2 \int_0^{t_k} \langle Y(s), X(s) \rangle \, ds \right)
\]

which proves the desired formula. From this it follows right away that \( t \to X(t) \) is continuous into \( H \) because it was just shown that \( t \to |X(t)| \) is continuous and \( t \to X(t) \) is weakly continuous. Since Hilbert space is uniformly convex, this implies the \( t \to X(t) \) is continuous. To see this in the special case of Hilbert space,

\[
|X(t) - X(s)|^2 = |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2
\]

Then \( \lim_{t \to s} \left( |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2 \right) = 0 \) by weak convergence of \( X(t) \) to \( X(s) \) and the convergence of \( |X(t)|^2 \) to \( |X(s)|^2 \).

### 31.4 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

\[
BX(t) = BX_0 + \int_0^t Y(s) \, ds
\]

This involves an operator \( B \in \mathcal{L}(W, W') \) and \( B \) satisfies

\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle
\]

for

\[
V \subseteq W, W' \subseteq V'
\]

Where \( V \) is dense in the Banach space \( W \). Before giving the theorem, here is a technical lemma. First is one which is not so technical.

**Lemma 31.4.1** Let \( V \) be a separable Banach space. Then there exists \( \{g_k\}_{k=1}^{\infty} \) which are linearly independent and whose span is dense in \( V \).
31.4. THE IMPLICIT CASE

**Proof:** Let \( \{f_k\} \) be a countable dense subset. Thus their span is dense. Delete \( f_{k_1} \) such that \( k_1 \) is the first index such that \( f_k \) is in the span of the other vectors. That is, it is the first which is a finite linear combination of the others. If no such vector exists, then you have what is wanted. Next delete \( f_{k_2} \) where \( k_2 \) is the next for which \( f_k \) is a linear combination of the others. Continue. The remaining vectors must be linearly independent. If not, there would be a first which is a linear combination of the others. Say \( f_m \). But the process would have eliminated it at the \( m \)th step. ■

**Lemma 31.4.2** Suppose \( V, W \) are separable Banach spaces such that \( V \) is dense in \( W \) and \( B \in \mathcal{L}(W, W') \) satisfies

\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle, B \neq 0.
\]

Then there exists a countable set \( \{e_i\} \) of vectors in \( V \) such that

\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]

and for each \( x \in W \),

\[
\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,
\]

and also

\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i,
\]

the series converging in \( W' \). If \( B = B(\omega) \) and \( B \) is \( \mathcal{F} \) measurable into \( \mathcal{L}(W, W') \) and if the \( e_i = e_i(\omega) \) are as described above, then these \( e_i \) are measurable into \( V \). If \( t \to B(t, \omega) \) is \( C^1([0, T], \mathcal{L}(W, W')) \) and if for each \( w \in W \),

\[
\langle B'(t, \omega) w, w \rangle \leq k_{w,\omega}(t) \langle B(t, \omega) w, w \rangle
\]

Where \( k_{w,\omega} \in L^1((0, T]) \), then the vectors \( e_i(t) \) can be chosen to also be right continuous functions of \( t \).

In the case of dependence on \( t \), the extra condition is trivial if \( \langle B(t, \omega) x, x \rangle \geq \delta \|w\|^2_W \) for example. This includes the usual case of evolution equations where \( W = H = H' = W' \). It also includes the case where \( B \) does not depend on \( t \).

**Proof:** Let \( \{g_k\}_{k=1}^{\infty} \) be linearly independent vectors of \( V \) whose span is dense in \( V \). This is possible because \( V \) is separable. Thus, their span is also dense in \( W \). Let \( n_1 \) be the first index such that \( \langle Bg_{n_1}, g_{n_1} \rangle \neq 0 \).

**Claim:** If there is no such index, then \( B = 0 \).

**Proof of claim:** First note that if there is no such first index, then if \( x = \sum_{i=1}^{k} a_i g_i \)

\[
|\langle Bx, x \rangle| = \left| \sum_{i \neq j} a_i a_j \langle Bg_i, g_j \rangle \right| \leq \sum_{i \neq j} |a_i| |a_j| |\langle Bg_i, g_j \rangle| \\
\leq \sum_{i \neq j} |a_i| |a_j| \langle Bg_i, g_i \rangle^{1/2} \langle Bg_j, g_j \rangle^{1/2} = 0
\]
Therefore, if $x$ is given, you could take $x_k$ in the span of $\{g_1, \cdots, g_k\}$ such that $\|x_k - x\|_W \to 0$. Then

$$\langle Bx, y \rangle = \lim_{k \to \infty} \langle Bx_k, y \rangle \leq \lim_{k \to \infty} \langle Bx_k, x_k \rangle^{1/2} \langle By, y \rangle^{1/2} = 0$$

because $\langle Bx_k, x_k \rangle$ is zero by what was just shown. Hence the conclusion of the lemma is trivially true. Just pick $e_1 = g_1$ and let $\{e_1\}$ be your set of vectors.

Thus assume there is such a first index. Let

$$e_1 \equiv \frac{g_{n_1}}{\langle Bg_{n_1}, g_{n_1} \rangle^{1/2}}$$

Then $\langle Be_1, e_1 \rangle = 1$. Now if you have constructed $e_j$ for $j \leq k$,

$$e_j \in \text{span} \ (g_{n_1}, \cdots, g_{n_k}), \quad \langle Be_i, e_j \rangle = \delta_{ij},$$

g_{n_{j+1}} being the first in the list $\{g_j\}$ for which

$$\langle Bg_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j+1}}, e_i \rangle Be_i, g_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j+1}}, e_i \rangle e_i \rangle \neq 0,$$

and

$$\text{span} \ (g_{n_1}, \cdots, g_{n_k}) = \text{span} \ (e_1, \cdots, e_k),$$

let $g_{n_{k+1}}$ be such that $g_{n_{k+1}}$ is the first in the list $\{g_n\}$ $n_{k+1} > n_k$ such that

$$\langle Bg_{n_{k+1}} - \sum_{i=1}^{k} \langle Bg_{n_{k+1}}, e_i \rangle Be_i, g_{n_{k+1}} - \sum_{i=1}^{k} \langle Bg_{n_{k+1}}, e_i \rangle e_i \rangle \neq 0.$$

Note the difference between this and the Gram Schmidt process. Here you don’t necessarily use all of the $g_k$ due to the possible degeneracy of $B$.

**Claim:** If there is no such first $g_{n_{k+1}}$, then $B(\text{span} \ (e_1, \cdots, e_k)) = BW$ so in this case, $\{Be_i\}_{i=1}^k$ is actually a basis for $BW$.

**Proof:** To see this, note that if $p \in (n_j, n_{j+1})$, then by assumption,

$$\langle B(\sum_{i=1}^{j} \langle Bg_p, e_i \rangle e_i), g_p - \sum_{i=1}^{j} \langle Bg_p, e_i \rangle e_i \rangle = 0$$

Therefore,

$$Bg_p = \sum_{i=1}^{j} \langle Bg_p, e_i \rangle Be_i$$

Also, by assumption, if $p > n_k$

$$\langle B(\sum_{i=1}^{k} \langle Bg_p, e_i \rangle e_i), g_p - \sum_{i=1}^{k} \langle Bg_p, e_i \rangle e_i \rangle = 0$$
31.4. THE IMPLICIT CASE

so

\[ Bg_p = \sum_{i=1}^{k} \langle Bg_p, e_i \rangle B e_i \]

which shows that \( \text{span} \left( \{ Bg_j \}_{j=1}^{\infty} \right) \subseteq \text{span} \left( \{ Be_i \}_{i=1}^{k} \right) \). If \( \sum_{i=1}^{k} c_i Be_i = 0 \), then for \( j \leq k \),

\[ 0 = \sum_{i=1}^{k} c_i \langle Be_i, e_j \rangle = c_j \]

so \( \{ Be_i \}_{i=1}^{k} \) is a basis for \( \text{span} \left( \{ Be_i \}_{i=1}^{k} \right) \). Hence if \( x \in W \), then letting \( x_r \in \text{span} \left( \{ Be_i \}_{i=1}^{k} \right) \) with \( x_r \to x \) in \( W \), it follows

\[ Bx_r = \sum_{i=1}^{k} a_i Be_i = \sum_{i=1}^{k} \langle Bx_r, e_i \rangle Be_i \]

Then passing to a limit, you get

\[ Bx = \sum_{i=1}^{k} \langle Bx, e_i \rangle Be_i \]

Thus \( \{ Be_i \}_{i=1}^{k} \) is a basis for \( BW \). This proves the claim.

If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

If the process does not stop, let

\[ e_{k+1} = \frac{g_{nk+1} - \sum_{i=1}^{k} \langle Bg_{nk+1}, e_i \rangle e_i}{\left( B \left( g_{nk+1} - \sum_{i=1}^{k} \langle Bg_{nk+1}, e_i \rangle e_i \right), g_{nk+1} - \sum_{i=1}^{k} \langle Bg_{nk+1}, e_i \rangle e_i \right)^{1/2}} \]

Thus, as in the usual argument for the Gram Schmidt process, \( \langle Be_i, e_j \rangle = \delta_{ij} \) for \( i, j \leq k + 1 \). This is already known for \( i, j \leq k \). Letting \( l \leq k \), and using the orthogonality already shown,

\[ \langle Be_{k+1}, e_l \rangle = C \left( B \left( g_{nk+1} - \sum_{i=1}^{k} \langle Bg_{nk+1}, e_i \rangle e_i \right), e_l \right) \]

\[ = C \left( \langle Bg_{k+1}, e_l \rangle - \langle Bg_{nk+1}, e_l \rangle \right) = 0 \]

Consider

\[ \left\langle Bg_p - B \left( \sum_{i=1}^{k} \langle Bg_p, e_i \rangle e_i \right), g_p - \sum_{i=1}^{k} \langle Bg_p, e_i \rangle e_i \right\rangle \]
If \( p \in (n_k, n_{k+1}) \), then the above equals zero which implies
\[
Bg_p = \sum_{i=1}^{k} \langle Bg_p, e_i \rangle Be_i
\]
On the other hand, suppose \( g_p = g_{n_{k+1}} \) for some \( n_{k+1} \) and so, from the construction,
\[g_{n_{k+1}} = g_p \in \text{span} \{e_1, \cdots, e_{k+1}\}\]
and therefore,
\[
g_p = \sum_{j=1}^{k+1} a_j e_j
\]
which requires easily that
\[
Bg_p = \sum_{i=1}^{k+1} \langle Bg_p, e_i \rangle Be_i,
\]
the above holding for all \( k \) large enough. To see this last claim, note that the coefficients of \( Bg = \sum_{j=1}^{m} a_j Be_j \) are required to be \( a_j = \langle Bg, e_j \rangle \) and from the construction, \( \langle Be_i, e_j \rangle = \delta_{ij} \). Thus if the upper limit is increased beyond what is needed, the new terms are all zero. It follows that for any \( x \in \text{span} \{ \{g_k\}_{k=1}^{\infty} \} \)
(\( \text{finite linear combination of vectors in } \{g_k\}_{k=1}^{\infty} \))
\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i
\] (31.4.18)
because for all \( k \) large enough,
\[
Bx = \sum_{i=1}^{k} \langle Bx, e_i \rangle Be_i
\]
Also note that for such \( x \in \text{span} \{ \{g_j\}_{j=1}^{\infty} \} \),
\[
\langle Bx, x \rangle = \left\langle \sum_{i=1}^{k} \langle Bx, e_i \rangle Be_i, x \right\rangle = \sum_{i=1}^{k} \langle Bx, e_i \rangle \langle Bx, e_i \rangle
\]
\[
= \sum_{i=1}^{k} |\langle Bx, e_i \rangle|^2 = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2
\]
Now for \( x \) arbitrary, let \( x_k \to x \) in \( W \) where \( x_k \in \text{span} \{ \{g_k\}_{k=1}^{\infty} \} \). Then by Fatou’s lemma,
\[
\sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \leq \lim \inf_{k \to \infty} \sum_{i=1}^{\infty} |\langle Bx_k, e_i \rangle|^2
\]
\[
= \lim \inf_{k \to \infty} \langle Bx_k, x_k \rangle = \langle Bx, x \rangle
\] (31.4.19)
\[
\leq \| Bx \|_W \| x \|_W \leq \| B \| \| x \|_W^2
\]
Thus the series on the left converges. Then also, from the above inequality,

\[
\left| \sum_{i=p}^{q} \langle Bx, e_i \rangle Be_i, y \right| \leq \sum_{i=p}^{q} |\langle Bx, e_i \rangle| |Be_i, y| \\
\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=p}^{q} |\langle By, e_i \rangle|^2 \right)^{1/2} \\
\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=1}^{\infty} |\langle By, e_i \rangle|^2 \right)^{1/2} 
\]

By (31.4.19)

\[
\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \|B\| \|y\|_{W}^2 \right)^{1/2} \leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2} \|y\|_{W} 
\]

It follows that

\[
\sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i
\]

converges in \( W' \) because it was just shown that

\[
\left\| \sum_{i=p}^{q} \langle Bx, e_i \rangle Be_i \right\|_{W'} \leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2}
\]

and it was shown above that \( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 < \infty \), so the partial sums of the series are a Cauchy sequence in \( W' \). Also, the above estimate shows that for \( \|y\| = 1 \),

\[
\left| \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i, y \right| \leq \left( \sum_{i=1}^{\infty} |\langle By, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \\
\leq \left( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2} 
\]

and so

\[
\left\| \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i \right\|_{W'} \leq \left( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2} 
\]  (31.4.21)
Now for $x$ arbitrary, let $x_k \in \text{span} \left( \{g_j\}_{j=1}^\infty \right)$ and $x_k \to x$ in $W$. Then for a fixed $k$ large enough,

$$
\left\| Bx - \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i \right\| 
\leq \|Bx - Bx_k\|
$$

$$
+ \left\| Bx_k - \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i \right\|
+ \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i - \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i
$$

$$
\leq \varepsilon + \left\| \sum_{i=1}^\infty \langle B(x_k - x), e_i \rangle Be_i \right\|,
$$

the term

$$
\left\| Bx_k - \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i \right\|
$$

equaling 0 by (31.4.18). From (31.4.21) and (31.4.19),

$$
\leq \varepsilon + \|B\|^{1/2} \left( \sum_{i=1}^\infty |\langle B(x_k - x), e_i \rangle|^2 \right)^{1/2}
$$

$$
\leq \varepsilon + \|B\|^{1/2} |\langle B(x_k - x), x_k - x \rangle|^{1/2} < 2\varepsilon
$$

whenever $k$ is large enough, the second inequality being implied by (31.4.19). Therefore,

$$
Bx = \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i
$$
in $W'$. It follows that

$$
\langle Bx, x \rangle = \lim_{k \to \infty} \left\langle \sum_{i=1}^k \langle Bx, e_i \rangle Be_i, x \right\rangle
= \lim_{k \to \infty} \sum_{i=1}^k |\langle Bx, e_i \rangle|^2
\equiv \sum_{i=1}^\infty |\langle Bx, e_i \rangle|^2
$$

Now consider the measurability assertion on the $e_i$. Consider first $e_1$. Begin by considering $n_1(\omega)$

$$
E_1 \equiv \{ \omega : \langle B(\omega) g_k, g_k \rangle \neq 0 \} \cap \bigcap_{j<k} \{ \omega : \langle B(\omega) g_j, g_j \rangle = 0 \}
$$

As explained above, $B(\omega) = 0$, if and only if $E_1 = \emptyset$ for all $k$. Also note that these $E_k$ are disjoint and $\mathcal{F}$ measurable. Then

$$
n_1(\omega) \equiv \begin{cases} 1 & \text{if } \omega \notin \bigcup_k E_1 \\ k & \text{if } \omega \in E_k \end{cases}
$$

Then $n_1(\omega)$ is clearly measurable because it is constant on measurable sets. Then from the algorithm,

$$
e_1(\omega) \equiv \mathcal{X}_{\bigcup_k E_1}(\omega) \frac{g_{n_1(\omega)}}{\langle By_{n_1(\omega)}, g_{n_1(\omega)} \rangle^{1/2}}
Thus $e_1(\omega) = 0$ if $\omega \notin \cup_k E_k^1$. Also $e_1(\omega)$ is measurable because $\omega \rightarrow n_1(\omega)$ is measurable. Thus $e_1$ has constant values on measurable sets. So suppose $n_i(\omega)$ is measurable for $i \leq m$. Then define $E_{p+1}^{m+1} =$
\[
\left\{ \omega : \left< Bg_p - \sum_{i=1}^{m} (Bg_p, e_i) Be_i, g_p - \sum_{i=1}^{m} (Bg_p, e_i) e_i \right> \neq 0 \right\} \cap \left\{ \omega : n_m(\omega) < p \right\}
\]
\[
\cap_{n_m(\omega) < r < p} \left\{ \omega : \left< Bg_r - \sum_{i=1}^{m} (Bg_r, e_i) Be_i, g_r - \sum_{i=1}^{m} (Bg_r, e_i) e_i \right> = 0 \right\}
\]
As earlier, these sets $\{E_{p+1}^{m+1}\}_{p=1}^{\infty}$ are disjoint and measurable. As before, let $n_{m+1}(\omega) = p$ where $\omega \in E_{p+1}^{m+1}$. Then from the algorithm, $e_{m+1}(\omega) = \chi_{\cup_{p}E_{p+1}^{m+1}}(\omega) g_{n_{m+1}(\omega)} - \sum_{i=1}^{m} (Bg_{n_{m+1}(\omega)}, e_i) e_i / D_m$
where $D_m = \left< B(\sum_{i=1}^{m} (Bg_{n_{m+1}(\omega)}, e_i) e_i), (\sum_{i=1}^{m} (Bg_{n_{m+1}(\omega)}, e_i) e_i) \right>_{W, W}^{1/2}$
Thus the $e_k(\omega)$ are all measurable into $W$ thanks to the algorithm. However, they all have values in $V$. Thus if $\phi \in V'$, let $\phi_n \rightarrow \phi$ in $V'$ where $\phi_n \in W'$
\[
\langle \phi, e_k(\omega) \rangle_{V', V} = \lim_{n \rightarrow \infty} \langle \phi_n, e_k(\omega) \rangle_{V', V} = \lim_{n \rightarrow \infty} \langle \phi_n, e_k(\omega) \rangle_{W', W}
\]
which is the limit of measurable functions. By the Pettis theorem, this shows $e_k$ is measurable into $V$ also.
To verify the assertion on right continuity, the same kind of argument holds. We suppress the dependence on $\omega$. Consider first $e_1$. Begin by considering $n_1(t) = E_k^1 = \{ t : \langle B(t) g_k, g_k \rangle 
eq 0 \} \cap \cup_{j<k} \{ t : \langle B(t) g_j, g_j \rangle = 0 \}$
As explained above, $B(t) = 0$, if and only if $E_k^1 = \emptyset$ for all $k$. Also note that these $E_k^1$ are disjoint. Then
\[
n_1(t) = \begin{cases} 1 & \text{if } t \notin \cup_k E_k^1 = \emptyset \\ k & \text{if } t \in E_k^1 \end{cases}
\]
If $t \in E_k^1$, then from the definition, $\langle B(t) g_k, g_k \rangle \neq 0$ and $k$ is the first index for which this is nonzero. Let $t_l \downarrow t$. Then by continuity, for all $l$ large enough, $\langle B(t_l) g_k, g_k \rangle \neq 0$. What of $\langle B(t_l) g_j, g_j \rangle$ for $j < k$? By assumption,
\[
\langle B'(t) g_j, g_j \rangle \leq k_{g_j}(t) \langle B(t) g_j, g_j \rangle
\]
and so, letting $K_{g_j}(t) = \int_{0}^{t} k_{g_j}(s) ds$,
\[
\frac{d}{dt} \left( e^{-K_{g_j}(t)} \langle B(t) g_j, g_j \rangle \right) \leq 0
\]
Thus one obtains right continuity of $t \to n_1 (t)$ and for $E_k^1$, there is an interval $[t, t + \delta) \subseteq E_k^1$. From the algorithm,

$$e_1 (t) \equiv X_{\cup_k E_k^1} (t) \frac{g_{n_1 (t)}}{\langle B g_{n_1 (t)}; g_{n_1 (t)} \rangle^{1/2}}$$

Thus $e_1 (t) = 0$ if $t \notin \cup_k E_k^1$. Also $e_1 (t)$ is right continuous because $t \to n_1 (t)$ is. Thus $e_1$ has constant values on a small interval starting at $t$. But what about $t \notin \cup_k E_k^1$? Why should it be right continuous there? If you have such a $t$, then as explained above, $B (t) = 0$. Then letting $s$ be arbitrary, $s > t$ and $x \in W$,

$$\langle B' (s) x, x \rangle \leq k_x \langle B (s) x, x \rangle$$

and so as above,

$$e^{-K_z (s)} \langle B (s) x, x \rangle \leq 0$$

Thus this case reduces to having $B (s) = 0$ for all $s \geq t$ and there is nothing to prove. You have $n_1 (s) = 1$ and $e_1 (s) = 0$ for all $s \geq t$.

Suppose $t \to n_i (t)$ is right continuous for $i \leq m$ and that $e_i$ is also. Then define $E_{p+1}^{m+1}$

$$\left\{ t : \left\langle B g_r - \sum_{i=1}^p (B g_r, e_i) B e_i, g_r - \sum_{i=1}^p (B g_r, e_i) e_i \right\rangle \neq 0 \right\} \cap \left\{ t : n_m (t) < p \right\}$$

As earlier, these sets $\{ E_{p+1}^{m+1} \}_{p=1}^\infty$ are disjoint. As before, let $n_{m+1} (t) = p$ where $t \in E_{p+1}^{m+1}$. Then by similar reasoning to the above, for small $\delta$, $[t, t + \delta) \subseteq E_{p+1}^{m+1}$ and $n_{m+1} (s) = p$ for $s \in [t, t + \delta)$. Then from the algorithm, $e_{m+1} (t) \equiv$

$$X_{\cup_p E_{p+1}^{m+1}} (t) \frac{g_{n_{m+1} (t)} - \sum_{i=1}^m \langle B g_{n_{m+1} (t)}, e_i \rangle e_i (t) \rangle e_i (t)}{D_m}$$

where $D_m =$

$$\left\langle B \left( g_{n_{m+1} (t)} - \sum_{i=1}^m \langle B g_{n_{m+1} (t)}, e_i (t) \rangle e_i (t) \right), \sum_{i=1}^m \langle B g_{n_{m+1} (t)}, e_i (t) \rangle e_i (t) \right\rangle^{1/2}$$

and so is right continuous. What of $t \notin \cup_p E_{p+1}^{m+1}$? In this case, the process has terminated and what is desired has been found. ■

Then the main result in this section is the following integration by parts theorem.
31.4. THE IMPLICIT CASE

Theorem 31.4.3 Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, and let $Y \in L^p (0, T; V')$ and

$$Bu(t) = Bu_0 + \int_0^t Y(s) \, ds \text{ in } V', \quad u_0 \in W, Bu(t) = B(u(t)) \text{ for a.e. } t \quad (31.4.22)$$

As indicated, $Bu$ is the name of a function satisfying the above equation which satisfies $Bu(t) = B(u(t))$ for a.e. $t$. Thus $Y = (Bu)'$ as a weak derivative in the sense of $V'$ valued distributions. It is known that $u \in L^p (0, T, V)$ for $p > 1$. Then $t \rightarrow Bu(t)$ is continuous into $W'$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \rightarrow \langle Bu, u \rangle (t)$ such that for all $t \notin N, \langle Bu, u \rangle (t) = \langle B(u(t)), u(t) \rangle, Bu(t) = B(u(t))$, and for all $t$,

$$\frac{1}{2} \langle Bu, u \rangle (t) = \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle Y(s), u(s) \rangle \, ds$$

Note that $\langle Bu, u \rangle (0) = \langle Bu_0, u_0 \rangle$.

Proof: By Lemma 31.4.1, there exists a sequence of partitions $\{\tau^n_k\}^m_n = \mathcal{P}_n, \mathcal{P}_n \subseteq \mathcal{P}_{n+1}$, of $[0, T]$ such that the lengths of the sub intervals converge uniformly to 0 as $n \rightarrow \infty$ and the step functions

$$\sum_{k=0}^{m_n-1} u(t^n_k) \mathcal{X}_{(t^n_k, t^n_{k+1}]} (t) = u^l (t)$$

$$\sum_{k=0}^{m_n-1} u(t^n_k+1) \mathcal{X}_{(t^n_{k+1}, t^n_{k+1}]} (t) = u^r (t)$$

converge to $u$ in $L^p (0, T; V) = K$. We assume that all of these partition points have empty intersection with the set of measure zero where $Bu(t) \neq B(u(t))$. Thus, at every partition point, $Bu(t_k) = B(u(t_k))$. As just mentioned, $L^p (0, T; V) = K, L^p (0, T; V') = K'$.

Lemma 31.4.4 Let $s < t$. Then for $u, Y$ satisfying $31.4.22$

$$\langle Bu(t), u(t) \rangle = \langle Bu(s), u(s) \rangle + 2 \int_s^t \langle Y(r), u(t) \rangle \, dr - \langle Bu(t) - Bu(s), u(t) - u(s) \rangle \quad (31.4.23)$$

Proof: It follows from the following computations

$$Bu(t) - Bu(s) = \int_s^t Y(r) \, dr$$

and so

$$2 \int_s^t \langle Y(r), u(t) \rangle \, dr - \langle Bu(t) - Bu(s), u(t) - u(s) \rangle$$
In the above situation, applied to the 31.4.4 appears to work. Thus, discarding the negative terms and denoting by $T_0$ of $[0, T]$ described above, $t \mapsto Bu(t)$ is weakly continuous with values in $W'$ on $N_C$ where $N$ is the set of measure zero where $Bu(t) \neq B(u(t))$.

**Proof:** From the above formula of Lemma 31.4.4 applied to the $k^{th}$ partition of $[0, T]$ described above,

$$\langle Bu(t_m), u(t_m) \rangle - \langle Bu_0, u_0 \rangle = \sum_{j=0}^{m-1} \langle Bu(t_{j+1}), u(t_{j+1}) \rangle - \langle Bu(t_j), u(t_j) \rangle$$

$$= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_{j+1}) \rangle dr - \langle B(u(t_{j+1}) - u(t_j)), u(t_{j+1}) - u(t_j) \rangle$$

$$= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(r), u_k^r(r) \rangle dr - \langle B(u(t_{j+1}) - u(t_j)), u(t_{j+1}) - u(t_j) \rangle$$

Thus, discarding the negative terms and denoting by $P_k$ the $k^{th}$ of these partitions,

$$\sup_{t_j \in P_k} \langle Bu(t_j), u(t_j) \rangle \leq \langle Bu_0, u_0 \rangle + 2 \int_0^T |\langle Y(r), u_k^r(r) \rangle| dr$$

$$\leq \langle Bu_0, u_0 \rangle + 2 \int_0^T \|Y(r)\|_{V'} \|u_k^r(r)\|_{V'} dr$$
31.4. THE IMPLICIT CASE

\[
\langle Bu_0; u_0 \rangle + 2 \left( \int_0^T \| Y(r) \|_{K'}^p \, dr \right)^{1/p'} \left( \int_0^T \| u_k^p(r) \|_{V'}^p \, dr \right)^{1/p} \le C(\| Y \|_{K'}, \| u \|_K)
\]

because these partitions are chosen such that

\[
\lim_{k \to \infty} \left( \int_0^T \| u_k^p(r) \|_{V'}^p \, dr \right)^{1/p} = \left( \int_0^T \| u(r) \|_{V'}^p \, dr \right)^{1/p}
\]

and so these are bounded. This has shown that for the dense subset of \([0, T] \subseteq \mathcal{D}

\[
\langle Bu; u \rangle(t) = \sum_{k=1}^{\infty} |\langle Bu(t), e_i \rangle|^2 = \sum_m \sum_{k=1}^{\infty} |\langle Bu(t), e_i \rangle|^2
\]

Thus, if \(s_n \to t, s_n \in D\), Fatou’s lemma implies

\[
\langle Bu, u \rangle(t) = (B u(t), u(t)) = \sum_{k=1}^{\infty} |\langle Bu(t), e_i \rangle|^2 \le \liminf_{n \to \infty} \sum_{k=1}^{\infty} |\langle Bu(s_n), e_i \rangle|^2 \le C(\| Y \|_{K'}, \| u \|_K)
\]

and so

\[
\sup_{t \in N^C} \langle Bu, u \rangle(t) = \sup_{t \in N^C} \langle B(u(t)), u(t) \rangle \le C(\| Y \|_{K'}, \| u \|_K)
\]

It only remains to verify the claim about weak continuity.

Consider now the claim that \(t \to Bu(t)\) is weakly continuous on \(N^C\). Letting \(v \in V, s \in N^C\),

\[
\lim_{t \to s} \langle Bu(t), v \rangle = \langle Bu(s), v \rangle = \langle Bu(s), v \rangle
\]

(31.4.24)

The limit follows from the formula (31.4.24) which implies \(t \to Bu(t)\) is continuous into \(V'\). Now for \(t \in N^C\),

\[
\| Bu(t) \| = \sup_{\| v \| \leq 1} |\langle Bu(t), v \rangle| \leq \langle v, v \rangle^{1/2} \langle Bu(t), u(t) \rangle^{1/2}
\]

which was shown to be bounded for \(t, s \in N^C\). Now let \(w \in W\). Then

\[
|\langle Bu(t), w \rangle - \langle Bu(s), w \rangle| \le |\langle Bu(t) - Bu(s), w - v \rangle| + |\langle Bu(t) - Bu(s), v \rangle|
\]

Then the first term is less than \(\varepsilon\) if \(v\) is close enough to \(w\) and the second converges to 0 so (31.4.24) holds for all \(v \in W\) and so this shows the weak continuity on \(N^C\).
Now pick \( t \in D \), the union of all the mesh points. Then for all \( k \) large enough, \( t \in \mathcal{P}_k \). Say \( t = t_m \). From Lemma \[31.4.4\],

\[
- \sum_{j=0}^{m-1} \langle B(u(t_{j+1}) - u(t_j)), (u(t_{j+1}) - u(t_j)) \rangle =
\]

\[
(Bu(t_m), u(t_m)) - (Bu_0, u_0) - 2 \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u_k^r(r) \rangle \, dr
\]

Thus, \( \langle Bu(t_m), u(t_m) \rangle \) is constant for all \( k \) large enough and the integral term converges to

\[
\int_0^{t_m} \langle Y(r), u(r) \rangle \, dr
\]

It follows that the term on the left does converge to something as \( k \to \infty \). It just remains to consider what it does converge to. However, from the equation solved by \( u \),

\[
Bu(t_{j+1}) - Bu(t_j) = \int_{t_j}^{t_{j+1}} Y(r) \, dr
\]

Therefore, this term is dominated by an expression of the form

\[
\left| \sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(r) \, dr, u(t_{j+1}) - u(t_j) \right) \right|
\]

\[
= \left| \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_{j+1}) - u(t_j) \rangle \, dr \right|
\]

\[
= \left| \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_{j+1}) \rangle - \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_j) \rangle \right|
\]

\[
= \left| \int_0^{t_m} \langle Y(r), u^r(r) \rangle \, dr - \int_0^{t_m} \langle Y(r), u^l(r) \rangle \, dr \right|
\]

\[
\leq \int_0^{t_m} \left| \langle Y(r), u^r(r) - u^l(r) \rangle \right| \, dr
\]

However, both \( u^r \) and \( u^l \) converge to \( u \) in \( K = L^p(0,T,V) \). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \( t \in D \), the desired formula holds. Thus, for such \( t \in D \),

\[
\langle Bu(t), u(t) \rangle = (Bu_0, u_0) + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr
\]
31.4. THE IMPLICIT CASE

It remains to verify that this holds for all \( t \notin N \). Let \( t \in N^C \setminus D \) and let \( t(k) \in \mathcal{P}_k \) be the largest point of \( \mathcal{P}_k \) which is less than \( t \). Suppose \( t(m) \leq t(k) \) so that \( m \leq k \). Then

\[
Bu(t(m)) = Bu_0 + \int_0^{t(m)} Y(s) \, ds,
\]

a similar formula for \( u(t(k)) \). Thus for \( t > t(m) \),

\[
Bu(t) - Bu(t(m)) = \int_{t(m)}^{t} Y(s) \, ds
\]

which is the same sort of thing already looked at except that it starts at \( t(m) \) rather than at 0 and \( u_0 = 0 \). Therefore,

\[
\langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle = 2 \int_{t(m)}^{t(k)} \langle Y(s), u(s) - u(t(m)) \rangle \, ds
\]

Thus, for \( m \leq k \)

\[
\lim_{m,k \to \infty} \langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle = 0 \quad (31.4.25)
\]

Hence \( \{Bu(t(k))\}_{k=1}^{\infty} \) is a convergent sequence in \( W' \) because

\[
|\langle B(u(t(k)) - u(t(m))), y \rangle| \\
\leq \langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle^{1/2} \langle By, y \rangle^{1/2} \\
\leq \langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle^{1/2} \|B\|^2 \|y\|_W
\]

Does it converge to \( Bu(t) \)? Let \( \xi(t) \in W' \) be what it does converge to. Let \( v \in V \). Then

\[
\langle \xi(t), v \rangle = \lim_{k \to \infty} \langle Bu(t(k)), v \rangle = \lim_{k \to \infty} \langle Bu(t(k)), v \rangle = \langle Bu(t), v \rangle
\]

because it is known that \( t \to Bu(t) \) is continuous into \( V' \). It is also known that for \( t \in N^C \), \( Bu(t) \in W' \subseteq V' \) and that the \( Bu(t) \) for \( t \in N^C \) are uniformly bounded in \( W' \). Therefore, since \( V \) is dense in \( W \), it follows that \( \xi(t) = Bu(t) \).

Now for every \( t \in D \), it was shown above that

\[
\langle Bu(t), u(t) \rangle = \langle Bu_0, u_0 \rangle + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr
\]

Also it was just shown that \( Bu(t(k)) \to Bu(t) \) for \( t \notin N \). Then for \( t \notin N \)

\[
|\langle Bu(t(k)), u(t(k)) \rangle - \langle Bu(t), u(t) \rangle| \\
\leq |\langle Bu(t(k)), u(t(k)) - u(t) \rangle| + |\langle Bu(t(k)) - Bu(t), u(t) \rangle|
\]
31.4.25

which converges to 0 as \( t \) so of the right side gives 0 and so the same is true of the left. Hence, From this, it follows that \( t \)

Also recall that \( t \)

Then using the lower semicontinuity of \( t \to \langle B (u (t (k))) - u(t) \rangle, u (t (k)) \rangle - u (t) \rangle \) on \( N^C \) which follows from the above, this is no larger than

provided \( k \) is large enough. This follows from \( \text{(31.28)} \). Since \( \varepsilon \) is arbitrary, it follows that

Then from the formula,

valid for \( t \in D \), it follows that the same formula holds for all \( t \not\in N \). Then define \( \langle Bu, u \rangle(t) \to \langle Bu(t), u(t) \rangle \) off \( N \) and the right side for \( t \in N \). Thus \( t \to \langle Bu, u \rangle(t) \) is continuous and for all \( t \in [0, T] \),

Also recall that \( t \to Bu(t) \) was shown to be weakly continuous into \( W' \) on \( N^C \). Then for \( t, s \in N^C \),

From this, it follows that \( t \to Bu(t) \) is continuous into \( W' \) on \( N^C \) because \( \lim_{t \to s} \) of the right side gives 0 and so the same is true of the left. Hence,

so

which converges to 0 as \( t \to s \).
Consider the case that \( t \to B(u(t)) \) has a weak derivative, denoted as \((Bu)'(t)\) which is in \( L^{p'}(0,T;V')\). Then as shown above, there is a continuous function, denoted as \( Bu(t) \) which equals \( B(u(t)) \) for a.e. \( t \) and

\[
Bu(t) = Bu(0) + \int_0^t (Bu)'(s) \, ds
\]

Then the above theorem applies. Then one obtains the following corollary.

**Corollary 31.4.6** Let \( V \subseteq W, W' \subseteq V' \) be separable Banach spaces, and \( B \in \mathcal{L}(W,W') \) is nonnegative and self adjoint. Also suppose \( t \to B(u(t)) \) has a weak derivative \((Bu)' \in L^{p'}(0,T;V')\) for \( u \in L^p(0,T;V)\). Then there is a continuous function denoted as \( Bu(t) \) which equals \( B(u(t)) \) a.e. \( t \). Say for \( t \notin N \). Suppose \( Bu(0) = Bu_0, \ u_0 \in W \). Then

\[
Bu(t) = Bu_0 + \int_0^t (Bu)'(s) \, ds \text{ in } V'
\]  

(31.4.26)

Then \( t \to Bu(t) \) is in \( C\left(N^c, W'\right) \) and also for such \( t \),

\[
\frac{1}{2} \langle Bu(t) , u(t) \rangle = \frac{1}{2} \langle Bu_0 , u_0 \rangle + \int_0^t \langle (Bu)'(s) , u(s) \rangle \, ds
\]

There exists a continuous function \( t \to \langle Bu, u \rangle(t) \) which equals the right side of the above for all \( t \) and equals \( \langle Bu(t), u(t) \rangle \) off \( N \). This also satisfies

\[
\sup_{t \in [0,T]} \langle Bu, u \rangle(t) \leq C \left( \|Bu\|_{L^p(0,T;V')} , \|u\|_{L^p(0,T;V)} \right)
\]

where we can take the right side to equal

\[
\langle Bu_0, u_0 \rangle + 2 \|Bu\|_{L^{p'}(0,T;V')} \|u\|_{L^p(0,T;V)}
\]

This follows from the above theorem, in particular Lemma \[\text{??}\].

This also makes it easy to verify continuity of pointwise evaluation of \( Bu \). Let \( Lu = (Bu)' \).

\[
u = D(L) = \left\{ u \in L^p(0,T;V) : Lu \equiv (Bu)' \in L^{p'}(0,T,V') \right\}
\]

\[
\|u\|_X = \|u\|_{L^p(0,T;V')} + \|Lu\|_{L^{p'}(0,T;V')}
\]  

(31.4.27)

Since \( L \) is closed, this \( X \) is a Banach space.

Then the following theorem is obtained.

**Theorem 31.4.7** Say \((Bu)' \in L^{p'}(0,T,V')\) so

\[
Bu(t) = Bu(0) + \int_0^t (Bu)'(s) \, ds \text{ in } V'
\]

the map \( u \to Bu(t) \) is continuous as a map from \( X \) to \( V' \). Also, if \( Y \) denotes those \( f \in L^p([0,T];V) \) for which \( f' \in L^p([0,T];V') \), so that \( f \) has a representative such that \( f(t) = f(0) + \int_0^t f'(s) \, ds \), then if \( \|f\|_Y \equiv \|f\|_{L^p([0,T];V)} + \|f'\|_{L^p([0,T];V')} \), the map \( f \to f(t) \) is continuous.
Proof: First, why is $Bu(0)$ continuous? Say $u, v \in X$ and say $p \geq 2$ first.

$$Bu(t) - Bv(t) = Bu(0) - Bv(0) + \int_0^t (Bu)'(s) - (Bv)'(s) \, ds$$

and so,

$$\|Bu(0) - Bv(0)\|_{V'} \leq \|Bu(t) - Bv(t)\|_{V'} + \int_0^t \|(Bu)'(s) - (Bv)'(s)\|_{V'} \, ds$$

then using the triangle inequality,

$$\left( \int_0^T \|Bu(0) - Bv(0)\|_{V'}^{p'} \, dt \right)^{1/p'} \leq \left( \int_0^T \|Bu(t) - Bv(t)\|_{V'}^{p'} \, dt \right)^{1/p'}$$

and so

$$\|Bu(0) - Bv(0)\|_{V'}, T^{1/p'} \leq$$

$$\left( \|B\| \|u - v\|_{L^{p'}([0,T];V')} + T^{1/p'} \|(Bu)' - (Bv)'\|_{L^{p'}([0,T];V')} \right)$$

$$\leq \left( \|B\| \|u - v\|_{L^p([0,T];V)} + T^{1/p'} \|(Bu)' - (Bv)'\|_{L^{p'}([0,T];V')} \right)$$

$$\leq C(\|B\|, T) \|u - v\|_X$$

Thus $u \to Bu(0)$ is continuous into $V'$. If $p < 2$, then you do something similar.
However, one could just as easily have done this for an arbitrary $s < T$ by repeating the argument for

$$Bu(t) = Bu(s) + \int_s^t (Bu)'(r) \, dr$$

Thus this mapping is certainly continuous into $V'$. The last assertion is similar. You just use $f$ instead of $Bu$ and make easy modifications in the argument. It is all happening in one space in the second case. ■

For $u \in X$ defined above,

$$Bu(t) = Bu(0) + \int_0^t (Bu)'(s) \, ds,$$

and also

$$\frac{1}{2} \langle Bu(t), u(t) \rangle = \frac{1}{2} \langle Bu, u \rangle (0) + \int_0^t \langle (Bu)'(s), u(s) \rangle \, ds$$

This follows from a similar argument given above, (Note we write $\langle Bu, u \rangle (0)$ instead of $\langle Bu_0, u_0 \rangle$ since no $u_0$ is mentioned. One could also use the above by considering the problem on $[s, t]$ where $s$ is not in the exceptional set where it makes a difference between writing $Bu(s)$ and $B(u(s))$. Then you would get the above with 0 replaced with $s$ and then let $s \to 0$ to finally obtain the above displayed formula.) and

$$\sup_{t \in [0, T]} \langle Bu, u \rangle (t) \leq C \left( \| (Bu)' \|_{L^p(0, T; V')} \| u \|_{L^p(0, T; V)} \right) = C \| u \|_X$$

where $X$ was defined in 31.4.27, then

$$\sup_{t \in [0, T]} \left\langle B \frac{u}{\| u \|_X}, \frac{u}{\| u \|_X} \right\rangle (t) \leq C \left( 1 \right) = C$$

and so

$$\sup_{t \in [0, T]} \langle Bu, u \rangle (t) \leq C \left\| u \right\|_X^2$$

Now define for $u, v \in X$

$$\langle Bu, v \rangle (t) \equiv \frac{1}{2} \left[ \langle B(u + v), u + v \rangle (t) - \langle Bu, u \rangle (t) - \langle Bv, v \rangle (t) \right]$$

and so for a.e. $t, \langle Bu, v \rangle (t) = \langle B(u(t)), v(t) \rangle$ and $t \to \langle Bu, v \rangle (t)$ is continuous. Also, there must exist $C$ such that for all $u, v$ and $t \in [0, T]$,

$$|\langle Bu, v \rangle (t)| \leq C \| u \|_X \| v \|_X$$

If this is not so, then you could get $u_n, v_n$ having norm equal to 1 in $X$ such that

$$\sup_{t \in [0, T]} |\langle Bu_n, v_n \rangle (t)| > n$$
But then, letting \( t_n \) be a point where \( |\langle Bu_n, v_n \rangle (t_n)| > n, \)
\[
n < |\langle Bu_n, v_n \rangle (t_n)| \leq \frac{1}{2} \left[ C \left( \|u_n + v_n\|_X^2 + \|u\|_X^2 + \|v\|_X^2 \right) \right] = \frac{C}{2} (4 + 1 + 1) = 3C
\]
which is clearly a contradiction. It follows that one can define \( K : X \to X' \) as follows.
\[
\langle Ku, v \rangle = \int_0^T \langle Lu, v \rangle \, ds + \langle Bu, v \rangle (0)
\]
Thus \( K \) is linear and continuous. In addition,
\[
\langle Ku, u \rangle = \frac{1}{2} [\langle Bu, u \rangle (T) + \langle Bu, u \rangle (0)]
\]
To see this, Corollary 31.4.6 implies
\[
\frac{1}{2} \langle Bu, u \rangle (T) = \frac{1}{2} \langle Bu, u \rangle (0) + \int_0^T \langle (Bu)'(s), u(s) \rangle \, ds
\]
and so
\[
\frac{1}{2} \langle Bu, u \rangle (T) + \langle Bu, u \rangle (0) = \frac{1}{2} \langle Bu, u \rangle (0) + \int_0^T \langle (Bu)'(s), u(s) \rangle \, ds + \langle Bu, u \rangle (0)
\]
and so, this yields
\[
\int_0^T \langle (Bu)'(s), u(s) \rangle \, ds + \langle Bu, u \rangle (0) = \langle Ku, u \rangle = \frac{1}{2} [\langle Bu, u \rangle (T) + \langle Bu, u \rangle (0)]
\]
as claimed. This proves most of the following.

**Proposition 31.4.8**  Let
\[
X = \left\{ u \in L^p(0, T; V) \mid V : Lu = (Bu)' \in L^{p'}(0, T, V') \right\}
\]
where \( V \) is a reflexive Banach space. Let a norm on \( X \) be given by
\[
\|u\|_X = \|u\|_V + \|Lu\|_{V'}
\]
Then there is a continuous function \( t \to \langle Bu, v \rangle (t) \) such that \( \langle Bu, v \rangle (t) = \langle B(u(t)), v(t) \rangle \) a.e. \( t \) such that
\[
\sup_{t \in [0, T]} |\langle Bu, v \rangle (t)| \leq C \|u\|_X \|v\|_X
\]
and if \( K : X \to X' \)
\[
\langle Ku, v \rangle = \int_0^T \langle Lu, v \rangle \, ds + \langle Bu, v \rangle (0)
\]
31.5. THE IMPLICIT CASE, $B = B(T)$

Then $K$ is continuous and linear and

$$\langle Ku, u \rangle = \frac{1}{2} [(Bu, u)(T) + \langle Bu, u \rangle(0)]$$

If $u \in X$ and $Bu(0) = 0$ then there exists a sequence $\{u_n\}$ such that $\|u_n - u\|_X \to 0$ but $u_n(t) = 0$ for all $t$ close to 0.

**Proof:** It only remains to verify the last assertion. Let $\psi_n$ be increasing and piecewise linear such that $\psi_n(t) = 1$ for $t \geq 2/n$ and equals 0 on $[0, 1/n]$. Then clearly $\psi_n u \to u$ in $V$.

$$\langle B(\psi_n u)', Bu + \psi_n (Bu)' \rangle$$

The second term converges to $(Bu)'$ in $V'$. It remains to consider the first term.

$$\int_0^T \|\psi'_n Bu\|_{V'}^p \, dt \leq \int_0^{2/n} n \int_0^t \|Bu\|_{V'}^p \, ds \, dt$$

$$\leq n \int_0^{2/n} t^{p'-1} \int_0^t \|Bu\|_{V'}^p \, ds \, dt \leq \int_0^{2/n} \|Bu\|_{V'}^p \, ds \frac{1}{p'} \left(\frac{2}{n}\right)^{p'} n$$

Since $p' > 1$, this converges to 0. ■

Note that, by convolving with a mollifier, we could assume each $u_n$ is also smooth. In addition to this, we can draw a similar conclusion at the right endpoint. That is, if $Bu(T) = 0$ there is a sequence $\{u_n\} \subseteq X$ where $u_n(t) = 0$ for $t$ near $T$ which converges to $u$ in $X$.

31.5 The Implicit Case, $B = B(t)$

The above theorem can be generalized to the case where the formula is of the form

$$BX(t) = BX_0 + \int_0^t Y(s) \, ds$$

This involves an operator $B(t) \in \mathcal{L}(W, W')$ and $B(t)$ satisfies

$$\langle B(t)x, x \rangle \geq 0, \quad \langle B(t)x, y \rangle = \langle B(t)y, x \rangle$$

for

$$V \subseteq W, W' \subseteq V'$$

Where we assume $t \to B(t)$ is in $C^1([0, T]; \mathcal{L}(W, W'))$ and $V$ is dense in the Banach space $W$.

Then the main result in this section is the following integration by parts theorem.
Theorem 31.5.1 Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, and let $Y \in L^p(0, T; V')$ and

$$Bu(t) = Bu_0 + \int_0^t Y(s) \, ds \text{ in } V', \quad u_0 \in W, Bu(t) = B(t)(u(t)) \text{ for a.e. } t$$

(31.5.28)

As indicated, $Bu$ is the name of a function satisfying the above equation which satisfies $Bu(t) = B(t)(u(t))$ for a.e. $t$. Thus $Y = (Bu)'$ as a weak derivative in the sense of $V'$ valued distributions. Suppose that $u \in L^p([0, T], V)$ and $(s, t) \rightarrow B'(s)u(t)$ is bounded in $V'$ in case $p < 2$. (If $B(t)$ is constant in $t$ this is obvious.) In the case where $p \geq 2$, it is enough to assume $B' \in C^1([0, T]; L(W, W'))$. Then $t \rightarrow Bu(t)$ is continuous into $W'$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \rightarrow \langle Bu, u \rangle(t)$ such that for all $t \notin N, \langle Bu, u \rangle(t) = \langle B(u(t)), u(t) \rangle, Bu(t) = B(t)(u(t))$, and for all $t$,

$$\frac{1}{2} \langle Bu, u \rangle(t) + \frac{1}{2} \int_0^t (B'u, u) \, ds = \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle Y(s), u(s) \rangle \, ds$$

Proof: By Lemma 31.5.1 there exists a sequence of partitions $\{t^n_k\}_{k=0}^{m_n} = \mathcal{P}_n, \mathcal{P}_n \subseteq \mathcal{P}_{n+1}$, of $[0, T]$ such that the lengths of the sub intervals converge uniformly to 0 as $n \to \infty$ and the step functions

$$\sum_{k=0}^{m_n-1} u(t^n_k) \chi_{(t^n_k, t^n_{k+1})}(t) = u^l_n(t)$$

$$\sum_{k=0}^{m_n-1} u(t^n_k) \chi_{(t^n_k, t^n_{k+1})}(t) = u^r_n(t)$$

converge to $u$ in $L^p(0, T; V) = K$. We assume that all of these partition points have empty intersection with the set of measure zero where $Bu(t) \neq B(t)(u(t))$. Thus, at every partition point, $Bu(t_k) = B(t_k)(u(t_k))$. As just mentioned, $L^p(0, T; V) = K, L^{p'}(0, T; V') = K'$. Taking a subsequence, we can have

$$\left\|u^l_n - u\right\|_K + \left\|u^r_n - u\right\|_K + \left\|Bu^l_n - Bu\right\|_{K'} + \left\|Bu^r_n - Bu\right\|_{K'}$$

$$+ \left\|B'u^l_n - B'u\right\|_{L^2([0, T], W')} + \left\|B'u^r_n - B'u\right\|_{L^2([0, T], W')} < 2^{-n}$$

(31.5.29)

and so, we can assume that a.e. convergence also takes place for $Bu^l_n, Bu^r_n, B'u^l_n, B'u^r_n, u^l_n, u^r_n$.

Is $Bu(0) = B(0)u_0$? The integral equation gives this it seems. To save notation, $B(0)u_0$ will be written as $Bu_0$. This is not inconsistent because $t \rightarrow B(t)u_0$ is continuous and its value at 0 is $B(0)u_0$.

Lemma 31.5.2 Let $s < t$. Then for $u, Y$ satisfying

$$\langle Bu(t), u(t) \rangle - \langle Bu(s), u(s) \rangle + \langle (B(t) - B(s))u(s), u(t) \rangle$$

31.5. THE IMPLICIT CASE, $B = B(T)$

\[+ \langle (B(t) - B(s))u(s) \rangle , u(t) - u(s) \rangle = 2 \int_s^t \langle Y(r) , u(t) \rangle \, dr \]
\[- \langle B(t)u(t) - B(t)u(s) , u(t) - u(s) \rangle \]

**Proof:** It follows from the following computations

\[B(t)u(t) - B(s)u(s) = \int_s^t Y(r) \, dr \]

and so

\[2 \int_s^t \langle Y(r) , u(t) \rangle \, dr - \langle B(t)u(t) - B(s)u(s) , u(t) - u(s) \rangle \]
\[= 2 \left( \int_s^t Y(r) \, dr , u(t) \right) - \langle B(t)u(t) - B(s)u(s) , u(t) - u(s) \rangle \]
\[= 2 \langle B(t)u(t) , u(t) \rangle - \langle B(s)u(s) , u(s) \rangle + \langle B(t)u(t) , u(s) \rangle - \langle B(s)u(s) , u(s) \rangle \]
\[= \langle B(t)u(t) , u(t) \rangle - \langle B(s)u(s) , u(s) \rangle \]
\[+ \langle \langle B(t) - B(s) \rangle u(s) , u(t) \rangle \]

Thus

\[\langle Bu(t) , u(t) \rangle - \langle Bu(s) , u(s) \rangle + (\langle B(t) - B(s) \rangle u(s) , u(t)) \]
\[= 2 \int_s^t \langle Y(r) , u(t) \rangle \, dr - \langle B(t)u(t) - B(s)u(s) , u(t) - u(s) \rangle \]

Now consider the last term. It equals

\[\langle B(t)u(t) - (B(s)^2 - B(t)^2 + B(t))u(s) , u(t) - u(s) \rangle \]
\[= \langle B(t)u(t) - (B(s)^2 - B(t)^2)u(s) + B(t)u(s) , u(t) - u(s) \rangle \]
\[= \langle B(t)u(t) - B(t)u(s) , u(t) - u(s) \rangle + \langle (B(t) - B(s))u(s) , u(t) - u(s) \rangle \]

It follows that

\[\langle Bu(t) , u(t) \rangle - \langle Bu(s) , u(s) \rangle + (\langle B(t) - B(s) \rangle u(s) , u(t)) \]
\[+ \langle (B(t) - B(s))u(s) , u(t) - u(s) \rangle \]
\[\int_s^t \langle Y(r), u(t) \rangle \, dr - \langle B(t) \, u(t) - B(t) \, u(s), u(t) - u(s) \rangle \]

Of course this computation is under the assumption that neither \(s, t\) are in the exceptional set of which \(B(t) \, u(t) = B(u(t))\). In case \(s = 0\) the same formula holds except you need to replace \(u(s)\) with \(u_0\) and \(B(u(s))\) with \(B(0) \, u(0) = B(0)\).

It is good to emphasize part of the above.

\[\langle B(t) \, u(t) - B(s) \, u(s), u(t) - u(s) \rangle - \langle B(t) \, u(t) - B(s) \, u(s), u(t) - u(s) \rangle = \langle (B(s) - B(t)) \, u(s), u(t) - u(s) \rangle\]

**Lemma 31.5.3** Let the partitions \(P_k\) be as above such that \(31.5.29, P_k = \{t^k_j\}_{j=0}^{m_k}\). Then for any \(m \leq m_k\),

\[\sum_{j=0}^{m-1} \langle B(t^k_{j+1}) \, u(t^k_j) - B(t^k_{j+1}) \, u(t^k_j), u(t^k_{j+1}) - u(t^k_j) \rangle - \sum_{j=0}^{m-1} \langle B(t^k_{j+1}) \, u(t^k_j) - B(t^k_{j+1}) \, u(t^k_j), u(t^k_{j+1}) - u(t^k_j) \rangle = \varepsilon^m(k)\]

where \(\lim_{k \to \infty} \varepsilon^m(k) = 0\). Here

\[\varepsilon^m(k) = \sum_{j=0}^{m-1} \langle (B(t^k_j) - B(t^k_{j+1})) \, u(t^k_j), u(t^k_{j+1}) - u(t^k_j) \rangle\]

**Proof:** From the above lemma, the absolute value of the left side is no larger than

\[\sum_{j=0}^{m-1} |\langle (B(t^k_j) - B(t^k_{j+1})) \, u(t^k_j), u(t^k_{j+1}) - u(t^k_j) \rangle|\]

\[\leq \sum_{j=0}^{m-1} \int_{t^k_j}^{t^k_{j+1}} \|B'(\tau) \, u(t^k_j)\|_W, d\tau \|u(t^k_{j+1}) - u(t^k_j)\|_W\]  \hspace{1cm} (31.5.31)
31.5. THE IMPLICIT CASE, $B = B(T)$

In case $p \geq 2$ then for $C \geq \max_s \|B'(s)\|_{L(W,W')}$, 

\[
\begin{align*}
&\leq C \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \|u^l(\tau)\|_W \|u_k^r(\tau) - u_k^l(\tau)\|_W d\tau \\
&= C \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \mathcal{X}_{[t_j^t, t_{j+1}]}(\tau) \|u_k^l(\tau)\|_W \|u_k^r(\tau) - u_k^l(\tau)\|_W d\tau \\
&= C \int_{0}^{t_m} \sum_{j=0}^{m-1} \mathcal{X}_{[t_j^t, t_{j+1}]}(\tau) \|u_k^l(\tau)\|_W \|u_k^r(\tau) - u_k^l(\tau)\|_W d\tau \\
&\leq C \left\|u_k^l\right\|_{L^p([0,T],V)} \left\|u_k^r(\tau) - u_k^l(\tau)\right\|_{L^p([0,T],V)} \\
&\leq \hat{C} (2)^{-k}
\end{align*}
\]

by [Lemma 31.5.4]. In case $p < 2$, then from assumption and [Lemma 31.5.4], the absolute value of the left side is no larger than

\[
\begin{align*}
&\sum_{j=0}^{m-1} C \left( t_{j+1}^k - t_j^k \right) \|u(t_{j+1}) - u(t_j)\|_W \\
&= C \sum_{j=0}^{m-1} \int_{t_j}^{t_k} \mathcal{X}_{[t_j^t, t_{j+1}]}(s) \|u_k^r(s) - u_k^l(s)\|_W \\
&= C \int_{0}^{t_m} \|u_k^r(s) - u_k^l(s)\|_W
\end{align*}
\]

which converges to 0 as $k \to \infty$ thanks to [Lemma 31.5.4].

Lemma 31.5.4 In the above situation,

\[
\sup_{t \in N^c} \langle Bu(t) , u(t) \rangle + \int_0^T \langle B'u , u \rangle \, ds \leq C \left( \|Y\|_{K'} , \|u\|_K \right)
\]

Also, $t \to Bu(t)$ is weakly continuous with values in $W'$ on $N^c$ where $N$ is a set of measure zero including the set where $Bu(t) \neq B(t)(u(t))$.

Proof: From the above formula of Lemma 31.5.4 applied to the $k^{th}$ partition of $[0,T]$ described above,

\[
\langle Bu(t_m), u(t_m) \rangle - \langle Bu_0, u_0 \rangle + \sum_{j=0}^{m-1} \langle (B(t_{j+1}) - B(t_j)) u(t_j), u(t_{j+1}) \rangle \\
+ \sum_{j=0}^{m-1} \langle (B(t_{j+1}) - B(t_j)) u(t_j), u(t_{j+1}) - u(t_j) \rangle
\]
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y (r) , u (t_{j+1}) \rangle dr - \langle B (t_{j+1}) u (t_{j+1}) - B (t_j) u (t_j) , u (t_{j+1}) - u (t_j) \rangle 

(31.5.32)

Consider the third term on the left,

\[ \sum_{j=0}^{m-1} \langle (B (t_{j+1}^n) - B (t_j^n)) u (t_j^n) , u (t_{j+1}^n) \rangle \]

\[ = \int_0^{t_m} \left\langle \sum_{j=0}^{m-1} \mathcal{X}_{(t_j^n, t_{j+1}^n)} (t) \frac{B (t_{j+1}^n) - B (t_j^n)}{t_{j+1}^n - t_j^n} u_j^n (t) , u_j^n (t) \right\rangle dt \]

Using a simple approximate identity argument and the assumption that \( t \to B (t) \) is in \( C^1 ([0, T] , \mathcal{L} (W, W')) \),

\[ \sum_{j=0}^{m-1} \mathcal{X}_{(t_j^n, t_{j+1}^n)} (t) \frac{B (t_{j+1}^n) - B (t_j^n)}{t_{j+1}^n - t_j^n} \to B' (t) \]

uniformly on \( (0, T] \). Then \( \sum_{j=0}^{m-1} \mathcal{X}_{(t_j^n, t_{j+1}^n)} (t) \frac{B (t_{j+1}^n) - B (t_j^n)}{t_{j+1}^n - t_j^n} u_j^n \to B' u \) strongly in \( L^2 ([0, T] , W') \) while \( u_j^n \to u \) strongly in \( L^2 ([0, T] ; W) \). It follows that the third term on the left in (31.5.33)

\[ \varepsilon (k) + 2 \int_0^T \langle B' u , u \rangle ds , \varepsilon (k) \to 0. \]

whenever \( n \) is sufficiently large. Also, \( T \) could be replaced with \( t_j \) for any of the mesh points.

Next consider the term labelled *. From Lemma \[\text{(31.5.33)}\], it is of the form \( \varepsilon^m (k) \) where \( \lim_{k \to \infty} \varepsilon^m (k) = 0 \). Thus (31.5.33) reduces to

\[ \langle B u (t_m) , u (t_m) \rangle - \langle B u_0 , u_0 \rangle + \int_0^{t_m} \langle B' u , u \rangle ds = \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y (r) , u_k^r (r) \rangle dr 

- \sum_{j=0}^{m-1} \langle B (t_{j+1}) u (t_{j+1}) - B (t_j) u (t_j) , u (t_{j+1}) - u (t_j) \rangle + \varepsilon (k) \]

(31.5.33)

where \( t_m \in \mathcal{P}_k \).

Thus, discarding the negative terms which occur at the end and denoting by \( \mathcal{P}_k \) the \( k \)th of these partitions,

\[ \sup_{t_j \in \mathcal{P}_k} \langle B u (t_j) , u (t_j) \rangle + \int_0^T \langle B' u , u \rangle ds \leq \langle B u_0 , u_0 \rangle + 2 \int_0^T \langle Y (r) , u_k^r (r) \rangle dr + \varepsilon 

\leq \langle B u_0 , u_0 \rangle + 2 \int_0^T \| Y (r) \|_{\mathcal{V}'} \| u_k^r (r) \|_{\mathcal{V}} dr + \varepsilon \]
31.5. THE IMPLICIT CASE, $B = B(T)$

\[
\leq \langle Bu_0, u_0 \rangle + 2 \left( \int_0^T \| Y(r) \|_{V'}^p \, dr \right)^{1/p'} \left( \int_0^T \| u_K^r(r) \|_{V'}^p \, dr \right)^{1/p} + \varepsilon
\]
\[
\leq C \left( \| Y \|_{K'}, \| u \|_K \right) + \varepsilon
\]

whenever $k$ is large enough because these partitions are chosen such that

\[
\lim_{k \to \infty} \left( \int_0^T \| u_K^r(r) \|_{V'}^p \, dr \right)^{1/p} = \left( \int_0^T \| u(r) \|_{V'}^p \, dr \right)^{1/p}
\]

and so these are bounded. This has shown that for the dense subset of $[0, T]$, $D \equiv \bigcup_k F_k$,

\[
\sup_{t \in D} \langle B(t) u(t), u(t) \rangle + \int_0^T \langle B'u, u \rangle \, ds < C \left( \| Y \|_{K'}, \| u \|_K \right) + \varepsilon
\]

However, $\varepsilon$ was arbitrary and the partitions are nested. Hence the above holds for all $\varepsilon$ and so

\[
\sup_{t \in D} \langle B(t) u(t), u(t) \rangle + \int_0^T \langle B'u, u \rangle \, ds < C \left( \| Y \|_{K'}, \| u \|_K \right)
\]

By the integral equation, there is a set of measure zero including all the earlier sets of measure zero $N$ such that for $t \notin N$, $u_n^r(t), u_n^r(t) \to u(t)$ pointwise in $V$. Also, $B(t) u_n^r(t) \to Bu(t)$ in $V'$. This last can be obtained from the integral equation solved, $t \to Bu(t)$ is continuous into $V'$. Then let $t \notin N$. We have $u_n^r(t) \to u(t)$ in $V$. Now $B(t) u_n^r(t) = B(t) u(s_n)$ where $s_n \in D$ and $s_n \to t$. Then $Bu(t) = B(t) u(t)$ and

\[
\| B(s_n) u(s_n) - B(t) u(t) \|_{V'} \leq \| (B(s_n) - B(t)) u(s_n) \|_{V'} + \| B(t) (u(s_n) - u(t)) \|_{V'}
\]

\[
\leq C_t \| B(s_n) - B(t) \| + C \| u(s_n) - u(t) \|_{V'}
\]

where $C_t$ is a constant which comes because $u(s_n) \to u(t)$ in $V$ and so is bounded. The constant $C$ is just $\max_{t \in [0, T]} \| B(t) \|$. Then, since the two terms on the right converge to 0 as $n \to \infty$, it follows that as $s_n \to t$, $B(s_n) u(s_n) \to B(t) u(t) = Bu(t)$ in $V'$ while $u(s_n) \to u(t)$ in $V$. It follows that for $t \notin N$,

\[
\langle Bu(t), u(t) \rangle + \int_0^T \langle B'u, u \rangle \, ds = \lim_{n \to \infty} \langle Bu(s_n), u(s_n) \rangle + \int_0^T \langle B'u, u \rangle \, ds \leq C \left( \| Y \|_{K'}, \| u \|_K \right)
\]

Hence,

\[
\sup_{t \notin N} \langle Bu(t), u(t) \rangle + \int_0^T \langle B'u, u \rangle \, ds \leq C \left( \| Y \|_{K'}, \| u \|_K \right)
\]

It only remains to verify the claim about weak continuity.

Consider now the claim that $t \to Bu(t)$ is weakly continuous on $N^C$. Letting $v \in V, s \in N^C$,

\[
\lim_{t \to s} \langle Bu(t), v \rangle = \langle Bu(s), v \rangle = \langle Bu(s), v \rangle
\]
The limit follows from the formula which implies \( t \to Bu(t) \) is continuous into \( V' \). Now for \( t \in N_C \),

\[
\|Bu(t)\|_{V'} = \sup_{\|v\|_{V'} \leq 1} |\langle Bu(t), v \rangle| \leq \langle Bv, v \rangle^{1/2} \langle Bu(t), u(t) \rangle^{1/2}
\]

\[
\leq \left( C \|Y\|_{K'}, \|u\|_K \right) - \int_0^T \langle B'u, u \rangle \, ds
\]

Now let \( w \in W \). Then

\[
|\langle Bu(t), w \rangle - \langle Bu(s), w \rangle| \leq |\langle Bu(t) - Bu(s), w - v \rangle| + |\langle Bu(t) - Bu(s), v \rangle|_{V', V}
\]

Then the first term is less than \( \varepsilon \) if \( v \) is close enough to \( w \) and the second converges to 0 by continuity of \( t \to Bu(t) \) which comes from the integral equation, so holds for all \( v \in W \) and so this shows the weak continuity of \( t \to Bu(t) \) on \( N_C \). ■

Now pick \( t \in D \), the union of all the mesh points. Then for all \( k \) large enough, \( t \in \mathcal{P}_k \). Say \( t = t_m \). From

\[
\langle Bu(t_m), u(t_m) \rangle - \langle Bu_0, u_0 \rangle + \int_0^{t_m} \langle B'u, u \rangle \, ds = \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(r), u^r(r) \rangle \, dr + \varepsilon(k)
\]

\[
- \sum_{j=0}^{m-1} \langle B(t_{j+1}) u(t_{j+1}) - B(t_j) u(t_j), u(t_{j+1}) - u(t_j) \rangle \tag{31.5.35}
\]

where \( \varepsilon(k) \to 0 \). By Lemma you can modify \( \varepsilon(k) \) and write this in the form

\[
\langle Bu(t_m), u(t_m) \rangle - \langle Bu_0, u_0 \rangle + \int_0^{t_m} \langle B'u, u \rangle \, ds = \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(r), u^r(r) \rangle \, dr + \varepsilon(k)
\]

\[
- \sum_{j=0}^{m-1} \langle B(t_{j+1}) u(t_{j+1}) - B(t_j) u(t_j), u(t_{j+1}) - u(t_j) \rangle \tag{31.5.36}
\]

Thus, \( \langle Bu(t_m), u(t_m) \rangle \) is constant for all \( k \) large enough and the integral term on the right converges as \( k \to \infty \) to

\[
\int_0^{t_m} \langle Y(r), u(r) \rangle \, dr
\]

It follows that the last term on the right does converge to something as \( k \to \infty \). It just remains to consider what it does converge to. However, from the equation solved by \( u \),

\[
Bu(t_{j+1}) - Bu(t_j) = \int_{t_j}^{t_{j+1}} Y(r) \, dr
\]
The implicit case, $B = B(T)$

Therefore, this term is dominated by an expression of the form

$$\left| \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} Y(r) \, dr, u(t_{j+1}) - u(t_j) \right|$$

$$= \left| \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_{j+1}) - u(t_j) \rangle \, dr \right|$$

$$= \left| \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_{j+1}) \rangle - \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(r), u(t_j) \rangle \right|$$

$$= \int_0^{t_m} \langle Y(r), u^+(r) \rangle \, dr - \int_0^{t_m} \langle Y(r), u^+(r) \rangle \, dr$$

$$\leq \int_0^T \left| \langle Y(r), u^+(r) - u^+(r) \rangle \right| \, dr$$

However, both $u^+$ and $u^-$ converge to $u$ in $K = L^p(0,T,V)$. Therefore, this term must converge to 0. Passing to a limit, it follows that for all $t \in D$, the desired formula holds. Thus, for such $t \in D$,

$$\langle Bu(t), u(t) \rangle + \int_0^t \langle B'u, u \rangle \, dr = \langle Bu_0, u_0 \rangle + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr$$

It remains to verify that this holds for all $t \notin N$. Let $t \in N^C \setminus D$ and let $t(k) \in \mathcal{P}_k$ be the largest point of $\mathcal{P}_k$ which is less than $t$. Suppose $t(m) \leq t(k)$ so that $m \leq k$. Then

$$Bu(t(m)) = Bu_0 + \int_0^{t(m)} Y(s) \, ds,$$

a similar formula for $u(t(k))$. Thus for $t > t(m)$,

$$Bu(t) - Bu(t(m)) = \int_{t(m)}^t Y(s) \, ds$$

which is the same sort of thing already looked at except that it starts at $t(m)$ rather than at 0 and $u_0 = 0$. Therefore,

$$\langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle$$

$$+ \int_{t(m)}^{t(k)} \langle B'(s)(u(s) - u(t(m))), u(s) - u(t(m)) \rangle$$

$$= 2 \int_{t(m)}^{t(k)} \langle Y(s), u(s) - u(t(m)) \rangle \, ds$$
Thus, for \( m \leq k \)
\[
\lim_{m,k \to \infty} \langle B(u(t(k)) - u(t(m))), u(t(k)) - u(t(m)) \rangle = 0 \quad (31.5.37)
\]

Hence \( \{Bu(t(k))\}_{k=1}^{\infty} \) is a convergent sequence in \( W' \) because
\[
\begin{align*}
|\langle B(u(t(k)) - u(t(m))), \gamma \rangle| & \leq \langle B(\gamma(t(k))) - u(t(m))), u(t(k)) - u(t(m))\rangle^{1/2} \langle By, y \rangle^{1/2} \\
& \leq \langle B(\gamma(t(k))) - u(t(m))), u(t(k)) - u(t(m))\rangle^{1/2} \|B\|^2 \|y\|_W
\end{align*}
\]

Does it converge to \( Bu(t) \)? Let \( \xi(t) \in W' \) be what it does converge to. Let \( v \in V \).

Then
\[
\langle \xi(t), v \rangle = \lim_{k \to \infty} \langle Bu(t(k)), v \rangle = \lim_{k \to \infty} \langle Bu(t(k)), v \rangle = \langle Bu(t), v \rangle
\]

because it is known that \( t \to Bu(t) \) is continuous into \( V' \). It is also known that for \( t \in NC, Bu(t) \in W' \subseteq V' \) and that the \( Bu(t) \) for \( t \in NC \) are uniformly bounded in \( W' \). Therefore, since \( V \) is dense in \( W \), it follows that \( \xi(t) = Bu(t) \).

Now for every \( t \in D \), it was shown above that
\[
\langle Bu(t), u(t) \rangle + \int_0^t \langle B'u, u \rangle \, dr = \langle Bu_0, u_0 \rangle + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr
\]

Also it was just shown that \( Bu(t(k)) \to Bu(t) \) for \( t \notin N \). Then for \( t \notin N \)
\[
\begin{align*}
|\langle Bu(t(k)), u(t(k)) \rangle - \langle Bu(t), u(t) \rangle| & \leq \|Bu(t(k)) - Bu(t)\| \|u(t(k)) - u(t)\| \\
& \leq \|Bu(t(k)) - Bu(t)\| \|u(t(k)) - u(t)\|^{1/2} \langle Bu(t(k)), u(t(k)) \rangle^{1/2}
\end{align*}
\]

Then the second term converges to 0. The first equals
\[
\begin{align*}
|\langle B(t(k)) u(t(k)) - B(t(k)) u(t), u(t(k)) \rangle| & \leq \|B(t(k)) u(t(k)) - u(t)\| \|u(t(k)) - u(t)\|^{1/2} \langle Bu(t(k)), u(t(k)) \rangle^{1/2}
\end{align*}
\]

From the above, this is dominated by an expression of the form
\[
\langle B(t(k)) u(t(k)) - u(t), u(t(k)) - u(t)\rangle^{1/2} C
\]

Then from the choice of \( N \) and the pointwise convergence of \( u_n^* \) to \( u \) off \( N \) the above converges to 0 for each \( t \notin N \). It follows that
\[
\lim_{k \to \infty} |\langle Bu(t(k)), u(t(k)) \rangle - \langle Bu(t), u(t) \rangle| = 0
\]

Then from the formula,
\[
\langle Bu(t), u(t) \rangle = \langle Bu_0, u_0 \rangle + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr - \int_0^t \langle B'u, u \rangle \, dr
\]
31.5. THE IMPLICIT CASE, $B = B(T)$

valid for $t \in D$, it follows that the same formula holds for all $t \notin N$. Then define $\langle Bu, u \rangle (t)$ to equal $\langle Bu(t), u(t) \rangle$ off $N$ and the right side for $t \in N$. Thus $t \to \langle Bu, u \rangle (t)$ is continuous and for all $t \in [0, T]$,

$$\langle Bu, u \rangle (t) = \langle Bu_0, u_0 \rangle + 2 \int_0^t \langle Y(r), u(r) \rangle \, dr - \int_0^t \langle B'u, u \rangle \, dr$$

Also recall that $t \to B(t)u(t)$ was shown to be weakly continuous into $W'$ on $N_C$. Is it continuous on $N_C$? Suppose $t \in N_C$ and let $s_n \to t$ where $s_n \in D$. Then $u(s_n) = u_{m_n}^n(t)$ because $s_n$ is one of the mesh points. Since $s_n \to t$ one can assume that $m_n \to \infty$. Hence $u(s_n) = u_{m_n}^n(t) \to u(t)$ by the pointwise convergence implied by \( s \in N \). Then obviously

$$B(s_n)u(s_n) = B(s_n)u_{m_n}^n(t) \to B(t)u(t)$$

Now suppose you just have $t_n \to t$ where each of $t_n, t$ are in $N_C$. Does it always follow that $B(t_n)u(t_n) \to B(t)u(t)$? Suppose not. Then there exists such a sequence $t_n \to t$ of points in $N_C$ and $\varepsilon > 0$ such that

$$\|B(t_n)u(t_n) - B(t)u(t)\| \geq \varepsilon$$

However, from the density of $D$ and what was just shown, there exists $s_n \in D$ such that $|s_n - t_n| < \frac{1}{2^n}$ and

$$\|B(s_n)u(s_n) - B(t_n)u(t_n)\| < \frac{1}{2^n}$$

Then

$$\varepsilon \leq \|B(t_n)u(t_n) - B(s_n)u(s_n)\| + \|B(s_n)u(s_n) - B(t)u(t)\| < \frac{1}{2^n} + \|B(s_n)u(s_n) - B(t)u(t)\|$$

Since $s_n \to t$, what was just shown implies both terms on the right converge to 0. This is a contradiction. Thus $t \to B(t)u(t)$ must be continuous on $N_C$ into $W'$. ■

Consider the case that $t \to B(u(t))$ has a weak derivative, denoted as $(Bu)'(t)$ which is in $L^{p'}(0,T;V')$. Then as shown above, there is a continuous function, denoted as $Bu(t)$ which equals $B(t)(u(t))$ for a.e. $t$ and

$$Bu(t) = Bu(0) + \int_0^t (Bu)'(s) \, ds$$

Then the above theorem applies. Then one obtains the following corollary.

**Corollary 31.5.5** Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, and $B(t) \in L(W, W')$ is nonnegative and self adjoint, $B \in C^1([0,T]; W')$. Also suppose $t \to B(u(t))$ has a weak derivative $(Bu)' \in L^{p'}(0,T;V')$ for $u \in L^p([0,T]; V) \cap L^2([0,T]; W)$. 

Then there is a continuous function denoted as $B_u(t)$ which equals $B(t)(u(t))$ a.e. $t$. Say for $t \notin N$. Suppose $B_u(0) = B_{u_0}$, $u_0 \in W$. Then

$$B_u(t) = B_{u_0} + \int_0^t (B_u)'(s) \, ds \text{ in } V' \quad (31.5.38)$$

Then $t \to B_u(t)$ is in $C(N^C, W')$ and also for such $t$,

$$\frac{1}{2} \langle B_u(t), u(t) \rangle + \frac{1}{2} \int_0^t (B'(s) u(s), u(s)) \, ds = \frac{1}{2} \langle B_{u_0}, u_0 \rangle + \int_0^t \langle (B_u)'(s), u(s) \rangle \, ds$$

There exists a continuous function $t \to \langle B_u, u \rangle(t)$ which equals the right side of the above for all $t$ and equals $\langle B(t)u(t), u(t) \rangle$ off $N$. This satisfies

$$\sup_{t \in [0,T]} \langle B_u, u \rangle(t) \leq C(\|Y\|_{K'}, \|u\|_K)$$

In particular, this last inequality follows from Lemma 31.9.4 and the assumption that $B'$ is bounded.

Note how if everything is nice and smooth, this integration by parts formula is what you would be expected to get. To see this, assume $u$ is smooth and formally work on the right side.

$$\frac{d}{dt} \langle B_u, u \rangle = \langle (B_u)', u \rangle + \langle B_u, u' \rangle$$

$$= \langle (B_u)', u \rangle + \langle B_u', u \rangle$$

$$= 2 \langle (B_u)', u \rangle - \langle B'u, u \rangle$$

Thus

$$\frac{1}{2} \langle B_{u_0}, u_0 \rangle + \frac{1}{2} \int_0^t \langle (B_u)'(s), u(s) \rangle \, ds$$

$$= \frac{1}{2} \langle B_{u_0}, u_0 \rangle + \frac{1}{2} \left[ \int_0^t \frac{d}{ds} \langle B_u, u \rangle \, ds + \int_0^t \langle B'u, u \rangle \, ds \right]$$

$$= \frac{1}{2} \langle B_u(t), u(t) \rangle + \frac{1}{2} \int_0^t \langle B'u, u \rangle \, ds$$

which equals the left side.

A related topic is the continuity of pointwise evaluation of $B_u$. Let $Lu = (B_u)'$.

$$u = D(L) \equiv \left\{ u \in L^p(0,T; V) : Lu \in L^{p'}(0,T; V') \right\}$$

$$\|u\|_X = \|u\|_{L^p(0,T; V)} + \|Lu\|_{L^{p'}(0,T; V')}$$

Since $L$ is closed, this $X$ is a Banach space. Then the following theorem is obtained.
Theorem 31.5.6 In the above corollary, the map \( u \rightarrow Bu(t) \) is continuous as a map from \( X \) to \( V' \). Also if \( Y \) denotes those \( f \in L^p([0,T];V) \) for which \( f \) has a representative such that \( f(t) = f(0) + \int_0^t f'(s) \, ds \), then if \( \|f\|_Y = \|f\|_{L^p([0,T];V)} + \|f'\|_{L^p([0,T];V')} \) the map \( f \rightarrow f(t) \) is continuous.

**Proof:** First, why is \( u \rightarrow Bu(0) \) continuous? Say \( u;v \in X \) and say \( p^2 \). Then

\[
Bu(t) - Bv(t) = Bu(0) - Bv(0) + \int_0^t (Bu)'(s) - (Bv)'(s) \, ds
\]

and so,

\[
\left( \int_0^T \|Bu(0) - Bv(0)\|_{V'}^{p'} \, dt \right)^{1/p'} \leq \left( \int_0^T \|Bu(t) - Bv(t)\|_{V'}^{p'} \, dt \right)^{1/p'}
\]

and so

\[
\|Bu(0) - Bv(0)\|_{V', T^{1/p'}} \leq \left( \|B\| \|u - v\|_{L^{p'}([0,T];V')} + T^{1/p'} \| (Bu)' - (Bv)' \|_{L^{p'}([0,T];V')} \right)
\]

\[
\leq C (\|B\|,T) \|u - v\|_X.
\]

Thus \( u \rightarrow Bu(0) \) is continuous into \( V' \). If \( p < 2 \), then you do something similar.

\[
\left( \int_0^T \|Bu(0) - Bv(0)\|_{V'}^p \, dt \right)^{1/p} \leq \left( \int_0^T \|Bu(t) - Bv(t)\|_{V'}^p \, dt \right)^{1/p}
\]

\[
\|Bu(0) - Bv(0)\|_{V', T^{1/p}} \leq \|B\| \|u - v\|_{L^p} + C (T) \| (Bu)' - (Bv)' \|_{L^{p'}([0,T];V')} \leq C (\|B\|,T) \|u - v\|_X.
\]

However, one could just as easily have done this for an arbitrary \( s < T \) by repeating the argument for

\[
Bu(t) = Bu(s) + \int_s^t (Bu)'(r) \, dr
\]

Thus this mapping is certainly continuous into \( V' \). The last assertion is similar. $$\blacksquare$$
31.6 Another Approach

The above approach is pretty interesting, but there is a quicker way to do it discussed in this section. I am also including the case where the operator $B$ is actually a function of $t$. I have never had a reason to use this level of generality, but it is here if it is of any interest. Also, this is presented in the context of complex Banach spaces. In addition, it is shown that by including $i$ in various formulas, you don’t need to have $V$ dense in $W$. Of course, this is typically not of any interest, but for the sake of generality, it is included. The approach is due to Lions. It is assumed for convenience that $p \geq 2$. This was apparently not needed in the last section. It may be that this approach can also be generalized to not require this.

Let $B(t) \in \mathcal{L}(W,W')$ satisfy

\[
\langle B(t)u,v \rangle = \langle B(t)v,u \rangle, \quad u,v \in W
\]

(31.6.39)

\[
\langle B(t)u,u \rangle \geq 0
\]

(31.6.40)

\[
B(t) = B(0) + \int_0^t B'(s) \, ds
\]

(31.6.41)

where $B' \in L^\infty(0,T;\mathcal{L}(W,W'))$. Here $W$ is a Banach space such that $V \subseteq W$. Also $V_I \equiv L^p(I;V)$ and $W_I \equiv L^2(I;W)$.

Now let $I = [a,b]$ and $c < a < b < d$. Here and in what follows $\phi_n(t) = n\phi(nt)$ where $\phi \geq 0$, $\phi \in C_0^\infty(-1,1)$, and $\int \phi \, dt = 1$. The following proposition is known and the essential features of its proof may be found in [83]. We give a proof for the convenience of the reader.

**Proposition 31.6.1** Suppose $D(t) \in \mathcal{L}(W,W')$ and $D(t) = 0$ if $t \notin (c,d)$. Suppose also that

\[
D(t) = \int_c^t D'(s) \, ds, \quad D' \in L^\infty(c,d;\mathcal{L}(W,W')).
\]

For $u \in W_I$ and $a - n^{-1} > c$, $b + n^{-1} < d$, define

\[
T_n u = (D(u \ast \phi_n))' - ((Du) \ast \phi_n)'
\]

(31.6.42)

where we let $u = 0$ off $I$. Then

\[
\|T_n u\|_{W_I'} \to 0
\]

(31.6.43)

**Proof:** First, we show that $\|T_n\|$ is uniformly bounded. Letting $w = 0$ off $I$,

\[
|\langle T_n u, w \rangle| = \left| \int \langle D'(t) \int u(s) \phi_n(t-s) \, ds, w(t) \rangle \, dt \right|
\]

\[
+ \left| \int \langle (D(t) - D(s)) u(s) \phi_n'(t-s) \, ds, w(t) \rangle \, dt \right|
\]

\[
\leq C \|u\|_{W_I} \|w\|_{W_I} + \int \|D(t) - D(s)\| \|u(s)\| n^2 |\phi'(n(t-s))| \|w(t)\| \, ds \, dt
\]
31.6. ANOTHER APPROACH

\[
\leq C \|u\|_{W_1} \|w\|_{W_j} + \\
\int_{\mathbb{R}} \int_{t_n}^{t_n+1} \left| D(t) - D\left(t - \frac{r}{n}\right) \right| \|u\left(t - \frac{r}{n}\right)\| n^2 |\phi'(r)| \|w(t)\| \frac{1}{n} dr dt
\]

\[
\leq C \|u\|_{W_1} \|w\|_{W_j} + C \int_{t_n}^{t_n+1} \left| u\left(t - \frac{r}{n}\right) \right| \|w'(t)\|_W dr dr
\]

\[
\leq C \|u\|_{W_1} \|w\|_{W_j}.
\]

Where \(C\) is a positive constant independent of \(n\) and \(u\). Thus \(\|T_n\|\) is bounded independent of \(n\).

Next let \(u \in C_0^\infty(I; V)\), a dense subset of \(W_1\). Then a little computation shows

\[
\langle T_n u, w \rangle_{W_1} \leq C(\phi) \int_a^b \int_{t_n}^{t_n+1} \left| D' (t) - D\left(t - \frac{r}{n}\right) \right| \|u\left(t - \frac{r}{n}\right)\| \|w(t)\|_W dr dt
\]

\[
+C(\phi) \int_a^b \int_{t_n}^{t_n+1} \left| D (t) - D\left(t - \frac{r}{n}\right) \right| \|u'\left(t - \frac{r}{n}\right)\| \|w(t)\|_W dr dt
\]

\[
= A + B.
\]

Now

\[
B \leq C(\phi, D') n^{-1/2} \|u''\|_{W_1} \|w\|_{W_j}.
\]

Since \(u\) is bounded,

\[
A \leq C(\phi, u) \int_a^b \int_{t_n}^{t_n+1} \left| D' (t) - D\left(t - \frac{r}{n}\right) \right| \|w(t)\|_W dr dt
\]

\[
\leq C(\phi, u) \int_a^b \|w(t)\|_W n \int_{t_n}^{t+n-1} \|D' (t) - D' (s)\| ds dt
\]

By Holder’s inequality, this is no larger than

\[
C(\phi, u) \left( \int_a^b (n \int_{t_n}^{t+n-1} \|D' (t) - D' (s)\| ds)^2 dt \right)^{1/2} \|w\|_{W_1}.
\]

If \(t\) is a Lebesgue point,

\[
n \int_{t_n}^{t+n-1} \|D' (t) - D' (s)\| ds \to 0
\]

and also

\[
n \int_{t_n}^{t+n-1} \|D' (t) - D' (s)\| ds \leq 4 \|D'\|_\infty
\]
so the dominated convergence theorem implies

\[
\int_a^b \left( n \int_{t-n}^{t+n-1} \left\| D'(t) - D'(s) \right\|^2 ds \right) dt \to 0.
\]

Hence

\[
\| T_n u \|_{W'_I} \leq C(\phi, u, D') \left( n^{-1/2} + \left( \int_a^b \left( n \int_{t-n}^{t+n-1} \left\| D'(t) - D'(s) \right\|^2 ds \right) dt \right)^{1/2} \right)
\]

and so \( T_n u \to 0 \) for all \( u \) in the dense subset, \( C_0^\infty(I; V) \).

We have also the following simple corollary.

**Corollary 31.6.2** In the situation of Proposition 31.6.1,

\[
\left\| (i^*D(u \ast \phi_n))' - ((i^*Du) \ast \phi_n)' \right\|_{W'_I} \to 0
\]

where \( i \) is the inclusion map of \( V \) into \( W \).

For \( f \in L^1(a,b; V') \) we define \( f' \) in the sense of \( V' \) valued distributions as follows. For \( \phi \in C_0^\infty(a,b) \),

\[
f'(\phi) \equiv - \int_a^b f(t) \phi'(t) dt.
\]

We say \( f' \in L^1(a,b; V') \) if there exists \( g \in L^1(a,b; V') \), necessarily unique, such that for all \( \phi \in C_0^\infty(a,b) \),

\[
\int_a^b g(t) \phi(t) dt = f'(\phi).
\]

To save on notation, we let \( V \equiv V_{[0,T]} \) and \( W \equiv W_{[0,T]} \). Define

\[
D(L) \equiv \{ u \in V : (i^*Bu)' \in V' \}, \quad (31.6.44)
\]

\[
Lu \equiv (i^*Bu)' \text{ for } u \in D(L). \quad (31.6.45)
\]

Note that for \( u \in D(L) \), it is automatically the case that \( i^*Bu \in \mathcal{V}' \).

**Lemma 31.6.3** \( L \) is a closed operator.

We define

\[
X \equiv D(L), \quad \|u\|_X \equiv \|Lu\|_{\mathcal{V}'} + \|u\|_{\mathcal{V}}.
\]

Then \( X \) is isometric to a closed subspace of a product of reflexive Banach spaces and so \( X \) is reflexive by Lemma 15.5.11.

**Theorem 31.6.4** Let \( p \geq 2 \) in what follows. For \( u,v \in X, \) the following hold.
31.6. ANOTHER APPROACH

1. \( t \to (B(t)u(t), v(t))_{W',W} \) equals an absolutely continuous function a.e., denoted by \((Bu, v)(\cdot)\).

2. \( \text{Re}(Lu(t), u(t)) = \frac{1}{2} [(Bu, u)'(t) + (B'(t)u(t), u(t))] \text{ a.e. } t \)

3. \(|(Bu, v)(t)| \leq C \|u\|_X \|v\|_X \) for some \( C > 0 \) and for all \( t \in [0, T] \).

4. \( t \to B(t)u(t) \) equals a function in \( C(0, T; W') \) a.e., denoted by \( Bu(\cdot) \).

5. \( \sup \{||Bu(t)||_{W'}, t \in [0, T]\} \leq C||u||_X \) for some \( C > 0 \).

If \( K : X \to X' \) is given by

\[
\langle Ku, v \rangle_{X',X} = \int_0^T (Lu(t), v(t))dt + \langle Bu, v \rangle(0),
\]

then

6. \( K \) is linear, continuous and weakly continuous.

7. \( \text{Re}(Ku, u) = \frac{1}{2} [(Bu, u)(T) + \langle Bu, u \rangle(0)] + \frac{1}{2} \int_0^T (B'(t)u(t), u(t))dt. \)

8. If \( Bu(0) = 0 \), for \( u \in X \), there exists \( u_n \to u \) in \( X \) such that \( u_n(t) \) is 0 near 0. A similar conclusion could be deduced at \( T \) if \( Bu(T) = 0 \).

Proof: For \( h \) a function defined on \( [0, T] \), let \( h_1 \) be even, \( 2T \) periodic, and \( h_1(t) = h(t) \) for all \( t \in [0, T] \). Let \( C(\cdot) \in C_0^\infty(-T, 2T), C(t) \in [0, 1], C(t) = 1 \) on \([0, T] \).

Let \( \tilde{B}(t) = C(t)B_1(t) \) for all \( t \in \mathbb{R} \) and define

\[
\tilde{u}(t) = \begin{cases} u_1(t), & t \in [-T, 2T] \\
0, & t \notin [-T, 2T] \end{cases}
\]
Now let \( u \in X \). Then
\[
\left( i^* \tilde{B}u \right)'(t) = \begin{cases} 
0, t < -T \\
C'(t) \left( i^* Bu \right)(-t) - C(t) \left( i^* Bu \right)'(-t), t \in [-T, 0] \\
\left( i^* Bu \right)'(t), t \in [0, T] \\
C'(t) \left( i^* Bu \right)(2T - t) - C(t) \left( i^* Bu \right)'(2T - t), t \in [T, 2T] \\
0, t > 2T 
\end{cases}
\] (31.6.46)
Thus, if \( I \supset [-T, 2T] \), then \( \left( i^* \tilde{B}u \right)' \in V_I' \). Defining \( u_n \equiv \tilde{u} * \phi_n \), then for a.e. \( t \),
\[
\text{Re} \left( \left( i^* \tilde{B}u_n \right)'(t), u_n(t) \right) = \frac{1}{2} \left[ \langle \tilde{B}u_n, u_n \rangle'(t) + \langle \tilde{B}'(t) u_n(t), u_n(t) \rangle \right].
\] (31.6.47)
From (31.6.46) and Proposition (31.6.39), the following holds in \( V'_{[-T,2T]} \):
\[
\lim_{n \to \infty} \left( i^* \tilde{B}u_n \right)' = \lim_{n \to \infty} \left( i^* \tilde{B} (\tilde{u} * \phi_n) \right)' \tag{31.6.48}
\]
\[
= \lim_{n \to \infty} \left( \left( i^* \tilde{B} \tilde{u} \right) * \phi_n \right)' \\
= \lim_{n \to \infty} \left( i^* \tilde{B}u \right)' * \phi_n \\
= \left( i^* \tilde{B}u \right)'
\]
Where the second equality follows from Corollary (31.6.44), the third follows from the pointwise a.e. equality of \( \left( i^* \tilde{B} \tilde{u} \right) * \phi_n \) and \( \left( i^* \tilde{B}u \right)' * \phi_n \), while the fourth follows from (31.6.36) and standard properties of convolutions.
By choosing a subsequence we can use (31.6.44) to obtain
\[
u_n \to u \text{ a.e. and in } V \tag{31.6.49}
\]
\[
\left( i^* \tilde{B}u_n \right)' \to \left( i^* Bu \right)' \text{ a.e. and in } V'.
\]
From (31.6.48)
\[
\text{Re} \left( \left( i^* \tilde{B}u_n \right)'(t), u_n(t) \right) \to \text{Re} \left( \left( i^* Bu \right)'(t), u(t) \right) \text{ a.e. } t \in [0, T] 
\] (31.6.50)
\[
\langle B'(t) u_n(t), u_n(t) \rangle \to \langle B'(t) u(t), u(t) \rangle \text{ a.e. } t \in [0, T]. 
\] (31.6.51)
If \( g \in L^\infty(0, T) \),
\[
\lim_{n \to \infty} \int_0^T g(t) \langle \left( i^* \tilde{B}u_n \right)'(t), u_n(t) \rangle dt = \lim_{n \to \infty} \langle \left( i^* \tilde{B}u_n \right)' , g u_n(t) \rangle \\
= \langle \left( i^* Bu \right)' , g u(t) \rangle = \int_0^T g(t) \langle \left( i^* Bu \right)'(t), u(t) \rangle dt.
\]
Thus we have the following weak convergence:

\[ \text{Re}(\langle \dot{B}u_n \rangle', u_n) \to \text{Re}(\langle \dot{B}u \rangle', u) \text{ in } L^1(0, T). \]

Similarly,

\[ \langle B'u_n, u_n \rangle \to \langle B'u, u \rangle \text{ in } L^1(0, T) \]

It follows from \( \text{[31.6.51]} \) that

\[ \langle \dot{B}u_n, u_n \rangle' (\cdot) \text{ converges a.e. and weakly in } L^1(0, T). \]

\[ \langle \dot{B}u_n, u_n \rangle (\cdot) \text{ converges a.e. and strongly in } L^1(0, T) \text{ to } \langle Bu, u \rangle (\cdot). \]

Therefore, \( \langle \dot{B}u_n, u_n \rangle' (\cdot) \) converges a.e. and weakly in \( L^1(0, T) \) to \( \langle Bu, u \rangle' (\cdot) \). Since \( \langle Bu, u \rangle' \) and \( \langle Bu, u \rangle' \) are both in \( L^1(0, T) \), this proves part \( \mathbb{I} \) in the case where \( v = u \).

This also establishes formula \( \mathbb{I} \). To get \( \mathbb{I} \) for \( u \neq v \), apply what was just shown to

\[ \langle B(t)(u(t) + v(t)), u(t) + v(t) \rangle. \]

Next let \( t \in [0, T] \) and use \( \text{[31.6.49]} \) to write

\[ \langle \dot{B}u_n, u_n \rangle(t) = 2 \text{Re} \int_{-T}^{t} \langle \dot{B}u_n \rangle(s), u_n(s) \rangle ds - 2 \text{Re} \int_{-T}^{t} \langle \dot{B}'(s)u_n(s), u_n(s) \rangle ds. \quad (31.6.52) \]

Using \( \text{[31.6.49]} \), we let \( n \to \infty \) in \( \text{[31.6.51]} \) and obtain

\[ \langle \dot{B}u, u \rangle(t) = 2 \text{Re} \int_{-T}^{t} \langle \dot{B}u \rangle(s), \dot{u}(s) \rangle ds - 2 \text{Re} \int_{-T}^{t} \langle \dot{B}'(s)\dot{u}(s), \dot{u}(s) \rangle ds. \quad (31.6.53) \]

Hence from \( \text{[31.6.49]} \),

\[ |\langle \dot{B}u, u \rangle(t)| \leq C \left[ ||\dot{B}u||^2_{V[-T, T]} + ||\dot{u}||^2_{V[-T, T]} \right] \]

\[ \leq C \left[ ||Lu||^2_{V_{[0, T]}} + ||u||^2_{V_{[0, T]}} \right] \leq C ||u||^2_X. \quad (31.6.54) \]

This verifies \( \mathbb{I} \) in the case \( u = v \). To obtain the general case,

\[ |\langle Bu, v \rangle(t)| \leq \langle Bu, u \rangle^{1/2}(t) \langle Bv, v \rangle^{1/2}(t) \leq C ||u||_X ||v||_X. \]

To verify \( \mathbb{I} \), use \( \text{[31.6.24]} \) to write for \( t \in [0, T] \) and \( I = [-T, 2T] \),

\[ |\langle \dot{B}u_n(t) - \dot{B}u_m(t), u_n(t) - u_m(t) \rangle| \]

\[ \leq 2 \int_{-T}^{2T} \langle \dot{B}(u_n - u_m)(t), u_n(s) - u_m(s) \rangle ds \]
+ \int_{-T}^{2T} \left| \langle \tilde{B}' (s) (u_n (s) - u_m (s)) , u_n (s) - u_m (s) \rangle \right| ds \leq \tag{31.6.55}
\left( \left\| \left( i^* \tilde{B} u_n \right)' - \left( i^* \tilde{B} u_m \right)' \right\|_W \right) \left( \left\| u_n - u_m \right\|_W + \left\| u_n - u_m \right\|_{W_j}^2 \right) = E_{nm}.
\]

Then from (31.6.38) \( \lim_{n,m \to \infty} E_{nm} = 0 \) and so, for \( t \in [0, T] \),
\[
\left| \langle \tilde{B} u_n (t) - \tilde{B} u_m (t) , w \rangle \right| \leq E_{nm}^{1/2} \langle B (t) w , w \rangle^{1/2} \leq CE_{nm}^{1/2} \| w \|_W.
\]

It follows that \( \tilde{B} u_n (\cdot) \) is uniformly Cauchy in \( C (0, T; W') \) and so it converges to \( z \in C (0, T; W') \). But \( B u_n \) converges in \( L^2 (0, T; W') \) to \( B u (\cdot) \). Therefore \( B (t) u (t) = z (t) \) a.e. Letting \( B u (\cdot) = z (\cdot) \), this shows \( \mathbb{A} \). Formula \( \mathbb{B} \) follows from \( \mathbb{A} \) and the following argument.
\[
\| (Bu) (t) , w \| \leq \langle Bu , u \rangle^{1/2} \langle Bw , w \rangle^{1/2} \leq C \| u \|_X \| w \|_W.
\]

Assertion \( \mathbb{B} \) follows easily from the first five parts. It remains to get \( \mathbb{A} \).
\[
\text{Re} \langle Ku , u \rangle = \int_0^T \text{Re} \langle Lu , u \rangle dt + \langle Bu , u \rangle (0)
\]
\[
= \int_0^T \frac{1}{2} \left[ \langle Bu , u \rangle' (t) + \langle B' (t) u (t) , u (t) \rangle \right] dt + \langle Bu , u \rangle (0)
\]
\[
= \frac{1}{2} \langle Bu , u \rangle (T) + \frac{1}{2} \langle Bu , u \rangle (0) + \frac{1}{2} \int_0^T \langle B' (t) u (t) , u (t) \rangle dt.
\]

It only remains to verify the last assertion. Let \( \psi_n \) be increasing and piecewise linear such that \( \psi_n (t) = 1 \) for \( t \geq 2/n \) and equals 0 on \( [0, 1/n] \). Then clearly \( \psi_n u \to u \) in \( \mathcal{V} \). Also
\[
(B \psi_n u)' = \psi_n' Bu + \psi_n (Bu)'.
\]

The latter term converges to \( (Bu)' \) in \( \mathcal{V}' \). Now consider the first term.
\[
\int_0^T \| \psi_n' Bu \|_{\mathcal{V}'}^p dt \leq \int_0^{2/n} \left( \int_0^t \| (Bu)' \|_{\mathcal{V}'}^p ds \right) dt
\]
\[
\leq n \int_0^{2/n} t^{p'-1} \left( \int_0^t \| (Bu)' \|_{\mathcal{V}'}^p ds \right) dt \leq \int_0^{2/n} \| (Bu)' \|_{\mathcal{V}'}^p ds \left( \frac{1}{p'} (2/n) \right)
\]
\[
\text{Since } p' > 1, \text{ this converges to 0.} \]

**Corollary 31.6.5** If \( Bu (0) = 0 \) for \( u \in X \), then \( \langle Bu , u \rangle (0) = 0 \). The converse is also true. An analogous result will hold with 0 replaced with \( T \).

**Proof:** Let \( u_n \to u \) in \( X \) with \( u_n (t) = 0 \) for all \( t \) close enough to 0. For \( t \) off a set of measure zero consisting of the union of sets of measure zero corresponding to \( u_n \) and \( u \),
\[
\langle Bu_n , u_n \rangle (t) = \langle B (t) u_n (t) , u_n (t) \rangle , \langle Bu , u \rangle (t) = \langle B (t) u (t) , u (t) \rangle.
\]

\[
\int_0^T \left( \left\| \left( i^* \tilde{B} u_n \right)' - \left( i^* \tilde{B} u_m \right)' \right\|_W \right) \left( \left\| u_n - u_m \right\|_W + \left\| u_n - u_m \right\|_{W_j}^2 \right) = E_{nm}.
\]
31.7. SOME IMBEDDING THEOREMS

\[
\langle B(u - u_n), u \rangle(t) = \langle B(t)(u(t) - u_n(t)), u(t) \rangle \\
\langle Bu_n, u - u_n \rangle(t) = \langle B(t)u_n(t), u(t) - u_n(t) \rangle
\]

Then, considering such \( t \),

\[
\langle B(t)u(t), u(t) \rangle - \langle B(t)u_n(t), u_n(t) \rangle = \langle B(t)(u(t) - u_n(t)), u(t) \rangle \\
+ \langle B(t)u_n(t), u(t) - u_n(t) \rangle
\]

Hence from Theorem 31.6.4,

\[
|\langle B(t)u(t), u(t) \rangle - \langle B(t)u_n(t), u_n(t) \rangle| \leq C ||u - u_n||_X (||u||_X + ||u_n||_X)
\]

Thus if \( n \) is sufficiently large,

\[
|\langle B(t)u(t), u(t) \rangle - \langle B(t)u_n(t), u_n(t) \rangle| < \varepsilon
\]

So let \( n \) be fixed and this large and now let \( t_k \rightarrow 0 \) to obtain \( \langle B(t_k)u_n(t_k), u_n(t_k) \rangle = 0 \) for \( k \) large enough. Hence

\[
\langle Bu, u \rangle(0) = \lim_{k \rightarrow \infty} \langle B(t_k)u(t_k), u(t_k) \rangle < \varepsilon
\]

Since \( \varepsilon \) is arbitrary, \( \langle Bu, u \rangle(0) = 0 \).

Next suppose \( \langle Bu, u \rangle(0) = 0 \). Then letting \( v \in X \), with \( v \) smooth,

\[
\langle Bu(0), v(0) \rangle = \langle Bu, v \rangle(0) = \langle Bu, u \rangle^{1/2}(0) \langle Bv, v \rangle^{1/2}(0) = 0
\]

and it follows that \( Bu(0) = 0 \). ☐

31.7 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling’s lemma.

Definition 31.7.1 Let \( E, W \) be Banach spaces such that \( E \subseteq W \) and the injection map from \( E \) into \( W \) is continuous. The injection map is said to be compact if every bounded set in \( E \) has compact closure in \( W \). In other words, if a sequence is bounded in \( E \) it has a convergent subsequence converging in \( W \). This is also referred to by saying that bounded sets in \( E \) are precompact in \( W \).

Theorem 31.7.2 Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Then for every \( \varepsilon > 0 \) there exists a constant, \( C_\varepsilon \) such that for all \( u \in E \),

\[
||u||_W \leq \varepsilon ||u||_E + C_\varepsilon ||u||_X
\]
Proof: Suppose not. Then there exists $\varepsilon > 0$ and for each $n \in \mathbb{N}$, $u_n$ such that

$$||u_n||_W > \varepsilon ||u_n||_E + n ||u_n||_X$$

Now let $v_n = u_n / ||u_n||_E$. Therefore, $||v_n||_E = 1$ and

$$||v_n||_W > \varepsilon + n ||v_n||_X$$

It follows there exists a subsequence, still denoted by $v_n$ such that $v_n$ converges to $v$ in $W$. However, the above inequality shows that $||v_n||_X \to 0$. Therefore, $v = 0$. But then the above inequality would imply that $||v_n||_W > \varepsilon$ and passing to the limit yields $0 > \varepsilon$, a contradiction.

Definition 31.7.3 Define $C([a,b];X)$ the space of functions continuous at every point of $[a,b]$ having values in $X$.

You should verify that this is a Banach space with norm

$$||u||_{\infty,X} = \max \{||u_{n_k}(t) - u(t)||_X : t \in [a,b]\}.$$  

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. It is like a well known result due to Simon [106]. It is an appropriate generalization when you do not have weak derivatives.

Theorem 31.7.4 Let $q > 1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$\{ u \text{ such that } ||u(t)||_E \leq R \text{ for all } t \in [a,b], \text{ and } ||u(s) - u(t)||_X \leq R|t - s|^{1/q}\}.$$  

Thus $S$ is bounded in $L^\infty(a,b,E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C([a,b];W)$ and if $\{u_n\} \subseteq S$, there exists a subsequence, $\{u_{n_k}\}$ which converges to a function $u \in C([a,b];W)$ in the following way.

$$\lim_{k \to \infty} ||u_{n_k} - u||_{\infty,W} = 0.$$  

Proof: First consider the issue of $S$ being a subset of $C([a,b];W)$. Let $\varepsilon > 0$ be given. Then by Theorem 31.7.2 there exists a constant, $C_{\varepsilon}$ such that for all $u \in W$

$$||u||_W \leq \frac{\varepsilon}{6R} ||u||_E + C_{\varepsilon} ||u||_X.$$  

Therefore, for all $u \in S$,

$$||u(t) - u(s)||_W \leq \frac{\varepsilon}{6R} ||u(t) - u(s)||_E + C_{\varepsilon} ||u(t) - u(s)||_X$$

$$\leq \frac{\varepsilon}{6R} (||u(t)||_E + ||u(s)||_E) + C_{\varepsilon} ||u(t) - u(s)||_X$$

$$\leq \frac{\varepsilon}{3} + C_{\varepsilon} R|t - s|^{1/q}.$$  

(31.7.56)
Since $\varepsilon$ is arbitrary, it follows $u \in C([a,b]; W)$. Let $D = \mathbb{Q} \cap [a,b]$ so $D$ is a countable dense subset of $[a,b]$. Let $D = \{ t_n \}_{n=1}^{\infty}$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n,1)}$ such that as $n \to \infty$, $u_{(n,1)}(t_1)$ converges to a point in $W$. Now take a subsequence of this, called $(n,2)$ such that as $n \to \infty$, $u_{(n,2)}(t_2)$ converges to a point in $W$. It follows that $u_{(n,2)}(t_1)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_k \equiv u_{(k,k)}$. This sequence is a subsequence of $u_{(n,l)}$ whenever $k > l$. Therefore, $u_k(t_j)$ converges for all $t_j \in D$.

**Claim:** Let $\{u_k\}$ be as just defined, converging at every point of $D \equiv [a,b] \cap \mathbb{Q}$. Then $\{u_k\}$ converges at every point of $[a,b]$.

**Proof of claim:** Let $\varepsilon > 0$ be given. Let $t \in [a,b]$. Pick $t_m \in D \cap [a,b]$ such that in (31.7.57) $C \leq |t - t_m| < \varepsilon/3$. Then there exists $N$ such that if $l, n > N$, then $\| u_l(t_m) - u_n(t_m) \|_X < \varepsilon/3$. It follows that for $l, n > N$,

$$||u_l(t) - u_n(t)||_W \leq ||u_l(t) - u_l(t_m)||_W + ||u_l(t_m) - u_n(t_m)||_W + ||u_n(t_m) - u_n(t)||_W \leq \frac{2\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{2\varepsilon}{3} < 2\varepsilon.$$  

Since $\varepsilon$ was arbitrary, this shows $\{u_k(t)\}_{k=1}^{\infty}$ is a Cauchy sequence. Since $W$ is complete, this shows this sequence converges.

Now for $t \in [a,b]$, it was just shown that if $\varepsilon > 0$ there exists $N_t$ such that if $n, m > N_t$, then

$$||u_n(t) - u_m(t)||_W < \frac{\varepsilon}{3}.$$  

Now let $s \neq t$. Then

$$||u_n(s) - u_m(s)||_W \leq ||u_n(s) - u_n(t)||_W + ||u_n(t) - u_m(t)||_W + ||u_m(t) - u_m(s)||_W.$$  

From (31.7.57)

$$||u_n(s) - u_m(s)||_W \leq 2 \left( \frac{\varepsilon}{3} + C \varepsilon |t - s|^{1/q} \right) + ||u_n(t) - u_m(t)||_W$$

and so it follows that if $\delta$ is sufficiently small and $s \in B(t, \delta)$, then when $n, m > N_t$

$$||u_n(s) - u_m(s)|| < \varepsilon.$$  

Since $[a,b]$ is compact, there are finitely many of these balls, $\{ B(t_i, \delta) \}_{i=1}^{\infty}$, such that for $s \in B(t_i, \delta)$ and $n, m > N_{t_i}$, the above inequality holds. Let $N > \max \{ N_{t_1}, \cdots, N_{t_p} \}$. Then if $m, n > N$ and $s \in [a,b]$ is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

**Claim:** Let $\varepsilon > 0$ be given. Then there exists $N$ such that if $m, n > N$, then $\|u_n - u_m\|_{W} < \varepsilon$.

Now let $u(t) = \lim_{k \to \infty} u_k(t)$.

$$||u(t) - u(s)||_W \leq ||u(t) - u_n(t)||_W + ||u_n(t) - u_m(t)||_W + ||u_m(t) - u_m(s)||_W + ||u_m(s) - u(s)||_W.$$  

(31.7.57)
Let $N$ be in the above claim and fix $n > N$. Then
\[
\|u(t) - u_n(t)\|_W = \lim_{m \to \infty} \|u_m(t) - u_n(t)\|_W \leq \varepsilon
\]
and similarly, $\|u_n(s) - u(s)\|_W \leq \varepsilon$. Then if $|t - s|$ is small enough, 
shows the middle term in $\mathbb{R}$ is also smaller than $\varepsilon$. Therefore, if $|t - s|$ is small enough,
\[
\|u(t) - u(s)\|_W < 3\varepsilon.
\]
Thus $u$ is continuous. Finally, let $N$ be as in the above claim. Then letting $m, n > N$, it follows that for all $t \in [a, b],$
\[
\|u_m(t) - u_n(t)\|_W < \varepsilon.
\]
Therefore, letting $m \to \infty$, it follows that for all $t \in [a, b],$
\[
\|u(t) - u_n(t)\|_W \leq \varepsilon.
\]
and so $\|u - u_n\|_{\infty, W} \leq \varepsilon.$

Here is an interesting corollary. Recall that for $E$ a Banach space $C^{0,\alpha} ([0, T], E)$ is the space of continuous functions $u$ from $[0, T]$ to $E$ such that
\[
\|u\|_{\alpha, E} \equiv \|u\|_{\infty, E} + \rho_{\alpha, E} (u) < \infty
\]
where here
\[
\rho_{\alpha, E} (u) \equiv \sup_{t \neq s} \frac{\|u(t) - u(s)\|_E}{|t - s|^{\alpha}}
\]

**Corollary 31.7.5** Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then if $\gamma > \alpha$, the embedding of $C^{0,\gamma} ([0, T], E)$ into $C^{0,\alpha} ([0, T], X)$ is compact.

**Proof:** Let $\phi \in C^{0,\gamma} ([0, T], E)$
\[
\frac{\|\phi(t) - \phi(s)\|_X}{|t - s|^\gamma} \leq \left( \frac{\|\phi(t) - \phi(s)\|_W}{|t - s|^\gamma} \right)^{\alpha/\gamma} \|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)}
\]
\[
\leq \left( \frac{\|\phi(t) - \phi(s)\|_E}{|t - s|^\gamma} \right)^{\alpha/\gamma} \|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)} \leq \rho_{\gamma, E} (\phi) \|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)}
\]
Now suppose $\{u_n\}$ is a bounded sequence in $C^{0,\gamma} ([0, T], E)$. By Theorem 31.7.4 above, there is a subsequence still called $\{u_n\}$ which converges in $C^0 ([0, T], W)$. Thus from the above inequality
\[
\frac{\|u_n(t) - u_m(t) - (u_n(s) - u_m(s))\|_X}{|t - s|^\gamma} \leq \rho_{\gamma, E} (u_n - u_m) \|u_n(t) - u_m(t) - (u_n(s) - u_m(s))\|_W^{1-(\alpha/\gamma)}
\]
\[
\leq C (\{u_n\}) \left( 2 \|u_n - u_m\|_{\infty, W} \right)^{1-(\alpha/\gamma)}
\]
which converges to 0 as \( n, m \to \infty \). Thus

\[
\rho_{a,x} (u_n - u_m) \to 0 \text{ as } n, m \to \infty
\]

Also \( \|u_n - u_m\|_{\infty, X} \to 0 \) as \( n, m \to \infty \) so this is a Cauchy sequence in \( C^{0, \alpha} ([0, T], X) \).

The next theorem is a well known result probably due to Lions, Teman, or Aubin.

**Theorem 31.7.6** Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Let \( p \geq 1 \), let \( q > 1 \), and define

\[
S = \{ u \in L^p ([a,b]; E) : \text{ for some } C, \|u(t) - u(s)\|_X \leq C|t - s|^{1/q} \}
\]

and \( \|u\|_{L^p([a,b];E)} \leq R \).

Thus \( S \) is bounded in \( L^p ([a,b]; E) \) and Holder continuous into \( X \). Then \( S \) is pre-compact in \( L^p ([a,b]; W) \). This means that if \( \{u_n\}_{n=1}^{\infty} \subseteq S \), it has a subsequence \( \{u_{n_k}\} \) which converges in \( L^p ([a,b]; W) \).

**Proof:** By Proposition 1211 on Page 1211 it suffices to show \( S \) has an \( \eta \) net in \( L^p ([a,b]; W) \) for each \( \eta > 0 \).

If not, there exists \( \eta > 0 \) and a sequence \( \{u_n\} \subseteq S \), such that

\[
\|u_n - u_m\| \geq \eta \quad (31.7.58)
\]

for all \( n \neq m \) and the norm refers to \( L^p ([a,b]; W) \). Let

\[
a = t_0 < t_1 < \cdots < t_k = b, \ t_i - t_{i-1} = (b - a)/k.
\]

Now define

\[
\pi_n (t) = \sum_{i=1}^{k} \pi_{ni} \chi_{[t_{i-1}, t_i)} (t), \ \pi_{ni} = \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds.
\]

The idea is to show that \( \pi_n \) approximates \( u_n \) well and then to argue that a subsequence of the \( \{\pi_n\} \) is a Cauchy sequence yielding a contradiction to (31.7.58).

Therefore,

\[
\begin{aligned}
u_n (t) - \pi_n (t) &= \sum_{i=1}^{k} u_n (t) \chi_{[t_{i-1}, t_i)} (t) - \sum_{i=1}^{k} \pi_{ni} \chi_{[t_{i-1}, t_i)} (t) \\
&= \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds \chi_{[t_{i-1}, t_i)} (t) - \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds \chi_{[t_{i-1}, t_i)} (t) \\
&= \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \chi_{[t_{i-1}, t_i)} (t).
\end{aligned}
\]
It follows from Jensen’s inequality that

\[ ||u_n(t) - \bar{u}_n(t)||_{W}^p \]

\[ = \sum_{i=1}^{k} \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n(t) - u_n(s)) \, ds \right|_{W}^p \, \chi_{[t_{i-1}, t_i)}(t) \]

\[ \leq \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} ||u_n(t) - u_n(s)||_{W}^p \, ds \chi_{[t_{i-1}, t_i)}(t) \]

and so

\[ \int_{a}^{b} ||(u_n(t) - \bar{u}_n(s))||_{W}^p \, ds \]

\[ \leq \int_{a}^{b} \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} ||u_n(t) - u_n(s)||_{W}^p \, ds \chi_{[t_{i-1}, t_i)}(t) \, dt \]

\[ = \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} ||u_n(t) - u_n(s)||_{W}^p \, ds \, dt \]

From Theorem 31.7.59, if \( \varepsilon > 0 \), there exists \( C_\varepsilon \) such that

\[ ||u_n(t) - u_n(s)||_{W}^p \leq \varepsilon ||u_n(t) - u_n(s)||_{W}^p + C_\varepsilon ||u_n(t) - u_n(s)||_{X} \]

\[ \leq 2^{p-1} \varepsilon (||u_n(t)||_{W}^p + ||u_n(s)||_{W}^p) + C_\varepsilon |t - s|^{p/q} \]

This is substituted into 31.7.59 to obtain

\[ \int_{a}^{b} ||(u_n(t) - \bar{u}_n(s))||_{W}^p \, ds \leq \]

\[ \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} \left( 2^{p-1} \varepsilon (||u_n(t)||_{W}^p + ||u_n(s)||_{W}^p) + C_\varepsilon |t - s|^{p/q} \right) \, ds \, dt \]

\[ = \sum_{i=1}^{k} 2^{p-1} \varepsilon \int_{t_{i-1}}^{t_i} ||u_n(t)||_{W}^p \, dt + C_\varepsilon \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} (t_i - t_{i-1})^{p/q} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} |t - s|^{p/q} \, ds \, dt \]

\[ \leq 2^{p} \varepsilon \int_{a}^{b} ||u_n(t)||_{W}^p \, dt + C_\varepsilon \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} (t_i - t_{i-1})^{p/q} (t_i - t_{i-1})^2 \]

\[ \leq 2^{p} \varepsilon R^p + C_\varepsilon \sum_{i=1}^{k} (t_i - t_{i-1})^{1+p/q} = 2^{p} \varepsilon R^p + C_\varepsilon k \left( \frac{b-a}{k} \right)^{1+p/q} . \]
Taking $\varepsilon$ so small that $2^p \varepsilon R^p < \eta^p / 8^p$ and then choosing $k$ sufficiently large, it follows

$$
||u_n - \pi_n||_{L^p([a,b];W)} < \frac{\eta}{4}.
$$

Thus $k$ is fixed and $\pi_n$ at a step function with $k$ steps having values in $E$. Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that \{\pi_n\} is Cauchy in $L^p (a, b; W)$ and use this to contradict \[31.7.58\]. The details follow.

Suppose $\pi_n (t) = \sum_{i=1}^{k} u_i^n \lambda_{t_{i-1}, t_i} (t)$. Thus

$$
||\pi_n (t)||_E = \sum_{i=1}^{k} ||u_i^n||_E \lambda_{t_{i-1}, t_i} (t)
$$

and so

$$
R \geq \int_a^b ||\pi_n (t)||_E^p dt = \frac{T}{k} \sum_{i=1}^{k} ||u_i^n||_E^p
$$

Therefore, the \{u_i^n\} are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence \{u_{n_k}\} such that $u_{n_k}$ is a Cauchy sequence in $L^p (a, b; W)$. You simply get a subsequence such that $u_{n_k}^i$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,

$$
||u_n - u_m||_{L^p(a,b;W)} \leq ||u_n - \pi_n||_{L^p(a,b;W)} + ||\pi_n - \pi_m||_{L^p(a,b;W)} + ||\pi_m - u_m||_{L^p(a,b;W)} \leq \frac{\eta}{4} + ||\pi_n - \pi_m||_{L^p(a,b;W)} + \frac{\eta}{4} < \eta
$$

provided $m, n$ are large enough, contradicting \[31.7.58\].

You can give a different version of the above to include the case where there is, instead of a Holder condition, a bound on $u'$ for $u \in S$. It is stated next. See [III].

**Corollary 31.7.7** Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $p \geq 1$, let $q > 1$, and define

$$
S = \{ u \in L^p ([a,b];E) : \text{for some } C, \| u(t) - u(s) \|_X \leq C |t-s|^{1/q} \text{ and } \| u' \|_{L^q([a,b];E)} \leq R \}.
$$

Thus $S$ is bounded in $L^p ([a,b];E)$ and Holder continuous into $X$. Then $S$ is pre-compact in $L^p ([a,b];W)$. This means that if $\{u_n\}_{n=1}^{\infty} \subseteq S$, it has a subsequence \{u_{n_k}\} which converges in $L^p ([a,b];W)$. The same conclusion can be drawn if it is known instead of the Holder condition that $\| u' \|_{L^q([a,b];X)}$ is bounded.

**Proof:** The first part is Theorem [31.7.7]. Therefore, we just prove the new stuff which involves a bound on the $L^1$ norm of the derivative. By Proposition [31.4.4] on Page [150] it suffices to show $S$ has an $\eta$ net in $L^p ([a,b];W)$ for each $\eta > 0$.

If not, there exists $\eta > 0$ and a sequence $\{u_n\} \subseteq S$, such that

$$
||u_n - u_m|| \geq \eta \quad (31.7.60)
$$
for all \( n \neq m \) and the norm refers to \( L^p ([a, b]; W) \). Let

\[ a = t_0 < t_1 < \cdots < t_k = b, \; t_i - t_{i-1} = (b - a) / k. \]

Now define

\[ \bar{u}_n (t) \equiv \sum_{i=1}^{k} \bar{u}_n \chi_{[t_{i-1}, t_i)} (t), \quad \bar{u}_{n_i} \equiv \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds. \]

The idea is to show that \( \bar{u}_n \) approximates \( u_n \) well and then to argue that a subsequence of the \( \{ \bar{u}_n \} \) is a Cauchy sequence yielding a contradiction to \( \text{31.7.61} \).

Therefore,

\[ u_n (t) - \bar{u}_n (t) = \sum_{i=1}^{k} u_n (t) \chi_{[t_{i-1}, t_i)} (t) - \sum_{i=1}^{k} \bar{u}_n \chi_{[t_{i-1}, t_i)} (t) \]

\[ = \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (t) \, ds \chi_{[t_{i-1}, t_i)} (t) - \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds \chi_{[t_{i-1}, t_i)} (t) \]

\[ = \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \chi_{[t_{i-1}, t_i)} (t). \]

It follows from Jensen’s inequality that

\[ ||u_n (t) - \bar{u}_n (t)||_W^p \]

\[ = \sum_{i=1}^{k} \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \right|_W^p \chi_{[t_{i-1}, t_i)} (t) \]

And so

\[ \int_0^T ||u_n (t) - \bar{u}_n (t)||_W^p \, dt = \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \right|_W^p \, dt \]

\[ \leq \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \varepsilon \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \right|_E^p \, dt \]

\[ + C \varepsilon \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \right|_X^p \, dt \quad (31.7.61) \]

Consider the second of these. It equals

\[ C \varepsilon \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n' (\tau) \, d\tau \, ds \right|_X^p \, dt \]
31.7. SOME IMBEDDING THEOREMS

This is no larger than

\[ \leq C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left( \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \left\| u_n'(\tau) \right\|_X d\tau ds \right)^p dt \]

\[ = C_{\varepsilon} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left( u_n'(\tau) \right\|_X d\tau \right)^p dt \]

\[ = C_{\varepsilon} \sum_{i=1}^{k} \left( (t_i - t_{i-1})^{1/p} \int_{t_{i-1}}^{t_i} \left\| u_n'(\tau) \right\|_X d\tau \right)^p \]

Since \( p \geq 1, \)

\[ \leq C_{\varepsilon} \left( \sum_{i=1}^{k} (t_i - t_{i-1})^{1/p} \int_{t_{i-1}}^{t_i} \left\| u_n'(\tau) \right\|_X d\tau \right)^p \]

\[ \leq C_{\varepsilon} \frac{(b - a)}{k} \left( \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left\| u_n'(\tau) \right\|_X d\tau \right)^p \]

\[ = C_{\varepsilon} \frac{(b - a)}{k} \left( \left\| u_n' \right\|_{L^1([a,b],X)} \right)^p < \frac{\eta^p}{10^p} \]

if \( k \) is chosen large enough. Now consider the first in \[31.7.61\]. By Jensen’s inequality

\[ \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \varepsilon \left\| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n(t) - u_n(s)) ds \right\|^p_E \]

\[ \leq \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \varepsilon \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \left\| u_n(t) - u_n(s) \right\|^p_E ds dt \]

\[ \leq \varepsilon 2^{p-1} \sum_{i=1}^{k} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \left( \left\| u_n(t) \right\|^p + \left\| u_n(s) \right\|^p \right) ds dt \]

\[ = 2\varepsilon 2^{p-1} \sum_{i=1}^{k} \int_{t_{i-1}}^{t_i} \left( \left\| u_n(t) \right\|^p \right) dt = \varepsilon (2) \left( 2^{p-1} \right) \left\| u_n \right\|_{L^p([a,b],E)} \leq M \varepsilon \]

Now pick \( \varepsilon \) sufficiently small that \( M \varepsilon < \frac{\eta^p}{10^p} \) and then \( k \) large enough that the second term in \[31.7.61\] is also less than \( \eta^p/10^p \). Then it will follow that

\[ \left\| \bar{u}_n - u_n \right\|_{L^p([a,b],W)} < \left( \frac{2\eta^p}{10^p} \right)^{1/p} = 2^{1/p} \frac{\eta}{10} \leq \frac{\eta}{5} \]

Thus \( k \) is fixed and \( \bar{u}_n \) at a step function with \( k \) steps having values in \( E \). Now use compactness of the embedding of \( E \) into \( W \) to obtain a subsequence such that
The details follow. Suppose \( u^n(t) = \sum_{i=1}^{k} u^n_i X_{[t_{i-1}, t_i]}(t) \). Thus
\[
\|\varpi_n(t)\|_E = \sum_{i=1}^{k} \|u^n_i\|_E X_{[t_{i-1}, t_i]}(t)
\]
and so
\[
R \geq \int_a^b \|\varpi_n(t)\|_E^p dt = \frac{T}{k} \sum_{i=1}^{k} \|u^n_i\|_E^p
\]
Therefore, the \( \{u^n_i\} \) are all bounded. It follows that after taking subsequences \( k \) times there exists a subsequence \( \{u_{n_k}\} \) such that \( u_{n_k} \) is a Cauchy sequence in \( L^p([a, b]; W) \). You simply get a subsequence such that \( u^n_k \) is a Cauchy sequence in \( W \) for each \( i \). Then denoting this subsequence by \( n \),
\[
\|u_n - u_m\|_{L^p([a, b]; W)} \leq \|u_n - \varpi_n\|_{L^p([a, b]; W)} + \|\varpi_n - \varpi_m\|_{L^p([a, b]; W)} + \|\varpi_m - u_m\|_{L^p([a, b]; W)} \leq \frac{\eta}{4} + \|\varpi_n - \varpi_m\|_{L^p([a, b]; W)} + \frac{\eta}{4} < \eta
\]
provided \( m, n \) are large enough, contradicting the contradiction.

### 31.8 Some Evolution Inclusions

Let \( H \) be a Hilbert space and let \( \mathcal{H} \) denote \( L^2(0, T; H) \). Here will be an application to an evolution equation having values in \( \mathcal{H} \). It will always be the case that \( H = H' \) so this is the simplest sort of a Gelfand triple, \( V = H = H' = V' \). First is given a maximal monotone operator.

**Definition 31.8.1** Let \( D(L) \equiv \{ u \in \mathcal{H} \text{ such that } u' \in \mathcal{H} \text{ and } u(0) = u_0 \} \). Then for \( u \in D(L) \), \( Lu \equiv u' \).

Note that \( L \) is not linear.

**Lemma 31.8.2** For \( L \) as just defined, \( L \) is maximal monotone \( L : \mathcal{H} \to \mathcal{H} \).

**Proof:** To show it is maximal monotone, it suffices to verify that \( L + I \) is onto. This is by Theorem 23.7.1 on Page 500. Thus consider the equation
\[
u' + u = f, \ u(0) = u_0
\]
Is there a solution? Of course there is and it equals
\[
u(t) = e^{-t}u_0 + \int_0^t e^{-(t-s)}f(s) \, ds
\]
by the usual application of integrating factors and so forth.

Then with this, the following is from Theorem 31.7.1 on Page 301. This is a well known result found in Brezis [23].
Theorem 31.8.3 Let $u_0 \in D(\phi)$ where $\phi : H \to [0, \infty]$ is proper, lower semicontinuous, and convex. Also let $f \in \mathcal{H}$ be given and $u_0 \in D(\phi)$. Then there exists a solution $u$ to the evolution initial value problem,

$$u'(t) + \partial \phi(u(t)) \ni f(t) \quad \text{a.e. in } H, \quad u(0) = u_0$$

This solution satisfies $u(t) \in D(\partial \phi)$ for a.e. $t$ there exists $z \in \mathcal{H}$ such that $z(t) \in \partial \phi(u(t))$ for a.e. $t$ such that the inclusion is an equation with $\partial \phi(u(t))$ replaced with $z(t)$.

Proof: Define a function $\Phi : \mathcal{H} \to \mathbb{R}$

$$\Phi(u) = \int_0^T \phi(u) \, dt$$

There are no measurability issues because $\phi$ is lower semicontinuous and so the composition $\phi(u)$ will be appropriately measurable. Then this is clearly convex. It is proper because $\Phi(u_0) = \phi(u_0)T$ so $u_0 \in D(\Phi)$. If $u_n \to u$ in $\mathcal{H}$, does it follow that

$$\lim \inf_{n \to \infty} \Phi(u_n) \geq \Phi(u)$$

Suppose not so $\Phi(u) > \lim \inf_{n \to \infty} \Phi(u_n)$. Then choosing a subsequence such that

$$u_n \to u \text{ pointwise a.e.},$$

we have

$$\Phi(u) > \lim \inf_{n \to \infty} \Phi(u_n) = \lim \inf_{n \to \infty} \int_0^T \phi(u_n) \, dt$$

$$\geq \int_0^T \lim \inf_{n \to \infty} \phi(u_n) \, dt = \int_0^T \phi(u) \, dt = \Phi(u)$$

which is a contradiction. Thus $\Phi$ is also lower semicontinuous.

The constant function $u \equiv u_0$ is in $D(L) \cap D(\Phi)$. To use Theorem [31.7.5] on Page 393, it is required to show that

$$\Phi(J_\lambda u) \leq \Phi(u) + C\lambda$$

In this case, the duality map is just the identity map. Hence $J_\lambda u$ is the solution to

$$0 = (J_\lambda u - u) + \lambda L(J_\lambda u)$$

Hence letting $J_\lambda u$ be denoted by $u_\lambda$, it follows that $u_\lambda$ would be the solution to

$$\lambda u_\lambda' + u_\lambda = u, \quad u_\lambda(0) = u_0$$

Using the usual integrating factor procedure, it follows that

$$u_\lambda(t) = e^{-(1/\lambda)t}u_0 + \int_0^t e^{-(1/\lambda)(t-s)}\frac{1}{\lambda} u(s) \, ds$$
Note that
\[ e^{-\frac{1}{\lambda}t} + \int_0^t \frac{1}{\lambda} e^{-\frac{1}{\lambda}(t-s)} ds = 1 \]
Thus by Jensen’s inequality,
\[ \phi(u_\lambda(t)) \leq e^{-\frac{1}{\lambda}t} \phi(u_0) + \int_0^t e^{-\frac{1}{\lambda}(t-s)} \frac{1}{\lambda} \phi(u(s)) ds \]
Then
\[ \Phi(u_\lambda) \leq \int_0^T e^{-\frac{1}{\lambda}t} \phi(u_0) dt + \int_0^T \int_0^t e^{-\frac{1}{\lambda}(t-s)} \frac{1}{\lambda} \phi(u(s)) ds dt \]
\[ = \int_0^T e^{-\frac{1}{\lambda}t} \phi(u_0) dt + \int_0^T \phi(u(s)) \int_s^T e^{-\frac{1}{\lambda}(t-s)} \frac{1}{\lambda} dt ds \]
Now \[ \int_s^T e^{-\frac{1}{\lambda}(t-s)} \frac{1}{\lambda} dt = 1 - e^{\frac{1}{\lambda}s-\frac{1}{\lambda}T} < 1 \] and since \( \phi \geq 0 \), this shows that
\[ \Phi(u_\lambda) \leq \phi(u_0) \int_0^\infty e^{-\frac{1}{\lambda}t} dt + \int_0^T \phi(u(s)) dt \]
so
\[ \Phi(u_\lambda) \leq \phi(u_0) \lambda + \Phi(u) \]
It follows that the conditions of Theorem 31.6.5 on Page 313 are satisfied and so \( L + \partial \Phi \) is maximal monotone. Thus if \( f \in H \), there exists \( u \in D(L) \cap D(\partial \Phi) \) such that for each \( v \in H \) there exists a solution \( u_v \) to
\[ u_v + z_v + u_v = f + v, \quad u_v(0) = u_0 \in D(\phi). \]
where \( z_v \in \partial \Phi(u_v) \). I will show that \( v \to u_v \) has a fixed point. Note that if \( z_i \in \partial \Phi(u_i) \), then
\[ \int_{t-h}^t (z_1 - z_2, u_1 - u_2) ds \geq 0, \text{ any } h \leq t \]
To see this, you could simply let \( u_2 = u_1 \) off \([t-h, t]\) and pick \( z_1 = z_2 \) also on this set. Also, you can conclude that \( u \in \partial \Phi \) implies \( u(t) \in \partial \phi \) for a.e. \( t \). I show this now. Let \([a, b] \in \mathcal{G}(\partial \phi)\). Then as just noted, for \([u, z] \in \mathcal{G}(\partial \Phi)\),
\[ \int_{t-h}^t (z - b, u - a) ds \geq 0 \]
Then by the fundamental theorem of calculus, for a.e. \( t \), \((z(t) - b, u(t) - a) \geq 0 \) a.e. Letting \([a_i, b_i]_{i=1}^\infty \) be a dense subset of \( \mathcal{G}(\partial \phi) \), one can take the union of countably many sets of measure zero, one for each \([a_i, b_i]\) and conclude that off this set of measure zero, \((z(t) - b_i, u(t) - a_i) \geq 0 \) for all \( t \). Hence this is also true for all \([a, b] \in \mathcal{G}(\partial \phi) \) and so \( z(t) \in \partial \phi(u(t)) \) for a.e. \( t \).
31.8. SOME EVOLUTION INCLUSIONS

Then if you have $v_i, i = 1, 2$

$$Lu_{v_1} - Lu_{v_2} + z_{v_1} - z_{v_2} + u_{v_1} - u_{v_2} = v_1 - v_2$$

Then taking inner products with $u_{v_1} - u_{v_2}$ and integrating up to $t$,

$$\frac{1}{2} \left| (u_{v_1} - u_{v_2}) (t) \right|^2_H + \int_0^t (z_{v_1} - z_{v_2}, u_{v_1} - u_{v_2}) dt + \int_0^t \left| u_{v_1} - u_{v_2} \right|^2 ds$$

$$\leq \frac{1}{2} \int_0^t \left| v_1 - v_2 \right|^2 ds + \frac{1}{2} \int_0^t \left| u_{v_1} - u_{v_2} \right|^2 ds$$

Now by monotonicity of $\phi$ and the above,

$$\left| (u_{v_1} - u_{v_2}) (t) \right|^2_H \leq \int_0^t \left| v_1 - v_2 \right|^2 ds$$

which shows that a high enough power of the mapping $v \rightarrow u_v$ is a contraction map on $\mathcal{H}$ and so there exists a unique fixed point $u$. Thus $u_u = u$ and so

$$u' + z + u = f + u, \quad u_v (0) = u_0 \in D (\phi), \quad z (t) \in \partial \phi (t) \text{ a.e.}$$

and so

$$u' + z = f \text{ in } \mathcal{H}, \quad u (t) \in D (\partial \phi) \text{ a.e., } z (t) \in \partial \phi (u (t)) \text{ a.e., } u' \in \mathcal{H}, \text{ and } u (0) = u_0 \blacksquare$$

Note that in the above, the initial condition only needs to be in $D (\phi)$, not in the smaller $D (\partial \phi)$, although the solution is in $D (\partial \phi)$ for a.e. $t$. Also note that $f$ has no smoothness. It only is in $\mathcal{H}$. This is really a nice result.
Chapter 32

Maximal Monotone Operators, Hilbert Space

32.1 Basic Theory

Here is provided a short introduction to some of the most important properties of maximal monotone operators in Hilbert space. The following definition describes them. It is more specialized than the earlier material on maximal monotone operators from a Banach space to its dual and therefore, better results can be obtained. More on this can be read in [23] and [105].

Definition 32.1.1 Let $H$ be a real Hilbert space and let $A : D(A) \to \mathcal{P}(H)$ have the following properties.

1. For each $y \in H$ there exists $x \in D(A)$ such that $y \in x + Ax$.
2. $A$ is monotone. That is, if $z \in Ax$ and $w \in Ay$ then

   $$(z - w, x - y) \geq 0$$

Such an operator is called a maximal monotone operator.

It turns out that whenever $A$ is maximal monotone, so is $\lambda A$ for all $\lambda > 0$.

Lemma 32.1.2 Suppose $A$ is maximal monotone. Then so is $\lambda A$. Also $J_\lambda \equiv (I + \lambda A)^{-1}$ makes sense for each $\lambda > 0$ and is Lipschitz continuous.

Proof: To begin with consider $(I + A)^{-1}$. Suppose

$$x_1, x_2 \in (I + A)^{-1}(y)$$

Then $y \in (I + A)x_i$ and so $y - x_i \in Ax_i$. By monotonicity

$$(y - x_1 - (y - x_2), x_1 - x_2) \geq 0$$
and so
\[ 0 \geq |x_1 - x_2|^2 \]
which shows \( J_1 \equiv (I + A)^{-1} \) makes sense. In fact this is Lipschitz with Lipschitz constant 1. Here is why. \( x \in (I + A)J_1x \) and \( y \in (I + A)J_1y \). Then
\[ x - J_1x \in AJ_1x, \ y - J_1y \in AJ_1y \]
and so by monotonicity
\[ 0 \leq (x - J_1x - (y - J_1y), J_1x - J_1y) \]
which yields
\[ |J_1x - J_1y|^2 \leq (x - y, J_1x - J_1y) \leq |x - y||J_1x - J_1y| \]
which yields the result.

Next consider the claim that \( \lambda A \) is maximal monotone. The monotone part is immediate. The only thing in question is whether \( I + \lambda A \) is onto. Let \( r \in (-1, 1) \) and pick \( f \in H \). Consider solving the equation for \( u \)
\[
(1 + r)u + Au \ni (1 + r)f
\]
This is equivalent to finding \( u \) such that
\[(I + A)u \ni (1 + r)f - ru \]
or in other words finding \( u \) such that
\[ u = J_1((1 + r)f - ru) \]
However, if
\[ Tu = J_1((1 + r)f - ru), \]
then since \(|r| < 1\), \( T \) is a contraction mapping and so there exists a unique solution to (32.1.1). Thus
\[ u + \frac{1}{1 + r}Au \ni f \]
It follows for any \(|r| < 1, (1 + r)^{-1}A\) is maximal monotone. This takes care of all \( \lambda \in \left( \frac{1}{2}, \infty \right) \). Now do the same thing for \((2/3)A\) to get the result for all \( \lambda \in \left( \left( \frac{2}{3} \right) \left( \frac{1}{2} \right), \infty \right) \). Now apply the same argument to \((2/3)^2A\) to get the result for all \( \lambda \in \left( \left( \frac{2}{3} \right)^2 \left( \frac{1}{2} \right), \infty \right) \). Next consider the same argument to \((2/3)^3A\) to get the desired result for all \( \lambda \in \left( \left( \frac{2}{3} \right)^3 \left( \frac{1}{2} \right), \infty \right) \). Continuing this way shows \( \lambda A \) is maximal monotone for all \( \lambda > 0 \). Also from the first part of the proof \((I + \lambda A)^{-1}\) is Lipschitz continuous with Lipschitz constant 1. This proves the lemma.
A maximal monotone operator can be approximated with a Lipschitz continuous operator which is also monotone and has certain salubrious properties. This operator is called the Yosida approximation and as in the case of linear operators it is obtained by formally considering

$$\frac{A}{1 + \lambda A}$$

If you do the division formally you get the definition for $A_\lambda$,

$$A_\lambda x = \frac{1}{\lambda} x - \frac{1}{\lambda} J_\lambda x \quad (32.1.2)$$

where $J_\lambda = (I + \lambda A)^{-1}$ as above. It is obvious that $A_\lambda$ is Lipschitz continuous with Lipschitz constant no more than $2/\lambda$. Actually you can show $1/\lambda$ also works but this is not important here.

**Lemma 32.1.3** $A_\lambda x \in AJ_\lambda x$ and $|A_\lambda x| \leq |y|$ for all $y \in Ax$ whenever $x \in D(A)$. Also $A_\lambda$ is monotone.

**Proof:** Consider the first claim. From the definition,

$$A_\lambda x = \frac{1}{\lambda} x - \frac{1}{\lambda} J_\lambda x$$

Is

$$\frac{1}{\lambda} x - \frac{1}{\lambda} J_\lambda x \in AJ_\lambda x?$$

Is

$$x - J_\lambda x \in \lambda AJ_\lambda x?$$

Is

$$x \in J_\lambda x + \lambda AJ_\lambda x?$$

Is

$$x \in (I + \lambda A) J_\lambda x?$$

Certainly so. This is how $J_\lambda$ is defined.

Now consider the second claim. Let $y \in Ax$ for some $x \in D(A)$. Then by monotonicity and what was just shown

$$0 \leq (A_\lambda x - y, J_\lambda x - x) = -\lambda (A_\lambda x - y, A_\lambda x)$$

and so

$$|A_\lambda x|^2 \leq (y, A_\lambda x) \leq |y| |A_\lambda x|$$

Finally, to show $A_\lambda$ is monotone,

$$(A_\lambda x - A_\lambda y, x - y) =$$

$$\left( \frac{1}{\lambda} x - \frac{1}{\lambda} J_\lambda x - \left( \frac{1}{\lambda} y - \frac{1}{\lambda} J_\lambda y \right), x - y \right)$$
CHAPTER 32. MAXIMAL MONOTONE OPERATORS, HILBERT SPACE

\[ = \frac{1}{\lambda} |x-y|^2 - \frac{1}{\lambda} (J_x y - J_y x, x-y) \]
\[ \geq \frac{1}{\lambda} |x-y|^2 - \frac{1}{\lambda} |x-y| |J_x y - J_y x| \]
\[ \geq \frac{1}{\lambda} |x-y|^2 - \frac{1}{\lambda} |x-y|^2 = 0 \]

and this proves the lemma.

**Proposition 32.1.4** Suppose \( D(A) \) is dense in \( H \). Then for all \( x \in H \),

\[ |J_x x - x| \to 0 \]

**Proof:** From the above, if \( u \in D(A) \) and \( y \in Au \), then

\[ \left| \frac{1}{\lambda} u - \frac{1}{\lambda} J_x u \right| \leq |y| \]

Hence \( J_x u \to u \). Now for \( x \) arbitrary,

\[ |J_x x - x| \leq |J_x x - J_x u| + |J_x u - u| + |u - x| \]
\[ < 2\varepsilon + |J_x u - u| \]

where the last term converges to 0 as \( \lambda \to 0 \). Since \( \varepsilon \) is arbitrary, this shows the proposition.

Thus in the case where \( D(A) \) is dense, if you have

\[ x \in \varepsilon Ax + x \]

so that \( x_e = J_x x \), then \( |x - x_e| \to 0 \).

The next lemma gives a way to determine whether a pair \([x, y]\) is in the graph of \( A \) defined as

\[ \{(x, y) : y \in Ax\} \equiv G(A) \]

Here I am writing \([,]\) rather than (\(,\)) to avoid confusion with the inner product. It is the conclusion of this lemma which accounts for the use of the term “maximal”. It essentially says there is no larger monotone graph which includes the one for \( A \).

**Lemma 32.1.5** Suppose \( (y_1 - y, x_1 - x) \geq 0 \) for all \([x, y] \in G(A)\) where \( A \) is maximal monotone. Then \( x_1 \in D(A) \) and \( y_1 \in Ax_1 \). Also if \([x_k, y_k] \in G(A) \) and \( x_k \to x, y_k \to y \) where the half arrow denotes weak convergence, then \([x, y] \in G(A)\).

**Proof:** I want to show \( y_1 \in Ax_1 \) or in other words I want to show

\[ x_1 + \lambda y_1 \in x_1 + \lambda Ax_1 \]

or in other words

\[ J_\lambda (x_1 + \lambda y_1) = x_1. \]

This is the motivation for the following argument.
32.1. BASIC THEORY

From Lemma 32.1.3 \( A(x_1 + \lambda y_1) \in AJ(\lambda)(x_1 + \lambda y_1) \) and so by the above assumption
\[
0 \leq (y_1 - A(x_1 + \lambda y_1), x_1 - J(\lambda)(x_1 + \lambda y_1))
\]
\[
= \left( y_1 - \left( \frac{1}{\lambda}(x_1 + \lambda y_1) - \frac{1}{\lambda}J(\lambda)(x_1 + \lambda y_1) \right), x_1 - J(\lambda)(x_1 + \lambda y_1) \right)
\]
\[
= \left( \left( -\frac{1}{\lambda}x_1 + \frac{1}{\lambda}J(\lambda)(x_1 + \lambda y_1) \right), x_1 - J(\lambda)(x_1 + \lambda y_1) \right)
\]
\[
= -\frac{1}{\lambda}(x_1 - J(\lambda)(x_1 + \lambda y_1), x_1 - J(\lambda)(x_1 + \lambda y_1))
\]
which requires
\[
x_1 = J(\lambda)(x_1 + \lambda y_1)
\]
and this says \( x_1 \in D(A) \) because \( J(\lambda) \) maps into \( D(A) \). Also it says
\[
x_1 + Ax_1 \ni x_1 + \lambda y_1
\]
and so \( y_1 \in Ax_1 \).

This makes the last claim pretty easy. Suppose \( x_k \to x \) where \( x_k \in D(A) \) and that \( y_k \in Ax_k \) and \( y_k \to y \). I need to verify \( y = Ax \) and \( x \in D(A) \). Let \( [u, v] \in G(A) \). Then
\[
(y - v, x - u) = \lim_{k \to \infty} (y_k - v, x_k - u) \geq 0
\]
and so, by the first part, \( x \in D(A) \) and \( y \in Ax \). Why does that limit hold? It is because
\[
\|(y - v, x - u) - (y_k - v, x_k - u)\| \leq |(y - v, x - u) - (y_k - v, x_k - u)| + |(y_k - v, x_k - x)|
\]
The second term is no larger than
\[
|y_k - v| |x_k - x|
\]
which converges to 0 since \( y_k \) is weakly convergent, hence bounded. The first term converges to 0 because of the assumption that \( y_k \) converges weakly to \( y \). This proves the lemma.

What about the sum of maximal monotone operators? This might not be maximal monotone but what you can say is the following.

**Proposition 32.1.6** Let \( A \) be maximal monotone and let \( B \) be Lipschitz and monotone. Then \( A + B \) is maximal monotone.

**Proof:** First suppose \( B \) has a Lipschitz constant less than 1. The monotonicity is obvious. I need to show that for any \( y \) there exists \( x \in D(A) \) such that
\[
y \in x + Bx + Ax
\]
CHAPTER 32. MAXIMAL MONOTONE OPERATORS, HILBERT SPACE

This happens if and only if

\[ y - Bx \in (I + A) x \]

if and only if \( x = (I + A)^{-1}(y - Bx) \). Let

\[ Tx \equiv (I + A)^{-1}(y - Bx) \]

Then \( T \) is clearly a contraction mapping because \((I + A)^{-1}\) is Lipschitz with Lipschitz constant 1. Therefore, there exists a unique fixed point and this shows \( A + B \) is maximal monotone. Now the same argument applied to \( A + B \) shows that \( A + 2B \) is maximal monotone. Continuing this way \( A + nB \) is maximal monotone. Now for arbitrary \( B \) let \( n \) be large enough that \( n^{-1}B \) has Lipschitz constant less than 1. Then as just explained, \( A + n (n^{-1}B) = A + B \) is maximal monotone. This proves the proposition.

The following is a useful result for determining conditions under which \( A + B \) is maximal monotone or more particularly whether a given \( y \) is in \((I + A + B)(H)\) where \( A, B \) are both maximal monotone.

**Theorem 32.1.7** Let \( A \) and \( B \) be maximal monotone, let

\[ y \in x_\lambda + B_\lambda x_\lambda + Ax_\lambda, \]

and suppose \( B_\lambda x_\lambda \) is bounded independent of \( \lambda \). Then there exists \( x \in D(A) \cap D(B) \) such that \( y = x + Ax + Bx \).

**Proof:** First of all, it follows from Proposition 32.1.6 that there exists a unique \( x_\lambda \). Note

\[
\begin{align*}
y - x_\lambda - B_\lambda x_\lambda & \in Ax_\lambda \\
y - x_\mu - B_\mu x_\mu & \in Ax_\mu
\end{align*}
\]

and so by monotonicity of \( A \),

\[
(x_\mu - x_\lambda + B_\mu x_\mu - B_\lambda x_\lambda, x_\lambda - x_\mu) \geq 0
\]

and so

\[
|x_\lambda - x_\mu|^2 \leq (B_\mu x_\mu - B_\lambda x_\lambda, x_\lambda - x_\mu) = - (B_\lambda x_\lambda - B_\mu x_\mu, x_\lambda - x_\mu)
\]

(32.1.3)

I want to write as many things as possible in terms of the \( B_\lambda \) and \( B_\mu \). Denote as \( J_\lambda(B) \) the operator \((I + \lambda B)^{-1}\). Then

\[
B_\lambda x_\lambda = \frac{1}{\lambda} (x_\lambda - J_\lambda(B) x_\lambda)
\]

and so

\[
x_\lambda = \lambda B_\lambda x_\lambda + J_\lambda(B) x_\lambda
\]
Thus becomes
\[ |x_\lambda - x_\mu|^2 = -(B_\lambda x_\lambda - B_\mu x_\mu, \lambda B_\lambda x_\lambda + J_\lambda (B) x_\lambda - (\mu B_\mu x_\mu + J_\mu (B) x_\mu)) \]
\[ = -(B_\lambda x_\lambda - B_\mu x_\mu, \lambda B_\lambda x_\lambda - \mu B_\mu x_\mu) + (B_\mu x_\mu - B_\lambda x_\lambda, J_\lambda (B) x_\lambda - J_\mu (B) x_\mu) \]
\[ = -(B_\lambda x_\lambda - B_\mu x_\mu, \lambda B_\lambda x_\lambda - \lambda B_\mu x_\mu) - (B_\lambda x_\lambda - B_\mu x_\mu, (\lambda - \mu) B_\mu x_\mu) \]
\[ - (B_\lambda x_\lambda - B_\mu x_\mu, J_\lambda (B) x_\lambda - J_\mu (B) x_\mu) \]

Now recall \( B_\mu x \in BJ_\mu (B) x \). Then by monotonicity the first and last terms to the right of the equal sign in the above are negative. Therefore,
\[ |x_\lambda - x_\mu|^2 \leq |(B_\lambda x_\lambda - B_\mu x_\mu, (\lambda - \mu) B_\mu x_\mu)| \leq C |\lambda - \mu| \]
where \( C \) is some constant which comes from the assumption the \( B_\lambda x_\lambda \) are bounded.

Therefore, letting \( \lambda \) denote a sequence converging to 0 it follows
\[ \lim_{\lambda \to 0} x_\lambda = x_1 \in H \]
for some \( x \), the convergence being strong convergence. Also taking a further subsequence and using weak compactness it can be assumed
\[ B_\lambda x_\lambda \rightharpoonup z_1 \]
where this time the convergence is weak. Taking another subsequence, it can also be assumed
\[ y - x_\lambda - B_\lambda x_\lambda \rightharpoonup z_2 \]
the convergence being weak convergence. Recall \( B_\lambda x_\lambda \in BJ_\lambda (B) x_\lambda \) and also note that by assumption there is a constant \( C \) independent of \( \lambda \) such that
\[ C \geq |B_\lambda x_\lambda| \geq \frac{1}{\lambda} (x_\lambda - J_\lambda (B) x) \]
which shows
\[ J_\lambda (B) x_\lambda \rightharpoonup x_1 \]
also. Now it follows from Lemma \ref{lemma} that \( x_1 \in D (B) \) and \( z_1 \in Bx_1 \). Recall
\[ y - x_\lambda - B_\lambda x_\lambda \in Ax_\lambda \]
and so by the same lemma again,
\[ x_1 \in D (A) , \; z_2 \in Ax_1 \]
By \ref{lemma} it follows
\[ y - x_1 - z_1 = z_2 \in Ax_1 \]
Thus
\[ y = x_1 + z_1 + z_2 \in x_1 + Bx_1 + Ax_1 \]
and this proves the theorem.
CHAPTER 32. MAXIMAL MONOTONE OPERATORS, HILBERT SPACE

32.2 Evolution Inclusions

One of the interesting things about maximal monotone operators is the concept of evolution inclusions. To facilitate this, here is a little lemma.

**Lemma 32.2.1** Let $f : [0, T] \to \mathbb{R}$ be continuous and suppose

$$D^+ f(t) \equiv \lim_{h \to 0^+} \sup h \frac{f(t + h) - f(t)}{h} < g(t)$$

where $g$ is a continuous function. Then

$$f(t) - f(0) \leq \int_0^t g(s) \, ds.$$

**Proof:** Suppose this is not so. Then let

$$S \equiv \left\{ t \in [0, T] : f(t) - f(0) > \int_0^t g(s) \, ds \right\}$$

and it would follow that $S \neq \emptyset$. Let $a = \inf S$. Then there exists a decreasing sequence $h_n \to 0$ such that

$$f(a + h_n) - f(0) > \int_0^{a + h_n} g(s) \, ds \quad (32.2.5)$$

First suppose $a = 0$. Then dividing by $h_n$ and taking the limit,

$$g(0) > D^+ f(0) \geq g(0),$$

a contradiction. Therefore, assume $a > 0$. Then by continuity

$$f(a) - f(0) \geq \int_0^a g(s) \, ds$$

If strict inequality holds, then $a \neq \inf S$. It follows

$$f(a) - f(0) = \int_0^a g(s) \, ds$$

and so from

$$\frac{f(a + h_n) - f(a)}{h_n} > \frac{1}{h_n} \int_a^{a + h_n} g(s) \, ds.$$  

Then doing $\limsup_{n \to \infty}$ to both sides,

$$g(a) > D^+ f(a) \geq g(a)$$

the same sort of contradiction obtained earlier. Thus $S = \emptyset$ and this proves the lemma.

The following is the main result.
32.2. EVOLUTION INCLUSIONS

**Theorem 32.2.2** Let $H$ be a Hilbert space and let $A$ be a maximal monotone operator as described above. Let $f : [0, T] \to H$ be continuous such that $f' \in L^2(0, T; H)$. Then there exists a unique solution to the evolution inclusion

$$y' + Ay \ni f, \quad y(0) = y_0 \in D(A)$$

Here $y'$ exists a.e., $y(t) \in D(A)$ a.e., $y$ is continuous.

**Proof:** Let $y_\lambda$ be the solution to

$$y'_\lambda + A_\lambda y_\lambda = f, \quad y_\lambda(0) = y_0$$

I will base the entire proof on estimating the solutions to the corresponding integral equation

$$y_\lambda(t) - y_0 + \int_0^t A_\lambda y_\lambda(s) \, ds = \int_0^t f(s) \, ds \quad (32.2.6)$$

Let $h, k$ be small positive numbers. Then

$$y_\lambda(t + h) - y_\lambda(t) + \int_t^{t+h} A_\lambda y_\lambda(s) \, ds = \int_t^{t+h} f(s) \, ds \quad (32.2.7)$$

Next consider the difference operator

$$D_k g(t) = \frac{g(t + k) - g(t)}{k}$$

Do this $D_k$ to both sides of (32.2.7) where $k < h$. This gives

$$D_k (y_\lambda(t + h) - y_\lambda(t)) + \frac{1}{k} \left( \int_{t+h}^{t+h+k} A_\lambda y_\lambda(s) \, ds - \int_t^{t+k} A_\lambda y_\lambda(s) \, ds \right)$$

$$= \frac{1}{k} \left( \int_{t+h}^{t+h+k} f(s) \, ds - \int_t^{t+k} f(s) \, ds \right) \quad (32.2.8)$$

Now multiply both sides by $y_\lambda(t + h + k) - y_\lambda(t + k)$. Consider the first term. To simplify the ideas consider instead

$$(D_k g(t), g(t + k)) = \frac{1}{k} \left( |g(t + k)|^2 - (g(t), g(t + k)) \right)$$

$$\geq \frac{1}{k} \left( |g(t + k)|^2 - |g(t)||g(t + h)| \right)$$

$$\geq \frac{1}{k} \left( \frac{1}{2} |g(t + k)|^2 - \frac{1}{2} |g(t)|^2 \right) \quad (32.2.9)$$

Then applying this simple observation to

$$\frac{1}{2} \frac{1}{k} \left( |y_\lambda(t + h + k) - y_\lambda(t + k)|^2 - |y_\lambda(t + h) - y_\lambda(t)|^2 \right) +$$
\begin{align*}
\left( \frac{1}{k} \left( \int_{t+h}^{t+h+k} A_{\lambda} y_{\lambda}(s) \, ds - \int_{t}^{t+k} A_{\lambda} y_{\lambda}(s) \, ds \right), y_{\lambda}(t+h+k) - y_{\lambda}(t+k) \right) + \\
\leq \left( \frac{1}{k} \left( \int_{t+h}^{t+h+k} f(s) \, ds - \int_{t}^{t+k} f(s) \, ds \right), y_{\lambda}(t+h+k) - y_{\lambda}(t+k) \right)
\end{align*}

Taking \( \lim \sup_{k \to 0} \) of both sides yields

\[ \frac{1}{2} D^+ \left( |y_{\lambda}(t+h) - y_{\lambda}(t)|^2 \right) + (A_{\lambda} y_{\lambda}(t+h) - A_{\lambda} y_{\lambda}(t), y_{\lambda}(t+h) - y_{\lambda}(t)) \leq (f(t+h) - f(t), y_{\lambda}(t+h) - y_{\lambda}(t)) \]

Now recall that \( A_{\lambda} \) is monotone. Therefore,

\[ D^+ \left( |y_{\lambda}(t+h) - y_{\lambda}(t)|^2 \right) \leq |f(t+h) - f(t)|^2 + |y_{\lambda}(t+h) - y_{\lambda}(t)|^2 \]

From Lemma 32.2.21 it follows that for all \( \varepsilon > 0, \)

\[ |y_{\lambda}(t+h) - y_{\lambda}(t)|^2 - |y_{\lambda}(h) - y_0|^2 \leq \int_0^t |f(s+h) - f(s)|^2 \, ds + \int_0^t |y_{\lambda}(s+h) - y_{\lambda}(s)|^2 \, ds + \varepsilon t \]

and so since \( \varepsilon \) is arbitrary, the term \( \varepsilon t \) can be eliminated. By Gronwall's inequality,

\[ |y_{\lambda}(t+h) - y_{\lambda}(t)|^2 \leq e^t \left( |y_{\lambda}(h) - y_0|^2 + \int_0^t |f(s+h) - f(s)|^2 \, ds \right). \tag{32.2.10} \]

The last integral equals

\[ \int_0^t \left[ \int_s^{s+h} f'(r) \, dr \right]^2 \, ds \leq \int_0^t h \int_s^{s+h} |f'(r)|^2 \, dr \, ds \]

\[ = h \left[ \int_0^h \int_0^r |f'(r)|^2 \, ds \, dr + \int_0^h \int_r^{r+h} |f'(r)|^2 \, ds \, dr + \int_0^t \int_{r-h}^t |f'(r)|^2 \, ds \, dr \right]^2 \]

\[ \leq h^2 \int_0^{t+h} |f'(r)|^2 \, dr \]

and now it follows that for all \( t+h < T, \)

\[ \left| \frac{y_{\lambda}(t+h) - y_{\lambda}(t)}{h} \right|^2 \leq e^T \left( \left| \frac{y_{\lambda}(h) - y_0}{h} \right|^2 + \|f'\|_{L^2(0,T;H)}^2 \right). \tag{32.2.11} \]

Now return to 32.2.7

\[ \left| \frac{y_{\lambda}(h) - y_0}{h} \right| \leq \left| \frac{1}{h} \int_0^h A_{\lambda} y_{\lambda}(s) \, ds \right| + \left| \frac{1}{h} \int_0^h f(s) \, ds \right| \]
Then taking \( \lim \sup_{h \to 0} \) of both sides
\[
\lim \sup_{h \to 0} \left| \frac{y_\lambda (t) - y_0}{h} \right| \leq |A_\lambda y_0| + |f (0)|
\]
From Lemma 32.2.11, \( |A_\lambda y_0| \leq |a| \) for all \( a \in A y_0 \). This is where \( y_0 \in D (A) \) is used. Thus from Lemma 32.2.11, there exists a constant \( C \) independent of \( t \) and \( h \) and \( \lambda \) such that
\[
\left| \frac{y_\lambda (t + h) - y_\lambda (t)}{h} \right|^2 \leq C
\]
From the estimate just obtained and (32.2.12), this implies
\[
\frac{y_\lambda (t + h) - y_\lambda (t)}{h} + \frac{1}{h} \int_t^{t+h} A_\lambda y_\lambda (s) \, ds = \frac{1}{h} \int_t^{t+h} f (s) \, ds \tag{32.2.12}
\]
Now letting \( h \to 0 \), it follows that for all \( t \in [0, T) \), there exists a constant \( C \) independent of \( t, \lambda \) such that
\[
|A_\lambda y_\lambda (t)| \leq C. \tag{32.2.13}
\]
This is a very nice estimate. The next task is to show uniform convergence of the \( y_\lambda \) as \( \lambda \to 0 \). From (32.2.12)
\[
(D_h (y_\lambda (t) - y_\mu (t)), y_\lambda (t + h) - y_\mu (t + h)) + 
\left( \frac{1}{h} \int_t^{t+h} (A_\lambda y_\lambda (s) - A_\mu y_\mu (s)) \, ds, y_\lambda (t + h) - y_\mu (t + h) \right) = 0
\]
Then from the argument in (32.2.13),
\[
\frac{1}{h} \frac{1}{2} \left( |y_\lambda (t + h) - y_\mu (t + h)|^2 - |y_\lambda (t) - y_\mu (t)|^2 \right)
+ \left( \frac{1}{h} \int_t^{t+h} (A_\lambda y_\lambda (s) - A_\mu y_\mu (s)) \, ds, y_\lambda (t + h) - y_\mu (t + h) \right) \leq 0
\]
Now take \( \lim \sup_{h \to 0} \) to obtain
\[
\frac{1}{2} \frac{1}{2} D^+ |y_\lambda (t) - y_\mu (t)|^2 + (A_\lambda y_\lambda (t) - A_\mu y_\mu (t), y_\lambda (t) - y_\mu (t)) \leq 0
\]
Using the definition of \( A_\lambda \) this equals
\[
\frac{1}{2} \frac{1}{2} D^+ |y_\lambda (t) - y_\mu (t)|^2 + 
\left( A_\lambda y_\lambda (t) - A_\mu y_\mu (t), \lambda A_\lambda y_\lambda (t) + J_\lambda y_\lambda (t) - (\mu A_\mu y_\mu (t) + J_\mu y_\mu (t)) \right) \leq 0
\]
Now this last term splits into the following sum
\[
(A_\lambda y_\lambda (t) - A_\mu y_\mu (t), \lambda A_\lambda y_\lambda (t) - \mu A_\mu y_\mu (t))
+ (A_\lambda y_\lambda (t) - A_\mu y_\mu (t), J_\lambda y_\lambda (t) - J_\mu y_\mu (t))
\]
By Lemma 32.1.3 the second of these terms is nonnegative. Also from the estimate 32.2.13, the first term converges to 0 uniformly in $t$ as $\lambda, \mu \to 0$. Then by Lemma 32.2.1 it follows that if $\lambda$ is any sequence converging to 0, $y_\lambda(t)$ is uniformly Cauchy.

Let

$$y(t) = \lim_{\lambda \to 0} y_\lambda(t).$$

Thus $y$ is continuous because it is the uniform limit of continuous functions. Since $A_\lambda y_\lambda(t)$ is uniformly bounded, it also follows

$$y(t) = \lim_{\lambda \to 0} J_\lambda y_\lambda(t) \quad \text{uniformly in } t. \quad (32.2.14)$$

Taking a further subsequence, you can assume

$$A_\lambda y_\lambda \rightharpoonup z \quad \text{weak} * \quad \text{in } L^\infty(0,T;H). \quad (32.2.15)$$

Thus $z \in L^\infty(0,T;H)$. Recall $A_\lambda y_\lambda \in AJ_\lambda y_\lambda$.

Now $A$ can be considered a maximal monotone operator on $L^2(0,T;H)$ according to the rule

$$Ay(t) \equiv A(y(t))$$

where

$$D(A) \equiv \{ f \in L^2(0,T;H) : f(t) \in D(A) \quad \text{a.e. } t \}$$

By Lemma 32.2.14 applied to $A$ considered as a maximal monotone operator on $L^2(0,T;H)$ and using 32.2.13 and 32.2.14, it follows $y(t) \in D(A)$ a.e. $t$ and $z(t) \in Ay(t)$ a.e. $t$. Then passing to the limit in 32.2.15 yields

$$y(t) - y_0 + \int_0^t z(s) \, ds = \int_0^t f(s) \, ds. \quad (32.2.16)$$

Then by fundamental theorem of calculus, $y'(t)$ exists a.e. $t$ and

$$y' + z = f, \quad y(0) = y_0$$

where $z(t) \in Ay(t)$ a.e.

It remains to verify uniqueness. Suppose $[y_1, z_1]$ is another pair which works.

Then from 32.2.11,

$$y(t) - y_1(t) + \int_0^t (z(r) - z_1(r)) \, dr = 0$$

$$y(s) - y_1(s) + \int_0^s (z(r) - z_1(r)) \, dr = 0$$

Therefore for $s < t$,

$$y(t) - y_1(t) - (y(s) - y_1(s)) = \int_s^t (z(r) - z_1(r)) \, dr$$
and so
\[ ||y(t) - y_1(t)|| \leq K |s - t| \]
for some \( K \) depending on \( ||z||_{L^\infty} , ||z_1||_{L^\infty} \). Since \( y, y_1 \) are bounded, it follows that \( t \to |y(t) - y_1(t)|^2 \) is also Lipschitz. Therefore by Corollary 24.4.3, it is the integral of its derivative which exists a.e. So what is this derivative? As before,
\[
(D_h (y(t) - y_1(t)) , y(t + h) - y_1(t + h)) + \left( \frac{1}{h} \int_t^{t+h} (z(s) - z_1(s)) \, ds , y(t + h) - y_1(t + h) \right)
\]
and so
\[
\frac{1}{h} \left( \frac{|y(t + h) - y_1(t + h)|^2}{2} - \frac{|y(t) - y_1(t)|^2}{2} \right)
\]
\[
+ \left( \frac{1}{h} \int_t^{t+h} (z(s) - z_1(s)) \, ds , y(t + h) - y_1(t + h) \right) \leq 0
\]
Then taking \( \lim_{h \to 0} \) it follows that for a.e. \( t \) (Lebesgue points of \( z - z_1 \) intersected with the points where \( |y - y_1|^2 \) has a derivative)
\[
\frac{1}{2} \frac{d}{dt} |y(t) - y_1(t)|^2 + (z(t) - z_1(t), y(t) - y_1(t)) \leq 0
\]
Thus for a.e. \( t \),
\[
\frac{d}{dt} |y(t) - y_1(t)|^2 \leq 0
\]
and so
\[
|y(t) - y_1(t)|^2 - |y_0 - y_0|^2 = \int_0^t \frac{d}{dt} |y(s) - y_1(s)|^2 \, ds \leq 0.
\]
This proves the theorem.

### 32.3 Subgradients

#### 32.3.1 General Results

**Definition 32.3.1** Let \( X \) be a real locally convex topological vector space. For \( x \in X \), \( \delta \phi(x) \subseteq X' \), possibly \( \emptyset \). This subset of \( X' \) is defined by \( y^* \in \delta \phi(x) \) means for all \( z \in X \),
\[ y^* (z - x) \leq \phi(z) - \phi(x). \]
Also \( x \in \delta \phi^* (y^*) \) means that for all \( z^* \in X' \),
\[ (z^* - y^*) (x) \leq \phi^* (z^*) - \phi^* (y^*). \]
We define \( \text{dom} (\delta \phi) \equiv \{ x : \delta \phi(x) \neq \emptyset \} \).
The subgradient is an attempt to generalize the derivative. For example, a
function may have a subgradient but fail to be differentiable at some point. A good
example is \( f(x) = |x| \). At \( x = 0 \), this function fails to have a derivative but it does
have a subgradient. In fact, \( \delta f(0) = [-1, 1] \).

To begin with consider the question of existence of the subgradient of a convex
function. There is a very simple criterion for existence. It is essentially that the
subgradient is nonempty at every point of the interior of the domain of \( \phi \). First recall
Lemma 16.2.15 which says the interior of a convex set is convex and if nonempty,
then every point of the convex set can be obtained as the limit of a sequence of
points of the interior.

**Theorem 32.3.2** Let \( \phi : X \to (-\infty, \infty] \) be convex and suppose for some \( u \in \text{dom}(\phi) \), \( \phi \) is continuous. Then \( \delta \phi(x) \neq \emptyset \) for all \( x \in \text{int}(\text{dom}(\phi)) \). Thus
\[
\text{dom}(\delta \phi) \supset \text{int}(\text{dom}(\phi)).
\]

**Proof:** Let \( x_0 \in \text{int}(\text{dom}(\phi)) \) and let
\[
A \equiv \{(x_0, \phi(x_0))\}, B \equiv \text{epi}(\phi) \cap X \times \mathbb{R}.
\]
Then \( A \) and \( B \) are both nonempty and convex. Recall \( \text{epi}(\phi) \) can contain a point
like \((x;1)\). Since \( \phi \) is continuous at \( u \in \text{dom}(\phi) \),
\[
(u, \phi(u) + 1) \in \text{int}(\text{epi}(\phi) \cap X \times \mathbb{R}).
\]
Thus \( \text{int}(B) \neq \emptyset \) and also \( \text{int}(B) \cap A = \emptyset \). By Lemma 16.2.16 \( \text{int}(B) \) is convex and
so by Theorem 16.2.14 \( \text{int}(B) \) is convex and
\[
(x^*, \beta) \neq (0, 0) \tag{32.3.17}
\]
and for all \((x, a) \in \text{int} B,
\[
x^*(x) + \beta a > x^*(x_0) + \beta \phi(x_0). \tag{32.3.18}
\]
From Lemma 16.2.16, whenever \( x \in \text{dom}(\phi) \),
\[
x^*(x) + \beta \phi(x) \geq x^*(x_0) + \beta \phi(x_0).
\]
If \( \beta = 0 \), this would mean \( x^*(x - x_0) \geq 0 \) for all \( x \in \text{dom}(\phi) \). Since \( x_0 \in \text{int}(\text{dom}(\phi)) \), this implies \( x^* = 0 \), contradicting 32.3.17. If \( \beta < 0 \), apply 32.3.18 to
the case when \( a = \phi(x_0) + 1 \) and \( x = x_0 \) to obtain a contradiction. It follows \( \beta > 0 \)
and so
\[
\phi(x) - \phi(x_0) \geq -\frac{x^*}{\beta} (x - x_0)
\]
which says \( -x^*/\beta \in \delta \phi(x_0) \). This proves the theorem.

**Definition 32.3.3** Let \( \phi : X \to (-\infty, \infty] \) be some function, not necessarily convex
but satisfying \( \phi(y) < \infty \) for some \( y \in X \). Define \( \phi^* : X' \to (-\infty, \infty] \) by
\[
\phi^*(x^*) \equiv \sup\{x^*(y) - \phi(y) : y \in X\}.
\]
This function, \( \phi^* \), defined above, is called the conjugate function of \( \phi \) or the polar of \( \phi \). Note \( \phi^* (x^*) \neq -\infty \) because \( \phi (y) < \infty \) for some \( y \).

**Theorem 32.3.4** Let \( X \) be a real Banach space. Then \( \phi^* \) is convex and l.s.c. 

**Proof:** Let \( \lambda \in [0,1] \). Then

\[
\phi^* (\lambda x^* + (1 - \lambda) y^*) = \sup \{ (\lambda x^* + (1 - \lambda) y^*) (y) - \phi (y) : y \in X \}
\]

\[
\leq \lambda \phi^* (x^*) + (1 - \lambda) \phi^* (y^*) .
\]

It remains to show the function is l.s.c. Consider \( f_y (x^*) \equiv x^* (y) - \phi (y) \). Then \( f_y \) is obviously convex. Also to say that \((x, \alpha) \in \text{epi} (\phi^*) \) is to say that \( \alpha \geq x^* (y) - \phi (y) \) for all \( y \). Thus

\[
\text{epi} (\phi^*) = \bigcap_{y \in X} \text{epi} (f_y).
\]

Therefore, if \( \text{epi} (f_y) \) is closed, this will prove the theorem. If \((x^*, a) \notin \text{epi} (f_y)\), then \( a < x^* (y) - \phi (y) \) and, by continuity, for \( b \) close enough to \( a \) and \( y^* \) close enough to \( x^* \) then

\[
b < y^* (y) - \phi (y) , \ (y^*, b) \notin \text{epi} (f_y)
\]

Thus \( \text{epi} (f_y) \) is closed. □

Note this theorem holds with no change in the proof if \( X \) is only a locally convex topological vector space and \( X' \) is given the weak * topology.

**Definition 32.3.5** We define \( \phi^{**} \) on \( X \) by

\[
\phi^{**} (x) \equiv \sup \{ x^* (x) - \phi^* (x^*) , x^* \in X' \}.
\]

The following lemma comes from separation theorems. First is a simple observation.

**Observation 32.3.6** \( f \in (X \times \mathbb{R})' \) if and only if there exists \( x^* \in X' \) and \( \alpha \in \mathbb{R} \) such that \( f (x, \lambda) = x^* (x) + \lambda \alpha \). To get \( x^* \), you can simply define \( x^* (x) \equiv f (x, 0) \) and to get \( \alpha \) you just let \( \alpha \lambda \equiv f (0, \lambda) \). Why does such an \( \alpha \) exist? You know that \( f (0, a \lambda + b \delta) = a f (0, \alpha) + b f (0, \delta) \) and so in fact \( \lambda \to f (0, \lambda) \) satisfies the Cauchy functional equation \( g (x + y) = g (x) + g (y) \) and is continuous so there is only one thing it can be and that is \( f (0, \lambda) = \alpha \lambda \) for some \( \alpha \).

This picture illustrates the conclusion of the following lemma.
Lemma 32.3.7 Let \( \phi : X \to (-\infty, \infty] \) be convex and lower semicontinuous and \( \phi(x) < \infty \) for some \( x \). (proper). Then if \( \beta < \phi(x_0) \) so that \( (x_0, \beta) \) is not in epi (\( \phi \)), it follows that there exists \( \delta > 0 \) and \( z^* \in X' \) such that for all \( y \),

\[
z^*(y-x_0) + \beta + \delta < \phi(y), \quad \text{all } y \in X
\]

**Proof:** Let \( C = \text{epi} (\phi) \cap (X \times \mathbb{R}) \). Then \( C \) is a closed convex nonempty set and it does not contain the point \( (x_0, \beta) \). Let \( \hat{\beta} > \beta \) be slightly larger so that also \( (x_0, \hat{\beta}) \notin C \). Thus there exists \( y^* \in X' \) and \( \alpha \in \mathbb{R} \) such that for some \( \hat{\alpha} \), and all \( y \in X \),

\[
y^*(x_0) + \alpha \hat{\beta} > \hat{\alpha} > y^*(y) + \alpha \phi(y)
\]

for all \( y \in X \). Now you can’t have \( \alpha \geq 0 \) because

\[
\alpha \left( \frac{-\phi(y)}{\hat{\beta} - \phi(x_0)} \right) > 0
\]

Hence \( \alpha < 0 \) and so, dividing by it yields that for all \( y \in X \),

\[
x^*(x_0) + \hat{\beta} < c < x^*(y) + \phi(y)
\]

where \( x^* = y^*/\alpha, \hat{\alpha}/\alpha \equiv c \). Then

\[
(-x^*) (y-x_0) + \beta + \hat{\beta} - \beta < c - x^*(y) < \phi(y)
\]

\[
(-x^*) (y-x_0) + \beta + \delta < \phi(y), \quad \delta \equiv \hat{\beta} - \beta
\]

Let \( z^* = -x^* \). 

**Theorem 32.3.8** \( \phi^{**}(x) \leq \phi(x) \) for all \( x \) and if \( \phi \) is convex and l.s.c., \( \phi^{**}(x) = \phi(x) \) for all \( x \in X \).

**Proof:**

\[
\phi^{**}(x) = \sup \left\{ x^*(x) - \sup \{x^*(y) - \phi(y) : y \in X \} : x^* \in X' \right\}
\]

\[
\leq \sup \{x^*(x) - (x^*(x) - \phi(x))\} = \phi(x).
\]

Next suppose \( \phi \) is convex and l.s.c. If \( \phi^{**}(x_0) < \phi(x_0) \), then using Lemma 32.3.7, there exists \( x_0^*, \delta > 0 \) such that for all \( y \in X \),

\[
(x_0^*) (y-x_0) + \phi^{**}(x_0) + \delta < \phi(y)
\]
32.3. SUBGRADIENTS

\[ x_0^*(y) - \phi(y) + \delta < x_0^*(x_0) - \phi^{**}(x_0) \]

Thus, since this holds for all \( y \),

\[
\begin{align*}
\phi^*(x_0) + \delta & \leq x_0^*(x_0) - \phi^{**}(x_0) \\
\phi^{**}(x_0) + \delta & \leq x_0^*(x_0) - \phi^*(x_0)
\end{align*}
\]

Then

\[
\phi^{**}(x_0) = \sup \{ x^*(x_0) - \phi^*(x^*), x^* \in X' \} \geq x_0^*(x_0) - \phi^*(x_0) \geq \phi^{**}(x_0) + \delta
\]

a contradiction.  

The following corollary is descriptive of the situation just discussed. It says that to find \( \text{epi} (\phi^{**}) \) it suffices to take the intersection of all closed convex sets which contain \( \text{epi} (\phi) \).

**Corollary 32.3.9** \( \text{epi} (\phi^{**}) \) is the smallest closed convex set containing \( \text{epi} (\phi) \).

**Proof:** \( \text{epi} (\phi^{**}) \supseteq \text{epi} (\phi) \) from Theorem 32.3.8. Also \( \text{epi} (\phi^{**}) \) is closed by the proof of Theorem 32.3.4. Suppose \( \text{epi} (\phi) \subseteq K \subseteq \text{epi} (\phi^{**}) \) and \( K \) is convex and closed. Let

\[
\psi(x) = \min \{ a : (x, a) \in K \}.
\]

\( \{ a : (x, a) \in K \} \) is a closed subset of \( (-\infty, \infty) \) so the minimum exists.) \( \psi \) is also a convex function with \( \text{epi} (\psi) = K \). To see \( \psi \) is convex, let \( \lambda \in [0, 1] \). Then, by the convexity of \( K \),

\[
\lambda (x, \psi(x)) + (1 - \lambda) (y, \psi(y)) = (\lambda x + (1 - \lambda) y, \lambda \psi(x) + (1 - \lambda) \psi(y)) \in K.
\]

It follows from the definition of \( \psi \) that

\[
\psi(\lambda x + (1 - \lambda) y) \leq \lambda \psi(x) + (1 - \lambda) \psi(y).
\]

Then

\[
\phi^{**} \leq \psi \leq \phi
\]

and so from the definitions,

\[
\phi^{****} \geq \psi \geq \phi^*
\]

which implies from the definitions and Theorem 32.3.8 that

\[
\phi^{**} = \phi^{****} \leq \psi^{**} = \psi \leq \phi^{**}.
\]

Therefore, \( \psi = \phi^{**} \) and \( \text{epi} (\phi^{**}) \) is the smallest closed convex set containing \( \text{epi} (\phi) \) as claimed.

There is an interesting symmetry which relates \( \delta \phi, \delta \phi^*, \phi, \) and \( \phi^* \).
Theorem 32.3.10 Suppose $\phi$ is convex, l.s.c. (lower semicontinuous or in other words having a closed epigraph), and proper. Then

$$y^* \in \delta \phi (x) \text{ if and only if } x \in \delta \phi^* (y^*)$$

where this last expression means

$$(z^* - y^*) (x) \leq \phi^* (z^*) - \phi^* (y^*)$$

for all $z^*$ and in this case,

$$y^* (x) = \phi^* (y^*) + \phi (x).$$

**Proof:** If $y^* \in \delta \phi (x)$ then $y^* (z - x) \leq \phi (z) - \phi (x)$ and so

$$y^* (z) - \phi (z) \leq y^* (x) - \phi (x)$$

for all $z \in X$. Therefore,

$$\phi^* (y^*) \leq y^* (x) - \phi (x) \leq \phi^* (y^*).$$

Hence

$$y^* (x) = \phi^* (y^*) + \phi (x). \tag{32.3.19}$$

Now if $z^* \in X'$ is arbitrary, 32.3.14 shows

$$(z^* - y^*) (x) = z^* (x) - y^* (x) = z^* (x) - \phi (x) - \phi^* (y^*) \leq \phi^* (z^*) - \phi^* (y^*)$$

and this shows $x \in \delta \phi^* (y^*)$.

Now suppose $x \in \delta \phi^* (y^*)$. Then for $z^* \in X'$,

$$(z^* - y^*) (x) \leq \phi^* (z^*) - \phi^* (y^*)$$

so

$$z^* (x) - \phi^* (z^*) \leq y^* (x) - \phi^* (y^*)$$

and so, taking sup over all $z^*$, and using Theorem 32.3.3,

$$\phi^{**} (x) = \phi (x) \leq y^* (x) - \phi^* (y^*) \leq \phi^{**} (x).$$

Thus

$$y^* (x) = \phi^* (y^*) + \phi^{**} (x) = \phi^* (y^*) + \phi (x) \geq \underbrace{y^* (z) - \phi (z)}_{\leq \phi^* (y^*)} + \phi (x)$$

for all $z \in X$ and this implies for all $z \in X$,

$$\phi (z) - \phi (x) \geq y^* (z - x)$$

so $y^* \in \delta \phi (x)$ and this proves the theorem.
Definition 32.3.11 If $X$ is a Banach space define $u \in W^{1,p}([0,T];X)$ if there exists $g \in L^p([0,T];X)$ such that

$$u(t) = u(0) + \int_0^t g(s) \, ds$$

When this occurs define $u'(\cdot) \equiv g(\cdot)$. As usual, $p > 1$.

The next Lemma is quite interesting for its own sake but it is also used in the next theorem.

Lemma 32.3.12 Suppose $g \in L^p(0,T;X)$. Then as $h \to 0$,

$$\frac{1}{h} \int_{(\cdot)+h}^{(\cdot)+h} g(s) \, ds \mathcal{X}_{[0,T-h]}(\cdot) \to g$$

in $L^p([0,T];X)$.

Proof: Let

$$\tilde{g}(u) = \begin{cases} g(u) & \text{if } u \in [0,T) \\ 0 & \text{if } u \notin [0,T] \end{cases} , \quad \phi_h(r) = \frac{1}{h} \mathcal{X}_{[-h,0]}(r) .$$

Thus $\tilde{g} \in L^p(\mathbb{R};X)$ and

$$\tilde{g} * \phi_h(t) \equiv \int_{\mathbb{R}} \tilde{g}(t-s) \phi_h(s) \, ds .$$

Then

$$\| \tilde{g} * \phi_h - \tilde{g} \|_{L^p(\mathbb{R};X)} \leq \left( \int_{\mathbb{R}} \left( \int_{\mathbb{R}} \| \tilde{g}(t-s) \|_X \phi_h(s) \, ds \right)^p \, dt \right)^{1/p}$$

which by Minkowski’s inequality for integrals is no larger than

$$\leq \int_{\mathbb{R}} \phi_h(s) \left( \int_{\mathbb{R}} \| \tilde{g}(t-s) \|_X^p \, dt \right)^{1/p} \, ds$$

$$= \frac{1}{h} \int_{-h}^0 \left( \int_{\mathbb{R}} \| \tilde{g}(t-s) \|_X^p \, dt \right)^{1/p} \, ds < \frac{1}{h} \int_{-h}^0 \varepsilon \, ds = \varepsilon$$

whenever $h$ is small enough. This follows from continuity of translation in $L^p(\mathbb{R};X)$, a consequence of the regularity of the measure. Thus, $\tilde{g} * \phi_h \to \tilde{g}$ in $L^p(\mathbb{R};X)$.

Now

$$\tilde{g} * \phi_h(t) - \frac{1}{h} \int_t^{t+h} g(s) \, ds \mathcal{X}_{[0,T-h]}(t)$$

$$= \begin{cases} 0 & \text{if } t \in [0,T-h] \\ \frac{1}{h} \int_t^{t+h} \tilde{g}(u) \, du & \text{if } t \notin [0,T-h] \end{cases}$$
and therefore,

\[
\left\| \hat{g} \ast \phi_{h} (\cdot) - \frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g (s) \, ds \mathcal{X}_{[0,T-h]} (\cdot) \right\|_{L^{p}(\mathbb{R};X)} =
\]

\[
\left( \int_{-h}^{0} \left\| \frac{1}{h} \int_{t}^{t+h} \tilde{g} (u) \, du \right\|_{X}^{p} \, dt \right)^{1/p} + \left( \int_{T-h}^{T} \left\| \frac{1}{h} \int_{t}^{t+h} \tilde{g} (u) \, du \right\|_{X}^{p} \, dt \right)^{1/p}
\]

\[
\leq \frac{1}{h} \left( \int_{-h}^{0} \left( \int_{-h}^{h} \| \tilde{g} (u) \|_{X} \, du \right)^{p} \, dt \right)^{1/p} + \frac{1}{h} \left( \int_{T-h}^{T} \left( \int_{T-h}^{T+h} \| \tilde{g} (u) \|_{X} \, du \right)^{p} \, dt \right)^{1/p}
\]

which by Minkowski’s inequality for integrals is no larger than

\[
\leq \frac{1}{h} \int_{-h}^{h} \left( \int_{-h}^{0} \| \tilde{g} (u) \|_{X} \, dt \right)^{1/p} \, du + \frac{1}{h} \int_{T-h}^{T} \left( \int_{T-h}^{T+h} \| \tilde{g} (u) \|_{X} \, dt \right)^{1/p} \, du
\]

\[
\leq \frac{1}{h} \int_{-h}^{h} \varepsilon \, du + \frac{1}{h} \int_{T-h}^{T} \varepsilon \, du = 4 \varepsilon
\]

whenever \( h \) is small enough because of the fact that \( \| \tilde{g} \|_{X}^{p} \in L^{1} (\mathbb{R};X) \). Since \( \varepsilon \) is arbitrary, this shows

\[
\left\| \hat{g} \ast \phi_{h} (\cdot) - \frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g (s) \, ds \mathcal{X}_{[0,T-h]} (\cdot) \right\|_{L^{p}(\mathbb{R};X)} \to 0
\]

and also, it was shown above that

\[
\| \hat{g} \ast \phi_{h} (\cdot) - \tilde{g} \|_{L^{p}(\mathbb{R};X)} \to 0
\]

It follows that

\[
\frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} g (s) \, ds \mathcal{X}_{[0,T-h]} (\cdot) \to \tilde{g}
\]

in \( L^{p} (\mathbb{R};X) \) and consequently in \( L^{p} ([0,T];X) \) as well. But \( \tilde{g} = g \) on \([0,T]\). 

The following theorem is a form of the chain rule in which the derivative is replaced by the subgradient.

**Theorem 32.3.13** Suppose \( u \in W^{1,p} ([0,T];X) \), \( z \in L^{p'} ([0,T];X') \), and \( z (t) \in \delta \phi (u (t)) \) a.e \( t \in [0,T] \). Then the function, \( t \to \phi (u (t)) \) is in \( L^{1} (0,T) \) and its weak derivative equals \( \langle z, u' \rangle \). In particular,

\[
\phi (u (t)) - \phi (u (0)) = \int_{0}^{t} \langle z (s), u' (s) \rangle \, ds
\]
32.3. SUBGRADIENTS

**Proof:** Modify $u$ on a set of measure zero such that $\delta \phi (u(t)) \neq \emptyset$ for all $t$. Next modify $z$ on a set of measure zero such that for $\bar{u}$ and $\bar{z}$ the modified functions, $\bar{z}(t) \in \delta \phi (\bar{u}(t))$ for all $t$. First I claim $t \to \phi (\bar{u}(t))$ is in $L^1(0,T)$. Pick $t_0 \in [0,T]$ and let

$$\bar{z}(t_0) \in \delta \phi (\bar{u}(t_0)).$$

Then for $t \in [0,T],

$$\langle \bar{z}(t_0), \bar{u}(t) - \bar{u}(t_0) \rangle + \phi (\bar{u}(t_0)) \leq \phi (\bar{u}(t)) \leq \langle \bar{z}(t), \bar{u}(t) - \bar{u}(t_0) \rangle + \phi (\bar{u}(t_0))$$

(32.3.20)

Then $\bar{z}(t) \to \phi (\bar{u}(t))$ is in $L^1(0,T)$ since $\bar{z} \in L^p([-T,T]; X')$ and $\bar{u} \in L^p([0,T]; X)$. Also, for $t \in [0,T-h],

$$\langle X_{[0,T-h]}(t), \bar{u}(t+h) - \bar{u}(t) \rangle \leq X_{[0,T-h]}(t) \frac{\phi (\bar{u}(t+h)) - \phi (\bar{u}(t))}{h}$$

$$\leq \left\langle X_{[0,T-h]}(t), \bar{z}(t+h), \frac{\bar{u}(t+h) - \bar{u}(t)}{h} \right\rangle$$

Now $X_{[0,T-h]}(\cdot) \bar{z}(\cdot+h) \to z(\cdot)$ in $L^p'(0,T; X')$ by continuity of translation. Also,

$$X_{[0,T-h]}(\cdot) \frac{\bar{u}(\cdot+h) - \bar{u}(\cdot)}{h} = X_{[0,T-h]}(\cdot) \frac{u(\cdot+h) - u(\cdot)}{h}$$

$$= X_{[0,T-h]}(\cdot) \frac{1}{h} \int_{(\cdot)}^{(\cdot)+h} u'(s) \, ds$$

in $L^p(0,T; X)$ and so by Lemma 32.3.12

$$X_{[0,T-h]}(\cdot) \frac{\phi (\bar{u}(\cdot+h)) - \phi (\bar{u}(\cdot))}{h} \to (z, u')$$

in $L^1(0,T)$.

It follows from the definition of weak derivatives that in the sense of weak derivatives,

$$\frac{d}{dt}(\phi (u(\cdot))) = (z, u') \in L^1(0,T).$$

Note that by Theorem 32.3.10 this implies that for a.e. $t \in [0,T]$, $\phi (u(t))$ is equal to a continuous function, $\phi \circ u$, and that

$$(\phi \circ u)(t) - (\phi \circ u)(0) = \int_{0}^{t} (z(s), u'(s)) \, ds \quad \blacksquare$$

There are other rules of calculus which have a generalization to subgradients. The following theorem is on such a generalization. It generalizes the theorem which states that the derivative of a sum equals the sum of the derivatives.
Theorem 32.3.14  Let \( \phi_1 \) and \( \phi_2 \) be convex, l.s.c. and proper having values in \((-\infty, \infty]\). Then
\[
\delta (\lambda \phi_1) (x) = \lambda \delta \phi_1 (x), \quad \delta (\phi_1 + \phi_2) (x) \supseteq \delta \phi_1 (x) + \delta \phi_2 (x)
\]
(32.3.21)
if \( \lambda > 0 \). If there exists \( \tau \in \text{dom} (\phi_1) \cap \text{dom} (\phi_2) \) and \( \phi_1 \) is continuous at \( \tau \) then for all \( x \in X \),
\[
\delta (\phi_1 + \phi_2) (x) = \delta \phi_1 (x) + \delta \phi_2 (x).
\]
(32.3.22)

Proof: It is obvious so we only need to show (32.3.22). Suppose \( \tau \) is as described. It is clear that (32.3.21) holds whenever \( x \notin \text{dom} (\phi_1) \cap \text{dom} (\phi_2) \) since then both sides equal \( \emptyset \). Therefore, assume
\[
x \in \text{dom} (\phi_1) \cap \text{dom} (\phi_2)
\]
in what follows. Let \( x^* \in \delta (\phi_1 + \phi_2) (x) \). Is \( x^* \) is the sum of an element of \( \delta \phi_1 (x) \) and \( \delta \phi_2 (x) \)? Does there exist \( x_1^* \) and \( x_2^* \) such that for every \( y \),
\[
x^* (y - x) = x_1^* (y - x) + x_2^* (y - x) \\
\leq \phi_1 (y) - \phi_1 (x) + \phi_2 (y) - \phi_2 (x). \tag{32.3.22}
\]
If so, then
\[
\phi_1 (y) - \phi_1 (x) - x^* (y - x) \geq \phi_2 (x) - \phi_2 (y).
\]
Define
\[
C_1 \equiv \{(y, a) \in X \times \mathbb{R} : \phi_1 (y) - \phi_1 (x) - x^* (y - x) \leq a \}, \\
C_2 \equiv \{(y, a) \in X \times \mathbb{R} : a \leq \phi_2 (x) - \phi_2 (y) \}.
\]
I will show \( \text{int} (C_1) \cap C_2 = \emptyset \) and then by Theorem 32.3.12 there exists an element of \( X' \) which does something interesting.

Both \( C_1 \) and \( C_2 \) are convex and nonempty. \( C_1 \) is nonempty because it contains \( (\tau, \phi_1 (\tau) - \phi_1 (x) - x^* (\tau - x)) \) since
\[
\phi_1 (\tau) - \phi_1 (x) - x^* (\tau - x) \leq \phi_1 (\tau) - \phi_1 (x) - x^* (\tau - x)
\]
\( C_2 \) is also nonempty because it contains \( (\tau, \phi_2 (x) - \phi_2 (\tau)) \) since
\[
\phi_2 (x) - \phi_2 (\tau) \leq \phi_2 (x) - \phi_2 (\tau)
\]
In addition to this,
\[
(\tau, \phi_1 (\tau) - x^* (\tau - x) - \phi_1 (x) + 1) \in \text{int} (C_1)
\]
due to the assumed continuity of \( \phi_1 \) at \( \tau \) and so \( \text{int} (C_1) \neq \emptyset \). If \( (y, a) \in \text{int} (C_1) \) then
\[
\phi_1 (y) - x^* (y - x) \leq a - \varepsilon
\]
whenever \( \varepsilon \) is small enough. Therefore, if \( (y, a) \) is also in \( C_2 \), the assumption that \( x^* \in \delta (\phi_1 + \phi_2) (x) \) implies
\[
a - \varepsilon \geq \phi_1 (y) - x^* (y - x) - \phi_1 (x) \geq \phi_2 (x) - \phi_2 (y) \geq a,
\]
32.3. SUBGRADIENTS

a contradiction. Therefore \( \text{int} (C_1) \cap C_2 = \emptyset \) and so by Theorem [16.2.14], there exists \((w^*, \beta) \in X' \times \mathbb{R} \) with

\[
(w^*, \beta) \neq (0, 0),
\]

(32.3.23)

and

\[
w^*(y) + \beta a \geq w^*(y_1) + \beta a_1,
\]

(32.3.24)

whenever \((y, a) \in C_1 \) and \((y_1, a_1) \in C_2\).

**Claim:** \( \beta > 0 \).

**Proof of claim:** If \( \beta < 0 \) let

\[
a = \phi_1(x) - x^*(x - x) - \phi_1(x) + 1,
\]

\[
a_1 = \phi_2(x) - \phi_2(x), \text{ and } y = y_1 = \overline{x}.
\]

Then from \([12, 24]\)

\[
\beta \left( \phi_1(x) - x^*(x - x) - \phi_1(x) + 1 \right) \geq \beta \left( \phi_2(x) - \phi_2(x) \right).
\]

Dividing by \( \beta \) yields

\[
\phi_1(x) - x^*(x - x) - \phi_1(x) + 1 \leq \phi_2(x) - \phi_2(x)
\]

and so

\[
\phi_1(x) + \phi_2(x) - (\phi_1(x) + \phi_2(x)) + 1 \leq x^*(x - x)
\]

\[
\leq \phi_1(x) + \phi_2(x) - (\phi_1(x) + \phi_2(x)),
\]

a contradiction. Therefore, \( \beta \geq 0 \).

Now suppose \( \beta = 0 \). Letting

\[
a = \phi_1(x) - x^*(x - x) - \phi_1(x) + 1,
\]

\[
(\overline{x}, a) \in \text{int} (C_1),
\]

and so there exists an open set \( U \) containing 0 and \( \eta > 0 \) such that

\[
\overline{x} + U \times (a - \eta, a + \eta) \subseteq C_1.
\]

Therefore, \([12, 24]\) applied to \((\overline{x} + z, a) \in C_1 \) and \((\overline{x}, \phi_2(x) - \phi_2(x)) \in C_2 \) for \( z \in U \) yields

\[
w^*(\overline{x} + z) \geq w^*(\overline{x})
\]

for all \( z \in U \). Hence \( w^*(z) = 0 \) on \( U \) which implies \( w^* = 0 \), contradicting \([12, 24]\).

This proves the claim.

Now with the claim, it follows \( \beta > 0 \) and so, letting \( z^* = w^*/\beta \), \([12, 24]\) and Lemma \([10, 24]\) implies

\[
z^*(y) + a \geq z^*(y_1) + a_1
\]

(32.3.25)

whenever \((y, a) \in C_1 \) and \((y_1, a_1) \in C_2\). In particular,

\[
(y, \phi_1(y) - \phi_1(x) - x^*(y - x)) \in C_1
\]

(32.3.26)
because
\[ \phi_1(y) - \phi_1(x) - x^*(y - x) \leq \phi_1(y) - x^*(y - x) - \phi_1(x) \]
and
\[ (y_1, \phi_2(x) - \phi_2(y_1)) \in C_2. \] (32.3.27)
by similar reasoning so letting \( y = x, \)
\[ z^*(x) + \left( \phi_1(x) - x^*(x - x) - \phi_1(x) \right) = 0 \]
\[ \geq z^*(y_1) + \phi_2(x) - \phi_2(y_1). \]

Therefore,
\[ z^*(y_1 - x) \leq \phi_2(y_1) - \phi_2(x) \]
for all \( y_1 \) and so \( z^* \in \delta \phi_2(x). \) Now let \( y_1 = x \) in (32.3.27) and using (32.3.25) and (32.3.26), it follows
\[ z^*(y) + \phi_1(y) - x^*(y - x) - \phi_1(x) \geq z^*(x) \]
\[ \phi_1(y) - \phi_1(x) \geq x^*(y - x) - z^*(y - x) \]
and so \( x^* - z^* \in \delta \phi_1(x) \) so \( x^* = z^* + (x^* - z^*) \in \delta \phi_2(x) + \delta \phi_1(x) \) and this proves the theorem.

Next is a very important example known as the duality map from a Banach space to its dual space. Before doing this, consider a Hilbert space \( H. \) Define a map \( R \) from \( H \) to \( H', \) called the Riesz map, by the rule
\[ R(x)(y) \equiv (y, x). \]
By the Riesz representation theorem, this map is onto and one to one with the properties
\[ R(x)(x) = ||x||^2, \text{ and } ||Rx||^2 = ||x||^2. \]
The duality map from a Banach space to its dual is an attempt to generalize this notion of Riesz map to an arbitrary Banach space.

**Definition 32.3.15** For \( X \) a Banach space define \( F : X \rightarrow \mathcal{P}(X') \) by
\[ F(x) \equiv \left\{ x^* \in X' : x^*(x) = ||x||^2, ||x^*|| \leq ||x|| \right\}. \] (32.3.28)

**Lemma 32.3.16** With \( F(x) \) defined as above, it follows that
\[ F(x) = \left\{ x^* \in X' : x^*(x) = ||x||^2, ||x^*|| = ||x|| \right\} \]
and \( F(x) \) is a closed, nonempty, convex subset of \( X'. \)
Proof: If $x^*$ is in the set described in (32.3.28),

$$x^* \left( \frac{x}{||x||} \right) = ||x||$$

and so $||x^*|| \geq ||x||$. Therefore

$$x^* \in \left\{ x^* \in X' : x^* (x) = ||x||^2, ||x^*|| = ||x|| \right\}.$$  

This shows this set and the set of (32.3.28) are equal. It is also clear the set of (32.3.28) is closed and convex. It only remains to show this set is nonempty.

Define $f : \mathbb{R} x \to \mathbb{R}$ by $f(\alpha x) = \alpha ||x||^2$. Then the norm of $f$ on $\mathbb{R} x$ is $||x||$ and $f(x) = ||x||^2$. By the Hahn Banach theorem, $f$ has an extension to all of $X x^*$, and this extension is in the set of (32.3.28), showing this set is nonempty as required.

The next theorem shows this duality map is the subgradient of $\frac{1}{2} ||x||^2$.

**Theorem 32.3.17** For $X$ a real Banach space, let $\phi(x) \equiv \frac{1}{2} ||x||^2$. Then $F(x) = \delta \phi(x)$.

**Proof:** Let $x^* \in F(x)$. Then

$$\langle x^*, y-x \rangle = \langle x^*, y \rangle - \langle x^*, x \rangle$$

$$\leq ||x|| \ ||y|| - ||x||^2 \leq \frac{1}{2} ||y||^2 - \frac{1}{2} ||x||^2.$$  

This shows $F(x) \subseteq \delta \phi(x)$.

Now let $x^* \in \delta \phi(x)$. Then for all $t \in \mathbb{R}$,

$$\langle x^*, ty \rangle = \langle x^*, (ty + x) - x \rangle \leq \frac{1}{2} \left( ||x + ty||^2 - ||x||^2 \right). \quad (32.3.29)$$

Now if $t > 0$, divide both sides by $t$. This yields

$$\langle x^*, y \rangle \leq \frac{1}{2t} \left( (||x|| + t \ ||y||)^2 - ||x||^2 \right)$$

$$= \frac{1}{2t} \left( 2t ||x|| \ ||y|| + t^2 ||y||^2 \right)$$

Letting $t \to 0$,

$$\langle x^*, y \rangle \leq ||x|| \ ||y||.$$  

(32.3.30)

Next suppose $t = -s$, where $s > 0$ in (32.3.28). Then, since when you divide by a negative, you reverse the inequality, for $s > 0$

$$\langle x^*, y \rangle \geq \frac{1}{2s} \left( ||x||^2 - ||x - sy||^2 \right) \geq$$

$$\frac{1}{2s} \left[ ||x - sy||^2 - 2 ||x - sy|| \ ||sy|| + ||sy||^2 - ||x - sy||^2 \right]. \quad (32.3.31)$$
\begin{align*}
\langle x^*, y \rangle & = -\|x\| \|y\|.
\end{align*}
(32.3.33)

It follows from (32.3.33) and (32.3.30) that
\begin{align*}
\|\langle x^*, y \rangle\| & \leq \|x\| \|y\|
\end{align*}
and that, therefore, \(|x^*| \leq \|x\| \) and \(|\langle x^*, x \rangle| \leq \|x\|^2\). Now return to (32.3.32) and let \(y = x\). Then
\begin{align*}
\langle x^*, x \rangle & \geq \frac{1}{2s} \left[ -2 \|x - sy\| \|sy\| + \|sy\|^2 \right] \\
& = -\|x\|^2 (1 - s) + s \|x\|^2
\end{align*}
Letting \(s \to 1\),
\begin{align*}
\langle x^*, x \rangle & \geq \|x\|^2.
\end{align*}
Since it was already shown that \(|\langle x^*, x \rangle| \leq \|x\|^2\), this shows \(\langle x^*, x \rangle = \|x\|^2\) and also \(\|x^*\| \leq \|x\|\). Thus
\begin{align*}
\|x^*\| & \geq \left\langle x^*, \frac{x}{\|x\|} \right\rangle = \|x\|
\end{align*}
so in fact \(x^* \in F(x)\). \(\square\)

The next result gives conditions under which the subgradient is onto. This means that if \(y^* \in X'\) then there exists \(x \in X\) such that \(y^* \in \partial \phi (x)\).

**Theorem 32.3.18** Suppose \(X\) is a reflexive Banach space and suppose \(\phi : X \to (-\infty, \infty)\) is convex, proper, l.s.c., and for all \(y^* \in X'\), \(x \to \phi (x) - y^* (x)\) is coercive. Then \(\partial \phi\) is onto.

**Proof:** The function \(x \to \phi (x) - y^* (x) \equiv \psi (x)\) is convex, proper, l.s.c., and coercive. Let
\begin{align*}
\lambda & = \inf \{ \phi (x) - y^* (x) : x \in X \}
\end{align*}
and let \(\{x_n\}\) be a minimizing sequence satisfying
\begin{align*}
\lambda & = \lim_{n \to \infty} \phi (x_n) - y^* (x_n)
\end{align*}
By coercivity,
\begin{align*}
\lim_{\|x\| \to \infty} \phi (x) - y^* (x) & = \infty
\end{align*}
and so this minimizing sequence is bounded. By the Eberlein Smulian theorem, Theorem 15.5.12, there is a weakly convergent subsequence \(x_{n_k} \to x\). By Theorem 16.2.11 \(\phi\) is also weakly lower semicontinuous. Therefore,
\begin{align*}
\lambda & = \phi (x) - y^* (x) \leq \lim_{k \to \infty} \inf_{k \to \infty} \phi (x_{n_k}) - y^* (x_{n_k}) = \lambda
\end{align*}
so there exists $x$ which minimizes $x \to \phi(x) - y^*(x) \equiv \psi(x)$. Therefore, $0 \in \delta \psi(x)$ because

$$\psi(y) - \psi(x) \geq 0 = 0(y - x)$$

by Theorem 32.3.14, $0 \in \delta \psi(x) = \delta \phi(x) - y^*$ and this proves the theorem.

**Corollary 32.3.19** Suppose $X$ is a reflexive Banach space and $\phi : X \to (-\infty, \infty]$ is convex, proper, and l.s.c. Then for each $y^* \in X'$ there exist $x \in X$, $x_1^* \in F(x)$, and $x_2^* \in \delta \phi(x)$ such that

$$y^* = x_1^* + x_2^*.$$ 

**Proof:** Apply Theorem 32.3.18 to the convex function $\frac{1}{2} ||x||^2 + \phi(x)$ and use Theorems 32.3.14 and 32.3.17.

### 32.3.2 Hilbert Space

In this section the subgradients are of a slightly different form and defined on a subset of $H$, a real Hilbert space. In Hilbert space the duality map is just the Riesz map defined earlier by

$$Rx(y) \equiv (y, x).$$

**Definition 32.3.20** $\text{dom} (\partial \phi) \equiv \text{dom} (\delta \phi)$ and for $x \in \text{dom} (\partial \phi)$,

$$\partial \phi(x) \equiv R^{-1} \delta \phi(x).$$

Thus $y \in \partial \phi(x)$ if and only if for all $z \in H$,

$$Ry(z - x) = (y, z - x) \leq \phi(z) - \phi(x).$$

Recall the definition of a maximal monotone operator.

**Definition 32.3.21** A mapping $A : D(A) \subseteq H \to P(H)$ is called monotone if whenever $y_i \in Ax_i$,

$$(y_1 - y_2, x_1 - x_2) \geq 0.$$ 

A monotone map is called maximal monotone if whenever $z \in H$, there exists $x \in D(A)$ and $y \in A(x)$ such that $z = y + x$. Put more simply, $I + A$ maps $D(A)$ onto $H$.

The following lemma states, among other things, that when $\phi$ is a convex, proper, l.s.c. function defined on a Hilbert space, $\partial \phi$ is maximal monotone.

**Lemma 32.3.22** If $\phi$ is a convex, proper, l.s.c. function defined on a Hilbert space, then $\partial \phi$ is maximal monotone and $(I + \partial \phi)^{-1}$ is a Lipschitz continuous map from $H$ to $\text{dom} (\partial \phi)$ having Lipschitz constant 1.
Proof: Let \( y \in H \). Then \( Ry \in H' \) and by Corollary 32.3.19, there exists \( x \in \text{dom} (\delta \phi) \) such that \( Rx + \delta \phi (x) \ni Ry \). Multiplying by \( R^{-1} \) we see \( y \in x + \partial \phi (x) \).

This shows \( I + \partial \phi \) is onto. If \( y_i \in \partial \phi (x_i) \), then \( Ry_i \in \delta \phi (x_i) \) and so by the definition of subgradients,

\[
(y_1 - y_2, x_1 - x_2) = R(y_1 - y_2)(x_1 - x_2) \\
= Ry_1(x_1 - x_2) - Ry_2(x_1 - x_2) \\
\geq \phi(x_1) - \phi(x_2) - (\phi(x_1) - \phi(x_2)) = 0
\]

showing \( \partial \phi \) is monotone. Now suppose \( x_i \in (I + \partial \phi)^{-1} (y) \). Then \( y - x_i \in \partial \phi (x_i) \) and by monotonicity of \( \partial \phi \),

\[-|x_1 - x_2|^2 = (y - x_1 - (y - x_2), x_1 - x_2) \geq 0\]

and so \( x_1 = x_2 \). Thus \( (I + \partial \phi)^{-1} \) is well defined. If \( x_i = (I + \partial \phi)^{-1} (y_i) \), then by the monotonicity of \( \partial \phi \),

\[(y_1 - x_1 - (y_1 - x_2), x_1 - x_2) \geq 0\]

and so

\[|y_1 - y_2| |x_1 - x_2| \geq |x_1 - x_2|^2\]

which shows

\[
|(I + \partial \phi)^{-1} (y_1) - (I + \partial \phi)^{-1} (y_2)| \leq |y_1 - y_2|.
\]

This proves the lemma.

Here is another proof.

Lemma 32.3.23 Let \( \phi \) be convex, proper and lower semicontinuous on \( X \) a reflexive Banach space having strictly convex norm, then for each \( \alpha > 0 \),

\[
I + \alpha \partial \phi
\]

is onto.

Proof: By separation theorems applied to the epigraph of \( \phi \), and since \( \phi \) is proper, there exists \( w^* \) such that

\[
(w^*, x) + b \leq \alpha \phi(x)
\]

for all \( x \). Pick \( y \in H \). Then consider

\[
\frac{1}{2} |y - x|^2 + \alpha \phi(x)
\]

This functional of \( x \) is bounded below by

\[
\frac{1}{2} |y - x|^2 + (w^*, x) + b
\]
32.3. SUBGRADIENTS

Thus it is clearly coercive. Hence any minimizing sequence has a weakly convergent subsequence. It follows from lower semicontinuity that there exists \( x_0 \) which minimizes this functional. Hence, if \( z \neq x_0 \),

\[
0 \leq \frac{1}{2} |y - z|^2 + \alpha \phi(z) - \left( \frac{1}{2} |y - x_0|^2 + \alpha \phi(x_0) \right)
\]

Then writing \(|y - z|^2 = |y - x_0|^2 + |z - x_0|^2 - 2(y - x_0, z - x_0)| \),

\[
= \frac{1}{2} |y - x_0|^2 + \frac{1}{2} |z - x_0|^2 - (y - x_0, z - x_0) + \alpha \phi(z) - \frac{1}{2} |y - x_0|^2 - \alpha \phi(x_0)
\]

\[
= \frac{1}{2} |z - x_0|^2 - (y - x_0, z - x_0) + \alpha \phi(z) - \alpha \phi(x_0)
\]

Thus, letting \( z \) be replaced with \( x_0 + t(z - x_0) \) for small positive \( t \),

\[
t(y - x_0, z - x_0) \leq \frac{t^2}{2} |z - x_0|^2 + \alpha \phi(x_0 + t(z - x_0)) - \alpha \phi(x_0)
\]

\[
\leq \frac{t^2}{2} |z - x_0|^2 + \alpha \phi(x_0 + t(z - x_0)) - \alpha \phi(x_0)
\]

Using convexity of \( \phi \),

\[
\leq \frac{t^2}{2} |z - x_0|^2 + t \alpha \phi(z) - t \alpha \phi(x_0)
\]

Divide by \( t \) and let \( t \to 0 \) to obtain that

\[
(y - x_0, z - x_0) \leq \alpha \phi(z) - \alpha \phi(x_0)
\]

and so

\[
y - x_0 \in \partial (\alpha \phi(x_0))
\]

Thus \( y = x_0 + \alpha \partial \phi(x_0) \) because \( \partial (\alpha \phi) = \alpha \partial \phi \). ■

Thus \( \partial \phi \) is maximal monotone.

There is a really amazing theorem, Moreau’s theorem. It is in [23], [12] and [11]. It involves approximating a convex function with one which is differentiable.

**Theorem 32.3.24** Let \( \phi \) be a convex lower semicontinuous proper function defined on \( H \). Define

\[
\phi_\lambda (x) \equiv \min_{y \in H} \left( \frac{1}{2\lambda} |x - y|^2 + \phi(y) \right)
\]

Then the function is well defined, convex, Frechet differentiable, and for all \( x \in H \),

\[
\lim_{\lambda \to 0} \phi_\lambda (x) = \phi(x),
\]

\( \phi_\lambda (x) \) increasing as \( \lambda \) decreases. In addition,

\[
\phi_\lambda (x) = \frac{1}{2\lambda} |x - J_\lambda x|^2 + \phi(J_\lambda (x))
\]
where $J_{\lambda}x \equiv (I + \lambda \partial \phi)^{-1}(x)$. The Frechet derivative at $x$ equals $A_{\lambda}x$ where

$$A_{\lambda} = \frac{1}{\lambda} - \frac{1}{\lambda} (I + \lambda \partial \phi)^{-1} = \frac{1}{\lambda} - \frac{1}{\lambda} J_{\lambda}$$

Also, there is an interesting relation between the domain of $\phi$ and the domain of $\partial \phi$

$$D(\partial \phi) \subseteq D(\phi) \subseteq D(\partial \phi)$$

Proof: First of all, why does the minimum take place? By the convexity, closed epigraph, and assumption that $\phi$ is proper, separation theorems apply and one can say that there exists $z^*$ such that for all $y \in H$,

$$\frac{1}{2\lambda} |x - y|^2 + \phi(y) \geq \frac{1}{2\lambda} |x - y|^2 + \langle z^*, y \rangle + c \quad (32.3.34)$$

It follows easily that a minimizing sequence is bounded and so from lower semicontinuity which implies weak lower semicontinuity, there exists $y_x$ such that

$$\min_{y \in H} \left( \frac{1}{2\lambda} |x - y|^2 + \phi(y) \right) = \left( \frac{1}{2\lambda} |x - y_x|^2 + \phi(y_x) \right)$$

Why is $\phi_x$ convex? For $\theta \in [0, 1]$,

$$\phi_x (\theta x + (1 - \theta) z) = \frac{1}{2\lambda} |\theta x + (1 - \theta) z - y_{\theta x + (1 - \theta) z}|^2 + \phi(y_{\theta x + (1 - \theta) z})$$

$$\leq \frac{1}{2\lambda} |\theta x + (1 - \theta) z - (\theta y_x + (1 - \theta) y_z)|^2 + \phi(\theta y_x + (1 - \theta) y_z)$$

$$\leq \frac{\theta}{2\lambda} |x - y_x|^2 + \frac{1 - \theta}{2\lambda} |z - y_z|^2 + \theta \phi(y_x) + (1 - \theta) \phi(y_z)$$

$$= \theta \phi_x (x) + (1 - \theta) \phi_x (z)$$

So is there a formula for $y_x$? Since it involves minimization of the functional, it follows as in Lemma 32.3.23 that

$$\frac{1}{\lambda} (x - y_x) \in \partial \phi(y_x)$$

Thus

$$x \in y_x + \lambda \partial \phi(y_x)$$

and so

$$y_x = J_{\lambda}x.$$
32.3. SUBGRADIENTS

This is so if and only if

\[ x \in J_\lambda x + \lambda \partial \phi (J_\lambda x) = (I + \lambda \partial \phi) (J_\lambda x) = (I + \lambda \partial \phi) (I + \lambda \partial \phi)^{-1} x \]

which is clearly true by definition.

Next consider the claim about differentiability.

\[ \phi_\lambda (y) - \phi_\lambda (x) = \frac{\lambda}{2} |A_\lambda y|^2 + \phi(J_\lambda y) - \left( \frac{\lambda}{2} |A_\lambda x|^2 + \phi(J_\lambda x) \right) \]

\[ = \frac{\lambda}{2} \left( |A_\lambda y|^2 - |A_\lambda x|^2 \right) + \phi(J_\lambda y) - \phi(J_\lambda x) \]

\[ \geq \frac{\lambda}{2} \left( |A_\lambda y|^2 - |A_\lambda x|^2 \right) + (A_\lambda x, y - x) + \lambda (A_\lambda x, A_\lambda x - A_\lambda y) \]

\[ \geq \frac{\lambda}{2} \left( |A_\lambda y|^2 - |A_\lambda x|^2 \right) + \frac{\lambda}{2} |A_\lambda x|^2 - \frac{\lambda}{2} |A_\lambda y|^2 + (A_\lambda x, y - x) \]

\[ = (A_\lambda x, y - x) = (A_\lambda x - A_\lambda y, y - x) + (A_\lambda y, y - x) \quad (32.3.35) \]

Then it follows that

\[ -(A_\lambda x - A_\lambda y, y - x) \geq \phi_\lambda (x) - \phi_\lambda (y) - (A_\lambda y, x - y) \]

However, \( A_\lambda \) is Lipschitz continuous with constant \( 1/\lambda \) and so

\[ \frac{1}{\lambda} |x - y|^2 \geq \phi_\lambda (x) - \phi_\lambda (y) - (A_\lambda y, x - y) \quad (32.3.36) \]

Then switching \( x, y \) in the equation \( 32.3.35 \),

\[ \frac{1}{\lambda} |x - y|^2 \geq \phi_\lambda (y) - \phi_\lambda (x) - (A_\lambda x, y - x) \quad (32.3.37) \]

But also that term on the end in \( 32.3.35 \) equals \( (A_\lambda y, y - x) \geq (A_\lambda x, y - x) \) and so it is also the case that

\[ \frac{1}{\lambda} |x - y|^2 \geq \phi_\lambda (x) - \phi_\lambda (y) + (A_\lambda y, y - x) \]

\[ = - (\phi_\lambda (y) - \phi_\lambda (x) - (A_\lambda x, y - x)) \quad (32.3.38) \]

From \( 32.3.36 \) and \( 32.3.37 \) it follows that

\[ \frac{1}{\lambda} |x - y|^2 \geq |\phi_\lambda (y) - \phi_\lambda (x) - (A_\lambda x, y - x)| \]
which shows that \( D\phi_\lambda(x) = A_\lambda x \). This proves the differentiability part.

Next recall that for any maximal monotone operator \( A \), if you have \( x \in \overline{D(A)} \), then
\[
\lim_{\lambda \to 0} J_\lambda x = x
\]
Recall why this was so. If \( x \in D(A) \), then
\[
\lim_{\lambda \to 0} J_\lambda x = x
\]
and so, \( |x - J_\lambda x| \to 0 \) as \( \lambda \to 0 \). If \( x \) is only in \( \overline{D(A)} \), it also works because for \( y \in \overline{D(A)} \)
\[
|x - J_\lambda x| \leq |x - y| + |y - J_\lambda y| + |J_\lambda y - J_\lambda x|
\]
\[
\leq 2|x - y| + |y - J_\lambda y|
\]
If \( \varepsilon \) is given, simply pick \( |y - x| < \varepsilon /2 \) and then
\[
|x - J_\lambda x| \leq \varepsilon + |y - J_\lambda y|
\]
and the last converges to 0. Therefore, \( J_\lambda x \to x \) on \( \overline{D(A)} \).

Returning to the proof of the theorem, if \( x \in \overline{D(\partial \phi)} \) then recall that
\[
\phi_\lambda(x) = \frac{1}{2\lambda} |x - J_\lambda x|^2 + \phi(J_\lambda x)
\]
and so,
\[
\lim_{\lambda \to 0} \phi_\lambda(x) \geq \liminf_{\lambda \to 0} \phi(J_\lambda x) \geq \phi(x) \geq \limsup_{\lambda \to 0} \phi_\lambda(x)
\]
which shows the desired result in case \( x \in \overline{D(\partial \phi)} \). Now consider the case where \( x \notin \overline{D(\partial \phi)} \). In this case, there is a positive lower bound \( \delta \) to \( |x - J_\lambda x| \) because each \( J_\lambda x \in D(\partial \phi) \). Then from the definition and what was shown above,
\[
\phi_\lambda(x) = \frac{\lambda}{2} |A_\lambda x|^2 + \phi(J_\lambda x) \geq \frac{\lambda}{2} |A_\lambda x|^2 + (z^*, J_\lambda x) + c
\]
\[
\geq \frac{\lambda}{2} |A_\lambda x|^2 + (z^*, J_\lambda x - x) + (z^*, x) + c
\]
\[
\geq \frac{1}{2} |A_\lambda x| |x - J_\lambda x| - |z^*| |J_\lambda x - x| - |z^*| |x| + c
\]
\[
\geq \frac{1}{2} (|A_\lambda x| - |z^*|) \delta - |z^*| |x| + c
\]
\[
\geq \frac{1}{2} \left( \frac{\delta}{\lambda} - |z^*| \right) \delta - |z^*| |x| + c
\]
Hence \( \phi_\lambda(x) \to \infty \) and since \( \phi(x) \geq \phi_\lambda(x) \) by construction, it follows that \( \phi(x) = \infty \). The construction of \( \phi_\lambda \) also shows that as \( \lambda \) decreases, \( \phi_\lambda(x) \) increases.

Note that the last part of the argument shows that if \( x \notin \overline{D(\partial \phi)} \), then \( x \notin D(\phi) \).

Hence this shows that
\[
D(\partial \phi) \subseteq D(\phi) \subseteq \overline{D(\partial \phi)} \]
32.4 A Perturbation Theorem

In this section is a simple perturbation theorem found in [23] and [105].

Recall that for $B$ a maximal monotone operator, $B_{\lambda}$, the Yosida approximation, is defined by

$$B_{\lambda}x \equiv \frac{1}{\lambda} (x - J_{\lambda}x), \quad J_{\lambda}x \equiv (I + \lambda B)^{-1} x.$$ 

This follows from Theorem 32.1.7 on Page 1226.

**Theorem 32.4.1** Let $A$ and $B$ be maximal monotone operators and let $x_{\lambda}$ be the solution to

$$y \in x_{\lambda} + B_{\lambda}x_{\lambda} + Ax_{\lambda}.$$ 

Then $y \in x + Bx + Ax$ for some $x \in D(A) \cap D(B)$ if $B_{\lambda}x_{\lambda}$ is bounded independent of $\lambda$.

The following is the perturbation theorem of this section. See [23] and [105].

**Theorem 32.4.2** Let $H$ be a real Hilbert space and let $\Phi$ be non negative, convex, proper, and lower semicontinuous. Suppose also that $A$ is a maximal monotone operator and there exists

$$x_{\lambda} \in D(A) \cap D(\Phi). \quad (32.4.39)$$

Suppose also that for $J_{\lambda}x \equiv (I + \lambda A)^{-1} x$,

$$\Phi(J_{\lambda}x) \leq \Phi(x) + C\lambda \quad (32.4.40)$$

Then $A + \partial \Phi$ is maximal monotone.

**Proof:** Letting $A_{\lambda}$ be the Yosida approximation of $A$,

$$A_{\lambda}x = \frac{1}{\lambda} (x - J_{\lambda}x),$$

and letting $y \in H$, it follows from the Hilbert space version of Proposition 32.1.6 there exists $x_{\lambda} \in H$ such that

$$y \in x_{\lambda} + A_{\lambda}x_{\lambda} + \partial \Phi(x_{\lambda}).$$

Consequently,

$$y - x_{\lambda} - A_{\lambda}x_{\lambda} \in \partial \Phi(x_{\lambda}) \quad (32.4.41)$$

and so

$$(y - x_{\lambda} - A_{\lambda}x_{\lambda}, J_{\lambda}x_{\lambda} - x_{\lambda}) \leq \Phi(J_{\lambda}x_{\lambda}) - \Phi(x_{\lambda}) \leq C\lambda \quad (32.4.42)$$

which implies

$$-(y - x_{\lambda} - A_{\lambda}x_{\lambda}, A_{\lambda}x_{\lambda}) = |A_{\lambda}x_{\lambda}|^2 - |y - x_{\lambda}| |A_{\lambda}x_{\lambda}| \leq C. \quad (32.4.43)$$
By monotonicity of \( A_\lambda \),

\[
\Phi (\xi) - \Phi (x_\lambda) \geq \left( \frac{\in \partial \Phi (x_\lambda)}{y - x_\lambda - A_\lambda x_\lambda, \xi - x_\lambda} \right)
\]

\[
= (y - x_\lambda, \xi - x_\lambda) - (A_\lambda x_\lambda, \xi - x_\lambda)
\]

\[
\geq (y - x_\lambda, \xi - x_\lambda) - (A_\lambda \xi, \xi - x_\lambda)
\]

\[
\geq (y - \xi, \xi - x_\lambda) + |\xi - x_\lambda|^2 - (A_\lambda \xi, \xi - x_\lambda)
\]

\[
= |\xi - x_\lambda|^2 + (y - \xi - A_\lambda \xi, \xi - x_\lambda)
\]

\[
\geq |\xi - x_\lambda|^2 - C_{\xi y} |\xi - x_\lambda|
\]

where \( C_{\xi y} \) depends on \( \xi \) and \( y \) but is independent of \( \lambda \) because of the assumption that \( \xi \in D(A) \cap D(\Phi) \) and Lemma which gives a bound on \( |A_\lambda \xi| \) in terms \( |y| \) for \( y \in Ax \). Therefore, there exist constants, \( C_1 \) and \( C_2 \), depending on \( \xi \) and \( y \) but not on \( \lambda \) such that

\[
\Phi (\xi) \geq \Phi (x_\lambda) + |x_\lambda|^2 - C_1 |x_\lambda| - C_2.
\]

Since \( \Phi \geq 0 \), this shows that \( |x_\lambda| \) is bounded independent of \( \lambda \).

\[
2 \left( \Phi (\xi) + C_2 + \frac{C_1^2}{2} \right) \geq \Phi (x_\lambda) + |x_\lambda|^2.
\]

This shows \( |x_\lambda| \) is bounded independent of \( \lambda \). Therefore, by \( |A_\lambda x_\lambda| \) is bounded independent of \( \lambda \). By Theorem this shows there exists \( x \in D(\partial \Phi) \cap D(A) \) such that

\[
y \in Ax + \partial \Phi (x) + x
\]

and so \( A + \partial \Phi \) is maximal monotone since \( y \in H \) was arbitrary.

### 32.5 An Evolution Inclusion

In this section is a theorem on existence and uniqueness for the initial value problem

\[
x' + \partial \phi (x) \ni f, \quad x(0) = x_0.
\]

Suppose \( \phi \) is a mapping from \( H \) to \([0, \infty]\) which satisfy the following axioms.

\( \phi \) is convex and lower semicontinuous, and proper, \hspace{1cm} (32.5.44)

**Lemma 32.5.1** For \( x \in L^2 (0, T; H) \), \( t \rightarrow \phi (x) \) is measurable.
32.5. AN EVOLUTION INCLUSION

**Proof:** This follows because $\phi$ is Borel measurable and so $\phi(x)$ is also measurable.

Now define the following function $\Phi$, on the Hilbert space, $L^2(0,T;H)$.

$$
\Phi(x) \equiv \begin{cases}
\int_0^T \phi(x(t)) dt & \text{if } x(t) \in D \text{ for a.e. } t \\
+\infty & \text{otherwise}
\end{cases} \quad (32.5.45)
$$

**Lemma 32.5.2** $\Phi$ is convex, nonnegative, and lower semicontinuous on $L^2(0,T;H)$.

**Proof:** Since $\phi$ is nonnegative and convex, it follows that $\Phi$ is also nonnegative and convex. It remains to verify lower semicontinuity. Suppose, $x_n \to x$ in $L^2(0,T;H)$ and let

$$
\lambda = \lim_{n \to \infty} \inf \Phi(x_n).
$$

Is $\lambda \geq \Phi(x)$? Then it suffices to assume $\lambda < \infty$. Suppose not. Then $\lambda < \Phi(x)$. Taking a subsequence, we can have $\lambda = \lim_{n \to \infty} \inf \Phi(x_n)$ and we can take a further subsequence for which convergence of $x_n$ to $x$ is pointwise a.e. Then

$$
\lambda < \Phi(x) \leq \int_0^T \phi(x(t)) dt \leq \int_0^T \lim_{n \to \infty} \phi(x_n(t)) dt
$$

$$
\leq \lim_{n \to \infty} \int_0^T \phi(x_n(t)) dt = \lim_{n \to \infty} \inf \Phi(x_n) = \lambda
$$

which is a contradiction.

Define

$$
D(L) \equiv \{ x \in L^2(0,T;H) : \text{such that} \}
$$

$$
x(t) = x_0 + \int_0^t x'(s) ds \text{ where } x' \in L^2(0,T;H) \}
$$

(32.5.46)

and for $x \in D(L)$,

$$
Lx \equiv x'.
$$

Then $L$ is maximal monotone. To see this, consider the equation

$$
\lambda x' + x = z, \quad x(0) = x_0
$$

It clearly has a solution so $\lambda L + I$ is onto. In fact, the solution is

$$
x = e^{\frac{\lambda t}{\lambda}} x_0 + \frac{1}{\lambda} e^{\frac{\lambda t}{\lambda}} \int_0^t e^{\frac{\lambda s}{\lambda}} z(s) ds
$$

Also,

$$
(Lx - Ly, x - y)_{L^2(0,T;H)} = \int_0^T ((x' - y'), x - y)_H dt
$$
Thus we have the following lemma.

**Lemma 32.5.3** \( L \) is maximal monotone and if \( z \in L^2(0,T;H) \), then \( J_Lz \) is given by

\[
J_L[z](t) = (I + \lambda L)^{-1}([z])(t) = e^{-\lambda t}x_0 + \frac{1}{\lambda} \int_0^t e^{-\lambda s}z(s)\,ds. \quad (32.5.47)
\]

The main theorem is the following.

**Theorem 32.5.4** Let \( x_0 \in D \equiv D(\phi) \). Then \( L + \partial\Phi \) is maximal monotone so there exists a unique solution to

\[
Lx + x + \partial\Phi(x) \ni f \quad (32.5.48)
\]

for every \( f \in L^2(0,T;H) \). Thus there exists \( x \in L^2(0,T;H) \) such that \( x' \in L^2(0,T;H), x(0) = x_0 \in D(\phi) \), and

\[
x' + x + \partial\Phi(x) \ni f, \quad x(0) = x_0
\]

**Proof:** This is from Theorem 32.4.2. Since \( x_0 \in D \), it follows that \( \phi(x_0) < \infty \).

Let \( z \in D(\Phi) \), the effective domain of \( \Phi \). Then \( \int_0^T \phi(z(t))\,dt < \infty \), so by convexity of \( \phi \) and \( \Phi \),

\[
\phi(J_Lz(t)) \leq e^{-\lambda t} \phi(x_0) + \frac{1}{\lambda} \int_0^t e^{-\lambda s} \phi(z(s))\,ds. \quad (32.5.49)
\]

Then

\[
\Phi(J_Lz) = \int_0^T \phi(J_Lz(t))\,dt \leq \phi(x_0) \lambda + \frac{1}{\lambda} \int_0^T \int_0^t e^{-\lambda (s-t)/\lambda} \phi(z(s))\,dsdt
\]

\[
\leq \lambda \phi(x_0) + \frac{1}{\lambda} \int_0^T \phi(z(s)) \int_s^T e^{-\lambda (t-s)/\lambda} dtds
\]

\[
\leq \lambda \phi(x_0) + \left( \int_0^T \phi(z(s))\,ds \right) \frac{1}{\lambda} \int_0^\infty e^{-t/\lambda} dt
\]

\[
= \phi(x_0) \lambda + \int_0^T \phi(z(s))\,ds
\]

\[
= \phi(x_0) \lambda + \Phi(z)
\]
The conditions of Theorem 32.4.2 are satisfied. This proves $L + \partial \Phi$ is maximal monotone on $L^2(0,T;H)$ and consequently there exists a unique solution to the differential inclusion of the theorem.

Then the main result is the following.

**Theorem 32.5.5** Let $f \in L^2(0,T;H)$ and $x_0 \in D$. Let $\phi$ be as described above, a lower semicontinuous convex proper function defined on $H$. Then there exists a unique solution $x \in L^2(0,T;H), x' \in L^2(0,T;H)$, to

$$x' + \partial \Phi(x) \ni f \text{ in } L^2(0,T;H), \quad x(0) = x_0$$

This satisfies the pointwise condition

$$x'(t) + \partial \phi(x(t)) \ni f(t) \text{ for a.e. } t, \quad x(0) = x_0$$

**Proof:** From Theorem 32.5.4 there exists a unique solution to

$$x'_v + \partial \Phi(x_v) + x_v \ni f + v \text{ in } L^2(0,T;H), \quad x_v(0) = x_0$$

whenever $v \in L^2(0,T;H)$. Then a simple argument based on fundamental theorem of calculus implies that for a.e. $t$,

$$x'_v(t) + \partial \phi(x_v(t)) + x_v(t) \ni f(t) + v(t)$$

Then for given $v, u$ one can act on $x_v(t) - x_u(t)$ and integrate. This yields

$$\frac{1}{2} |x_v(t) - x_u(t)|_H^2 + \int_0^t |x_v - x_u|^2 ds \leq \int_0^t |v(s) - u(s)|_H^2 ds$$

It follows that a sufficiently high power of the mapping $u \rightarrow x_u$ is a contraction map on $L^2(0,T;H)$ and so there exists a unique fixed point $v$ in $L^2(0,T;H)$. Thus

$$x_v = v$$

and so

$$v' + \partial \Phi(v) \ni f \text{ in } L^2(0,T;H), \quad v(0) = x_0$$

### 32.6 A More Complicated Perturbation Theorem

In this section is a simple perturbation theorem which is a small generalization of one found in [20] and [11].

Recall that for $B$ a maximal monotone operator, $B_\lambda$, the Yosida approximation, is defined by

$$B_\lambda x \equiv \frac{1}{\lambda} (x - J_\lambda x), \quad J_\lambda x \equiv (I + \lambda B)^{-1} x.$$  

This follows from Theorem 32.1.7 on Page 1220.

**Theorem 32.6.1** Let $A$ and $B$ be maximal monotone operators and let $x_\lambda$ be the solution to

$$y \in x_\lambda + B_\lambda x_\lambda + Ax_\lambda.$$  

Then $y \in x + Bx + Ax$ for some $x \in D(A) \cap D(B)$ if $B_\lambda x_\lambda$ is bounded independent of $\lambda$. 
The following is the perturbation theorem of this section. It generalizes a well known result in [23] and [105].

**Theorem 32.6.2** Let $H$ be a real Hilbert space and let $\Phi$ be non negative, convex, proper, and lower semicontinuous. Suppose also that $A$ is a maximal monotone operator and there exists

$$\xi \in D(A) \cap D(\Phi). \quad (32.6.50)$$

Suppose also that for $J_\lambda x \equiv (I + \lambda A)^{-1} x$,

$$\Phi(J_\lambda x) \leq \Phi(x) + C(x) \lambda \quad (32.6.51)$$

where for some constants, $K_1, K_2$,

$$K_2 + K_1 \left( \Phi(x) + |x|^2 \right) \geq C(x). \quad (32.6.52)$$

Then $A + \partial \Phi$ is maximal monotone.

**Proof:** Letting $A_\lambda$ be the Yosida approximation of $A$,

$$A_\lambda x = \frac{1}{\lambda} (x - J_\lambda x),$$

and letting $y \in H$, it follows from the Hilbert space version of Proposition there exists $x_\lambda \in H$ such that

$$y \in x_\lambda + A_\lambda x_\lambda + \partial \Phi(x_\lambda).$$

Consequently,

$$y - x_\lambda - A_\lambda x_\lambda \in \partial \Phi(x_\lambda) \quad (32.6.53)$$

and so

$$(y - x_\lambda - A_\lambda x_\lambda, J_\lambda x_\lambda - x_\lambda) \leq \Phi(J_\lambda x_\lambda) - \Phi(x_\lambda) \leq C(x_\lambda) \lambda \quad (32.6.54)$$

which implies

$$- (y - x_\lambda - A_\lambda x_\lambda, A_\lambda x_\lambda) \leq C(x_\lambda). \quad (32.6.55)$$

I claim $\{C(x_\lambda)\}$ and $\{|x_\lambda|\}$ are bounded independent of $\lambda$.

By and monotonicity of $A_\lambda$,

$$\Phi(\xi) - \Phi(x_\lambda) \geq (y - x_\lambda - A_\lambda x_\lambda, \xi - x_\lambda)$$

$$\geq (y - x_\lambda, \xi - x_\lambda) - (A_\lambda x_\lambda, \xi - x_\lambda)$$

$$\geq (y - x_\lambda, \xi - x_\lambda) - (A_\lambda \xi, \xi - x_\lambda)$$

$$\geq (y - \xi, \xi - x_\lambda) + \xi - x_\lambda)^2 - (A_\lambda \xi, \xi - x_\lambda)$$

$$\geq |\xi - x_\lambda|^2 - C_{\xi y} |\xi - x_\lambda|$$
where $C_{\xi y}$ depends on $\xi$ and $y$ but is independent of $\lambda$ because of the assumption that $\xi \in D(A) \cap D(\Phi)$ and Lemma 32.6.8 which gives a bound on $|A_\lambda \xi|$ in terms of $|y|$ for $y \in Ax$. Therefore, there exist constants, $C_1$ and $C_2$, depending on $\xi$ and $y$ but not on $\lambda$ such that

$$\Phi(\xi) \geq \Phi(x_\lambda) + |x_\lambda|^2 - C_1 |x_\lambda| - C_2.$$ 

Since $\Phi \geq 0$,

$$2 \left( \Phi(\xi) + C_2 + \frac{C_1^2}{2} \right) \geq \Phi(x_\lambda) + |x_\lambda|^2.$$

This shows $|x_\lambda|$ is bounded independent of $\lambda$. Therefore, by 32.6.52

$$K_2 + 2K_1 \left( \Phi(\xi) + C_2 + \frac{C_1^2}{2} \right) \geq K_2 + K_1 \left( \Phi(x_\lambda) + |x_\lambda|^2 \right) \geq C(x_\lambda),$$

showing that both $|x_\lambda|$ and $C(x_\lambda)$ are bounded independent of $\lambda$. Therefore, from 32.6.52, it follows $A_\lambda x_\lambda$ is bounded independent of $\lambda$. By Theorem 32.6.1 this shows there exists $x \in D(\partial \Phi) \cap D(A)$ such that

$$y \in Ax + \partial \Phi(x) + x$$

and so $A + \partial \Phi$ is maximal monotone since $y \in H$ was arbitrary. This proves the theorem.

### 32.7 An Evolution Inclusion

In this section is a theorem on existence and uniqueness for the initial value problem

$$x' + \partial_2 \phi(t, x) \ni f, \ x(0) = x_0.$$ 

Suppose $\{\phi(t, \cdot)\}_{t \in [0,T]}$ is a family of functions mapping $H$ to $[0, \infty]$ which satisfy the following axioms.

$$\phi(t, \cdot) \text{ is convex and lower semicontinuous}, \quad (32.7.56)$$

$$D(\phi(t, \cdot)) = D, \quad \text{independent of } t \in [0, T], \quad (32.7.57)$$

There exists a constant, $K$, such that for all $x \in D$,

$$|\phi(t, x) - \phi(s, x)| \leq K \left( \phi(r, x) + |x|^2 + 1 \right) |t - s| \quad (32.7.58)$$

for all $r \in [0, T]$.

**Lemma 32.7.1** Under the conditions, 32.7.56 - 32.7.58, $\phi : H \times [0,T] \to [0, \infty]$ is lower semicontinuous.
Proof: Let \((x_n,t_n) \to (x,t)\) and let \(\lambda \equiv \liminf_{n \to \infty} \phi(t_n,x_n)\). Is
\[
\phi(t,x) \leq \lambda?
\]
It suffices to assume \(\lambda < \infty\) and by taking a subsequence, \(x_n \in D\) for all \(n\) and
\[
\phi(t_n,x_n) \to \lambda.
\]
Then
\[
\liminf_{n \to \infty} \phi(t_n,x_n) = \liminf_{n \to \infty} \left[ \phi(t_n,x_n) - \phi(t,x) + \phi(t,x_n) \right].
\]
(32.7.59)
Now
\[
\limsup_{n \to \infty} |\phi(t_n,x_n) - \phi(t,x_n)| \leq \limsup_{n \to \infty} K \left( \phi(t_n,x_n) + |x_n|^2 + 1 \right) |t_n - t| = 0.
\]
Therefore, from (32.7.59)
\[
\lambda = \liminf_{n \to \infty} \phi(t_n,x_n) = \liminf_{n \to \infty} \phi(t,x_n) \geq \phi(t,x)
\]
because of the assumption that \(\phi(t,\cdot)\) is lower semicontinuous. This proves the lemma.

In all that follows \([x]\) is an element of \(L^2(0,T;H)\). Thus \([x]\) is the equivalence class of measurable square integrable functions which equal \(x\) a.e. This seems a little fuzzy but since the existence results are based on surjectivity theorems and the Hilbert space they apply to is \(L^2(0,T;H)\), it seems best to emphasize the equivalence classes of functions by using this notation, at least while proving theorems on existence and uniqueness.

Corollary 32.7.2 For \([x] \in L^2(0,T;H)\), \(t \to \phi(t,x(t))\) is measurable.

Proof: This follows because, due to Lemma 32.7.1, \(\phi\) is Borel measurable and so \(\phi \circ x\) is also measurable.

Now define the following function, \(\Phi\), on the Hilbert space, \(L^2(0,T;H)\).
\[
\Phi([x]) \equiv \begin{cases} 
\int_0^T \phi(t,x(t)) \, dt & \text{if } x(t) \in D \text{ for all } t \text{ for some } x(\cdot) \in [x] \\
+\infty & \text{otherwise} \end{cases}
\]
(32.7.60)
Note that since the functions \(\phi(t,\cdot)\) are proper, the top condition is equivalent to the condition
\[
\int_0^T \phi(t,x(t)) \, dt \text{ if } x(t) \in D \text{ a.e. for all } x(\cdot) \in [x].
\]

Lemma 32.7.3 \(\Phi\) is convex, nonnegative, and lower semicontinuous on \(L^2(0,T;H)\).
32.7. AN EVOLUTION INCLUSION

**Proof:** Since each \( \phi (t, \cdot) \) is nonnegative and convex, it follows that \( \Phi \) is also nonnegative and convex. It remains to verify lower semicontinuity. Suppose, \( [x_n] \to [x] \) in \( L^2 (0, T; H) \) and let

\[
\lambda = \lim \inf_{n \to \infty} \Phi ([x_n]) .
\]

Is \( \lambda \geq \Phi ([x]) \)? It suffices to assume \( \lambda < \infty \), \( x_n (t) \in D \) for all \( t \), and \( x_n (t) \to x (t) \) a.e. say for \( t \notin N \) where \( N \) has measure zero. Let

\[
\bar{x} (t) = \begin{cases} 
  x (t) & \text{if } t \notin N \\
  x_1 (t) & \text{if } t \in N
\end{cases}
\]

Then \( [\bar{x}] = [x] \) and \( \bar{x} (t) \in D \) for all \( t \). Then by pointwise convergence and Fatou's lemma,

\[
\Phi ([x]) = \Phi ([\bar{x}]) = \int_0^T \phi (t, \bar{x} (t)) \, dt \leq \int_0^T \lim \inf_{n \to \infty} \phi (t, x_n (t)) \, dt
\]

\[
\leq \lim \inf_{n \to \infty} \int_0^T \phi (t, x_n (t)) \, dt = \lim \inf_{n \to \infty} \Phi ([x_n]) \equiv \lambda .
\]

This proves the lemma.

Define

\[
D (L) \equiv \{ [x] \in L^2 (0, T; H) : \text{for some } x \in [x] \text{ such that} \}
\]

\[
ex (t) = x_0 + \int_0^t x' (s) \, ds \text{ where } [x'] \in L^2 (0, T; H) \}
\]

and for \( [x] \in D (L) \),

\[
L [x] \equiv [x'] .
\]

The following lemma is easily obtained.

**Lemma 32.7.4** \( L \) is maximal monotone and if \( [z] \in L^2 (0, T; H) \), then the equivalence class, \( [J_\lambda [z]] \) is determined by the function,

\[
J_\lambda [z] (t) = (I + \lambda L)^{-1} ([z]) (t) = e^{-\lambda t} x_0 + \frac{1}{\lambda} e^{-\lambda t} \int_0^t e^{\lambda s} z (s) \, ds .
\]

The main theorem is the following.

**Theorem 32.7.5** Let \( x_0 \in D \). Then \( L + \partial \Phi \) is maximal monotone so there exists a unique solution to

\[
L [x] + [x] + \partial \Phi ([x]) \ni [f]
\]

for every \( [f] \in L^2 (0, T; H) \).
**Proof:** This is from Theorem 32.4. Since \( x_0 \in D \), it follows from 32.6.3 that 
\( \phi(t,x_0) \) is bounded.

Let \( [z] \in D(\Phi) \), the effective domain of \( \Phi \). Then there exists \( z \in [z] \) such that 
\( z(t) \in D \) for all \( t \), and \( \int_0^T \phi(t,z(t)) \, dt < \infty \), so by convexity of \( \phi(t,\cdot) \) and 32.7.66,

\[
\phi(t,J_\lambda[z](t)) \leq e^{\frac{t}{\lambda}} \phi(t,x_0) + \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} \phi(t,z(s)) \, ds.
\]  
(32.7.64)

Now the first term in 32.7.64 is bounded so consider the second. The integral in this term is of the form

\[
\int_0^t e^{\frac{s}{\lambda}} \phi(t,z(s)) \, ds + \int_0^t e^{\frac{s}{\lambda}} (\phi(t,z(s)) - \phi(s,z(s))) \, ds.
\]  
(32.7.65)

Since \( [z] \in D(\Phi) \), \( \phi(s,z(s)) < \infty \) for all \( s \) and also the first integral in 32.7.65 is finite. By 32.7.68, the second term in 32.7.65 is dominated by

\[
C_\lambda \int_0^t K \left( 1 + \phi(s,z(s)) + |z(s)|^2 \right) |t - s| \, ds < \infty.
\]

This shows \( \phi(t,J_\lambda[z](t)) < \infty \) for all \( t \) and so \( \Phi([J_\lambda[z]]) \) is given by the top line of 32.7.65. Therefore, by convexity of \( \phi(t,\cdot) \) and Jensen’s inequality,

\[
\Phi([J_\lambda[z]]) = \int_0^T \phi \left( t, e^{\frac{t}{\lambda}} x_0 + \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} z(s) \, ds \right) \, dt
\]

\[
\leq \int_0^T \left( e^{\frac{t}{\lambda}} \phi(t,x_0) + \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} \phi(t,z(s)) \, ds \right) \, dt
\]

\[
= \int_0^T e^{\frac{t}{\lambda}} \phi(t,x_0) \, dt + \int_0^T \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} \phi(s,z(s)) \, dsdt
\]

\[
+ \int_0^T \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} (\phi(t,z(s)) - \phi(s,z(s))) \, dsdt.
\]  
(32.7.66)

By 32.7.68, the last term is dominated by

\[
\int_0^T \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t \left( 1 + \phi(s,z(s)) + |z(s)|^2 \right) |t - s| \, dsdt =
\]

\[
\frac{1}{\lambda} \int_0^t e^{\frac{t}{\lambda}} \left( 1 + \phi(s,z(s)) + |z(s)|^2 \right) \, ds \leq C_\lambda + C_\lambda \left( \Phi([z]) + ||z||^2 \right).
\]  
(32.7.67)

for some constant, \( C \). From 32.7.68, \( \phi(t,x_0) \) is bounded and so the first term in 32.7.60 is dominated by an expression of the form \( C \lambda \). Now consider the middle term of 32.7.60. Since \( \phi \) is nonnegative,

\[
\int_0^T \frac{1}{\lambda} e^{\frac{t}{\lambda}} \int_0^t e^{\frac{s}{\lambda}} \phi(s,z(s)) \, dsdt = \int_0^T \frac{1}{\lambda} e^{\frac{t}{\lambda}} dt \phi(s,z(s)) \, ds
\]
32.7. AN EVOLUTION INCLUSION

\[ \leq \int_0^T \int_0^\infty e^{-u} du \phi (s, z(s)) ds = \Phi ([z]). \] (32.7.68)

It follows

\[ \Phi ([J_{\lambda} [z]]) \leq \Phi ([z]) + C\lambda + C\lambda \left( \Phi ([z]) + ||z||^2 \right). \]

The conditions of Theorem 32.6.2 are satisfied with \( K_1 = K_2 = C \). This proves \( L + \partial \Phi \) is maximal monotone on \( L^2 (0, T; H) \) and consequently there exists a unique solution to the differential inclusion of the theorem.

Of course it is desirable to be able to say that \([y] \in \partial \Phi ([x])\) if and only if \( y(t) \in \partial \phi (t, x(t)) \) for some \( x \in [x]\). To obtain this, here are two more assumptions. For all \( x \in H \),

\[ t \rightarrow J_1 (t) x \text{ is measurable,} \] (32.7.69)

where \( J_1 (t) x \) is the solution, \( y \), to \( y(t) + \partial \phi (t, y(t)) \ni x \), and there exists \([\xi] \in L^2 (0, T; H)\) such that

\[ [J_1 (\cdot) [\xi]] \in L^2 (0, T; H). \] (32.7.70)

**Lemma 32.7.6** If 32.7.63 and 32.7.64 hold, and if \([y] \in L^2 (0, T; H)\), then \([y] \in \partial \Phi ([x])\) if and only if there exists \( x \in [x]\) such that \( \partial \phi (t, x(t)) \neq \emptyset \) for all \( t \) and \( y(t) \in \partial \phi (t, x(t)) \text{ a.e.} \).

**Proof:** First suppose \( y(t) \in \partial \phi (t, x(t)) \text{ a.e.} \) and \( \partial \phi (t, x(t)) \neq \emptyset \) for all \( t \) where \( x \in [x]\). Then for all \([w] \in L^2 (0, T; H)\),

\[ ([y], [w])_{L^2 (0, T; H)} = \int_0^T (y(t), w(t))_H \] ~\[ \leq \int_0^T \phi (t, x(t) + w(t)) dt - \int_0^T \phi (t, x(t)) dt \leq \Phi ([x] + [w]) - \Phi ([x]). \]

To prove the converse, define \( A : D(\partial \Phi) \rightarrow \mathcal{P}(L^2 (0, T; H)) \) as follows.

\([y] \in A [x] \text{ if and only if for some } x \in [x], \]

\( \partial \phi (t, x(t)) \neq \emptyset \text{ for all } t \text{ and } y(t) \in \partial \phi (t, x(t)) \text{ a.e. } t. \)

It follows \( A \) is monotone. I will show \( A \) is maximal monotone. From the first part of the proof, the graph of \( A \) is contained in the graph of \( \partial \Phi \). Since \( A \) is maximal, this will imply \( A = \partial \Phi \) and prove the lemma.

It remains to show \( A \) is maximal monotone. By 32.7.61, for each \( x \in H \), \( J_1 (t) x \) is measurable. Now from 32.7.61 and using the fact that \( J_1 (t) \) is a contraction,

\[ |J_1 (t) x - J_1 (t) \xi (t)| \leq |x - \xi (t)| \]

and so \([J_1 (\cdot) x] \text{ is } L^2 (0, T; H). \) Now if

\[ s(t) = \sum_{i=1}^n X_{E_i} (t) x_i \]
Suppose there exists \( [\xi] \in L^2(0, T; H) \) such that
\[
J_1(t) \xi(t), \phi(t, J_1(t) \xi(t))
\]
are bounded independent of \( t \in [0, T] \) and \( t \to J_1(t) \xi(t) \) is measurable. Then the conclusion of Lemma 32.7.6 holds.

**Proof:** Let \( y(t) = J_1(t) \xi(t) \). Thus
\[
y(t) + \partial_2 \phi(t, y(t)) \ni \xi(t).
\]
Now suppose \( x \in H \) and let
\[
x(s) + z(s) = x \tag{32.7.71}
\]
where \( z(s) \in \partial_2 \phi(s, x(s)) \), so \( x(s) = J_1(s) x \). Take the inner product of both sides with \( x(s) - y(s) \) to obtain
\[
(x(s), x(s) - y(s))_H + (z(s), x(s) - y(s))_H = (x, x(s) - y(s))_H
\]
and therefore,
\[
\frac{1}{2} |x(s)|_H^2 - \frac{1}{2} |y(s)|_H^2 \leq \phi(s, y(s)) - \phi(s, x(s))
\]
\[
+ |x|_H |x(s)|_H + |x|_H |y(s)|_H \leq \frac{1}{4} |x(s)|_H^2 + c |x|_H^2 + \frac{1}{2} |y(s)|_H^2 + \phi(s, y(s)) - \phi(s, x(s)).
\]
Consequently,
\[
\phi(s, x(s)) + \frac{1}{4} |x(s)|_H^2 \leq |y(s)|_H^2 + c |x|_H^2 + \phi(s, y(s)) < C \tag{32.7.72}
\]
a constant depending on \(x\). Replacing \(s\) with \(t\) in (32.7.71) and subtracting yields
\[
x(t) - x(s) + z(t) - z(s) = 0.
\]
Now taking the inner product of this with \(x(t) - x(s)\) it follows from (32.7.58),
\[
|x(s) - x(t)|^2_H = (z(s) - z(t), x(t) - x(s))_H
\]
\[
\leq \phi(s, x(t)) - \phi(s, x(s)) + \phi(t, x(s)) - \phi(t, x(t))
\]
\[
\leq \left(K \left(\phi(t, x(t)) + |x(t)|^2_H + 1\right) + K \left(\phi(s, x(s)) + |x(s)|^2_H + 1\right)\right) |t - s|
\]
which shows by (32.7.72) that \(x(t)\) is Lipschitz continuous and is therefore measurable which verifies (32.7.69). The assumptions of the lemma include (32.7.70). It follows the conclusion of Lemma 32.7.6.

**Remark 32.7.8** Note that if \(\phi(t, \cdot)\) has a minimum at \(\xi(t)\) and if \(t \to \xi(t)\) and \(t \to \phi(t, \xi(t))\) are bounded and measurable, then
\[
\xi(t) + 0 = \xi(t)
\]
and \(0 \in \partial_2 \phi(t, \xi(t))\). Therefore, in this case \(J_1(t) \xi(t) = \xi(t)\) and so the hypotheses of Lemma 32.7.7 hold.

**Corollary 32.7.9** Assume (32.7.56) - (32.7.58) and (32.7.69), (32.7.70). Let \(x_0 \in D\) and let \([f] \in L^2(0, T; H)\). Then there exists a unique function, \(x\), satisfying
\[
[x] \text{ and } [x'] \text{ are in } L^2(0, T; H)
\]
which is a solution to
\[
x' + \partial_2 \phi(t, x) \ni f \text{ a.e., } x(0) = x_0, x(t) = x_0 + \int_0^t x'(s) \, ds. \quad (32.7.73)
\]

**Proof:** Let \([v] \in L^2(0, T; H)\) and let \([x]\) be the unique solution to
\[
L[x] + [x] + \partial \Phi([x]) \ni [f] + [v]. \quad (32.7.74)
\]
Letting \([x_i]\) be the solution corresponding to (32.7.74) in which \(v\) is replaced with \(v_i\), and \(x_i \in [x_i]\) is such that
\[
x_i(t) = x_0 + \int_0^t x_i'(s) \, ds, \; i = 1, 2,
\]
from Lemma 32.7.6 and 32.7.10 that for each \(t \in [0, T]\),
\[
\frac{1}{2} |x_1(t) - x_2(t)|^2_H + \frac{1}{2} \int_0^t |x_1 - x_2|^2_H ds \leq \frac{1}{2} \int_0^t |v_1(s) - v_2(s)|^2_H ds
\]
and so
\[ |x_1(t) - x_2(t)|_H^2 \leq \int_0^t |v_1(s) - v_2(s)|_H^2 \, ds. \]

Now define a mapping, \( \Lambda : L^2(0,T;H) \to L^2(0,T;H) \) by \( \Lambda [v] = [x] \) where \([x]\) is the solution to \(32.7.74\). Then, if \([v_i]\) is in \(L^2(0,T;H)\) and \([x_i]\) is the corresponding solution to \(32.7.74\),

\[ ||\Lambda [v_1] - \Lambda [v_2]||^2_{L^2(0,t;H)} \equiv \int_0^t |x_1(s) - x_2(s)|_H^2 \, ds \leq \int_0^t \int_0^s |v_1(r) - v_2(r)|_H^2 \, dr \, ds. \]

Iterating this inequality, by replacing \( \Lambda \) with \( \Lambda^k \), it follows that for all \( k \) large enough, \( \Lambda^k \) is a contraction map on \( L^2(0,T;H) \). Thus there exists a unique fixed point for \( \Lambda, [x] \). Thus

\[ L[x] + [x] + \partial \phi ([x]) \ni [f] + [x]. \]

Let \( x \in [x] \) be such that

\[ x(t) = x_0 + \int_0^t x'(s) \, ds. \]

By Lemma \(32.7.6\),

\[ x' + x + \partial_2 \phi (t,x) \ni f + x \]

This function, \( x(\cdot) \) is the unique solution to \(32.7.73\) because if \( x_1 \) is another solution, then \([x_1] = [x]\) and since both functions are continuous, they must coincide. This proves the corollary.
Part III

Sobolev Spaces
Chapter 33

Weak Derivatives

33.1 Weak * Convergence

A very important sort of convergence in applications of functional analysis is the concept of weak or weak * convergence. It is important because it allows you to assert the existence of a convergent subsequence of a given bounded sequence. The only problem is the convergence is very weak so it does not tell you as much as you would like. Nevertheless, it is a very useful concept. The big theorems in the subject are the Eberlein Smulian theorem and the Banach Alaoglu theorem about the weak or weak * compactness of the closed unit balls in either a Banach space or its dual space. These theorems are proved in Yosida [115]. Here I will present a special case which turns out to be by far the most important in applications and it is not hard to get from the Riesz representation theorem for $L^p$. First I define weak and weak * convergence.

**Definition 33.1.1** Let $X'$ be the dual of a Banach space $X$ and let $\{x^*_n\}$ be a sequence of elements of $X'$. Then $x^*_n$ converges weak * to $x^*$ if and only if for all $x \in X$,

$$
\lim_{n \to \infty} x^*_n(x) = x^*(x).
$$

A sequence in $X$, $\{x_n\}$ converges weakly to $x \in X$ if and only if for all $x^* \in X'$

$$
\lim_{n \to \infty} x^*(x_n) = x^*(x).
$$

The main result is contained in the following lemma.

**Lemma 33.1.2** Let $X'$ be the dual of a Banach space, $X$ and suppose $X$ is separable. Then if $\{x^*_n\}$ is a bounded sequence in $X'$, there exists a weak * convergent subsequence.

**Proof:** Let $D$ be a dense countable set in $X$. Then the sequence, $\{x^*_n(x)\}$ is bounded for all $x$ and in particular for all $x \in D$. Use the Cantor diagonal process to
obtain a subsequence, still denoted by \( n \) such that \( x^*_n (d) \) converges for each \( d \in D \). Now let \( x \in X \) be completely arbitrary. In fact \( \{x^*_n (x)\} \) is a Cauchy sequence. Let \( \varepsilon > 0 \) be given and pick \( d \in D \) such that for all \( n \)

\[
|x^*_n (x) - x^*_n (d)| < \frac{\varepsilon}{3}.
\]

This is possible because \( D \) is dense. By the first part of the proof, there exists \( N_\varepsilon \) such that for all \( m, n > N_\varepsilon \),

\[
|x^*_n (d) - x^*_m (d)| < \frac{\varepsilon}{3}.
\]

Then for such \( m, n \),

\[
|x^*_n (x) - x^*_m (x)| \leq |x^*_n (x) - x^*_n (d)| + |x^*_n (d) - x^*_m (d)| + |x^*_m (d) - x^*_m (x)| < \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} = \varepsilon.
\]

Since \( \varepsilon \) is arbitrary, this shows \( \{x^*_n (x)\} \) is a Cauchy sequence for all \( x \in X \).

Now define \( f (x) \equiv \lim_{n \to \infty} x^*_n (x) \). Since each \( x^*_n \) is linear, it follows \( f \) is also linear. In addition to this,

\[
|f (x)| = \lim_{n \to \infty} |x^*_n (x)| \leq K ||x||
\]

where \( K \) is some constant which is larger than all the norms of the \( x^*_n \). Such a constant exists because the sequence, \( \{x^*_n\} \) was bounded. This proves the lemma.

The lemma implies the following important theorem.

**Theorem 33.1.3** Let \( \Omega \) be a measurable subset of \( \mathbb{R}^n \) and let \( \{f_k\} \) be a bounded sequence in \( L^p (\Omega) \) where \( 1 < p < \infty \). Then there exists a weak \* convergent subsequence.

**Proof:** Since \( L^p (\Omega) \) is separable, this follows from the Riesz representation theorem.

Note that from the Riesz representation theorem, it follows that if \( p < \infty \), then the sequence converges weakly.

### 33.2 Test Functions And Weak Derivatives

In elementary courses in mathematics, functions are often thought of as things which have a formula associated with them and it is the formula which receives the most attention. For example, in beginning calculus courses the derivative of a function is defined as the limit of a difference quotient. You start with one function which tends to be identified with a formula and, by taking a limit, you get another formula for the derivative. A jump in abstraction occurs as soon as you encounter the derivative of a function of \( n \) variables where the derivative is defined as a certain linear transformation which is determined not by a formula but by what it does to
vectors. When this is understood, it reduces to the usual idea in one dimension. The idea of weak partial derivatives goes further in the direction of defining something in terms of what it does rather than by a formula, and extra generality is obtained when it is used. In particular, it is possible to differentiate almost anything if the notion of what is meant by the derivative is sufficiently weak. This has the advantage of allowing the consideration of the weak partial derivative of a function without having to agonize over the important question of existence but it has the disadvantage of not being able to say much about the derivative. Nevertheless, it is the idea of weak partial derivatives which makes it possible to use functional analytic techniques in the study of partial differential equations and it is shown in this chapter that the concept of weak derivative is useful for unifying the discussion of some very important theorems. Certain things which should be true are.

Let \( \Omega \subseteq \mathbb{R}^n \). A distribution on \( \Omega \) is defined to be a linear functional on \( C^\infty_c(\Omega) \), called the space of test functions. The space of all such linear functionals will be denoted by \( \mathcal{D}(\Omega) \). Actually, more is sometimes done here. One imposes a topology on \( C^\infty_c(\Omega) \) making it into a topological vector space, and when this has been done, \( \mathcal{D}'(\Omega) \) is defined as the dual space of this topological vector space. To see this, consult the book by Yosida \[115\] or the book by Rudin \[103\].

Example: The space \( L^1_{\text{loc}}(\Omega) \) may be considered as a subset of \( \mathcal{D}'(\Omega) \) as follows.

\[
f(\phi) \equiv \int_{\Omega} f(x) \phi(x) \, dx
\]

for all \( \phi \in C^\infty_c(\Omega) \). Recall that \( f \in L^1_{\text{loc}}(\Omega) \) if \( f|_K \in L^1(\Omega) \) whenever \( K \) is compact.

Example: \( \delta_x \in \mathcal{D}'(\Omega) \) where \( \delta_x(\phi) \equiv \phi(x) \).

It will be observed from the above two examples and a little thought that \( \mathcal{D}'(\Omega) \) is truly enormous. The derivative of a distribution will be defined in such a way that it agrees with the usual notion of a derivative on those distributions which are also continuously differentiable functions. With this in mind, let \( f \) be the restriction to \( \Omega \) of a smooth function defined on \( \mathbb{R}^n \). Then \( D_x f \) makes sense and for \( \phi \in C^\infty_c(\Omega) \)

\[
D_x f(\phi) \equiv \int_{\Omega} D_x f(x) \phi(x) \, dx = -\int_{\Omega} f D_x \phi \, dx = -f(D_x \phi).
\]

This motivates the following definition.

**Definition 33.2.1** For \( T \in \mathcal{D}'(\Omega) \)

\[
D_x T(\phi) \equiv -T(D_x \phi).
\]

Of course one can continue taking derivatives indefinitely. Thus,

\[
D_{x_1 x_2} T \equiv D_{x_1} (D_{x_2} T)
\]

and it is clear that all mixed partial derivatives are equal because this holds for the functions in \( C^\infty_c(\Omega) \). In this weak sense, the derivative of almost anything
exists, even functions that may be discontinuous everywhere. However the notion of “derivative” is very weak, hence the name, “weak derivatives”.

**Example:** Let \( \Omega = \mathbb{R} \) and let

\[
H(x) = \begin{cases} 
1 & \text{if } x \geq 0, \\
0 & \text{if } x < 0.
\end{cases}
\]

Then

\[
DH(\phi) = - \int H(x) \phi'(x) \, dx = \phi(0) = \delta_0(\phi).
\]

Note that in this example, \( DH \) is not a function.

What happens when \( Df \) is a function?

**Theorem 33.2.2** Let \( \Omega = (a, b) \) and suppose that \( f \) and \( Df \) are both in \( L^1(a, b) \). Then \( f \) is equal to a continuous function a.e., still denoted by \( f \) and

\[
f(x) = f(a) + \int_a^x Df(t) \, dt.
\]

In proving Theorem 33.2.2 the following lemma is useful.

**Lemma 33.2.3** Let \( T \in D^* (a, b) \) and suppose \( DT = 0 \). Then there exists a constant \( C \) such that

\[
T(\phi) = \int_a^b C \phi dx.
\]

**Proof:** \( T(D\phi) = 0 \) for all \( \phi \in C^\infty_c (a, b) \) from the definition of \( DT = 0 \). Let

\[
\phi_0 \in C^\infty_c (a, b), \quad \int_a^b \phi_0 (x) \, dx = 1,
\]

and let

\[
\psi_\phi(x) = \int_a^x [\phi(t) - \left( \int_a^b \phi(y) \, dy \right) \phi_0(t)] \, dt
\]

for \( \phi \in C^\infty_c (a, b) \). Thus \( \psi_\phi \in C^\infty_c (a, b) \) and

\[
D\psi_\phi = \phi - \left( \int_a^b \phi(y) \, dy \right) \phi_0.
\]

Therefore,

\[
\phi = D\psi_\phi + \left( \int_a^b \phi(y) \, dy \right) \phi_0
\]

and so

\[
T(\phi) = T(D\psi_\phi) + \left( \int_a^b \phi(y) \, dy \right) T(\phi_0) = \int_a^b T(\phi_0) \phi(y) \, dy.
\]
Let $C = T\phi_0$. This proves the lemma.

**Proof of Theorem 33.2.2** Since $f$ and $Df$ are both in $L^1(a,b)$,

$$Df (\phi) - \int_a^b Df (x) \phi (x) \, dx = 0.$$ Consider

$$f (\cdot) - \int_a^b Df (t) \, dt$$

and let $\phi \in C_c^\infty (a,b)$.

$$D \left( f (\cdot) - \int_a^b Df (t) \, dt \right) (\phi)$$

$$\equiv - \int_a^b f (x) \phi' (x) \, dx + \int_a^b \left( \int_a^x Df (t) \, dt \right) \phi' (x) \, dx$$

$$= Df (\phi) + \int_a^b \int_t^b Df (t) \phi' (x) \, dx \, dt$$

$$= Df (\phi) - \int_a^b Df (t) \phi (t) \, dt = 0.$$ By Lemma 33.2.3, there exists a constant, $C$, such that

$$\left( f (\cdot) - \int_a^b Df (t) \, dt \right) (\phi) = \int_a^b C\phi (x) \, dx$$

for all $\phi \in C_c^\infty (a,b)$. Thus

$$\int_a^b \left\{ (f (x) - \int_a^x Df (t) \, dt) - C \right\} \phi (x) \, dx = 0$$

for all $\phi \in C_c^\infty (a,b)$. It follows from Lemma 33.2.3 in the next section that

$$f (x) - \int_a^x Df (t) \, dt - C = 0 \text{ a.e. } x.$$ Thus let $f (a) = C$ and write

$$f (x) = f (a) + \int_a^x Df (t) \, dt.$$ This proves Theorem 33.2.2.

Theorem 33.2.2 says that

$$f (x) = f (a) + \int_a^x Df (t) \, dt.$$
whenever it makes sense to write \( \int_a^x Df(t) \, dt \), if \( Df \) is interpreted as a weak derivative. Somehow, this is the way it ought to be. It follows from the fundamental theorem of calculus that \( f'(x) \) exists for a.e. \( x \) where the derivative is taken in the sense of a limit of difference quotients and \( f'(x) = Df(x) \). This raises an interesting question. Suppose \( f \) is continuous on \([a,b]\) and \( f'(x) \) exists in the classical sense for a.e. \( x \). Does it follow that

\[
 f(x) = f(a) + \int_a^x f'(t) \, dt?
\]

The answer is no. To see an example, consider Problem 9 on Page 953 which gives an example of a function which is continuous on \([0,1]\), has a zero derivative for a.e. \( x \) but climbs from 0 to 1 on \([0,1]\). Thus this function is not recovered from integrating its classical derivative.

In summary, if the notion of weak derivative is used, one can at least give meaning to the derivative of almost anything, the mixed partial derivatives are always equal, and, in one dimension, one can recover the function from integrating its derivative. None of these claims are true for the classical derivative. Thus weak derivatives are convenient and rule out pathologies.

### 33.3 Weak Derivatives in \( L^p_{\text{loc}} \)

**Definition 33.3.1** Let \( U \) be an open set in \( \mathbb{R}^n \). \( f \in L^p_{\text{loc}}(U) \) if \( f \chi_K \in L^p \) whenever \( K \) is a compact subset of \( U \).

**Definition 33.3.2** For \( \alpha = (k_1, \ldots, k_n) \) where the \( k_i \) are nonnegative integers, define

\[
|\alpha| = \sum_{i=1}^n |k_i|, \quad D^\alpha f(x) = \frac{\partial^{|\alpha|} f(x)}{\partial x_1^{k_1} \partial x_2^{k_2} \cdots \partial x_n^{k_n}}.
\]

Also define \( \phi_k \) to be a mollifier if \( \text{spt}(\phi_k) \subseteq B(0, \frac{1}{k}) \), \( \phi_k \geq 0 \), \( \int \phi_k \, dx = 1 \), and \( \phi_k \in C^\infty_c(B(0, \frac{1}{k})) \). In the case a Greek letter like \( \delta \) or \( \varepsilon \) is used as a subscript, it will mean \( \text{spt}(\phi_\delta) \subseteq B(0, \delta) \), \( \phi_\delta \geq 0 \), \( \int \phi_\delta \, dx = 1 \), and \( \phi_\delta \in C^\infty_c(B(0, \delta)) \). You can always get a mollifier by letting \( \phi \geq 0 \), \( \phi \in C^\infty_c(B(0, 1)) \), \( \int \phi \, dx = 1 \), and then defining \( \phi_k(x) = k^n \phi(kx) \) or in the case of a Greek subscript, \( \phi_\delta(x) = \frac{1}{\delta^n} \phi(\frac{x}{\delta}) \).

Consider the case where \( u \) and \( D^\alpha u \) for \( |\alpha| = 1 \) are each in \( L^p_{\text{loc}}(\mathbb{R}^n) \). The next lemma is the one alluded to in the proof of Theorem 33.2.2.

**Lemma 33.3.3** Suppose \( f \in L^1_{\text{loc}}(U) \) and suppose

\[
\int f \phi \, dx = 0
\]

for all \( \phi \in C^\infty_c(U) \). Then \( f(x) = 0 \) a.e. \( x \).
33.3. WEAK DERIVATIVES IN \( L^p_{\text{loc}} \)

**Proof:** Without loss of generality \( f \) is real valued. Let

\[
E \equiv \{ x : f(x) > \varepsilon \}
\]
and let

\[
E_m = E \cap B(0, m).
\]

Is \( m(E_m) = 0 \)? If not, there exists an open set, \( V \), and a compact set \( K \) satisfying

\[
K \subseteq E_m \subseteq V \subseteq B(0, m), \quad m(V \setminus K) < 4^{-1}m(E_m),
\]
and

\[
\int_{V \setminus K} |f| \, dx < \varepsilon 4^{-1}m(E_m).
\]

Let \( H \) and \( W \) be open sets satisfying

\[
K \subseteq H \subseteq \overline{H} \subseteq W \subseteq \overline{W} \subseteq V
\]
and let

\[
\overline{H} \prec g \prec W
\]
where the symbol, \( \prec \), in the above implies \( \text{spt}(g) \subseteq W \), \( g \) has all values in \([0,1]\), and \( g(x) = 1 \) on \( \overline{H} \). Then let \( \phi_\delta \) be a mollifier and let \( h \equiv g * \phi_\delta \) for \( \delta \) small enough that

\[
K \prec h \prec V.
\]

Thus

\[
0 = \int fh \, dx = \int_K f \, dx + \int_{V \setminus K} fh \, dx \\
\geq \varepsilon m(K) - \varepsilon 4^{-1}m(E_m) \\
\geq \varepsilon (m(E_m) - 4^{-1}m(E_m)) - \varepsilon 4^{-1}m(E_m) \\
\geq 2^{-1} \varepsilon m(E_m).
\]

Therefore, \( m(E_m) = 0 \), a contradiction. Thus

\[
m(E) \leq \sum_{m=1}^{\infty} m(E_m) = 0
\]
and so, since \( \varepsilon > 0 \) is arbitrary,

\[
m(\{ x : f(x) > 0 \}) = 0.
\]

Similarly \( m(\{ x : f(x) < 0 \}) = 0 \). This proves the lemma.

This lemma allows the following definition.

**Definition 33.3.4** Let \( U \) be an open subset of \( \mathbb{R}^n \) and let \( u \in L^1_{\text{loc}}(U) \). Then \( D^\alpha u \in L^1_{\text{loc}}(U) \) if there exists a function \( g \in L^1_{\text{loc}}(U) \), necessarily unique by Lemma 33.3.3, such that for all \( \phi \in C^\infty_c(U) \),

\[
\int_U g \phi \, dx = D^\alpha u(\phi) \equiv \int_U (-1)^{|\alpha|} u(D^\alpha \phi) \, dx.
\]

Then \( D^\alpha u \) is defined to equal \( g \) when this occurs.
Lemma 33.3.5 Let \( u \in L^1_{\text{loc}}(\mathbb{R}^n) \) and suppose \( u,i \in L^1_{\text{loc}}(\mathbb{R}^n) \), where the subscript on the \( u \) following the comma denotes the \( i \)th weak partial derivative. Then if \( \phi_\varepsilon \) is a mollifier and \( u_\varepsilon \equiv u \ast \phi_\varepsilon \), it follows \( u_{\varepsilon,i} \equiv u,i \ast \phi_\varepsilon \).

Proof: If \( \psi \in C_c^\infty(\mathbb{R}^n) \), then

\[
\int u(x - y)\psi_i(x)\,dx = \int u(z)\psi_i(z + y)\,dz
\]

\[
= -\int u,i(z)\psi(z + y)\,dz
\]

\[
= -\int u,i(x - y)\psi(x)\,dx.
\]

Therefore,

\[
u_{\varepsilon,i}(\psi) = -\int u_\varepsilon \psi_i = -\int \int u(x - y)\phi_\varepsilon(y)\psi_i(x)\,d\,y\,d\,x
\]

\[
= -\int \int u(x - y)\psi_i(x)\phi_\varepsilon(y)\,d\,x\,d\,y
\]

\[
= \int \int u,i(x - y)\psi(x)\phi_\varepsilon(y)\,d\,x\,d\,y
\]

\[
= \int u,i \ast \phi_\varepsilon(x)\psi(x)\,dx.
\]

The technical questions about product measurability in the use of Fubini’s theorem may be resolved by picking a Borel measurable representative for \( u \). This proves the lemma.

What about the product rule? Does it have some form in the context of weak derivatives?

Lemma 33.3.6 Let \( U \) be an open set, \( \psi \in C^\infty(U) \) and suppose \( u,u,i \in L^p_{\text{loc}}(U) \). Then \( (u\psi),i \) and \( u\psi \) are in \( L^p_{\text{loc}}(U) \) and

\[
(u\psi),i = u,i\psi + u\psi,i.
\]

Proof: Let \( \phi \in C_c^\infty(U) \) then

\[
(u\psi),i(\phi) = -\int_U u\psi\phi,i\,dx
\]

\[
= -\int_U [(u\psi)\phi,i - \phi\psi,i]\,dx
\]

\[
= \int_U (u,i\psi\phi + u\psi,i\phi)\,dx
\]

\[
= \int_U (u,i\psi + u\psi,i)\phi\,dx.
\]

This proves the lemma.
Recall the notation for the gradient of a function.
\[ \nabla u(x) \equiv (u_1(x) \cdots u_n(x))^T \]
thus
\[ Du(x)v = \nabla u(x) \cdot v. \]

33.4 Morrey’s Inequality

The following inequality will be called Morrey’s inequality. It relates an expression which is given pointwise to an integral of the \( p \)th power of the derivative.

**Lemma 33.4.1** Let \( u \in C^1(\mathbb{R}^n) \) and \( p > n \). Then there exists a constant, \( C \), depending only on \( n \) such that for any \( x, y \in \mathbb{R}^n \),
\[
|u(x) - u(y)| \leq C \left( \int_{B(x,2|x-y|)} |\nabla u(z)|^p dz \right)^{1/p} \left( |x - y|^{(1-n/p)} \right).
\] (33.4.1)

**Proof:** In the argument \( C \) will be a generic constant which depends on \( n \). Consider the following picture.

This is a picture of two balls of radius \( r \) in \( \mathbb{R}^n \), \( U \) and \( V \) having centers at \( x \) and \( y \) respectively, which intersect in the set, \( W \). The center of \( U \) is on the boundary of \( V \) and the center of \( V \) is on the boundary of \( U \) as shown in the picture. There exists a constant, \( C \), independent of \( r \) depending only on \( n \) such that
\[
\frac{m(W)}{m(U)} = \frac{m(W)}{m(V)} = C.
\]
You could compute this constant if you desired but it is not important here.

Define the average of a function over a set, \( E \subseteq \mathbb{R}^n \) as follows.
\[
\int_E f \, dx \equiv \frac{1}{m(E)} \int_E f \, dx.
\]
Then

\[
|u(x) - u(y)| = \int_W |u(x) - u(y)| \, dz
\]

\[
\leq \int_W |u(x) - u(z)| \, dz + \int_W |u(z) - u(y)| \, dz
\]

\[
= \frac{C}{m(U)} \left[ \int_W |u(x) - u(z)| \, dz + \int_W |u(z) - u(y)| \, dz \right]
\]

\[
\leq C \left[ \int_U |u(x) - u(z)| \, dz + \int_V |u(y) - u(z)| \, dz \right]
\]

Now consider these two terms. Using spherical coordinates and letting \( U_0 \) denote the ball of the same radius as \( U \) but with center at \( 0 \),

\[
\int_U |u(x) - u(z)| \, dz
\]

\[
= \frac{1}{m(U_0)} \int_0^{U_0} |u(x) - u(z + x)| \, dz
\]

\[
= \frac{1}{m(U_0)} \int_0^r \rho^{n-1} \int_{S^{n-1}} |u(x) - u(\rho w + x)| \, d\sigma (w) \, d\rho
\]

\[
\leq \frac{1}{m(U_0)} \int_0^r \rho^{n-1} \int_{S^{n-1}} \int_0^\rho |\nabla u(x + tw) \cdot w| \, dt \, d\sigma \, d\rho
\]

\[
\leq \frac{1}{m(U_0)} \int_0^r \rho^{n-1} \int_{S^{n-1}} \int_0^\rho |\nabla u(x + tw)| \, dt \, d\sigma \, d\rho
\]

\[
\leq C \int_0^r \int_{S^{n-1}} \int_0^\rho |\nabla u(x + tw)| \, dt \, d\sigma \, d\rho
\]

\[
= C \int_{S^{n-1}} \int_0^r \frac{|\nabla u(x + tw)|}{t^{n-1}} t^{n-1} dt \, d\sigma
\]

\[
= C \int_{U_0} \frac{|\nabla u(x + z)|}{|z|^{n-1}} \, dz
\]

\[
\leq C \left( \int_{U_0} |\nabla u(x + z)|^p \, dz \right)^{1/p} \left( \int_{U_0} |z|^{p' - np'} \right)^{1/p'}
\]

\[
= C \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \rho^{p' - np'} \rho^{n-1} \, d\rho \, d\sigma \right)^{(p-1)/p}
\]

\[
= C \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} \left( \int_{S^{n-1}} \int_0^r \frac{1}{\rho^{p-1}} \, d\rho \, d\sigma \right)^{(p-1)/p}
\]
33.4. MORREY’S INEQUALITY

\[
\begin{align*}
&= C \left( \frac{p-1}{p-n} \right)^{\frac{1}{p-1/p}} \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} r^{1-\frac{p}{p-1}} \\
&= C \left( \frac{p-1}{p-n} \right)^{\frac{1}{p-1/p}} \left( \int_U |\nabla u(z)|^p \, dz \right)^{1/p} |x-y|^{1-\frac{p}{p-1}}
\end{align*}
\]

Similarly,

\[
\int_V |u(y) - u(z)| \, dz \leq C \left( \frac{p-1}{p-n} \right)^{\frac{1}{p-1/p}} \left( \int_V |\nabla u(z)|^p \, dz \right)^{1/p} |x-y|^{1-\frac{p}{p-1}}
\]

Therefore,

\[
|u(x) - u(y)| \leq C \left( \frac{p-1}{p-n} \right)^{\frac{1}{p-1/p}} \left( \int_{B(x,2|x-y|)} |\nabla u(z)|^p \, dz \right)^{1/p} |x-y|^{1-\frac{p}{p-1}}
\]

because \( B(x,2|x-y|) \supseteq V \cup U \). This proves the lemma.

The following corollary is also interesting

**Corollary 33.4.2** Suppose \( u \in C^1(\mathbb{R}^n) \). Then

\[
|u(y) - u(x) - \nabla u(x) \cdot (y-x)|
\]

\[
\leq C \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x-y|. \quad (33.4.2)
\]

**Proof:** This follows easily from letting \( g(y) \equiv u(y) - u(x) - \nabla u(x) \cdot (y-x) \). Then \( g \in C^1(\mathbb{R}^n) \), \( g(x) = 0 \), and \( \nabla g(z) = \nabla u(z) - \nabla u(x) \). From Lemma \[35.4.1\],

\[
|u(y) - u(x) - \nabla u(x) \cdot (y-x)| = |g(y)| - |g(x)|
\]

\[
\leq C \left( \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x-y|^{1-\frac{p}{p-1}}
\]

\[
= C \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p \, dz \right)^{1/p} |x-y|
\]

This proves the corollary.

It may be interesting at this point to recall the definition of differentiability on Page 123. If you knew the above inequality held for \( \nabla u \) having components in \( L^1_{\text{loc}}(\mathbb{R}^n) \), then at Lebesgue points of \( \nabla u \), the above would imply \( Du(x) \) exists. This is exactly the approach taken below.
33.5 Rademacher’s Theorem

The inequality of Corollary 33.4.2 can be extended to the case where \( u \) and \( u_i \) are in \( L^p_{\text{loc}}(\mathbb{R}^n) \) for \( p > n \). This leads to an elegant proof of the differentiability a.e. of a Lipschitz continuous function as well as a more general theorem.

**Theorem 33.5.1** Suppose \( u \) and all its weak partial derivatives, \( u_i \), are in \( L^p_{\text{loc}}(\mathbb{R}^n) \). Then there exists a set of measure zero, \( E \) such that if \( x, y \notin E \) then inequalities 33.4.2 and 33.4.1 are both valid. Furthermore, \( u \) equals a continuous function a.e.

**Proof:** Let \( u \in L^p_{\text{loc}}(\mathbb{R}^n) \) and \( \psi_k \in C^\infty_c(\mathbb{R}^n), \psi_k \geq 0 \), and \( \psi_k(z) = 1 \) for all \( z \in B(0, k) \). Then it is routine to verify that

\[
(u \psi_k)_i, (u \psi_k)_i \in L^p(\mathbb{R}^n).
\]

Here is why:

\[
(u \psi_k)_i(\phi) = - \int_{\mathbb{R}^n} u \psi_k \phi_i dx
\]

\[
= - \int_{\mathbb{R}^n} u \psi_k \phi_i dx - \int_{\mathbb{R}^n} u \psi_k \phi dx + \int_{\mathbb{R}^n} u \psi_k \phi dx
\]

\[
= - \int_{\mathbb{R}^n} u (\psi_k \phi)_i dx + \int_{\mathbb{R}^n} u \psi_k \phi dx
\]

\[
= \int_{\mathbb{R}^n} (u_i \psi_k + u \psi_k)_i \phi dx
\]

which shows

\[
(u \psi_k)_i = u_i \psi_k + u \psi_k_i
\]

as expected.

Let \( \phi_\varepsilon \) be a mollifier and consider

\[
(u \psi_k)_\varepsilon = u \psi_k * \phi_\varepsilon.
\]

By Lemma 33.3.2 on Page 1276,

\[
(u \psi_k)_\varepsilon, i = (u \psi_k)_i * \phi_\varepsilon.
\]

Therefore

\[
(u \psi_k)_\varepsilon, i \to (u \psi_k)_i \text{ in } L^p(\mathbb{R}^n) \quad (33.5.3)
\]

and

\[
(u \psi_k)_\varepsilon \to u \psi_k \text{ in } L^p(\mathbb{R}^n) \quad (33.5.4)
\]

as \( \varepsilon \to 0 \). By 33.5.3, there exists a subsequence \( \varepsilon \to 0 \) such that for \( |z| < k \) and for each \( i = 1, 2, \cdots, n \)

\[
(u \psi_k)_{\varepsilon, i}(z) \to (u \psi_k)_i(z) = u_i(z) \text{ a.e.}
\]
(u\psi_k)_\varepsilon(z) \to u\psi_k(z) = u(z) \text{ a.e.} \quad (33.5.5)

Denoting the exceptional set by \( E_k \), let

\[
\mathbf{x}, \mathbf{y} \notin \bigcup_{k=1}^\infty E_k \equiv E
\]

and let \( k \) be so large that

\[
B(0,k) \supseteq B(x,2|x-y|).
\]

Then by 33.4.1 and for \( \mathbf{x}, \mathbf{y} \notin E \),

\[
|(u\psi_k)_\varepsilon(\mathbf{x}) - (u\psi_k)_\varepsilon(\mathbf{y})| 
\leq C \left( \int_{B(x,2|\mathbf{y}-\mathbf{x}|)} |\nabla (u\psi_k)_\varepsilon(\mathbf{z})|^p d\mathbf{z} \right)^{1/p} |\mathbf{x} - \mathbf{y}|^{(1-n/p)}
\]

where \( C \) depends only on \( n \). Similarly, by 33.4.2,

\[
|(u\psi_k)_\varepsilon(\mathbf{x}) - (u\psi_k)_\varepsilon(\mathbf{y}) - \nabla (u\psi_k)_\varepsilon(\mathbf{x}) \cdot (\mathbf{y} - \mathbf{x})| 
\leq C \left( \frac{1}{m(B(\mathbf{x},2|\mathbf{y}-\mathbf{x}|))} \int_{B(x,2|x-y|)} |\nabla (u\psi_k)_\varepsilon(\mathbf{z}) - \nabla (u\psi_k)_\varepsilon(\mathbf{x})|^p d\mathbf{z} \right)^{1/p} |\mathbf{x} - \mathbf{y}|.
\]

Now by 33.4.1 and 33.4.2 passing to the limit as \( \varepsilon \to 0 \) yields

\[
|u(\mathbf{x}) - u(\mathbf{y})| \leq C \left( \int_{B(x,2|\mathbf{y}-\mathbf{x}|)} |\nabla u|^p d\mathbf{z} \right)^{1/p} |\mathbf{x} - \mathbf{y}|^{(1-n/p)} \quad (33.5.6)
\]

and

\[
|u(\mathbf{y}) - u(\mathbf{x}) - \nabla u(\mathbf{x}) \cdot (\mathbf{y} - \mathbf{x})| 
\leq C \left( \frac{1}{m(B(\mathbf{x},2|\mathbf{y}-\mathbf{x}|))} \int_{B(x,2|x-y|)} |\nabla u(\mathbf{z}) - \nabla u(\mathbf{x})|^p d\mathbf{z} \right)^{1/p} |\mathbf{x} - \mathbf{y}|. \quad (33.5.7)
\]

Redefining \( u \) on the set of measure zero, \( E \) yields 33.5.6 for all \( \mathbf{x}, \mathbf{y} \). This proves the theorem.

**Corollary 33.5.2** Let \( u, u_i \in L^p_{\text{loc}}(\mathbb{R}^n) \) for \( i = 1, \cdots, n \) and \( p > n \). Then the representative of \( u \) described in Theorem 33.5.1 is differentiable a.e.

**Proof:** From Theorem 33.5.1

\[
|u(\mathbf{y}) - u(\mathbf{x}) - \nabla u(\mathbf{x}) \cdot (\mathbf{y} - \mathbf{x})| 
\leq C \left( \frac{1}{m(B(\mathbf{x},2|\mathbf{y}-\mathbf{x}|))} \int_{B(x,2|x-y|)} |\nabla u(\mathbf{z}) - \nabla u(\mathbf{x})|^p d\mathbf{z} \right)^{1/p} |\mathbf{x} - \mathbf{y}|. \quad (33.5.8)
\]
and at every Lebesgue point, \( x \) of \( \nabla u \)

\[
\lim_{y \to x} \left( \frac{1}{m(B(x,2|x-y|))} \int_{B(x,2|x-y|)} |\nabla u(z) - \nabla u(x)|^p dz \right)^{1/p} = 0
\]

and so at each of these points,

\[
\lim_{y \to x} \frac{|u(y) - u(x) - \nabla u(x) \cdot (y - x)|}{|x - y|} = 0
\]

which says that \( u \) is differentiable at \( x \) and \( Du(x)(v) = \nabla u(x) \cdot (v) \). See Page 124. This proves the corollary.

**Definition 33.5.3** Now suppose \( u \) is Lipschitz on \( \mathbb{R}^n \),

\[
|u(x) - u(y)| \leq K |x - y|
\]

for some constant \( K \). Define \( \text{Lip}(u) \) as the smallest value of \( K \) that works in this inequality.

The following corollary is known as Rademacher’s theorem. It states that every Lipschitz function is differentiable a.e.

**Corollary 33.5.4** If \( u \) is Lipschitz continuous then \( u \) is differentiable a.e. and \( ||u||_{L^p} \leq \text{Lip}(u) \).

**Proof:** This is done by showing that Lipschitz continuous functions have weak derivatives in \( L^\infty(\mathbb{R}^n) \) and then using the previous results. Let \( D_h e_i u(x) = h^{-1} [u(x + he_i) - u(x)] \).

Then \( D_{e_i}^h u \) is bounded in \( L^\infty(\mathbb{R}^n) \) and

\[
||D_{e_i}^h u||_{\infty} \leq \text{Lip}(u).
\]

It follows that \( D_{e_i}^h u \) is contained in a ball in \( L^\infty(\mathbb{R}^n) \), the dual space of \( L^1(\mathbb{R}^n) \). By Theorem 33.1.3 on Page 1270, there is a subsequence \( h \to 0 \) such that

\[
D_{e_i}^h u \to w, \quad ||w||_{\infty} \leq \text{Lip}(u)
\]

where the convergence takes place in the weak * topology of \( L^\infty(\mathbb{R}^n) \). Let \( \phi \in C_c^\infty(\mathbb{R}^n) \). Then

\[
\int w \phi dx = \lim_{h \to 0} \int D_{e_i}^h u \phi dx
\]

\[
= \lim_{h \to 0} \int u(x) \frac{(\phi(x - he_i) - \phi(x))}{h} dx
\]

\[
= -\int u(x) \phi_i(x) dx.
\]

Thus \( w = u_i \) and \( u_i \in L^\infty(\mathbb{R}^n) \) for each \( i \). Hence \( u_i \in L^p_{loc}(\mathbb{R}^n) \) for all \( p > n \) and so \( u \) is differentiable a.e. by Corollary 33.5.2. This proves the corollary.
33.6 Change Of Variables Formula Lipschitz Maps

With Rademacher’s theorem, one can give a general change of variables formula involving Lipschitz maps. First here is an elementary estimate.

**Lemma 33.6.1** Suppose $V$ is an $n - 1$ dimensional subspace of $\mathbb{R}^n$ and $K$ is a compact subset of $V$. Then letting $K_\varepsilon \equiv \bigcup_{x \in K} B(x, \varepsilon) = K + B(0, \varepsilon)$, it follows that

$$m_n(K_\varepsilon) \leq 2^n \varepsilon (\text{diam}(K) + \varepsilon)^{n-1}.$$

**Proof:** Let an orthonormal basis for $V$ be $\{v_1, \ldots, v_{n-1}\}$ and let $\{v_1, \ldots, v_{n-1}, v_n\}$ be an orthonormal basis for $\mathbb{R}^n$. Now define a linear transformation, $Q$ by $Qv_i = e_i$. Thus $QQ^* = Q^*Q = I$ and $Q$ preserves all distances because

$$\left| Q \sum_i a_i e_i \right|^2 = \sum_i a_i v_i \right|^2 = \sum_i |a_i|^2 = \left| \sum_i a_i e_i \right|^2.$$

Letting $k_0 \in K$, it follows $K \subseteq B(k_0, \text{diam}(K))$ and so,

$$QK \subseteq B^{n-1}(Qk_0, \text{diam}(QK)) = B^{n-1}(Qk_0, \text{diam}(K))$$

where $B^{n-1}$ refers to the ball taken with respect to the usual norm in $\mathbb{R}^{n-1}$. Every point of $K_\varepsilon$ is within $\varepsilon$ of some point of $K$ and so it follows that every point of $QK_\varepsilon$ is within $\varepsilon$ of some point of $QK$. Therefore,

$$QK_\varepsilon \subseteq B^{n-1}(Qk_0, \text{diam}(QK) + \varepsilon) \times (-\varepsilon, \varepsilon),$$

To see this, let $x \in QK_\varepsilon$. Then there exists $k \in QK$ such that $|k - x| < \varepsilon$. Therefore, $|(x_1, \ldots, x_{n-1}) - (k_1, \ldots, k_{n-1})| < \varepsilon$ and $|x_n - k_n| < \varepsilon$ and so $x$ is contained in the set on the right in the above inclusion because $k_n = 0$. However, the measure of the set on the right is smaller than

$$[2(\text{diam}(QK) + \varepsilon)]^{n-1} (2\varepsilon) = 2^n [(\text{diam}(K) + \varepsilon)]^{n-1} \varepsilon.$$

This proves the lemma.

Next is the definition of a point of density. This is sort of like an interior point but not as good.

**Definition 33.6.2** Let $E$ be a Lebesgue measurable set. $x \in E$ is a point of density if

$$\lim_{r \to 0} \frac{m(E \cap B(x, r))}{m(B(x, r))} = 1.$$
CHAPTER 33. WEAK DERIVATIVES

You see that if $x$ were an interior point of $E$, then this limit will equal 1. However, it is sometimes the case that the limit equals 1 even when $x$ is not an interior point. In fact, these points of density make sense even for sets that have empty interior.

**Lemma 33.6.3** Let $E$ be a Lebesgue measurable set. Then there exists a set of measure zero, $N$, such that if $x \in E \setminus N$, then $x$ is a point of density of $E$.

**Proof:** Consider the function, $f(x) = \mathcal{L}_E(x)$. This function is in $L^1_{\text{loc}}(\mathbb{R}^n)$. Let $N^C$ denote the Lebesgue points of $f$. Then for $x \in E \setminus N$,

$$1 = \mathcal{L}_E(x) = \lim_{r \to 0} \frac{1}{m_n(B(x,r))} \int_{B(x,r)} \mathcal{L}_E(y) \, dm_n$$

$$= \lim_{r \to 0} \frac{m_n(B(x,r) \cap E)}{m_n(B(x,r))}.$$

In this section, $\Omega$ will be a Lebesgue measurable set in $\mathbb{R}^n$ and $h: \Omega \to \mathbb{R}^n$ will be Lipschitz. Recall the following definition and theorems. See Page 11.4.2 for the proofs and more discussion.

**Definition 33.6.4** Let $F$ be a collection of balls that cover a set, $E$, which have the property that if $x \in E$ and $\varepsilon > 0$, then there exists $B \in F$, diameter of $B < \varepsilon$ and $x \in B$. Such a collection covers $E$ in the sense of Vitali.

**Theorem 33.6.5** Let $E \subseteq \mathbb{R}^n$ and suppose $m_n^*(E) < \infty$ where $m_n^*$ is the outer measure determined by $m_n$, $n$ dimensional Lebesgue measure, and let $F$, be a collection of closed balls of bounded radii such that $F$ covers $E$ in the sense of Vitali. Then there exists a countable collection of disjoint balls from $F$, $\{B_j\}_{j=1}^\infty$, such that $m_n^*(E \setminus \bigcup_{j=1}^\infty B_j) = 0$.

Now this theorem implies a simple lemma which is what will be used.

**Lemma 33.6.6** Let $V$ be an open set in $\mathbb{R}^r, m_r(V) < \infty$. Then there exists a sequence of disjoint open balls $\{B_i\}$ having radii less than $\delta$ and a set of measure 0, $T$, such that $V = \bigcup_{i=1}^\infty B_i \cup T$.

As in the proof of the change of variables theorem given earlier, the first step is to show that $h$ maps Lebesgue measurable sets to Lebesgue measurable sets. In showing this the key result is the next lemma which states that $h$ maps sets of measure zero to sets of measure zero.

**Lemma 33.6.7** If $m_n(T) = 0$ then $m_n(h(T)) = 0$.

**Proof:** Let $V$ be an open set containing $T$ whose measure is less than $\varepsilon$. Now using the Vitali covering theorem, there exists a sequence of disjoint balls $\{B_i\}$,
33.6. CHANGE OF VARIABLES FORMULA LIPSCHITZ MAPS

\[ B_i = B(x_i, r_i) \] which are contained in \( V \) such that the sequence of enlarged balls, \( \{\tilde{B}_i\} \), having the same center but 5 times the radius, covers \( T \). Then

\[
m_n(h(T)) \leq m_n\left(h\left(\bigcup_{i=1}^{\infty} \tilde{B}_i\right)\right)
\]

\[
\leq \sum_{i=1}^{\infty} m_n\left(h\left(\tilde{B}_i\right)\right)
\]

\[
\leq \sum_{i=1}^{\infty} \alpha(n) (\text{Lip}(h))^n 5^n r_i^n = 5^n (\text{Lip}(h))^n \sum_{i=1}^{\infty} m_n(B_i)
\]

\[
\leq (\text{Lip}(h))^n 5^n m_n(V) \leq \varepsilon (\text{Lip}(h))^n 5^n.
\]

Since \( \varepsilon \) is arbitrary, this proves the lemma.

With the conclusion of this lemma, the next lemma is fairly easy to obtain.

**Lemma 33.6.8** If \( A \) is Lebesgue measurable, then \( h(A) \) is \( m_n \) measurable. Furthermore,

\[
m_n(h(A)) \leq (\text{Lip}(h))^n m_n(A).
\]

**Proof:** Let \( A_k = A \cap B(0, k), k \in \mathbb{N} \). Let \( V \supseteq A_k \) and let \( m_n(V) < \infty \). By Lemma 33.6.6, there is a sequence of disjoint balls \( \{B_i\} \) and a set of measure 0, \( T \), such that

\[
V = \bigcup_{i=1}^{\infty} B_i \cup T, \quad B_i = B(x_i, r_i).
\]

By Lemma 33.6.7,

\[
\overline{m}_n(h(A_k)) \leq \overline{m}_n(h(V))
\]

\[
\leq \overline{m}_n(h(\bigcup_{i=1}^{\infty} B_i)) + \overline{m}_n(h(T)) = \overline{m}_n(h(\bigcup_{i=1}^{\infty} B_i))
\]

\[
\leq \sum_{i=1}^{\infty} \overline{m}_n(h(B_i)) \leq \sum_{i=1}^{\infty} \overline{m}_n(B(h(x_i), \text{Lip}(h)r_i))
\]

\[
\leq \sum_{i=1}^{\infty} \alpha(n) (\text{Lip}(h)r_i)^n = \text{Lip}(h)^n \sum_{i=1}^{\infty} m_n(B_i) = \text{Lip}(h)^n m_n(V).
\]

Therefore,

\[
\overline{m}_n(h(A_k)) \leq \text{Lip}(h)^n m_n(V).
\]

Since \( V \) is an arbitrary open set containing \( A_k \), it follows from regularity of Lebesgue measure that

\[
\overline{m}_n(h(A_k)) \leq \text{Lip}(h)^n m_n(A_k).
\]

(33.6.10)

Now let \( k \to \infty \) to obtain (33.6.9). This proves the formula. It remains to show \( h(A) \) is measurable.
By inner regularity of Lebesgue measure, there exists a set, \( F \), which is the countable union of compact sets and a set \( T \) with \( m_n (T) = 0 \) such that

\[
F \cup T = A_k.
\]

Then \( h(F) \subseteq h(A_k) \subseteq h(F) \cup h(T) \). By continuity of \( h \), \( h(F) \) is a countable union of compact sets and so it is Borel. By 33.6.10 with \( T \) in place of \( A_k \),

\[
m_n (h(T)) = 0
\]

and so \( h(T) \) is \( m_n \) measurable. Therefore, \( h(A_k) \) is \( m_n \) measurable because \( m_n \) is a complete measure and this exhibits \( h(A_k) \) between two \( m_n \) measurable sets whose difference has measure 0. Now

\[
h(A) = \bigcup_{k=1}^{\infty} h(A_k)
\]

so \( h(A) \) is also \( m_n \) measurable and this proves the lemma.

The following lemma, depending on the Brouwer fixed point theorem and found in Rudin [102], will be important for the following arguments. The idea is that if a continuous function mapping a ball in \( \mathbb{R}^k \) to \( \mathbb{R}^k \) doesn’t move any point very much, then the image of the ball must contain a slightly smaller ball.

**Lemma 33.6.9** Let \( B = B(0, r) \), a ball in \( \mathbb{R}^k \) and let \( F : \overline{B} \to \mathbb{R}^k \) be continuous and suppose for some \( \varepsilon < 1 \),

\[
|F(v) - v| < \varepsilon r
\]

for all \( v \in \overline{B} \). Then

\[
F(\overline{B}) \supseteq \overline{B}(0, r(1 - \varepsilon)).
\]

**Proof:** Suppose \( a \in \overline{B}(0, r(1 - \varepsilon)) \setminus F(\overline{B}) \) and let

\[
G(v) \equiv \frac{r(a - F(v))}{|a - F(v)|}.
\]

Then by the Brouwer fixed point theorem, \( G(v) = v \) for some \( v \in \overline{B} \). Using the formula for \( G \), it follows \( |v| = r \). Taking the inner product with \( v \),

\[
(G(v), v) = |v|^2 = r^2 = \frac{r}{|a - F(v)|} (a - F(v), v)
\]

\[
= \frac{r}{|a - F(v)|} (a - v + v - F(v), v)
\]

\[
= \frac{r}{|a - F(v)|} [(a - v, v) + (v - F(v), v)]
\]

\[
= \frac{r}{|a - F(v)|} [(a, v) - |v|^2 + (v - F(v), v)]
\]

\[
\leq \frac{r}{|a - F(v)|} [r^2 (1 - \varepsilon) - r^2 + r^2 \varepsilon] = 0,
\]
33.6. CHANGE OF VARIABLES FORMULA LIPSCHITZ MAPS

a contradiction. Therefore, \( \mathbb{B}(0, r(1 - \varepsilon)) \setminus \mathbf{F}(\mathbb{B}) = \emptyset \) and this proves the lemma.

Now let \( \Omega \) be a Lebesgue measurable set and suppose \( h: \mathbb{R}^n \to \mathbb{R}^n \) is Lipschitz continuous and one to one on \( \Omega \). Let

\[
N \equiv \{ x \in \Omega : D h(x) \text{ does not exist} \} \tag{33.6.11}
\]
\[
S \equiv \{ x \in \Omega \setminus N : D h(x)^{-1} \text{ does not exist} \} \tag{33.6.12}
\]

**Lemma 33.6.10** Let \( x \in \Omega \setminus (S \cup N) \). Then if \( \varepsilon \in (0, 1) \) the following hold for all \( r \) small enough.

\[
m_n \left( \mathbf{h} \left( B(x, r) \right) \right) \geq m_n \left( D h(x) B(0, r(1 - \varepsilon)) \right), \tag{33.6.13}
\]
\[
h \left( B(x, r) \right) \subseteq h(x) + D h(x) B(0, r(1 + \varepsilon)), \tag{33.6.14}
\]
\[
m_n \left( \mathbf{h} \left( B(x, r) \right) \right) \leq m_n \left( D h(x) B(0, r(1 + \varepsilon)) \right) \tag{33.6.15}
\]

If \( x \in \Omega \setminus (S \cup N) \) is also a point of density of \( \Omega \), then

\[
\lim_{r \to 0} \frac{m_n(h(B(x, r) \cap \Omega))}{m_n(h(B(x, r)))} = 1. \tag{33.6.16}
\]

If \( x \in \Omega \setminus N \), then

\[
|\det D h(x)| = \lim_{r \to 0} \frac{m_n(h(B(x, r)))}{m_n(B(x, r))} \quad \text{a.e.} \tag{33.6.17}
\]

**Proof:** Since \( D h(x)^{-1} \) exists,

\[
h(x + v) = h(x) + D h(x) v + o(|v|) \tag{33.6.18}
\]
\[
= h(x) + D h(x) \left( v + D h(x)^{-1} o(|v|) \right) \tag{33.6.19}
\]

Consequently, when \( r \) is small enough, \(33.6.13\) holds. Therefore, \(33.6.14\) holds. From \(33.6.11\) and the assumption that \( D h(x)^{-1} \) exists,

\[
D h(x)^{-1} h(x + v) - D h(x)^{-1} h(x) = o(|v|). \tag{33.6.20}
\]

Letting

\[
\mathbf{F}(v) = D h(x)^{-1} h(x + v) - D h(x)^{-1} h(x),
\]

apply Lemma 33.6.10 in \(33.6.20\) to conclude that for \( r \) small enough, whenever \( |v| < r \),

\[
D h(x)^{-1} h(x + v) - D h(x)^{-1} h(x) \supseteq B(0, (1 - \varepsilon) r).
\]

Therefore,

\[
h(B(x, r)) \supseteq h(x) + D h(x) B(0, (1 - \varepsilon) r)
\]
which implies

\[ m_n \left( h \left( B(x, r) \setminus \Omega \right) \right) \geq m_n \left( Dh(x) B(0, r (1 - \varepsilon)) \right) \]

which shows (33.6.13).

Now suppose that \( x \) is a point of density of \( \Omega \) as well as being a point where \( Dh(x)^{-1} \) and \( Dh(x) \) exist. Then whenever \( r \) is small enough,

\[ 1 - \varepsilon < \frac{m_n \left( h(B(x, r) \cap \Omega) \right)}{m_n \left( h(B(x, r)) \right)} \leq 1 \]

and so

\[ 1 - \varepsilon < \frac{m_n \left( h(B(x, r) \cap \Omega^C) \right)}{m_n \left( h(B(x, r)) \right)} + \frac{m_n \left( h(B(x, r) \cap \Omega) \right)}{m_n \left( h(B(x, r)) \right)} \leq \frac{m_n \left( h(B(x, r)) \right)}{m_n \left( h(B(x, r)) \right)} + 1. \]

which implies

\[ m_n (B(x, r) \setminus \Omega) < \varepsilon \alpha(n) r^n. \quad (33.6.21) \]

Then for such \( r \),

\[ 1 \geq \frac{m_n \left( h(B(x, r) \cap \Omega) \right)}{m_n \left( h(B(x, r)) \right)} \geq \frac{m_n \left( h(B(x, r)) \right) - m_n \left( h(B(x, r) \setminus \Omega) \right)}{m_n \left( h(B(x, r)) \right)}. \]

From Lemma (33.6.8), (33.6.9), and (33.6.11), this is no larger than

\[ 1 - \frac{\text{Lip}(h)^n \varepsilon \alpha(n) r^n}{m_n (Dh(x) B(0, r (1 - \varepsilon)))}. \]

By the theorem on the change of variables for a linear map, this expression equals

\[ 1 - \frac{\text{Lip}(h)^n \varepsilon \alpha(n) r^n}{|\text{det}(Dh(x))| r^n \alpha(n) (1 - \varepsilon) n} = 1 - g(\varepsilon) \]

where \( \lim_{\varepsilon \to 0} g(\varepsilon) = 0 \). Then for all \( r \) small enough,

\[ 1 \geq \frac{m_n \left( h(B(x, r) \cap \Omega) \right)}{m_n \left( h(B(x, r)) \right)} \geq 1 - g(\varepsilon) \]

which shows (33.6.14) since \( \varepsilon \) is arbitrary. It remains to verify (33.6.17).

In case \( x \in S \), for small \( |v| \),

\[ h(x + v) = h(x) + Dh(x) v + o(|v|) \]

where \( |o(|v|)| < \varepsilon |v| \). Therefore, for small enough \( r \),

\[ h(B(x, r)) - h(x) \subseteq K + B(0, r \varepsilon) \]
where $K$ is a compact subset of an $n-1$ dimensional subspace contained in $Dh (x) ( \mathbb{R}^n )$ which has diameter no more than $2 ||Dh (x)|| r$. By Lemma 33.6.1 on Page 1283,

$$m_n (h (B (x, r))) = m_n (h (B (x, r)) - h (x)) \leq 2^n \varepsilon r (2 ||Dh (x)|| r + r^2 r)$$

and so, in this case, letting $r$ be small enough,

$$\frac{m_n (h (B (x, r)))}{m_n (B (x, r))} \leq \frac{2^n \varepsilon r (2 ||Dh (x)|| r + r^2 r)}{\alpha (n) r^n} \leq C \varepsilon.$$

Since $\varepsilon$ is arbitrary, the limit as $r \to 0$ of this quotient equals 0.

If $x \notin S$, use 33.6.13-33.6.15 along with the change of variables formula for linear maps. This proves the Lemma.

Since $h$ is one to one, there exists a measure, $\mu$, defined by

$$\mu (E) = m_n (h (E))$$

on the Lebesgue measurable subsets of $\Omega$. By Lemma 33.6.8 $\mu \ll m_n$ and so by the Radon Nikodym theorem, there exists a nonnegative function, $J (x)$ in $L^1_{loc} (\mathbb{R}^n)$ such that whenever $E$ is Lebesgue measurable,

$$\mu (E) = m_n (h (E \cap \Omega)) = \int_{E \cap \Omega} J (x) \, dm_n. \quad (33.6.22)$$

Extend $J$ to equal zero off $\Omega$.

**Lemma 33.6.11** The function, $J (x)$ equals $|\det Dh (x)|$ a.e.

**Proof:** Define

$$Q \equiv \{x \in \Omega : x \text{ is not a point of density of } \Omega\} \cup N \cup$$

$$\{x \in \Omega : x \text{ is not a Lebesgue point of } J\}.$$

Then $Q$ is a set of measure zero and if $x \notin Q$, then by 33.6.15 and 33.6.14,

$$\lim_{r \to 0} \frac{m_n (h (B (x, r)))}{m_n (B (x, r))} = \lim_{r \to 0} \frac{m_n (h (B (x, r))) - m_n (h (x))}{m_n (B (x, r)) - m_n (B (x, r))} = \lim_{r \to 0} \frac{1}{m_n (B (x, r))} \int_{B (x, r) \cap \Omega} J (y) \, dm_n$$

the last equality because $J$ was extended to be zero off $\Omega$. This proves the lemma.

Here is the change of variables formula for Lipschitz mappings. It is a special case of the area formula.
Theorem 33.6.12 Let $\Omega$ be a Lebesgue measurable set, let $f \geq 0$ be Lebesgue measurable. Then for $h$ a Lipschitz mapping defined on $\mathbb{R}^n$ which is one to one on $\Omega$,
\[
\int_{h(\Omega)} f(y) \, dm_n = \int_\Omega f(h(x)) |\det Dh(x)| \, dm_n. \tag{33.6.23}
\]

**Proof:** Let $F$ be a Borel set. It follows that $h^{-1}(F)$ is a Lebesgue measurable set. Therefore, by 33.6.22,
\[
m_n \left( h^{-1}(F) \cap \Omega \right) \leq \int_{h(\Omega)} X_F(y) \, dm_n = \int_\Omega X_{h^{-1}(F)}(x) J(x) \, dm_n \leq \int_{h(\Omega)} X_F(h(x)) J(x) \, dm_n.
\]

What if $F$ is only Lebesgue measurable? Note there are no measurability problems with the above expression because $x \mapsto X_F(h(x))$ is Borel measurable due to the assumption that $h$ is continuous while $J$ is given to be Lebesgue measurable. However, if $F$ is Lebesgue measurable, not necessarily Borel measurable, then it is no longer clear that $x \mapsto X_F(h(x)) J(x)$ is measurable. In fact this is not always even true. However, $x \mapsto X_F(h(x)) J(x)$ is measurable and 33.6.24 holds.

Let $F$ be Lebesgue measurable. Then by inner regularity, $F = H \cup N$ where $N$ has measure zero, $H$ is the countable union of compact sets so it is a Borel set, and $H \cap N = \emptyset$. Therefore, letting $N'$ denote a Borel set of measure zero which contains $N$,
\[
b(x) \equiv X_H(h(x)) J(x) \leq X_F(h(x)) J(x)
\]
\[
= X_H(h(x)) J(x) + X_N(h(x)) J(x) 
\]
\[
\leq X_H(h(x)) J(x) + X_{N'}(h(x)) J(x) \equiv u(x)
\]

Now since $N'$ is Borel,
\[
\int_\Omega (u(x) - b(x)) \, dm_n = \int_\Omega X_{N'}(h(x)) J(x) \, dm_n 
\]
\[
= m_n \left( h^{-1}(N' \cap \Omega) \right) = m_n \left( N' \cap h(\Omega) \right) = 0
\]
and this shows $X_H(h(x)) J(x) = X_F(h(x)) J(x)$ except on a set of measure zero. By completeness of Lebesgue measure, it follows $x \mapsto X_F(h(x)) J(x)$ is Lebesgue measurable and also since $h$ maps sets of measure zero to sets of measure zero,
\[
\int_{h(\Omega)} X_F(h(x)) J(x) \, dm_n = \int_{h(\Omega)} X_H(y) \, dm_n = \int_{h(\Omega)} X_F(y) \, dm_n.
\]
33.6. CHANGE OF VARIABLES FORMULA LIPSCHITZ MAPS

It follows that if \( s \) is any nonnegative Lebesgue measurable simple function,

\[
\int_{\Omega} s(h(x)) \, J(x) \, dm_n = \int_{h(\Omega)} s(y) \, dm_n \quad (33.6.25)
\]

and now, if \( f \geq 0 \) is Lebesgue measurable, let \( s_k \) be an increasing sequence of Lebesgue measurable simple functions converging pointwise to \( f \). Then since \(33.6.25\) holds for \( s_k \), the monotone convergence theorem applies and yields \(33.6.24\). This proves the theorem.

It turns out that a Lipschitz function defined on some subset of \( \mathbb{R}^n \) always has a Lipschitz extension to all of \( \mathbb{R}^n \). The next theorem gives a proof of this. For more on this sort of theorem see Federer [47]. He gives a better but harder theorem than what follows.

**Theorem 33.6.13** If \( h : \Omega \to \mathbb{R}^m \) is Lipschitz, then there exists \( \overline{h} : \mathbb{R}^n \to \mathbb{R}^m \) which extends \( h \) and is also Lipschitz.

**Proof:** It suffices to assume \( m = 1 \) because if this is shown, it may be applied to the components of \( h \) to get the desired result. Suppose

\[
|h(x) - h(y)| \leq K|x - y|. \quad (33.6.26)
\]

Define

\[
\overline{h}(x) \equiv \inf \{h(w) + K|x - w| : w \in \Omega\}. \quad (33.6.27)
\]

If \( x \in \Omega \), then for all \( w \in \Omega \),

\[
h(w) + K|x - w| \geq h(x)
\]

by \(33.6.26\). This shows \( h(x) \leq \overline{h}(x) \). But also you could take \( w = x \) in \(33.6.26\) which yields \( \overline{h}(x) \leq h(x) \). Therefore \( \overline{h}(x) = h(x) \) if \( x \in \Omega \).

Now suppose \( x, y \in \mathbb{R}^n \) and consider \( |\overline{h}(x) - \overline{h}(y)| \). Without loss of generality assume \( \overline{h}(x) \geq \overline{h}(y) \). (If not, repeat the following argument with \( x \) and \( y \) interchanged.) Pick \( w \in \Omega \) such that

\[
h(w) + K|y - w| - \varepsilon < \overline{h}(y).
\]

Then

\[
|\overline{h}(x) - \overline{h}(y)| = |\overline{h}(x) - \overline{h}(y)| \leq h(w) + K|x - w| - [h(w) + K|y - w| - \varepsilon] \leq K|x - y| + \varepsilon.
\]

Since \( \varepsilon \) is arbitrary,

\[
|\overline{h}(x) - \overline{h}(y)| \leq K|x - y|
\]

and this proves the theorem.

This yields a simple corollary to Theorem 33.6.12.

**Corollary 33.6.14** Let \( h : \Omega \to \mathbb{R}^n \) be Lipschitz continuous and one to one where \( \Omega \) is a Lebesgue measurable set. Then if \( f \geq 0 \) is Lebesgue measurable,

\[
\int_{h(\Omega)} f(y) \, dm_n = \int_{\Omega} f(h(x)) \left|\det D\overline{h}(x)\right| \, dm_n. \quad (33.6.28)
\]

where \( \overline{h} \) denotes a Lipschitz extension of \( h \).
Chapter 34
The Area And Coarea Formulas

34.1 The Area Formula Again

Recall the area formula presented earlier. For convenience, here it is.

**Theorem 34.1.1** Let \( g : h(A) \to [0, \infty] \) be \( \mathcal{H}^n \) measurable where \( h \) is a continuous function and \( A \) is a Lebesgue measurable set satisfying certain conditions. That is, \( U \) is an open set in \( \mathbb{R}^n \) on which \( h \) is defined and \( A \subseteq U \) is a Lebesgue measurable set, \( m \geq n \), and

\[
\begin{align*}
    h &: U \to \mathbb{R}^m \text{ is continuous}, \\
    Dh(x) &\text{ exists for all } x \in A, \\
    |h(z) - h(y)| &\leq L_x |x - y|
\end{align*}
\]

Also assume that for every \( x \in A \), there exists \( r_x \) and \( L_x \) such that for all \( y, z \in B(x, r_x) \),

\[
|h(z) - h(y)| \leq L_x |x - y|
\]

Then

\[
x \to (g \circ h)(x) J(x)
\]

is Lebesgue measurable and

\[
\int_{h(A)} g(y) \, d\mathcal{H}^n = \int_A g(h(x)) J(x) \, dm
\]

where \( J(x) = \det(U(x)) = \det(Dh(x)^* Dh(x))^{1/2} \).

Obviously, one can obtain improved versions of this important theorem by using Rademacher’s theorem and condition \( 34.1.3 \). As mentioned earlier, a function which satisfies \( 34.1.3 \) is called locally Lipschitz at \( x \). Here is a simple lemma which is in the spirit of similar lemmas presented in the chapter on Hausdorff measures.
Lemma 34.1.2 Let $U$ be an open set in $\mathbb{R}^n$ and let $h : U \to \mathbb{R}^m$ where $m \geq n$. Let $A \subseteq U$ and let $h$ be locally Lipschitz at every point of $A$. Then if $N \subseteq A$ has Lebesgue measure zero, it follows that $H^n(h(N)) = 0$.

Proof: Let $N_k$ be defined as

$$N_k = \{ x \in N : \text{for some } R_x > 0, |h(z) - h(y)| \leq k|z - y| \text{ for all } y, z \in B(x, R_x) \}$$

Thus $N_k \uparrow N$. Let $\varepsilon > 0$ be given and let $U \supseteq V_k \supseteq N$ be open and $m_n(V_k) < \frac{\varepsilon}{5^n k^n}$. Now fix $\delta > 0$. For $x \in N_k$ let $B(x, 5r_x) \subseteq V_k$ such that $r_x < \min\left(\frac{\delta}{5^k}, R_x\right)$. By the Vitali covering theorem, there exists a disjoint sequence of these balls, $\{B_i\}_{i=1}^{\infty}$, such that $\sum_{i=1}^{\infty} \text{diam}^n(B_i) < \varepsilon$.

Since $\delta$ was arbitrary, this shows $H^n(h(N_k)) \leq \varepsilon$. Since $k$ was arbitrary, this shows $H^n(h(N)) = \lim_{k \to \infty} H^n(h(N_k)) \leq \varepsilon$. Since $\varepsilon$ is arbitrary, this shows $H^n(h(N)) = 0$. This proves the lemma.

Now with this lemma, here is one of many possible generalizations of the area formula.

Theorem 34.1.3 Let $U$ be an open set in $\mathbb{R}^n$ and $h : U \to \mathbb{R}^n$. Let $h$ be locally Lipschitz and one to one on $A$, a Lebesgue measurable subset of $U$ and let $g : h(A) \to \mathbb{R}$ be a nonnegative $H^n$ measurable function. Then

$$x \mapsto (g \circ h)(x) J(x)$$

is Lebesgue measurable and

$$\int_{h(A)} g(y) dH^n = \int_A g(h(x)) J(x) dm_n$$

where $J(x) = \det(U(x)) = \det(Dh(x)^* Dh(x))^{1/2}$.

Proof: For $x \in A$, there exists a ball, $B_x$ on which $h$ is Lipschitz. By Rademacher’s theorem, $h$ is differentiable a.e. on $B_x$. There is a countable cover of $A$
34.1. THE AREA FORMULA AGAIN

consisting of such balls on which \( h \) is Lipschitz. Therefore, \( h \) is differentiable on \( A_0 \subseteq A \) where \( m_n(A \setminus A_0) = 0 \). Then by the earlier area formula,

\[
\int_{h(A_0)} g(y) \, dH^n = \int_{A_0} g(h(x)) J(x) \, dm_n
\]

By Lemma 34.1.2

\[
\int_{h(A)} g(y) \, dH^n = \int_{h(A_0)} g(y) \, dH^n = \int_{A_0} g(h(x)) J(x) \, dm_n = \int_{A} g(h(x)) J(x) \, dm_n
\]

This proves the theorem.

Note how a special case of this occurs when \( h \) is one to one and \( C^1 \). Of course this yields the earlier change of variables formula as a still more special case.

In addition to this, recall the divergence theorem, Theorem 26.6.14 on Page 1023. This theorem was stated for bounded open sets which have a Lipschitz boundary. This definition of Lipschitz boundary involved an assumption that certain Lipschitz mappings had a derivative a.e. Rademacher’s theorem makes this assumption redundant. Therefore, the statement of Theorem 26.6.14 remains valid with the following definition of a Lipschitz boundary.

**Definition 34.1.4** A bounded open set, \( U \subseteq \mathbb{R}^n \) is said to have a Lipschitz boundary and to lie on one side of its boundary if the following conditions hold. There exist open boxes, \( Q_1, \cdots, Q_N \),

\[
Q_i = \prod_{j=1}^{n} (a_{i,j}^j, b_{i,j}^j)
\]

such that \( \partial U \equiv \overline{U} \setminus U \) is contained in their union. Also, for each \( Q_i \), there exists \( k \) and a Lipschitz function, \( g_i \) such that \( U \cap Q_i \) is of the form

\[
\begin{aligned}
\left\{ x : (x_1, \cdots, x_{k-1}, x_{k+1}, \cdots, x_n) \in \prod_{j=1}^{k-1} (a_{i,j}^j, b_{i,j}^j) \times \\
\prod_{j=k+1}^{n} (a_{i,j}^j, b_{i,j}^j) \text{ and } a_{i,k}^k < x_k < b_{i,k}^k \right\} \quad \text{(34.1.4)}
\end{aligned}
\]

or else of the form

\[
\begin{aligned}
\left\{ x : (x_1, \cdots, x_{k-1}, x_{k+1}, \cdots, x_n) \in \prod_{j=1}^{k-1} (a_{i,j}^j, b_{i,j}^j) \times \\
\prod_{j=k+1}^{n} (a_{i,j}^j, b_{i,j}^j) \text{ and } g_i(x_1, \cdots, x_{k-1}, x_{k+1}, \cdots, x_n) < x_k < b_{i,k}^k \right\} \quad \text{(34.1.5)}
\end{aligned}
\]

Also, there exists an open set, \( Q_0 \) such that \( Q_0 \subseteq \overline{Q_0} \subseteq U \) and \( U = Q_0 \cup Q_1 \cup \cdots \cup Q_N \).
34.2 Mappings That Are Not One To One

Next I will consider the case where $h$ is not necessarily one to one. Recall the major theorem presented earlier on which the proof of the area formula depended, Theorem 26.5.1 on Page 1000. Here it is.

**Theorem 34.2.1** Let $h : U \to \mathbb{R}^m$ where $U$ is an open set in $\mathbb{R}^n$ for $n \leq m$ and suppose $h$ is locally Lipschitz at every point of a Lebesgue measurable subset, $A$ of $U$. Also suppose that for every $x \in A$, $Dh(x)$ exists. Then for $x \in A$,

$$J(x) = \lim_{r \to 0} \frac{\mathcal{H}^n(h(B(x,r)))}{m_n(B(x,r))},$$

(34.2.6)

where $J(x) = \det(U(x)) = \det(Dh(x))^{1/2}$.

The next lemma is a version of Sard’s lemma.

**Lemma 34.2.2** Let $h : U \to \mathbb{R}^m$ where $U$ is an open set in $\mathbb{R}^n$ for $n \leq m$ and suppose $h$ is locally Lipschitz at every point of a Lebesgue measurable subset, $A$ of $U$. Let

$$N \equiv \{x \in A : Dh(x) \text{ does not exist}\}$$

(34.2.7)

and let

$$S \equiv \{x \in A_0 \equiv A \setminus N : J(x) = 0\}$$

(34.2.8)

Then $\mathcal{H}^n(h(S \cup N)) = 0$.

**Proof:** By Rademacher’s theorem, $N$ has measure 0. Therefore, $\mathcal{H}^n(h(N)) = 0$ by Lemma 34.1.2.

It remains to show $\mathcal{H}^n(h(S)) = 0$. Let $S_k = B(0,k) \cap S$ for $k$ a positive integer large enough that $S_k \neq \emptyset$. By Theorem 26.5.10 on Page 1000 stated above, if $x \in S_k$, there exists $r_x$ such that $5r_x < \min(R_x, 1)$ and if $r \leq 5r_x$,

$$\frac{\mathcal{H}^n(h(B(x,r)))}{m_n(B(x,r))} < \frac{\varepsilon}{5^n k^n}, B(x,r) \subseteq B(0,k) \cap U$$

(34.2.9)

Then by the Vitali covering theorem, there exists a sequence of disjoint balls of this sort, $\{B_i\}_{i=1}^{\infty}$ such that the balls having 5 times the radius but the same center, $\{\widehat{B}_i\}_{i=1}^{\infty}$ cover $S_k$. Then $\{h(\widehat{B}_i)\}_{i=1}^{\infty}$ covers $h(S_k)$. Then from Lemma 34.4,

$$\mathcal{H}^n(h(S_k)) \leq \sum_{i=1}^{\infty} \mathcal{H}^n(h(\widehat{B}_i)) \leq \sum_{i=1}^{\infty} 5^n \mathcal{H}^n(h(B_i))$$

$$\leq \sum_{i=1}^{\infty} 5^n \frac{\varepsilon}{5^n k^n} m_n(B_i) \leq \frac{\varepsilon}{k^n} m_n(B(0,k)) = \varepsilon \alpha(n)$$

Since $\varepsilon > 0$ is arbitrary, it follows $\mathcal{H}^n(h(S_k)) = 0$ and now letting $k \to 0$, it follows $\mathcal{H}^n(h(S)) = 0$. This proves the lemma.

The following very technical lemma provides the necessary theory to generalize to functions which are not one to one.
Lemma 34.2.3 Let $h : U \to \mathbb{R}^m$ where $U$ is an open set in $\mathbb{R}^n$ for $n \leq m$ and suppose $h$ is locally Lipschitz at every point of a Lebesgue measurable subset, $A$ of $U$. Let

$$N \equiv \{ x \in A : Dh(x) \text{ does not exist} \}$$

and let

$$S \equiv \{ x \in A_0 \equiv A \setminus N : J(x) = 0 \}$$

Let $B = A \setminus (S \cup N)$. Then there exist measurable disjoint sets, $\{ E_i \}_{i=1}^\infty$ such that $A = \bigcup_{i=1}^\infty E_i$ and $h$ is one to one on $E_i$. Furthermore, $h^{-1}$ is Lipschitz on $h(E_i)$.

**Proof:** Let $\mathcal{C}$ be a dense countable subset of $B$ and let $\mathcal{F}$ be a countable dense subset of the invertible elements of $\mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$. For $i$ a positive integer and $T \in \mathcal{F}, c \in \mathcal{C}$

$$E(c, T, i) \equiv \left\{ b \in B \left( c, \frac{1}{i} \right) \cap B : (a), (b) \text{ both hold} \right\}$$

where $(a), (b)$ are given by

$$\frac{2}{3} |Tv| \leq |U(b)v| \text{ for all } v$$

$$|h(a) - h(b) - Dh(b)(a - b)| \leq \frac{1}{2} |T(a - b)|.$$  \hspace{1cm} (b)

for all $a \in B \left( b, \frac{2}{i} \right)$.

First I will show these sets, $E(c, T, i)$ cover $B$ and that they are measurable sets. To begin with consider the measurability question. Inequality $(a)$ is the same as saying

$$\frac{2}{3} |Tv| \leq |Dh(b)v| \text{ for all } v$$

which is the same as saying

$$\frac{2}{3} |v| \leq |Dh(b)T^{-1}v| \text{ for all } v.$$
Let \( \{v_i\} \) denote a dense countable subset of \( \mathbb{R}^n \). Letting

\[
S_i = \left\{ b : \frac{2}{3} |v_i| \leq |Dh(b)T^{-1}v_i| \right\}
\]

it follows easily that \( S_i \) is measurable because the component functions of the matrix of \( Dh(b) \) are limits of difference quotients of continuous functions so they are Borel measurable. (Note that if \( B \) were Borel, then \( S_i \) would also be Borel.) Now by continuity,

\[
\bigcup_{i=1}^{\infty} S_i = \left\{ b : \frac{2}{3} |v| \leq |Dh(b)T^{-1}v| \quad \text{for all } v \right\}
\]

and so this set is measurable also. Inequality \((b)\) also determines a measurable set by similar reasoning. It is the same as saying that for all \(|v| < 2/i\),

\[
|h(b + v) - h(b) - Dh(b)(v)| \leq \frac{1}{2} |Tv|
\]

Use \( \{v_i\} \) a countable dense subset of \( B(0,2/i) \) in a similar fashion to \((a)\).

Next I need to show these sets cover \( B \). Let \( x \in B \). Then pick \( c_i \in B(x, \frac{1}{2}) \) and \( T_i \in B(U(x), \frac{1}{2}) \). I need to show that \( x \in E(c_i, T_i, i) \) for \( i \) large enough. For \( i \) large enough, \( \|T_iU(x)^{-1}\| < \frac{3}{2} \). Therefore, for such \( i \)

\[
\left|T_iU(x)^{-1}(v)\right| < \frac{3}{2} |v|
\]

for all \( v \) and so

\[
|Tiw| < \frac{3}{2} |U(x)w|
\]

for all \( w \). Next consider \((b)\). An equivalent norm is \( v \rightarrow |U(x)v| \) and so, for \( i \) large enough,

\[
|h(a) - h(x) - Dh(x)(a-x)| \leq \frac{1}{8} |U(x)(a-x)| \quad \text{(34.2.10)}
\]

whenever \(|a-x| < 2/i\). Now also, for \( i \) large enough, \( ||U(x)T_i^{-1}|| < 4 \) and so for all \( w \),

\[
|U(x)T_i^{-1}w| < 4 |w|
\]

which implies

\[
|U(x)v| < 4 |T_iv|.
\]

Applying this in \((34.2.10)\) yields

\[
|h(a) - h(x) - Dh(x)(a-x)| \leq \frac{1}{2} |T_i(a-x)|
\]

with implies \( x \in E(c_i, T_i, i) \).
Next I need to show \( h \) is one to one on \( E(c,T,i) \). Suppose \( b_1, b_2 \in E(c,T,i) \). From (b) and (a),

\[
|T(b_2 - b_1)| \leq \frac{3}{2} |U(b_1)(b_2 - b_1)| = \frac{3}{2} |Dh(b_1)(b_2 - b_1)|
\]

which is a contradiction unless \( b_2 = b_1 \).

There are clearly countably many \( E(c,T,i) \). Denote them as \( \{F_i\}_{i=1}^{\infty} \). Then let \( E_1 = F_1 \) and if \( E_1, \ldots, E_m \) have been chosen, let

\[
E_{m+1} = F_{m+1} \setminus \bigcup_{i=1}^{m} E_i.
\]

Thus the \( E_i \) are disjoint measurable sets whose union is \( B \) and \( h \) is one to one on each \( E_i \).

Now consider one of the \( E_i \). This is a subset of some \( E(c,T,i) \). Let \( a, b \in E_i \). Then using (a) and (b),

\[
|T(a - b)| \leq \frac{3}{2} |U(b)(a-b)| = \frac{3}{2} |Dh(b)(a-b)| \leq \frac{3}{2} |h(a) - h(b)| + \frac{3}{4} |T(a - b)|.
\]

Hence

\[
\frac{1}{4} |T(a - b)| \leq \frac{3}{2} |h(a) - h(b)|
\]

Since \( v \rightarrow |Tv| \) is an equivalent norm, there exists some \( r > 0 \) such that \( |Tv| \geq r |v| \) for all \( v \). Therefore,

\[
|a - b| \leq \frac{6}{r} |h(a) - h(b)|.
\]

In other words,

\[
|h^{-1}(h(a)) - h^{-1}(h(b))| = |a - b| \leq \frac{6}{r} |h(a) - h(b)|.
\]

which completes the proof.

With these lemmas, here is the main theorem which is a generalization of Theorem 34.1.3. First remember that from Lemma 26.5.3 on Page 994 a locally Lipschitz function maps Lebesgue measurable sets to Hausdorff measurable sets.

**Theorem 34.2.4** Let \( U \) be an open set in \( \mathbb{R}^n \) and \( h : U \rightarrow \mathbb{R}^m \). Let \( h \) be locally Lipschitz on \( A \), a Lebesgue measurable subset of \( U \) and let \( g : h(A) \rightarrow \mathbb{R} \) be a nonnegative \( \mathcal{H}^n \) measurable function. Also let

\[
\#(y) \equiv \text{Number of elements of } h^{-1}(y)
\]
Then \( \# \) is \( \mathcal{H}^n \) measurable,
\[
x \to (g \circ h)(x)J(x)
\]
is Lebesgue measurable, and
\[
\int_{h(A)} \#(y)g(y)\,d\mathcal{H}^n = \int_A g(h(x))J(x)\,dm_n
\]
where \( J(x) = \det(U(x)) = \det(Dh(x)^*\,Dh(x))^{1/2} \).

**Proof:** Let \( B = A \setminus (S \cup N) \) where \( S \) is the set of points where \( J(x) = 0 \) and \( N \) is the set of points, \( x \) of \( A \) where \( Dh(x) \) does not exist. Also from Lemma 34.2.3 there exists \( \{E_i\}_{i=1}^\infty \), a sequence of disjoint measurable sets whose union equals \( B \) such that \( h \) is one to one on each \( E_i \). Then from Theorem 34.1.3
\[
\int_A g(h(x))J(x)\,dm_n
\]
\[
= \int_B g(h(x))J(x)\,dm_n + \sum_{i=1}^\infty \int_{h(E_i)} g(y)\,d\mathcal{H}^n
\]
\[
= \sum_{i=1}^\infty \int_{h(E_i)} g(y)\,d\mathcal{H}^n = \sum_{i=1}^\infty \int_{h(E_i)} g(h(y))\,d\mathcal{H}^n = \int_{h(B)} (\sum_{i=1}^\infty \mathcal{X}_{h(E_i)}(y)) g(y)\,d\mathcal{H}^n. \tag{34.2.11}
\]
Now \( \#(y) = (\sum_{i=1}^\infty \mathcal{X}_{h(E_i)}(y)) \) on \( h(B) \) and \( \# \) differs from this \( \mathcal{H}^n \) measurable function only on \( h(S \cup N) \), which by Lemma 34.2.2 is a set of \( \mathcal{H}^n \) measure zero. Therefore, \( \# \) is \( \mathcal{H}^n \) measurable and the last term of (34.2.11) equals
\[
\int_{h(A)} \left(\sum_{i=1}^\infty \mathcal{X}_{h(E_i)}(y)\right) g(y)\,d\mathcal{H}^n = \int_{h(A)} \#(y)g(y)\,d\mathcal{H}^n.
\]
This proves the theorem.

### 34.3 The Coarea Formula

The coarea formula involves a function, \( h \) which maps a subset of \( \mathbb{R}^n \) to \( \mathbb{R}^m \) where \( m \leq n \) instead of \( m \geq n \) as in the area formula. The symbol, \( \text{Lip}(h) \) will denote the Lipschitz constant for \( h \).

It is possible to obtain the coarea formula as a computation involving the area formula and some simple linear algebra and this is the approach taken here. To begin with, here is the necessary linear algebra.

**Theorem 34.3.1** Let \( A \) be an \( m \times n \) matrix and let \( B \) be an \( n \times m \) matrix for \( m \leq n \). Then
\[
p_{BA}(t) = t^{n-m}p_{AB}(t),
\]
so the eigenvalues of \( BA \) and \( AB \) are the same including multiplicities except that \( BA \) has \( n-m \) extra zero eigenvalues.
34.3. THE COAREA FORMULA

**Proof:** Use block multiplication to write
\[
\begin{pmatrix} AB & 0 \\ B & 0 \end{pmatrix} \begin{pmatrix} I & A \\ 0 & I \end{pmatrix} = \begin{pmatrix} AB & ABA \\ B & BA \end{pmatrix}
\]
\[
\begin{pmatrix} I & A \\ 0 & I \end{pmatrix} \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix} = \begin{pmatrix} AB & ABA \\ B & BA \end{pmatrix}.
\]
Therefore,
\[
\begin{pmatrix} I & A \\ 0 & I \end{pmatrix}^{-1} \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix}
\]
It follows that \( \begin{pmatrix} 0 & 0 \\ B & BA \end{pmatrix} \) and \( \begin{pmatrix} AB & 0 \\ B & 0 \end{pmatrix} \) have the same characteristic polynomials because the two matrices are similar. Thus
\[
det \begin{pmatrix} tI - AB & 0 \\ -B & tI \end{pmatrix} = \det \begin{pmatrix} tI & 0 \\ -B & tI - BA \end{pmatrix}
\]
and so noting that \( BA \) is an \( n \times n \) matrix and \( AB \) is an \( m \times m \) matrix,
\[
t^m \det (tI - BA) = t^n \det (tI - AB)
\]
and so \( \det (tI - BA) = p_{BA}(t) = t^{n-m} \det (tI - AB) = t^{n-m} p_{AB}(t) \). This proves the theorem.

The following corollary is what will be used to prove the coarea formula.

**Corollary 34.3.2** Let \( A \) be an \( m \times n \) matrix. Then
\[
det (I + AA^*) = \det (I + A^*A).
\]

**Proof:** Assume \( m \leq n \). From Theorem AA* and \( A^*A \) have the eigenvalues, \( \lambda_1, \ldots, \lambda_m \), necessarily nonnegative, with the same multiplicities and some zero eigenvalues which have differing multiplicities. The eigenvalues, \( \lambda_1, \ldots, \lambda_m \), are the zeros of \( p_{AA^*}(t) \). Thus there is an orthogonal transformation, \( P \) such that
\[
A^*A = P \begin{pmatrix} 
\lambda_1 & \ldots & 0 \\
& \ddots & \vdots \\
0 & \ldots & \lambda_m \\
\end{pmatrix} P^*.
\]
Therefore,
\[
I + A^*A = P \begin{pmatrix} 
\lambda_1 + 1 & \ldots & 0 \\
& \ddots & \vdots \\
0 & \ldots & \lambda_m + 1 \\
\end{pmatrix} P^*
\]
and so
\[
\det (I + A^*A) = \det \begin{pmatrix}
\lambda_1 + 1 & 0 \\
& \ddots & \ddots \\
0 & & \lambda_m + 1
\end{pmatrix} = \det (I + AA^*).
\]

This proves the corollary.

The other main ingredient is the following version of the chain rule.

**Theorem 34.3.3** Let \( h \) and \( g \) be locally Lipschitz mappings from \( \mathbb{R}^n \) to \( \mathbb{R}^n \) with \( h(g(x)) = x \) on \( A \), a Lebesgue measurable set. Then for a.e. \( x \in A \), \( Dg(h(x)) \), \( Dh(x) \), and \( D(g \circ h)(x) \) all exist and
\[
I = D (g \circ h)(x) = Dg(h(x)) Dh(x).
\]

The proof of this theorem is based on the following lemma.

**Lemma 34.3.4** If \( h : \mathbb{R}^n \to \mathbb{R}^n \) is locally Lipschitz, then if \( h(x) = 0 \) for all \( x \in A \), then \( \det (Dh(x)) = 0 \) a.e.

**Proof:** By the case of the Area formula which involves mappings which are not one to one, \( 0 = \int_{\{0\}} \#(y) \, dy = \int_A \abs{\det (Dh(x))} \, dx \) and so \( \det (Dh(x)) = 0 \) a.e.

**Proof of the theorem:** On \( A \), \( g(h(x)) - x = 0 \) and so by the lemma, there exists a set of measure zero, \( N_1 \) such that if \( x \notin N_1 \), \( D(g \circ h)(x) - I = 0 \). Let \( M \) be the set of measure zero of points in \( h(\mathbb{R}^n) \) where \( g \) fails to be differentiable and let \( N_2 \equiv g(M) \cap A \), also a set of measure zero because locally Lipschitz maps take sets of measure zero to sets of measure zero. Finally let \( N_3 \) be the set of points where \( h \) fails to be differentiable. Then if \( x \notin N_1 \cup N_2 \cup N_3 \), the chain rule implies \( I = D (g \circ h)(x) = Dg(h(x)) Dh(x) \). This proves the theorem.

**Lemma 34.3.5** Let \( h : \mathbb{R}^p \to \mathbb{R}^m \) be Lipschitz continuous and \( \delta > 0 \). Then if \( A \subseteq \mathbb{R}^p \) is either open or compact,
\[
y \to \mathcal{H}_\delta^*(A \cap h^{-1}(y))
\]
is Borel measurable.

**Proof:** Suppose first that \( A \) is compact and suppose for \( \delta > 0 \),
\[
\mathcal{H}_\delta^*(A \cap h^{-1}(y)) < t
\]
Then there exist sets \( S_i \), satisfying
\[
diam(S_i) < \delta, \ A \cap h^{-1}(y) \subseteq \bigcup_{i=1}^\infty S_i,
\]
and
\[
\sum_{i=1}^\infty \alpha(s) (r(S_i))^s < t.
\]
I claim these sets can be taken to be open sets. Choose \( \lambda > 1 \) but close enough to 1 that
\[
\sum_{i=1}^{\infty} \alpha(s) (\lambda r(S_i))^s < t
\]
Replace \( S_i \) with \( S_i + B(0, \eta_i) \) where \( \eta_i \) is small enough that
\[
diam(S_i) + 2\eta_i < \lambda diam(S_i).
\]
Then
\[
diam(S_i + B(0, \eta_i)) \leq \lambda diam(S_i)
\]
and so \( r(S_i + B(0, \eta_i)) \leq \lambda r(S_i) \). Thus
\[
\sum_{i=1}^{\infty} \alpha(s) r(S_i + B(0, \eta_i))^s < t.
\]
Hence you could replace \( S_i \) with \( S_i + B(0, \eta_i) \) and so one can assume the sets \( S_i \) are open.

**Claim:** If \( z \) is close enough to \( y \), then \( A \cap h^{-1}(z) \subseteq \cup_{i=1}^{\infty} S_i \).

**Proof:** If not, then there exists a sequence \( \{z_k\} \) such that
\[
z_k \to y, \quad x_k \to x \in A \setminus \cup_{i=1}^{\infty} S_i.
\]
By compactness of \( A \), there exists a subsequence still denoted by \( k \) such that
\[
z_k \to y, \quad x_k \to x \in A \setminus \cup_{i=1}^{\infty} S_i.
\]
Hence
\[
h(x) = \lim_{k \to \infty} h(x_k) = \lim_{k \to \infty} z_k = y.
\]
But \( x \notin \cup_{i=1}^{\infty} S_i \) contrary to the assumption that \( A \cap h^{-1}(y) \subseteq \cup_{i=1}^{\infty} S_i \).

It follows from this claim that whenever \( z \) is close enough to \( y \),
\[
\mathcal{H}^s_\delta(A \cap h^{-1}(z)) < t.
\]
This shows
\[
\{ z \in \mathbb{R}^p : \mathcal{H}^s_\delta(A \cap h^{-1}(z)) < t \}
\]
is an open set and so \( y \to \mathcal{H}^s_\delta(A \cap h^{-1}(y)) \) is Borel measurable whenever \( A \) is compact. Now let \( V \) be an open set and let
\[
A_k \uparrow V, \quad A_k \text{ compact}.
\]
Then
\[
\mathcal{H}^s_\delta(V \cap h^{-1}(y)) = \lim_{k \to \infty} \mathcal{H}^s_\delta(A_k \cap h^{-1}(y))
\]
so \( y \to \mathcal{H}^s_\delta(V \cap h^{-1}(y)) \) is Borel measurable for all \( V \) open. This proves the lemma.
Lemma 34.3.6 Let \( h : \mathbb{R}^p \to \mathbb{R}^m \) be Lipschitz continuous. Suppose \( A \) is either open or compact in \( \mathbb{R}^p \). Then \( y \to \mathcal{H}^s (A \cap h^{-1}(y)) \) is also Borel measurable and
\[
\int_{\mathbb{R}^m} \mathcal{H}^s (A \cap h^{-1}(y)) \, dy \leq 2^m (\text{Lip}(h))^m \frac{\alpha(s) \alpha(m)}{\alpha(s+m)} \mathcal{H}^{s+m}(A)
\]
In particular, if \( s = n - m \) and \( p = n \)
\[
\int_{\mathbb{R}^m} \mathcal{H}^{n-m} (A \cap h^{-1}(y)) \, dy \leq 2^m (\text{Lip}(h))^m \frac{\alpha(n-m) \alpha(m)}{\alpha(n)} m_n (A)
\]

Proof: From Lemma 34.3.5 \( y \to \mathcal{H}^s (A \cap h^{-1}(y)) \) is Borel measurable for each \( \delta > 0 \). Without loss of generality, \( \mathcal{H}^{s+m}(A) < \infty \). Now let \( B_i \) be closed sets with \( \text{diam} (B_i) < \delta, A \subseteq \bigcup_{i=1}^{\infty} B_i \), and
\[
\mathcal{H}^{s+m}(A) + \varepsilon > \sum_{i=1}^{\infty} \alpha(s+m) r(B_i)^{s+m}.
\]
Note each \( B_i \) is compact so \( y \to \mathcal{H}^s (B_i \cap h^{-1}(y)) \) is Borel measurable. Thus
\[
\int_{\mathbb{R}^m} \mathcal{H}^s (A \cap h^{-1}(y)) \, dy
\]
\[
\leq \int_{\mathbb{R}^m} \sum_i \mathcal{H}^s (B_i \cap h^{-1}(y)) \, dy
\]
\[
= \sum_i \int_{\mathbb{R}^m} \mathcal{H}^s (B_i \cap h^{-1}(y)) \, dy
\]
\[
\leq \sum_i \int_{h(B_i)} \mathcal{H}^s (B_i) \, dy
\]
\[
= \sum_i m_m (h(B_i)) \mathcal{H}^s (B_i)
\]
\[
\leq \sum_i (\text{Lip}(h))^m 2^m \alpha(m) r(B_i)^m \alpha(s) r(B_i)^s
\]
\[
= (\text{Lip}(h))^m \frac{\alpha(m) \alpha(s)}{\alpha(m+s)} 2^m \sum_i \alpha(s+m) r(B_i)^{m+s}
\]
\[
\leq (\text{Lip}(h))^m \frac{\alpha(m) \alpha(s)}{\alpha(m+s)} 2^m (\mathcal{H}^{s+m}(A) + \varepsilon)
\]
Since \( \varepsilon \) is arbitrary,
\[
\int_{\mathbb{R}^m} \mathcal{H}^s (A \cap h^{-1}(y)) \, dy \leq (\text{Lip}(h))^m \frac{\alpha(m) \alpha(s)}{\alpha(m+s)} 2^m \mathcal{H}^{s+m}(A)
\]
Taking a limit as \( \delta \to 0 \) this proves the lemma.

Next I will show that whenever \( A \) is Lebesgue measurable,
\[
y \to \mathcal{H}^{n-m} (A \cap h^{-1}(y))
\]
is \( m_m \) measurable and the above estimate holds.
34.3. THE COAREA FORMULA

Lemma 34.3.7 Let $A$ be a Lebesgue measurable subset of $\mathbb{R}^n$ and let $h : \mathbb{R}^n \to \mathbb{R}^m$ be Lipschitz. Then

$$y \to H^{n-m}(A \cap h^{-1}(y))$$

is Lebesgue measurable. Furthermore, for all $A$ Lebesgue measurable,

$$\int_{\mathbb{R}^m} H^{n-m}(A \cap h^{-1}(y)) dy \leq 2^m (\text{Lip}(h))^m \frac{\alpha(n) \alpha(m)}{\alpha(n)} m_n(A)$$

**Proof:** Let $A$ be a bounded Lebesgue measurable set in $\mathbb{R}^n$. Then by inner and outer regularity of Lebesgue measure there exists an increasing sequence of compact sets, $\{K_k\}$ contained in $A$ and a decreasing sequence of open sets, $\{V_k\}$ containing $A$ such that $m_n(V_k \setminus K_k) < 2^{-k}$. Thus $m_n(V_1) \leq m_n(A) + 1$. By Lemma 34.3.6

$$\int_{\mathbb{R}^m} H^{n-m}_\delta(K_k \cap h^{-1}(y)) dy \leq \int_{\mathbb{R}^m} H^{n-m}_\delta(A \cap h^{-1}(y)) dy \leq \int_{\mathbb{R}^m} H^{n-m}_\delta(V_k \cap h^{-1}(y)) dy$$

(34.3.12)

By Lemma 34.3.6

$$= \int_{\mathbb{R}^m} (H^{n-m}_\delta(V_k \cap h^{-1}(y)) - H^{n-m}_\delta(K_k \cap h^{-1}(y))) dy$$

$$= \int_{\mathbb{R}^m} H^{n-m}_\delta((V_k - K_k) \cap h^{-1}(y)) dy$$

$$\leq 2^m (\text{Lip}(h))^m \frac{\alpha(n) \alpha(m)}{\alpha(n)} m_n(V_k \setminus K_k)$$

$$< 2^m (\text{Lip}(h))^m \frac{\alpha(n) \alpha(m)}{\alpha(n)} 2^{-k}$$

Let the Borel measurable functions, $g$ and $f$ be defined by

$$g(y) = \lim_{k \to \infty} H^{n-m}_\delta(V_k \cap h^{-1}(y)), \quad f(y) = \lim_{k \to \infty} H^{n-m}_\delta(K_k \cap h^{-1}(y))$$

It follows from the dominated convergence theorem and Lemma 34.3.6 that

$$f(y) \leq H^{n-m}_\delta(A \cap h^{-1}(y)) \leq g(y)$$

and

$$\int_{\mathbb{R}^m} (g(y) - f(y)) dy = 0.$$

By completeness of $m_n$, this establishes $y \to H^{n-m}_\delta(A \cap h^{-1}(y))$ is Lebesgue measurable. Then by Lemma 34.3.1 again,

$$\int_{\mathbb{R}^m} H^{n-m}_\delta(A \cap h^{-1}(y)) dy \leq 2^m (\text{Lip}(h))^m \frac{\alpha(n) \alpha(m)}{\alpha(n)} m_n(A).$$
Letting $\delta \to 0$ and using the monotone convergence theorem yields the desired inequality for $\mathcal{H}^{n-m} (A \cap h^{-1}(y))$.

The case where $A$ is not bounded can be handled by considering $A_r = A \cap B(0,r)$ and letting $r \to \infty$. This proves the lemma.

By fussing with the isodiametric inequality one can remove the factor of $2^n$ in the above inequalities obtaining much more attractive formulas. This is done in [14]. See also [17] which follows [14] and [17]. This last reference probably has the most complete treatment of these topics.

With these lemmas, it is now possible to give a proof of the coarea formula.

Define $\Lambda(n,m)$ as all possible ordered lists of $m$ numbers taken from $\{1, 2, \ldots, n\}$.

**Lemma 34.3.8** Let $A$ be a measurable set in $\mathbb{R}^n$ and let $h: \mathbb{R}^n \to \mathbb{R}^m$ be a Lipschitz map where $m \leq n$ which is differentiable at every point of $A$ and for which

$$Jh(x) \equiv \det (Dh(x)Dh(x)^*)^{1/2} \neq 0.$$ 

Then the following formula holds along with all measurability assertions needed for it to make sense.

$$\int_{\mathbb{R}^m} \mathcal{H}^{n-m} (A \cap h^{-1}(y)) \, dy = \int_A Jh(x) \, dx \quad (34.3.13)$$

**Proof:** For $x \in \mathbb{R}^n$, and $i \in \Lambda(n,m)$, with $i = (i_1, \ldots, i_m)$, define $x_i \equiv (x_{i_1}, \ldots, x_{i_m})$, and $\pi_i x \equiv x_i$. Also for $i \in \Lambda(n,m)$, let $i_\ast \in \Lambda(n,n-m)$ consist of the remaining indices taken in order. For $h : \mathbb{R}^n \to \mathbb{R}^m$ where $m \leq n$, define $Jh(x) \equiv \det (Dh(x)Dh(x)^*)^{1/2}$. For each $i \in \Lambda(n,m)$, define

$$h^i(x) \equiv \begin{pmatrix} h(x) \\
 x_{i_\ast} \end{pmatrix}.$$ 

By Lemma 32.2.3, there exist disjoint measurable sets $\{F_j^i\}_{j=1}^\infty$ such that $h^i$ is one to one on $F_j^i$, $(h^i)^{-1}$ is Lipschitz on $h^i(F_j^i)$, and

$$\bigcup_{j=1}^\infty F_j^i = \{ x \in A : \det (Dh^i(x)) \neq 0 \}.$$ 

For $x \in A$, $\det (D_{x_i}h(x)) \neq 0$ for some $i \in \Lambda(n,m)$. But $\det (D_{x_i}h(x)) = \det (Dh^i(x))$ and so $x \in F_j^i$ for some $i$ and $j$. Hence

$$\bigcup_{i,j} F_j^i = A.$$ 

Now let $\{E_j^i\}$ be measurable sets such that $E_j^i \subseteq F_j^i$ for some $k$, the sets are disjoint, and their union coincides with $\bigcup_{i,j} F_j^i$. Then

$$\int_A Jh(x) \, dx = \sum_{i \in \Lambda(n,m)} \sum_{j=1}^\infty \int_{E_j^i \cap A} \det (Dh(x)Dh(x)^*)^{1/2} \, dx. \quad (34.3.14)$$
34.3. THE COAREA FORMULA

Let \( g : \mathbb{R}^n \to \mathbb{R}^n \) be a Lipschitz extension of \( (h^i)^{-1} \) so \( g \circ h^i(x) = x \) for all \( x \in E^i_j \). First, using Theorem 34.3.14, and the fact that Lipschitz mappings take sets of measure zero to sets of measure zero, replace \( E^i_j \) with a measurable set, \( \tilde{E}^i_j \subseteq E^i_j \) such that \( E^i_j \setminus \tilde{E}^i_j \) has measure zero and

\[
Dh^i(g(y)) Dg(y) = I
\]
on \( \tilde{E}^i_j \). Changing the variables using the area formula, the expression in 34.3.14 equals

\[
\int_A Jh(x) \, dx = \sum_{i \in \Lambda(n,m)} \sum_{j=1}^{\infty} \int_{h(E^i_j \cap A)} \text{det} (Dh(g(y)) Dg(y))^* \frac{1}{2} \frac{\text{det} Dh^i(g(y))}{\text{det} Dg(y)} \, dy.
\]

Note the integrands are all Borel measurable functions because they are continuous functions of the entries of matrices which entries come from taking limits of difference quotients of continuous functions. Thus,

\[
\int_{\tilde{E}^i_j \cap A} \text{det} (Dh(x) Dh(x)^*) \frac{1}{2} \, dx = \int_{\mathbb{R}^n} X_{h^i} h(E^i_j \cap A)(y) \text{det} (Dh(g(y)) Dg(y))^* \frac{1}{2} \frac{\text{det} Dh^i(g(y))}{\text{det} Dg(y)} \, dy
\]

\[
= \int_{\mathbb{R}^n} \pi_{i_1, g(h^{-1}(y_1) \cap \tilde{E}^i_j \cap A)}(y) \text{det} (Dh(g(y)) Dg(y))^* \frac{1}{2} \frac{\text{det} Dh_{x_i}(g(y))}{\text{det} Dg(y)} \, dy dy_1
\]

where \( y_1 = h(x) \) and \( y_2 = x_{i_1} \). Thus

\[
y_2 = \pi_{1, g}(y) = \pi_{1, g} (h^i(x)) = x_{i_1}.
\]

Now consider the inner integral in 34.3.16 in which \( y_1 \) is fixed. The integrand equals

\[
\text{det} \left[ \begin{array}{cc} D_{x_1} h(g(y)) & D_{x_{i_1}} h(g(y)) \\ D_{x_{i_1}} h(g(y)) & D_{x_1} h(g(y))^* \end{array} \right] \frac{1}{2} \frac{1}{\text{det} Dg(y)} \]

I want to massage the above expression slightly. Since \( y_1 \) is fixed, and \( y_1 = h(\pi_{1, g}(y), \pi_{1, g}(y)) = h(g(y)), \) it follows from 34.3.17 that

\[
0 = D_{x_1} h(g(y)) D_{y_2} \pi_{i_1} g(y) + D_{x_{i_1}} h(g(y)) D_{y_2} \pi_{i_1} g(y)
\]

\[
= D_{x_1} h(g(y)) D_{y_2} \pi_{i_1} g(y) + D_{x_{i_1}} h(g(y)).
\]
Letting $A = D_x h (g(y))$ and $B = D_y \pi_1 g (y)$ and using the above formula, is of the form

$$\det \left[ \begin{array}{c} (A) \\ (B) \end{array} \right]^{1/2} = \det A^{-1}$$

which, by Corollary 34.3.2, equals $\det (I + B^* B)^{1/2}$. (Note the size of the identity changes in these two expressions, the first being an $m \times m$ matrix and the second being a $n \times n - m$ matrix.)

By Lemma 34.3.17, $\pi_1 g (y) = y_2$ and so,

$$\det (I + B^* B)^{1/2} = \det \left[ \begin{array}{c} (B) \\ (I) \end{array} \right]^{1/2}$$

$$= \det \left[ \begin{array}{cc} D_y \pi_1 g (y) & D_y \pi_1 g (y) \\ D_y \pi_1 g (y) & D_y \pi_1 g (y) \end{array} \right]^{1/2}$$

$$= \det (D_y g (y) D_y g (y))^{1/2}.$$ 

Therefore, 34.3.16 reduces to

$$\int_{E_j \cap A} \det (Dh (x) Dh (x)^*)^{1/2} dx =$$

$$\int_{\mathbb{R}^m} \int_{\pi_1 (h^{-1}(y_1) \cap E_j \cap A)} \det (D_y g (y) D_y g (y))^{1/2} dy dy_1. \quad (34.3.19)$$

By the area formula applied to the inside integral, this integral equals

$$\mathcal{H}^{n-m} (h^{-1}(y_1) \cap E_j \cap A)$$

and so

$$\int_{E_j \cap A} \det (Dh (x) Dh (x)^*)^{1/2} dx =$$

$$= \int_{\mathbb{R}^m} \mathcal{H}^{n-m} (h^{-1}(y_1) \cap E_j \cap A) dy_1.$$ 

Using Lemma 34.3.7, along with the inner regularity of Lebesgue measure, $E_j$ can be replaced with $E_j^i$. Therefore, summing the terms over all $i$ and $j$, 

$$\int_A \det (Dh (x) Dh (x)^*)^{1/2} dx = \int_{\mathbb{R}^m} \mathcal{H}^{n-m} (h^{-1}(y) \cap A) dy.$$
This proves the lemma.

Now the following is the coarea formula.

**Corollary 34.3.9** Let \( A \) be a measurable set in \( \mathbb{R}^n \) and let \( h : \mathbb{R}^n \to \mathbb{R}^m \) be a Lipschitz map where \( m \leq n \). Then the following formula holds along with all measurability assertions needed for it to make sense.

\[
\int_{\mathbb{R}^m} H^{n-m} \left( A \cap h^{-1}(y) \right) dy = \int_A Jh(x) dx
\] (34.3.20)

where \( Jh(x) \equiv \det \left( Dh(x) Dh(x)^* \right)^{1/2} \).

**Proof:** By Lemma 34.3.7 again, this formula is true for all measurable \( A \subseteq \mathbb{R}^n \setminus S \). It remains to verify the formula for all measurable sets, \( A \), whether or not they intersect \( S \).

Consider the case where

\[
A \subseteq S \equiv \{ x : J (Dh (x)) = 0 \}.
\]

Let \( A \) be compact so that by Lemma 34.3.6, \( y \to H^{n-m} \left( A \cap h^{-1}(y) \right) \) is Borel. For \( \varepsilon > 0 \), define \( k, p : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^m \) by

\[
k(x, y) \equiv h(x) + \varepsilon y, \ p(x, y) \equiv y.
\]

Then

\[
Dk(x, y) = (Dh(x), \varepsilon I) = (UR, \varepsilon I)
\]

where the dependence of \( U \) and \( R \) on \( x \) has been suppressed. Thus

\[
Jk^2 = \det \left( UR, \varepsilon I \right) = \det \left( U^2 + \varepsilon^2 I \right)
\]

\[
= \det \left( Q^* DQQ^* DQ + \varepsilon^2 I \right) = \det \left( D^2 + \varepsilon^2 I \right)
\]

\[
= \prod_{i=1}^{m} \left( \lambda_i^2 + \varepsilon^2 \right) \in [\varepsilon^{2m}, C^2 \varepsilon^2] \] (34.3.21)

since one of the \( \lambda_i \) equals 0. All the eigenvalues must be bounded independent of \( x \), since \( ||Dh(x)|| \) is bounded independent of \( x \) due to the assumption that \( h \) is Lipschitz. Since \( Jk \neq 0 \), the first part of the argument implies

\[
\varepsilon Cm_{n+m} \left( A \times B(0,1) \right) \geq \int_{A \times B(0,1)} |Jk| dm_{n+m}
\]

\[
= \int_{\mathbb{R}^m} H^n \left( k^{-1}(y) \cap A \times B(0,1) \right) dy
\]

Which by Lemma 34.3.8

\[
\geq C_{nm} \int_{\mathbb{R}^m} \int_{\mathbb{R}^m} H^{n-m} \left( k^{-1}(y) \cap p^{-1}(w) \cap A \times B(0,1) \right) dwdy
\] (34.3.22)
where $C_{nm} = \frac{\alpha(n)}{\alpha(n-m)\alpha(m)}$.

Claim:
\[
\mathcal{H}^{n-m} \left( k^{-1}(y) \cap p^{-1}(w) \cap A \times B(0,1) \right) 
\geq \lambda_{B(0,1)}(w) \mathcal{H}^{n-m} \left( h^{-1}(y - \varepsilon w) \cap A \right).
\]

Proof of the claim: If $w \notin B(0,1)$, there is nothing to prove so assume $w \in B(0,1)$. For such $w$,
\[
(x, w_1) \in k^{-1}(y) \cap p^{-1}(w) \cap A \times B(0,1)
\]
if and only if $h(x) + \varepsilon w_1 = y$, $w_1 = w$, and $x \in A$, if and only if
\[
(x, w_1) \in h^{-1}(y - \varepsilon w) \cap A \times \{w\}.
\]
Therefore for $w \in B(0,1)$,
\[
\mathcal{H}^{n-m} \left( k^{-1}(y) \cap p^{-1}(w) \cap A \times B(0,1) \right) 
\geq \mathcal{H}^{n-m} \left( h^{-1}(y - \varepsilon w) \cap A \times \{w\} \right) = \mathcal{H}^{n-m} \left( h^{-1}(y - \varepsilon w) \cap A \right).
\]

(Actually equality holds in the claim.) From the claim, \(34.3.22\) is at least as large as
\[
C_{nm} \int_{\mathbb{R}^m} \int_{B(0,1)} \mathcal{H}^{n-m} \left( h^{-1}(y - \varepsilon w) \cap A \right) dw dy \tag{34.3.23}
\]
\[
= C_{nm} \int_{B(0,1)} \int_{\mathbb{R}^m} \mathcal{H}^{n-m} \left( h^{-1}(y - \varepsilon w) \cap A \right) dy dw 
\]
\[
= \frac{\alpha(n)}{\alpha(n-m)} \int_{\mathbb{R}^m} \mathcal{H}^{n-m} \left( h^{-1}(y) \cap A \right) dy. \tag{34.3.24}
\]
The use of Fubini's theorem is justified because the integrand is Borel measurable.

Now by \(34.3.23\), it follows since $\varepsilon > 0$ is arbitrary,
\[
\int_{\mathbb{R}^m} \mathcal{H}^{n-m} \left( A \cap h^{-1}(y) \right) dy = 0 = \int_A Jh(x) dx.
\]

Since this holds for arbitrary compact sets in $S$, it follows from Lemma \(34.3.8\) and inner regularity of Lebesgue measure that the equation holds for all measurable subsets of $S$. This completes the proof of the coarea formula. There is a simple corollary to this theorem in the case of locally Lipschitz maps.

**Corollary 34.3.10** Let $h : \mathbb{R}^n \to \mathbb{R}^m$ where $m \leq n$ and $h$ is locally Lipschitz. Then the Coarea formula, \(34.3.13\), holds for $h$. 

Proof: The assumption that $h$ is locally Lipschitz implies that for each $r > 0$ it follows $h$ is Lipschitz on $B(0,r)$. To see this, cover the compact set, $B(0,r)$ with finitely many balls on which $h$ is Lipschitz.

Let $A \subseteq B(0,r)$ and let $h_r$ be Lipschitz with $h(x) = h_r(x)$
for $x \in B(0,r+1)$. Then

$$\int_A J(Dh(x)) \, dx = \int_A J(Dh_r(x)) \, dx = \int_{R^m} \mathcal{H}^{n-m}(A \cap h^{-1}_r(y)) \, dy$$

$$= \int_{h_r(A)} \mathcal{H}^{n-m}(A \cap h^{-1}_r(y)) \, dy = \int_{h(A)} \mathcal{H}^{n-m}(A \cap h^{-1}(y)) \, dy$$

$$= \int_{R^m} \mathcal{H}^{n-m}(A \cap h^{-1}(y)) \, dy$$

Now for arbitrary measurable $A$ the above shows for $k = 1, 2, \cdots$

$$\int_{A \cap B(0,k)} J(Dh(x)) \, dx = \int_{R^m} \mathcal{H}^{n-m}(A \cap B(0,k) \cap h^{-1}(y)) \, dy.$$ 

Use the monotone convergence theorem to obtain (34.3.13).

From the definition of Hausdorff measure it follows $\mathcal{H}^0(E)$ equals the number of elements in $E$. Thus, if $n = m$, the Coarea formula implies

$$\int_A J(Dh(x)) \, dx = \int_{h(A)} \mathcal{H}^0(A \cap h^{-1}(y)) \, dy = \int_{h(A)} \#(y) \, dy$$

This gives a version of Sard’s theorem by letting $S = A$.

### 34.4 A Nonlinear Fubini’s Theorem

Coarea formula holds for $h : \mathbb{R}^n \rightarrow \mathbb{R}^m, n \geq m$ if whenever $A$ is a Lebesgue measurable subset of $\mathbb{R}^n$, the following formula is valid.

$$\int_{R^m} \mathcal{H}^{n-m}(A \cap h^{-1}(y)) \, dy = \int_A Jh(x) \, dx$$  \hspace{1cm} (34.4.25)

Note this is the same as

$$\int_A J(Dh(x)) \, dx = \int_{h(A)} \mathcal{H}^{n-m}(A \cap h^{-1}(y)) \, dy$$

because if $y \notin h(A)$, then $h^{-1}(y) = \emptyset$. Now let

$$s(x) = \sum_{i=1}^{p} c_i x_{E_i}(x)$$
where $E_i$ is measurable and $c_i \geq 0$. Then

\[
\int_{\mathbb{R}^n} s(x) J((Dh(x))) \, dx = \sum_{i=1}^{p} c_i \int_{E_i} J(Dh(x)) \, dx
\]

\[
= \sum_{i=1}^{p} c_i \int_{h(E_i)} \mathcal{H}^{n-m}(E_i \cap h^{-1}(y)) \, dy
\]

\[
= \int_{h(\mathbb{R}^n)} \left[ \int_{h^{-1}(y)} s \, d\mathcal{H}^{n-m} \right] \, dy
\]

\[
= \int_{h(\mathbb{R}^n)} \left[ \int_{h^{-1}(y)} s \, d\mathcal{H}^{n-m} \right] \, dy.
\] (34.4.26)

**Theorem 34.4.1** Let $g \geq 0$ be Lebesgue measurable and let

\[ h : \mathbb{R}^n \to \mathbb{R}^m, \quad n \geq m \]

satisfy the Coarea formula. For example, it could be locally Lipschitz. Then

\[
\int_{\mathbb{R}^n} g(x) J((Dh(x))) \, dx = \int_{h(\mathbb{R}^n)} \left[ \int_{h^{-1}(y)} g \, d\mathcal{H}^{n-m} \right] \, dy.
\]

**Proof:** Let $s_i \uparrow g$ where $s_i$ is a simple function satisfying 34.4.26. Then let $i \to \infty$ and use the monotone convergence theorem to replace $s_i$ with $g$. This proves the change of variables formula.

Note that this formula is a nonlinear version of Fubini’s theorem. The “$n - m$ dimensional surface”, $h^{-1}(y)$, plays the role of $\mathbb{R}^{n-m}$ and $\mathcal{H}^{n-m}$ is like $n - m$ dimensional Lebesgue measure. The term, $J((Dh(x)))$, corrects for the error occurring because of the lack of flatness of $h^{-1}(y)$. 

Chapter 35

Integration On Manifolds

You can do integration on various manifolds by using the Hausdorff measure of an appropriate dimension. However, it is possible to discuss this through the use of the Riesz representation theorem and some of the machinery for accomplishing this is interesting for its own sake so I will present this alternate point of view.

35.1 Partitions Of Unity

This material has already been mostly discussed starting on Page 1011. However, that was a long time ago and it seems like it might be good to go over it again and so, for the sake of convenience, here it is again.

Definition 35.1.1 Let $C$ be a set whose elements are subsets of $\mathbb{R}^n$. Then $C$ is said to be locally finite if for every $x \in \mathbb{R}^n$, there exists an open set, $U_x$ containing $x$ such that $U_x$ has nonempty intersection with only finitely many sets of $C$.

Lemma 35.1.2 Let $C$ be a set whose elements are open subsets of $\mathbb{R}^n$ and suppose $\cup C \supseteq H$, a closed set. Then there exists a countable list of open sets, $\{U_i\}_{i=1}^{\infty}$ such that each $U_i$ is bounded, each $U_i$ is a subset of some set of $C$, and $\cup_{i=1}^{\infty} U_i \supseteq H$.

Proof: Let $W_k \equiv B(0,k), W_0 = W_{-1} = \emptyset$. For each $x \in H \cap \overline{W}_k$ there exists an open set, $U_x$ such that $U_x$ is a subset of some set of $C$ and $U_x \subseteq W_{k+1} \setminus \overline{W}_{k-1}$. Then since $H \cap \overline{W}_k$ is compact, there exist finitely many of these sets, $\{U_i^k\}_{i=1}^{m(k)}$ whose union contains $H \cap \overline{W}_k$. If $H \cap \overline{W}_k = \emptyset$, let $m(k) = 0$ and there are no such sets obtained. The desired countable list of open sets is $\cup_{k=1}^{\infty} \{U_i^k\}_{i=1}^{m(k)}$. Each open set in this list is bounded. Furthermore, if $x \in \mathbb{R}^n$, then $x \in W_k$ where $k$ is the first positive integer with $x \in W_k$. Then $W_k \setminus \overline{W}_{k-1}$ is an open set containing $x$ and this open set can have nonempty intersection only with with a set of $\{U_i^k\}_{i=1}^{m(k)} \cup \{U_i^{k-1}\}_{i=1}^{m(k-1)}$, a finite list of sets. Therefore, $\cup_{k=1}^{\infty} \{U_i^k\}_{i=1}^{m(k)}$ is locally finite.

1The definition applies with no change to a general topological space in place of $\mathbb{R}^n$. 1313
The set, \( \{U_i\}_{i=1}^{\infty} \) is said to be a locally finite cover of \( H \). The following lemma gives some important reasons why a locally finite list of sets is so significant. First of all consider the rational numbers, \( \{r_i\}_{i=1}^{\infty} \) each rational number is a closed set.

\[
\mathbb{Q} = \{r_i\}_{i=1}^{\infty} = \bigcup_{i=1}^{\infty} \{r_i\} \neq \bigcup_{i=1}^{\infty} \{r_i\} = \mathbb{R}
\]

The set of rational numbers is definitely not locally finite.

**Lemma 35.1.3** Let \( \mathcal{C} \) be locally finite. Then

\[
\overline{\mathcal{C}} = \bigcup \{ \overline{H} : H \in \mathcal{C} \}.
\]

Next suppose the elements of \( \mathcal{C} \) are open sets and that for each \( U \in \mathcal{C} \), there exists a differentiable function, \( \psi_U \), having \( \text{spt} (\psi_U) \subseteq U \). Then you can define the following finite sum for each \( x \in \mathbb{R}^n \)

\[
f (x) = \sum \{ \psi_U(x) : x \in U \}.
\]

Furthermore, \( f \) is also a differentiable function\(^2\) and

\[
Df (x) = \sum \{ D\psi_U (x) : x \in U \}.
\]

**Proof:** Let \( p \) be a limit point of \( \cup \mathcal{C} \) and let \( W \) be an open set which intersects only finitely many sets of \( \mathcal{C} \). Then \( p \) must be a limit point of one of these sets. It follows \( p \in \bigcup \{ \overline{H} : H \in \mathcal{C} \} \) and so \( \overline{\mathcal{C}} \subseteq \bigcup \{ \overline{H} : H \in \mathcal{C} \} \). The inclusion in the other direction is obvious.

Now consider the second assertion. Letting \( x \in \mathbb{R}^n \), there exists an open set, \( W \) intersecting only finitely many open sets of \( \mathcal{C}, U_1, U_2, \ldots, U_m \). Then for all \( y \in W \),

\[
f (y) = \sum_{i=1}^{m} \psi_{U_i} (y)
\]

and so the desired result is obvious. It merely says that a finite sum of differentiable functions is differentiable. Recall the following definition.

**Definition 35.1.4** Let \( K \) be a closed subset of an open set, \( U \). \( K \prec f \prec U \) if \( f \) is continuous, has values in \([0,1]\), equals 1 on \( K \), and has compact support contained in \( U \).

**Lemma 35.1.5** Let \( U \) be a bounded open set and let \( K \) be a closed subset of \( U \). Then there exist an open set, \( W \), such that \( W \subseteq \overline{W} \subseteq U \) and a function, \( f \in C^\infty_c (U) \) such that \( K \prec f \prec U \).

\(^2\)If each \( \psi_U \) were only continuous, one could conclude \( f \) is continuous. Here the main interest is differentiable.
35.1. PARTITIONS OF UNITY

Proof: The set, \( K \) is compact so is at a positive distance from \( U^C \). Let

\[
W \equiv \{ x : \text{dist} (x, K) < 3^{-1} \text{dist} (K, U^C) \}.
\]

Also let

\[
W_1 \equiv \{ x : \text{dist} (x, K) < 2^{-1} \text{dist} (K, U^C) \}.
\]

Then it is clear

\[
K \subseteq W \subseteq W_1 \subseteq \overline{W_1} \subseteq U
\]

Now consider the function,

\[
h(x) \equiv \frac{\text{dist} (x, W^C)}{\text{dist} (x, W_1^C) + \text{dist} (x, \overline{W})}
\]

Since \( \overline{W} \) is compact it is at a positive distance from \( W_1^C \) and so \( h \) is a well defined continuous function which has compact support contained in \( \overline{W_1} \), equals 1 on \( W \), and has values in \([0, 1]\). Now let \( \phi_k \) be a mollifier. Letting

\[
k^{-1} < \min (\text{dist} (K, W^C), 2^{-1} \text{dist} (\overline{W_1}, U^C)),
\]

it follows that for such \( k \), the function, \( h \ast \phi_k \in C^\infty_c (U) \), has values in \([0, 1]\), and equals 1 on \( K \). Let \( f = h \ast \phi_k \).

The above lemma is used repeatedly in the following.

Lemma 35.1.6 Let \( K \) be a closed set and let \( \{V_i\}_{i=1}^\infty \) be a locally finite list of bounded open sets whose union contains \( K \). Then there exist functions, \( \psi_i \in C^\infty_c (V_i) \) such that for all \( x \in K \),

\[
1 = \sum_{i=1}^\infty \psi_i (x)
\]

and the function \( f(x) \) given by

\[
f(x) = \sum_{i=1}^\infty \psi_i (x)
\]

is in \( C^\infty (\mathbb{R}^n) \).

Proof: Let \( K_1 = K \setminus \bigcup_{i=2}^\infty V_i \). Thus \( K_1 \) is compact because \( K_1 \subseteq V_1 \). Let

\[
K_1 \subseteq W_1 \subseteq \overline{W_1} \subseteq V_1
\]

Thus \( W_1, V_2, \ldots, V_n \) covers \( K \) and \( \overline{W_1} \subseteq V_1 \). Suppose \( W_1, \ldots, W_r \) have been defined such that \( \overline{W_i} \subseteq V_i \) for each \( i \), and \( W_1, \ldots, W_r, V_{r+1}, \ldots, V_n \) covers \( K \). Then let

\[
K_{r+1} \equiv K \setminus \left( \bigcup_{i=r+2}^\infty V_i \right) \cup \left( \bigcup_{j=1}^r W_j \right).
\]

It follows \( K_{r+1} \) is compact because \( K_{r+1} \subseteq V_{r+1} \). Let \( W_{r+1} \) satisfy

\[
K_{r+1} \subseteq W_{r+1} \subseteq \overline{W_{r+1}} \subseteq V_{r+1}
\]
Continuing this way defines a sequence of open sets, \( \{W_i\}\infty_{i=1} \) with the property
\[
W_i \subseteq V_i, \quad K \subseteq \bigcup_{i=1}^\infty W_i.
\]
Note \( \{W_i\}\infty_{i=1} \) is locally finite because the original list, \( \{V_i\}\infty_{i=1} \) was locally finite.

Now let \( U_i \) be open sets which satisfy
\[
W_i \subseteq U_i \subseteq \overline{U_i} \subseteq V_i.
\]
Similarly, \( \{U_i\}\infty_{i=1} \) is locally finite.

Since the set, \( \{W_i\}\infty_{i=1} \) is locally finite, it follows \( \bigcup_{i=1}^\infty W_i = \bigcup_{i=1}^\infty W_i \) and so it is possible to define \( \phi_i \) and \( \gamma_i \), infinitely differentiable functions having compact support such that
\[
U_i \prec \phi_i \prec V_i, \quad \bigcup_{i=1}^\infty W_i \prec \gamma_i \prec \bigcup_{i=1}^\infty U_i.
\]

Now define
\[
\psi_i(x) = \begin{cases} 
\gamma(x)\phi_i(x)/\sum_{j=1}^\infty \phi_j(x) & \text{if } \sum_{j=1}^\infty \phi_j(x) \neq 0, \\
0 & \text{if } \sum_{j=1}^\infty \phi_j(x) = 0.
\end{cases}
\]

If \( x \) is such that \( \sum_{j=1}^\infty \phi_j(x) = 0 \), then \( x \notin \bigcup_{i=1}^\infty U_i \) because \( \phi_i \) equals one on \( U_i \).
Consequently \( \gamma(y) = 0 \) for all \( y \) near \( x \) thanks to the fact that \( \bigcup_{i=1}^\infty U_i \) is closed and so \( \psi_i \) is infinitely differentiable at such \( x \). If \( \sum_{j=1}^\infty \phi_j(x) \neq 0 \), this situation persists near \( x \) because each \( \phi_j \) is continuous and so \( \psi_i \) is infinitely differentiable at such points also thanks to Lemma 35.1.8. Therefore \( \psi_i \) is infinitely differentiable. If \( x \in K \), then \( \gamma(x) = 1 \) and so \( \sum_{j=1}^\infty \psi_j(x) = 1 \).
Clearly \( 0 \leq \psi_i(x) \leq 1 \) and \( \text{spt}(\psi_j) \subseteq V_j \). This proves the theorem.

The method of proof of this lemma easily implies the following useful corollary.

**Corollary 35.1.7** If \( H \) is a compact subset of \( V_i \) for some \( V_i \), there exists a partition of unity such that \( \psi_i(x) = 1 \) for all \( x \in H \) in addition to the conclusion of Lemma 35.1.8.

**Proof:** Keep \( V_i \) the same but replace \( V_j \) with \( \overline{V_j} = V_j \setminus H \). Now in the proof above, applied to this modified collection of open sets, if \( j \neq i, \phi_j(x) = 0 \) whenever \( x \in H \). Therefore, \( \psi_i(x) = 1 \) on \( H \).

**Theorem 35.1.8** Let \( H \) be any closed set and let \( \mathcal{C} \) be any open cover of \( H \). Then there exist functions \( \{\psi_i\}_{i=1}^\infty \) such that \( \text{spt}(\psi_i) \) is contained in some set of \( \mathcal{C} \) and \( \psi_i \) is infinitely differentiable having values in \([0,1]\) such that on \( H \), \( \sum_{i=1}^\infty \psi_i(x) = 1 \).
Furthermore, the function, \( f(x) = \sum_{i=1}^\infty \psi_i(x) \) is infinitely differentiable on \( \mathbb{R}^n \).
Also, \( \text{spt}(\psi_i) \subseteq U_i \) where \( U_i \) is a bounded open set with the property that \( \{U_i\}_{i=1}^\infty \) is locally finite and each \( U_i \) is contained in some set of \( \mathcal{C} \).
35.2. Integration On Manifolds

Manifolds are things which locally appear to be \( \mathbb{R}^n \) for some \( n \). The extent to which they have such a local appearance varies according to various analytical characteristics which the manifold possesses.

Definition 35.2.1 Let \( U \subseteq \mathbb{R}^n \) be an open set and let \( h : U \rightarrow \mathbb{R}^m \). Then for \( r \in (0, 1) \), \( h \in C^{k,r}(U) \) for \( k \) a nonnegative integer means that \( D^\alpha h \) exists for all \( |\alpha| \leq k \) and each \( D^\alpha h \) is Holder continuous with exponent \( r \). That is

\[
|D^\alpha h(x) - D^\alpha h(y)| \leq K |x - y|^r.
\]

Also \( h \in C^{k,r}(U) \) if it is the restriction of a function of \( C^{k,r}(\mathbb{R}^n) \) to \( U \).

Definition 35.2.2 Let \( \Gamma \) be a closed subset of \( \mathbb{R}^p \) where \( p \geq n \). Suppose \( \Gamma = \bigcup_{i=1}^\infty \Gamma_i \) where \( \Gamma_i = \Gamma \cap W_i \) for \( W_i \) a bounded open set. Suppose also \( \{W_i\}_{i=1}^\infty \) is locally finite. This means every bounded open set intersects only finitely many. Also suppose there are open bounded sets, \( U_i \) having Lipschitz boundaries and functions \( h_i : U_i \rightarrow \Gamma_i \) which are one to one, onto, and in \( C^{m,1}(U_i) \). Suppose also there exist functions, \( g_i : W_i \rightarrow U_i \) such that \( g_i \) is \( C^{m,1}(W_i) \), and \( g_i \circ h_i = id \) on \( U_i \) while \( h_i \circ g_i = id \) on \( \Gamma_i \). The collection of sets, \( \Gamma_j \) and mappings, \( g_j \), \( \{ \{ \Gamma_j, g_j \} \} \) is called an atlas and an individual entry in the atlas is called a chart. Thus \( \{ \Gamma_j, g_j \} \) is a chart. Then \( \Gamma \) as just described is called a \( C^{m,1} \) manifold. The number, \( m \), is just a nonnegative integer. When \( m = 0 \) this would be called a Lipschitz manifold, the least smooth of the manifolds discussed here.

For example, take \( p = n + 1 \) and let

\[
h_i(u) = (u_1, \cdots, u_i, \phi_i(u), u_{i+1}, \cdots, u_n)^T
\]
for $u = (u_1, \cdots, u_i, u_{i+1}, \cdots, u_n)^T \in U_i$ for $\phi_i \in C^{m,1}(U_i)$ and $g_i : U_i \times \mathbb{R} \to U_i$ given by
\[ g_i(u_1, \cdots, u_i, y, u_{i+1}, \cdots, u_n) = u \]
for $i = 1, 2, \cdots, p$. Then for $u \in U_i$, the definition gives
\[ g_i \circ h_i(u) = g_i(u_1, \cdots, u_i, \phi_i(u), u_{i+1}, \cdots, u_n) = u \]
and for $\Gamma_i \equiv h_i(U_i)$ and $(u_1, \cdots, u_i, \phi_i(u), u_{i+1}, \cdots, u_n)^T \in \Gamma_i$,
\[ h_i \circ g_i(u_1, \cdots, u_i, \phi_i(u), u_{i+1}, \cdots, u_n) = h_i(u) = (u_1, \cdots, u_i, \phi_i(u), u_{i+1}, \cdots, u_n)^T. \]

This example can be used to describe the boundary of a bounded open set and since $\phi_i \in C^{m,1}(U_i)$, such an open set is said to have a $C^{m,1}$ boundary. Note also that in this example, $U_i$ could be taken to be $\mathbb{R}^n$ or if $U_i$ is given, both $h_i$ and $g_i$ can be taken as restrictions of functions defined on all of $\mathbb{R}^n$ and $\mathbb{R}^p$ respectively.

The symbol, $I$ will refer to an increasing list of $n$ indices taken from $\{1, \cdots, p\}$. Denote by $(p; n)$ the set of all such increasing lists of $n$ indices.

Let
\[ J_i(u) \equiv \left[ \sum_{I \in \Lambda(p, n)} \left( \frac{\partial (x_1^1 \cdots x_i^n)}{\partial (u_1^1 \cdots u_n^1)} \right)^2 \right]^{1/2} \]
where here the sum is taken over all possible increasing lists of $n$ indices, $I$, from $\{1, \cdots, p\}$ and $x = h_i u$. Thus there are $\binom{p}{n}$ terms in the sum. In this formula, $\frac{\partial (x_1^1 \cdots x_i^n)}{\partial (u_1^1 \cdots u_n^1)}$ is defined to be the determinant of the following matrix.
\[
\begin{pmatrix}
\frac{\partial x_1^1}{\partial u_1} & \cdots & \frac{\partial x_i^1}{\partial u_1} \\
\vdots & \ddots & \vdots \\
\frac{\partial x_i^n}{\partial u_1} & \cdots & \frac{\partial x_i^n}{\partial u_n}
\end{pmatrix}
\]

Note that if $p = n$ there is only one term in the sum, the absolute value of the determinant of $Dx(u)$. Define a positive linear functional, $\Lambda$ on $C_c(\Gamma)$ as follows: First let $\{\psi_i\}$ be a $C^\infty$ partition of unity subordinate to the open sets, $\{W_i\}$. Thus $\psi_i \in C_c^\infty(W_i)$ and $\sum_i \psi_i(x) = 1$ for all $x \in \Gamma$. Then
\[ \Lambda f \equiv \sum_{i=1}^{\infty} \int_{h_i \Gamma_i} f \psi_i(h_i(u)) J_i(u) \, du. \quad (35.2.1) \]

Is this well defined?

**Lemma 35.2.3** The functional defined in (35.2.1) does not depend on the choice of atlas or the partition of unity.
Proof: In [34.2.1], let \( \{ \psi_i \} \) be a \( C^\infty \) partition of unity which is associated with the atlas \( (\Gamma_i, g_i) \) and let \( \{ \eta_i \} \) be a \( C^\infty \) partition of unity associated in the same manner with the atlas \( (\Gamma'_i, g'_i) \). In the following argument, the local finiteness of the \( \Gamma_i \) implies that all sums are finite. Using the change of variables formula with \( u = (g_i \circ h'_j) v \)

\[
\sum_{i=1}^{\infty} \int_{g_i(\Gamma'_i)} \psi_i f(h_i(u)) J_i(u) \, du = \tag{35.2.2}
\]

\[
\sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{g_i(\Gamma'_i)} \eta_j \psi_i f(h_i(u)) J_i(u) \, du = \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{g'_i(\Gamma'_i \cap \Gamma'_j)} \eta_j (h'_j(v)) \psi_i (h'_j(v)) f(h'_j(v)) J_i(u) \left| \frac{\partial (u^1, \ldots, u^n)}{\partial (v^1, \ldots, v^n)} \right| \, dv
\]

\[
= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} \int_{g'_i(\Gamma'_i \cap \Gamma'_j)} \eta_j (h'_j(v)) \psi_i (h'_j(v)) f(h'_j(v)) J_j(v) \, dv \tag{35.2.3}
\]

Thus the definition of \( \Lambda f \) using \( (\Gamma_i, g_i) \) is

\[
\sum_{i=1}^{\infty} \int_{g_i(\Gamma'_i)} \psi_i f(h_i(u)) J_i(u) \, du = \tag{35.2.4}
\]

\[
\sum_{i=1}^{\infty} \int_{g'_i(\Gamma'_i \cap \Gamma'_j)} \eta_j (h'_j(v)) \psi_i (h'_j(v)) f(h'_j(v)) J_j(v) \, dv
\]

This proves the lemma.

This lemma and the Riesz representation theorem for positive linear functionals implies the part of the following theorem which says the functional is well defined.

**Theorem 35.2.4** Let \( \Gamma \) be a \( C^{m,1} \) manifold. Then there exists a unique Radon measure, \( \mu \), defined on \( \Gamma \) such that whenever \( f \) is a continuous function having compact support which is defined on \( \Gamma \) and \( (\Gamma_i, g_i) \) denotes an atlas and \( \{ \psi_i \} \) a partition of unity subordinate to this atlas,

\[
\Lambda f = \int f \, d\mu = \sum_{i=1}^{\infty} \int_{g_i(\Gamma'_i)} \psi_i f(h_i(u)) J_i(u) \, du.
\]
Proof: To begin, here is a claim.

Claim: A set, \( S \subseteq \Gamma_i \), has \( \mu \) measure zero if and only if \( \mathbf{g}_i S \) has measure zero in \( \mathbf{g}_i \Gamma_i \) with respect to the measure, \( \nu_i \).

Proof of the claim: Let \( \varepsilon > 0 \) be given. By outer regularity, there exists a set, \( V \subseteq \Gamma_i \), open in \( \Gamma \) such that \( \mu (V) < \varepsilon \) and \( S \subseteq V \subseteq \Gamma_i \). Then \( \mathbf{g}_i V \) is open in \( \mathbb{R}^n \) and contains \( \mathbf{g}_i S \). Letting \( h \prec \mathbf{g}_i V \) and \( h_1 (x) \equiv h (\mathbf{g}_i (x)) \) for \( x \in \Gamma_i \) it follows \( h_1 \prec V \). By Corollary 35.1.7 on Page 1316 there exists a partition of unity such that \( \text{spt} (h_1) \subseteq \{ x \in \mathbb{R}^p : \psi_i (x) = 1 \} \). Thus \( \psi_j h_1 (\mathbf{h}_j (u)) = 0 \) unless \( j = i \) when this reduces to \( h_1 (\mathbf{h}_i (u)) \). It follows

\[
\varepsilon \geq \mu (V) \geq \int_V h_1 d\mu = \int_{\Gamma_i} h_1 d\mu \\
= \sum_{j=1}^{\infty} \int_{\mathbf{g}_i \Gamma_i} \psi_j h_1 (\mathbf{h}_j (u)) J_j (u) du \\
= \int_{\mathbf{g}_i \Gamma_i} h_1 (\mathbf{h}_i (u)) J_i (u) du = \int_{\mathbf{g}_i \Gamma_i} h (u) J_i (u) du \\
= \int_{\mathbf{g}_i V} h (u) J_i (u) du
\]

Now this holds for all \( h \prec \mathbf{g}_i V \) and so

\[
\int_{\mathbf{g}_i V} J_i (u) du \leq \varepsilon.
\]

Since \( \varepsilon \) is arbitrary, this shows \( \mathbf{g}_i V \) has measure no more than \( \varepsilon \) with respect to the measure, \( \nu_i \). Since \( \varepsilon \) is arbitrary, \( \mathbf{g}_i S \) has measure zero.

Consider the converse. Suppose \( \mathbf{g}_i S \) has \( \nu_i \) measure zero. Then there exists an open set, \( O \subseteq \mathbf{g}_i \Gamma_i \) such that \( O \supseteq \mathbf{g}_i S \) and

\[
\int_{O} J_i (u) du < \varepsilon.
\]

Thus \( \mathbf{h}_i (O) \) is open in \( \Gamma \) and contains \( S \). Let \( h \prec \mathbf{h}_i (O) \) be such that

\[
\int_{\Gamma} h d\mu + \varepsilon > \mu (\mathbf{h}_i (O)) \geq \mu (S) \quad (35.2.5)
\]

As in the first part, Corollary 35.1.7 on Page 1316 implies there exists a partition of unity such that \( h (x) = 0 \) off the set,

\[
\{ x \in \mathbb{R}^p : \psi_i (x) = 1 \}
\]

3This means \( V \) is the intersection of an open set with \( \Gamma \). Equivalently, it means that \( V \) is an open set in the traditional way regarding \( \Gamma \) as a metric space with the metric it inherits from \( \mathbb{R}^m \).
and so as in this part of the argument,

$$\int_{\Gamma} h d\mu = \sum_{j=1}^{\infty} \int_{g_j U_j} \psi_j h \left( h_j (u) \right) J_j (u) \, du$$

$$= \int_{g_i F_i} h \left( h_i (u) \right) J_i (u) \, du$$

$$= \int_{g_i (G \setminus F)} h \left( h_i (u) \right) J_i (u) \, du$$

$$\leq \int_{O \cap g_i \Gamma_i} J_i (u) \, du < \varepsilon \quad (35.2.6)$$

and so from $35.2.5$ and $35.2.6$ $\mu (S) \leq 2\varepsilon$. Since $\varepsilon$ is arbitrary, this proves the claim.

For the last part of the theorem, it suffices to let $A \subseteq \Gamma_r$ because otherwise, the above argument would apply to $A \cap \Gamma_r$. Thus let $A \subseteq \Gamma_r$ be $\mu$ measurable. By the regularity of the measure, there exists an $F_\sigma$ set, $F$ and a $G_\delta$ set, $G$ such that $\Gamma_r \supseteq G \supseteq A \supseteq F$ and $\mu (G \setminus F) = 0$. (Recall a $G_\delta$ set is a countable intersection of open sets and an $F_\sigma$ set is a countable union of closed sets.) Then since $\Gamma_r$ is compact, it follows each of the closed sets whose union equals $F$ is a compact set. Thus if $F = \bigcup_{k=1}^{\infty} F_k$, $g_r (F_k)$ is also a compact set and so $g_r (F) = \bigcup_{k=1}^{\infty} g_r (F_k)$ is a Borel set. Similarly, $g_r (G)$ is also a Borel set. Now by the claim,

$$\int_{g_r (G \setminus F)} J_r (u) \, du = 0.$$

Since $g_r$ is one to one,

$$g_r (G \setminus F) = g_r (G \setminus F)$$

and so

$$g_r (F) \subseteq g_r (A) \subseteq g_r (G)$$

where $g_r (G) \setminus g_r (F)$ has measure zero. By completeness of the measure, $\nu_r$, $g_r (A)$ is measurable. It follows that if $A \subseteq \Gamma$ is measurable, then $g_r (\Gamma_r \cap A)$ is $\nu_r$ measurable for all $r$. The converse is entirely similar. This proves the theorem.

**Corollary 35.2.5** Let $f \in L^1 (\Gamma_r; \mu)$ and suppose $f (x) = 0$ for all $x \notin \Gamma_r$ where $(\Gamma_r, g_r)$ is a chart. Then

$$\int_{\Gamma} f \, d\mu = \int_{\Gamma_r} f \, d\mu = \int_{g_r \Gamma_r} f \left( h_r (u) \right) J_r (u) \, du. \quad (35.2.7)$$

Furthermore, if $\{(\Gamma_i, g_i)\}$ is an atlas and $\{\psi_i\}$ is a partition of unity as described earlier, then for any $f \in L^1 (\Gamma, \mu)$,

$$\int_{\Gamma} f \, d\mu = \sum_{r=1}^{\infty} \int_{g_r \Gamma_r} \psi_r f \left( h_r (u) \right) J_r (u) \, du. \quad (35.2.8)$$
Proof: Let \( f \in L^1(\Gamma, \mu) \) with \( f = 0 \) off \( \Gamma_r \). Without loss of generality assume \( f \geq 0 \) because if the formulas can be established for this case, the same formulas are obtained for an arbitrary complex valued function by splitting it up into positive and negative parts of the real and imaginary parts in the usual way. Also, let \( K \subseteq \Gamma_r \) a compact set. Since \( \mu \) is a Radon measure there exists a sequence of continuous functions, \( \{f_k\} \), \( f_k \in C_c(\Gamma_r) \), which converges to \( f \) in \( L^1(\Gamma, \mu) \) and for \( \mu \) a.e. \( x \). Take the partition of unity, \( \{\psi_i\} \) to be such that

\[
K \subseteq \{x : \psi_r(x) = 1\}.
\]

Therefore, the sequence \( \{f_k(h_r(\cdot))\} \) is a Cauchy sequence in the sense that

\[
\lim_{k,l \to \infty} \int_{g_r(K)} |f_k(h_r(u)) - f_l(h_r(u))| J_r(u) \, du = 0
\]

It follows there exists \( g \) such that

\[
\int_{g_r(K)} |f_k(h_r(u)) - g(u)| J_r(u) \, du \to 0,
\]

and

\[
g \in L^1(g_rK; \nu_r).
\]

By the pointwise convergence and the claim used in the proof of Theorem 35.2.4,

\[
g(u) = f(h_r(u))
\]

for \( \mu \) a.e. \( h_r(u) \in K \). Therefore,

\[
\int_K f \, d\mu = \lim_{k \to \infty} \int_K f_k \, d\mu = \lim_{k \to \infty} \int_{g_r(K)} f_k(h_r(u)) J_r(u) \, du = \int_{g_r(K)} g(u) J_r(u) \, du = \int_{g_r(K)} f(h_r(u)) J_r(u) \, du.
\]

(35.2.9)

Now let \( \cdots K_j \subseteq K_{j+1} \cdots \quad \cup_{j=1}^{\infty} K_j = \Gamma_r \) where \( K_j \) is compact for all \( j \). Replace \( K \) in \( 35.2.9 \) with \( K_j \) and take a limit as \( j \to \infty \). By the monotone convergence theorem,

\[
\int_{\Gamma_r} f \, d\mu = \int_{g_r(\Gamma_r)} f(h_r(u)) J_r(u) \, du.
\]

This establishes \( 35.2.7 \).

To establish \( 35.2.8 \), let \( f \in L^1(\Gamma, \mu) \) and let \( \{(\Gamma_i, g_i)\} \) be an atlas and \( \{\psi_i\} \) be a partition of unity. Then \( f\psi_i \in L^1(\Gamma, \mu) \) and is zero off \( \Gamma_i \). Therefore, from what was just shown,

\[
\int_\Gamma f \, d\mu = \sum_{i=1}^\infty \int_{\Gamma_i} f \psi_i \, d\mu = \sum_{r=1}^\infty \int_{g_r(\Gamma_r)} \psi_r f(h_r(u)) J_r(u) \, du
\]
35.3 Comparison With $\mathcal{H}^n$

The above gives a measure on a manifold, $\Gamma$. I will now show that the measure obtained is nothing more than $\mathcal{H}^n$, the $n$ dimensional Hausdorff measure. Recall $A(p, n)$ was the set of all increasing lists of $n$ indices taken from $\{1, \ldots, p\}$.

Recall

$$J_i(u) \equiv \left[ \sum_{I \in \Lambda(p, n)} \left( \frac{\partial (x^{i_1} \cdots x^{i_n})}{\partial (u^{1} \cdots u^{n})} \right)^2 \right]^{1/2}$$

where here the sum is taken over all possible increasing lists of $n$ indices, $I$, from $\{1, \cdots, p\}$ and $x = h_i u$ and the functional was given as

$$A f \equiv \sum_{i=1}^{\infty} \int_{\mathbb{R}^n} f_{\psi_i}(h_i(u)) J_i(u) \,du$$

(35.3.10)

where the $\{\psi_i\}_{i=1}^{\infty}$ was a partition of unity subordinate to the open sets, $\{W_i\}_{i=1}^{\infty}$ as described above. I will show

$$J_i(u) = \det (Dh(u)^* Dh(u))^{1/2}$$

and then use the area formula. The key result is really a special case of the Binet Cauchy theorem and this special case is presented in the next lemma.

**Lemma 35.3.1** Let $A = (a_{ij})$ be a real $p \times n$ matrix in which $p \geq n$. For $I \in \Lambda(p, n)$ denote by $A_I$ the $n \times n$ matrix obtained by deleting from $A$ all rows except for those corresponding to an element of $I$. Then

$$\sum_{I \in \Lambda(p, n)} \det(A_I)^2 = \det(A^*A)$$

**Proof:** For $(j_1, \cdots, j_n) \in \Lambda(p, n)$, define $\theta(j_k) \equiv k$. Then let for $\{k_1, \cdots, k_n\} = \{j_1, \cdots, j_n\}$ define

$$\text{sgn}(k_1, \cdots, k_n) \equiv \text{sgn}(\theta(k_1), \cdots, \theta(k_n)).$$

Then from the definition of the determinant and matrix multiplication,

$$\det(A^*A) = \sum_{i_1, \cdots, i_n} \text{sgn}(i_1, \cdots, i_n) \sum_{k_1=1}^{p} a_{k_1 i_1} a_{k_1 1} \sum_{k_2=1}^{p} a_{k_2 i_2} a_{k_2 2} \cdots \sum_{k_n=1}^{p} a_{k_n i_n} a_{k_n n}$$

$$= \sum_{J \in \Lambda(p, n)} \sum_{\{k_1, \cdots, k_n\} = J} \sum_{i_1, \cdots, i_n} \text{sgn}(i_1, \cdots, i_n) a_{k_1 i_1} a_{k_1 1} a_{k_2 i_2} a_{k_2 2} \cdots a_{k_n i_n} a_{k_n n}$$
\[ \sum_{J \in \Lambda(p,n)} \sum_{J_1, \ldots, J_n} \text{sgn} \left( i_1, \ldots, i_n \right) a_{k_1 i_1} a_{k_2 i_2} \cdots a_{k_n i_n} \cdot a_{k_1} a_{k_2} \cdots a_{k_n} \]

\[ = \sum_{J \in \Lambda(p,n)} \sum_{J_1, \ldots, J_n} \text{sgn} \left( k_1, \ldots, k_n \right) \det (A_J) a_{k_1} a_{k_2} \cdots a_{k_n} \]

and this proves the lemma.

It follows from this lemma that

\[ J_i (u) = \det (Dh (u)^* Dh (u))^{1/2}. \]

From (35.3.10) and the area formula, the functional equals

\[ \Lambda f = \sum_{i=1}^{\infty} \int_{\mathbb{R}^n} f \psi_i (h_i (u)) J_i (u) \, du \]

\[ = \sum_{i=1}^{\infty} \int_{\Gamma} f \psi_i (y) \, d\mathcal{H}^n = \int_{\Gamma} f (y) \, d\mathcal{H}^n. \]

Now \( \mathcal{H}^n \) is a Borel measure defined on \( \Gamma \) which is finite on all compact subsets of \( \Gamma \). This finiteness follows from the above formula. If \( K \) is a compact subset of \( \Gamma \), then there exists an open set, \( W \) whose closure is compact and a continuous function with compact support, \( f \) such that \( K \prec f \prec W \). Then \( \mathcal{H}^n (K) \leq \int_{\Gamma} f (y) \, d\mathcal{H}^n < \infty \) because of the above formula.

**Lemma 35.3.2** \( \mu = \mathcal{H}^n \) on every \( \mu \) measurable set.

**Proof:** The Riesz representation theorem shows that

\[ \int_{\Gamma} f \, d\mu = \int_{\Gamma} f \, d\mathcal{H}^n \]

for every continuous function having compact support. Therefore, since every open set is the countable union of compact sets, it follows \( \mu = \mathcal{H}^n \) on all open sets. Since compact sets can be obtained as the countable intersection of open sets, these two measures are also equal on all compact sets. It follows they are also equal on all countable unions of compact sets. Suppose now that \( E \) is a \( \mu \) measurable set of finite measure. Then there exist sets, \( F, G \) such that \( G \) is the countable intersection of open sets each of which has finite measure and \( F \) is the countable union of compact sets such that \( \mu (G \setminus F) = 0 \) and \( F \subseteq E \subseteq G \). Thus \( \mathcal{H}^n (G \setminus F) = 0 \),

\[ \mathcal{H}^n (G) = \mu (G) = \mu (F) = \mathcal{H}^n (F) \]

By completeness of \( \mathcal{H}^n \) it follows \( E \) is \( \mathcal{H}^n \) measurable and \( \mathcal{H}^n (E) = \mu (E) \). If \( E \) is not of finite measure, consider \( E_r \equiv E \cap B (0, r) \). This is contained in the compact set \( \Gamma \cap \overline{B (0, r)} \) and so \( \mu (E_r) \) if finite. Thus from what was just shown, \( \mathcal{H}^n (E_r) = \mu (E_r) \) and so, taking \( r \to \infty \), \( \mathcal{H}^n (E) = \mu (E) \).

This shows you can simply use \( \mathcal{H}^n \) for the measure on \( \Gamma \).
Chapter 36

Basic Theory Of Sobolev Spaces

Definition 36.0.1 Let $U$ be an open set of $\mathbb{R}^n$. Define $X^{m,p}(U)$ as the set of all functions in $L^p(U)$ whose weak partial derivatives up to order $m$ are also in $L^p(U)$ where $1 \leq p$. The norm $\|\cdot\|_{m,p}$ in this space is given by

$$\|u\|_{m,p} = \left( \int_U \sum_{|\alpha| \leq m} |D^\alpha u|^p \, dx \right)^{1/p},$$

where $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{N}^n$ and $|\alpha| \equiv \sum \alpha_i$. Here $D^\alpha u \equiv u$. $C^\infty(\overline{U})$ is defined to be the set of functions which are restrictions to $U$ of a function in $C^\infty(\mathbb{R}^n)$. Thus $C^\infty(\overline{U}) \subseteq W^{m,p}(U)$. The Sobolev space, $W^{m,p}(U)$ is defined to be the closure of $C^\infty(\overline{U})$ in $X^{m,p}(U)$ with respect to the above norm. Denote this norm by $\|u\|_{W^{m,p}(U)}, \|u\|_{X^{m,p}(U)}$, or $\|u\|_{m,p,U}$ when it is important to identify the open set, $U$.

Also the following notation will be used pretty consistently.

Definition 36.0.2 Let $u$ be a function defined on $U$. Define

$$\overline{u}(x) \equiv \begin{cases} u(x) & \text{if } x \in U \\ 0 & \text{if } x \notin U \end{cases}.$$

Theorem 36.0.3 Both $X^{m,p}(U)$ and $W^{m,p}(U)$ are separable reflexive Banach spaces provided $p > 1$.
Theorem 36.0.5

Let $U$ be an open set and let $U_0$ be an open subset of $U$ with the property that $\dist(U_0,U^C) > 0$. Then if $u \in X^{m,p}(U)$ and $\bar{u}$ denotes the zero extension of $u$ off $U$,

$$
\lim_{l \to \infty} \|\bar{u} * \phi_l - u\|_{X^{m,p}(U_0)} = 0.
$$

Proof: Define $\Lambda : X^{m,p}(U) \to L^p(U)^w$ where $w$ equals the number of multi indices, $\alpha$, such that $|\alpha| \leq m$ as follows. Letting $\{\alpha_l\}_{l=1}^{w}$ be the set of all multi indices with $\alpha_1 = 0$,

$$
\Lambda(u) \equiv (D^{\alpha_1}u, D^{\alpha_2}u, \cdots, D^{\alpha_w}u) = (u, D^{\alpha_2}u, \cdots, D^{\alpha_w}u).
$$

Then $\Lambda$ is one to one because one of the multi indices is $0$. Also

$$
\Lambda(X^{m,p}(U))
$$

is a closed subspace of $L^p(U)^w$. To see this, suppose

$$(u_k, D^{\alpha_2}u_k, \cdots, D^{\alpha_w}u_k) \to (f_1, f_2, \cdots, f_w)$$

in $L^p(U)^w$. Then $u_k \to f_1$ in $L^p(U)$ and $D^{\alpha_2}u_k \to f_j$ in $L^p(U)$. Therefore, letting $\phi \in C_c^\infty(U)$ and letting $k \to \infty$,

$$
\int_U (D^{\alpha_j}u_k) \phi \, dx = (-1)^{|\alpha|} \int_U u_k D^{\alpha_j} \phi \, dx
$$

in $L^p(U)^w$. Then $u_k \to f_1$ in $L^p(U)$ and $D^{\alpha_2}u_k \to f_j$ in $L^p(U)$. Therefore, letting $\phi \in C_c^\infty(U)$ and letting $k \to \infty$,

$$
\int_U (D^{\alpha_j}u_k) \phi \, dx = (-1)^{|\alpha|} \int_U f_1 D^{\alpha_j} \phi \, dx
$$

It follows $D^{\alpha_j}(f_1) = f_j$ and so $\Lambda(X^{m,p}(U))$ is closed as claimed. This is clearly also a subspace of $L^p(U)^w$ and so it follows that $\Lambda(X^{m,p}(U))$ is a reflexive Banach space. This is because $L^p(U)^w$, being the product of reflexive Banach spaces, is reflexive and any closed subspace of a reflexive Banach space is reflexive. Now $\Lambda$ is an isometry of $X^{m,p}(U)$ and $\Lambda(X^{m,p}(U))$ which shows that $X^{m,p}(U)$ is a reflexive Banach space. Finally, $W^{m,p}(U)$ is a closed subspace of the reflexive Banach space, $X^{m,p}(U)$ and so it is also reflexive. To see $X^{m,p}(U)$ is separable, note that $L^p(U)^w$ is separable because it is the finite product of the separable hence completely separable metric space, $L^p(U)$ and $\Lambda(X^{m,p}(U))$ is a subset of $L^p(U)^w$. Therefore, $\Lambda(X^{m,p}(U))$ is separable and since $\Lambda$ is an isometry, it follows $X^{m,p}(U)$ is separable also. Now $W^{m,p}(U)$ must also be separable because it is a subset of $X^{m,p}(U)$.

The following theorem is obvious but is worth noting because it says that if a function has a weak derivative in $L^p(U)$ on a large open set, $U$ then the restriction of this weak derivative is also the weak derivative for any smaller open set.

Theorem 36.0.4 Suppose $U$ is an open set and $U_0 \subseteq U$ is another open set. Suppose also $D^\alpha u \in L^p(U)$. Then for all $\psi \in C_c^\infty(U_0)$,

$$
\int_{U_0} (D^\alpha u) \psi \, dx = (-1)^{|\alpha|} \int_{U_0} u (D^\alpha \psi) \, dx.
$$

The following theorem is a fundamental approximation result for functions in $X^{m,p}(U)$.

Theorem 36.0.5 Let $U$ be an open set and let $U_0$ be an open subset of $U$ with the property that $\dist(U_0,U^C) > 0$. Then if $u \in X^{m,p}(U)$ and $\bar{u}$ denotes the zero extension of $u$ off $U$,

$$
\lim_{l \to \infty} \|\bar{u} * \phi_l - u\|_{X^{m,p}(U_0)} = 0.
$$
Proof: Always assume $l$ is large enough that $1/l < \text{dist} \left( \overline{U}_0, U^c \right)$. Thus for $x \in U_0$,

$$\tilde{u} * \phi_l (x) = \int_{B(0, \frac{1}{l})} u(x - y) \phi_l (y) dy. \tag{36.0.1}$$

The theorem is proved if it can be shown that $D^a (\tilde{u} * \phi_l) \rightarrow D^a u$ in $L^p (U_0)$. Let $\psi \in C^\infty_c (U_0)$

$$D^a (\tilde{u} * \phi_l) (\psi) = (-1)^{|\alpha|} \int_{U_0} (\tilde{u} * \phi_l) (D^a \psi) dx$$

$$= (-1)^{|\alpha|} \int_{U_0} \int_{U} \tilde{u} (y) \phi_l (x - y) (D^a \psi)(x) dy dx$$

$$= (-1)^{|\alpha|} \int_{U} u(y) \int_{U_0} \phi_l (x - y) (D^a \psi)(x) dx dy.$$

Also,

$$\left( \overline{D^a u} * \phi_l \right) (\psi) = \int_{U_0} \left( \int_U \overline{D^a u}(y) \phi_l (x - y) dy \right) \psi(x) dx$$

$$= \int_{U_0} \left( \int_U D^a u(y) \phi_l (x - y) dy \right) \psi(x) dx$$

$$= \int_{U_0} \left( \int_U u(y) (D^a \phi_l)(x - y) dy \right) \psi(x) dx$$

$$= \int_U u(y) \int_{U_0} (D^a \phi_l)(x - y) \psi(x) dx dy$$

$$= (-1)^{|\alpha|} \int_U u(y) \int_{U_0} \phi_l (x - y) (D^a \psi)(x) dx dy.$$

It follows that $D^a (\tilde{u} * \phi_l) = \left( \overline{D^a u} * \phi_l \right)$ as weak derivatives defined on $C^\infty_c (U_0)$.

Therefore,

$$||D^a (\tilde{u} * \phi_l) - D^a u||_{L^p(U_0)} = \left| \left| \overline{D^a u} * \phi_l - D^a u \right| \right|_{L^p(U_0)}$$

$$\leq \left| \left| \overline{D^a u} * \phi_l - \overline{D^a u} \right| \right|_{L^p(\mathbb{R}^n)} \rightarrow 0.$$

This proves the theorem.

As part of the proof of the theorem, the following corollary was established.

**Corollary 36.0.6** Let $U_0$ and $U$ be as in the above theorem. Then for all $l$ large enough and $\phi_l$ a mollifier,

$$D^a (\tilde{u} * \phi_l) = \left( \overline{D^a u} * \phi_l \right) \tag{36.0.2}$$

as distributions on $C^\infty_c (U_0)$. 

Definition 36.0.7 Let $U$ be an open set. $C^\infty(U)$ denotes the set of functions which are defined and infinitely differentiable on $U$.

Note that $f(x) = \frac{1}{x}$ is a function in $C^\infty(0, 1)$. However, it is not equal to the restriction to $(0, 1)$ of some function which is in $C^\infty(\mathbb{R})$. This illustrates the distinction between $C^\infty(U)$ and $C^\infty(\overline{U})$. The set, $C^\infty(\overline{U})$ is a subset of $C^\infty(U)$.

The following theorem is known as the Meyer Serrin theorem.

Theorem 36.0.8 (Meyer Serrin) Let $U$ be an open subset of $\mathbb{R}^n$. Then if $\delta > 0$ and $u \in X^{m,p}(U)$, there exists $J \in C^\infty(U)$ such that $\|J - u\|_{m,p,U} < \delta$.

Proof: Let $\cdots U_k \subseteq \overline{U_k} \subseteq U_{k+1} \cdots$ be a sequence of open subsets of $U$ whose union equals $U$ such that $\overline{U_k}$ is compact for all $k$. Also let $U_{-3} = U_{-2} = U_{-1} = U_0 = \emptyset$. Now define $V_k \equiv U_{k+1} \setminus U_{k-1}$. Thus $\{V_k\}_{k=1}^\infty$ is an open cover of $U$. Note the open cover is locally finite and therefore, there exists a partition of unity subordinate to this open cover, $\{\eta_k\}_{k=1}^\infty$ such that each $\text{spt}(\eta_k) \subset C_c(V_k)$. Let $\psi_m$ denote the sum of all the $\eta_k$ which are non zero at some point of $V_m$. Thus

$$\text{spt}(\psi_m) \subseteq U_{m+2} \setminus \overline{U_{m-2}}; \psi_m \in C^\infty_c(U), \sum_{m=1}^\infty \psi_m(x) = 1 \quad (36.0.3)$$

for all $x \in U$, and $\psi_m u \in W^{m,p}(U_{m+2})$.

Now let $\phi_l$ be a mollifier and consider

$$J \equiv \sum_{m=0}^\infty \omega \psi_m * \phi_l_m \quad (36.0.4)$$

where $l_m$ is chosen large enough that the following two conditions hold:

$$\text{spt}(\omega \psi_m * \phi_l_m) \subseteq U_{m+3} \setminus \overline{U_{m-3}}, \quad (36.0.5)$$

$$\|((\omega \psi_m) * \phi_l_m - \psi_m)\|_{m,p,U_{m+3}} = \|((\omega \psi_m) * \phi_l_m - \psi_m)\|_{m,p,U} < \frac{\delta}{2m+5}, \quad (36.0.6)$$

where $(36.0.5)$ is obtained from Theorem $(36.0.5)$. Because of $\omega \psi_m$ only finitely many terms of the series in $(36.0.4)$ are nonzero and therefore, $J \in C^\infty(U)$. Now let $N > 10$, some large value.

$$\|J - u\|_{m,p,U_{N-3}} = \left\| \sum_{k=0}^N (\omega \psi_k * \phi_l_k - \psi_k) \right\|_{m,p,U_{N-3}}$$

$$\leq \sum_{k=0}^N \|\omega \psi_k * \phi_l_k - \psi_k\|_{m,p,U_{N-3}}$$

$$\leq \sum_{k=0}^N \frac{\delta_k}{2m+5} < \delta.$$
Now apply the monotone convergence theorem to conclude that \( \|J - u\|_{m,p,U} \leq \delta \). This proves the theorem.

Note that \( J = 0 \) on \( \partial U \). Later on, you will see that this is pathological.

In the study of partial differential equations it is the space \( W^{m,p}(U) \) which is of the most use, not the space \( X^{m,p}(U) \). This is because of the density of \( C^\infty(\overline{U}) \). Nevertheless, for reasonable open sets, \( U \), the two spaces coincide.

**Definition 36.0.9** An open set, \( U \subseteq \mathbb{R}^n \) is said to satisfy the segment condition if for all \( z \in \overline{U} \), there exists an open set \( U_z \) containing \( z \) and a vector \( a \) such that

\[
U \cap U_z + ta \subseteq U
\]

for all \( t \in (0,1) \).

\[\begin{align*}
U & \quad \overline{U} \quad z
\end{align*}\]

You can imagine open sets which do not satisfy the segment condition. For example, a pair of circles which are tangent at their boundaries. The condition in the above definition breaks down at their point of tangency.

Here is a simple lemma which will be used in the proof of the following theorem.

**Lemma 36.0.10** If \( u \in W^{m,p}(U) \) and \( \psi \in C^\infty_c(\mathbb{R}^n) \), then \( u\psi \in W^{m,p}(U) \).

**Proof:** Let \( |\alpha| \leq m \) and let \( \phi \in C^\infty_c(U) \). Then

\[
(D_x, (u\psi))(\phi) = -\int_U u\psi \phi_{,x_i} dx
\]

\[
= -\int_U u \left( (\psi \phi)_{,x_i} - \phi \psi_{,x_i} \right) dx
\]

\[
= (D_x,u)(\psi \phi) + \int_U u\psi_{,x_i} \phi dx
\]

\[
= \int_U (\psi D_x,u + u\psi_{,x_i}) \phi dx
\]

Therefore, \( D_x, (u\psi) = \psi D_x,u + u\psi_{,x_i} \in L^p(U) \). In other words, the product rule holds. Now considering the terms in the last expression, you can do the same
argument with each of these as long as they all have derivatives in $L^p(U)$. Therefore, continuing this process the lemma is proved.

**Theorem 36.0.11** Let $U$ be an open set and suppose there exists a locally finite covering of $U$ which is of the form $\{U_i\}_{i=1}^{\infty}$ such that each $U_i$ is a bounded open set which satisfies the conditions of Definition 36.0.9. Thus there exist vectors, $\mathbf{a}_i$ such that for all $t \in (0, 1)$,

$$U_i \cap U + t\mathbf{a}_i \subseteq U.$$ 

Then $C^\infty(U)$ is dense in $X^{m,p}(U)$ and so $W^{m,p}(U) = X^{m,p}(U)$.

**Proof:** Let $\{\psi_i\}_{i=1}^{\infty}$ be a partition of unity subordinate to the given open cover with $\psi_i \in C_c^\infty(U_i)$ and let $u \in X^{m,p}(U)$. Thus

$$u = \sum_{k=1}^{\infty} \psi_k u.$$ 

Consider $U_k$ for some $k$. Let $\mathbf{a}_k$ be the special vector associated with $U_k$ such that

$$t\mathbf{a}_k + U \cap U_k \subseteq U \quad (36.0.7)$$ 

for all $t \in (0, 1)$ and consider only $t$ small enough that

$$\text{spt} (\psi_k) - t\mathbf{a}_k \subseteq U_k \quad (36.0.8)$$ 

Pick $l(t) > 1/t$ which is also large enough that

$$t\mathbf{a}_k + U \cap U_k + B\left(0, \frac{1}{l(t)}\right) \subseteq U, \quad \text{spt} (\psi_k) + B\left(0, \frac{1}{l(t_k)}\right) - t\mathbf{a}_k \subseteq U_k. \quad (36.0.9)$$ 

This can be done because $t\mathbf{a}_k + U \cap U_k$ is a compact subset of $U$ and so has positive distance to $U^C$ and $\text{spt} (\psi_k) - t\mathbf{a}_k$ is a compact subset of $U_k$ having positive distance to $U_k^C$. Let $t_k$ be such a value for $t$ and for $\phi_i$ a mollifier, define

$$v_{t_k}(x) = \int_{\mathbb{R}^n} \bar{u}(x + t_k \mathbf{a}_k - y) \psi_k(x + t_k \mathbf{a}_k - y) \phi_{l(t_k)}(y) \, dy \quad (36.0.10)$$

where as usual, $\bar{u}$ is the zero extension of $u$ off $U$. For $v_{t_k}(x) \neq 0$, it is necessary that $x + t_k \mathbf{a}_k - y \in \text{spt} (\psi_k)$ for some $y \in B\left(0, \frac{1}{l(t_k)}\right)$. Therefore, using \footnote{This is never a problem in $\mathbb{R}^n$. In fact, every open covering has a locally finite subcovering in $\mathbb{R}^n$ or more generally in any metric space due to Stone's theorem. These are issues best left to you in case you are interested. I am usually interested in bounded sets, $U$, and for these, there is a finite covering.} for $v_{t_k}(x) \neq 0$, it is necessary that

$$x \in y - t_k \mathbf{a}_k + U \cap \text{spt} (\psi_k) \subseteq B\left(0, \frac{1}{l(t_k)}\right) + \text{spt} (\psi_k) - t_k \mathbf{a}_k$$
showing that \( v_{t_k} \) has compact support in \( U_k \). Now change variables in 36.0.10 to obtain
\[
v_{t_k}(x) = \int_{\mathbb{R}^n} \tilde{u}(y) \psi_k(y) \phi_{l(t_k)}(x + t_k a_k - y) \, dy.
\]
(36.0.11)

For \( x \in U \cap U_k \), the above equals zero unless
\[
y - t_k a_k - x \in B \left( 0, \frac{1}{l(t_k)} \right)
\]
which implies by 36.0.9 that
\[
y \in t_k a_k + U \cap U_k + B \left( 0, \frac{1}{l(t_k)} \right) \subseteq U
\]
Therefore, for such \( x \in U \cap U_k \), 36.0.11 reduces to
\[
v_{t_k}(x) = \int_{\mathbb{R}^n} u(y) \psi_k(y) \phi_{l(t_k)}(x + t_k a_k - y) \, dy
\]
\[
= \int_{U} u(y) \psi_k(y) \phi_{l(t_k)}(x + t_k a_k - y) \, dy.
\]

It follows that for \( |\alpha| \leq m \), and \( x \in U \cap U_k \)
\[
D^\alpha v_{t_k}(x) = \int_{U} u(y) \psi_k(y) D^\alpha \phi_{l(t_k)}(x + t_k a_k - y) \, dy
\]
\[
= \int_{U} D^\alpha (u\psi_k)(y) \phi_{l(t_k)}(x + t_k a_k - y) \, dy
\]
\[
= \int_{\mathbb{R}^n} D^\alpha (u\psi_k)(y) \phi_{l(t_k)}(x + t_k a_k - y) \, dy
\]
\[
= \int_{\mathbb{R}^n} D^\alpha (u\psi_k)(x + t_k a_k - y) \phi_{l(t_k)}(y) \, dy.
\]
(36.0.12)

Actually, this formula holds for all \( x \in U \). If \( x \in U \) but \( x \not\in U_k \), then the left side of the above formula equals zero because, as noted above, \( \text{spt}(v_{t_k}) \subseteq U_k \). The integrand of the right side equals zero unless
\[
x \in B \left( 0, \frac{1}{l(t_k)} \right) + \text{spt}(\psi_k) - t_k a_k \subseteq U_k
\]
bym 36.0.9 and here \( x \not\in U_k \).

Next an estimate is obtained for \( \|D^\alpha v_{t_k} - D^\alpha (u\psi_k)\|_{L^p(U)} \). By 36.0.12,
\[
\|D^\alpha v_{t_k} - D^\alpha (u\psi_k)\|_{L^p(U)} \leq
\]
\[ \left( \int_U \left( \int_{\mathbb{R}^n} \left| \frac{\partial}{\partial x} (u \psi_k) (x + t_k a_k - y) - \frac{\partial}{\partial x} (u \psi_k) (x) \right| \phi_{(t_k)} (y) \, dy \right)^p \, dx \right)^{1/p} \]

\[ \leq \int_{\mathbb{R}^n} \phi_{(t_k)} (y) \left( \int_U \left| \frac{\partial}{\partial x} (u \psi_k) (x + t_k a_k - y) - \frac{\partial}{\partial x} (u \psi_k) (x) \right|^p \, dx \right)^{1/p} \, dy \]

\[ \leq \frac{\varepsilon}{2^k} \]

whenever \( t_k \) is taken small enough. Pick \( t_k \) this small and let \( w_k \equiv v_{t_k} \). Thus

\[ \| \frac{\partial}{\partial x} w_k - \frac{\partial}{\partial x} (u \psi_k) \|_{L^p(U)} \leq \frac{\varepsilon}{2^k} \]

and \( w_k \in C_c^\infty (\mathbb{R}^n) \). Now let

\[ J (x) = \sum_{k=1}^{\infty} w_k. \]

Since the \( U_k \) are locally finite and \( \text{spt} (w_k) \subseteq U_k \) for each \( k \), it follows

\[ \frac{\partial}{\partial x} J = \sum_{k=0}^{\infty} \frac{\partial}{\partial x} w_k \]

and the sum is always finite. Similarly,

\[ \sum_{k=1}^{\infty} (\psi_k u) = \sum_{k=1}^{\infty} (\psi_k u) \]

and the sum is always finite. Therefore,

\[ \| \frac{\partial}{\partial x} J - \frac{\partial}{\partial x} u \|_{L^p(U)} = \left\| \sum_{k=1}^{\infty} \frac{\partial}{\partial x} w_k - \frac{\partial}{\partial x} (\psi_k u) \right\|_{L^p(U)} \]

\[ \leq \sum_{k=1}^{\infty} \| \frac{\partial}{\partial x} w_k - \frac{\partial}{\partial x} (\psi_k u) \|_{L^p(U)} \leq \sum_{k=1}^{\infty} \frac{\varepsilon}{2^k} = \varepsilon. \]

By choosing \( t_k \) small enough, such an inequality can be obtained for

\[ \| \frac{\partial}{\partial \beta} J - \frac{\partial}{\partial \beta} u \|_{L^p(U)} \]

for each multi index, \( \beta \) such that \( |\beta| \leq m \). Therefore, there exists

\[ J \in C_c^\infty (\mathbb{R}^n) \]

such that

\[ \| J - u \|_{W^{m,p}(U)} \leq \varepsilon K \]

where \( K \) equals the number of multi indices no larger than \( m \). Since \( \varepsilon \) is arbitrary, this proves the theorem.
Corollary 36.0.12 Let $U$ be an open set which has the segment property. Then 
$W^{m,p}(U) = X^{m,p}(U)$.

Proof: Start with an open covering of $U$ whose sets satisfy the segment condition 
and obtain a locally finite refinement consisting of bounded sets which are of the 
sort in the above theorem.

Now consider a situation where $h : U \to V$ where $U$ and $V$ are two open sets 
in $\mathbb{R}^n$ and $D^\alpha h$ exists and is continuous and bounded if $|\alpha| < m - 1$ and $D^\alpha h$ is 
Lipschitz if $|\alpha| = m - 1$.

Definition 36.0.13 Whenever $h : U \to V$, define $h^*$ mapping the functions which 
are defined on $V$ to the functions which are defined on $U$ as follows.

$h^*f(x) \equiv f(h(x))$.

$h : U \to V$ is bilipschitz if $h$ is one to one, onto and Lipschitz and $h^{-1}$ is also one 
to one, onto and Lipschitz.

Theorem 36.0.14 Let $h : U \to V$ be one to one and onto where $U$ and $V$ are two 
open sets. Also suppose that $D^\alpha h$ and $D^\alpha (h^{-1})$ exist and are Lipschitz continuous 
if $|\alpha| \leq m - 1$ for $m$ a positive integer. Then 

$h^* : W^{m,p}(V) \to W^{m,p}(U)$

is continuous, linear, one to one, and has an inverse with the same properties, the 
inverse being $(h^{-1})^*$.

Proof: It is clear that $h^*$ is linear. It is required to show it is one to one and 
continuous. First suppose $h^*f = 0$. Then 

$0 = \int_V |f(h(x))|^p \, dx$

and so $f(h(x)) = 0$ for a.e. $x \in U$. Since $h$ is Lipschitz, it takes sets of measure 
zero to sets of measure zero. Therefore, $f(y) = 0$ a.e. This shows $h^*$ is one to one.

By the Meyer Serrin theorem, Theorem 36.0.8, it suffices to verify that $h^*$ is 
continuous on functions in $C^\infty(V)$. Let $f$ be such a function. Then using the chain 
rule and product rule, $(h^*f)_i(x) = f_k(h(x)) h_{k,i}(x),$ 

$(h^*f)_{ij}(x) = (f_k(h(x)) h_{k,i}(x))_j$

$= f_{kl}(h(x)) h_{l,j}(x) h_{k,i}(x) + f_{k,l}(h(x)) h_{k,l}(x)$

etc. In general, for $|\alpha| \leq m - 1$, successive applications of the product rule and 
chain rule yield that $D^\alpha(h^*f)(x)$ has the form 

$D^\alpha(h^*f)(x) = \sum_{|\beta| \leq |\alpha|} h^*(D^\beta f)(x) g_\beta(x)$
where \( g_\beta \) is a bounded Lipschitz function with Lipschitz constant dependent on \( h \) and its derivatives. It only remains to take one more derivative of the functions, \( D^\alpha f \) for \( |\alpha| = m - 1 \). This can be done again but this time you have to use Rademacher’s theorem which assures you that the derivative of a Lipschitz function exists a.e. in order to take the partial derivative of the \( g_\beta (x) \). When this is done, the above formula remains valid for all \( |\alpha| \leq m \). Therefore, using the change of variables formula for multiple integrals, Corollary 33.6.14 on Page 1291.

\[
\int_{U} |D^\alpha (h^* f) (x)|^p \, dx \leq C_{m,p,h} \sum_{|\beta| \leq m} \int_{U} |h^* (D^\beta f) (x)|^p \, dx
\]

\[
= C_{m,p,h} \sum_{|\beta| \leq m} \int_{U} |(D^\beta f) (h (x))|^p \, dx
\]

\[
= C_{m,p,h} \sum_{|\beta| \leq m} \int_{Y} |(D^\beta f) (y)|^p |\det D h^{-1} (y)| \, dy
\]

\[
\leq C_{m,p,h,h^{-1}} \|f\|_{m,p,V}
\]

This shows \( h^* \) is continuous on \( C^\infty (V) \cap W^{m,p} (U) \) and since this set is dense, this proves \( h^* \) is continuous. The same argument applies to \((h^{-1})^* \) and now the definitions of \( h^* \) and \((h^{-1})^* \) show these are inverses.

## 36.1 Embedding Theorems For \( W^{m,p} (\mathbb{R}^n) \)

Recall Theorem 33.5.1 which is listed here for convenience.

**Theorem 36.1.1** Suppose \( u, u_i \in L^p_{\text{loc}} (\mathbb{R}^n) \) for \( i = 1, \cdots, n \) and \( p > n \). Then \( u \) has a representative, still denoted by \( u \), such that for all \( x, y \in \mathbb{R}^n \),

\[
|u (x) - u (y)| \leq C \left( \int_{B (x, 2|x-y|)} |\nabla u|^p dz \right)^{1/p} |x - y|^{(1-n/p)}. \tag{36.1.13}
\]

This amazing result shows that every \( u \in W^{m,p} (\mathbb{R}^n) \) has a representative which is continuous provided \( p > n \).

Using the above inequality, one can give an important embedding theorem.

**Definition 36.1.2** Let \( X, Y \) be two Banach spaces and let \( f : X \to Y \) be a function. Then \( f \) is a compact map if whenever \( S \) is a bounded set in \( X \), it follows that \( f (S) \) is precompact in \( Y \).

**Theorem 36.1.3** Let \( U \) be a bounded open set and for \( u \) a function defined on \( \mathbb{R}^n \), let \( r_U u (x) = u (x) \) for \( x \in \overline{U} \). Then if \( p > n \), \( r_U : W^{1,p} (\mathbb{R}^n) \to C (\overline{U}) \) is continuous and compact.
36.1. EMBEDDING THEOREMS FOR $W^{M,p}(\mathbb{R}^N)$

Proof: First suppose $u_k \to 0$ in $W^{1,p}(\mathbb{R}^n)$. Then if $r_U u_k$ does not converge to 0, it follows there exists a sequence, still denoted by $k$ and $\varepsilon > 0$ such that $u_k \to 0$ in $W^{1,p}(\mathbb{R}^n)$ but $||r_U u_k||_\infty \geq \varepsilon$. Selecting a further subsequence which is still denoted by $k$, you can also assume $u_k(x) \to 0$ a.e. Pick such an $x_0 \in U$ where this convergence takes place. Then from 1335, for all $x \in U$,

$$|u_k(x)| \leq |u_k(x_0)| + C ||u_k||_{1,p,\mathbb{R}^n} \text{diam}(U)$$

showing that $u_k$ converges uniformly to 0 on $U$ contrary to $||r_U u_k||_\infty \geq \varepsilon$. Therefore, $r_U$ is continuous as claimed.

Next let $S$ be a bounded subset of $W^{1,p}(\mathbb{R}^n)$ with $||u||_{1,p} < M$ for all $u \in S$. Then for $u \in S$

$$r^p m_n (|u| > r) \leq \int_{|u| > r} |u|^p \, dm_n \leq M^p$$

and so

$$m_n (|u| > r) \leq \frac{M^p}{r^p}.$$ 

Now choosing $r$ large enough, $M^p / r^p < m_n (U)$ and so, for such $r$, there exists $x_u \in U$ such that $|u(x_u)| \leq r$. Therefore from 36.1.13 whenever $x \in U$,

$$|u(x)| \leq |u(x_u)| + CM \text{diam}(U)^{1-n/p}$$

$$\leq r + CM \text{diam}(U)^{1-n/p}$$

showing that $\{r_U u : u \in S\}$ is uniformly bounded. But also, for $x, y \in U$ implies

$$|u(x) - u(y)| \leq CM |x - y|^{1 - \frac{n}{p}}$$

showing that $\{r_U u : u \in S\}$ is equicontinuous. By the Ascoli Arzela theorem, it follows $r_U(S)$ is precompact and so $r_U$ is compact.

Definition 36.1.4 Let $\alpha \in (0,1]$ and $K$ a compact subset of $\mathbb{R}^n$

$$C^\alpha(K) \equiv \{ f \in C(K) : \rho_\alpha(f) + ||f|| \leq ||f||_\alpha < \infty \}$$

where

$$||f|| \equiv ||f||_\infty \equiv \sup\{|f(x)| : x \in K\}$$

and

$$\rho_\alpha(f) \equiv \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{1 - \frac{n}{p}}} : x, y \in K, x \neq y \right\}.$$ 

Then $(C^\alpha(K),||\cdot||_\alpha)$ is a complete normed linear space called a Holder space.

The verification that this is a complete normed linear space is routine and is left for you. More generally, one considers the following class of Holder spaces.
Definition 36.1.5 Let $K$ be a compact subset of $\mathbb{R}^n$ and let $\lambda \in (0, 1]$. $C^{m, \lambda}(K)$ denotes the set of functions, $u$ which are restrictions of functions defined on $\mathbb{R}^n$ to $K$ such that for $|\alpha| \leq m$,
\[ D^\alpha u \in C(K) \]
and if $|\alpha| = m$,
\[ D^\alpha u \in C^\lambda(K). \]
Thus $C^{0,\lambda}(K) = C^\lambda(K)$. The norm of a function in $C^{m,\lambda}(K)$ is given by
\[ ||u||_{m,\lambda} = \sup_{|\alpha| = m} \rho_\lambda(D^\alpha u) + \sum_{|\alpha| \leq m} ||D^\alpha u||_\infty. \]

Lemma 36.1.6 Let $m$ be a positive integer, $K$ a compact subset of $\mathbb{R}^n$, and let $0 < \beta < \lambda \leq 1$. Then the identity map from $C^{m,\lambda}(K)$ into $C^{m,\beta}(K)$ is compact.

Proof: First note that the containment is obvious because for any function, $f$, if
\[ \rho_\lambda(f) = \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{\lambda}} : x, y \in K, x \neq y \right\} < \infty, \]
Then
\[ \rho_\lambda(f) = \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{\lambda}} : x, y \in K, x \neq y \right\} \]
\[ = \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{\lambda}} : x, y \in K, x \neq y \right\} \]
\[ \leq \sup \left\{ \frac{|f(x) - f(y)|}{|x - y|^{\lambda}} : x, y \in K, x \neq y \right\} < \infty. \]

Suppose the identity map, id, is not compact. Then there exists $\varepsilon > 0$ and a sequence, $\{f_k\}_{k=1}^{\infty} \subseteq C^{m,\lambda}(K)$ such that $||f_k||_{m,\lambda} < M$ for all $k$ but $||f_k - f_l||_{\beta} \geq \varepsilon$ whenever $k \neq l$. By the Ascoli Arzelà theorem, there exists a subsequence of this, still denoted by $f_k$ such that $\sum_{|\alpha| \leq m} ||D^\alpha (f_1 - f_k)||_\infty < \delta$ where $\delta$ satisfies
\[ 0 < \delta < \min \left( \frac{\varepsilon}{2}, \frac{\varepsilon}{8} \left( \frac{\varepsilon}{8M} \right)^{\beta/(\lambda-\beta)} \right). \]
(36.1.14)

Therefore, $\sup_{|\alpha| = m} \rho_\beta(D^\alpha (f_k - f_l)) \geq \varepsilon - \delta$ for all $k \neq l$. It follows that there exist pairs of points and a multi index, $\alpha$ with $|\alpha| = m$, $\{x_{kl}, y_{kl}, \alpha\}$ such that
\[ \frac{\varepsilon - \delta}{2} < \frac{|(D^\alpha f_k - D^\alpha f_l)(x_{kl}) - ((D^\alpha f_k - D^\alpha f_l)(y_{kl}))|}{|x_{kl} - y_{kl}|^{\beta}} \leq 2M |x_{kl} - y_{kl}|^{\lambda-\beta} \]
(36.1.15)
and so considering the ends of the above inequality,
\[ \left( \frac{\varepsilon - \delta}{4M} \right)^{1/(\lambda-\beta)} < |x_{kl} - y_{kl}|. \]
Now also, since \( \sum_{|\alpha| \leq m} ||D^\alpha (f_1 - f_k)||_{\infty} < \delta \), it follows from the first inequality in 36.1.13 that

\[
\frac{\varepsilon - \delta}{2} < \frac{2\delta}{(\varepsilon - \delta)^{\beta/(\lambda - \beta)}}.
\]

Since \( \delta < \varepsilon/2 \), this implies

\[
\frac{\varepsilon}{4} < \frac{2\delta}{(\varepsilon/8)^{\beta/(\lambda - \beta)}}
\]

and so

\[
(\varepsilon/8) (\varepsilon/8)^{\beta/(\lambda - \beta)} < \delta
\]

contrary to 36.1.14. This proves the lemma.

**Corollary 36.1.7** Let \( p > n, U \) and \( r_U \) be as in Theorem 36.1.4 and let \( m \) be a nonnegative integer. Then \( r_U : W^{m+1,p}(\mathbb{R}^n) \to C^{m,\lambda}(\overline{U}) \) is continuous as a map into \( C^{m,\lambda}(\overline{U}) \) for all \( \lambda \in [0, 1 - \frac{n}{p}] \) and \( r_U \) is compact if \( \lambda < 1 - \frac{n}{p} \).

**Proof:** Suppose \( u_k \to 0 \) in \( W^{m+1,p}(\mathbb{R}^n) \). Then from 36.1.5, if \( \lambda \leq 1 - \frac{n}{p} \) and \( |\alpha| = m \)

\[
\rho_\lambda(D^\alpha u_k) \leq C ||D^\alpha u_k||_{1,p} \text{diam}(U)^{1 - \frac{n}{p} - \lambda}.
\]

Therefore, \( \rho_\lambda(D^\alpha u_k) \to 0 \). From Theorem 36.1.3 it follows that for \( |\alpha| \leq m \),

\[
||D^\alpha u_k||_{\infty} \to 0
\]

and so \( ||u_k||_{m,\lambda} \to 0 \). This proves the claim about continuity. The claim about compactness for \( \lambda < 1 - \frac{n}{p} \) follows from Lemma 36.1.4 and this.

(Bounded in \( W^{m,p}(\mathbb{R}^n) \) \( \overset{\text{U}}{\rightarrow} \) Bounded in \( C^{m,1-\frac{n}{p}}(\overline{U}) \) \( \overset{\text{I}d}{\rightarrow} \) Compact in \( C^{m,\lambda}(\overline{U}) \).)

It is just as important to consider the case where \( p < n \). To do this case the following lemma due to Gagliardo \[11\] will be of interest. See also \[11\].

**Lemma 36.1.8** Suppose \( n \geq 2 \) and \( w_j \) does not depend on the \( j^{th} \) component of \( x, x_j \). Then

\[
\int_{\mathbb{R}^n} \prod_{j=1}^n |w_j(x)| \, dm_n \leq \prod_{i=1}^n \left( \int_{\mathbb{R}^{n-1}} |w_j(x)|^{n-1} \, dm_{n-1} \right)^{1/(n-1)}.
\]

In this inequality, assume all the functions are continuous so there can be no measurability questions.

**Proof:** First note that for \( n = 2 \) the inequality reduces to the statement

\[
\int \int |w_1(x_2)| |w_2(x_1)| \, dx_1 \, dx_2 \leq \int |w_1(x_2)| \, dx_2 \int |w_2(x_1)| \, dx_1
\]
which is obviously true. Suppose then that the inequality is valid for some \( n \). Using Fubini’s theorem, Holder’s inequality, and the induction hypothesis,

\[
\int_{\mathbb{R}^{n+1}} \prod_{j=1}^{n+1} |w_j(x)| \, dm_{n+1}
\]

\[
= \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} |w_{n+1}(x)| \prod_{j=1}^n |w_j(x)| \, dm_n \, dx_{n+1}
\]

\[
= \int_{\mathbb{R}^n} |w_{n+1}(x)| \int_{\mathbb{R}^n} \prod_{j=1}^n |w_j(x)| \, dx_{n+1} \, dm_n
\]

\[
= \int_{\mathbb{R}^n} |w_{n+1}(x)| \left( \prod_{j=1}^n \int_{\mathbb{R}} |w_j(x)|^n \, dx_{n+1} \right)^{1/n} \, dm_n
\]

\[
= \int_{\mathbb{R}^n} |w_{n+1}(x)| \prod_{j=1}^n \left( \int_{\mathbb{R}} |w_j(x)|^n \, dx_{n+1} \right)^{1/n} \, dm_n
\]

\[
\leq \left( \int_{\mathbb{R}^n} |w_{n+1}(x)|^n \, dm_n \right)^{1/n} \cdot \left( \int_{\mathbb{R}^n} \left( \prod_{j=1}^n \left( \int_{\mathbb{R}} |w_j(x)|^n \, dx_{n+1} \right)^{1/n} \right)^{n/(n-1)} \, dm_n \right)^{(n-1)/n}
\]

\[
= \left( \int_{\mathbb{R}^n} |w_{n+1}(x)|^n \, dm_n \right)^{1/n} \cdot \left( \int_{\mathbb{R}^n} \prod_{j=1}^n \left( \int_{\mathbb{R}} |w_j(x)|^n \, dx_{n+1} \right)^{1/(n-1)} \, dm_n \right)^{(n-1)/n}
\]

\[
\leq \left( \int_{\mathbb{R}^n} |w_{n+1}(x)|^n \, dm_n \right)^{1/n} \cdot \left( \prod_{j=1}^n \left( \int_{\mathbb{R}^n} \left( \int_{\mathbb{R}} |w_j(x)|^n \, dx_{n+1} \right)^{1/(n-1)} \, dm_{n-1} \right)^{1/(n-1)} \right)^{(n-1)/n}
\]

\[
= \left( \int_{\mathbb{R}^n} |w_{n+1}(x)|^n \, dm_n \right)^{1/n} \prod_{j=1}^n \left( \int_{\mathbb{R}^n} |w_j(x)|^n \, dm_n \right)^{1/n}
\]

\[
= \prod_{j=1}^{n+1} \left( \int_{\mathbb{R}^n} |w_j(x)|^n \, dm_n \right)^{1/n}
\]

This proves the lemma.
Lemma 36.1.9 If \( \phi \in C_c^\infty (\mathbb{R}^n) \) and \( n \geq 1 \), then
\[
\| \phi \|_{n/(n-1)} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} \left\| \frac{\partial \phi}{\partial x_j} \right\|_1 .
\]

Proof: The case where \( n = 1 \) is obvious if \( n/(n-1) \) is interpreted as \( \infty \). Assume then that \( n > 1 \) and note that for \( a_i \geq 0 \),
\[
\prod_{i=1}^{n} a_i \leq \left( \sum_{j=1}^{n} a_i \right)^{n}.
\]
In fact, the term on the left is one of many terms of the expression on the right. Therefore, taking \( n^{th} \) roots
\[
\prod_{i=1}^{n} a_i^{1/n} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} a_i .
\]
Then observe that for each \( j = 1, 2, \ldots, n \),
\[
\left| \phi (x) \right| \leq \int_{-\infty}^{\infty} \left| \phi_j (x) \right| dx_j
\]
so
\[
\| \phi \|_{n/(n-1)}^{n/(n-1)} = \left( \int_{\mathbb{R}^n} \left| \phi (x) \right|^{n/(n-1)} \right) dm_n
\]
\[
\leq \int_{\mathbb{R}^n} \prod_{j=1}^{n} \left( \int_{-\infty}^{\infty} \left| \phi_j (x) \right| dx_j \right)^{1/(n-1)} dm_n
\]
and from Lemma 36.1.8 this is dominated by
\[
\leq \prod_{j=1}^{n} \left( \int_{\mathbb{R}^n} \left| \phi_j (x) \right| dm_n \right)^{1/(n-1)} .
\]
Hence \( \prod_{i=1}^{n} a_i^{1/n} \leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} a_i \)
\[
\| \phi \|_{n/(n-1)} \leq \prod_{j=1}^{n} \left( \int_{\mathbb{R}^n} \left| \phi_j (x) \right| dm_n \right)^{1/n}
\]
\[
\leq \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} \int_{\mathbb{R}^n} \left| \phi_j (x) \right| dm_n
\]
\[
= \frac{1}{\sqrt[n]{n}} \sum_{j=1}^{n} \left\| \phi_j \right\|_1
\]
and this proves the lemma.

The above lemma is due to Gagliardo and Nirenberg.

With this lemma, it is possible to prove a major embedding theorem which follows.
Theorem 36.1.10 Let $1 \leq p < n$ and $\frac{1}{q} = \frac{1}{p} - \frac{1}{n}$. Then if $f \in W^{1,p}(\mathbb{R}^n)$,

$$
\|f\|_q \leq \frac{1}{\sqrt[n]{n}} \frac{(n-1)p}{n-p} \|f\|_{1,p,\mathbb{R}^n}.
$$

Proof: From the definition of $W^{1,p}(\mathbb{R}^n)$, $C^1_c(\mathbb{R}^n)$ is dense in $W^{1,p}(\mathbb{R}^n)$. Here $C^1_c(\mathbb{R}^n)$ is the space of continuous functions having continuous derivatives which have compact support. The desired inequality will be established for such $\phi$ and then the density of this set in $W^{1,p}(\mathbb{R}^n)$ will be exploited to obtain the inequality for all $f \in W^{1,p}(\mathbb{R}^n)$. First note that the case where $p = 1$ follows immediately from the above lemma and so it is only necessary to consider the case where $p > 1$.

Let $\phi \in C^1_c(\mathbb{R}^n)$ and consider $|\phi|^r$ where $r > 1$. Then a short computation shows $|\phi|^r \in C^1_c(\mathbb{R}^n)$ and

$$
\|\phi\|_q = r \|\phi\|^{r-1} \|\phi\|.
$$

Therefore, from Lemma 36.1.9,

$$
\left( \int |\phi|^{rn}dm_n \right)^{(n-1)/n}
\leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n} \int |\phi|^{r-1}|\phi|dm_n
\leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n} \left( \int |\phi|^{r} \right)^{1/p} \left( \int |\phi|^{r-1} \right)^{(p-1)/p} dm_n.
$$

Now choose $r$ such that

$$
\frac{(r-1)p}{p-1} = \frac{rn}{n-1}.
$$

That is, let $r = \frac{p(n-1)}{n-p} > 1$ and so $\frac{rn}{n-1} = \frac{np}{n-p}$. Then this reduces to

$$
\left( \int |\phi|^{np}dm_n \right)^{(n-1)/n} \leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n} \left( \int |\phi|^{p} \right)^{1/p} \left( \int |\phi|^{np} dm_n \right)^{(p-1)/p}.
$$

Also, $\frac{n-1}{n} - \frac{p-1}{p} = \frac{n-p}{np}$ and so, dividing both sides by the last term yields

$$
\left( \int |\phi|^{np}dm_n \right)^{\frac{n-p}{np}} \leq \frac{r}{\sqrt[n]{n}} \sum_{i=1}^{n} \left( \int |\phi|^{p} \right)^{1/p} \leq \frac{r}{\sqrt[n]{n}} \|\phi\|_{1,p,\mathbb{R}^n}.
$$

Letting $q = \frac{np}{n-p}$, it follows $\frac{1}{q} = \frac{n-p}{np} = \frac{1}{p} - \frac{1}{n}$ and

$$
\|\phi\|_q \leq \frac{r}{\sqrt[n]{n}} \|\phi\|_{1,p,\mathbb{R}^n}.
$$
Now let \( f \in W^{m,p}(\mathbb{R}^n) \) and let \( \|\phi_k - f\|_{1,p,\mathbb{R}^n} \to 0 \) as \( k \to \infty \). Taking another subsequence, if necessary, you can also assume \( \phi_k(x) \to f(x) \) a.e. Therefore, by Fatou’s lemma,

\[
\|f\|_q \leq \liminf_{k \to \infty} \left( \int_{\mathbb{R}^n} |\phi_k(x)|^q \, dm_n \right)^{1/q} \\
\leq \liminf_{k \to \infty} \frac{r}{\sqrt{n}} \|\phi_k\|_{1,p,\mathbb{R}^n} = \|f\|_{1,p,\mathbb{R}^n}.
\]

This proves the theorem.

**Corollary 36.1.11** Suppose \( mp < n \). Then \( W^{m,p}(\mathbb{R}^n) \subseteq L^q(\mathbb{R}^n) \) where \( q = \frac{np}{n-mp} \) and the identity map, \( \text{id} : W^{m,p}(\mathbb{R}^n) \to L^q(\mathbb{R}^n) \) is continuous.

**Proof:** This is true if \( m = 1 \) according to Theorem 36.1.10. Suppose it is true for \( m - 1 \) where \( m > 1 \). If \( u \in W^{m,p}(\mathbb{R}^n) \) and \( |\alpha| \leq 1 \), then \( D^\alpha u \in W^{m-1,p}(\mathbb{R}^n) \) so by induction, for all such \( \alpha \),

\[
D^\alpha u \in L_{n-mp/n}^{np/n} (\mathbb{R}^n).
\]

Thus \( u \in W^{1,q_1}(\mathbb{R}^n) \) where

\[
q_1 = \frac{np}{n - (m-1)p}
\]

By Theorem 36.1.10, it follows that \( u \in L^q(\mathbb{R}^n) \) where

\[
\frac{1}{q} = \frac{n - (m-1)p}{np} - 1 = \frac{n - mp}{np}.
\]

This proves the corollary.

There is another similar corollary of the same sort which is interesting and useful.

**Corollary 36.1.12** Suppose \( m \geq 1 \) and \( j \) is a nonnegative integer satisfying \( jp < n \). Then

\[
W^{m+j,p}(\mathbb{R}^n) \subseteq W^{m,q}(\mathbb{R}^n)
\]

for

\[
q = \frac{np}{n-jp}
\]

and the identity map is continuous.

**Proof:** If \( |\alpha| \leq m \), then \( D^\alpha u \in W^{j,p}(\mathbb{R}^n) \) and so by Corollary 36.1.11, \( D^\alpha u \in L^q(\mathbb{R}^n) \) where \( q \) is given above. This means \( u \in W^{m,q}(\mathbb{R}^n) \).

The above corollaries imply yet another interesting corollary which involves embeddings in the Holder spaces.
Corollary 36.1.13 Suppose \( j^p < n < (j + 1)p \) and let \( m \) be a positive integer. Let \( U \) be any bounded open set in \( \mathbb{R}^n \). Then letting \( r_U \) denote the restriction to \( U \), \( r_U : W^{m+j,p}(\mathbb{R}^n) \to C^{m-1,\lambda}(\overline{U}) \) is continuous for every \( \lambda \leq \lambda_0 \equiv (j + 1) - \frac{n}{p} \) and if \( \lambda < (j + 1) - \frac{n}{p} \), then \( r_U \) is compact.

Proof: From Corollary 36.1.12 \( W^{m+j,p}(\mathbb{R}^n) \subseteq W^{m,q}(\mathbb{R}^n) \) where \( q \) is given by 36.1.16. Therefore, \( \frac{np}{n-jp} > n \) and so by Corollary 36.1.7, \( W^{m,q}(\mathbb{R}^n) \subseteq C^{m-1,\lambda}(\overline{U}) \) for all \( \lambda \) satisfying

\[
0 < \lambda < 1 - \left( \frac{(n-jp)n}{np} \right) = \frac{p(j + 1) - n}{p} = (j + 1) - \frac{n}{p}.
\]

The assertion about compactness follows from the compactness of the embedding of \( C^{m-1,\lambda_0}(\overline{U}) \) into \( C^{m-1,\lambda}(\overline{U}) \) for \( \lambda < \lambda_0 \). See Lemma 36.1.6.

There are other embeddings of this sort available. You should see Adams [1] for a more complete listing of these. Next are some theorems about compact embeddings. This requires some consideration of which subsets of \( L^p(U) \) are compact. The main theorem is the following. See [1].

**Theorem 36.1.14** Let \( K \) be a bounded subset of \( L^p(U) \) and suppose that for all \( \varepsilon > 0 \), there exist a \( \delta > 0 \) such that if \( |h| < \delta \), then

\[
\int_{\mathbb{R}^n} |\bar{u}(x + h) - \bar{u}(x)|^p \, dx < \varepsilon^p
\]  \hspace{1cm} (36.1.17)

Suppose also that for each \( \varepsilon > 0 \) there exists an open set, \( G \subseteq U \) such that \( \overline{G} \) is compact and for all \( u \in K \),

\[
\int_{U \setminus \overline{G}} |u(x)|^p \, dx < \varepsilon^p
\]  \hspace{1cm} (36.1.18)

Then \( K \) is precompact in \( L^p(\mathbb{R}^n) \).

Proof: To save fussing first consider the case where \( U = \mathbb{R}^n \) so that \( \bar{u} = u \). Suppose the two conditions hold and let \( \phi_k \) be a mollifier of the form \( \phi_k(x) = k^n \phi(kx) \) where \( \text{spt}(\phi) \subseteq B(0,1) \). Consider

\[
K_k \equiv \{ u * \phi_k : u \in K \}.
\]

and verify the conditions for the Ascoli Arzela theorem for these functions defined on \( \overline{G} \). Say \( ||u||_p \leq M \) for all \( u \in K \).
36.1. EMBEDDING THEOREMS FOR $W^{M,P} (\mathbb{R}^N)$

First of all, for $u \in K$ and $x \in \mathbb{R}^n$,
\[
|u \ast \phi_k (x)|^p \leq \left( \int |u(x - y) \phi_k (y)| \, dy \right)^p
\]
\[
= \left( \int |u(y) \phi_k (x - y)| \, dy \right)^p
\]
\[
\leq \int |u(y)|^p \phi_k (x - y) \, dy
\]
\[
\leq \left( \sup_{z \in \mathbb{R}^n} \phi_k (z) \right) \int |u(y)| \, dy \leq M \left( \sup_{z \in \mathbb{R}^n} \phi_k (z) \right)
\]
showing the functions in $K_k$ are uniformly bounded.

Next suppose $x, x_1 \in K_k$ and consider
\[
|u \ast \phi_k (x) - u \ast \phi_k (x_1)|
\]
\[
\leq \int |u(x - y) - u(x_1 - y)| \phi_k (y) \, dy
\]
\[
\leq \left( \int |u(x - y) - u(x_1 - y)|^p \, dy \right)^{1/p} \left( \int \phi_k (y)^q \, dy \right)^q
\]
which by assumption $36.1.17$ is small independent of the choice of $u$ whenever $|x - x_1|$ is small enough. Note that $k$ is fixed in the above. Therefore, the set, $K_k$ is precompact in $C (\overline{G})$ thanks to the Ascoli Arzela theorem. Next consider how well $u \in K$ is approximated by $u \ast \phi_k$ in $L^p (\mathbb{R}^n)$. By Minkowski’s inequality,
\[
\left( \int |u(x) - u \ast \phi_k (x)|^p \, dx \right)^{1/p}
\]
\[
\leq \left( \int \left( \int |u(x) - u(x - y)| \phi_k (y) \, dy \right)^p \, dx \right)^{1/p}
\]
\[
\leq \int_{B(0, \frac{1}{k})} \phi_k (y) \left( \int |u(x) - u(x - y)|^p \, dx \right)^{1/p} \, dy.
\]
Now let $\eta > 0$ be given. From $36.1.17$ there exists $k$ large enough that for all $u \in K$,
\[
\int_{B(0, \frac{1}{k})} \phi_k (y) \left( \int |u(x) - u(x - y)|^p \, dx \right)^{1/p} \, dy \leq \int_{B(0, \frac{1}{k})} \phi_k (y) \eta \, dy = \eta.
\]

Now let $\varepsilon > 0$ be given and let $\delta$ and $G$ correspond to $\varepsilon$ as given in the hypotheses and let $1/k < \delta$ and also $k$ is large enough that for all $u \in K$,
\[
||u - u \ast \phi_k||_p < \varepsilon
\]
as in the above inequality. By the Ascoli Arzela theorem there exists an
\[
\left( \frac{\varepsilon}{m (G + B(0, 1))} \right)^{1/p}
\]
CHAPTER 36. BASIC THEORY OF SOBOLEV SPACES

net for $K_k$ in $C(G)$. That is, there exist $\{u_i\}_{i=1}^{m} \subseteq K$ such that for any $u \in K$,

$$||u \ast \phi_k - u_j \ast \phi_k||_\infty < \left( \frac{\varepsilon}{m(G + B(0, 1))} \right)^{1/p}$$

for some $j$. Letting $u \in K$ be given, let $u_j \in \{u_i\}_{i=1}^{m} \subseteq K$ be such that the above inequality holds. Then

$$||u - u_j||_p \leq ||u - u \ast \phi_k||_p + ||u \ast \phi_k - u_j \ast \phi_k||_p + ||u_j \ast \phi_k - u_j||_p$$

$$< 2\varepsilon + ||u \ast \phi_k - u_j \ast \phi_k||_p$$

$$\leq 2\varepsilon + \left( \int_{G + B(0, 1)} |u \ast \phi_k - u_j \ast \phi_k|^p \, dx \right)^{1/p}$$

$$+ \left( \int_{\mathbb{R}^n \setminus (G + B(0, 1))} |u \ast \phi_k - u_j \ast \phi_k|^p \, dx \right)^{1/p}$$

$$\leq 2\varepsilon + \varepsilon^{1/p}$$

$$+ \int \phi_k(y) \left( \int_{\mathbb{R}^n \setminus (G + B(0, 1))} (|u(x - y)| + |u_j(x - y)|)^p \, dx \right)^{1/p} \, dy$$

$$\leq 2\varepsilon + \varepsilon^{1/p} + \int \phi_k(y) \left( \int_{\mathbb{R}^n \setminus (G)} (|u(x)| + |u_j(x)|)^p \, dx \right)^{1/p} \, dy$$

$$\leq 2\varepsilon + \varepsilon^{1/p} + 2^{p-1} \int \phi_k(y) \left( \int_{\mathbb{R}^n \setminus (G)} (|u(x)|^p + |u_j(x)|^p) \, dx \right)^{1/p} \, dy$$

$$\leq 2\varepsilon + \varepsilon^{1/p} + 2^{p-1} \varepsilon$$

and since $\varepsilon > 0$ is arbitrary, this shows that $K$ is totally bounded and is therefore precompact.

Now for an arbitrary open set, $U$ and $K$ given in the hypotheses of the theorem, let $\tilde{K} \equiv \{ \tilde{u} : u \in K \}$ and observe that $\tilde{K}$ is precompact in $L^p(\mathbb{R}^n)$. But this is the same as saying that $K$ is precompact in $L^p(U)$. This proves the theorem.

Actually the converse of the above theorem is also true [1] but this will not be needed so I have left it as an exercise for anyone interested.

**Lemma 36.1.15** Let $u \in W^{1,1}(U)$ for $U$ an open set and let $\phi \in C_c^\infty(U)$. Then there exists a constant,

$$C\left(\phi, ||u||_{1,1,U}\right),$$
36.1. EMBEDDING THEOREMS FOR $W^{1,p} (\mathbb{R}^N)$

depending only on the indicated quantities such that whenever $v \in \mathbb{R}^n$ with $|v| < \text{dist} (\text{spt } (\phi), U^C)$, it follows that

$$
\int_{\mathbb{R}^n} \left| \tilde{\phi} u (x + v) - \tilde{\phi} u (x) \right| \, dx \leq C \left( \phi, ||u||_{1,1,U} \right) |v|.
$$

Proof: First suppose $u \in C^\infty (\bar{U})$. Then for any $x \in \text{spt } (\phi) \cup (\text{spt } (\phi) - v) \equiv G_v$, the chain rule implies

$$
|\phi u (x + v) - \phi u (x)| \leq \int_0^1 \sum_{i=1}^n \left| (\phi u)_{,i} (x + tv) v_i \right| \, dt
$$

$$
\leq \int_0^1 \sum_{i=1}^n \left| (\phi u + u, i \phi) (x + tv) \right| \, dt |v|.
$$

Therefore, for such $u$,

$$
\int_{\mathbb{R}^n} \left| \tilde{\phi} u (x + v) - \tilde{\phi} u (x) \right| \, dx
$$

$$
= \int_{G_v} \left| \tilde{\phi} u (x + v) - \tilde{\phi} u (x) \right| \, dx
$$

$$
\leq \int_{G_v} \int_0^1 \sum_{i=1}^n \left| (\phi u + u, i \phi) (x + tv) \right| \, dt \, dx |v|
$$

$$
\leq \int_0^1 \int_{G_v} \sum_{i=1}^n \left| (\phi u + u, i \phi) (x + tv) \right| \, dx \, dt |v|
$$

$$
\leq C \left( \phi, ||u||_{1,1,U} \right) |v|
$$

where $C$ is a continuous function of $||u||_{1,1,U}$. Now for general $u \in W^{1,1} (U)$, let $u_k \rightarrow u$ in $W^{1,1} (U)$ where $u_k \in C^\infty (\bar{U})$. Then for $|v| < \text{dist} (\text{spt } (\phi), U^C)$,

$$
\int_{\mathbb{R}^n} \left| \tilde{\phi} u (x + v) - \tilde{\phi} u (x) \right| \, dx
$$

$$
= \int_{G_v} \left| \tilde{\phi} u (x + v) - \tilde{\phi} u (x) \right| \, dx
$$

$$
= \lim_{k \rightarrow \infty} \int_{G_v} \left| \phi u_k (x + v) - \phi u_k (x) \right| \, dx
$$

$$
\leq \lim_{k \rightarrow \infty} C \left( \phi, ||u_k||_{1,1,U} \right) |v|
$$

$$
= C \left( \phi, ||u||_{1,1,U} \right) |v|.
$$

This proves the lemma.
Lemma 36.1.16 Let $U$ be a bounded open set and define for $p > 1$

$$S \equiv \left\{ u \in W^{1,1}(U) \cap L^p(U) : ||u||_{1,1,U} + ||u||_{L^p(U)} \leq M \right\} \quad (36.1.19)$$

and let $\phi \in C_\infty(U)$ and

$$S_1 \equiv \{ u\phi : u \in S \}.$$ \quad (36.1.20)

Then $S_1$ is precompact in $L^q(U)$ where $1 < q < p$.

**Proof:** This depends on Theorem 36.1.14. The second condition is satisfied by taking $G \equiv \text{spt} (\phi)$. Thus, for $u \in S_1$,

$$\int_{U \setminus G} |w(x)|^q dx = 0 < \varepsilon^p.$$ 

It remains to satisfy the first condition. It is necessary to verify there exists $\delta > 0$ such that if $|v| < \delta$, then

$$\int_{\mathbb{R}^n} \left| \tilde{\phi} u(x + v) - \tilde{\phi} u(x) \right|^q dx < \varepsilon^p. \quad (36.1.21)$$

Let $\text{spt} (\phi) \cup (\text{spt} (\phi) - v) \equiv G_v$. Now if $h$ is any measurable function, and if $\theta \in (0,1)$ is chosen small enough that $\theta q < 1$,

$$\int_{G_v} |h|^q dx = \int_{G_v} |h|^{\theta q} |h|^{(1-\theta) q} dx$$

$$\leq \left( \int_{G_v} |h| dx \right)^{\theta q} \left( \int_{G_v} |h|^{(1-\theta) q} \right)^{1-\theta q}$$

$$= \left( \int_{G_v} |h| dx \right)^{\theta q} \left( \int_{G_v} |h|^{\frac{(1-\theta) q}{1-\theta q}} \right)^{1-\theta q}. \quad (36.1.22)$$

Now let $\theta$ also be small enough that there exists $r > 1$ such that

$$r \frac{(1-\theta) q}{1-\theta q} = p$$

and use Holder’s inequality in the last factor of the right side of (36.1.22). Then (36.1.22) is dominated by

$$\left( \int_{G_v} |h| dx \right)^{\theta q} \left( \int_{G_v} |h|^p \right)^{1-\theta q} \left( \int_{G_v} 1 dx \right)^{1/r'}$$

$$= C \left( ||h||_{L^p(G_v)} , m_n(G_v) \right) \left( \int_{G_v} |h| dx \right)^{\theta q}.$$ 

Therefore, for $u \in S$,

$$\int_{\mathbb{R}^n} \left| \tilde{\phi} u(x + v) - \tilde{\phi} u(x) \right|^q dx = \int_{G_v} |\tilde{\phi} u(x + v) - \tilde{\phi} u(x)|^q dx \leq$$
36.1. EMBEDDING THEOREMS FOR $W^{M,P}(\mathbb{R}^N)$

\[ C \left( \| \phi u (\cdot + v) - \phi u (\cdot) \|_{L^p(G_n), m_n(G_n)} \right) \left( \int_{G_n} |\phi u (x + v) - \phi u (x)| \, dx \right)^{\frac{\theta_q}{q}} \]

\[ \leq C \left( 2 \| \phi u (\cdot) \|_{L^p(U), m_n(U)} \right) \left( \int_{G_n} |\phi u (x + v) - \phi u (x)| \, dx \right)^{\frac{\theta_q}{q}} \]

\[ \leq C (\phi, M, m_n(U)) \left( \int_{G_n} |\phi u (x + v) - \phi u (x)| \, dx \right)^{\frac{\theta_q}{q}} \]

\[ = C (\phi, M, m_n(U)) \left( \int_{\mathbb{R}^n} |\widetilde{\phi} u (x + v) - \widetilde{\phi} u (x)| \, dx \right)^{\frac{\theta_q}{q}}. \quad (36.1.23) \]

Now by Lemma 36.1.16,

\[ \int_{\mathbb{R}^n} \left| \widetilde{\phi} u (x + v) - \widetilde{\phi} u (x) \right| \, dx \leq C \left( \phi, \| u \|_{L^1(U)} \right) |v| \quad (36.1.24) \]

and so from 36.1.24 and 36.1.23, and adjusting the constants

\[ \int_{\mathbb{R}^n} \left| \widetilde{\phi} u (x + v) - \widetilde{\phi} u (x) \right|^q \, dx \leq C (\phi, M, m_n(U)) \left( C \left( \phi, \| u \|_{L^1(U)} \right) |v| \right)^{\frac{\theta_q}{q}} \]

\[ = C (\phi, M, m_n(U)) |v|^{\frac{\theta_q}{q}} \]

which verifies 36.1.21 whenever $|v|$ is sufficiently small. This proves the lemma because the conditions of Theorem 36.1.17 are satisfied.

**Theorem 36.1.17** Let $U$ be a bounded open set and define for $p > 1$

\[ S \equiv \left\{ u \in W^{1,1}(U) \cap L^p(U) : \| u \|_{L^1(U)} + \| u \|_{L^p(U)} \leq M \right\} \quad (36.1.25) \]

Then $S$ is precompact in $L^q(U)$ where $1 \leq q < p$.

**Proof:** If suffices to show that every sequence, $\{u_k\}_{k=1}^\infty \subseteq S$ has a subsequence which converges in $L^q(U)$. Let $\{K_m\}_{m=1}^\infty$ denote a sequence of compact subsets of $U$ with the property that $K_m \subseteq K_{m+1}$ for all $m$ and $\cup_{m=1}^\infty K_m = U$. Now let $\phi_m \in C_c^{\infty}(U)$ such that $\phi_m (x) \in [0,1]$ and $\phi_m (x) = 1$ for all $x \in K_m$. Let $S_m \equiv \{ \phi_m u : u \in S \}$. By Lemma 36.1.16 there exists a subsequence of $\{u_k\}_{k=1}^\infty$, denoted here by $\{u_{1,k}\}_{k=1}^\infty$, such that $\{\phi_1 u_{1,k}\}_{k=1}^\infty$ converges in $L^q(U)$. Now $S_2$ is also precompact in $L^q(U)$ and so there exists a subsequence of $\{u_{1,k}\}_{k=1}^\infty$, denoted by $\{u_{2,k}\}_{k=1}^\infty$, such that $\{\phi_2 u_{2,k}\}_{k=1}^\infty$ converges in $L^2(U).$ Thus it is also the case that $\{\phi_1 u_{1,k}\}_{k=1}^\infty$ converges in $L^q(U)$. Continue taking subsequences in this manner such that for all $l \leq m$, $\{\phi_l u_{m,k}\}_{k=1}^\infty$ converges in $L^q(U)$. Let $\{w_m\}_{m=1}^\infty = \{u_{m,m}\}_{m=1}^\infty$ so that $\{w_k\}_{k=1}^\infty$ is a subsequence of $\{u_{m,k}\}_{k=1}^\infty$. Then it follows for all $k$, $\{\phi_k w_m\}_{m=1}^\infty$
must converge in $L^q(U)$. For $u \in S$,

$$
\|u - \phi_k u\|_{L^q(U)}^q = \int_U |u|^q (1 - \phi_k)^q \, dx \\
\leq \left( \int_U |u|^p \, dx \right)^{q/p} \left( \int_U (1 - \phi_k)^q r \, dx \right)^{1/r} \\
\leq M \left( \int_U (1 - \phi_k)^q r \, dx \right)^{1/r}
$$

where $q/p + 1/r = 1$. Now $\phi_l(x) \to X_U(x)$ and so the integrand in the last integral converges to 0 by the dominated convergence theorem. Therefore, $k$ may be chosen large enough that for all $u \in S$,

$$
\|u - \phi_k u\|_{L^q(U)} \leq \left( \frac{\varepsilon}{3} \right)^q .
$$

Fix such a value of $k$. Then

$$
\|w_q - w_p\|_{L^q(U)} \leq

\|w_q - \phi_k w_q\|_{L^q(U)} + \|\phi_k w_q - \phi_k w_p\|_{L^q(U)} + \|w_p - \phi_k w_p\|_{L^q(U)}
$$

$$
\leq \frac{2\varepsilon}{3} + \|\phi_k w_q - \phi_k w_p\|_{L^q(U)}
$$

But $\{\phi_k w_m\}_{m=1}^{\infty}$ converges in $L^q(U)$ and so the last term in the above is less than $\varepsilon/3$ whenever $p, q$ are large enough. Thus $\{w_m\}_{m=1}^{\infty}$ is a Cauchy sequence and must therefore converge in $L^q(U)$. This proves the theorem.

### 36.2 An Extension Theorem

**Definition 36.2.1** An open subset, $U$, of $\mathbb{R}^n$ has a Lipschitz boundary if it satisfies the following conditions. For each $p \in \partial U \equiv U \setminus U$, there exists an open set, $Q$, containing $p$, an open interval $(a, b)$, a bounded open box $B \subseteq \mathbb{R}^{n-1}$, and an orthogonal transformation $R$ such that

$$
RQ = B \times (a, b),
$$

$$
R(Q \cap U) = \{ y \in \mathbb{R}^n : \tilde{y} \in B, a < y_n < g(\tilde{y}) \}
$$

where $g$ is Lipschitz continuous on $\overline{B}, a < \min \{ g(x) : x \in \overline{B} \}$, and

$$
\tilde{y} \equiv (y_1, \ldots, y_{n-1}).
$$

Letting $W = Q \cap U$ the following picture describes the situation.
The following lemma is important.

**Lemma 36.2.2** If $U$ is an open subset of $\mathbb{R}^n$ which has a Lipschitz boundary, then it satisfies the segment condition and so $X^{m,p}(U) = W^{m,p}(U)$.

**Proof:** For $x \in \partial U$, simply look at a single open set, $Q_x$ described in the above which contains $x$. Then consider an open set whose intersection with $U$ is of the form $R^T\{y : \tilde{y} \in B, g(\tilde{y}) - \varepsilon < y_n < g(\tilde{y})\}$ and a vector of the form $\varepsilon R^T(-e_n)$ where $\varepsilon$ is chosen smaller than $\min \{g(x) : x \in \overline{B}\} - a$. There is nothing to prove for points of $U$.

One way to extend many of the above theorems to more general open sets than $\mathbb{R}^n$ is through the use of an appropriate extension theorem. In this section, a fairly general one will be presented.

**Lemma 36.2.3** Let $B \times (a,b)$ be as described in Definition 36.2.1 and let

$$V^- \equiv \{(\tilde{y}, y_n) : y_n < g(\tilde{y})\}, \quad V^+ \equiv \{(\tilde{y}, y_n) : y_n > g(\tilde{y})\},$$

for $g$ a Lipschitz function of the sort described in this definition. Suppose $u^+$ and $u^-$ are Lipschitz functions defined on $\overline{V^-}$ and $\overline{V^+}$ respectively and suppose that $u^+(\tilde{y}, g(\tilde{y})) = u^-(\tilde{y}, g(\tilde{y}))$ for all $\tilde{y} \in B$. Let

$$u(\tilde{y}, y_n) \equiv \begin{cases} u^+(\tilde{y}, y_n) & \text{if } (\tilde{y}, y_n) \in V^+ \\ u^-(\tilde{y}, y_n) & \text{if } (\tilde{y}, y_n) \in V^- \end{cases}$$

and suppose spt $(u) \subseteq B \times (a,b)$. Then extending $u$ to be 0 off of $B \times (a,b)$, $u$ is continuous and the weak partial derivatives, $u_{i,j}$, are all in $L^\infty(\mathbb{R}^n) \cap L^p(\mathbb{R}^n)$ for all $p > 1$ and $u_{i,j} = (u^+)^{i,j}$ on $V^+$ and $u_{i,j} = (u^-)^{i,j}$ on $V^-$. 

**Proof:** Consider the following picture which is descriptive of the situation.
Note first that $u$ is Lipschitz continuous. To see this, consider $|u(y_1) - u(y_2)|$ where $(\tilde{y}, y_n) = y_i$. There are various cases to consider depending on whether $y_n$ is above $g(\tilde{y})$. Suppose $y_n < g(\tilde{y})$ and $y_n > g(\tilde{y})$. Then letting $K \geq \max (\text{Lip}(u^+), \text{Lip}(u^-), \text{Lip}(g))$,

$$|u(\tilde{y}, y_n) - u(\tilde{y}, y_n')| \leq K|y_n - y_n'|$$

The other cases are similar. Thus $u$ is a Lipschitz continuous function which has compact support. By Corollary \textit{[Corollary]} on Page \textit{[Page]} it follows that $u_i \in L^\infty(\mathbb{R}^n) \cap L^p(\mathbb{R}^n)$ for all $p > 1$. It remains to verify $u_i = (u^+)_i$ on $V^+$ and $u_i = (u^-)_i$ on $V^-$. The last claim is obvious from the definition of weak derivatives.

**Lemma 36.2.4** In the situation of Lemma \textit{[Lemma]} let $u \in C^1(V^-) \cap C^1_c(B \times (a, b))$ and define

$$w(\tilde{y}, y_n) \equiv \begin{cases} 
  u(\tilde{y}, y_n) & \text{if } \tilde{y} \in B \text{ and } y_n \leq g(\tilde{y}), \\
  u(\tilde{y}, 2g(\tilde{y}) - y_n) & \text{if } \tilde{y} \in B \text{ and } y_n > g(\tilde{y}) \\
  0 & \text{if } \tilde{y} \notin B.
\end{cases}$$

Then $w \in W^{1,p}(\mathbb{R}^n)$ and there exists a constant, $C$ depending only on $\text{Lip}(g)$ and dimension such that

$$||w||_{W^{1,p}(\mathbb{R}^n)} \leq C||u||_{W^{1,p}(V^-)}.$$
36.2. AN EXTENSION THEOREM

Proof: As in the previous lemma, \( w \) is Lipschitz continuous and has compact support so it is clear \( w \in W^{1,p}(\mathbb{R}^n) \). The main task is to find \( w, i \) for \( \tilde{y} \in B \) and \( y_n > g(\tilde{y}) \) and then to extract an estimate of the right sort. Denote by \( U \) the set of points of \( \mathbb{R}^n \) with the property that \((\tilde{y}, y_n) \in U \) if and only if \( \tilde{y} \notin B \) or \( \tilde{y} \in B \) and \( y_n > g(\tilde{y}) \). Then letting \( \phi \in C_c^\infty(U) \), suppose first that \( i < n \). Then

\[
\int_U w(\tilde{y}, y_n) \phi_i(y) \, dy
\]

\[
= \lim_{h \to 0} \int_U \phi(y) \frac{u(\tilde{y} - he_i^{n-1}, 2g(\tilde{y} - he_i^{n-1}) - y_n) - u(\tilde{y}, 2g(\tilde{y}) - y_n)}{h} \, dy
\]

\[
= \lim_{h \to 0} \left\{ -\frac{1}{h} \int_U \phi(y) \left[ D_1 u(\tilde{y}, 2g(\tilde{y}) - y_n)(he_i^{n-1}) + 2D_2 u(\tilde{y}, 2g(\tilde{y}) - y_n)(g(\tilde{y} - he_i^{n-1}) - g(\tilde{y})) \right] \, dy \\
\quad + \frac{1}{h} \int_U \phi(y) \left[ o(g(\tilde{y} - he_i^{n-1}) - g(\tilde{y})) + o(h) \right] \, dy \right\}
\]

where \( e_i^{n-1} \) is the unit vector in \( \mathbb{R}^{n-1} \) having all zeros except for a 1 in the \( i \)th position. Now by Rademacher’s theorem, \( Dg(\tilde{y}) \) exists for a.e. \( \tilde{y} \) and so except for a set of measure zero, the expression, \( o(g(\tilde{y} - he_i^{n-1}) - g(\tilde{y})) = o(h) \) and also for \( \tilde{y} \) not in the exceptional set,

\[
g(\tilde{y} - he_i^{n-1}) - g(\tilde{y}) = -hDg(\tilde{y})e_i^{n-1} + o(h).
\]

Therefore, since the integrand in \( 36.2.28 \) has compact support and because of the Lipschitz continuity of all the functions, the dominated convergence theorem may be applied to obtain

\[
\int_U w(\tilde{y}, y_n) \phi_i(y) \, dy =
\]

\[
\int_U \phi(y) \left[ -D_1 u(\tilde{y}, 2g(\tilde{y}) - y_n)(e_i^{n-1}) + 2D_2 u(\tilde{y}, 2g(\tilde{y}) - y_n)(Dg(\tilde{y})e_i^{n-1}) \right] \, dy
\]

\[
= \int_U \phi(y) \left[ -\frac{\partial u}{\partial y_i}(\tilde{y}, 2g(\tilde{y}) - y_n) + 2\frac{\partial u}{\partial y_n}(\tilde{y}, 2g(\tilde{y}) - y_n) \frac{\partial g(\tilde{y})}{\partial y_i} \right] \, dy
\]

and so

\[
w_i(y) = \frac{\partial u}{\partial y_i}(\tilde{y}, 2g(\tilde{y}) - y_n) - 2\frac{\partial u}{\partial y_n}(\tilde{y}, 2g(\tilde{y}) - y_n) \frac{\partial g(\tilde{y})}{\partial y_i}
\]

\[
(36.2.29)
\]

whenever \( i < n \) which is what you would expect from a formal application of the chain rule. Next suppose \( i = n \).

\[
\int_U w(\tilde{y}, y_n) \phi_n(y) \, dy
\]
\[ = \lim_{h \to 0} - \int_U \frac{u(\tilde{y}, 2g(\tilde{y}) - (y_n + h)) - u(\tilde{y}, 2g(\tilde{y}) - y_n)}{h} \phi(y) \, dy \]
\[ = \lim_{h \to 0} \int_U \frac{D_2 u(\tilde{y}, 2g(\tilde{y}) - y_n) h + o(h)}{h} \phi(y) \, dy \]
\[ = \int_U \frac{\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \phi(y) \, dy \]
showing that
\[ w_{n, i}(y) = -\frac{\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \quad (36.2.30) \]
which is also expected.

From the definition, for \( y \in \mathbb{R}^n \setminus U = \{(\tilde{y}, y_n) : y_n \leq g(\tilde{y})\} \) it follows \( w_{n, i} = u_{i, n} \) and on \( U, w_{i, n} \) is given by \( 36.2.29 \) and \( 36.2.30 \). Consider \( \|w_{i, n}\|_{L^p(U)} \) for \( i < n \). From \( 36.2.29 \)
\[
\|w_{i, n}\|_{L^p(U)}^p = \int_U \left| \frac{\partial u}{\partial y_i} (\tilde{y}, 2g(\tilde{y}) - y_n) - 2 \frac{\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \frac{\partial g(\tilde{y})}{\partial y_i} \right|^p \, dy 
\[ \leq 2^{p-1} \int_U \left| \frac{\partial u}{\partial y_i} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p 
\[ + 2^p \left| \frac{\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p \text{Lip}(g)^p \, dy 
\[ \leq 4^p (1 + \text{Lip}(g))^p \int_U \left| \frac{\partial u}{\partial y_i} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p 
\[ + \left| \frac{\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p \, dy 
\[ = 4^p (1 + \text{Lip}(g))^p \int_B \int_{\tilde{g}(\tilde{y})}^{\tilde{g}(\tilde{y})} \left| \frac{\partial u}{\partial y_i} (\tilde{y}, \tilde{z}_n) \right|^p 
\[ + \left| \frac{\partial u}{\partial y_n} (\tilde{y}, \tilde{z}_n) \right|^p \, d\tilde{y} \, d\tilde{z}_n 
\[ = 4^p (1 + \text{Lip}(g))^p \int_B \int_{\tilde{g}(\tilde{y})}^{\tilde{g}(\tilde{y})} \left| \frac{\partial u}{\partial y_i} (\tilde{y}, \tilde{z}_n) \right|^p 
\[ + \left| \frac{\partial u}{\partial y_n} (\tilde{y}, \tilde{z}_n) \right|^p \, d\tilde{y} \, d\tilde{z}_n 
\[ \leq 4^p (1 + \text{Lip}(g))^p \|u\|_{L^p(U)}^p 
\]
36.2. AN EXTENSION THEOREM

Now by similar reasoning,

\[ \|w_n\|_{L^p(U)}^p = \int_U \left| \frac{-\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p dy \]
\[ = \int_B \int_{g(\tilde{y})}^{\infty} \left| \frac{-\partial u}{\partial y_n} (\tilde{y}, 2g(\tilde{y}) - y_n) \right|^p dy_n d\tilde{y} \]
\[ = \int_B \int_a^{g(\tilde{y})} \left| \frac{-\partial u}{\partial y_n} (\tilde{y}, z_n) \right|^p dz_n d\tilde{y} = \|u_n\|_{1,p,V^-}^p. \]

It follows

\[ \|w\|_{1,p,\mathbb{R}^n}^p = \|w\|_{1,p,U}^p + \|u\|_{1,p,V^-}^p \leq 4^n (1 + \text{Lip}(g)^p) \|u\|_{1,p,V^-}^p + \|u\|_{1,p,V^-}^p \]

and so

\[ \|w\|_{1,p,\mathbb{R}^n}^p \leq 4^n (2 + \text{Lip}(g)^p) \|u\|_{1,p,V^-}^p \]

which implies

\[ \|w\|_{1,p,\mathbb{R}^n} \leq 4^{n/p} (2 + \text{Lip}(g)^p)^{1/p} \|u\|_{1,p,V^-} \]

It is obvious that \( E_0 \) is a continuous linear mapping. This proves the lemma.

Now recall Definition \( \text{[10],[11]} \), listed here for convenience.

**Definition 36.2.5** An open subset, \( U \), of \( \mathbb{R}^n \) has a Lipschitz boundary if it satisfies the following conditions. For each \( p \in \partial U \equiv \overline{U} \setminus U \), there exists an open set, \( Q \), containing \( p \), an open interval \( (a,b) \), a bounded open box \( B \subseteq \mathbb{R}^{n-1} \), and an orthogonal transformation \( R \) such that

\[ RQ = B \times (a,b), \quad (36.2.31) \]
\[ R(Q \cap U) = \{ y \in \mathbb{R}^n : \hat{y} \in B, \ a < y_n < g(\hat{y}) \} \quad (36.2.32) \]

where \( g \) is Lipschitz continuous on \( \overline{B}, a < \min \{ g(x) : x \in \overline{B} \} \), and

\[ \hat{y} = (y_1, \cdots, y_{n-1}). \]

Letting \( W = Q \cap U \) the following picture describes the situation.
Lemma 36.2.6 In the situation of Definition 36.2.1 let \( u \in C^1(U) \cap C^1_c(Q) \) and define
\[
E u \equiv R^* E_0 \left( R^T \right)^* u.
\]
where \( (R^T)^* \) maps \( W^{1,p}(U \cap Q) \) to \( W^{1,p}(R(W)) \). Then \( E \) is linear and satisfies
\[
\|Eu\|_{W^{1,p}(\mathbb{R}^n)} \leq C \|u\|_{W^{1,p}(Q \cap U)}, \quad Eu(x) = u(x) \quad \text{for } x \in Q \cap U.
\]
where \( C \) depends only on the dimension and \( \text{Lip}(g) \).

Proof: This follows from Theorem 36.0.14 and Lemma 36.2.4.

The following theorem is a general extension theorem for Sobolev spaces.

Theorem 36.2.7 Let \( U \) be a bounded open set which has Lipschitz boundary. Then for each \( p \geq 1 \), there exists \( E \in \mathcal{L}(W^{1,p}(U), W^{1,p}(\mathbb{R}^n)) \) such that \( Eu(x) = u(x) \) a.e. \( x \in U \).

Proof: Let \( \partial U \subseteq \bigcup_{i=1}^p Q_i \) Where the \( Q_i \) are as described in Definition 36.2.5. Also let \( R_i \) be the orthogonal transformation and \( g_i \) the Lipschitz functions associated with \( Q_i \) as in this definition. Now let \( Q_0 \subseteq Q_0 \subseteq U \) be such that \( U \subseteq \bigcup_{i=0}^p Q_i \), and let \( \psi_i \in C^\infty(Q_i) \) with \( \psi_i(x) \in [0,1] \) and \( \sum_{i=0}^p \psi_i(x) = 1 \) on \( U \). For \( u \in C^\infty(U) \), let \( E_0(\psi_0 u) = \psi_0 u \) on \( Q_0 \) and 0 off \( Q_0 \). Thus
\[
\|E_0(\psi_0 u)\|_{1,p,\mathbb{R}^n} = \|\psi_0 u\|_{1,p,U}.
\]
For \( i \geq 1 \), let
\[
E_i(\psi_i u) \equiv R_i^* E_0 \left( R^T \right)^* (\psi_i u).
\]
Thus, by Lemma 36.2.4
\[
\|E_1(\psi_1 u)\|_{1,p,\mathbb{R}^n} \leq C \|\psi_1 u\|_{1,p,Q_i \cap U}
\]
where the constant depends on \( \text{Lip}(g_i) \) but is independent of \( u \in C^\infty(U) \). Now define \( E \) as follows.
\[
Eu \equiv \sum_{i=0}^p E_i(\psi_i u).
\]
Thus for \( u \in C^\infty(U) \), it follows \( Eu(x) = u(x) \) for all \( x \in U \). Also,
\[
\|Eu\|_{1,p,\mathbb{R}^n} \leq \sum_{i=0}^p \|E_i(\psi_i u)\| \leq \sum_{i=0}^p C_i \|\psi_i u\|_{1,p,Q_i \cap U}
\]
\[
= \sum_{i=0}^p C_i \|\psi_i u\|_{1,p,U} \leq \sum_{i=0}^p C_i \|u\|_{1,p,U}
\]
\[
\leq (p+1) \sum_{i=0}^p C_i \|u\|_{1,p,U} \equiv C \|u\|_{1,p,U}. \quad (36.2.33)
\]
where $C$ depends on the $\psi_i$ and the $g_i$ but is independent of $u \in C^\infty (\overline{U})$. Therefore, by density of $C^\infty (\overline{U})$ in $W^{1,p} (U)$, $E$ has a unique continuous extension to $W^{1,p} (U)$ still denoted by $E$ satisfying the inequality determined by the ends of Theorem 36.2.33. It remains to verify that $Eu (x) = u (x)$ a.e. for $x \in U$.

Let $u_k \to u$ in $W^{1,p} (U)$ where $u_k \in C^\infty (\overline{U})$. Therefore, by Theorem 36.2.33, $Eu_k \to Eu$ in $W^{1,p} (\mathbb{R}^n)$. Since $Eu_k (x) = u_k (x)$ for each $k$,

$$||u - Eu||_{L^p(U)} = \lim_{k \to \infty} ||u_k - Eu_k||_{L^p(U)}$$

$$= \lim_{k \to \infty} ||Eu_k - Eu||_{L^p(U)} = 0$$

which shows $u (x) = Eu (x)$ for a.e. $x \in U$ as claimed. This proves the theorem.

**Definition 36.2.8** Let $U$ be an open set. Then $W_0^{m,p} (U)$ is the closure of the set, $C_c^\infty (U)$ in $W^{m,p} (U)$.

**Corollary 36.2.9** Let $U$ be a bounded open set which has Lipschitz boundary and let $W$ be an open set containing $\overline{U}$. Then for each $p \geq 1$, there exists $E_W \in \mathcal{L} \left( W^{1,p} (U), W_0^{1,p} (W) \right)$ such that $E_W u (x) = u (x)$ a.e. $x \in U$.

**Proof:** Let $\psi \in C_c^\infty (W)$ and $\psi = 1$ on $U$. Then let $E_W u \equiv \psi Eu$ where $E$ is the extension operator of Theorem 36.2.7.

Extension operators of the above sort exist for many open sets, $U$, not just for bounded ones. In particular, the above discussion would apply to an open set, $U$, not necessarily bounded, if you relax the condition that the $Q_i$ be bounded but require the existence of a finite partition of unity $\{\psi_i\}_{i=1}^p$ having the property that $\psi_i$ and $\psi_{i,j}$ are uniformly bounded for all $i,j$. The proof would be identical to the above. My main interest is in bounded open sets so the above theorem will suffice. Such an extension operator will be referred to as a $(1,p)$ extension operator.

### 36.3 General Embedding Theorems

With the extension theorem it is possible to give a useful theory of embeddings.

**Theorem 36.3.1** Let $1 \leq p < n$ and $\frac{1}{q} = \frac{1}{p} - \frac{1}{n}$ and let $U$ be any open set for which there exists a $(1,p)$ extension operator. Then if $u \in W^{1,p} (U)$, there exists a constant independent of $u$ such that

$$||u||_{L^q(U)} \leq C ||u||_{1,p,U}.$$ 

If $U$ is bounded and $r < q$, then $\text{id} : W^{1,p} (U) \to L^r (U)$ is also compact.

**Proof:** Let $E$ be the $(1,p)$ extension operator. Then by Theorem 36.3.1 on Page 1351:

$$||u||_{L^q(U)} \leq ||Eu||_{L^q(\mathbb{R}^n)} \leq \frac{1}{\sqrt{n}} \frac{(n - 1)p}{(n - p)} ||Eu||_{1,p,\mathbb{R}^n} \leq C ||u||_{1,p,U}.$$
1356  **CHAPTER 36. BASIC THEORY OF SOBOLEV SPACES**

It remains to prove the assertion about compactness. If \( S \subseteq W^{1,p}(U) \) is bounded then
\[
\sup_{u \in S} \left\{ \|u\|_{1,1,U} + \|u\|_{L^q(U)} \right\} < \infty
\]
and so by Theorem 36.1.17 on Page 1347 it follows \( S \) is precompact in \( L^r(U) \). This proves the theorem.

**Corollary 36.3.2**  Suppose \( mp < n \) and \( U \) is an open set satisfying the segment condition which has a \((1,p)\) extension operator for all \( p \). Then \( \text{id} \in L(W^{m,p}(U), L^q(U)) \) where \( q = \frac{np}{n-mp} \).

**Proof:** This is true if \( m = 1 \) according to Theorem 36.3.1. Suppose it is true for \( m \leq 1 \) where \( m > 1 \). If \( u \in W^{m,p}(U) \) and \( |\alpha| \leq 1 \), then \( D^\alpha u \in W^{m-1,p}(U) \) so by induction, for all such \( \alpha \),
\[
D^\alpha u \in L^\frac{np}{n-(m-1)p}(U).
\]
Thus, since \( U \) has the segment condition, \( u \in W^{1,q}(U) \) where
\[
q_1 = \frac{np}{n-(m-1)p}.
\]
By Theorem 36.3.1 it follows \( u \in L^q(\mathbb{R}^n) \) where
\[
\frac{1}{q} = \frac{n-(m-1)p}{np} - \frac{1}{n} = \frac{n-mp}{np}.
\]
This proves the corollary.

There is another similar corollary of the same sort which is interesting and useful.

**Corollary 36.3.3**  Suppose \( m \geq 1 \) and \( j \) is a nonnegative integer satisfying \( jp < n \). Also suppose \( U \) has a \((1,p)\) extension operator for all \( p \geq 1 \) and satisfies the segment condition. Then
\[
\text{id} \in L(W^{m+j,p}(U), W^{m,q}(U))
\]
where
\[
q = \frac{np}{n-jp}.
\]
(36.3.34)
If, in addition to the above, \( U \) is bounded and \( 1 \leq r < q \), then
\[
\text{id} \in L(W^{m+j,p}(U), W^{m,q}(U))
\]
and is compact.

**Proof:** If \( |\alpha| \leq m \), then \( D^\alpha u \in W^{j,p}(U) \) and so by Corollary 36.3.2 \( D^\alpha u \in L^q(U) \) where \( q \) is given above. Since \( U \) has the segment property, this means \( u \in W^{m,q}(U) \). It remains to verify the assertion about compactness of \( \text{id} \).
Let \( S \) be bounded in \( W^{m+j,p}(U) \). Then \( S \) is bounded in \( W^{m,q}(U) \) by the first part. Now let \( \{u_k\}_{k=1}^\infty \) be any sequence in \( S \). The corollary will be proved
36.3. \textbf{GENERAL EMBEDDING THEOREMS} 

if it is shown that any such sequence has a convergent subsequence in $W^{m,r}(U)$. Let \( \{\alpha_1, \alpha_2, \cdots, \alpha_k\} \) denote the indices satisfying \( |\alpha| \leq m \). Then for each of these indices, \( \alpha \),

\[
\sup_{u \in S} \left\{ \|D^{\alpha}u\|_{1,1,U} + \|D^{\alpha}u\|_{L^p(U)} \right\} < \infty
\]

and so for each such \( \alpha \), satisfying \( |\alpha| \leq m \), it follows from Lemma 36.1.10 on Page 1345 that \( \{D^{\alpha}u : u \in S\} \) is precompact in $L^r(U)$. Therefore, there exists a subsequence, still denoted by \( u_k \) such that $D^{\alpha_1}u_k$ converges in $L^r(U)$. Applying the same lemma, there exists a subsequence of this subsequence such that both $D^{\alpha_3}u_k$ and $D^{\alpha_2}u_k$ converge in $L^r(U)$. Continue taking subsequences until you obtain a subsequence, \( \{u_k\}_{k=1}^\infty \) for which \( \{D^{\alpha}u_k\}_{k=1}^\infty \) converges in $L^r(U)$ for all \( |\alpha| \leq m \). But this must be a convergent subsequence in $W^{m,r}(U)$ and this proves the corollary.

\textbf{Theorem 36.3.4} \textit{Let} $U$ \textit{be a bounded open set having a} $(1,p)$ \textit{extension operator and let} $p > n$. \textit{Then} \( \text{id} : W^{1,p}(U) \rightarrow C(\overline{U}) \) \textit{is continuous and compact.}

\textbf{Proof:} Theorem 36.3.3 on Page 1348 implies \( r_U : W^{1,p}(\mathbb{R}^n) \rightarrow C(\overline{U}) \) \text{ is continuous and compact. Thus}

\[
\|u\|_{\infty,U} = \|Eu\|_{\infty,U} \leq C \|Eu\|_{1,p,\mathbb{R}^n} \leq C \|u\|_{1,p,U}.
\]

This proves continuity. If \( S \) is a bounded set in $W^{1,p}(U)$, then define \( S_1 = \{Eu : u \in S\} \). Then \( S_1 \) is a bounded set in $W^{1,p}(\mathbb{R}^n)$ and so by Theorem 36.3.3 the set of restrictions to \( U \), is precompact. However, the restrictions to \( U \) are just the functions of \( S \). Therefore, \( \text{id} \) is compact as well as continuous.

\textbf{Corollary 36.3.5} \textit{Let} $p > n$, \textit{let} $U$ \textit{be a bounded open set having a} $(1,p)$ \textit{extension operator which also satisfies the segment condition, and let} $m$ \textit{be a nonnegative integer. Then} \( \text{id} : W^{m+1,p}(U) \rightarrow C^{m,\lambda}(\overline{U}) \) \textit{is continuous for all} \( \lambda \in [0,1 - \frac{n}{p}] \) \textit{and} \( \text{id} \) \textit{is compact if} \( \lambda < 1 - \frac{n}{p} \).

\textbf{Proof:} Let \( u_k \rightarrow 0 \) in $W^{m+1,p}(U)$. Then it follows that for each \( |\alpha| \leq m \), $D^{\alpha}u_k \rightarrow 0$ in $W^{1,p}(U)$. Therefore,

\[
E(D^{\alpha}u_k) \rightarrow 0 \text{ in } W^{1,p}(\mathbb{R}^n).
\]

Then from Morrey’s inequality, 36.3.4 on Page 1349, if \( \lambda \leq 1 - \frac{n}{p} \) and \( |\alpha| = m \)

\[
\rho_\lambda(E(D^{\alpha}u_k)) \leq C \|E(D^{\alpha}u_k)\|_{1,p,\mathbb{R}^n} \text{ diam}(U)^{1 - \frac{n}{p} - \lambda}.
\]

Therefore, \( \rho_\lambda(E(D^{\alpha}u_k)) = \rho_\lambda(D^{\alpha}u_k) \rightarrow 0 \). From Theorem 36.3.3 it follows that for \( |\alpha| \leq m \), $\|D^{\alpha}u_k\|_{\infty} \rightarrow 0$ and so $\|u_k\|_{m,\lambda} \rightarrow 0$. This proves the claim about continuity. The claim about compactness for \( \lambda < 1 - \frac{n}{p} \) follows from Lemma 36.1.10 on Page 1348 and this. (Bounded in $W^{m,p}(U) \xrightarrow{\text{id}}$ Bounded in $C^{m,\frac{1}{2}}(\overline{U}) \xrightarrow{\text{id}}$ Compact in $C^{m,\lambda}(\overline{U})$.)
Theorem 36.3.6 Suppose \( j p < n < (j + 1)p \) and let \( m \) be a positive integer. Let \( U \) be any bounded open set in \( \mathbb{R}^n \) which has a \((1, p)\) extension operator for each \( p \geq 1 \) and the segment property. Then \( \text{id} \in L \left( W^{m+j,p}(U), C^{m-1,1}(\overline{U}) \right) \) for every \( \lambda \leq \lambda_0 \equiv (j + 1) - \frac{n}{p} \) and if \( \lambda < (j + 1) - \frac{n}{p} \), \( \text{id} \) is compact.

Proof: From Corollary 36.3.3 \( W^{m+j,p}(U) \subseteq W^{m,q}(U) \) where \( q \) is given by 36.3.34. Therefore,
\[
\frac{np}{n - jp} > n
\]
and so by Corollary 36.3.6, \( W^{m,q}(U) \subseteq C^{m-1,1}(\overline{U}) \) for all \( \lambda \) satisfying
\[
0 < \lambda < 1 - \frac{(n - jp)n}{np} = \frac{p(j + 1) - n}{p} = (j + 1) - \frac{n}{p}.
\]
The assertion about compactness follows from the compactness of the embedding of \( C^{m-1,\lambda_0}(\overline{U}) \) into \( C^{m-1,1}(\overline{U}) \) for \( \lambda < \lambda_0 \), Lemma 36.1.6 on Page 1336.

36.4 More Extension Theorems

The theorem about the existence of a \((1, p)\) extension is all that is needed to obtain general embedding theorems for Sobolev spaces. However, a more general theory is needed in order to tie the theory of Sobolev spaces presented thus far to a very appealing description using Fourier transforms. First the problem of extending \( W^{k,p}(H) \) to \( W^{k,p}(\mathbb{R}^n) \) is considered for \( H^- \) a half space
\[
H^- = \{ \mathbf{y} \in \mathbb{R}^n : y_n < 0 \}.
\]
I am following Adams [1].

Lemma 36.4.1 Let \( H^- \) be a half space as in 36.4.35. Let \( H^+ \) be the half space in which \( y_n < 0 \) is replaced with \( y_n > 0 \). Also let \( (\mathbf{y}', y_n) = \mathbf{y} \)
\[
u(\mathbf{y}', y_n) = \begin{cases} u^+(\mathbf{y}', y_n) & \text{if } \mathbf{y} \in H^+ \\ u^-(\mathbf{y}', y_n) & \text{if } \mathbf{y} \in H^- \end{cases},
\]
suppose \( u^+ \in C^\infty \left( \overline{H^+} \right) \) and \( u^- \in C^\infty \left( \overline{H^-} \right) \), and that for \( l \leq k - 1 \),
\[
D^{le_n}u^+(\mathbf{y}', 0) = D^{le_n}u^-(\mathbf{y}', 0).
\]
Then \( u \in W^{k,p}(\mathbb{R}^n) \). Furthermore,
\[
D^{a}u(\mathbf{y}', y_n) = \begin{cases} D^{a}u^+(\mathbf{y}', y_n) & \text{if } \mathbf{y} \in H^+ \\ D^{a}u^-(\mathbf{y}', y_n) & \text{if } \mathbf{y} \in H^- \end{cases}
\]
**Proof:** Consider the following for \( \phi \in C^\infty_c(\mathbb{R}^n) \) and \( |\alpha| \leq k \).

\[
(-1)^{|\alpha|} \left( \int_{\mathbb{R}^{n-1}} \int_0^\infty u^+ D_\alpha \phi \, dy \, dy' + \int_{\mathbb{R}^{n-1}} \int_{-\infty}^0 u^- D_\alpha \phi \, dy \, dy' \right).
\]

Integrating by parts, this yields

\[
(-1)^{|\alpha|} (-1)^{|\beta|} \left( \int_{\mathbb{R}^{n-1}} \int_0^\infty D_\beta u^+ D^{\alpha_n} \phi \, dy \, dy' + \int_{\mathbb{R}^{n-1}} \int_{-\infty}^0 D_\beta u^- D^{\alpha_n} \phi \, dy \, dy' \right)
\]

where \( \beta \equiv (\alpha_1, \alpha_2, \cdots, \alpha_{n-1}, 0) \). Do integration by parts on the inside integral and by assumption, the boundary terms will cancel and the whole thing reduces to

\[
(-1)^{|\alpha|} (-1)^{|\beta|} (-1)^{|\alpha|} \left( \int_{\mathbb{R}^{n-1}} \int_0^\infty D^\alpha u^+ \phi \, dy \, dy' + \int_{\mathbb{R}^{n-1}} \int_{-\infty}^0 D^\alpha u^- \phi \, dy \, dy' \right)
\]

which proves the lemma.

**Lemma 36.4.2** Let \( H^- \) be the half space in 36.4.35 and let \( u \in C^\infty(\overline{H^-}) \). Then there exists a mapping,

\[ E : C^\infty(\overline{H^-}) \to W^{k,p}(\mathbb{R}^n) \]

and a constant, \( C \) which is independent of \( u \in C^\infty(\overline{H^-}) \) such that \( E \) is linear and for all \( l \leq k \),

\[
||Eu||_{l,p,\mathbb{R}^n} \leq C \ ||u||_{l,p,\overline{H^-}}. \tag{36.4.36}
\]

**Proof:** Define

\[ Eu(x',x_n) = \begin{cases} 
    u(x',x_n) & \text{if } x_n < 0 \\
    \sum_{j=1}^k \lambda_j u(x',-jx_n) & \text{if } x_n \geq 0
\end{cases} \]

where the \( \lambda_j \) are chosen in such a way that for \( l \leq k - 1 \),

\[
D^{\alpha_n} u(x',0) - D^{\alpha_n} \left( \sum_{j=1}^k \lambda_j u \right)(x',0) = 0
\]
so that Lemma 36.4.1 may be applied. Do there exist such \( \lambda_j \)? It is necessary to have the following hold for each \( r = 0, 1, \cdots, k - 1 \).

\[
\sum_{j=1}^{k} (-j)^r \lambda_j D^{r \alpha_n} u(x', 0) = D^{r \alpha_n} u(x', 0) .
\]

This is satisfied if

\[
\sum_{j=1}^{k} (-j)^r \lambda_j = 1
\]

for \( r = 0, 1, \cdots, k - 1 \). This is a system of \( k \) equations for the \( k \) variables, the \( \lambda_j \).

The matrix of coefficients is of the form

\[
\begin{pmatrix}
1 & 1 & 1 & \cdots & 1 \\
-2 & -3 & -4 & \cdots & -k \\
1 & 4 & 9 & \cdots & k^2 \\
& & & & \\
(-1)^k & (-2)^k & (-3)^k & \cdots & (-k)^k
\end{pmatrix}
\]

This matrix has an inverse because its determinant is nonzero.

Now from Lemma 36.4.1, it follows from the above description of \( E \) that for \( |\alpha| \leq k \),

\[
D^\alpha (Eu)(x', x_n) \equiv \begin{cases} D^\alpha u(x', x_n) \text{ if } x_n < 0 \\ \sum_{j=1}^{k} \lambda_j (-j)^{\alpha_n} (D^\alpha u) (x', -jx_n) \text{ if } x_n \geq 0 \end{cases}
\]

It follows that \( E \) is linear and there exists a constant, \( C \) independent of \( u \) such that 36.4.36 holds. This proves the lemma.

**Corollary 36.4.3** Let \( H^- \) be the half space of 36.4.34. There exists \( E \) with the property that \( E : W^{l,p}_c (H^-) \to W^{l,p} (\mathbb{R}^n) \) and is linear and continuous for each \( l \leq k \).

**Proof:** This immediate from the density of \( C^\infty_c (\overline{H^-}) \) in \( W^{k,p}_c (\overline{H^-}) \) and Lemma 36.4.2.

There is nothing sacred about a half space or this particular half space. It is clear that everything works as well for a half space of the form

\[
H^-_k \equiv \{ x : x_k < 0 \}.
\]

Thus the half space featured in the above discussion is \( H^-_k \).

**Corollary 36.4.4** Let \( \{ k_1, \cdots, k_r \} \subseteq \{ 1, \cdots, n \} \) where the \( k_i \) are distinct and let

\[
H^-_{k_1 \cdots k_r} \equiv H^-_{k_1} \cap H^-_{k_2} \cap \cdots \cap H^-_{k_r} . \tag{36.4.37}
\]

Then there exists \( E : W^{k,p} (H^-_{k_1 \cdots k_r}) \to W^{k,p} (\mathbb{R}^n) \) such that \( E \) is linear and continuous.
36.4. MORE EXTENSION THEOREMS

Proof: Follow the above argument with minor modifications to first extend from $H_{k_1 \cdots k_r}$ to $H_{k_1 \cdots k_{r-1}}^-$ and then from $H_{k_1 \cdots k_{r-1}}^-$ to $H_{k_1 \cdots k_{r-2}}^-$ etc.

This easily implies the ability to extend off bounded open sets which near their boundaries look locally like an intersection of half spaces.

Theorem 36.4.5 Let $U$ be a bounded open set and suppose $U_0, U_1, \ldots, U_m$ are open sets with the property that $U \subseteq \bigcup_{k=0}^m U_k$, $U_0 \subseteq U$, and $\partial U \subseteq \bigcup_{k=1}^m U_k$. Suppose also there exist one to one and onto functions, $h_k : \mathbb{R}^n \to \mathbb{R}^n$, $h_k(U_k \cap U) = W_k$ where $W_k$ equals the intersection of a bounded open set with a finite intersection of half spaces, $H_{k_1 \cdots k_r}^-$, as in 36.4.37 such that $h_k(\partial U \cap U_k) \subseteq \partial H_{k_1 \cdots k_r}^-$. Suppose also that for all $j$, $j \neq k$, $Dh_j$ and $Dh_k$ exist and are Lipschitz continuous. Then there letting $W$ be an open set which contains $\bar{U}$, there exists $E : W^{k,p}(U) \to W^{k,p}(W)$ such that $E$ is a linear continuous map from $W^{l,p}(U)$ to $W^{l,p}(W)$ for each $l \leq k$.

Proof: Let $\psi_j \in C^\infty_c(U_j)$, $\psi_j(x) \in [0, 1]$ for all $x \in \mathbb{R}^n$, and $\sum_{j=0}^m \psi_j(x) = 1$ on $U$. This is a $C^\infty$ partition of unity on $\bar{U}$. By Theorem 36.0.12 $(h_j^{-1})^* u \psi_j \in W^{k,p}(W_j)$.

By the assumption that $h_j(\partial U \cap U_j) \subseteq \partial H_{k_1 \cdots k_r}^-$, the zero extension of $(h_j^{-1})^* u \psi_j$ to the rest of $H_{k_1 \cdots k_r}^-$ results in an element of $W^{k,p}(H_{k_1 \cdots k_r}^-)$. Apply Corollary 36.4.4 to conclude there exists $E_j : W^{k,p}(H_{k_1 \cdots k_r}^-) \to W^{k,p}(\mathbb{R}^n)$ which is continuous and linear. Abusing notation slightly, by using $(h_j^{-1})^* u \psi_j$ as the above zero extension, it follows $E_j \left((h_j^{-1})^* u \psi_j\right) \in W^{k,p}(\mathbb{R}^n)$. Now let $\eta$ be a function in $C^\infty_c(h(W))$ such that $\eta(y) = 1$ on $h(U)$. Then Define

$$Eu \equiv \sum_{j=0}^m h_j^* \eta E_j \left((h_j^{-1})^* (u \psi_j)\right).$$

Clearly $Eu(x) = u(x)$ if $x \in U$. It is also clear that $E$ is linear. It only remains to verify $E$ is continuous. In what follows, $C_j$ will denote a constant which is
independent of \( u \) which may change from line to line. By Theorem 36.0.14,

\[
\| E u \|_{k,p,W} \leq \sum_{j=0}^{m} \left\| h_j^* \eta E_j \left( (h_j^{-1})^* (u \psi_j) \right) \right\|_{k,p,W}
\]

\[
\leq \sum_{j=0}^{m} C_j \left\| \eta E_j \left( (h_j^{-1})^* (u \psi_j) \right) \right\|_{k,p,h(W)}
\]

\[
= \sum_{j=0}^{m} C_j \left\| \eta E_j \left( (h_j^{-1})^* (u \psi_j) \right) \right\|_{k,p,\mathbb{R}^n}
\]

\[
\leq \sum_{j=0}^{m} C_j \left\| E_j \left( (h_j^{-1})^* (u \psi_j) \right) \right\|_{k,p,\mathbb{R}^n}
\]

\[
\leq \sum_{j=0}^{m} C_j \left\| (h_j^{-1})^* (u \psi_j) \right\|_{k,p,h_j(U \cap U_j)}
\]

\[
\leq \sum_{j=0}^{m} C_j \left\| \psi_j \right\|_{k,p,U \cap U_k}
\]

\[
\leq \sum_{j=0}^{m} C_j \| u \|_{k,p,U \cap U_k} \leq \left( \sum_{j=0}^{m} C_j \right) \| u \|_{k,p,U}.
\]

Similarly \( E : W^{l,p} \to W^{l,p} \) for \( l \leq k \). This proves the theorem.

**Definition 36.4.6** When \( E \) is a linear continuous map from \( W^{l,p} \) to \( W^{l,p} \) for each \( l \leq k \), it is called a strong \((k,p)\) extension map.

There is also a very easy sort of extension theorem for the space, \( W^{m,p}_0 \) which does not require any assumptions on the boundary of \( U \) other than \( m_n(\partial U) = 0 \). First here is the definition of \( W^{m,p}_0 \).

**Definition 36.4.7** Denote by \( W^{m,p}_0 \) the closure of \( C^{\infty}_c \) in \( W^{m,p} \).

**Theorem 36.4.8** For \( u \in W^{m,p}_0 \), define

\[
E(u)(x) = \begin{cases} 
    u(x) & \text{if } x \in U \\
    0 & \text{if } x \notin U
\end{cases}
\]

Then \( E \) is a strong \((k,p)\) extension map.

**Proof:** Letting \( l \leq m \), it is clear that for \( |\alpha| \leq l \),

\[
D^\alpha E(u) = \begin{cases} 
    D^\alpha u & \text{for } x \in U \\
    0 & \text{for } x \notin U
\end{cases}
\]

This follows because, since \( m_n(\partial U) = 0 \) it suffices to consider \( \phi \in C^{\infty}_c(U) \) and \( \phi \in C^{\infty}_c(B^C) \). Therefore, \( \|E(u)\|_{l,p,\mathbb{R}^n} = \|u\|_{l,p,\mathbb{R}^n} \).
There are many other extension theorems and if you are interested in pursuing this further, consult Adams [1]. One of the most famous which is discussed in this reference is due to Calderon and depends on the theory of singular integrals.
Chapter 37

Sobolev Spaces Based On $L^2$

37.1 Fourier Transform Techniques

Much insight can be obtained easily through the use of Fourier transform methods. This technique will be developed in this chapter. When this is done, it is necessary to use Sobolev spaces of the form $W^{k,2}(U)$, those Sobolev spaces which are based on $L^2(U)$. It is true that there are generalizations which use Fourier transform methods in the context of $L^p$ but the spaces so considered are called Bessel potential spaces. They are not really Sobolev spaces. Furthermore, it is Mihlin’s theorem rather than the Plancherel theorem which is the main tool of the analysis. This is a hard theorem.

It is convenient to consider the Schwartz class of functions, $\mathcal{S}$. These are functions which have infinitely many derivatives and vanish quickly together with their derivatives as $|x| \to \infty$. In particular, $C_c^\infty(\mathbb{R}^n)$ is contained in $\mathcal{S}$ which is not true of the functions, $\mathcal{G}$ used earlier in defining the Fourier transforms which are a subspace of $\mathcal{S}$. Recall the following definition.

**Definition 37.1.1** $f \in \mathcal{S}$, the Schwartz class, if $f \in C^\infty(\mathbb{R}^n)$ and for all positive integers $N$,

$$\rho_N(f) < \infty$$

where

$$\rho_N(f) = \sup \{(1 + |x|^2)^N |D^\alpha f(x)| : x \in \mathbb{R}^n, |\alpha| \leq N\}.$$  

Thus $f \in \mathcal{S}$ if and only if $f \in C^\infty(\mathbb{R}^n)$ and

$$\sup \{|x^\beta D^\alpha f(x)| : x \in \mathbb{R}^n\} < \infty$$

(37.1.1)

for all multi indices $\alpha$ and $\beta$.

Thus all partial derivatives of a function in $\mathcal{S}$ are in $L^p(\mathbb{R}^n)$ for all $p \geq 1$. Therefore, for $f \in \mathcal{S}$, the Fourier and inverse Fourier transforms are given in the
usual way,

\[ Ff(t) = \left(\frac{1}{2\pi}\right)^{n/2} \int_{\mathbb{R}^n} f(x) e^{-it \cdot x} dx, \quad F^{-1}f(t) = \left(\frac{1}{2\pi}\right)^{n/2} \int_{\mathbb{R}^n} f(x) e^{it \cdot x} dx. \]

Also recall that the Fourier transform and its inverse are one to one and onto maps from \( S \) to \( S \).

To tie the Fourier transform technique in with what has been done so far, it is necessary to make the following assumption on the set, \( U \):

**Assumption 37.1.2** Assume \( U \) satisfies the segment condition and that for any \( m \) of interest, there exists \( E \in \mathcal{L}(W^{m,p}(U), W^{m,p}(\mathbb{R}^n)) \) such that for each \( k \leq m \), \( E \in \mathcal{L}(W^{k,p}(U), W^{k,p}(\mathbb{R}^n)) \). That is, there exists a strong \((m,p)\) extension operator.

**Lemma 37.1.3** The Schwartz class, \( S \), is dense in \( W^{m,p}(\mathbb{R}^n) \).

**Proof:** The set, \( \mathbb{R}^n \) satisfies the segment condition and so \( C^\infty_c(\mathbb{R}^n) \) is dense in \( W^{m,p}(\mathbb{R}^n) \). However, \( C^\infty_c(\mathbb{R}^n) \subseteq S \). This proves the lemma.

Recall now Plancherel’s theorem which states that \( \|f\|_{L^2(\mathbb{R}^n)} = \|Ff\|_{L^2(\mathbb{R}^n)} \) whenever \( f \in L^2(\mathbb{R}^n) \). Also it is routine to verify from the definition of the Fourier transform that for \( u \in S \),

\[ F\partial_k u = ix_k Fu. \]

From this it follows that

\[ \|D^\alpha u\|_{0,2,\mathbb{R}^n} = \|x^\alpha Fu\|_{0,2,\mathbb{R}^n}. \]

Here \( x^\alpha \) denotes the function \( x \mapsto x^\alpha \). Therefore,

\[ \|u\|_{m,2,\mathbb{R}^n} = \left( \int_{\mathbb{R}^n} \sum_{|\alpha| \leq m} x_1^{2\alpha_1} \cdots x_n^{2\alpha_n} |Fu(x)|^2 \, dx \right)^{1/2}. \]

Also, it is not hard to verify that

\[ \sum_{|\alpha| \leq m} x_1^{2\alpha_1} \cdots x_n^{2\alpha_n} \leq \left( 1 + \sum_{j=1}^{n} x_j^2 \right)^m \leq C(n,m) \sum_{|\alpha| \leq m} x_1^{2\alpha_1} \cdots x_n^{2\alpha_n} \]

where \( C(n,m) \) is the largest of the multinomial coefficients obtained in the expansion,

\[ \left( 1 + \sum_{j=1}^{n} x_j^2 \right)^m. \]
Therefore, for all \( u \in \mathcal{S} \),
\[
\|u\|_{m,2,\mathbb{R}^n} \leq \left( \int_{\mathbb{R}^n} \left( 1 + |x|^2 \right)^m |F u(x)|^2 \, dx \right)^{1/2} \leq C(n,m) \|u\|_{m,2,\mathbb{R}^n}.
\] (37.1.2)

This motivates the following definition.

**Definition 37.1.4** Let \( H^m(\mathbb{R}^n) \equiv \)
\[
\left\{ u \in L^2(\mathbb{R}^n) : \|u\|_{H^m(\mathbb{R}^n)} \equiv \left( \int_{\mathbb{R}^n} \left( 1 + |x|^2 \right)^m |F u(x)|^2 \, dx \right)^{1/2} < \infty \right\}.
\] (37.1.3)

**Lemma 37.1.5** \( \mathcal{S} \) is dense in \( H^m(\mathbb{R}^n) \) and \( H^m(\mathbb{R}^n) = W^{2,m}(\mathbb{R}^n) \). Furthermore, the norms are equivalent.

**Proof:** First it is shown that \( \mathcal{S} \) is dense in \( H^m(\mathbb{R}^n) \). Let \( u \in H^m(\mathbb{R}^n) \). Let \( \mu(E) \equiv \int_E \left( 1 + |x|^2 \right)^m \, dx \). Thus \( \mu \) is a regular measure and \( u \in H^m(\mathbb{R}^n) \) just means that \( F u \in L^2(\mu) \), the space of functions which are in \( L^2(\mathbb{R}^n) \) with respect to this measure, \( \mu \). Therefore, from the regularity of the measure, \( \mu \), there exists \( u_k \in C_c(\mathbb{R}^n) \) such that
\[
\|u_k - F u\|_{L^2(\mu)} \to 0.
\]

Now let \( \psi \) be a mollifier and pick \( \epsilon_k \) small enough that
\[
\left\| u_k \ast \psi_{\epsilon_k} - u_k \right\|_{L^2(\mu)} < \frac{1}{2^k}.
\]

Then \( u_k \ast \psi_{\epsilon_k} \in C_c^\infty(\mathbb{R}^n) \subseteq \mathcal{S} \). Therefore, there exists \( w_k \in \mathcal{S} \) such that \( F w_k = u_k \ast \psi_{\epsilon_k} \). It follows
\[
\|F w_k - F u\|_{L^2(\mu)} \leq \|F w_k - u_k\|_{L^2(\mu)} + \|u_k - F u\|_{L^2(\mu)}
\]
and these last two terms converge to 0 as \( k \to \infty \). Therefore, \( w_k \to u \) in \( H^m(\mathbb{R}^n) \) and this proves the first part of this lemma.

Now let \( u \in H^m(\mathbb{R}^n) \). By what was just shown, there exists a sequence, \( u_k \to u \) in \( H^m(\mathbb{R}^n) \) where \( u_k \in \mathcal{S} \). It follows from (37.1.2) that
\[
\|u_k - u\|_{H^m} \geq \|u_k - u\|_{m,2,\mathbb{R}^n}
\]
and so \( \{u_k\} \) is a Cauchy sequence in \( W^{m,2}(\mathbb{R}^n) \). Therefore, there exists \( w \in W^{m,2}(\mathbb{R}^n) \) such that
\[
\|u_k - w\|_{m,2,\mathbb{R}^n} \to 0.
\]

But this implies
\[
0 = \lim_{k \to \infty} \|u_k - w\|_{0,2,\mathbb{R}^n} = \lim_{k \to \infty} \|u_k - u\|_{0,2,\mathbb{R}^n}
\]
showing \( u = w \) which verifies \( H^m(\mathbb{R}^n) \subseteq W^{2,m}(\mathbb{R}^n) \). The opposite inclusion is proved the same way, using density of \( \mathcal{S} \) and the fact that the norms in both spaces
Chapter 37. Sobolev Spaces Based on $L^2$

are larger than the norms in $L^2(\mathbb{R}^n)$. The equivalence of the norms follows from the density of $\mathcal{S}$ and the equivalence of the norms on $\mathcal{S}$. This proves the lemma.

The conclusion of this lemma with the density of $\mathcal{S}$ and (37.1.2) implies you can use either norm, $||u||_{H^m(\mathbb{R}^n)}$ or $||u||_{m,2,\mathbb{R}^n}$ when working with these Sobolev spaces.

What of open sets satisfying Assumption (37.1.2)? How does $W^{m,2}(U)$ relate to the Fourier transform?

Definition 37.1.6 Let $U$ be an open set in $\mathbb{R}^n$. Then

$$H^m(U) \equiv \{ u : u = v|_U \text{ for some } v \in H^m(\mathbb{R}^n) \} \quad (37.1.4)$$

Here the notation, $v|_U$ means $v$ restricted to $U$. Define the norm in this space by

$$||u||_{H^m(U)} \equiv \inf \left\{ ||v||_{H^m(\mathbb{R}^n)} : v|_U = u \right\} . \quad (37.1.5)$$

Lemma 37.1.7 $H^m(U)$ is a Banach space.

Proof: First it is necessary to verify that the given norm really is a norm. Suppose then that $u = 0$. Is $||u||_{H^m(U)} = 0$? Of course it is. Just take $v \equiv 0$. Then $v|_U = u$ and $||v||_{H^m(U)} = 0$. Next suppose $||u||_{H^m(U)} = 0$. Does it follow that $u = 0$? Letting $\varepsilon > 0$ be given, there exists $v \in H^m(\mathbb{R}^n)$ such that $v|_U = u$ and $||v||_{H^m(R^n)} < \varepsilon$. Therefore,

$$||u||_{0,U} \leq ||v||_{0,R^n} \leq ||v||_{H^m(U)} < \varepsilon.$$  

Since $\varepsilon > 0$ is arbitrary, it follows $u = 0$ a.e. Next suppose $u_i \in H^m(U)$ for $i = 1, 2$. There exists $v_i \in H^m(\mathbb{R}^n)$ such that

$$||v_i||_{H^m(\mathbb{R}^n)} < ||u_i||_{H^m(U)} + \varepsilon.$$  

Therefore,

$$||u_1 + u_2||_{H^m(U)} \leq ||v_1 + v_2||_{H^m(\mathbb{R}^n)} \leq ||v_1||_{H^m(\mathbb{R}^n)} + ||v_2||_{H^m(\mathbb{R}^n)}$$

$$\leq ||u_1||_{H^m(U)} + ||u_2||_{H^m(U)} + 2\varepsilon$$

and since $\varepsilon > 0$ is arbitrary, this shows the triangle inequality.

The interesting question is the one about completeness. Suppose then $\{u_k\}$ is a Cauchy sequence in $H^m(U)$. There exists $N_k$ such that if $k, l \geq N_k$, it follows $||u_k - u_l||_{H^m(U)} < \frac{1}{2^k}$ and the numbers, $N_k$ can be taken to be strictly increasing in $k$. Thus for $l \geq N_k$, $||u_l - u_{N_k}||_{H^m(U)} < 1/2^l$. Therefore, there exists $w_l \in H^m(\mathbb{R}^n)$ such that

$$w_l|_U = u_l - u_{N_k}, \quad ||w_l||_{H^m(\mathbb{R}^n)} < \frac{1}{2^l}.$$  

Also let $v_{N_k}|_U = u_{N_k}$ with $v_{N_k} \in H^m(\mathbb{R}^n)$ and

$$||v_{N_k}||_{H^m(\mathbb{R}^n)} < ||u_{N_k}||_{H^m(U)} + \frac{1}{2^k}.$$  

Therefore,

$$||w_l||_{H^m(U)} \leq ||v_{N_k}||_{H^m(U)} + ||w_l||_{H^m(\mathbb{R}^n)}$$

$$\leq ||v_{N_k}||_{H^m(U)} + \frac{1}{2^k} + \frac{1}{2^l}.$$  

Since $l \geq N_k$, we have $2^l > 2^k$. Therefore,

$$||w_l||_{H^m(U)} < ||v_{N_k}||_{H^m(U)} + 2\frac{1}{2^k}.$$  

Since $\frac{1}{2^k}$ is arbitrary, it follows $w_l \to v_{N_k}$ in $H^m(U)$. Thus $\{u_k\}$ converges to $v_{N_k}$ in $H^m(U)$.
37.1. FOURIER TRANSFORM TECHNIQUES

Now for \( l > N_k \), define \( v_l \) by \( v_l - v_{N_k} = w_{N_k} \) so that \( \| v_l - v_{N_k} \|_{H^m(\mathbb{R}^n)} < \frac{1}{2^k} \). In particular,
\[
\| v_{N_k+1} - v_{N_k} \|_{H^m(\mathbb{R}^n)} < \frac{1}{2^k}
\]
which shows that \( \{ v_{N_k} \}_{k=1}^\infty \) is a Cauchy sequence. Consequently it must converge to \( v \in H^m(\mathbb{R}^n) \). Let \( u = v|_U \). Then
\[
\| u - u_{N_k} \|_{H^m(U)} \leq \| v - v_{N_k} \|_{H^m(\mathbb{R}^n)}
\]
which shows the subsequence, \( \{ u_{N_k} \} \), converges to \( u \). Since \( \{ u_k \} \) is a Cauchy sequence, it follows too must converge to \( u \). This proves the lemma.

The main result is next.

Theorem 37.1.8 Suppose \( U \) satisfies Assumption [37.1.8]. Then for \( m \) a nonnegative integer, \( H^m(U) = W^{m,2}(U) \) and the two norms are equivalent.

Proof: Let \( u \in H^m(U) \). Then there exists \( v \in H^m(\mathbb{R}^n) \) such that \( v|_U = u \). Hence \( v \in W^{k,2}(\mathbb{R}^n) \) and so all its weak derivatives up to order \( m \) are in \( L^2(\mathbb{R}^n) \). Therefore, the restrictions of these weak derivatives are in \( L^2(U) \). Since \( U \) satisfies the segment condition, it follows \( u \in W^{m,2}(U) \) which shows \( H^m(U) \subseteq W^{m,2}(U) \).

Next take \( u \in W^{m,2}(U) \). Then \( Eu \in W^{m,2}(\mathbb{R}^n) = H^m(\mathbb{R}^n) \) and this shows \( u \in H^m(U) \). This has shown the two spaces are the same. It remains to verify their norms are equivalent. Let \( u \in H^m(U) \) and let \( v|_U = u \) where \( v \in H^m(\mathbb{R}^n) \) and
\[
\| u \|_{H^m(U)} + \varepsilon > \| v \|_{H^m(\mathbb{R}^n)}.
\]
Then recalling that \( \| \cdot \|_{H^m(\mathbb{R}^n)} \) and \( \| \cdot \|_{m,2,\mathbb{R}^n} \) are equivalent norms for \( H^m(\mathbb{R}^n) \), there exists a constant, \( C \) such that
\[
\| u \|_{H^m(U)} + \varepsilon > \| v \|_{H^m(\mathbb{R}^n)} \geq C \| v \|_{m,2,\mathbb{R}^n} \geq C \| u \|_{m,2,U}
\]
Now consider the two Banach spaces,
\[
\left( H^m(U), \| \cdot \|_{H^m(U)} \right), \left( W^{m,2}(U), \| \cdot \|_{m,2,U} \right).
\]
The above inequality shows since \( \varepsilon > 0 \) is arbitrary that \( \text{id} : \left( H^m(U), \| \cdot \|_{H^m(U)} \right) \rightarrow \left( W^{m,2}(U), \| \cdot \|_{m,2,U} \right) \) is continuous. By the open mapping theorem, it follows id is continuous in the other direction. Thus there exists a constant, \( K \) such that \( \| u \|_{H^m(U)} \leq K \| u \|_{k,2,U} \). Hence the two norms are equivalent as claimed.

Specializing Corollary [37.1.7] and Theorem [37.1.7] starting on Page 1369 to the case of \( p = 2 \) while also assuming more on \( U \) yields the following embedding theorems.

Theorem 37.1.9 Suppose \( m \geq 0 \) and \( j \) is a nonnegative integer satisfying \( 2j < n \). Also suppose \( U \) is an open set which satisfies Assumption [37.1.8]. Then \( \text{id} \in \mathcal{L} \left( H^{m+j}(U), W^{m,q}(U) \right) \) where
\[
q = \frac{2n}{n - 2j}.
\]
If, in addition to the above, \( U \) is bounded and \( 1 \leq r < q \), then
\[
\text{id} \in \mathcal{L} \left( H^{m+j}(U), W^{m,r}(U) \right)
\]
and is compact.

**Theorem 37.1.10** Suppose for \( j \) a nonnegative integer, \( 2j < n < 2(j+1) \) and let \( m \) be a positive integer. Let \( U \) be any bounded open set in \( \mathbb{R}^n \) which satisfies Assumption 37.1.2. Then \( \text{id} \in \mathcal{L} \left( H^{m+j}(U), C^{m-1,\lambda} \left( \overline{U} \right) \right) \) for every \( \lambda \leq \lambda_0 \equiv (j+1) - \frac{n}{2} \) and if \( \lambda < (j+1) - \frac{n}{2} \), \( \text{id} \) is compact.

### 37.2 Fractional Order Spaces

What has been gained by all this? The main thing is that \( H^{m+s}(U) \) makes sense for any \( s \in (0,1) \) and \( m \) an integer. You simply replace \( m \) with \( m+s \) in the above for \( s \in (0,1) \). This gives what is meant by \( H^{m+s}(\mathbb{R}^n) \)

**Definition 37.2.1** For \( m \) an integer and \( s \in (0,1) \), let \( H^{m+s}(\mathbb{R}^n) \equiv \)
\[
\left\{ u \in L^2(\mathbb{R}^n) : ||u||_{H^{m+s}(\mathbb{R}^n)} = \left( \int_{\mathbb{R}^n} \left( 1 + |x|^2 \right)^{m+s} |Fu(x)|^2 \, dx \right)^{1/2} < \infty \right\}.
\]  
(37.2.7)

You could also simply refer to \( H^t(\mathbb{R}^n) \) where \( t \) is a real number replacing the \( m+s \) in the above formula with \( t \) but I want to emphasize the notion that \( t = m+s \) where \( m \) is a nonnegative integer. Therefore, I will often write \( m+s \). Let \( U \) be an open set in \( \mathbb{R}^n \). Then
\[
H^{m+s}(U) \equiv \left\{ u : u = v|_U \text{ for some } v \in H^{m+s}(\mathbb{R}^n) \right\}.
\]  
(37.2.8)

Define the norm in this space by
\[
||u||_{H^{m+s}(U)} = \inf \left\{ ||v||_{H^{m+s}(\mathbb{R}^n)} : v|_U = u \right\}.
\]  
(37.2.9)

**Lemma 37.2.2** \( H^{m+s}(U) \) is a Banach space.

**Proof:** Just repeat the proof of Lemma 37.1.7. The theorem about density of \( \mathcal{S} \) also remains true in \( H^{m+s}(\mathbb{R}^n) \). Just repeat the proof of that part of Lemma 37.1.5 replacing the integer, \( m \), with the symbol, \( m+s \).

**Lemma 37.2.3** \( \mathcal{S} \) is dense in \( H^{m+s}(\mathbb{R}^n) \).

In fact, more can be said.

**Corollary 37.2.4** Let \( U \) be an open set and let \( \mathcal{S}|_U \) denote the restrictions of functions of \( \mathcal{S} \) to \( U \). Then \( \mathcal{S}|_U \) is dense in \( H^t(U) \).
37.2. FRACTIONAL ORDER SPACES

Proof: Let \( u \in H^t(U) \) and let \( v \in H^t(\mathbb{R}^n) \) such that \( v|_U = u \) a.e. Then since \( \mathcal{S} \) is dense in \( H^t(\mathbb{R}^n) \), there exists \( w \in \mathcal{S} \) such that

\[
\|w - v\|_{H^t(\mathbb{R}^n)} < \varepsilon.
\]

It follows that

\[
\|u - w\|_{H^t(U)} \leq \|u - v\|_{H^t(U)} + \|v - w\|_{H^t(U)} \leq 0 + \|v - w\|_{H^t(\mathbb{R}^n)} < \varepsilon.
\]

These fractional order spaces are important when trying to understand the trace on the boundary. The Fourier transform description also makes it very easy to establish interesting inequalities such as interpolation inequalities.

Lemma 37.2.5 Let \( 0 \leq r < s < t \). Then if \( u \in H^t(\mathbb{R}^n) \),

\[
\|u\|_{H^r(\mathbb{R}^n)} \leq \|u\|_{H^s(\mathbb{R}^n)} \|u\|_{H^t(\mathbb{R}^n)}^{1-\theta}
\]

where \( \theta \) is a positive number such that \( \theta r + (1 - \theta) t = s \).

Proof: This follows from Holder’s inequality applied to the measure \( \mu \) given by

\[
\mu(E) = \int_E |Fu|^2 \, dx
\]

Thus

\[
\int \left( 1 + |x|^2 \right)^s |Fu|^2 \, dx
= \int \left( 1 + |x|^2 \right)^{r\theta} \left( 1 + |x|^2 \right)^{(1-\theta)t} |Fu|^2 \, dx
\leq \left( \int \left( 1 + |x|^2 \right)^r |Fu|^2 \, dx \right)^\theta \left( \int \left( 1 + |x|^2 \right)^{(1-\theta)t} |Fu|^2 \, dx \right)^{1-\theta}
= \|u\|_{H^r(\mathbb{R}^n)}^{2\theta} \|u\|_{H^t(\mathbb{R}^n)}^{2(1-\theta)}.
\]

Taking square roots yields the desired inequality.

Corollary 37.2.6 Let \( U \) be an open set satisfying Assumption [7,13] and let \( p < q \) where \( p, q \) are two nonnegative integers. Also let \( t \in (p, q) \). Then exists a constant, \( C \) independent of \( u \in H^q(U) \) such that for all \( u \in H^q(U) \),

\[
\|u\|_{H^t(U)} \leq C \|u\|_{H^q(U)}^{\theta} \|u\|_{H^q(U)}^{1-\theta}
\]

where \( \theta \) is such that \( t = \theta p + (1 - \theta) q \).
CHAPTER 37. SOBOLEV SPACES BASED ON L²

Proof: Let \( E \in \mathcal{L}(H^q(U), H^q(\mathbb{R}^n)) \) such that for all positive integers, \( l \) less than or equal to \( q \), \( E \in \mathcal{L}(H^l(U), H^l(\mathbb{R}^n)) \). Then \( Eu|_U = u \) and \( Eu \in H^l(\mathbb{R}^n) \). Therefore, by Lemma 37.2.5,

\[
\|u\|_{H^l(U)} \leq \|Eu\|_{H^l(\mathbb{R}^n)} \leq \|Eu\|_{H^\theta(\mathbb{R}^n)} \|Eu\|_{H^{1-\theta}(\mathbb{R}^n)} \leq C \|u\|_{H^\theta(U)} \|u\|_{H^{1-\theta}(U)}.
\]

Now recall the very important Theorem 36.0.14 on Page 1333 which is listed here for convenience.

Theorem 37.2.7 Let \( h : U \to V \) be one to one and onto where \( U \) and \( V \) are two open sets. Also suppose that \( D^\alpha h \) and \( D^\alpha (h^{-1}) \) exist and are Lipschitz continuous if \( |\alpha| \leq m - 1 \) for \( m \) a positive integer. Then

\[ h^* : W^{m,p}(V) \to W^{m,p}(U) \]

is continuous, linear, one to one, and has an inverse with the same properties, the inverse being \((h^{-1})^*\).

37.3 An Intrinsic Norm

Is there something like this for the fractional order spaces? Yes there is. However, in order to prove it, it is convenient to use an equivalent norm for \( H^{m+s}(\mathbb{R}^n) \) which does not depend explicitly on the Fourier transform. The following theorem is similar to one in [14]. It describes the norm in \( H^{m+s}(\mathbb{R}^n) \) in terms which are free of the Fourier transform. This is also called an intrinsic norm [14].

Theorem 37.3.1 Let \( s \in (0, 1) \) and let \( m \) be a nonnegative integer. Then an equivalent norm for \( H^{m+s}(\mathbb{R}^n) \) is

\[
||u||_{m+s}^2 = ||u||_{2,\mathbb{R}^n}^2 + \sum_{|\alpha| = m} \int \int |D^\alpha u(x) - D^\alpha u(y)|^2 |x - y|^{-n-2s} \, dx \, dy.
\]

Also if \( |\beta| \leq m \), there are constants, \( m(s) \) and \( M(s) \) such that

\[
m(s) \int |Fu(z)|^2 |z|^2 |z|^{2s} \, dz \leq \int \int |D^\beta u(x) - D^\beta u(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]

\[
\leq M(s) \int |Fu(z)|^2 |z|^2 |z|^{2s} \, dz \quad (37.3.10)
\]

Proof: Let \( u \in \mathcal{G} \) which is dense in \( H^{m+s}(\mathbb{R}^n) \). The Fourier transform of the function, \( y \to D^\alpha u(x + y) - D^\alpha u(y) \) equals

\[ (e^{i|x|} - 1) FD^\alpha u(z). \]
37.3. AN INTRINSIC NORM

Now by Fubini’s theorem and Plancherel’s theorem along with the above, taking $|\alpha| = m$,

$$
\int \int |D^\alpha u(x) - D^\alpha u(y)|^2 |x - y|^{-n-2s} \, dx \, dy
$$

$$
= \int \int |D^\alpha u(y + t) - D^\alpha u(y)|^2 |t|^{-n-2s} \, dt \, dy
$$

$$
= \int |t|^{-n-2s} \int |D^\alpha u(y + t) - D^\alpha u(y)|^2 \, dy \, dt
$$

$$
= \int |t|^{-n-2s} \int \left| (e^{it\cdot z} - 1) \, F D^\alpha u(z) \right|^2 \, dz \, dt
$$

$$
= \int |F D^\alpha u(z)|^2 \left( \int |t|^{-n-2s} \left| (e^{it\cdot z} - 1) \right|^2 \, dt \right) \, dz. \tag{37.3.11}
$$

Consider the inside integral, the one taken with respect to $t$.

$$
G(z) \equiv \left( \int |t|^{-n-2s} \left| (e^{it\cdot z} - 1) \right|^2 \, dt \right).
$$

The essential thing to notice about this function of $z$ is that it is a positive real number whenever $z \neq 0$. This is because for small $|t|$, the integrand is dominated by $C |t|^{-n+2(1-s)}$. Changing to polar coordinates, you see that

$$
\int_{||t|| \leq 1} |t|^{-n-2s} \left| (e^{it\cdot z} - 1) \right|^2 \, dt < \infty
$$

Next, for $|t| > 1$, the integrand is bounded by $4 |t|^{-n-2s}$, and changing to polar coordinates shows

$$
\int_{||t|| > 1} |t|^{-n-2s} \left| (e^{it\cdot z} - 1) \right|^2 \, dt \leq 4 \int_{||t|| > 1} |t|^{-n-2s} \, dt < \infty.
$$

Now for $\alpha > 0$,

$$
G(\alpha z) = \int |t|^{-n-2s} \left| (e^{it\cdot \alpha z} - 1) \right|^2 \, dt
$$

$$
= \int |t|^{-n-2s} \left| (e^{it\cdot z} - 1) \right|^2 \, dt
$$

$$
= \int \frac{r}{\alpha}^{-n-2s} \left| (e^{ir\cdot z} - 1) \right|^2 \, \frac{1}{\alpha^s} \, dr
$$

$$
= \alpha^{2s} \int |r|^{-n-2s} \left| (e^{ir\cdot z} - 1) \right|^2 \, dr = \alpha^{2s} G(z).
$$

Also $G$ is continuous and strictly positive. Letting

$$
0 < m(s) = \min \{ G(w) : |w| = 1 \}$$. 
CHAPTER 37. SOBOLEV SPACES BASED ON $L^2$

and

$$\text{Max} \| G(w) : \|w\| = 1 \|,$$

it follows from this, and letting $a = |z|$, $w \equiv z/|z|$, that

$$G(z) \in \left( m(s) |z|^{2s} , M(s) |z|^{2s} \right).$$

More can be said but this will suffice. Also observe that for $s \in (0, 1)$ and $b > 0$,

$$(1 + b)^s \leq 1 + b^s, \quad 2^{1-s} (1 + b)^s \geq 1 + b^s.$$

In what follows, $C(s)$ will denote a constant which depends on the indicated quantities which may be different on different lines of the argument. Then from (37.3.11),

$$\int \int |D^\alpha u(x) - D^\alpha u(y)|^2 |x - y|^{n-2s} dxdy$$

$$\leq M(s) \int |FD^\alpha u(z)|^2 |z|^{2s} dz$$

$$= M(s) \int |F u(z)|^2 |z|^2 |z|^{2s} dz.$$

No reference was made to $|\alpha| = m$ and so this establishes the top half of (37.3.10). Therefore,

$$\|u\|_{m+s}^2 \equiv \|u\|_{m, 2, \mathbb{R}^n}^2 + \sum_{|\alpha| = m} \int \int |D^\alpha u(x) - D^\alpha u(y)|^2 |x - y|^{n-2s} dxdy$$

$$\leq C \int \left( 1 + |z| \right)^m |F u(z)|^2 dz + M(s) \int |F u(z)|^2 \sum_{|\alpha| = m} |z|^2 |z|^{2s} dz$$

Recall that

$$\sum_{|\alpha| \leq m} z_1^{2\alpha_1} \cdots z_n^{2\alpha_n} \leq \left( 1 + \sum_{j=1}^n z_j^2 \right)^m \leq C(n, m) \sum_{|\alpha| \leq m} z_1^{2\alpha_1} \cdots z_n^{2\alpha_n}. \quad (37.3.12)$$

Therefore, where $C(n, m)$ is the largest of the multinomial coefficients obtained in the expansion,

$$\left( 1 + \sum_{j=1}^n z_j^2 \right)^m.$$

Therefore,

$$\|u\|_{m+s}^2 \leq C \int \left( 1 + |z| \right)^m |F u(z)|^2 dz + M(s) \int |F u(z)|^2 \sum_{|\alpha| = m} |z|^2 |z|^{2s} dz$$

$$\leq C \int \left( 1 + |z| \right)^{m+s} |F u(z)|^2 dz + M(s) \int |F u(z)|^2 \left( 1 + |z| \right)^m |z|^{2s} dz$$

$$\leq C \int \left( 1 + |z| \right)^{m+s} |F u(z)|^2 dz = C \|u\|_{H^{m+s}(\mathbb{R}^n)}.$$
It remains to show the other inequality. From 37.3.11,
\[
\int \int |D^{\alpha}u(x) - D^{\alpha}u(y)|^2 |x - y|^{-n-2s} \, dx \, dy \\
\geq m(s) \int |F D^{\alpha}u(z)|^2 |z|^{2s} \, dz \\
= m(s) \int |F u(z)|^2 |z|^2 |z|^{2s} \, dz.
\]
No reference was made to $|\alpha| = m$ and so this establishes the bottom half of 37.3.10. Therefore, from 37.3.12,
\[
|||u|||^2_{m+s} \\
\geq C \int \left(1 + |z|^2\right)^m |F u(z)|^2 \, dz + m(s) \int |F u(z)|^2 \sum_{|\alpha|=m} |z|^2 |z|^{2s} \, dz \\
\geq C \int \left(1 + |z|^2\right)^m |F u(z)|^2 \, dz + C \int |F u(z)|^2 \left(1 + |z|^2\right)^m |z|^{2s} \, dz \\
= C \int \left(1 + |z|^2\right)^m \left(1 + |z|^2\right)^s |F u(z)|^2 \, dz \\
\geq C \int \left(1 + |z|^2\right)^{m+s} |F u(z)|^2 \, dz \\
= C \int \left(1 + |z|^2\right)^{m+s} |F u(z)|^2 \, dz = ||u||_{H^{m+s}(\mathbb{R}^n)}.
\]
This proves the theorem.

With the above intrinsic norm, it becomes possible to prove the following version of Theorem 37.2.7.

**Lemma 37.3.2** Let $h : \mathbb{R}^n \to \mathbb{R}^n$ be one to one and onto. Also suppose that $D^{\alpha} h$ and $D^{\alpha} (h^{-1})$ exist and are Lipschitz continuous if $|\alpha| \leq m$ for $m$ a positive integer. Then
\[
h^* : H^{m+s}(\mathbb{R}^n) \to H^{m+s}(\mathbb{R}^n)
\]
is continuous, linear, one to one, and has an inverse with the same properties, the inverse being $(h^{-1})^*$.

**Proof:** Let $u \in \mathcal{E}$. From Theorem 37.2.7 and the equivalence of the norms in
In the second term, let

\[
\|h^* u\|_{H^m}^2 + \int \sum_{|\alpha| = m} |D^\alpha h^* u(x) - D^\alpha h^* u(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]

\[
\leq C \|u\|_{H^m}^2 + \int \sum_{|\alpha| = m} |D^\alpha h^* u(x) - D^\alpha h^* u(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]

\[
= C \|u\|_{H^m}^2 + \int \sum_{|\alpha| = m} \sum_{|\beta(\alpha)| \leq m} h^* (D^{\beta(\alpha)} u) g_{\beta(\alpha)}(x)
\]

\[
- h^* (D^{\beta(\alpha)} u) g_{\beta(\alpha)}(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]

\[
\leq C \|u\|_{H^m}^2 + C \int \sum_{|\alpha| = m} \sum_{|\beta(\alpha)| \leq m} h^* (D^{\beta(\alpha)} u) g_{\beta(\alpha)}(x)
\]

\[
- h^* (D^{\beta(\alpha)} u) g_{\beta(\alpha)}(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]

A single term in the last sum corresponding to a given \(\alpha\) is then of the form,

\[
\int \int |h^* (D^\beta u) g_{\beta}(x) - h^* (D^\beta u) g_{\beta}(y)|^2 |x - y|^{-n-2s} \, dx \, dy
\]  \hspace{1cm} (37.3.13)

\[
\leq \left[ \int \int |h^* (D^\beta u) (x) g_{\beta}(x) - h^* (D^\beta u) (y) g_{\beta}(x)|^2 |x - y|^{-n-2s} \, dx \, dy + \int \int |h^* (D^\beta u) (y) g_{\beta}(x) - h^* (D^\beta u) (y) g_{\beta}(y)|^2 |x - y|^{-n-2s} \, dx \, dy \right]
\]

\[
\leq \left[ C(h) \int \int |h^* (D^\beta u) (x) - h^* (D^\beta u) (y)|^2 |x - y|^{-n-2s} \, dx \, dy + \int \int |h^* (D^\beta u) (y)|^2 |g_{\beta}(x) - g_{\beta}(y)|^2 |x - y|^{-n-2s} \, dx \, dy \right].
\]

Changing variables, and then using the names of the old variables to simplify the notation,

\[
\leq \left[ C(h, h^{-1}) \int \int |(D^\beta u)(x) - (D^\beta u)(y)|^2 |x - y|^{-n-2s} \, dx \, dy + \int \int |h^* (D^\beta u) (y)|^2 |g_{\beta}(x) - g_{\beta}(y)|^2 |x - y|^{-n-2s} \, dx \, dy \right].
\]

By (37.3.11)

\[
\leq C(h) \int |F(u)(z)|^2 |z|^2 |z|^{2s} \, dz
\]

\[
+ \int \int |h^* (D^\beta u) (y)|^2 |g_{\beta}(x) - g_{\beta}(y)|^2 |x - y|^{-n-2s} \, dx \, dy.
\]

In the second term, let \(t = x - y\). Then this term is of the form

\[
\int |h^* (D^\beta u) (y)|^2 \int |g_{\beta}(y + t) - g_{\beta}(y)|^2 |t|^{-n-2s} \, dt \, dy
\]  \hspace{1cm} (37.3.15)

\[
\leq C \int |h^* (D^\beta u) (y)|^2 \, dy \leq C \|u\|_{H^m}^2 \hspace{1cm} (37.3.16)
\]
because the inside integral equals a constant which depends on the Lipschitz constants and bounds of the function, \( g_\beta \) and these things depend only on \( h \). The reason this integral is finite is that for \(|t| \leq 1\),

\[
|g_\beta(y + t) - g_\beta(y)|^2 |t|^{-n-2s} \leq K |t|^2 |t|^{-n-2s}
\]

and using polar coordinates, you see

\[
\int_{|t| \leq 1} |g_\beta(y + t) - g_\beta(y)|^2 |t|^{-n-2s} dt < \infty.
\]

Now for \(|t| > 1\), the integrand in (37.3.17) is dominated by \( 4 |t|^{-n-2s} \) and using polar coordinates, this yields

\[
\int_{|t| > 1} |g_\beta(y + t) - g_\beta(y)|^2 |t|^{-n-2s} dt \leq 4 \int_{|t| > 1} |t|^{-n-2s} dt < \infty.
\]

It follows (37.3.18) is dominated by an expression of the form

\[
C(h) \int |F(u)(z)|^2 |z|^2 |z|^{2s} dz + C \|u\|_{H^m(\mathbb{R}^n)}^2
\]

and so the sum in (37.3.19) is dominated by

\[
C(m, h) \int |F(u)(z)|^2 |z|^2 \sum_{|\beta| \leq m} |z|^{2s} dz + C \|u\|_{H^m(\mathbb{R}^n)}^2
\]

\[
\leq C(m, h) \int |F(u)(z)|^2 \left(1 + |z|^2\right)^s \left(1 + |z|^2\right)^m dz + C \|u\|_{H^m(\mathbb{R}^n)}^2
\]

\[
\leq C \|u\|_{H^{m+s}(\mathbb{R}^n)}^2.
\]

This proves the theorem because the assertion about \( h^{-1} \) is obvious. Just replace \( h \) with \( h^{-1} \) in the above argument.

Next consider the case where \( U \) is an open set.

**Lemma 37.3.3** Let \( h(U) \subseteq V \) where \( U \) and \( V \) are open subsets of \( \mathbb{R}^n \) and suppose that \( h, h^{-1} : \mathbb{R}^n \to \mathbb{R}^n \) are both functions in \( C^{m,1}(\mathbb{R}^n) \). Recall this means \( D^\alpha h \) and \( D^\alpha h^{-1} \) exist and are Lipschitz continuous for all \(|\alpha| \leq m\). Then \( h^* \in \mathcal{L}(H^{m+s}(V), H^{m+s}(U)) \).

**Proof:** Let \( u \in H^{m+s}(V) \) and let \( v \in H^{m+s}(\mathbb{R}^n) \) such that \( v|_V = u \). Then from the above, \( h^* v \in H^{m+s}(\mathbb{R}^n) \) and so \( h^* u \in H^{m+s}(U) \) because \( h^* u = h^* v|_U \). Then by Lemma 37.3.2,

\[
\|h^* u\|_{H^{m+s}(U)} \leq \|h^* v\|_{H^{m+s}(\mathbb{R}^n)} \leq C \|v\|_{H^{m+s}(\mathbb{R}^n)}
\]

Since this is true for all \( v \in H^{m+s}(\mathbb{R}^n) \), it follows that

\[
\|h^* u\|_{H^{m+s}(U)} \leq C \|u\|_{H^{m+s}(V)}.
\]
With harder work, you don’t need to have $h, h^{-1}$ defined on all of $\mathbb{R}^n$ but I don’t feel like including the details so this lemma will suffice.

Another interesting application of the intrinsic norm is the following.

**Lemma 37.3.4** Let $\phi \in C^{m,1}(\mathbb{R}^n)$ and suppose $\text{spt}(\phi)$ is compact. Then there exists a constant, $C_\phi$ such that whenever $u \in H^{m+s}(\mathbb{R}^n)$,

$$
\|\phi u\|_{H^{m+s}(\mathbb{R}^n)} \leq C_\phi \|u\|_{H^{m+s}(\mathbb{R}^n)}.
$$

**Proof:** It is a routine exercise in the product rule to verify that

$$
\|\phi u\|_{H^{m+s}(\mathbb{R}^n)} \leq C_\phi \|u\|_{H^{m+s}(\mathbb{R}^n)}.
$$

It only remains to consider the term involving the integral. A typical term is

$$
\int \int |D^\alpha \phi u(x) - D^\alpha \phi u(y)|^2 |x - y|^{-n-2s} dx dy.
$$

This is a finite sum of terms of the form

$$
\int \int |D^\gamma \phi(x) D^\beta u(x) - D^\gamma \phi(y) D^\beta u(y)|^2 |x - y|^{-n-2s} dx dy
$$

where $|\gamma|$ and $|\beta| \leq m$.

$$
\leq 2 \int \int |D^\gamma \phi(x)|^2 |D^\beta u(x) - D^\beta u(y)|^2 |x - y|^{-n-2s} dx dy
$$

$$
+2 \int \int |D^\beta u(y)|^2 |D^\gamma \phi(x) - D^\gamma \phi(y)|^2 |x - y|^{-n-2s} dx dy
$$

By Lemma 37.3.10 and the Lipschitz continuity of all the derivatives of $\phi$, this is dominated by

$$
CM(s) \int \int |Fu(z)|^2 |z^\beta|^2 |z|^{2s} dz
$$

$$
+K \int \int |D^{\beta} u(y)|^2 |x - y|^2 |x - y|^{-n-2s} dx dy
$$

$$
= CM(s) \int \int |Fu(z)|^2 |z^\beta|^2 |z|^{2s} dz
$$

$$
+K \int \int |D^{\beta} u(y)|^2 \int |t|^{-n+2(1-s)} dt dy
$$

$$
\leq C(s) \left( \int |Fu(z)|^2 |z^\beta|^2 |z|^{2s} dz + K \int |D^{\beta} u(y)|^2 dy \right)
$$

$$
\leq C(s) \left( 1 + |y|^2 \right)^{m+s} |Fu(y)|^2 dy.
$$

Since there are only finitely many such terms, this proves the lemma.

**Corollary 37.3.5** Let $t = m + s$ for $s \in [0, 1)$ and let $U, V$ be open sets. Let $\phi \in C^{m,1}_c(V)$. This means $\text{spt}(\phi) \subseteq V$ and $\phi \in C^{m,1}(\mathbb{R}^n)$. Then if $u \in H^t(U)$ it follows that $u \phi \in H^t(U \cap V)$ and $\|u \phi\|_{H^t(U \cap V)} \leq C \|u\|_{H^t(U)}$. 

37.4. EMBEDDING THEOREMS

Proof: Let \(v|_U = u\) a.e. where \(v \in H^t(\mathbb{R}^n)\). Then by Lemma 37.3.4, \(\phi v \in H^t(\mathbb{R}^n)\) and \(\phi v|_{U \cap V} = \phi u\) a.e. Therefore, \(\phi u \in H^t(U \cap V)\) and

\[
\|\phi u\|_{H^t(U \cap V)} \leq \|\phi v\|_{H^t(\mathbb{R}^n)} \leq C_\phi \|v\|_{H^t(\mathbb{R}^n)}.
\]

Taking the infimum for all such \(v\) whose restrictions equal \(u\), this yields

\[
\|\phi u\|_{H^t(U \cap V)} \leq C_\phi \|u\|_{H^t(U)}.
\]

This proves the corollary.

37.4 Embedding Theorems

The Fourier transform description of Sobolev spaces makes possible fairly easy proofs of various embedding theorems.

Definition 37.4.1 Let \(C^m_b(\mathbb{R}^n)\) denote the functions which are \(m\) times continuously differentiable and for which

\[
\sup_{|\alpha| \leq m} \sup_{x \in \mathbb{R}^n} |D^\alpha u(x)| \equiv \|u\|_{C^m_b(\mathbb{R}^n)} < \infty.
\]

For \(U\) an open set, \(C^m(U)\) denotes the functions which are restrictions of \(C^m_b(\mathbb{R}^n)\) to \(U\).

It is clear this is a Banach space, the proof being a simple exercise in the use of the fundamental theorem of calculus along with standard results about uniform convergence.

Lemma 37.4.2 Let \(u \in \mathcal{S}\) and let \(\frac{n}{2} + m < t\). Then there exists \(C\) independent of \(u\) such that

\[
\|u\|_{C^m_b(\mathbb{R}^n)} \leq C \|u\|_{H^t(\mathbb{R}^n)}.
\]

Proof: Using the fact that the Fourier transform maps \(\mathcal{S}\) to \(\mathcal{S}\) and the definition of the Fourier transform,

\[
|D^\alpha u(x)| \leq C \|FD^\alpha u\|_{L^1(\mathbb{R}^n)}
\]

\[
= C \int |x^\alpha| |Fu(x)| \, dx
\]

\[
\leq C \int \left(1 + |x|^2\right)^{\frac{|\alpha|}{2}} |Fu(x)| \, dx
\]

\[
\leq C \int \left(1 + |x|^2\right)^{\frac{m}{2}} \left(1 + |x|^2\right)^{-\frac{t}{2}} \left(1 + |x|^2\right)^{\frac{t}{2}} |Fu(x)| \, dx
\]

\[
\leq C \left(\int \left(1 + |x|^2\right)^{m-t} \, dx\right)^{1/2} \left(\int \left(1 + |x|^2\right)^t |Fu(x)|^t \, dx\right)^{1/2}
\]

\[
\leq C \|u\|_{H^t(\mathbb{R}^n)}
\]
because for the given values of \( t \) and \( m \) the first integral is finite. This follows from a use of polar coordinates. Taking sup over all \( x \in \mathbb{R}^n \) and \( |\alpha| \leq m \), this proves the lemma.

**Corollary 37.4.3** Let \( u \in H^t(\mathbb{R}^n) \) where \( t > m + \frac{n}{2} \). Then \( u \) is a.e. equal to a function of \( C^m_{\mathbb{R}^n} \) still denoted by \( u \). Furthermore, there exists a constant, \( C \) independent of \( u \) such that

\[
||u||_{C^m_{\mathbb{R}^n}} \leq C ||u||_{H^t(\mathbb{R}^n)}.
\]

**Proof:** This follows from the above lemma. Let \( \{u_k\} \) be a sequence of functions of \( \mathcal{S} \) which converges to \( u \) in \( H^t \) and a.e. Then by the inequality of the above lemma, this sequence is also Cauchy in \( C^m_{\mathbb{R}^n} \) and taking the limit,

\[
||u||_{C^m_{\mathbb{R}^n}} = \lim_{k \to \infty} ||u_k||_{C^m_{\mathbb{R}^n}} \leq C \lim_{k \to \infty} ||u_k||_{H^t(\mathbb{R}^n)} = C ||u||_{H^t(\mathbb{R}^n)}.
\]

What about open sets, \( U \)?

**Corollary 37.4.4** Let \( t > m + \frac{n}{2} \) and let \( U \) be an open set with \( u \in H^t(U) \). Then \( u \) is a.e. equal to a function of \( C^m(U) \) still denoted by \( u \). Furthermore, there exists a constant, \( C \) independent of \( u \) such that

\[
||u||_{C^m(U)} \leq C ||u||_{H^t(U)}.
\]

**Proof:** Let \( u \in H^t(U) \) and let \( v \in H^t(\mathbb{R}^n) \) such that \( v|_U = u \). Then

\[
||u||_{C^m(U)} \leq ||v||_{C^m(\mathbb{R}^n)} \leq C ||v||_{H^t(\mathbb{R}^n)}.
\]

Now taking the inf for all such \( v \) yields

\[
||u||_{C^m(U)} \leq C ||u||_{H^t(U)}.
\]

### 37.5 The Trace On The Boundary Of A Half Space

It is important to consider the restriction of functions in a Sobolev space onto a smaller dimensional set such as the boundary of an open set.

**Definition 37.5.1** For \( u \in \mathcal{S} \), define \( \gamma u \) a function defined on \( \mathbb{R}^{n-1} \) by \( \gamma u(x') \equiv u(x',0) \) where \( x' \in \mathbb{R}^{n-1} \) is defined by \( x = (x',x_n) \).

The following elementary lemma featuring trig. substitutions is the basis for the proof of some of the arguments which follow.

**Lemma 37.5.2** Consider the integral,

\[
\int_\mathbb{R} (a^2 + x^2)^{-t} dx.
\]

for \( a > 0 \) and \( t > 1/2 \). Then this integral is of the form \( C_t a^{-2t+1} \) where \( C_t \) is some constant which depends on \( t \).
37.5. THE TRACE ON THE BOUNDARY OF A HALF SPACE

Proof: Letting \( x = a \tan \theta \),

\[
\int_{\mathbb{R}} \left( a^2 + x^2 \right)^{-t} \, dx = a^{-2t+1} \int_{-\pi/2}^{\pi/2} \cos^{2t-2} (\theta) \, d\theta
\]

and since \( t > 1/2 \) the last integral is finite. This yields the desired conclusion and proves the lemma.

Lemma 37.5.3 Let \( u \in \mathcal{S} \). Then there exists a constant, \( C_n \), depending on \( n \) but independent of \( u \in \mathcal{S} \) such that

\[
F \gamma u (\mathbf{x}') = C_n \int_{\mathbb{R}} F u (\mathbf{x}', x_n) \, dx_n.
\]

Proof: Using the dominated convergence theorem,

\[
\int_{\mathbb{R}} F u (\mathbf{x}', x_n) \, dx_n \equiv \lim_{\varepsilon \to 0} \int_{\mathbb{R}} e^{-(\varepsilon x_n)^2} F u (\mathbf{x}', x_n) \, dx_n
\]

\[
= \lim_{\varepsilon \to 0} \int_{\mathbb{R}} e^{-(\varepsilon x_n)^2} \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} e^{-i(x' \cdot y + \varepsilon x_n y_n)} u (\mathbf{y}', y_n) \, dy \, dy_n \, dx_n
\]

\[
= \lim_{\varepsilon \to 0} \left( \frac{1}{2\pi} \right)^{n/2} \int_{\mathbb{R}^n} u (\mathbf{y}', y_n) e^{-i\mathbf{x}' \cdot \mathbf{y}'} \int_{\mathbb{R}} e^{-(\varepsilon x_n)^2} e^{-ix_n y_n} \, dx_n \, dy \, dy_n.
\]

Now \( -\varepsilon x_n^2 - ix_n y_n = -\varepsilon^2 (x_n + \frac{iy_n}{2})^2 - \varepsilon^2 \frac{y_n^2}{4} \) and so the above reduces to an expression of the form

\[
\lim_{\varepsilon \to 0} K_n \int_{\mathbb{R}} e^{-\varepsilon^2 \mathbf{x}' \cdot \mathbf{x}'} \int_{\mathbb{R}^{n-1}} u (\mathbf{y}', y_n) e^{-i\mathbf{x}' \cdot \mathbf{y}'} \, dy \, dy_n = K_n \int_{\mathbb{R}} u (\mathbf{y}', 0) e^{-i\mathbf{x}' \cdot \mathbf{y}'} \, dy'
\]

and this proves the lemma with \( C_n \equiv K_n^{-1} \).

Earlier \( H^1 (\mathbb{R}^n) \) was defined and then for \( U \) an open subset of \( \mathbb{R}^n \), \( H^1 (U) \) was defined to be the space of restrictions of functions of \( H^1 (\mathbb{R}^n) \) to \( U \) and a norm was given which made \( H^1 (U) \) into a Banach space. The next task is to consider \( \mathbb{R}^{n-1} \times \{0\} \), a smaller dimensional subspace of \( \mathbb{R}^n \) and examine the functions defined on this set, denoted by \( \mathbb{R}^{n-1} \) for short which are restrictions of functions in \( H^1 (\mathbb{R}^n) \). You note this is somewhat different because heuristically, the dimension of the domain of the function is changing. An open set in \( \mathbb{R}^n \) is considered an \( n \) dimensional thing but \( \mathbb{R}^{n-1} \) is only \( n-1 \) dimensional. I realize this is vague because the standard definition of dimension requires a vector space and an open set is not a vector space. However, think in terms of fatness. An open set is fat in \( n \) directions whereas \( \mathbb{R}^{n-1} \) is only fat in \( n-1 \) directions. Therefore, something interesting is likely to happen.

Let \( \mathcal{S} \) denote the Schwartz class of functions on \( \mathbb{R}^n \) and \( \mathcal{S}' \) the Schwartz class of functions on \( \mathbb{R}^{n-1} \). Also, \( \mathbf{y}' \in \mathbb{R}^{n-1} \) while \( \mathbf{y} \in \mathbb{R}^n \). Let \( u \in \mathcal{S} \). Then from Lemma
and $s > 0$,

$$
\int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s |F \gamma u (y')|^2 \, dy'
= C_n \int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s \left|\int_{\mathbb{R}} F u (y', y_n) \, dy_n\right|^2 \, dy'
= C_n \int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s \left|\int_{\mathbb{R}} F u (y', y_n) \left(1 + |y|^2\right)^{t/2} \left(1 + |y|^2\right)^{-t/2} \, dy_n\right|^2 \, dy'
$$

Then by the Cauchy Schwarz inequality,

$$
\leq C_n \int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s \left|\int_{\mathbb{R}} F u (y', y_n)^2 \left(1 + |y|^2\right)^t \, dy_n\int_{\mathbb{R}} \left(1 + |y|^2\right)^{-t} \, dy_n dy'.
$$

Consider

$$
\int_{\mathbb{R}} \left(1 + |y|^2\right)^{-t} \, dy_n = \int_{\mathbb{R}} \left(1 + |y'|^2 + y_n^2\right)^{-t} \, dy_n
$$

by Lemma and taking $a = \left(1 + |y'|^2\right)^{1/2}$, this equals

$$
C_t \left(\left(1 + |y'|^2\right)^{1/2}\right)^{-2t+1} = C_t \left(1 + |y'|^2\right)^{-2t+1/2}.
$$

Now using this in

$$
\int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s |F \gamma u (y')|^2 \, dy'
\leq C_{n,t} \int_{\mathbb{R}^{n-1}} \left(1 + |y'|^2\right)^s \left|\int_{\mathbb{R}} F u (y', y_n)^2 \left(1 + |y|^2\right)^t \, dy_n\right|^2 \left(1 + |y'|^2\right)^{-2t+1/2} \, dy'.
$$

What is the correct choice of $t$ so that the above reduces to $\|u\|^2_{H^s(\mathbb{R}^n)}$? It is clearly the one for which

$$
s + (-2t + 1)/2 = 0
$$

which occurs when $t = s + 1/2$. Then for this choice of $t$, the following inequality is obtained for any $u \in \mathcal{S}$.

$$
\|\gamma u\|_{H^{s+1/2}(\mathbb{R}^{n-1})} \leq C_{n,t} \|u\|_{H^s(\mathbb{R}^n)}.
$$

This has proved part of the following theorem.
37.5. THE TRACE ON THE BOUNDARY OF A HALF SPACE

Theorem 37.5.4 For each \( t > 1/2 \) there exists a unique mapping

\[
\gamma \in \mathcal{L} \left( H^t(\mathbb{R}^n) , H^{t-1/2}(\mathbb{R}^{n-1}) \right)
\]

which has the property that for \( u \in \mathcal{S} \), \( \gamma u (x') = u (x',0) \). In addition to this, \( \gamma \) is onto. In fact, there exists a continuous map, \( \zeta \in \mathcal{L} \left( H^{t-1/2}(\mathbb{R}^{n-1}) , H^t(\mathbb{R}^n) \right) \) such that \( \gamma \circ \zeta = \text{id} \).

**Proof:** It only remains to verify that \( \gamma \) is onto and that the continuous map, \( \zeta \) exists. Now define

\[
\phi (y) \equiv \phi (y', y_n) \equiv \frac{\left( 1 + \lvert y' \rvert^2 \right)^{t-1/2}}{\left( 1 + \lvert y \rvert^2 \right)^t}.
\]

Then for \( u \in \mathcal{S}' \), let

\[
\zeta u (x) \equiv CF^{-1} (\phi Fu) (x) =
\]

\[
C \int_{\mathbb{R}^n} e^{iy' \cdot x} \frac{\left( 1 + \lvert y' \rvert^2 \right)^{t-1/2}}{\left( 1 + \lvert y \rvert^2 \right)^t} Fu (y') dy
\]

(37.5.19)

Here the inside Fourier transform is taken with respect to \( \mathbb{R}^{n-1} \) because \( u \) is only defined on \( \mathbb{R}^{n-1} \) and \( C \) will be chosen in such a way that \( \gamma \circ \zeta = \text{id} \). First the existence of \( C \) such that \( \gamma \circ \zeta = \text{id} \) will be shown. Since \( u \in \mathcal{S}' \) it follows

\[
y \rightarrow \frac{\left( 1 + \lvert y' \rvert^2 \right)^{t-1/2}}{\left( 1 + \lvert y \rvert^2 \right)^t} Fu (y')
\]

is in \( \mathcal{S} \). Hence the inverse Fourier transform of this function is also in \( \mathcal{S} \) and so for \( u \in \mathcal{S}' \), it follows \( \zeta u \in \mathcal{S} \). Therefore, to check \( \gamma \circ \zeta = \text{id} \) it suffices to plug in \( x_n = 0 \). From Lemma \ref{lem:1} this yields

\[
\gamma (\zeta u) (x',0)
\]

\[
= C \int_{\mathbb{R}^n} e^{iy' \cdot x} \frac{\left( 1 + \lvert y' \rvert^2 \right)^{t-1/2}}{\left( 1 + \lvert y \rvert^2 \right)^t} Fu (y') dy
\]

\[
= C \int_{\mathbb{R}^{n-1}} \left( 1 + \lvert y' \rvert^2 \right)^{t-1/2} e^{iy' \cdot x'} Fu (y') \int_{\mathbb{R}} \frac{1}{\left( 1 + \lvert y \rvert^2 \right)^t} dy_n dy'
\]

\[
= CC_t \int_{\mathbb{R}^{n-1}} \left( 1 + \lvert y' \rvert^2 \right)^{t-1/2} e^{iy' \cdot x'} Fu (y') \left( 1 + \lvert y' \rvert^2 \right)^{-2t+1} dy'
\]

\[
= CC_t \int_{\mathbb{R}^{n-1}} e^{iy' \cdot x'} Fu (y') dy' = CC_t (2\pi)^{n/2} F^{-1} (Fu) (x')
\]
and so the correct value of $C$ is $\left( C_t (2\pi)^{n/2} \right)^{-1}$ to obtain $\gamma \circ \zeta = \text{id}$. It only remains to verify that $\zeta$ is continuous. From \ref{Thm:inclusion-L2} and Lemma \ref{Lem:trace-lemma},
\begin{align*}
||\zeta u||_{H^1(\mathbb{R}^n)}^2 &= \int_{\mathbb{R}^n} (1+|x|^2)^t |F\zeta u(x)|^2 \, dx \\
&= C^2 \int_{\mathbb{R}^n} (1+|x|^2)^t |F (F^{-1} (\phi Fu) (x))|^2 \, dx \\
&= C^2 \int_{\mathbb{R}^n} (1+|x|^2)^t |\phi(x) Fu(x')|^2 \, dx \\
&= C^2 \int_{\mathbb{R}^n} (1+|x|^2)^t \left| \frac{(1+|x'|^2)^{t-1/2}}{(1+|x|^2)^t} Fu(x') \right|^2 \, dx \\
&= C^2 \int_{\mathbb{R}^n} (1+|x|^2)^{-t} \left| (1+|x'|^2)^{t-1/2} Fu(x') \right|^2 \, dx \\
&= C^2 \int_{\mathbb{R}^n} (1+|x'|^2)^{2t-1} |Fu(x')|^2 \int_{\mathbb{R}} (1+|x|^2)^{-t} \, dx \, dx' \\
&= C^2 C_t \int_{\mathbb{R}^n} (1+|x'|^2)^{2t-1} |Fu(x')|^2 \left( 1+|y'|^2 \right)^{-\frac{2t+1}{2}} \, dx' \\
&= C^2 C_t \int_{\mathbb{R}^n} (1+|x'|^2)^{t-1/2} |Fu(x')|^2 \, dx' = C^2 C_t ||u||_{H^{t-1/2}(\mathbb{R}^{n-1})}^2.
\end{align*}

This proves the theorem because $\mathcal{S}$ is dense in $\mathbb{R}^n$.

Actually, the assertion that $\gamma u (x') = u (x', 0)$ holds for more functions, $u$ than just $u \in \mathcal{S}$. I will make no effort to obtain the most general description of such functions but the following is a useful lemma which will be needed when the trace on the boundary of an open set is considered.

**Lemma 37.5.5** Suppose $u$ is continuous and $u \in H^1 (\mathbb{R}^n)$. Then there exists a set of $m_1$ measure zero, $N$ such that if $x_n \notin N$, then for every $\phi \in L^2 (\mathbb{R}^{n-1})$
\begin{align*}
(\gamma u, \phi)_H + \int_0^{x_n} (u, u_n (\cdot, t), \phi)_H \, dt &= (u (\cdot, x_n), \phi)_H
\end{align*}
where here
\begin{align*}
(f, g)_H &= \int_{\mathbb{R}^{n-1}} f \overline{g} \, dx',
\end{align*}
just the inner product in $L^2 (\mathbb{R}^{n-1})$. Furthermore,
\begin{align*}
u (\cdot, 0) &= \gamma u \text{ a.e. } x'.
\end{align*}
37.5. THE TRACE ON THE BOUNDARY OF A HALF SPACE

**Proof:** Let \( \{u_k\} \) be a sequence of functions from \( \mathcal{S} \) which converges to \( u \) in \( H^1(\mathbb{R}^n) \) and let \( \{\phi_k\} \) denote a countable dense subset of \( L^2(\mathbb{R}^{n-1}) \). Then

\[
(\gamma u_k, \phi_j)_H + \int_0^{x_n} (u_{k,n} (\cdot, t), \phi_j)_H dt = (u_k (\cdot, x_n), \phi_j)_H \tag{37.5.20}
\]

Now

\[
\left( \int_0^\infty \left( (u_k (\cdot, x_n), \phi_j)_H - (u (\cdot, x_n), \phi_j)_H \right)^2 dx_n \right)^{1/2} \\
= \left( \int_0^\infty \left( |u_k (\cdot, x_n) - u (\cdot, x_n)|^2 \phi_j^2 dx_n \right)^{1/2} \\
\leq |\phi_j|_H^2 \left( \int_0^\infty |u_k (\cdot, x_n) - u (\cdot, x_n)|^2 dx_n \right)^{1/2} \\
= |\phi_j|_H^2 \left( \int_0^\infty \int_{\mathbb{R}^{n-1}} |u_k (\mathbf{x}', x_n) - u (\mathbf{x}', x_n)|^2 d\mathbf{x}' dx_n \right)^{1/2}
\]

which converges to zero. Therefore, there exists a set of measure zero, \( N_j \) and a subsequence, still denoted by \( k \) such that if \( x_n \notin N_j \), then

\[
(\gamma u_k, \phi_j)_H \to (u (\cdot, x_n), \phi_j)_H.
\]

Now by Theorem 37.5.11, \( \gamma u_k \to \gamma u \) in \( H = L^2(\mathbb{R}^{n-1}) \). It only remains to consider the term of \( \gamma u_k \) which involves an integral.

\[
\left| \int_0^{x_n} (u_{k,n} (\cdot, t), \phi_j)_H dt - \int_0^{x_n} (u_n (\cdot, t), \phi_j)_H dt \right| \\
\leq \int_0^{x_n} \left| (u_{k,n} (\cdot, t) - u_n (\cdot, t), \phi_j)_H \right| dt \\
\leq \int_0^{x_n} |u_{k,n} (\cdot, t) - u_n (\cdot, t)|_H^2 \phi_j^2_H dt \\
\leq \left( \int_0^{x_n} |u_{k,n} (\cdot, t) - u_n (\cdot, t)|^2 dt \right)^{1/2} \left( \int_0^{x_n} |\phi_j|_H^2 dt \right)^{1/2} \\
= x_n^{1/2} |\phi_j|_H \left( \int_0^{x_n} \int_{\mathbb{R}^{n-1}} |u_{k,n} (\mathbf{x}', t) - u_n (\mathbf{x}', t)|^2 d\mathbf{x}' dt \right)^{1/2} \\
\]

and this converges to zero as \( k \to \infty \). Therefore, using a diagonal sequence argument, there exists a subsequence, still denoted by \( k \) and a set of measure zero, \( N \equiv \bigcup_{j=1}^\infty N_j \) such that for \( x_n \notin N \), you can pass to the limit in (37.5.20) and obtain that for all \( \phi_j \),

\[
(\gamma u, \phi_j)_H + \int_0^{x_n} (u_n (\cdot, t), \phi_j)_H dt = (u (\cdot, x_n), \phi_j)_H.
\]
By density of \( \{ \phi_j \} \), this equality holds for all \( \phi \in L^2(\mathbb{R}^{n-1}) \). In particular, the equality holds for every \( \phi \in C_c(\mathbb{R}^{n-1}) \). Since \( u \) is uniformly continuous on the compact set, \( \text{spt}(\phi) \times [0,1] \), there exists a sequence, \( (x_n)_k \to 0 \) such that the above equality holds for \( x_n \) replaced with \( (x_n)_k \) and \( \phi \) in place of \( \phi_j \). Now taking \( k \to \infty \), this uniform continuity implies

\[
(\gamma u, \phi)_H = (u(\cdot,0), \phi)_H
\]

This implies since \( C_c(\mathbb{R}^{n-1}) \) is dense in \( L^2(\mathbb{R}^{n-1}) \) that \( \gamma u = u(\cdot,0) \) a.e. and this proves the lemma.

**Lemma 37.5.6** Suppose \( U \) is an open subset of \( \mathbb{R}^n \) of the form

\[
U \equiv \{ u \in \mathbb{R}^n : u' \in U' \text{ and } 0 < u_n < \phi(u') \}
\]

where \( U' \) is an open subset of \( \mathbb{R}^{n-1} \) and \( \phi(u') \) is a positive function such that \( \phi(u') \leq \infty \) and

\[
\inf \{ \phi(u') : u' \in U' \} = \delta > 0
\]

Suppose \( v \in H^1(\mathbb{R}^n) \) such that \( v = 0 \) a.e. on \( U \). Then \( \gamma v = 0 \) \( m_{n-1} \) a.e. point of \( U' \). Also, if \( v \in H^1(\mathbb{R}^n) \) and \( \phi \in C_c^\infty(\mathbb{R}^n) \), then \( \gamma v \gamma \phi = \gamma (\phi v) \).

**Proof:** First consider the second claim. Let \( v \in H^1(\mathbb{R}^n) \) and let \( v_k \to v \) in \( H^1(\mathbb{R}^n) \) where \( v_k \in \mathcal{S} \). Then from Lemma 37.5.3 and Theorem 37.5.3

\[
||\gamma (\phi v) - \gamma \phi \gamma v||_{H^{1/2}(\mathbb{R}^{n-1})} = \lim_{k \to \infty} ||\gamma (\phi v_k) - \gamma \phi \gamma v_k||_{H^{1/2}(\mathbb{R}^{n-1})} = 0
\]

because each term in the sequence equals zero due to the observation that for \( v_k \in \mathcal{S} \) and \( \phi \in C_c^\infty(U) \), \( \gamma (\phi v_k) = \gamma v_k \gamma \phi \).

Now suppose \( v = 0 \) a.e. on \( U \). Define for \( 0 < r < \delta \), \( v_r(x) \equiv v(x', x_n + r) \).

**Claim:** If \( u \in H^1(\mathbb{R}^n) \), then

\[
\lim_{r \to 0} ||v_r - v||_{H^1(\mathbb{R}^n)} = 0.
\]

**Proof of claim:** First of all, let \( v \in \mathcal{S} \). Then \( v \in H^m(\mathbb{R}^n) \) for all \( m \) and so by Lemma 37.4.3,

\[
||v_r - v||_{H^1(\mathbb{R}^n)} \leq ||v_r - v||_{H^m(\mathbb{R}^n)} ||v_r - v||_{H^{m+1}(\mathbb{R}^n)}^{1-\theta}
\]

where \( t \in [m, m + 1] \). It follows from continuity of translation in \( L^p(\mathbb{R}^n) \) that

\[
\lim_{r \to 0} ||v_r - v||_{H^m(\mathbb{R}^n)} ||v_r - v||_{H^{m+1}(\mathbb{R}^n)}^{1-\theta} = 0
\]

and so the claim is proved if \( v \in \mathcal{S} \). Now suppose \( u \in H^1(\mathbb{R}^n) \) is arbitrary. By density of \( \mathcal{S} \) in \( H^1(\mathbb{R}^n) \), there exists \( v \in \mathcal{S} \) such that

\[
||u - v||_{H^1(\mathbb{R}^n)} < \epsilon/3.
\]
Therefore,
\[
\|u_r - u\|_{H^t(\mathbb{R}^n)} \leq \|u_r - v\|_{H^t(\mathbb{R}^n)} + \|v - v_r\|_{H^t(\mathbb{R}^n)} = 2\varepsilon/3 + \|v_r - v\|_{H^t(\mathbb{R}^n)}.
\]

Now using what was just shown, it follows that for \(r\) small enough, \(\|u_r - u\|_{H^t(\mathbb{R}^n)} < \varepsilon\) and this proves the claim.

Now suppose \(v \in H^t(\mathbb{R}^n)\). By the claim,
\[
\|v_r - v\|_{H^t(\mathbb{R}^n)} \to 0
\]
and so by continuity of \(\gamma\),
\[
\gamma v_r \to \gamma v \text{ in } H^{t-1/2}(\mathbb{R}^{n-1}). \tag{37.5.21}
\]

Note \(v_r = 0\) a.e. on
\[
U_r = \{u \in \mathbb{R}^n : u' \in U' \text{ and } -r < u_n < \phi(u') - r\}
\]

Let \(\phi \in C_c^\infty(U_r)\) and consider \(\phi v_r\). Then it follows \(\phi v_r = 0\) a.e. on \(\mathbb{R}^n\). Let \(w \equiv 0\). Then \(w \in \mathcal{S}\) and so \(\gamma w = 0 = \gamma (\phi v_r) = \gamma \phi v_r\) in \(H^{t-1/2}(\mathbb{R}^{n-1})\). It follows that for \(m_{n-1}\) a.e. \(x' \in [0 \neq 0] \cap \mathbb{R}^{n-1}, \gamma v_r(x') = 0\). Now let \(U' = \bigcup_{k=1}^\infty K_k\) where the \(K_k\) are compact sets such that \(K_k \subseteq K_{k+1}\) and let \(\phi_k \in C_c^\infty(U)\) such that \(\phi_k\) has values in \([0,1]\) and \(\phi_k(x') = 1\) if \(x' \in K_k\). Then from what was just shown, \(\gamma v_r = 0\) for a.e. point of \(K_k\). Therefore, \(\gamma v_r = 0\) for \(m_{n-1}\) a.e. point in \(U'\). Therefore, since each \(\gamma v_r = 0\), it follows from \(37.5.21\) that \(\gamma v = 0\) also. This proves the lemma.

**Theorem 37.5.7** Let \(t > 1/2\) and let \(U\) be of the form
\[
\{u \in \mathbb{R}^n : u' \in U' \text{ and } 0 < u_n < \phi(u')\}
\]
where \(U'\) is an open subset of \(\mathbb{R}^{n-1}\) and \(\phi(u')\) is a positive function such that \(\phi(u') \leq \infty\) and
\[
\inf \{\phi(u') : u' \in U'\} = \delta > 0.
\]
Then there exists a unique
\[
\gamma \in \mathcal{L}\left(H^t(U), H^{t-1/2}(U')\right)
\]
which has the property that if \(u = v|_U\) where \(v\) is continuous and also a function of \(H^1(\mathbb{R}^n)\), then \(\gamma u(x') = u(x',0)\) for a.e. \(x' \in U'\).

**Proof:** Let \(u \in H^t(U)\). Then \(u = v|_U\) for some \(v \in H^t(\mathbb{R}^n)\). Define
\[
\gamma u \equiv \gamma v|_{U'}.
\]
Is this well defined? The answer is yes because if \(v_1|_U = u\) a.e., then \(\gamma(v_1 - v_2) = 0\) a.e. on \(U'\) which implies \(\gamma v_1 = \gamma v_2\) a.e. and so the two different versions of \(\gamma u\) differ only on a set of measure zero.
If \( u = v|_U \) where \( v \) is continuous and also a function of \( H^1(\mathbb{R}^n) \), then for a.e. \( x' \in \mathbb{R}^{n-1} \), it follows from Lemma \( 37.5.5 \) on Page \( 1384 \) that \( \gamma v (x') = v (x', 0) \).

Hence, it follows that for a.e. \( x' \in U' \), \( \gamma u (x') \equiv u (x', 0) \).

In particular, \( \gamma \) is determined by \( \gamma u (x') = u (x', 0) \) on \( \mathcal{G}|_U \) and the density of \( \mathcal{G}|_U \) and continuity of \( \gamma \) shows  \( \gamma \) is unique.

It only remains to show \( \gamma \) is continuous. Let \( u \in H^1(U) \). Thus there exists \( v \in H^1(\mathbb{R}^n) \) such that \( u = v|_U \). Then

\[
||\gamma u||_{H^{s-1/2}(U')} \leq ||\gamma v||_{H^{s-1/2}(\mathbb{R}^n)} \leq C ||v||_{H^s(\mathbb{R}^n)}
\]

for \( C \) independent of \( v \). Then taking the inf for all such \( v \in H^1(\mathbb{R}^n) \) which are equal to \( u \) a.e. on \( U \), it follows

\[
||\gamma u||_{H^{s-1/2}(U')} \leq C ||v||_{H^s(\mathbb{R}^n)}
\]

and this proves \( \gamma \) is continuous.

### 37.6 Sobolev Spaces On Manifolds

#### 37.6.1 General Theory

The type of manifold, \( \Gamma \) for which Sobolev spaces will be defined on is:

**Definition 37.6.1**

1. \( \Gamma \) is a closed subset of \( \mathbb{R}^p \) where \( p \geq n \).
2. \( \Gamma = \bigcup_{i=1}^\infty \Gamma_i \) where \( \Gamma_i = \Gamma \cap W_i \) for \( W_i \) a bounded open set.
3. \( \{W_i\}_{i=1}^\infty \) is locally finite.
4. There are open bounded sets, \( U_i \) and functions \( h_i : U_i \rightarrow \Gamma_i \) which are one to one, onto, and in \( C^{m,1}(U_i) \). There exists a constant, \( C \), such that \( C \geq \text{Lip } h_r \) for all \( r \).
5. There exist functions, \( g_i : W_i \rightarrow U_i \) such that \( g_i \) is \( C^{m,1}(W_i) \), and \( g_i \circ h_i = \text{id} \) on \( U_i \) while \( h_i \circ g_i = \text{id} \) on \( \Gamma_i \).

This will be referred to as a \( C^{m,1} \) manifold.

**Lemma 37.6.2** Let \( g_i, h_i, U_i, W_i, \) and \( \Gamma_i \) be as defined above. Then

\[
g_i \circ h_k : U_k \cap h_k^{-1}(\Gamma_i) \rightarrow U_i \cap h_i^{-1}(\Gamma_k)
\]

is \( C^{m,1} \). Furthermore, the inverse of this map is \( g_k \circ h_i \).

**Proof:** First it is well to show it does indeed map the given open sets. Let \( x \in U_i \cap h_i^{-1}(\Gamma_i) \). Then \( h_i(x) \in \Gamma_i \cap \Gamma_i \) and so \( g_i(h_k(x)) \in U_i \) because \( h_k(x) \in \Gamma_i \).

Now since \( h_k(x) \in \Gamma_i \), \( g_i(h_k(x)) \in h_i^{-1}(\Gamma_i) \) also and this proves the mappings do what they should in terms of mapping the two open sets. That \( g_i \circ h_k \) is \( C^{m,1} \) follows immediately from the chain rule and the assumptions that the functions \( g_i \) and \( h_k \)
are $C^{m,1}$. The claim about the inverse follows immediately from the definitions of the functions.

Let $\{\psi_i\}_{i=1}^{\infty}$ be a partition of unity subordinate to the open cover $\{W_i\}$ satisfying $\psi_i \in C_c^\infty(W_i)$. Then the following definition provides a norm for $H^{m+s}(\Gamma)$.

**Definition 37.6.3** Let $s \in (0, 1)$ and $m$ is a nonnegative integer. Also let $\mu$ denote the surface measure for $\Gamma$ defined in the last section. A measurable function, $u$ is in $H^{m+s}(\Gamma)$ if whenever $\{W_i, \psi_i, \Gamma_i, U_i, h_i, g_i\}_{i=1}^{\infty}$ is described above, $h_i^\ast(u\psi_i) \in H^{m+s}(U_i)$ and

$$
||u||_{H^{m+s}(\Gamma)} = \left( \sum_{i=1}^{\infty} ||h_i^\ast(u\psi_i)||_{H^{m+s}(U_i)}^2 \right)^{1/2} < \infty.
$$

Are there functions which are in $H^{m+s}(\Gamma)$? The answer is yes. Just take the restriction to $\Gamma$ of any function, $u \in C_c^\infty(\mathbb{R}^m)$. Then each $h_i^\ast(u\psi_i) \in H^{m+s}(U_i)$ and the sum is finite because $\text{spt } u$ has nonempty intersection with only finitely many $W_i$.

It is not at all obvious this norm is well defined. What if $g_i$ is a Cauchy sequence in $H^{m+s}(\Gamma)$ if whenever $\{W_i, \psi_i, \Gamma_i, U_i, h_i, g_i\}_{i=1}^{\infty}$ is as just described, is a Banach space.

**Lemma 37.6.4** $H^{m+s}(\Gamma)$ as just described, is a Banach space.

**Proof:** Let $\{u_j\}_{j=1}^{\infty}$ be a Cauchy sequence in $H^{m+s}(\Gamma)$. Then $\{h_i^\ast(u_j\psi_i)\}_{j=1}^{\infty}$ is a Cauchy sequence in $H^{m+s}(U_i)$ for each $i$. Therefore, for each $i$, there exists $w_i \in H^{m+s}(U_i)$ such that

$$
\lim_{j \to \infty} h_i^\ast(u_j\psi_i) = w_i \text{ in } H^{m+s}(U_i). \quad (37.6.22)
$$

It is required to show there exists $u \in H^{m+s}(\Gamma)$ such that $w_i = h_i^\ast(u\psi_i)$ for each $i$.

Now from Corollary 37.6.2 it follows easily by approximating with simple functions that for every nonnegative $\mu$ measurable function, $f$,

$$
\int_{\Gamma} f d\mu = \sum_{r=1}^{\infty} \int_{g_r, \Gamma_r} \psi_r f(h_r(u)) J_r(u) du.
$$

Therefore,

$$
\int_{\Gamma} |u_j - u_k|^2 d\mu = \sum_{r=1}^{\infty} \int_{g_r, \Gamma_r} \psi_r |u_j - u_k|^2 (h_r(u)) J_r(u) du
\leq C \sum_{r=1}^{\infty} \int_{g_r, \Gamma_r} \psi_r |u_j - u_k|^2 (h_r(u)) du
= C \sum_{r=1}^{\infty} ||h_i^\ast \psi_r(u_j - u_k)||^2_{0,2, U_r}
\leq C||u_j - u_k||_{H^{m+s}(\Gamma)}
$$
and it follows there exists \( u \in L^2(\Gamma) \) such that
\[
|u_j - u|_{0,2,\Gamma} \to 0.
\]
and a subsequence, still denoted by \( u_j \) such that \( u_j(\mathbf{x}) \to u(\mathbf{x}) \) for \( \mu \) a.e. \( \mathbf{x} \in \Gamma \). It is required to show that \( u \in H^{m+s}(\Gamma) \) such that \( w_i = h_i^*(u \psi_i) \) for each \( i \). First of all, \( u \) is measurable because it is the limit of measurable functions. The pointwise convergence just established and the fact that sets of measure zero on \( \Gamma_i \) correspond to sets of measure zero on \( U_i \) which was discussed in the claim found in the proof of Theorem 35.2.4 on Page 1319 shows that
\[
|u_j|_{H^{m+s}(\Gamma)} \to |u|_{H^{m+s}(\Gamma)}
\]
a.e. \( \mathbf{x} \). Therefore,
\[
h_i^*(u \psi_i)(\mathbf{x}) = w_i
\]
and this shows that \( h_i^*(u \psi_i) \in H^{m+s}(U_i) \). It remains to verify that \( u \in H^{m+s}(\Gamma) \).

This follows from Fatou’s lemma. From (37.6.22)
\[
\sum_{i=1}^{\infty} |h_i^*(u_j \psi_i)|^2_{H^{m+s}(U_i)} \to \sum_{i=1}^{\infty} |h_i^*(w \psi_i)|^2_{H^{m+s}(U_i)}
\]
and so
\[
\sum_{i=1}^{\infty} |h_i^*(u \psi_i)|^2_{H^{m+s}(U_i)} \leq \lim_{j \to \infty} \sum_{i=1}^{\infty} |h_i^*(u_j \psi_i)|^2_{H^{m+s}(U_i)} = \lim_{j \to \infty} |u_j|^2_{H^{m+s}(\Gamma)} < \infty.
\]
This proves the lemma.

In fact any two such norms are equivalent. This follows from the open mapping theorem. Suppose \(|\cdot|_1\) and \(|\cdot|_2\) are two such norms and consider the norm \(|\cdot|_3 \equiv \max(|\cdot|_1, |\cdot|_2)\). Then \((H^{m+s}(\Gamma), |\cdot|_3)\) is also a Banach space and the identity map from this Banach space to \((H^{m+s}(\Gamma), |\cdot|_i)\) for \( i = 1, 2 \) is continuous. Therefore, by the open mapping theorem, there exist constants, \( C, C' \) such that for all \( u \in H^{m+s}(\Gamma) \),
\[
|u|_1 \leq |u|_3 \leq C |u|_2 \leq C |u|_3 \leq C'C |u|_1
\]
Therefore,
\[
|u|_3 \leq C |u|_2, \quad |u|_2 \leq C' |u|_1.
\]
This proves the following theorem.

**Theorem 37.6.5** Let \( \Gamma \) be described above. Defining \( H^1(\Gamma) \) as in Definition 37.6.3, any two norms like those given in this definition are equivalent.

Suppose \((\Gamma, W, U, \Gamma, h_i, g_i)\) are as defined above where \( h_i, g_i \) are \( C^{m,1} \) functions. Take \( W \), an open set in \( \mathbb{R}^p \) and define \( \Gamma' \equiv W \cap \Gamma \). Then letting
\[
W_i' \equiv W \cap W_i, \quad \Gamma_i' \equiv W_i' \cap \Gamma,
\]
and
\[ U_i' \equiv \mathbf{g}_i (\Gamma_i') = \mathbf{h}_i^{-1} (W_i' \cap \Gamma), \]

it follows that \( U_i' \) is an open set because \( \mathbf{h}_i \) is continuous and \((\Gamma', W_i', U_i', \Gamma_i', \mathbf{h}_i', \mathbf{g}_i')\) is also a \( C^{m,1} \) manifold if you define \( \mathbf{h}_i' \) to be the restriction of \( \mathbf{h}_i \) to \( U_i' \) and \( \mathbf{g}_i' \) to be the restriction of \( \mathbf{g}_i \) to \( W_i' \).

As a case of this, consider a \( C^{m,1} \) manifold, \( \Gamma \) where \((\Gamma, W_i, U_i, \Gamma_i, \mathbf{h}_i, \mathbf{g}_i)\) are as described in Definition 37.6.1 and the submanifold consisting of \( \Gamma_i \). The next lemma shows there is a simple way to define a norm on \( H^k (\Gamma_i) \) which does not depend on dragging in a partition of unity.

**Lemma 37.6.6** Suppose \( \Gamma \) is a \( C^{m,1} \) manifold and \((\Gamma, W_i, U_i, \Gamma_i, \mathbf{h}_i, \mathbf{g}_i)\) are as described in Definition 37.6.1. Then for \( t \in [m, m + s) \), it follows that if \( u \in H^t (\Gamma) \), then \( u \in H^t (\Gamma_i) \) and the restriction map is continuous. Also an equivalent norm for \( H^t (\Gamma_i) \) is given by

\[ \|u\|_i \equiv \| \mathbf{h}_i^* u \|_{H^t (\Gamma_i)}. \]

**Proof:** Let \( u \in H^t (\Gamma) \) and let \((\Gamma_i, W_i', U_i', \Gamma_i', \mathbf{h}_i', \mathbf{g}_i')\) be the sets and functions which define what is meant by \( \Gamma_i \) being a \( C^{m,1} \) manifold as described in Definition 37.6.1. Also let \((\Gamma, W_i, U_i, \Gamma_i, \mathbf{h}_i, \mathbf{g}_i)\) be pertain to \( \Gamma \) in the same way and let \( \{ \phi_j \} \) be a \( C^\infty \) partition of unity for the \( \{ W_j \} \). Since the \( \{ W_i' \} \) are locally finite, only finitely many can intersect \( \Gamma_i \), say \( \{ W_1', \cdots, W_q' \} \). Also only finitely many of the \( W_i \) can intersect \( \Gamma_i \), say \( \{ W_1, \cdots, W_q \} \). Then letting \( \{ \psi_i' \} \) be a \( C^\infty \) partition of unity subordinate to the \( \{ W_i' \} \).

\[
\begin{align*}
\sum_{i=1}^{\infty} \| \mathbf{h}_i^* (u \psi_i') \|_{H^t (U_i')} \\
= \sum_{i=1}^{s} \left\| \mathbf{h}_i^* \left( \sum_{j=1}^{q} \phi_j u \psi_i' \right) \right\|_{H^t (U_i')} \\
\leq \sum_{i=1}^{s} \sum_{j=1}^{q} \| \mathbf{h}_i^* \phi_j u \psi_i' \|_{H^t (U_i')} \\
= \sum_{j=1}^{q} \sum_{i=1}^{s} \| \mathbf{h}_i^* \phi_j u \psi_i' \|_{H^t (U_i')} \\
= \sum_{j=1}^{q} \sum_{i=1}^{s} \| (\mathbf{g}_j \circ \mathbf{h}_i')^* \mathbf{h}_j^* \phi_j u \psi_i' \|_{H^t (U_i')}. 
\end{align*}
\]

By Lemma 37.6.6 on page 1379, there exists a single constant, \( C \) such that the above is dominated by

\[ C \sum_{j=1}^{q} \sum_{i=1}^{s} \| \mathbf{h}_j^* \phi_j u \psi_i' \|_{H^t (U_i')}. \]
Now by Corollary 37.3.5 on Page 1378, this is no larger than

\[ C \sum_{j=1}^{q} \sum_{i=1}^{s} C_{\psi_j'} \left| h_j^* \phi_j u \right|_{H^t(U_j)} \leq C \sum_{j=1}^{q} \sum_{i=1}^{s} \left| h_j^* \phi_j u \right|_{H^t(U_j)} \]

\[ \leq C \sum_{j=1}^{q} \left| h_j^* \phi_j u \right|_{H^t(U_j)} < \infty. \]

This shows that \( u \) restricted to \( \Gamma_k \) is in \( H^t(\Gamma_k) \). It also shows that the restriction map of \( H^t(\Gamma) \) to \( H^t(\Gamma_k) \) is continuous.

Now consider the norm \( \| \cdot \|_t \). For \( u \in H^t(\Gamma_k) \), let \( (\Gamma_k, W'_i, U'_i, \Gamma'_i, h'_i, g'_i) \) be sets and functions which define an atlas for \( \Gamma_k \). Since the \( \{W'_i\} \) are locally finite, only finitely many can have nonempty intersection with \( \Gamma_k \), say \( \{W_1, \ldots, W_s\} \). Thus \( i \leq s \) for some finite \( s \). The problem is to compare \( \| \cdot \|_t \) with \( \| \cdot \|_{H^t(U_k)} \). As above, let \( \{\psi'_j\} \) denote a \( C^\infty \) partition of unity subordinate to the \( \{W'_j\} \). Then

\[ \|u\|_t \equiv \left\| h_k^* u \right\|_{H^t(U_k)} = \left\| h_k^* \sum_{j=1}^{s} \psi_j' u \right\|_{H^t(U_k)} \]

\[ \leq \sum_{j=1}^{s} \left\| h_j^* (\psi_j' u) \right\|_{H^t(U_k)} \]

\[ = \sum_{j=1}^{s} \left\| (g'_j \circ h_k)^* h_j^* (\psi_j' u) \right\|_{H^t(U_k)} \]

\[ \leq C \sum_{j=1}^{s} \left\| h_j^* (\psi_j' u) \right\|_{H^t(U'_j)} \]

\[ \leq C \left( \sum_{j=1}^{s} \left( \left\| h_j^* (\psi_j' u) \right\|_{H^t(U'_j)}^2 \right) \right)^{1/2} = \|u\|_{H^t(\Gamma_k)}. \]

where Lemma 37.3.4 on page 1378 was used in the last step. Now also, from Lemma
This proves the lemma.

### 37.6.2 The Trace On The Boundary

**Definition 37.6.7** A bounded open subset, $\Omega$, of $\mathbb{R}^n$ has a $C^{m,1}$ boundary if it satisfies the following conditions. For each $p \in \Gamma \equiv \overline{\Omega} \setminus \Omega$, there exists an open set, $W$, containing $p$, an open interval $(0, b)$, a bounded open box $U' \subseteq \mathbb{R}^{n-1}$, and an affine orthogonal transformation, $R_W$ consisting of a distance preserving linear transformation followed by a translation such that

$$R_W W = U' \times (0, b),$$

$$R_W (W \cap \Omega) = \{ u \in \mathbb{R}^n : u' \in U', \ 0 < u_n < \phi_W (u') \} \equiv U_W$$

where $\phi_W \in C^{m,1}(U')$ meaning $\phi_W$ is the restriction to $U'$ of a function, still denoted by $\phi_W$ which is in $C^{m,1}(\mathbb{R}^{n-1})$ and

$$\inf \{ \phi_W (u') : u' \in U' \} > 0$$

The following picture depicts the situation.
For the situation described in the above definition, let \( h_W : U' \to \Gamma \cap W \) be defined by

\[
h_W(u') \equiv R_W^{-1}(u', \phi_W(u')) , \quad g_W(x) \equiv (R_W x)' , \quad H_W(u) \equiv R_W^{-1}(u', \phi_W(u') - u_n),
\]

where \( x' \equiv (x_1, \ldots, x_{n-1}) \) for \( x = (x_1, \ldots, x_n) \). Thus \( g_W \circ h_W = \text{id} \) on \( U' \) and \( h_W \circ g_W = \text{id} \) on \( \Gamma \cap W \). Also note that \( H_W \) is defined on all of \( \mathbb{R}^n \) is \( C^{m,1} \), and has an inverse with the same properties. To see this, let \( G_W(u) = (u', \phi_W(u') - u_n) \). Then \( H_W = R_W^{-1} \circ G_W \) and \( G_W^{-1} = (u', \phi_W(u') - u_n) \) and so \( H_W = G_W^{-1} \circ R_W \).

Note also that as indicated in the picture,

\[
R_W(W \cap \Omega) = \{ u \in \mathbb{R}^n : u' \in U' \text{ and } 0 < u_n < \phi_W(u') \}.
\]

Since \( \Gamma = \partial \Omega \) is compact, there exist finitely many of these open sets, \( W \), denoted by \( \{W_i\}_{i=1}^q \) such that \( \Gamma \subseteq \bigcup_{i=1}^q W_i \). Let the corresponding sets, \( U' \) be denoted by \( U'_i \) and let the functions, \( \phi \) be denoted by \( \phi_i \). Also let \( h_i = h_{W_i} \), etc. Now let \( \{\psi_i\}_{i=1}^q \) be a \( C^\infty \) partition of unity subordinate to the \( \{W_i\}_{i=1}^q \). If \( u \in H^t(\Omega) \), then by Corollary 37.6.8 on Page 1394 it follows that \( u\psi_i \in H^t(W_i \cap \Omega) \). Now

\[
H_i : U_i \equiv \{ u \in \mathbb{R}^n : u' \in U'_i, 0 < u_n < \phi_i(u') \} \to W_i \cap \Omega
\]

and \( H_i \) and its inverse are defined on \( \mathbb{R}^n \) and are in \( C^{m,1}(\mathbb{R}^n) \). Therefore, by Lemma 37.6.4 on Page 1394

\[
H_i^* \in \mathcal{L}(H^t(W_i \cap \Omega), H^t(U_i)).
\]

Provide \( t = m + s \) where \( s > 0 \).

Now it is possible to define the trace on \( \Gamma \equiv \partial \Omega \). For \( u \in H^t(\Omega) \),

\[
\gamma u \equiv \sum_{i=1}^q g_i^* \left( \gamma H_i^* (u \psi_i) \right).
\]  \hspace{1cm} (37.6.25)

I must show it satisfies what it should. Recall the definition of what it means for a function to be in \( H^{t-1/2}(\Gamma) \) where \( t = m + s \).

**Definition 37.6.8** Let \( s \in (0,1) \) and \( m \) is a nonnegative integer. Also let \( \mu \) denote the surface measure for \( \Gamma \). A \( \mu \) measurable function, \( u \) is in \( H^{m+s}(\Gamma) \) if whenever \( \{W_i, \psi_i, \Gamma_i, U_i, h_i, g_i\}_{i=1}^\infty \) is described above, \( h_i^* (u \psi_i) \in H^{m+s}(U_i) \) and

\[
||u||_{H^{m+s}(\Gamma)} \equiv \left( \sum_{i=1}^\infty ||h_i^* (u \psi_i)||_{H^{m+s}(U_i)}^2 \right)^{1/2} < \infty.
\]

Recall that all these norms which are obtained from various partitions of unity and functions, \( h_i \) and \( g_i \), are equivalent. Here there are only finitely many \( W_i \) so the sum is a finite sum. The theorem is the following.
Theorem 37.6.9 Let $\Omega$ be a bounded open set having $C^{m,1}$ boundary as discussed above in Definition 37.6.7. Then for $t \leq m + 1$, there exists a unique

$$\gamma \in \mathcal{L} \left( H^t(\Omega), H^{t-1/2}(\Gamma) \right)$$

which has the property that for $\mu$ the measure on the boundary,

$$\gamma u(x) = u(x) \text{ for } \mu \text{ a.e. } x \in \Gamma \text{ whenever } u \in \mathcal{S}_\Omega.$$  \hspace{1cm} (37.6.26)

Proof: First consider the claim that $\gamma \in \mathcal{L} \left( H^t(\Omega), H^{t-1/2}(\Gamma) \right)$. This involves first showing that for $u \in H^t(\Omega), \gamma u \in H^{t-1/2}(\Gamma)$. To do this, use the above definition.

$$h_j^* (\psi_j (\gamma u)) = \sum_{i=1}^{q} h_i^* (\psi_j g_i^* (\gamma H_i^* (u \psi_i)))$$

$$= \sum_{i=1}^{q} (h_j^* \psi_j) (h_i^* (g_i^* (\gamma H_i^* (u \psi_i))))$$

$$= \sum_{i=1}^{q} (h_j^* \psi_j) (g_i \circ h_j)^* (\gamma H_i^* (u \psi_i))$$ \hspace{1cm} (37.6.27)

First note that

$$\gamma H_i^* (u \psi_i) \in H^{t-1/2}(U'_i)$$

Now $g_i \circ h_j$ and its inverse, $g_j \circ h_i$, are both functions in $C^{m,1} (\mathbb{R}^{n-1})$ and

$$g_i \circ h_j : U'_j \to U'_i.$$ 

Therefore, by Lemma 37.3.3 on Page 1378,

$$(g_i \circ h_j)^* (\gamma H_i^* (u \psi_i)) \in H^{t-1/2}(U'_j)$$

and

$$|| (g_i \circ h_j)^* (\gamma H_i^* (u \psi_i)) ||_{H^{t-1/2}(U'_j)} \leq C_{ij} || \gamma H_i^* (u \psi_i) ||_{H^{t-1/2}(U'_i)}. \hspace{1cm} (37.6.28)$$

Also $h_j^* \psi_j \in C^{m,1} (U'_j)$ and has compact support in $U'_j$ and so by Corollary 37.3.5 on Page 1378

$$(h_j^* \psi_j) (g_i \circ h_j)^* (\gamma H_i^* (u \psi_i)) \in H^{t-1/2}(U'_j)$$

and

$$|| (h_j^* \psi_j) (g_i \circ h_j)^* (\gamma H_i^* (u \psi_i)) ||_{H^{t-1/2}(U'_j)}$$

$$\leq C_{ij} || (g_i \circ h_j)^* (\gamma H_i^* (u \psi_i)) ||_{H^{t-1/2}(U'_j)} \leq C_{ij} || \gamma H_i^* (u \psi_i) ||_{H^{t-1/2}(U'_i)}. \hspace{1cm} (37.6.29)$$
CHAPTER 37. SOBOLEV SPACES BASED ON $L^2$

This shows $\gamma u \in H^{t-1/2} (\Gamma)$ because each $h_j^* (\psi_j (\gamma u)) \in H^{t-1/2} (U_j')$. Also from (37.6.29) and (37.6.27)

$$\|\gamma u\|^2_{H^{t-1/2} (\Gamma)} \leq \sum_{j=1}^{q} \|h_j^* (\psi_j (\gamma u))\|^2_{H^{t-1/2} (U_j')}$$

$$= \sum_{j=1}^{q} \|h_j^* (\psi_j (\gamma u))\|^2_{H^{t-1/2} (U_j')}$$

$$= \sum_{j=1}^{q} \left( \sum_{i=1}^{q} (h_j^* \psi_j) (g_i \circ h_j)^* (\gamma H_i^* (u\psi_i)) \right)^2_{H^{t-1/2} (U_j')}$$

$$\leq C_q \sum_{j=1}^{q} \left( \sum_{i=1}^{q} (h_j^* \psi_j) (g_i \circ h_j)^* (\gamma H_i^* (u\psi_i)) \right)^2_{H^{t-1/2} (U_j')}$$

$$\leq C_q \sum_{j=1}^{q} \sum_{i=1}^{q} \|H_i^* (u\psi_i)\|^2_{H^{t-1/2} (U_j')}$$

$$\leq C_q \sum_{i=1}^{q} \|H_i^* (u\psi_i)\|^2_{H^t (\Omega)}$$

$$\leq C_q \sum_{i=1}^{q} \|u\psi_i\|^2_{H^t (\Omega)} \leq C_q \|u\|^2_{H^t (\Omega)}.$$

Does $\gamma$ satisfy (37.6.28)? Let $x \in \Gamma$ and $u \in \mathcal{S}_{|\Omega}$. Let

$$I_x \equiv \{i \in \{1, 2, \cdots, q\} : x = h_i (u'_i) \text{ for some } u'_i \in U_i' \}.$$ Then

$$\gamma u (x) = \sum_{i \in I_x} (\gamma H_i^* (u\psi_i)) (g_i (x))$$

$$= \sum_{i \in I_x} (\gamma H_i^* (u\psi_i)) (g_i (h_i (u'_i)))$$

$$= \sum_{i \in I_x} (\gamma H_i^* (u\psi_i)) (u'_i).$$

Now because $H_i$ is Lipschitz continuous and $u\psi \in \mathcal{S}$, it follows that $H_i^* (u\psi_i) \in$
$H^1(\mathbb{R}^n)$ and is continuous and so by Theorem 37.5.7 on Page 1387 for a.e. $u'_i,$

\[
\begin{align*}
    &= \sum_{i \in I_x} \mathbf{H}^i (u \psi_i) (u'_i, 0) \\
    &= \sum_{i \in I_x} h^i (u \psi_i) (u'_i) \\
    &= \sum_{i \in I_x} (u \psi_i) (h_i (u'_i)) = u(x) \text{ for } \mu \text{ a.e. } x. \quad (37.6.30)
\end{align*}
\]

This verifies 37.6.26 and completes the proof of the theorem.
Chapter 38

Weak Solutions

38.1 The Lax Milgram Theorem

The Lax Milgram theorem is a fundamental result which is useful for obtaining weak solutions to many types of partial differential equations. It is really a general theorem in functional analysis.

Definition 38.1.1 Let $A \in \mathcal{L}(V, V')$ where $V$ is a Hilbert space. Then $A$ is said to be coercive if

$$A(v)(v) \geq \delta ||v||^2$$

for some $\delta > 0$.

Theorem 38.1.2 (Lax Milgram) Let $A \in \mathcal{L}(V, V')$ be coercive. Then $A$ maps one to one and onto.

Proof: The proof that $A$ is onto involves showing $A(V)$ is both dense and closed.

Consider first the claim that $A(V)$ is closed. Let $A x_n \rightarrow y^* \in V'$. Then

$$\delta ||x_n - x_m||_V^2 \leq ||A x_n - A x_m||_{V'} ||x_n - x_m||_V .$$

Therefore, $\{x_n\}$ is a Cauchy sequence in $V$. It follows $x_n \rightarrow x \in V$ and since $A$ is continuous, $A x_n \rightarrow A x$. This shows $A(V)$ is closed.

Now let $R : V \rightarrow V'$ denote the Riesz map defined by $R x (y) = (y, x)$. Recall that the Riesz map is one to one, onto, and preserves norms. Therefore, $R^{-1}(A(V))$ is a closed subspace of $V$. If there $R^{-1}(A(V)) \neq V$, then $(R^{-1}(A(V)))^\perp \neq \{0\}$. Let $x \in (R^{-1}(A(V)))^\perp$ and $x \neq 0$. Then in particular,

$$0 = (x, R^{-1}A x) = R \left( R^{-1} (A(x)) \right) (x) = A(x)(x) \geq \delta ||x||^2_V ,$$

a contradiction to $x \neq 0$. Therefore, $R^{-1}(A(V)) = V$ and so $A(V) = R(V) = V'$.
CHAPTER 38. WEAK SOLUTIONS

Since \( A(V) \) is both closed and dense, \( A(V) = V' \). This shows \( A \) is onto.

If \( Ax = Ay \), then \( 0 = A(x - y)(x - y) \geq \delta ||x - y||_V^2 \), and this shows \( A \) is one to one. This proves the theorem.

Here is a simple example which illustrates the use of the above theorem. In the example the repeated index summation convention is being used. That is, you sum over the repeated indices.

**Example 38.1.3** Let \( U \) be an open subset of \( \mathbb{R}^n \) and let \( V \) be a closed subspace of \( H^1(U) \). Let \( \alpha^{ij} \in L^\infty(U) \) for \( i, j = 1, 2, \cdots, n \). Now define \( A : V \to V' \) by

\[
A(u)(v) = \int_U \left( \alpha^{ij}(x) u_i(x) v_j(x) + u(x) v(x) \right) dx.
\]

Suppose also that

\[
\alpha^{ij} v_i v_j \geq \delta |v|^2
\]

whenever \( v \in \mathbb{R}^n \). Then \( A \) maps \( V \) to \( V' \) one to one and onto.

Here is why. It is obvious that \( A \) is in \( \mathcal{L}(V, V') \). It only remains to verify that it is coercive.

\[
A(u)(u) = \int_U \left( \alpha^{ij}(x) u_i(x) u_j(x) + u(x) u(x) \right) dx \geq \int_U \delta |\nabla u(x)|^2 + |u(x)|^2 dx \geq \delta ||u||_{H^1(U)}^2
\]

This proves coercivity and verifies the claim.

What has been obtained in the above example? This depends on how you choose \( V \). In Example 38.1.3 suppose \( U \) is a bounded open set with \( C^{0,1} \) boundary and \( V = H^1_0(U) \) where

\[
H^1_0(U) = \{ u \in H^1(U) : \gamma u = 0 \}.
\]

Also suppose \( f \in L^2(U) \). Then you can consider \( F \in V' \) by defining

\[
F(v) = \int_U f(x) v(x) dx.
\]

According to the Lax–Milgram theorem and the verification of its conditions in Example 38.1.3, there exists a unique solution to the problem of finding \( u \in H^1_0(U) \) such that for all \( v \in H^1_0(U) \),

\[
\int_U \left( \alpha^{ij}(x) u_i(x) v_j(x) + u(x) v(x) \right) dx = \int_U f(x) v(x) dx \tag{38.1.1}
\]

In particular, this holds for all \( v \in C_\infty^\infty(U) \). Thus for all such \( v \),

\[
\int_U \left( - (\alpha^{ij}(x) u_i(x)) v_j(x) + u(x) - f(x) \right) v(x) dx = 0.
\]
38.1. THE LAX MILGRAM THEOREM

Therefore, in terms of weak derivatives,

\[-(\alpha^{ij} u_{,i})_{,j} + u = f\]

and since \(u \in H^1_0(U)\), it must be the case that \(\gamma u = 0\) on \(\partial U\). This is why the solution to (38.1.1) is referred to as a weak solution to the boundary value problem

\[-(\alpha^{ij}(x) u_{,i}(x))_{,j} + u(x) = f(x), \quad u = 0 \text{ on } \partial U.\]

Of course you then begin to ask the important question whether \(u\) really has two derivatives. It is not immediately clear that just because \(-(\alpha^{ij}(x) u_{,i}(x))_{,j} \in L^2(U)\) it follows that the second derivatives of \(u\) exist. Actually this will often be true and is discussed somewhat in the next section.

Next suppose you choose \(V = H^1(U)\) and let \(g \in H^{1/2}(\partial U)\). Define \(F \in V'\) by

\[F(v) = \int_U f(x) v(x) \, dx + \int_{\partial U} g(x) \gamma v(x) \, d\mu.\]

Everything works the same way and you get the existence of a unique \(u \in H^1(U)\) such that for all \(v \in H^1(U)\),

\[\int_U (\alpha^{ij}(x) u_{,i}(x) v_{,j}(x) + u(x) v(x)) \, dx = \int_U f(x) v(x) \, dx + \int_{\partial U} g(x) \gamma v(x) \, d\mu\]

is satisfied. If you pretend \(u\) has all second order derivatives in \(L^2(U)\) and apply the divergence theorem, you find that you have obtained a weak solution to

\[-(\alpha^{ij} u_{,i})_{,j} + u = f, \quad \alpha^{ij} u_{,i} n_j = g \text{ on } \partial U\]

where \(n_j\) is the \(j\)th component of \(n\), the unit outer normal. Therefore, \(u\) is a weak solution to the above boundary value problem.

The conclusion is that the Lax Milgram theorem gives a way to obtain existence and uniqueness of weak solutions to various boundary value problems. The following theorem is often very useful in establishing coercivity. To prove this theorem, here is a definition.

**Definition 38.1.4** Let \(U\) be an open set and \(\delta > 0\). Then

\[U_\delta \equiv \{x \in U : \text{dist}(x,U^C) > \delta\} .\]

**Theorem 38.1.5** Let \(U\) be a connected bounded open set having \(C^{0,1}\) boundary such that for some sequence, \(\eta_k \downarrow 0\),

\[U = \bigcup_{k=1}^\infty U_{\eta_k} \quad (38.1.3)\]

and \(U_{\eta_k}\) is a connected open set. Suppose \(\Gamma \subseteq \partial U\) has positive surface measure and that

\[V \equiv \{u \in H^1(U) : \gamma u = 0 \text{ a.e. on } \Gamma\} .\]
Then the norm \( |||\cdot||| \) given by
\[
|||u||| = \left( \int_U |\nabla u|^2 \, dx \right)^{1/2}
\]
is equivalent to the usual norm on \( V \).

**Proof:** First it is necessary to verify this is actually a norm. It clearly satisfies all the usual axioms of a norm except for the condition that \( |||u||| = 0 \) if and only if \( u = 0 \). Suppose then that \( |||u||| = 0 \). Let \( \delta_0 = \eta_k \) for one of those \( \eta_k \) mentioned above and define
\[
u(k) = \int_{B(0, \delta)} u(x - y) \phi_{\delta} (y) \, dy
\]
where \( \phi_{\delta} \) is a mollifier having support in \( B(0, \delta) \). Then changing the variables, it follows that for \( x \in U_{\delta_0} \)
\[
\nabla \nu(k) (x) = \int_U u(t) \nabla \phi_{\delta} (x - t) \, dt = \int_{B(0, \delta)} \nabla u(x - y) \phi_{\delta} (y) \, dy = 0.
\]
Therefore, \( u_\delta \) equals a constant on \( U_{\delta_0} \) because \( U_{\delta_0} \) is a connected open set and \( u_\delta \) is a smooth function defined on this set which has its gradient equal to \( 0 \). By Minkowski’s inequality,
\[
\left( \int_{U_{\delta_0}} |u(x) - u_\delta(x)|^2 \, dx \right)^{1/2} \leq \int_{B(0, \delta)} \phi_{\delta} (y) \left( \int_{U_{\delta_0}} |u(x) - u(x - y)|^2 \, dx \right)^{1/2} \, dy
\]
and this converges to 0 as \( \delta \to 0 \) by continuity of translation in \( L^2 \). It follows there exists a sequence of constants, \( c_\delta \equiv u_\delta(x) \) such that \( \{c_\delta\} \) converges to \( u \) in \( L^2(U_{\delta_0}) \). Consequently, a subsequence, still denoted by \( u_\delta \), converges to \( u \) a.e. By Eggoroff’s theorem there exists a set, \( N_k \) having measure no more than \( 3^{-k}m_n(U_{\delta_0}) \) such that \( u_\delta \) converges to \( u \) uniformly on \( N_k^c \). Thus \( u \) is constant on \( N_k^c \). Now \( \sum_k m_n(N_k) \leq \frac{1}{2}m_n(U_{\delta_0}) \) and so there exists \( x_0 \in U_{\delta_0} \setminus \bigcup_{k=1}^{\infty} N_k \). Therefore, if \( x \notin N_k \) it follows \( u(x) = u(x_0) \) and so, if \( u(x) \neq u(x_0) \) it must be the case that \( x \in \bigcap_{k=1}^{\infty} N_k \), a set of measure zero. This shows that \( u \) equals a constant a.e. on \( U_{\delta_0} = U_{\delta_0} \). Since \( k \) is arbitrary, \( \text{**Lemma**} \) shows \( u \) is a.e. equal to a constant on \( U \). Therefore, \( u \) equals the restriction of a function of \( \mathcal{G} \) to \( U \) and so \( \gamma u \) equals this constant in \( L^2(\partial \Omega) \). Since the surface measure of \( \Gamma \) is positive, the constant must equal zero. Therefore, \( |||\cdot||| \) is a norm.
It remains to verify that it is equivalent to the usual norm. It is clear that 
\[ ||u|| \leq ||u||_{1,2}. \] What about the other direction? Suppose it is not true that for some constant, \( K, \) \[ ||u||_{1,2} \leq K ||u||. \] Then for every \( k \in \mathbb{N}, \) there exists \( u_k \in V \) such that 
\[ ||u_k||_{1,2} > k ||u||. \]
Replacing \( u_k \) with \( u_k/||u_k||_{1,2}, \) it can be assumed that \( ||u_k||_{1,2} = 1 \) for all \( k. \)
Therefore, using the compactness of the embedding of \( H^1(U) \) into \( L^2(U), \) there exists a subsequence, still denoted by \( u_k \) such that
\[ u_k \rightarrow u \text{ weakly in } V, \]
\[ u_k \rightarrow u \text{ strongly in } L^2(U), \]
\[ ||u_k|| \rightarrow 0, \]
\[ u_k \rightarrow u \text{ weakly in } (V, ||||||). \]
From 38.1.6 and 38.1.7 it follows \( u = 0. \) Therefore, \( |u_k|_{L^2(U)} \rightarrow 0. \) This with 38.1.6 contradicts the fact that \( ||u_k||_{1,2} = 1 \) and this proves the equivalence of the two norms.

The proof of the above theorem yields the following interesting corollary.

**Corollary 38.1.6** Let \( U \) be a connected open set with the property that for some sequence, \( \eta_k \downarrow 0, \)
\[ U = \bigcup_{k=1}^{\infty} U_{\eta_k} \]
for \( U_{\eta_k} \) a connected open set and suppose \( u \in W^{1,p}(U) \) and \( \nabla u = 0 \text{ a.e.} \) Then \( u \) equals a constant a.e.

**Example 38.1.7** Let \( U \) be a bounded open connected subset of \( \mathbb{R}^n \) and let \( V \) be a closed subspace of \( H^1(U) \) defined by
\[ V \equiv \{ u \in H^1(U): \gamma u = 0 \text{ on } \Gamma \} \]
where the surface measure of \( \Gamma \) is positive.
Let \( \alpha^{ij} \in L^\infty(U) \) for \( i, j = 1, 2, \ldots, n \) and define \( A: V \rightarrow V' \) by
\[ A(u)(v) \equiv \int_U \alpha^{ij}(x) u_{,i}(x) v_{,j}(x) \, dx. \]
for \( \alpha^{ij} v_i v_j \geq \delta |v|^2 \)
whenever \( v \in \mathbb{R}^n. \) Then \( A \) maps \( V \) to \( V' \) one to one and onto.

This follows from Theorem 38.1.5 using the equivalent norm defined there. Define \( F \in V' \) by
\[ \int_U f(x) v(x) \, dx + \int_{\partial U \setminus \Gamma} g(x) \gamma v(x) \, dx \]
for \( f \in L^2(U) \) and \( g \in H^{1/2}(\partial U) \). Then the equation,
\[
Au = F \text{ in } V'
\]
which is equivalent to \( u \in V \) and for all \( v \in V 
\[
\int_U \alpha^{ij}(x) u_i(x) v_j(x) \, dx = \int_U f(x) v(x) \, dx + \int_{\partial U \setminus \Gamma} g(x) \gamma v(x) \, d\mu
\]
is a weak solution for the boundary value problem,
\[
- \frac{\partial u_i}{\partial x_i} = f \text{ in } U, \quad \frac{\partial u_i}{\partial x_i} n_j = g \text{ on } \partial U \setminus \Gamma, \quad u = 0 \text{ on } \Gamma
\]
as you can verify by using the divergence theorem formally.

### 38.2 An Application Of The Mountain Pass Theorem

Recall the mountain pass theorem \[22.1.3\].

**Theorem 38.2.1** Let \( H \) be a Hilbert space and let \( I : H \to \mathbb{R} \) be a \( C^1 \) functional having \( I' \) Lipschitz continuous and such that \( I \) satisfies the Palais Smale condition. Suppose \( I(0) = 0 \) and \( I(u) \geq a > 0 \) for all \( \|u\| = r \). Suppose also that there exists \( v, \|v\| > r \) such that \( I(v) = 0 \). Then define
\[
\Gamma \equiv \{ g \in C([0,1];H) : g(0) = 0, g(1) = v \}
\]
Let
\[
c \equiv \inf_{g \in \Gamma} \max_{0 \leq t \leq 1} I(g(t))
\]
Then \( c \) is a critical value of \( I \) meaning that there exists \( u \) such that \( I(u) = c \) and \( I'(u) = 0 \). In particular, there is \( u \neq 0 \) such that \( I'(u) = 0 \).

This nice example is in Evans \[46\]. Let the Hilbert space be \( H^1_0(U) \) where \( U \) is a bounded open set. To avoid cases, assume \( U \) is in \( \mathbb{R}^3 \) or higher. The main results will work in general but it would involve cases. Consider the functional
\[
\frac{1}{2} \|u\|^2_{H^1_0} - \int_U F(u) \, dx \equiv I_1(u) - I_2(u)
\]
where \( F'(u) = f(u) \), \( f(0) = 0 \). Here it is assumed that
\[
|f(u)| \leq C(1 + |u|^p), \quad |f'(u)| \leq C \left( 1 + |u|^{p-1} \right), \quad 1 < p < \frac{n+2}{n-2} \tag{38.2.8}
\]
Also suppose that
\[
0 \leq F(u) \leq \gamma f(u) u \quad \text{where } 0 < \gamma < 1/2 \tag{38.2.9}
\]
and finally that
\[
\alpha |u|^{p+1} \leq F(u) \leq A |u|^{p+1}, \quad \alpha, A > 0 \tag{38.2.10}
\]
Let \( R : H^1_0(U) \to H^{-1}(U) \) be the Riesz map.
38.2. AN APPLICATION OF THE MOUNTAIN PASS THEOREM

Showing Functional is $C^{1,1}$

Then it is not hard to verify that $(I_1(u), v) = (u, v)$ and so it is clearly the case that $I'(u)$ exists and is a continuous function of $u$. In addition to this, it is Lipschitz.

Next consider $I_2$.

$$I_2(u + v) - I_2(u) = \int_U F(u + v) - F(u) \, dx$$

$$= \int_U f(u) v + \frac{1}{2} f'(\hat{u}) v^2 \, dx, \quad \hat{u} \in [u, u + v]$$

Now $H^1_0(U)$ embeds continuously into $L^{2n/(n-2)}(U)$. Because of the estimate for $f(u)$, we can regard $f(u)$ as being in $H^1(U)$ as follows.

$$\left| \int_U f(u) v \, dx \right| \leq \left( \int_U |f(u)|^{2n/(n+2)} \, dx \right)^{(n+2)/2n} \left( \int_U |v|^{2n/(n-2)} \right)^{(n-2)/2n}$$

$$\leq \left( \int_U C \left(1 + |u|^{2n/(n-2)}\right) \, dx \right)^{(n+2)/2n} \|v\|_{H^1_0}$$

where $C$ will be adjusted as needed here and elsewhere. Thus, writing in terms of the inner product on $H^1_0$,

$$(I_2'(u), v)_{H^1_0} = (R^{-1} f(u), v)_{H^1_0}$$

This is so if the $\frac{1}{2} f'(\hat{u}) v^2$ term is as it should be. We need to verify that

$$\frac{\int_U \frac{1}{2} f'(\hat{u}) v^2 \, dx}{\|v\|_{H^1_0}} \to 0$$

However, we can use the estimate and write that this is no larger than

$$\frac{\int_U C \left(1 + |v|^{p-1} + |u|^{p-1}\right) |v|^2 \, dx}{\left( \int_U |v|^{2n/(n-2)} \right)^{(n-2)/2n}}$$

(38.2.11)

Then consider the term involving $|u|$.

$$\int_U |u|^{p-1} |v|^2 \, dx \leq \left( \int_U |u|^{p+1} \right)^{\frac{p+1}{p}} \left( \int_U |v|^{p+1} \right)^{2/(p+1)}$$

Now $p + 1 \leq \frac{2n}{n-2}$ and so the first factor is finite. As to the second, it equals

$$\left( \left( \int_U |v|^{2n/(n-2)} \right)^{\frac{1}{n(n-2)}} \right)^2$$
and so this term from \(38.2.11\) is \(o(v)\) on \(H^1_0(U)\). The term involving \(|v|^{p-1}\) is obviously \(o(v)\). Consider the constant term.

\[
\int_U |v|^2 \, dx \leq \left( \int_U |v|^{2n/(n-2)} \, dx \right)^{(n-2)/2n}^2
\]

so it is also all right. Thus the derivative is as claimed. Is this derivative Lipschitz on bounded sets?

\[
f(\hat{u}) - f(u) = \int_0^1 f'(u + t(\hat{u} - u)) (\hat{u} - u) \, dt
\]

Thus in \(H^{-1}\) and using the estimates,

\[
\left| \int_U (f(\hat{u}) - f(u)) v \, dx \right| \leq \int_U \int_0^1 C \left( 1 + |u + t(\hat{u} - u)|^{p-1} \right) |\hat{u} - u| \, dt \, dx
\]

\[
= \int_0^1 \int_U C \left( 1 + |u + t(\hat{u} - u)|^{p-1} \right) |\hat{u} - u| \, dx \, dt
\]

\[
\leq C \left( \int_U \left( 1 + |\hat{u}|^{p-1} + |u|^{p-1} \right)^{2n/(n+2)} \right)^{\frac{n+2}{2n}} \left( \int_U |\hat{u} - u|^{2n/(n-2)} \right)^{(n-2)/2n} ||\hat{u} - u||_{H^1_0(U)}
\]

Now \((p - 1) \frac{2n}{n+2} \leq \left( \frac{n+2}{n+2} - 1 \right) \frac{2n}{n+2} = 8 \frac{n}{n+2} - 2 \frac{n}{n+2} \leq \frac{2n}{n+2}\) and so the derivative is Lipschitz on bounded sets of \(H^1_0(U)\).

**Palais Smale Conditions**

Here we verify the Palais Smale conditions. Suppose then that \(I(u_k)\) is bounded and \(I'(u_k) \to 0\) in \(H^1_0(U)\). Then

\[
\left| \frac{1}{2} \left\| u_k \right\|^2_{H^1_0} - \int_U F(u_k) \, dx \right| \leq C \tag{38.2.12}
\]

Since \(I'(u_k) \to 0\),

\[
u_k - R^{-1} f(u_k) \to 0 \text{ in } H^1_0(U) \tag{38.2.13}
\]

Take inner product of the second term with \(u_k\).

\[
(R^{-1} f(u_k), u_k) = \langle f(u_k), u_k \rangle_{H^{-1}, H^1_0} = \int_U f(u_k) u_k \, dx
\]

Then by assumption, for \(\varepsilon > 0\), and all \(k\) large enough,

\[
|\langle I'(u_k), u_k \rangle| \leq \left| \left\| u_k \right\|^2_{H^1_0(U)} - \int_U f(u_k) u_k \, dx \right| \leq \varepsilon \left\| u_k \right\|_{H^1_0(U)}
\]
Then also for large $k$, letting $\varepsilon = 1$,
\[
\left| \int_U f (u_k) \, u_k \, dx \right| \leq \| u_k \|_{H_0^1 (U)}^2 + \| u_k \|_{H_0^1 (U)}
\]
Now from the estimates assumed and (38.2.12)
\[
\frac{1}{2} \| u_k \|_{H_0^1}^2 \leq C + \int_U F (u_k) \, dx \leq C + \gamma \int_U f (u_k) \, u_k \, dx
\]
\[
\leq C + \gamma \left( \| u_k \|_{H_0^1 (U)}^2 + \| u_k \|_{H_0^1 (U)} \right)
\]
and since $\gamma < 1/2$,
\[
\left( \frac{1}{2} - \gamma \right) \| u_k \|_{H_0^1}^2 \leq C + \| u_k \|_{H_0^1 (U)}
\]
and so $\| u_k \|_{H_0^1 (U)}$ is bounded. Hence it has a subsequence still denoted as $u_k$ which converges weakly in $H_0^1 (U)$ to $u \in H_0^1 (U)$. Since $p < \frac{n+2}{n-2}$, it follows that
\[
p + 1 < \frac{n + 2}{n - 2} + 1 = \frac{2n}{n - 2}
\]
and so by compactness of the embedding, it follows that $u_k \to u$ strongly in $L^{p+1} (U)$. We can assume convergence also takes place pointwise by taking a suitable subsequence.

Now $|f (u) \, v| \leq C \left( 1 + |u|^p \right) |v|$. Therefore, adjusting the constants,
\[
|f (u) \, v| \leq C \left( 1 + |u|^p \right) |v| \leq C \left( 1 + |u|^{p+1} \right)^{p/(p+1)} |v|
\]
\[
\left| \int_U f (u) \, v \, dx \right| \leq C \left( \int_U \left( 1 + |u|^{p+1} \right)^{p/(p+1)} \left( \int_U |v|^{p+1} \right)^{1/(p+1)} \right)
\]
\[
\leq C \left( \int_U \left( 1 + |u|^{p+1} \right)^{p/(p+1)} \| v \|_{H_0^1 (U)} \right)
\]
and so
\[
\| f (u) \|_{H^{-1} (U)} \leq \| f (u) \|_{L^{p+1} (U)} \leq C \left( \int_U \left( 1 + |u|^{p+1} \right)^{p/(p+1)} \right)
\]
It follows that
\[
f (u_k) \to f (u) \text{ pointwise}
\]
and also
\[
|f (u_k) - f (u)|^{p+1} \leq C_p \left( |f (u_k)|^{p+1} + |f (u)|^{p+1} \right)
\]
where
\[
\lim_{k \to \infty} \int_U \left( |f (u_k)|^{p+1} + |f (u)|^{p+1} \right) \, dx = \int_U 2 |f (u)|^{p+1} \, dx
\]
then by the dominated convergence theorem or more precisely Corollary 9.4.10,
\[
\lim_{k \to \infty} \left( \int_U |f(u_k) - f(u)|^{p+1} \right)^{1/(p+1)} = 0
\]
It follows that \( f(u_k) \to f(u) \) in \( H^{-1}(U) \). Hence \( R^{-1}f(u_k) \to R^{-1}f(u) \) in \( H_0^1(U) \)
and so from 38.2.13, \( u_k \to u \) strongly in \( H_0^1(U) \) also. Thus \( \{u_k\} \) is precompact.
This verifies the Palais Smale conditions.

mountain pass conditions

It is clear that \( I(0) = 0 \). It remains to verify that for some \( r > 0 \), \( I(u) \geq a > 0 \)
whenever \( \|u\|_{H_0^1(U)} = r \) and for some \( v \) with \( \|v\| > r, I(v) = 0 \). Now consider \( ru \)
where \( \|u\| = 1 \).
\[
I(ru) = \frac{1}{2} r^2 - \int_U F(ru) \, dx
\]
From the assumed estimates and Sobolev embedding,
\[
I(ru) \geq \frac{1}{2} r^2 - \int_U A|u|^{p+1} r^{p+1} \, dx \geq \frac{1}{2} r^2 - CAr^{p+1} \|u\|_{H_0^1(U)}^{p+1}
\]
\[
= \frac{1}{2} r^2 - CAr^{p+1}
\]
Now this is independent of \( u \) such that \( \|u\| = 1 \). Then the derivative of the right side is
\[
r - (p + 1) CAr^p
\]
where \( p > 1 \). Thus this is positive for a while and then when \( r \) is larger, it becomes
negative. Thus there is \( r_0 > 0 \) where \( \frac{1}{2} r_0^2 - CAr_0^{p+1} \equiv a > 0 \). Hence when \( \|u\| = r_0 \),
you have \( I(u) \geq a > 0 \). This is part of the mountain pass conditions. Now consider
the other part. Letting \( \|u\| = 1 \) be fixed, the estimates imply
\[
I(ru) \leq \frac{1}{2} r^2 - \int_U \alpha |u|^{p+1} r^{p+1} \, dx \leq \frac{1}{2} r^2 - r^{p+1} C
\]
Hence, for \( r \) large enough, the right side becomes negative because \( p + 1 > 2 \).
Therefore, \( r \to I(ru) \) is positive for small \( r \) and is eventually negative as \( r \) gets
larger. hence there is some value of \( r \) where this equals 0. Then \( v = ru \). This
verifies the conditions for the mountain pass theorem.

conclusions

It follows from the mountain pass theorem that there is some \( u \neq 0 \) such that
\( I'(u) = 0 \). From the above computations,
\[
u - R^{-1}f(u) = 0
\]
Now $R = -\Delta$ the Laplacian. In terms of weak derivatives,

$$\langle -\Delta u, v \rangle_{H^{-1}, H^1_0} = \int_U \nabla u \cdot \nabla v dx = (u, v)_{H^1_0(U)}$$

and so in terms of weak derivatives,

$$-\Delta u = f(u) \text{ in } H^{-1}(U), \ u \in H^1_0(U) \text{ so } u = 0 \text{ on } \partial U.$$ 

This proves the following theorem.

**Theorem 38.2.2** Suppose the conditions 38.2.8 - 38.2.10 hold. Then there exists a nonzero $u \in H^1_0(U)$ such that

$$-\Delta u = f(u)$$

One can verify that an example of such a function $f(u)$ is

$$f(u) = |u|^{p-2} u$$

This is very exciting to a large number of people because it gives an interesting example of non uniqueness of a boundary value problem. It is clear that $u = 0$ works.
Chapter 39

Korn’s Inequality

A fundamental inequality used in elasticity to obtain coercivity and then apply the Lax-Milgram theorem or some other theorem is Korn’s inequality. The proof given here of this fundamental result follows [92] and [43].

39.1 A Fundamental Inequality

The proof of Korn’s inequality depends on a fundamental inequality involving negative Sobolev space norms. The theorem to be proved is the following.

**Theorem 39.1.1** Let $f \in L^2(\Omega)$ where $\Omega$ is a bounded Lipschitz domain. Then there exist constants, $C_1$ and $C_2$ such that

$$C_1 \|f\|_{0,2,\Omega} \leq \left( \|f\|_{-1,2,\Omega} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\Omega} \right) \leq C_2 \|f\|_{0,2,\Omega},$$

where here $\|\cdot\|_{0,2,\Omega}$ represents the $L^2$ norm and $\|\cdot\|_{-1,2,\Omega}$ represents the norm in the dual space of $H^1_0(\Omega)$, denoted by $H^{-1}(\Omega)$.

Similar conventions will apply for any domain in place of $\Omega$. The proof of this theorem will proceed through the use of several lemmas.

**Lemma 39.1.2** Let $U^-$ denote the set,

$$\{(x,x_n) \in \mathbb{R}^n : x_n < g(x)\}$$

where $g : \mathbb{R}^{n-1} \to \mathbb{R}$ is Lipschitz and denote by $U^+$ the set

$$\{(x,x_n) \in \mathbb{R}^n : x_n > g(x)\}.$$

Let $f \in L^2(U^-)$ and extend $f$ to all of $\mathbb{R}^n$ in the following way.

$$f(x,x_n) \equiv -3f(x,2g(x) - x_n) + 4f(x,3g(x) - 2x_n).$$
CHAPTER 39. KORN’S INEQUALITY

Then there is a constant, $C_g$, depending on $g$ such that

$$\|f\|_{-1,2,\mathbb{R}^n} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} \leq C_g \left( \|f\|_{-1,2,U^-} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,U^-} \right).$$

Proof: Let $\phi \in C_c^\infty (\mathbb{R}^n)$. Then,

$$\int_{\mathbb{R}^n} f \frac{\partial \phi}{\partial x_n} \, dx = \int_{U^-} \frac{\partial \phi}{\partial x_n} \left[ -3f (x,2g(x) - x_n) + 4f (x,3g(x) - 2x_n) \right] \, dx$$

$$+ \int_{U^-} f \frac{\partial \phi}{\partial x_n} \, dx. \tag{39.1.1}$$

Consider the first integral on the right in \text{39.1.1}. Changing the variables, letting $y_n = 2g(x) - x_n$ in the first term of the integrand and $3g(x) - 2x_n$ in the next, it equals

$$-3 \int_{U^-} \frac{\partial \phi}{\partial x_n} (x,2g(x) - y_n) f (x,y_n) \, dy_n \, dx$$

$$+ 2 \int_{U^-} \frac{\partial \phi}{\partial x_n} \left( x, \frac{3}{2}g(x) - \frac{y_n}{2} \right) f (x,y_n) \, dy_n \, dx.$$ 

For $(x,y_n) \in U^-$, and defining

$$\psi (x,y_n) \equiv \phi (x,y_n) + 3\phi (x,2g(x) - y_n) - 4\phi (x,\frac{3}{2}g(x) - \frac{y_n}{2}),$$

it follows $\psi = 0$ when $y_n = g(x)$ and so

$$\int_{\mathbb{R}^n} f \frac{\partial \phi}{\partial x_n} \, dx = \int_{U^-} \frac{\partial \psi}{\partial y_n} f (x,y_n) \, dx \, dy_n.$$ 

Now from the definition of $\psi$ given above,

$$\|\psi\|_{1,2,U^-} \leq C_g \|\phi\|_{1,2,U^-} \leq C_g \|\phi\|_{1,2,\mathbb{R}^n}$$

and so

$$\left\| \frac{\partial f}{\partial x_n} \right\|_{-1,2,\mathbb{R}^n} \equiv$$

$$\sup \left\{ \int_{\mathbb{R}^n} f \frac{\partial \phi}{\partial x_n} \, dx : \phi \in C_c^\infty (\mathbb{R}^n), \|\phi\|_{1,2,\mathbb{R}^n} \leq 1 \right\} \leq$$

$$\sup \left\{ \int_{U^-} f \frac{\partial \psi}{\partial x_n} \, dx \, dy_n : \psi \in H^1_0 (U^-), \|\psi\|_{1,2,U^-} \leq C_g \right\} \leq$$

$$C_g \left\| \frac{\partial f}{\partial x_n} \right\|_{-1,2,U^-} \tag{39.1.2}$$
39.1. A FUNDAMENTAL INEQUALITY

It remains to establish a similar inequality for the case where the derivatives are taken with respect to \( x_i \) for \( i < n \). Let \( \phi \in C_c^\infty (\mathbb{R}^n) \). Then

\[
\int_{\mathbb{R}^n} f \frac{\partial \phi}{\partial x_i} \, dx = \int_{U^-} f \frac{\partial \phi}{\partial x_i} \, dx \]

\[
\int_{U^+} \frac{\partial \phi}{\partial x_i} \left[ -3f (x, g(x) - x_n) + 4f (x, 3g(x) - 2x_n) \right] \, dx.
\]

Changing the variables as before, this last integral equals

\[
\begin{align*}
-3 \int_{U^-} D_i \phi (x, 2g(x) - y_n) f(x, y_n) \, dy_n \, dx \\
+ 2 \int_{U^-} D_i \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right) f(x, y_n) \, dy_n \, dx.
\end{align*}
\]

(39.1.3)

Now let

\[
\psi_1(x, y_n) \equiv \phi (x, 2g(x) - y_n), \quad \psi_2(x, y_n) \equiv \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right).
\]

Then

\[
\frac{\partial \psi_1}{\partial x_i} = D_i \phi (x, 2g(x) - y_n) + D_n \phi (x, 2g(x) - y_n) 2D_i g(x),
\]

\[
\frac{\partial \psi_2}{\partial x_i} = D_i \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right) + D_n \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right) \frac{3}{2} D_i g(x).
\]

Also

\[
\frac{\partial \psi_1}{\partial y_n} (x, y_n) = -D_n \phi (x, 2g(x) - y_n),
\]

\[
\frac{\partial \psi_2}{\partial y_n} (x, y_n) = \left( \frac{-1}{2} \right) D_n \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right).
\]

Therefore,

\[
\frac{\partial \psi_1}{\partial x_i} (x, y_n) = D_i \phi (x, 2g(x) - y_n) - 2 \frac{\partial \psi_1}{\partial y_n} (x, y_n) D_i g(x),
\]

\[
\frac{\partial \psi_2}{\partial x_i} (x, y_n) = D_i \phi \left( x, \frac{3}{2} g(x) - \frac{y_n}{2} \right) - 3 \frac{\partial \psi_2}{\partial y_n} (x, y_n) D_i g(x).
\]

Using this in (39.1.3), the integrals in this expression equal

\[
\begin{align*}
-3 \int_{U^-} \left[ \frac{\partial \psi_1}{\partial x_i} (x, y_n) + 2 \frac{\partial \psi_1}{\partial y_n} (x, y_n) D_i g(x) \right] f(x, y_n) \, dy_n \, dx + \\
2 \int_{U^-} \left[ \frac{\partial \psi_2}{\partial x_i} (x, y_n) + 3 \frac{\partial \psi_2}{\partial y_n} (x, y_n) D_i g(x) \right] f(x, y_n) \, dy_n \, dx
\end{align*}
\]
\[ = \int_{U} \left[-3 \frac{\partial \psi_1(x,y)}{\partial x_i} + 2 \frac{\partial \psi_2(x,y_n)}{\partial x_i}\right] f(x,y_n) dy_n dx. \]

Therefore,
\[ \int_{\mathbb{R}^n} \frac{\partial \phi}{\partial x_i} f dx = \int_{U} \left[ \frac{\partial \phi}{\partial x_i} - 3 \frac{\partial \psi_1}{\partial x_i} + 2 \frac{\partial \psi_2}{\partial x_i}\right] f dx dy_n \]

and also
\[ \phi(x,g(x)) - 3\psi_1(x,g(x)) + 2\psi_2(x,g(x)) = \]
\[ \phi(x,g(x)) - 3\phi(x,g(x)) + 2\phi(x,g(x)) = 0 \]

and so \( \phi - 3\psi_1 + 2\psi_2 \in H_0^1(U^-) \). It also follows from the definition of the functions, \( \psi_i \) and the assumption that \( g \) is Lipschitz, that
\[ \|\psi_i\|_{1,2,U^-} \leq C_g \|\phi\|_{1,2,U^-} \leq C_g \|\phi\|_{1,2,\mathbb{R}^n}. \] (39.1.4)

Therefore,
\[ \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} = \sup \left\{ \int_{\mathbb{R}^n} f \frac{\partial \phi}{\partial x_i} dx : \|\phi\|_{1,2,\mathbb{R}^n} \leq 1 \right\} \]
\[ = \sup \left\{ \int_{U^-} f \left[ \frac{\partial \phi}{\partial x_i} - 3 \frac{\partial \psi_1}{\partial x_i} + 2 \frac{\partial \psi_2}{\partial x_i}\right] dx : \|\phi\|_{1,2,\mathbb{R}^n} \leq 1 \right\} \]
\[ \leq C_g \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,U^-} \]

where \( C_g \) is a constant which depends on \( g \). This inequality along with (39.1.2) yields
\[ \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} \leq C_g \left( \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,U^-} \right). \]

The inequality,
\[ \|f\|_{-1,2,\mathbb{R}^n} \leq C_g \|f\|_{-1,2,U^-} \]
follows from (39.1.2) and the equation,
\[ \int_{\mathbb{R}^n} f \phi dx = \int_{U^-} f \phi dx - 3 \int_{U^-} f(x,y_n) \psi_1(x,y_n) dx dy_n \]
\[ + 2 \int_{U^-} f(x,y_n) \psi_2(x,y_n) dx dy_n \]

which results in the same way as before by changing variables using the definition of \( f \) off \( U^- \). This proves the lemma.

The next lemma is a simple application of Fourier transforms.

**Lemma 39.1.3** If \( f \in L^2(\mathbb{R}^n) \), then the following formula holds.
\[ C_n \|f\|_{0,2,\mathbb{R}^n} = \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} + \|f\|_{-1,2,\mathbb{R}^n} \]
Proof: For $\phi \in C^\infty_c(\mathbb{R}^n)$

$$\|\phi\|_{1,2,\mathbb{R}^n} \equiv \left( \int_{\mathbb{R}^n} \left( 1 + |t|^2 \right) |F\phi|^2 \, dt \right)^{1/2}$$

is an equivalent norm to the usual Sobolev space norm for $H^1_0(\mathbb{R}^n)$ and is used in the following argument which depends on Plancherel’s theorem and the fact that $F\left( \frac{\partial \phi}{\partial x_i} \right) = t_i F(\phi)$.

$$\left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} = \sup \left\{ \left\| \int_{\mathbb{R}^n} \frac{\partial \phi}{\partial x_i} f \, dx \right\| : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \sup \left\{ \int_{\mathbb{R}^n} t_i (F\phi) \overline{(Ff)} \, dt : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \sup \left\{ \int_{\mathbb{R}^n} t_i (F\phi) \left( 1 + |t|^2 \right)^{-1/2} \overline{(Ff)} \, dt : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \left( \int_{\mathbb{R}^n} \frac{|Ff|^2 t_i^2}{(1 + |t|^2)^{1/2}} \, dt \right)^{1/2}$$

(39.1.5)

Also,

$$\|f\|_{-1,2} \equiv \sup \left\{ \left| \int_{\mathbb{R}^n} \phi \overline{f} \, dx \right| : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \sup \left\{ \left| \int_{\mathbb{R}^n} (F\phi) \overline{(Ff)} \, dx \right| : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \sup \left\{ \left| \int_{\mathbb{R}^n} F\phi \left( 1 + |t|^2 \right)^{-1/2} \overline{(Ff)} \, dt \right| : \|\phi\|_{1,2} \leq 1 \right\}$$

$$= C_n \left( \int_{\mathbb{R}^n} \frac{|Ff|^2}{(1 + |t|^2)^{1/2}} \, dt \right)^{1/2}$$

This along with 39.1.5 yields the conclusion of the lemma because

$$\sum_{i=1}^n \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2}^2 + \|f\|_{-1,2}^2 = C_n \int_{\mathbb{R}^n} |Ff|^2 \, dx = C_n \|f\|_{0,2}^2.$$ 

Now consider Theorem 39.1.1. First note that by Lemma 39.1.2 and $U$ defined there, Lemma 39.1.3 implies that for $f$ extended as in Lemma 39.1.2,

$$\|f\|_{0,2,U^-} \leq \|f\|_{0,2,\mathbb{R}^n} = C_n \left( \|f\|_{-1,2,\mathbb{R}^n} + \sum_{i=1}^n \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\mathbb{R}^n} \right)$$
CHAPTER 39. KORN’S INEQUALITY

\[ C_{2n} \left( \|f\|_{-1,2,R^n} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,R^n} \right). \]  

(39.1.6)

Let \( \Omega \) be a bounded open set having Lipschitz boundary which lies locally on one side of its boundary. Let \( \{Q_i\}_{i=0}^{p} \) be cubes of the sort used in the proof of the divergence theorem such that \( Q_0 \subseteq \Omega \) and the other cubes cover the boundary of \( \Omega \). Let \( \{\psi_i\} \) be a \( C^\infty \) partition of unity with \( \text{spt}(\psi_i) \subseteq Q_i \) and let \( f \in L^2(\Omega) \). Then for \( \phi \in C_c^\infty(\Omega) \) and \( \psi \) one of these functions in the partition of unity,

\[ \frac{\partial (f \psi)}{\partial x_i} \leq \sup_{\|\theta\|_{1,2} \leq 1} \left| \int_{\Omega} f \frac{\partial \theta}{\partial x_i} \psi \, dx \right| + \sup_{\|\psi\|_{1,2} \leq 1} \left| \int_{\Omega} f \psi \frac{\partial \theta}{\partial x_i} \, dx \right| \]

Now if \( \|\phi\|_{1,2} \leq 1 \), then for a suitable constant, \( C_\psi \),

\[ \|\psi\|_{1,2} \leq C_\psi \|\phi\|_{1,2} \leq C_\psi, \quad \left\| \frac{\partial \psi}{\partial x_i} \right\|_{1,2} \leq C_\psi. \]

Therefore,

\[ \left\| \frac{\partial (f \psi)}{\partial x_i} \right\|_{1,2,\Omega} \leq \sup_{\|\phi\|_{1,2} \leq 1} \left| \int_{\Omega} f \frac{\partial \phi}{\partial x_i} \psi \, dx \right| + \sup_{\|\phi\|_{1,2} \leq 1} \left| \int_{\Omega} f \psi \frac{\partial \phi}{\partial x_i} \, dx \right| \]

\[ \leq C_\psi \left( \left\| \frac{\partial f}{\partial x_i} \right\|_{1,2,\Omega} + \|f\|_{-1,2,\Omega} \right). \]  

(39.1.7)

Now using 39.1.7 and 39.1.6

\[ \left\| f \psi_j \right\|_{0,2,\Omega} \leq C_\theta \left( \left\| f \psi_j \right\|_{-1,2,\Omega} + \sum_{i=1}^{n} \left\| \frac{\partial (f \psi_j)}{\partial x_i} \right\|_{-1,2,\Omega} \right) \]

\[ \leq C_\psi C_\theta \left( \|f\|_{-1,2,\Omega} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\Omega} \right). \]

Therefore, letting \( C = \sum_{j=1}^{p} C_\psi C_\theta \),

\[ \|f\|_{0,2,\Omega} \leq \sum_{j=1}^{p} \left\| f \psi_j \right\|_{0,2,\Omega} \leq C \left( \|f\|_{-1,2,\Omega} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\Omega} \right). \]  

(39.1.8)

This proves the hard half of the inequality of Theorem 39.1.1.

To complete the proof, let \( \tilde{f} \) denote the zero extension of \( f \) off \( \Omega \). Then

\[ \|f\|_{-1,2,\Omega} + \sum_{i=1}^{n} \left\| \frac{\partial f}{\partial x_i} \right\|_{-1,2,\Omega} \leq \left\| \tilde{f} \right\|_{-1,2,R^n} + \sum_{i=1}^{n} \left\| \frac{\partial \tilde{f}}{\partial x_i} \right\|_{-1,2,R^n} \]

\[ \leq C_n \|\tilde{f}\|_{0,2,R^n} = C_n \|f\|_{0,2,\Omega}. \]

This along with 39.1.8 proves Theorem 39.1.1.
39.2. KORN’S INEQUALITY

The inequality in this section is known as Korn’s second inequality. It is also known as coercivity of strains. For \( \mathbf{u} \) a vector valued function in \( \mathbb{R}^n \), define

\[
\varepsilon_{ij}(\mathbf{u}) = \frac{1}{2} (u_{i,j} + u_{j,i})
\]

This is known as the strain or small strain. Korn’s inequality says that the norm given by,

\[
\|\|\mathbf{u}\|\|_0 = \left( \sum_{i=1}^n \|u_i\|_{0,2,\Omega}^2 + \sum_{i=1}^n \sum_{j=1}^n \|\varepsilon_{ij}(\mathbf{u})\|_{0,2,\Omega}^2 \right)^{1/2}
\]

is equivalent to the norm,

\[
\|\mathbf{u}\| = \left( \sum_{i=1}^n \|u_i\|_{0,2,\Omega}^2 + \sum_{i=1}^n \sum_{j=1}^n \left\| \frac{\partial u_i}{\partial x_j} \right\|_{0,2,\Omega}^2 \right)^{1/2}
\]

(39.2.9)

(39.2.10)

It is very significant because it is the strain as just defined which occurs in many of the physical models proposed in continuum mechanics. The inequality is far from obvious because the strains only involve certain combinations of partial derivatives.

**Theorem 39.2.1** (Korn’s second inequality) Let \( \Omega \) be any domain for which the conclusion of Theorem 39.1.1 holds. Then the two norms in (39.2.9) and (39.2.10) are equivalent.

**Proof:** Let \( \mathbf{u} \) be such that \( u_i \in H^1(\Omega) \) for each \( i = 1, \cdots, n \). Note that

\[
\frac{\partial^2 u_i}{\partial x_j \partial x_k} = \frac{\partial}{\partial x_j} (\varepsilon_{ik}(\mathbf{u})) + \frac{\partial}{\partial x_k} (\varepsilon_{ij}(\mathbf{u})) - \frac{\partial}{\partial x_i} (\varepsilon_{jk}(\mathbf{u})).
\]

Therefore, by Theorem 39.1.1,

\[
\left\| \frac{\partial u_i}{\partial x_j} \right\|_{0,2,\Omega} \leq C \left[ \left\| \frac{\partial u_i}{\partial x_j} \right\|_{-1,2,\Omega} + \sum_{k=1}^n \left\| \frac{\partial u_i}{\partial x_j, \partial x_k} \right\|_{-1,2,\Omega} \right]
\]

\[
\leq C \left[ \left\| \frac{\partial u_i}{\partial x_j} \right\|_{-1,2,\Omega} + \sum_{r,s,p} \left\| \varepsilon_{rs}(\mathbf{u}) \right\|_{-1,2,\Omega} \right]
\]

\[
\leq C \left[ \left\| \frac{\partial u_i}{\partial x_j} \right\|_{-1,2,\Omega} + \sum_{r,s} \left\| \varepsilon_{rs}(\mathbf{u}) \right\|_{0,2,\Omega} \right].
\]

But also by this theorem,

\[
\left\| u_i \right\|_{-1,2,\Omega} + \sum_p \left\| \frac{\partial u_i}{\partial x_p} \right\|_{-1,2,\Omega} \leq C \left\| u_i \right\|_{0,2,\Omega}
\]
and so
\[
\left\| \frac{\partial u_i}{\partial x_j} \right\|_{0,2,\Omega} \leq C \left[ ||u_i||_{0,2,\Omega} + \sum_{r,s} ||\varepsilon_{rs}(u)||_{0,2,\Omega} \right]
\]
This proves the theorem.

Note that \( \Omega \) did not need to be bounded. It suffices to be able to conclude the result of Theorem 39.1.1 which would hold whenever the boundary of \( \Omega \) can be covered with finitely many boxes of the sort to which Lemma 39.1.2 can be applied.
Chapter 40

Elliptic Regularity And Nirenberg Differences

40.1 The Case Of A Half Space

Regularity theorems are concerned with obtaining more regularity given a weak solution. This extra regularity is essential in order to obtain error estimates for various problems. In this section a regularity is given for weak solutions to various elliptic boundary value problems. To save on notation, I will use the repeated index summation convention. Thus you sum over repeated indices. Consider the following picture.

Here $V$ is an open set,

$$U \equiv \{y \in V : y_n < 0\}, \Gamma \equiv \{y \in V : y_n = 0\}$$

and $U_1$ is an open set as shown for which $U_1 \subseteq V \cap U$. Assume also that $V$ is
bounded. Suppose
\[
f \in L^2(U),
\]
\[
\alpha^{rs} \in C^{0,1}(\overline{U}),
\]
\[
\alpha^{rs}(y)v_r v_s \geq \delta |v|^2, \quad \delta > 0.
\]

The following technical lemma gives the essential ideas.

Lemma 40.1.1 Suppose
\[
w \in H^1(U),
\]
\[
\alpha^{rs} \in C^{0,1}(\overline{U}),
\]
\[
h_s \in H^1(U),
\]
\[
f \in L^2(U).
\]

and
\[
\int_U \alpha^{rs}(y) \frac{\partial w}{\partial y^r} \frac{\partial z}{\partial y^s} dy + \int_U h_s(y) \frac{\partial z}{\partial y^s} dy = \int_U f z dy
\]
for all \( z \in H^1(U) \) having the property that \( \text{spt}(z) \subseteq V \). Then \( w \in H^2(U_1) \) and for some constant \( C \), independent of \( f, w, \) and \( g \), the following estimate holds.
\[
||w||_{H^2(U_1)}^2 \leq C \left( ||w||_{H^1(U)}^2 + ||f||_{L^2(U)}^2 + \sum_s ||h_s||_{H^1(U)}^2 \right).
\]

Proof: Define for small real \( h \),
\[
D_h^k l(y) = \frac{1}{h} (l(y + h e_k) - l(y)).
\]

Let \( U_1 \subseteq \overline{U_1} \subseteq W \subseteq \overline{W} \subseteq V \) and let \( \eta \in C^\infty_c(W) \) with \( \eta(y) \in [0,1] \), and \( \eta = 1 \) on \( \overline{U_1} \) as shown in the following picture.
40.1. THE CASE OF A HALF SPACE

For \( h \) small \((3h < \text{dist}(W, V^C))\), let

\[
\begin{align*}
\frac{1}{h} \left( \eta^2 (y - he_k) \left[ \frac{w(y) - w(y - he_k)}{h} \right] - \eta^2 (y) \left[ \frac{w(y + he_k) - w(y)}{h} \right] \right) & \\
= -D_{k}^{-h} (\eta^2 D_{k}^h w),
\end{align*}
\]

(40.1.9)

where here \( k < n \). Thus \( z \) can be used in equation (40.1.7). Begin by estimating the left side of (40.1.7).

\[
\int_U \alpha^{rs} (y) \frac{\partial w}{\partial y^r} \frac{\partial z}{\partial y^s} dy
\]

\[
= \frac{1}{h} \int_U \alpha^{rs} (y + he_k) \frac{\partial w}{\partial y^r} (y + he_k) \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy
\]

\[
- \frac{1}{h} \int_U \alpha^{rs} (y) \frac{\partial w}{\partial y^r} \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy
\]

\[
= \int_U \alpha^{rs} (y + he_k) \frac{\partial (D_{k}^h w)}{\partial y^r} \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy +
\]

\[
\frac{1}{h} \int_U (\alpha^{rs} (y + he_k) - \alpha^{rs} (y)) \frac{\partial w}{\partial y^r} \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy
\]

(40.1.11)

Now

\[
\frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} = 2\eta \frac{\partial \eta}{\partial y^s} D_{k}^h w + \eta^2 \frac{\partial (D_{k}^h w)}{\partial y^s}.
\]

(40.1.12)

therefore,

\[
= \int_U \eta^2 \alpha^{rs} (y + he_k) \frac{\partial (D_{k}^h w)}{\partial y^r} \frac{\partial (D_{k}^h w)}{\partial y^s} dy
\]

\[
+ \left\{ \int_{W \cap U} \alpha^{rs} (y + he_k) \frac{\partial (D_{k}^h w)}{\partial y^r} \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy \right\}
\]

\[
\left\{ \int_{W \cap U} (\alpha^{rs} (y + he_k) - \alpha^{rs} (y)) \frac{\partial w}{\partial y^r} \frac{\partial (\eta^2 D_{k}^h w)}{\partial y^s} dy \right\} \equiv A + \{B\}.
\]

(40.1.13)

Now consider these two terms. From (40.1.14),

\[
A \geq \delta \int_U \eta^2 |\nabla D_{k}^h w|^2 dy.
\]

Using the Lipschitz continuity of \( \alpha^{rs} \) and (40.1.12),

\[
B \leq C (\eta, \text{Lip}(\alpha), \alpha) \left\{ \left| \left| D_{k}^h w \right| \right|_{L^2(W \cap U)} \left| \left| \eta \nabla D_{k}^h w \right| \right|_{L^2(W \cap U; \mathbb{R}^n)} +
\]

\[
\right.
\]

(40.1.15)
\[ \|\eta \nabla w\|_{L^2(W;\mathbb{R}^n)} \|\eta \nabla D_k^h w\|_{L^2(W;\mathbb{R}^n)} + \|\eta \nabla w\|_{L^2(W;\mathbb{R}^n)} \|D_k^h w\|_{L^2(W;\mathbb{R}^n)} \}\right) \leq C(\eta, \operatorname{Lip}(\alpha), \alpha) C_\varepsilon \left(\|D_k^h w\|_{L^2(W;\mathbb{R}^n)}^2 + \|\eta \nabla w\|_{L^2(W;\mathbb{R}^n)}^2 + \|\eta \nabla w\|_{L^2(W;\mathbb{R}^n)}^2\right) + \varepsilon C(\eta, \operatorname{Lip}(\alpha), \alpha) \left(\|\eta \nabla D_k^h w\|_{L^2(W;\mathbb{R}^n)}^2 + \|D_k^h w\|_{L^2(W;\mathbb{R}^n)}^2\right). \] 

Now
\[ \|D_k^h w\|_{L^2(W)} \leq \|\nabla w\|_{L^2(U;\mathbb{R}^n)}. \] 

To see this, observe that if \( w \) is smooth, then
\[ \left(\int_W \left( \frac{|w(y + h e_k) - w(y)|^2}{h} \right) dy \right)^{1/2} \leq \left(\int_W \left( \frac{1}{h} \int_0^h \nabla w(y + t e_k) \cdot e_k \, dt \right)^2 \right)^{1/2} \leq \left(\int_0^h \left( \int_W |\nabla w(y + t e_k) \cdot e_k|^2 \, dy \right)^{1/2} \right)^{1/2} \leq \left(\int_0^h \left( \int_W \nabla w(y + t e_k) \cdot e_k dt \right)^2 \right) \leq \|\nabla w\|_{L^2(U;\mathbb{R}^n)} \] 

so by density of such functions in \( H^1(U) \), \( \text{HOLD} \) holds. Therefore, changing \( \varepsilon \), yields
\[ B. \leq C_\varepsilon (\eta, \operatorname{Lip}(\alpha), \alpha) \|\nabla w\|_{L^2(U;\mathbb{R}^n)}^2 + \varepsilon \|\eta \nabla D_k^h w\|_{L^2(W;\mathbb{R}^n)}^2. \] 

With \( \text{HOLD} \) and \( \text{HOLD} \) established, consider the other terms of \( \text{HOLD} \)
\[ \left| \int_U f \, dy \right| \]
\[ \leq \left| \int_U f \left( -D_k^{-h} \eta^2 D_k^h w \right) \, dy \right| \leq \left( \int_U |f|^2 \, dy \right)^{1/2} \left( \int_U \left| D_k^{-h} (\eta^2 D_k^h w) \right|^2 \, dy \right)^{1/2} \leq \|f\|_{L^2(U)} \|\nabla (\eta^2 D_k^h w)\|_{L^2(U;\mathbb{R}^n)} \leq \|f\|_{L^2(U)} \left(\|2\nabla \eta D_k^h w\|_{L^2(U;\mathbb{R}^n)} + \|\eta \nabla D_k^h w\|_{L^2(U;\mathbb{R}^n)}^2 + \|\eta \nabla D_k^h w\|_{L^2(U;\mathbb{R}^n)} \right) \right) \leq C_\varepsilon \left(\|f\|_{L^2(U)}^2 + \|\nabla w\|_{L^2(U;\mathbb{R}^n)}^2 + \varepsilon \|\eta \nabla D_k^h w\|_{L^2(U;\mathbb{R}^n)}^2 \right) \]
Letting \( \varepsilon \to 0 \), small enough and adjusting constants yields

\[
\begin{align*}
& \left| \int U h_s(y) \frac{\partial z}{\partial y^s} dy \right| \\
\leq& \left| \int U \left( \frac{\partial}{\partial y^s} \left( \eta^2 D^h_k w \right) \right) dy \right| \\
\leq& \left| \int U \left( \eta D^h_k h_s(y) \frac{\partial \left( \eta^2 D^h_k w \right)}{\partial y^s} \right) dy \right|
\leq \int U \left[ \left. \left( \eta D^h_k h_s(y) \right) \frac{\partial \left( \eta^2 D^h_k w \right)}{\partial y^s} \right| \right] dy \\
\leq& C \sum_s ||h_s||_{H^1(U)} \left( ||w||_{H^1(U)} + ||\eta \nabla D^h_k w||_{L^2(U;\mathbb{R}^n)} \right) \\
\leq& C \varepsilon \sum_s ||h_s||_{H^1(U)}^2 + ||w||^2_{H^1(U)} + \varepsilon \left| |\eta \nabla D^h_k w||_{L^2(U;\mathbb{R}^n)} \right|^2.
\end{align*}
\]

Therefore,

\[
\begin{align*}
& \delta \left| \eta \nabla D^h_k w \right|_{L^2(U;\mathbb{R}^n)}^2 \\
\leq& C \varepsilon \left( \eta, \text{Lip}(\alpha) \right) \left| \nabla w \right|_{L^2(U;\mathbb{R}^n)}^2 + ||\eta \nabla D^h_k w||_{L^2(U;\mathbb{R}^n)}^2 \\
& \left( ||f||_{L^2(U)}^2 + ||\nabla w||_{L^2(U;\mathbb{R}^n)}^2 \right) + \varepsilon \left| |\eta \nabla D^h_k w||_{L^2(U;\mathbb{R}^n)} \right|^2.
\end{align*}
\]

Letting \( \varepsilon \) be small enough and adjusting constants yields

\[
\begin{align*}
& \left| \nabla D^h_k w \right|_{L^2(U;\mathbb{R}^n)}^2 \leq \left| \eta \nabla D^h_k w \right|_{L^2(U;\mathbb{R}^n)}^2 \leq \left( ||w||_{H^1(U)}^2 + ||f||_{L^2(U)}^2 + C \varepsilon \sum_s ||h_s||_{H^1(U)} \right).
\end{align*}
\]
where the constant, $C$, depends on $\eta, \operatorname{Lip}(\alpha), \alpha, \delta$. Since this holds for all $h$ small enough, it follows $\frac{\partial w}{\partial y^{k}} \in H^{1}(U_{1})$ and

$$\left\|\nabla \frac{\partial w}{\partial y^{k}}\right\|_{L^{2}(U_{1}; \mathbb{R}^{n})} \leq C\left(||w||_{H^{1}(U)}^{2} + ||f||_{L^{2}(U)}^{2} + C\varepsilon \sum_{s} ||h_{s}||_{H^{1}(U)}^{2}\right)$$

(40.1.21)

for each $k < n$. It remains to estimate $\left\|\frac{\partial^{2} w}{\partial y^{k} \partial y^{l}}\right\|_{L^{2}(U_{1})}$. To do this return to (40.1.7) which must hold for all $z \in C^{\infty}_{c}(U_{1})$. Therefore, using (40.1.7) it follows that for all $z \in C^{\infty}_{c}(U_{1})$,

$$\int_{U} \alpha^{rs}(y) \frac{\partial w}{\partial y^{r}} \frac{\partial z}{\partial y^{s}} dy = - \int_{U} \frac{\partial h_{s}}{\partial y^{s}} z dy + \int_{U} f z dy.$$

Now from the Lipschitz assumption on $\alpha^{rs}$, it follows

$$F \equiv \sum_{r, s \leq n-1} \frac{\partial}{\partial y^{r}} \left(\alpha^{rs} \frac{\partial w}{\partial y^{s}}\right) + \sum_{s \leq n-1} \frac{\partial}{\partial y^{s}} \left(\alpha^{ns} \frac{\partial w}{\partial y^{n}}\right) - \sum_{s} \frac{\partial h_{s}}{\partial y^{s}} + f$$

$$\in L^{2}(U_{1})$$

and

$$||F||_{L^{2}(U_{1})} \leq C\left(||w||_{H^{1}(U)}^{2} + ||f||_{L^{2}(U)}^{2} + C\varepsilon \sum_{s} ||h_{s}||_{H^{1}(U)}^{2}\right).$$

(40.1.22)

Therefore, from density of $C^{\infty}_{c}(U_{1})$ in $L^{2}(U_{1})$,

$$- \frac{\partial}{\partial y^{n}} \left(\alpha^{nn}(y) \frac{\partial w}{\partial y^{n}}\right) = F, \text{ no sum on } n$$

and so

$$- \frac{\partial \alpha^{nn}}{\partial y^{n}} \frac{\partial w}{\partial y^{n}} - \alpha^{nn} \frac{\partial^{2} w}{\partial (y^{n})^{2}} = F.$$

By (40.1.22) $\alpha^{nn}(y) \geq \delta$ and so it follows from (40.1.22) that there exists a constant, $C$ depending on $\delta$ such that

$$\left|\frac{\partial^{2} w}{\partial (y^{n})^{2}}\right|_{L^{2}(U_{1})} \leq C\left(||F||_{L^{2}(U_{1})} + ||w||_{H^{2}(U_{1})}\right)$$
40.1. THE CASE OF A HALF SPACE

which with \([\text{40.1.21}]\) and \([\text{40.1.22}]\) implies the existence of a constant, \(C\) depending on \(\delta\) such that

\[
||w||_{H^2(U_1)}^2 \leq C \left(||w||_{H^1(U)}^2 + ||f||_{L^2(U)}^2 + C_\varepsilon \sum_s ||h_s||_{H^1(U)}^2\right),
\]

proving the lemma.

What if more regularity is known for \(f, h_s, \alpha^{rs}\) and \(w\)? Could more be said about the regularity of the solution? The answer is yes and is the content of the next corollary.

First here is some notation. For a multi-index with \(j^i = k^1, \ldots, n\) define

\[
D^h_l(y) \equiv \prod_{k=1}^n (D^h_k)^{\alpha_k} l(y).
\]

Also, for \(\alpha\) and \(\tau\) multi indices, \(\tau < \alpha\) means \(\tau_i < \alpha_i\) for each \(i\).

**Corollary 40.1.2** Suppose in the context of Lemma \([\text{40.1.1}]\) the following for \(k \geq 1\).

\[
w \in H^k(U), \\
\alpha^{rs} \in C^{k-1,1}(U), \\
h_s \in H^k(U), \\
f \in H^{k-1}(U),
\]

and

\[
\int_U \alpha^{rs}(y) \frac{\partial w}{\partial y^r} \frac{\partial z}{\partial y^s} dy + \int_U h_s(y) \frac{\partial z}{\partial y^s} dy = \int_U f z dy \quad (40.1.23)
\]

for all \(z \in H^1(U)\) or \(H^1_0(U)\) such that \(\text{spt}(z) \subseteq V\). Then there exists \(C\) independent of \(w\) such that

\[
||w||_{H^{k+1}(U_1)} \leq C \left(||f||_{H^{k-1}(U)} + \sum_s ||h_s||_{H^k(U)} + ||w||_{H^k(U)}\right). \quad (40.1.24)
\]

**Proof:** The proof involves the following claim which is proved using the conclusion of Lemma \([\text{40.1.1}]\) on Page \([\text{1420}]\).

**Claim:** If \(\alpha = (\alpha', 0)\) where \(|\alpha'| \leq k - 1\), then there exists a constant independent of \(w\) such that

\[
||D^\alpha w||_{H^2(U_1)} \leq C \left(||f||_{H^{k-1}(U)} + \sum_s ||h_s||_{H^k(U)} + ||w||_{H^k(U)}\right). \quad (40.1.25)
\]

**Proof of claim:** First note that if \(|\alpha| = 0\), then \([\text{40.1.1}]\) follows from Lemma \([\text{40.1}]\) on Page \([\text{1420}]\). Now suppose the conclusion of the claim holds for all \(|\alpha| \leq j - 1\) where \(j < k\). Let \(|\alpha| = j\) and \(\alpha = (\alpha', 0)\). Then for \(z \in H^1(U)\) having compact support in \(V\), it follows that for \(h\) small enough,

\[
D^{-h}_\alpha z \in H^1(U), \text{spt}(D^h_\alpha z) \subseteq V.
\]
Therefore, you can replace \( z \) in \( 40.1.23 \) with \( D^h z \). Now note that you can apply the following manipulation.

\[
\int_U p(y) D^h z (y) \, dy = \int_U D^h p(y) z (y) \, dy
\]

and obtain

\[
\int_U \left( D^h \left( \alpha^r \frac{\partial w}{\partial y^r} \right) \frac{\partial z}{\partial y^s} + D^h (h_s) \frac{\partial z}{\partial y^s} \right) \, dy = \int_U ((D^h f) z) \, dy. \tag{40.1.26}
\]

Letting \( h \to 0 \), this gives

\[
\int_U \left( D^a \left( \alpha^r \frac{\partial w}{\partial y^r} \right) \frac{\partial z}{\partial y^s} + D^a (h_s) \frac{\partial z}{\partial y^s} \right) \, dy = \int_U ((D^a f) z) \, dy.
\]

Now

\[
D^a \left( \alpha^r \frac{\partial w}{\partial y^r} \right) = \alpha^r \frac{\partial (D^a w)}{\partial y^r} + \sum_{\tau < \alpha} C(\tau) D^{a-\tau} (\alpha^r) \frac{\partial (D^\tau w)}{\partial y^r}
\]

where \( C(\tau) \) is some coefficient. Therefore, from \( 40.1.26 \),

\[
\int_U \alpha^r \frac{\partial (D^a w)}{\partial y^r} \frac{\partial z}{\partial y^s} \, dy + \int_U \left( \sum_{\tau < \alpha} C(\tau) D^{a-\tau} (\alpha^r) \frac{\partial (D^\tau w)}{\partial y^r} + D^a (h_s) \right) \frac{\partial z}{\partial y^s} \, dy
\]

\[
= \int_U (D^a f) z dy. \tag{40.1.27}
\]

Let \( \tilde{U}_1 \) be as indicated in the following picture.

Now apply the induction hypothesis to \( \tilde{U}_1 \) in order to write

\[
\left\| \frac{\partial (D^\tau w)}{\partial y^r} \right\|_{H^1(\tilde{U}_1)} \leq \left\| D^\tau w \right\|_{H^2(\tilde{U}_1)}
\]
40.1. THE CASE OF A HALF SPACE

\[ \leq C \left( \|f\|_{H^{k-1}(U)} + \sum_s \|h_s\|_{H^k(U)} + \|w\|_{H^k(U)} \right). \]

Since \( \alpha^r \in C^{k-1,1}(\tilde{U}) \), it follows that each term from the sum in (40.1.27) satisfies an inequality of the form

\[ \left\| C (\tau) D^{\alpha-\tau}(\alpha^r) \frac{\partial (D^\tau w)}{\partial y^r} \right\|_{H^1(\tilde{U}_1)} \leq \]

\[ C \left( \|f\|_{H^{k-1}(U)} + \sum_s \|h_s\|_{H^k(U)} + \|w\|_{H^k(U)} \right) \]

and consequently,

\[ \left\| \sum_{\tau < \alpha} C (\tau) D^{\alpha-\tau}(\alpha^r) \frac{\partial (D^\tau w)}{\partial y^r} + D^\alpha (h_s) \right\|_{H^1(\tilde{U}_1)} \leq \]

\[ C \left( \|f\|_{H^{k-1}(U)} + \sum_s \|h_s\|_{H^k(U)} + \|w\|_{H^k(U)} \right). \quad (40.1.28) \]

Now consider (40.1.27). The equation remains true if you replace \( U \) with \( \hat{U}_1 \) and require that \( \text{spt}(z) \subseteq \hat{U}_1 \). Therefore, by Lemma 40.1.1 on Page 1420 there exists a constant, \( C \) independent of \( w \) such that

\[ \|D^\alpha w\|_{H^2(\hat{U}_1)} \leq C \left( \|D^\alpha f\|_{L^2(\tilde{U}_1)} + \|D^\alpha w\|_{H^1(\tilde{U}_1)} + \right. \]

\[ + \sum_s \left\| \sum_{\tau < \alpha} C (\tau) D^{\alpha-\tau}(\alpha^r) \frac{\partial (D^\tau w)}{\partial y^r} + D^\alpha (h_s) \right\|_{H^1(\tilde{U}_1)} \right) \]

and by (40.1.28), this implies

\[ \|D^\alpha w\|_{H^2(\hat{U}_1)} \leq C \left( \|f\|_{H^{k-1}(U)} + \|w\|_{H^k(U)} + \sum_s \|h_s\|_{H^k(U)} \right) \]

which proves the Claim.

To establish (40.1.29) it only remains to verify that if \( |\alpha| \leq k+1 \), then

\[ \|D^\alpha w\|_{L^2(\hat{U}_1)} \leq C \left( \|f\|_{H^{k-1}(U)} + \|w\|_{H^k(U)} + \sum_s \|h_s\|_{H^k(U)} \right). \quad (40.1.29) \]

If \( |\alpha| < k+1 \), there is nothing to show because it is given that \( w \in H^k(U) \). Therefore, assume \( |\alpha| = k+1 \). If \( \alpha_n \) equals 0 the conclusion follows from the claim
because in this case, you can subtract 1 from a pair of positive \( \alpha_i \) and obtain a new multi index, \( \beta \) such that \( |\beta| = k - 1 \) and \( \beta_n = 0 \) and then from the claim,

\[
\|D^\alpha w\|_{L^2(U_1)} \leq \|D^\beta w\|_{H^2(U_1)} \leq C \left( \|f\|_{H^{k-1}(U)} + \|w\|_{H^k(U)} + \sum \|h_s\|_{H^k(U)} \right).
\]

If \( \alpha_n = 1 \), then subtract 1 from some positive \( \alpha_i \) and consider

\[
\beta = (\alpha_1, \ldots, \alpha_i - 1, \alpha_i + 1, \ldots, \alpha_{n-1}, 0)
\]

Then from the claim,

\[
\|D^\alpha w\|_{L^2(U_1)} \leq \|D^\beta w\|_{H^2(U_1)} \leq C \left( \|f\|_{H^{k-1}(U)} + \|w\|_{H^k(U)} + \sum \|h_s\|_{H^k(U)} \right).
\]

Suppose \( 40.1.29 \) holds for \( \alpha_n \leq j - 1 \) where \( j - 1 \geq 1 \) and consider \( \alpha \) for which \( |\alpha| = k + 1 \) and \( \alpha_n = j \). Let

\[
\beta \equiv (\alpha_1, \ldots, \alpha_{n-1}, \alpha_n - 2).
\]

Thus \( D^n = D^\beta D^2_n \). Restricting \( 40.1.29 \) to \( z \in C^\infty_c(U_1) \) and using the density of this set of functions in \( L^2(U_1) \), it follows that

\[
-\partial \frac{\partial}{\partial y^s} \left( \alpha^rs(y) \frac{\partial w}{\partial y^r} \right) - \partial h_s = f.
\]

Therefore, from the product rule,

\[
\frac{\partial \alpha^rs}{\partial y^s} \frac{\partial w}{\partial y^r} + \alpha^rs \frac{\partial^2 w}{\partial y^s \partial y^r} + \frac{\partial h_s}{\partial y^s} = -f
\]

and so

\[
\alpha^{nn} D^2_n w = - \left( \frac{\partial \alpha^rs}{\partial y^s} \frac{\partial w}{\partial y^r} + \sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^rs \frac{\partial^2 w}{\partial y^r \partial y^s} + \sum_s \alpha^{ns} \frac{\partial^2 w}{\partial y^s \partial y^n} + \sum_r \alpha^{rn} \frac{\partial^2 w}{\partial y^n \partial y^r} + \frac{\partial h_s}{\partial y^s} + f \right).
\]

As noted earlier, the condition, \( 40.1.2 \) implies \( \alpha^{nn}(y) \geq \delta > 0 \) and so

\[
D^2_n w = - \frac{1}{\alpha^{nn}} \left( \frac{\partial \alpha^rs}{\partial y^s} \frac{\partial w}{\partial y^r} + \sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^rs \frac{\partial^2 w}{\partial y^r \partial y^s} + \sum_s \alpha^{ns} \frac{\partial^2 w}{\partial y^s \partial y^n} + \sum_r \alpha^{rn} \frac{\partial^2 w}{\partial y^n \partial y^r} + \frac{\partial h_s}{\partial y^s} + f \right).
\]
40.2. THE CASE OF BOUNDED OPEN SETS

It follows from \( D^\alpha = D^\beta D_n^2 \) that
\[
D^\alpha w \ = \ D^\beta \left[ -\frac{1}{\alpha^{n\alpha}} \left( \frac{\partial \alpha^{rs}}{\partial y^s} \frac{\partial w}{\partial y^r} + \sum_{r \leq n-1} \sum_{s \leq n-1} \alpha^{rs} \frac{\partial^2 w}{\partial y^s \partial y^r} + \right. \right.
\]
\[
\left. \sum_s \alpha^{ns} \frac{\partial^2 w}{\partial y^s \partial y^n} + \sum_r \alpha^{rn} \frac{\partial^2 w}{\partial y^n \partial y^r} + \frac{\partial h_n}{\partial y^n} + f \right) \right].
\]

Now you note that terms like \( D^\beta \left( \frac{\partial^2 w}{\partial y^r \partial y^s} \right) \) have \( \alpha_n = j - 1 \) and so, from the induction hypothesis along with the assumptions on the given functions,
\[
||D^\alpha w||_{L^2(U, 1)} \leq C \left( ||f||_{H^{k-1}(U)} + ||w||_{H^k(U)} + \sum_s ||h_s||_{H^k(U)} \right).
\]

This proves the corollary.

40.2 The Case Of Bounded Open Sets

The main interest in all this is in the application to bounded open sets. Recall the following definition.

**Definition 40.2.1** A bounded open subset, \( \Omega \), of \( \mathbb{R}^n \) has a \( C^{m, 1} \) boundary if it satisfies the following conditions. For each \( p \in \Gamma \equiv \Omega \setminus \Omega \), there exists an open set, \( W \), containing \( p \), an open interval \((0, b)\), a bounded open box \( U' \subseteq \mathbb{R}^{n-1} \), and an affine orthogonal transformation, \( R_W \) consisting of a distance preserving linear transformation followed by a translation such that
\[
R_W W = U' \times (0, b),
\]
\[
R_W (W \cap \Omega) = \{ u \in \mathbb{R}^n : \ u' \in U', \ 0 < u_n < \phi_W (u') \}
\]
where \( \phi_W \in C^{m, 1} (U') \) meaning \( \phi_W \) is the restriction to \( U' \) of a function, still denoted by \( \phi_W \) which is in \( C^{m, 1} (\mathbb{R}^{n-1}) \) and
\[
\inf \{ \phi_W (u') : \ u' \in U' \} > 0
\]

The following picture depicts the situation.
For the situation described in the above definition, let \( h_W : U' \to \Gamma \cap W \) be defined by
\[
h_W(u') = R_W^{-1}(u', \phi_W(u')), \quad g_W(x) = (R_W x)', \quad H_W(u) = R_W^{-1}(u', \phi_W(u') - u_n).
\]
where \( x' = (x_1, \ldots, x_{n-1}) \) for \( x = (x_1, \ldots, x_n) \). Thus \( g_W \circ h_W = \text{id} \) on \( U' \) and \( h_W \circ g_W = \text{id} \) on \( \Gamma \cap W \). Also note that \( H_W \) is defined on all of \( \mathbb{R}^n \) is \( C^{m,1} \), and has an inverse with the same properties. To see this, let \( G_W(u) = (u', \phi_W(u') - u_n) \) and \( H_W^{-1} = G_W^{-1} \circ R_W \).

Since \( \Gamma = \partial \Omega \) is compact, there exist finitely many of these open sets, \( W_i \) denoted by \( \{W_i\}_{i=1}^q \) such that \( \Gamma \subseteq \bigcup_{i=1}^q W_i \). Let the corresponding sets, \( U' \) be denoted by \( U'_i \) and let the functions, \( \phi \) be denoted by \( \phi_i \). Also let \( h_i = h_{W_i}, G_{W_i} = G_i \) etc. Now let
\[
\Phi_i : G_i R_i (\Omega \cap W) \equiv V_i \to \Omega \cap W_i
\]
be defined by
\[
\Phi_i(y) \equiv R_i^{-1} \circ G_i^{-1}(y).
\]
Thus \( \Phi_i, \Phi_i^{-1} \in C^{m,1}(\mathbb{R}^n) \). The following picture might be helpful.
40.2. THE CASE OF BOUNDED OPEN SETS

Therefore, by Lemma 37.3.3 on Page 1377, it follows that for $t \in [m, m+1)$,

$$\Phi^*_t \in \mathcal{L}\left(H^1 \left(W_t \cap \Omega \right)\right).$$

Assume

$$a^{ij}(x) v_i v_j \geq \delta |v|^2.$$  \hspace{1cm} (40.2.32)

**Lemma 40.2.2** Let $W$ be one of the sets described in the above definition and let $m \geq 1$. Let $W_1 \subseteq W \subseteq W$ where $W_1$ is an open set. Suppose also that

$$u \in H^1(\Omega),$$
$$\alpha^{rs} \in C^{0,1}(\Omega),$$
$$f \in L^2(\Omega),$$
$$h_k \in H^1(\Omega),$$

and that for all $v \in H^1(\Omega \cap W)$ such that spt $(v) \subseteq \Omega \cap W$,

$$\int_{\Omega} a^{ij}(x) u_{,i}(x) v_{,j}(x) \, dx + \int_{\Omega} h_k(x) v_{,k}(x) \, dx = \int_{\Omega} f(x) v(x) \, dx.$$ \hspace{1cm} (40.2.33)

Then there exists a constant, $C$, independent of $f, u$, and $g$ such that

$$||v||_{H^2(\Omega \cap W_1)}^2 \leq C \left(||f||_{L^2(\Omega)}^2 + ||u||_{H^1(\Omega)}^2 + \sum_k ||h_k||_{H^1(\Omega)}^2\right).$$ \hspace{1cm} (40.2.34)

**Proof:** Let

$$E \equiv \{ v \in H^1(\Omega \cap W) : \text{spt}(v) \subseteq W \}$$

where $u$ restricted to $W \cap \Omega$ is in $H^1(\Omega \cap W)$. Then

$$\int_{\Omega \cap W} a^{ij}(x) u_{,i}(x) v_{,j}(x) \, dx + \int_{\Omega} h_k(x) v_{,k}(x) \, dx = \int_{\Omega} f(x) v(x) \, dx \quad \text{for all } v \in E.$$ \hspace{1cm} (40.2.35)

Now let $\Phi_i(y) = x$. For this particular $W$, denote $\Phi_i$ more simply by $\Phi$, $U_i \equiv \Phi_i(\Omega \cap W_i)$ by $U$, and $V_i$ by $V$. Denoting the coordinates of $V$ by $y$, and letting $u(x) \equiv w(y)$ and $v(x) \equiv z(y)$, it follows that in terms of the new coordinates, (40.2.35) takes the form

\[
\int_{U} a^{ij}(\Phi(y)) \frac{\partial w}{\partial y^r} \frac{\partial z}{\partial y^s} \left| \det D\Phi(y) \right| dy \\
+ \int_{U} h_k(\Phi(y)) \frac{\partial z}{\partial y^l} \left| \det D\Phi(y) \right| dx \\
= \int_{U} f(\Phi(y)) z(y) \left| \det D\Phi(y) \right| dy
\]

Let

$$\alpha^{rs}(y) \equiv a^{ij}(\Phi(y)) \frac{\partial y^r}{\partial x^i} \frac{\partial y^s}{\partial x^j} \left| \det D\Phi(y) \right|,$$ \hspace{1cm} (40.2.36)
\[ \vec{h}_i(y) = h_k(\Phi(y)) \frac{\partial y^l}{\partial x^k} |\det D\Phi(y)|, \quad (40.2.37) \]

and
\[ \vec{f}(y) = \Phi^* f |\det D\Phi(y)| \equiv f(\Phi(y)) |\det D\Phi(y)|. \quad (40.2.38) \]

Now the function on the right in (40.2.36) is in \( C^{0,1}(\overline{U}) \). This is because of the assumption that \( m \geq 1 \) in the statement of the lemma. This function is therefore a finite product of bounded functions in \( C^{0,1}(\overline{U}) \).

The function \( e_h \) defined in (40.2.37) is in \( H^1(U) \) and
\[ \left\| \vec{h}_l \right\|_{H^1(U)} \leq C \sum_k \|h_k\|_{H^1(U \cap V)} \]
again because \( m \geq 1 \).

Finally, the right side of (40.2.38) is a function in \( L^2(U) \) by Lemma 37.3.3 on Page 1377 and the observation that \( |\det D\Phi(\cdot)| \in C^{0,1}(\overline{U}) \) which follows from the assumption of the lemma that \( m \geq 1 \) so \( \Phi \in C^{1,1}(\mathbb{R}^n) \). Also
\[ \left\| \vec{f} \right\|_{L^2(U)} \leq C \|f\|_{L^2(U \cap V)} \]
for all \( z \in H^1(U) \) having support in \( V \).

**Claim:** There exists \( r > 0 \) independent of \( y \in \overline{U} \) such that for all \( y \in \overline{U} \),
\[ a^{rs}(y) v_r v_s \geq r |v|^2. \]

**Proof of the claim:** If this is not so, there exist vectors, \( v^n, |v^n| = 1 \), and \( y_n \in \overline{U} \) such that \( a^{rs}(y_n) v^n_r v^n_s \leq \frac{1}{n} \). Taking a subsequence, there exists \( y \in \overline{U} \) and \( |v| = 1 \) such that \( a^{rs}(y) v_r v_s = 0 \) contradicting (40.2.32).

Therefore, by Lemma 37.1.1 there exists a constant, \( C \), independent of \( f, g, \) and \( w \) such that
\[ \left\| w \right\|^2_{H^2(\Phi^{-1}(W \cap \Omega))} \leq C \left( \left\| \vec{f} \right\|^2_{L^2(U)} + \left\| w \right\|^2_{H^1(U)} + \sum_l \left\| \vec{h}_l \right\|^2_{H^1(U)} \right). \]

Therefore,
\[ \left\| w \right\|^2_{H^2(W \cap \Omega)} \leq C \left( \left\| f \right\|^2_{L^2(W \cap \Omega)} + \left\| w \right\|^2_{H^1(W \cap \Omega)} + \sum_k \left\| h_k \right\|^2_{H^1(W \cap \Omega)} \right) \]
\[ \leq C \left( \left\| f \right\|^2_{L^2(\Omega)} + \left\| w \right\|^2_{H^1(\Omega)} + \sum_k \left\| h_k \right\|^2_{H^1(\Omega)} \right). \]

which proves the lemma.

With this lemma here is the main result.
40.2. THE CASE OF BOUNDED OPEN SETS

**Theorem 40.2.3** Let \( \Omega \) be a bounded open set with \( C^{1,1} \) boundary as in Definition 40.2.1, let \( f \in L^2(\Omega) \), \( h_k \in H^1(\Omega) \), and suppose that for all \( x \in \Omega \),

\[
a^{ij}(x) v_i v_j \geq \delta |v|^2.
\]

Suppose also that \( u \in H^1(\Omega) \) and

\[
\int_\Omega a^{ij}(x) u_i(x) v_j(x) \, dx + \int_\Omega h_k(x) v_{k}(x) \, dx = \int_\Omega f(x) v(x) \, dx
\]

for all \( v \in H^1(\Omega) \). Then \( u \in H^2(\Omega) \) and for some \( C \) independent of \( f, g, \) and \( u \),

\[
\|u\|_{H^2(\Omega)}^2 \leq C \left( \|f\|_{L^2(\Omega)}^2 + \|u\|_{H^1(\Omega)}^2 + \sum_k \|h_k\|_{H^1(\Omega)}^2 \right).
\]

**Proof:** Let the \( W_i \) for \( i = 1, \cdots, l \) be as described in Definition 40.2.1. Thus \( \partial \Omega \subseteq \bigcup_{j=1}^l W_j \). Then let \( C_1 \equiv \partial \Omega \setminus \bigcup_{i=2}^l W_i \), a closed subset of \( W_1 \). Let \( D_1 \) be an open set satisfying

\[
C_1 \subseteq D_1 \subseteq \overline{D_1} \subseteq W_1.
\]

Then \( D_1, W_2, \cdots, W_l \) cover \( \partial \Omega \). Let \( C_2 = \partial \Omega \setminus (D_1 \cup (\bigcup_{i=3}^l W_i)) \). Then \( C_2 \) is a closed subset of \( W_2 \). Choose an open set, \( D_2 \) such that

\[
C_2 \subseteq D_2 \subseteq \overline{D_2} \subseteq W_2.
\]

Thus \( D_1, D_2, W_3 \cdots, W_l \) covers \( \partial \Omega \). Continue in this way to get \( \overline{D_i} \subseteq W_i \), and \( \partial \Omega \subseteq \bigcup_{i=1}^l D_i \), and \( D_i \) is an open set. Now let

\[
D_0 \equiv \Omega \setminus \bigcup_{i=1}^l \overline{D_i}.
\]

Also, let \( \overline{D_i} \subseteq V_i \subseteq \overline{V_i} \subseteq W_i \). Therefore, \( D_0, V_1, \cdots, V_l \) covers \( \Omega \). Then the same estimation process used above yields

\[
\|u\|_{H^2(D_0)} \leq C \left( \|f\|_{L^2(\Omega)}^2 + \|u\|_{H^1(\Omega)}^2 + \sum_k \|h_k\|_{H^1(\Omega)}^2 \right).
\]

From Lemma 40.2.2

\[
\|u\|_{H^2(V_i \cap \Omega)} \leq C \left( \|f\|_{L^2(\Omega)}^2 + \|u\|_{H^1(\Omega)}^2 + \sum_k \|h_k\|_{H^1(\Omega)}^2 \right)
\]

also. This proves the theorem since

\[
\|u\|_{H^2(\Omega)} \leq \sum_{i=1}^l \|u\|_{H^2(V_i \cap \Omega)} + \|u\|_{H^2(D_0)}.
\]

What about the Dirichlet problem? The same differencing procedure as above yields the following.
Theorem 40.2.4 Let \( \Omega \) be a bounded open set with \( C^{1,1} \) boundary, brownian motion theorem as in Definition 40.2.1, let \( f \in L^2(\Omega) \), \( h_k \in H^1(\Omega) \), and suppose that for all \( x \in \Omega \),

\[
a_{ij}(x)v_i v_j \geq \delta |v|^2.
\]

Suppose also that \( u \in H^1_0(\Omega) \) and

\[
\int_{\Omega} a_{ij}(x) u_i(x) v_j(x) \, dx + \int_{\Omega} h_k(x) v_k(x) \, dx = \int_{\Omega} f(x) v(x) \, dx
\]

for all \( v \in H^1_0(\Omega) \). Then \( u \in H^2(\Omega) \) and for some \( C \) independent of \( f, g, \) and \( u \),

\[
||u||_{H^2(\Omega)} \leq C \left( ||f||^2_{L^2(\Omega)} + ||u||^2_{H^1(\Omega)} + \sum_k ||h_k||^2_{H^1(\Omega)} \right).
\]

What about higher regularity?

Lemma 40.2.5 Let \( W \) be one of the sets described in Definition 40.2.1 and let \( m \geq k \). Let \( W_1 \subseteq \overline{W_1} \subseteq W \) where \( W_1 \) is an open set. Suppose also that

\[
u \in H^k(\Omega), \quad \alpha^{rs} \in C^{k-1,1}(\overline{\Omega}), \quad f \in H^{k-1}(\Omega), \quad h_s \in H^k(\Omega),
\]

and that for all \( v \in H^1(\Omega \cap W) \) such that \( \text{spt}(v) \subseteq \Omega \cap W \),

\[
\int_{\Omega} a_{ij}(x) u_i(x) v_j(x) \, dx + \int_{\Omega} h_s(x) v_s(x) \, dx = \int_{\Omega} f(x) v(x) \, dx. \tag{40.2.40}
\]

Then there exists a constant, \( C \), independent of \( f, u, \) and \( g \) such that

\[
||u||^2_{H^{k+1}(\Omega \cap W_1)} \leq C \left( ||f||^2_{H^{k-1}(\Omega)} + ||u||^2_{H^k(\Omega)} + \sum_s ||h_s||^2_{H^k(\Omega)} \right). \tag{40.2.41}
\]

Proof: Let

\[
E \equiv \{ v \in H^k(\Omega \cap W) : \text{spt}(v) \subseteq W \}
\]

\( u \) restricted to \( W \cap \Omega \) is in \( H^k(\Omega \cap W) \) and

\[
\int_{\Omega \cap W} a_{ij}(x) u_i(x) v_j(x) \, dx + \int_{\Omega} h_s(x) v_s(x) \, dx = \int_{\Omega} f(x) v(x) \, dx \quad \text{for all } v \in E. \tag{40.2.42}
\]

Now let \( \Phi_1(y) = x \). For this particular \( W \), denote \( \Phi_1 \) more simply by \( \Phi \), \( U_1 \equiv \Phi_1(\Omega \cap W_1) \) by \( U \), and \( V_1 \) by \( V \). Denoting the coordinates of \( V \) by \( y \), and letting
40.2. THE CASE OF BOUNDED OPEN SETS

\( u(x) \equiv w(y) \) and \( v(x) \equiv z(y) \), it follows that in terms of the new coordinates, takes the form

\[
\int_{U} a_{ij} (\Phi(y)) \frac{\partial w}{\partial y^r} \frac{\partial z}{\partial y^s} |\det D\Phi(y)| \, dy \\
+ \int_{U} h_k (\Phi(y)) \frac{\partial z}{\partial y^l} \frac{\partial y^l}{\partial x^j} |\det D\Phi(y)| \, dx \\
= \int_{U} f (\Phi(y)) z(y) |\det D\Phi(y)| \, dy
\]

Let

\[
\alpha^{rs} (y) \equiv a_{ij} (\Phi(y)) \frac{\partial y^r}{\partial x^j} \frac{\partial y^s}{\partial x^j} |\det D\Phi(y)|, \quad (40.2.43)
\]

\[
\tilde{h}_l (y) \equiv h_k (\Phi(y)) \frac{\partial y^l}{\partial x^k} |\det D\Phi(y)|, \quad (40.2.44)
\]

and

\[
\tilde{f} (y) \equiv \Phi^* f |\det D\Phi(y) = f (\Phi(y)) |\det D\Phi(y)|. \quad (40.2.45)
\]

Now the function on the right in (40.2.43) is in \( C^{k,1} (U) \). This is because of the assumption that \( m \geq k \) in the statement of the lemma. This function is therefore a finite product of bounded functions in \( C^{k,1} (U) \).

The function \( \tilde{h}_l \) defined in (40.2.44) is in \( H^k (U) \) and

\[
\left\| \tilde{h}_l \right\|_{H^k(U)} \leq C \sum_s \|h_s\|_{H^k(\Omega \setminus W)}
\]

again because \( m \geq k \).

Finally, the right side of (40.2.43) is a function in \( H^{k-1} (U) \) by Lemma 37.3.3 on Page 1377 and the observation that \( |\det D\Phi(\cdot)| \in C^{k-1,1} (U) \) which follows from the assumption of the lemma that \( m \geq k \) so \( \Phi \in C^{k-1,1} (\mathbb{R}^n) \). Also

\[
\left\| \tilde{f} \right\|_{H^{k-1}(U)} \leq C \|f\|_{H^{k-1}(\Omega \setminus W)}
\]

Therefore, (40.2.43) is of the form

\[
\int_{U} \alpha^{rs} (y) w_r z_s \, dy + \int_{U} \tilde{h}_l z_l \, dy = \int_{U} \tilde{f} z \, dy, \quad (40.2.46)
\]

for all \( z \in H^1 (U) \) having support in \( V \).

**Claim:** There exists \( r > 0 \) independent of \( y \in U \) such that for all \( y \in U \),

\[
\alpha^{rs} (y) v_r v_s \geq r |v|^2.
\]

**Proof of the claim:** If this is not so, there exist vectors, \( v^n, |v^n| = 1 \), and \( y_n \in \overline{U} \) such that \( \alpha^{rs} (y_n) v^n_r v^n_s \leq \frac{1}{n} \). Taking a subsequence, there exists \( y \in U \) and \( |v| = 1 \) such that \( \alpha^{rs} (y) v_r v_s = 0 \) contradicting (40.2.42).
Therefore, by Corollary 40.1.2, there exists a constant, $C$, independent of $f, g,$ and $w$ such that
\[
\|w\|_{H^{k+1}(\Phi^{-1}(W_1 \cap \Omega))}^2 \leq C \left( \|f\|_{H^{k-1}(U)}^2 + \|w\|_{H^k(U)}^2 + \sum_l \|h_l\|_{H^k(U)}^2 \right).
\]
Therefore,
\[
\|u\|_{H^{k+1}(W_1 \cap \Omega)}^2 \leq C \left( \|f\|_{H^{k-1}(W \cap \Omega)}^2 + \|w\|_{H^k(W \cap \Omega)}^2 + \sum_s \|h_s\|_{H^k(W \cap \Omega)}^2 \right)
\]
\[
\leq C \left( \|f\|_{H^{k-1}(\Omega)}^2 + \|w\|_{H^k(\Omega)}^2 + \sum_s \|h_s\|_{H^k(\Omega)}^2 \right).
\]
which proves the lemma.

Now here is a theorem which generalizes the one above in the case where more regularity is known.

**Theorem 40.2.6** Let $\Omega$ be a bounded open set with $C^{k,1}$ boundary as in Definition 40.2.1, let $f \in H^{k-1}(\Omega), h_s \in H^k(\Omega),$ and suppose that for all $x \in \Omega,$
\[
a^{ij}(x) v_i v_j \geq \delta |v|^2.
\]
Suppose also that $u \in H^k(\Omega)$ and
\[
\int_{\Omega} a^{ij}(x) u_i(x) v_j(x)\,dx + \int_{\Omega} h_k(x) v_k(x)\,dx = \int_{\Omega} f(x) v(x)\,dx
\]
for all $v \in H^k(\Omega).$ Then $u \in H^{k+1}(\Omega)$ and for some $C$ independent of $f, g,$ and $u,$
\[
\|u\|_{H^{k+1}(\Omega)}^2 \leq C \left( \|f\|_{H^{k-1}(\Omega)}^2 + \|w\|_{H^k(\Omega)}^2 + \sum_s \|h_s\|_{H^k(\Omega)}^2 \right).
\]

**Proof:** Let the $W_i$ for $i = 1, \ldots, l$ be as described in Definition 40.2.1. Thus $\partial \Omega \subseteq \bigcup_{j=1}^l W_j.$ Then let $C_1 = \partial \Omega \setminus \bigcup_{i=2}^l W_i,$ a closed subset of $W_1.$ Let $D_1$ be an open set satisfying
\[
C_1 \subseteq D_1 \subseteq \overline{D_1} \subseteq W_1.
\]
Then $D_1, W_2, \ldots, W_l$ cover $\partial \Omega.$ Let $C_2 = \partial \Omega \setminus \left( D_1 \cup \bigcup_{i=3}^l W_i \right).$ Then $C_2$ is a closed subset of $W_2.$ Choose an open set, $D_2$ such that
\[
C_2 \subseteq D_2 \subseteq \overline{D_2} \subseteq W_2.
\]
Thus $D_1, D_2, W_3, \ldots, W_l$ covers $\partial \Omega.$ Continue in this way to get $\overline{D_i} \subseteq W_i,$ and $\partial \Omega \subseteq \bigcup_{i=1}^l D_i,$ and $D_i$ is an open set. Now let
\[
D_0 = \Omega \setminus \bigcup_{i=1}^l D_i.
\]
Also, let $D_i \subseteq V_i \subseteq \overline{V}_i \subseteq W_i$. Therefore, $D_0, V_1, \ldots, V_i$ covers $\Omega$. Then the same estimation process used above yields

$$
||u||_{H^{k+1}(D_0)} \leq C \left( ||f||^2_{H^{k-1}(\Omega)} + ||u||^2_{H^k(\Omega)} + \sum_k ||h_k||^2_{H^k(\Omega)} \right).
$$

From Lemma 40.2.5

$$
||u||_{H^{k+1}(V_i \cap \Omega)} \leq C \left( ||f||^2_{H^{k-1}(\Omega)} + ||u||^2_{H^k(\Omega)} + \sum_k ||h_k||^2_{H^k(\Omega)} \right)
$$

also. This proves the theorem since

$$
||u||_{H^{k+1}(\Omega)} \leq \sum_{i=1}^l ||u||_{H^{k+1}(V_i \cap \Omega)} + ||u||_{H^{k+1}(D_0)}.
$$
Chapter 41

Interpolation In Banach Space

41.1 Some Standard Techniques In Evolution Equations

41.1.1 Weak Vector Valued Derivatives

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

Lemma 41.1.1 Suppose \( g \in L^1([a,b]; X) \) where \( X \) is a Banach space. Then if \( \int_a^b g(t) \phi(t) \, dt = 0 \) for all \( \phi \in C^\infty_c(a,b) \), then \( g(t) = 0 \) a.e.

Proof: Let \( E \) be a measurable subset of \((a,b)\) and let \( K \subseteq E \subseteq V \subseteq (a,b) \) where \( K \) is compact, \( V \) is open and \( m(V \setminus K) < \epsilon \). Let \( K \prec h \prec V \) as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging \( K \) slightly and convolving with a mollifier, it can be assumed \( h \in C^\infty_c(a,b) \). Then

\[
\left| \int_a^b X_E(t) g(t) \, dt \right| = \left| \int_a^b (X_E(t) - h(t)) g(t) \, dt \right| \\
\leq \int_a^b |X_E(t) - h(t)||g(t)|| \, dt \\
\leq \int_{V \setminus K} ||g(t)|| \, dt.
\]

Now let \( K_n \subseteq E \subseteq V_n \) with \( m(V_n \setminus K_n) < 2^{-n} \). Then from the above,

\[
\left| \int_a^b X_E(t) g(t) \, dt \right| \leq \int_a^b X_{V_n \setminus K_n}(t)||g(t)|| \, dt
\]

1439
and the integrand of the last integral converges to 0 a.e. as \( n \to \infty \) because \( \sum_n m(V_n \setminus K_n) < \infty \). By the dominated convergence theorem, this last integral converges to 0. Therefore, whenever \( E \subseteq (a, b) \),

\[
\int_a^b X_E(t) g(t) \, dt = 0.
\]

Since the endpoints have measure zero, it also follows that for any measurable \( E \), the above equation holds.

Now \( g \in L^1 ([a, b]; X) \) and so it is measurable. Therefore, \( g([a, b]) \) is separable. Let \( D \) be a countable dense subset and let \( E \) denote the set of linear combinations of the form \( \sum a_i d_i \) where \( a_i \) is a rational point of \( \mathbb{F} \) and \( d_i \in D \). Thus \( E \) is countable. Denote by \( Y \) the closure of \( E \) in \( X \). Thus \( Y \) is a separable closed subspace of \( X \) which contains all the values of \( g \).

Now let \( S_n = g^{-1}(B(y_n, ||y_n||/2)) \) where \( E = \{y_n\}_{n=1}^\infty \). Therefore, \( \cup_n S_n = g^{-1}(X \setminus \{0\}) \). This follows because if \( x \in Y \) and \( x \neq 0 \), then in \( B \left( x, \frac{||x||}{4} \right) \) there is a point of \( E, y_n \). Therefore, \( ||y_n|| > \frac{3}{4} ||x|| \) and so \( ||y_n|| > \frac{3||x||}{4} > \frac{||x||}{4} \) so \( x \in B(y_n, ||y_n||/2) \). It follows that if each \( S_n \) has measure zero, then \( g(t) = 0 \) for a.e. \( t \). Suppose then that for some \( n \), the set, \( S_n \) has positive measure. Then from what was shown above,

\[
||y_n|| = \left| \frac{1}{m(S_n)} \int_{S_n} g(t) \, dt - y_n \right| \leq \frac{1}{m(S_n)} \int_{S_n} ||g(t) - y_n|| \, dt \leq \frac{1}{m(S_n)} \int_{S_n} ||y_n||/2 \, dt = ||y_n||/2
\]

and so \( y_n = 0 \) which implies \( S_n = \emptyset \), a contradiction to \( m(S_n) > 0 \). This contradiction shows each \( S_n \) has measure zero and so as just explained, \( g(t) = 0 \) a.e.

\textbf{Definition 41.1.2} For \( f \in L^1 (a, b; X) \), define an extension, \( \overline{f} \) defined on

\[
[2a - b, 2b - a] = [a - (b - a), b + (b - a)]
\]

as follows.

\[
\overline{f}(t) = \begin{cases} 
  f(t) & \text{if } t \in [a, b] \\
  f(2a - t) & \text{if } t \in [2a - b, a] \\
  f(2b - t) & \text{if } t \in [b, 2b - a]
\end{cases}
\]

\textbf{Definition 41.1.3} Also if \( f \in L^p (a, b; X) \) and \( h > 0 \), define for \( t \in [a, b] \), \( f_h(t) = \overline{f}(t - h) \) for all \( h < b - a \). Thus the map \( f \to f_h \) is continuous and linear on \( L^p (a, b; X) \). It is continuous because

\[
\int_a^b ||f_h(t)||^p \, dt = \int_a^{a+h} ||f(2a - t + h)||^p \, dt + \int_a^{b-h} ||f(t)||^p \, dt = \int_a^{a+h} ||f(t)||^p \, dt + \int_a^{b-h} ||f(t)||^p \, dt \leq 2 ||f||_p^p.
\]
41.1. SOME STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

The following lemma is on continuity of translation in $L^p(a,b;X)$.

**Lemma 41.1.4** Let $\overline{f}$ be as defined in Definition [text]. Then for $f \in L^p(a,b;X)$ for $p \in [1, \infty)$,

$$\lim_{\delta \to 0} \int_a^b \|\overline{f}(t - \delta) - f(t)\|^p_X dt = 0.$$

**Proof:** Regarding the measure space as $(a,b)$ with Lebesgue measure, by Lemma 19.5.9 there exists $g \in C_c(a,b;X)$ such that $\|f - g\|_p < \varepsilon$. Here the norm is the norm in $L^p(a,b;X)$. Therefore,

$$\|f_h - f\|_p \leq \|f_h - g_h\|_p + \|g_h - g\|_p + \|g - f\|_p \leq (2^{1/p} + 1)\|f - g\|_p + \|g_h - g\|_p < (2^{1/p} + 1)\varepsilon + \varepsilon$$

whenever $h$ is sufficiently small. This is because of the uniform continuity of $g$. Therefore, since $\varepsilon > 0$ is arbitrary, this proves the lemma. ■

**Definition 41.1.5** Let $f \in L^1(a,b;X)$. Then the distributional derivative in the sense of $X$ valued distributions is given by

$$f'(\phi) \equiv -\int_a^b f(t) \phi'(t) dt$$

Then $f' \in L^1(a,b;X)$ if there exists $h \in L^1(a,b;X)$ such that for all $\phi \in C_c^\infty(a,b)$,

$$f'(\phi) = \int_a^b h(t) \phi(t) dt.$$

Then $f'$ is defined to equal $h$. Here $f$ and $f'$ are considered as vector valued distributions in the same way as was done for scalar valued functions.

**Lemma 41.1.6** The above definition is well defined.

**Proof:** Suppose both $h$ and $g$ work in the definition. Then for all $\phi \in C_c^\infty(a,b)$,

$$\int_a^b (h(t) - g(t)) \phi(t) dt = 0.$$

Therefore, by Lemma [text], $h(t) - g(t) = 0$ a.e. ■

The other thing to notice about this is the following lemma. It follows immediately from the definition.

**Lemma 41.1.7** Suppose $f, f' \in L^1(a,b;X)$. Then if $[c,d] \subseteq [a,b]$, it follows that $(f|_{[c,d]})' = f'|_{[c,d]}$. This notation means the restriction to $[c,d]$. 
Recall that in the case of scalar valued functions, if you had both $f$ and its weak derivative, $f'$ in $L^1(a,b)$, then you were able to conclude that $f$ is almost everywhere equal to a continuous function, still denoted by $f$ and

$$f(t) = f(a) + \int_a^t f'(s) \, ds.$$ 

In particular, you can define $f(a)$ to be the initial value of this continuous function.

It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if $f'$ equals 0 where the derivative is taken in the sense of $X$ valued distributions, then $f$ equals a constant.

**Lemma 41.1.8** Suppose $f \in L^1(a,b; X)$ and for all $\phi \in C_c^\infty(a,b)$,

$$\int_a^b f(t) \phi'(t) \, dt = 0.$$ 

Then there exists a constant, $a \in X$ such that $f(t) = a$ a.e.

**Proof:** Let $\phi_0 \in C_c^\infty(a,b)$, $\int_a^b \phi_0(x) \, dx = 1$ and define for $\phi \in C_c^\infty(a,b)$

$$\psi_\phi(x) \equiv \int_a^x \left[ \phi(t) - \left( \int_a^b \phi(y) \, dy \right) \phi_0(t) \right] dt.$$ 

Then $\psi_\phi \in C_c^\infty(a,b)$ and $\psi'_\phi = \phi - \left( \int_a^b \phi(y) \, dy \right) \phi_0$. Then

$$\int_a^b f(t) (\phi(t)) \, dt = \int_a^b f(t) \left( \psi'_\phi(t) + \left( \int_a^b \phi(y) \, dy \right) \phi_0(t) \right) \, dt$$

$$= 0 \text{ by assumption}$$

$$= \int_a^b f(t) \psi'_\phi(t) \, dt + \left( \int_a^b \phi(y) \, dy \right) \int_a^b f(t) \phi_0(t) \, dt$$

$$= \left( \int_a^b \left( \int_a^b f(t) \phi_0(t) \, dt \right) \phi(y) \, dy \right).$$ 

It follows that for all $\phi \in C_c^\infty(a,b)$,

$$\int_a^b \left( f(y) - \left( \int_a^b f(t) \phi_0(t) \, dt \right) \right) \phi(y) \, dy = 0$$

and so by Lemma 41.1.1, $f(y) - \left( \int_a^b f(t) \phi_0(t) \, dt \right) = 0$ a.e. $y$.■
41.1. SOME STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

Theorem 41.1.9 Suppose \( f, f' \) both are in \( L^1(a, b; X) \) where the derivative is taken in the sense of \( X \) valued distributions. Then there exists a unique point of \( X \), denoted by \( f(a) \) such that the following formula holds a.e. \( t \):

\[
f(t) = f(a) + \int_a^t f'(s) \, ds
\]

Proof:

\[
\int_a^b \left( f(t) - \int_a^t f'(s) \, ds \right) \phi'(t) \, dt = \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt.
\]

Now consider \( \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt \). Let \( \Lambda \in X' \). Then it is routine from approximating \( f' \) with simple functions to verify

\[
\Lambda \left( \int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt \right) = \int_a^b \int_a^t \Lambda(f'(s)) \phi'(t) \, ds \, dt.
\]

Now the ordinary Fubini theorem can be applied to obtain

\[
= \int_a^b \int_s^b \Lambda(f'(s)) \phi'(t) \, dt \, ds
\]

\[
= \Lambda \left( \int_a^b \int_s^b f'(s) \phi'(t) \, dt \, ds \right).
\]

Since \( X' \) separates the points of \( X \), it follows

\[
\int_a^b \int_a^t f'(s) \phi'(t) \, ds \, dt = \int_a^b f'(s) \phi'(t) \, ds \, dt.
\]

Therefore,

\[
\int_a^b \left( f(t) - \int_a^t f'(s) \, ds \right) \phi'(t) \, dt
\]

\[
= \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_s^b f'(s) \phi'(t) \, dt \, ds
\]

\[
= \int_a^b f(t) \phi'(t) \, dt - \int_a^b f'(s) \int_s^b \phi'(t) \, dt \, ds
\]

\[
= \int_a^b f(t) \phi'(t) \, dt + \int_a^b f'(s) \phi(s) \, ds = 0.
\]

Therefore, by Lemma 41.1.8, there exists a constant, denoted as \( f(a) \) such that

\[
f(t) - \int_a^t f'(s) \, ds = f(a)
\]

The integration by parts formula is also important.
Corollary 41.1.10 Suppose \( f, f' \in L^1 (a, b; X) \) and suppose \( \phi \in C^1 ([a, b]) \). Then the following integration by parts formula holds.

\[
\int_a^b f (t) \phi' (t) \, dt = f (b) \phi (b) - f (a) \phi (a) - \int_a^b f' (t) \phi (t) \, dt.
\]

**Proof:** From Theorem 41.1.9

\[
\int_a^b f (t) \phi' (t) \, dt = \int_a^b \left( f (a) + \int_a^t f' (s) \, ds \right) \phi' (t) \, dt
\]

\[
= f (a) (\phi (b) - \phi (a)) + \int_a^b \int_a^t f' (s) \, ds \phi' (t) \, dt
\]

\[
= f (a) (\phi (b) - \phi (a)) + \int_a^b f' (s) \int_s^b \phi' (t) \, dt \, ds
\]

\[
= f (a) (\phi (b) - \phi (a)) + \int_a^b f' (s) (\phi (b) - \phi (s)) \, ds
\]

\[
= f (a) (\phi (b) - \phi (a)) - \int_a^b f' (s) \phi (s) \, ds + (f (b) - f (a)) \phi (b)
\]

\[
= f (b) \phi (b) - f (a) \phi (a) - \int_a^b f' (s) \phi (s) \, ds.
\]

The interchange in order of integration is justified as in the proof of Theorem 41.1.9.

There is an interesting theorem which is easy to present at this point.

**Definition 41.1.11** Let

\[ H^1 (0, T, X) \]

denote the functions \( f \in L^2 (0, T, X) \) whose weak derivative \( f' \) is also in \( L^2 (0, T, X) \).

**Proposition 41.1.12** Let \( f \in H^1 (0, T, X) \). Then \( f \in C^{0, (1/2)} ([0, T], X) \) and the inclusion map is continuous.

**Proof:** First note that

\[
f (t) - f (s) = \int_s^t f' (r) \, dr
\]

and so

\[
\|f (t) - f (s)\|_X \leq \int_s^t \|f' (r)\|_X \, dr \leq \|f\|_{H^1} |t - s|^{1/2}
\]

It follows that

\[
\sup_{0 \leq s < t \leq T} \frac{\|f (t) - f (s)\|}{|t - s|^{1/2}} \leq \|f\|_{H^1}
\]
Also
\[ f(t) = f(0) + \int_0^t f'(s) \, ds \]
so
\[ \| f(t) \| \leq \| f(0) \| + \int_0^t \| f'(s) \| \, ds \leq \| f(0) \| + T^{1/2} \| f \|_{H^1} \]

Now consider \( \| f(0) \| \). Then integrating by parts yields
\[
\int_0^T (T-t) f'(t) \, dt = (T-t) f(t) \big|_0^T + \int_0^T f(t) \, dt
\]
and so
\[ T \| f(0) \| \leq \int_0^T \| f(t) \| \, dt + T \int_0^T \| f'(t) \| \, dt \leq C(T) \| f \|_{H^1}. \]
Hence
\[ \sup_{t \in [0,T]} \| f(t) \| \leq C(T) \| f \|_{H^1} \]
Therefore, this has shown that
\[ \| f \|_{C^{0,(1/2)}([0,T];X)} \equiv \sup_{t \in [0,T]} \| f(t) \| + \sup_{0 \leq s < t \leq T} \frac{\| f(t) - f(s) \|}{|t-s|^{1/2}} \leq C(T) \| f \|_{H^1}. \]

You could imagine that other interesting versions of this are available with similar proof for the case where the function and its weak derivative are in \( L^p(0,T;X) \) for \( p > 1 \).

With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define \( \overline{f} \) as in Definition 41.1.2.

**Lemma 41.1.13** Let \( \overline{f} \) be given in Definition 41.1.2 and suppose \( f, f' \in L^1(a,b;X) \). Then \( \overline{f}, \overline{f}' \in L^1(2a-b,2b-a;X) \) also and

\[
\overline{f}'(t) \equiv \begin{cases} 
  f'(t) & \text{if } t \in [a,b] \\
  -f'(2a-t) & \text{if } t \in [2a-b,a] \\
  -f'(2b-t) & \text{if } t \in [b,2b-a] 
\end{cases}
\]  

**Proof:** It is clear from the definition of \( \overline{f} \) that \( \overline{f} \in L^1(2a-b,2b-a;X) \) and that in fact
\[ \| \overline{f} \|_{L^1(2a-b,2b-a;X)} \leq 3 \| f \|_{L^1(a,b;X)}. \]
Let $\phi \in C_c^\infty(2a-b,2b-a)$. Then from the integration by parts formula,
\[
\int_{2a-b}^{2b-a} f(t) \phi'(t) \, dt = \int_a^b f(t) \phi'(t) \, dt + \int_{2a-b}^b f(2b-t) \phi'(t) \, dt + \int_a^{2a-b} f(2a-t) \phi'(t) \, dt \\
= \int_a^b f(t) \phi'(t) \, dt + \int_{2a-b}^b f(u) \phi'(2b-u) \, du + \int_a^{2a-b} f(u) \phi'(2a-u) \, du \\
= f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(t) \phi(t) \, dt - f(b) \phi(b) + f(a) \phi(2b-a) \\
+ \int_a^b f'(u) \phi(2b-u) \, du - f(b) \phi(2a-b) + f(a) \phi(a) + \int_a^b f'(u) \phi(2a-u) \, du \\
= - \int_a^b f'(t) \phi(t) \, dt + \int_a^b f'(u) \phi(2b-u) \, du + \int_a^b f'(u) \phi(2a-u) \, du \\
= - \int_a^b f'(t) \phi(t) \, dt - \int_{2a-b}^b -f'(2b-t) \phi(t) \, dt - \int_{2a-b}^a -f'(2a-t) \phi(t) \, dt \\
= - \int_{2a-b}^{2b-a} \tilde{f}(t) \phi(t) \, dt
\]
where $\tilde{f}'(t)$ is given in $f(t)$. 

**Definition 41.1.14** Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H = L^2(\Omega)$) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write

$$V \subseteq H = H' \subseteq V'.$$

When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g \rangle$ to denote $f(g)$ for $f \in V'$ and $g \in V$. This may also be written as $\langle f, g \rangle_{V',V}$. Another term is that $V \subseteq H = H' \subseteq V'$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^p(0,T;V)$ while $f' \in L^p(0,T;V')$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

**Theorem 41.1.15** Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 41.1.14. Suppose $f \in L^p(0,T;V)$ and $f' \in L^p(0,T;V')$. Then $f$ is
41.1. SOME STANDARD TECHNIQUES IN EVOLUTION EQUATIONS 1447

a.e. equal to a continuous function mapping \([0, T]\) to \(H\). Furthermore, there exists \(f(0) \in H\) such that

\[
\frac{1}{2} |f(t)|^2_H - \frac{1}{2} |f(0)|^2_H = \int_0^t \langle f'(s), f(s) \rangle \, ds, \tag{41.1.3}
\]

and for all \(t \in [0, T]\),

\[
\int_0^t f'(s) \, ds \in H, \tag{41.1.4}
\]

and for a.e. \(t \in [0, T]\),

\[f(t) = f(0) + \int_0^t f'(s) \, ds \text{ in } H, \tag{41.1.5}\]

Here \(f'\) is being taken in the sense of \(V'\) valued distributions and \(\frac{1}{p} + \frac{1}{p'} = 1\) and \(p \geq 2\).

**Proof:** Let \(\Psi \in C_c^\infty (-T, 2T)\) satisfy \(\Psi(t) = 1\) if \(t \in [-T/2, 3T/2]\) and \(\Psi(t) \geq 0\). For \(t \in \mathbb{R}\), define

\[
\hat{f}(t) = \begin{cases} \int (-T, 2T) \Psi(t) & \text{if } t \in [-T, 2T] \\
0 & \text{if } t \notin [-T, 2T] 
\end{cases}
\]

and

\[
f_n(t) = \int_{-1/n}^{1/n} \hat{f}(t-s) \phi_n(s) \, ds \tag{41.1.6}
\]

where \(\phi_n\) is a mollifier having support in \((-1/n, 1/n)\). Then by Minkowski’s inequality

\[
\left\| f_n - \hat{f} \right\|_{L^p(\mathbb{R}; V)} = \left( \int_{\mathbb{R}} \left\| \hat{f}(t) - \int_{-1/n}^{1/n} \hat{f}(t-s) \phi_n(s) \, ds \right\|_V^p \, dt \right)^{1/p}
\]

\[
= \left( \int_{\mathbb{R}} \left( \int_{-1/n}^{1/n} \left| \hat{f}(t) - \hat{f}(t-s) \right|^{1/n} \phi_n(s) \, ds \right)_V^p \, dt \right)^{1/p}
\]

\[
\leq \left( \int_{\mathbb{R}} \left( \int_{-1/n}^{1/n} \left| \hat{f}(t) - \hat{f}(t-s) \right|_V^{p} \, ds \right) \phi_n(s) \, dt \right)^{1/p}
\]

\[
\leq \int_{-1/n}^{1/n} \phi_n(s) \left( \int_{\mathbb{R}} \left| \hat{f}(t) - \hat{f}(t-s) \right|_V^{p} \, dt \right)^{1/p} \, ds
\]

\[
\leq \int_{-1/n}^{1/n} \phi_n(s) \, ds = \varepsilon
\]

provided \(n\) is large enough. This follows from continuity of translation in \(L^p\) with Lebesgue measure. Since \(\varepsilon > 0\) is arbitrary, it follows \(f_n \to \hat{f}\) in \(L^p(\mathbb{R}; V)\). Similarly,
\( f_n \to f \) in \( L^2(\mathbb{R};H) \). This follows because \( p \geq 2 \) and the norm in \( V \) and norm in \( H \) are related by \( |x|_H \leq C|x|_V \) for some constant, \( C \). Now

\[
\hat{f}(t) = \begin{cases} 
\Psi(t)f(t) & \text{if } t \in [0,T], \\
\Psi(t)f(2T-t) & \text{if } t \in [T,2T], \\
\Psi(t)f(-t) & \text{if } t \in [0,T], \\
0 & \text{if } t \notin [-T,2T].
\end{cases}
\]

An easy modification of the argument of Lemma \[41.1.3\] yields

\[
\hat{f'}(t) = \begin{cases} 
\Psi'(t)f(t) + \Psi(y)f'(t) & \text{if } t \in [0,T], \\
\Psi'(t)f(2T-t) - \Psi(y)f'(2T-t) & \text{if } t \in [T,2T], \\
\Psi'(t)f(-t) - \Psi(y)f'(t) & \text{if } t \in [-T,0], \\
0 & \text{if } t \notin [-T,2T].
\end{cases}
\]

Recall

\[
f_n(t) = \int_{-1/n}^{1/n} \hat{f}(t-s)\phi_n(s)\,ds = \int_{-1/n}^{1/n} \hat{f}(t)\phi_n(s)\,ds
\]

\[
= \int_{-1/n}^{1/n} \hat{f}(s)\phi_n(t-s)\,ds.
\]

Therefore,

\[
f'_n(t) = \int_{-1/n}^{1/n} \hat{f}'(s)\phi_n'(t-s)\,ds = \int_{-1/n}^{1/n} \hat{f}'(s)\phi_n'(t-s)\,ds
\]

\[
= \int_{-1/n}^{1/n} \hat{f}'(s)\phi_n(t-s)\,ds
\]

\[
= \int_{-1/n}^{1/n} \hat{f}'(t-s)\phi_n(t)\,ds
\]

and it follows from the first line above that \( f'_n \) is continuous with values in \( V \) for all \( t \in \mathbb{R} \). Also note that both \( f'_n \) and \( f_n \) equal zero if \( t \notin [-T,2T] \) whenever \( n \) is large enough. Exactly similar reasoning to the above shows that \( f'_n \to \hat{f}' \) in \( L^p(\mathbb{R};V') \).

Now let \( \phi \in C_0^\infty(0,T) \).

\[
\int_{\mathbb{R}} |f_n(t)|_H^2 \phi'(t)\,dt = \int_{\mathbb{R}} (f_n(t),f_n(t))_H \phi'(t)\,dt \quad \text{(41.1.7)}
\]

\[
= -\int_{\mathbb{R}} 2 \langle f'_n(t),f_n(t) \rangle \phi(t)\,dt = -\int_{\mathbb{R}} 2 \langle f'_n(t),f_n(t) \rangle \phi(t)\,dt
\]

Now

\[
\left| \int_{\mathbb{R}} \langle f'_n(t),f_n(t) \rangle \phi(t)\,dt - \int_{\mathbb{R}} \langle f'(t),f(t) \rangle \phi(t)\,dt \right|
\]

\[
\leq \int_{\mathbb{R}} \left| \langle f'_n(t) - f'(t),f_n(t) \rangle \phi(t)\,dt \right| + \int_{\mathbb{R}} \left| \langle f'(t),f_n(t) - f(t) \rangle \phi(t)\,dt \right|.
\]
From the first part of this proof which showed that \( f_n \to \hat{f} \) in \( L^p(\mathbb{R}; V) \) and \( f'_n \to \hat{f}' \) in \( L^{p'}(\mathbb{R}; V') \), an application of Holder’s inequality shows the above converges to 0 as \( n \to \infty \). Therefore, passing to the limit as \( n \to \infty \) in the RHS,

\[
\int_{\mathbb{R}} |\hat{f}(t)|^2_H \phi' (t) dt = - \int_{\mathbb{R}} 2 \langle \hat{f}'(t), \hat{f}(t) \rangle \phi(t) dt
\]

which shows \( t \to |\hat{f}(t)|^2_H \) equals a continuous function a.e. and it also has a weak derivative equal to \( 2 \langle \hat{f}'', \hat{f} \rangle \).

It remains to verify that \( \hat{f} \) is continuous on \([0,T]\). Of course \( \hat{f} = f \) on this interval. Let \( N \) be large enough that \( f_n(-T) = 0 \) for all \( n > N \). Then for \( m, n > N \) and \( t \in [-T,2T] \)

\[
|f_n(t) - f_m(t)|^2_H = 2 \int_{-T}^t (f'_n(s) - f'_m(s), f_n(s) - f_m(s)) ds = 2 \int_{-T}^t (f'_n(s) - f'_m(s), f_n(s) - f_m(s))_{V',V} ds \\
\leq 2 \int_{-T}^t ||f'_n(s) - f'_m(s)||_{V'} ||f_n(s) - f_m(s)||_V ds \\
\leq 2 ||f_n - f_m||_{L^p(\mathbb{R}; V')} ||f_n - f_m||_{L^p(\mathbb{R}; V)}
\]

which shows from the above that \( \{f_n\} \) is uniformly Cauchy on \([-T,2T]\) with values in \( H \). Therefore, there exists \( g \) a continuous function defined on \([-T,2T]\) having values in \( H \) such that

\[
\lim_{n \to \infty} \max \{|f_n(t) - g(t)|_H ; t \in [-T,2T]\} = 0.
\]

However, \( g = \hat{f} \) a.e. because \( f_n \) converges to \( f \) in \( L^p(0,T;V) \). Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that \( V \subseteq H = H' \subseteq V' \) and Theorem 41.1.8, there exists \( f(0) \in V' \) such that for a.e. \( t \),

\[
f(t) = f(0) + \int_0^t f'(s) ds \text{ in } V'
\]

Now \( g = f \) a.e. and \( g \) is continuous with values in \( H \) hence continuous with values in \( V' \) and so

\[
g(t) = f(0) + \int_0^t f'(s) ds \text{ in } V'
\]

for all \( t \). Since \( g \) is continuous with values in \( H \) it is continuous with values in \( V' \). Taking the limit as \( t \downarrow 0 \) in the above, \( g(a) = \lim_{t \to 0^+} g(t) = f(0) \), showing that \( f(0) \in H \). Therefore, for a.e. \( t \),

\[
f(t) = f(0) + \int_0^t f'(s) ds \text{ in } H, \int_0^t f'(s) ds \in H. \]
Note that if \( f \in L^p(0, T; V) \) and \( f' \in L^{p'}(0, T; V') \), then you can consider the initial value of \( f \) and it will be in \( H \). What if you start with something in \( H \)? Is it an initial condition for a function \( f \in L^p(0, T; V) \) such that \( f' \in L^{p'}(0, T; V') \)? This is worth thinking about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if \( V \) is a closed subspace of the Sobolev space, \( W^{1,p}(\Omega) \) which contains \( W^{1,0}(\Omega) \) for \( p \geq 2 \) and \( H = L^2(\Omega) \) the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

### 41.2 An Important Formula

It is not necessary to have \( p > 2 \) in order to do the sort of thing just described. Here is a major result which will have a much more difficult stochastic version presented later. First is a simple version of an approximation theorem of Doob.

**Lemma 41.2.1** Let \( Y : [0, T] \to E \), be \( B([0, T]) \) measurable and suppose

\[
Y \in L^p(0, T; E) \equiv K, \quad p \geq 1
\]

Then there exists a sequence of nested partitions, \( \mathcal{P}_k \subseteq \mathcal{P}_{k+1} \),

\[
\mathcal{P}_k \equiv \{ t_0^k, \ldots, t_m^k \}
\]

such that the step functions given by

\[
Y^r_k(t) = \sum_{j=1}^{m_k} Y(t_{j-1}^k) \mathcal{X}_{[t_{j-1}^k, t_j^k)}(t)
\]

\[
Y^l_k(t) = \sum_{j=1}^{m_k} Y(t_{j-1}^k) \mathcal{X}_{(t_{j-1}^k, t_j^k]}(t)
\]

both converge to \( Y \) in \( K \) as \( k \to \infty \) and

\[
\lim_{k \to \infty} \max \{ |t_j^k - t_{j+1}^k| : j \in \{0, \ldots, m_k\} \} = 0.
\]

Also, each \( Y(t_j^k) \), \( Y(t_{j-1}^k) \) is in \( E \). One can also assume that \( Y(0) = 0 \). The mesh points \( \{ t_j^k \}_{j=0}^{m_k} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that

\[
|t_j^k - t_{j-1}^k| = 2^{-nk}
\]

except for the case where \( j = 1 \) or \( j = m_k \) when this might not be so. In the case of the last subinterval defined by the partition, we can assume

\[
|t_m^k - t_{m-1}^k| = |T - t_{m-1}^k| \geq 2^{-(nk+1)}
\]
Proof: For \( t \in \mathbb{R} \) let \( \gamma_n(t) = k/2^n, \delta_n(t) = (k + 1)/2^n \), where \( t \in (k/2^n, (k + 1)/2^n] \), and \( 2^{-n} < T/4 \). Also suppose \( Y \) is defined to equal 0 on \([0, T]\). Then \( t \rightarrow \| Y(t) \| \) is in \( L^p(\mathbb{R}) \). Therefore by continuity of translation, as \( n \to \infty \) it follows that for \( t \in [0, T] \),

\[
\int_{\mathbb{R}} \| Y(\gamma_n(t) + s) - Y(t + s) \|_E^p \, ds \to 0
\]

The above is dominated by

\[
\int_{\mathbb{R}} 2^{p-1} (||Y(s)||^p + ||Y(s)||^p) X_{[-2T,2T]}(s) \, ds
\]

\[
= \int_{-2T}^{2T} 2^{p-1} (||Y(s)||^p + ||Y(s)||^p) \, ds < \infty
\]

Therefore,

\[
\lim_{n \to \infty} \int_{-2T}^{2T} \left( \int_{\mathbb{R}} ||Y(\gamma_n(t) + s) - Y(t + s)\|_E^p \, ds \right) \, dt = 0
\]

by the dominated convergence theorem. Now Fubini. The above equals

\[
\int_{\mathbb{R}} \int_{-2T}^{2T} ||Y(\gamma_n(t) + s) - Y(t + s)\|_E^p \, dtds
\]

Change the variables on the inside.

\[
\int_{\mathbb{R}} \int_{-2T+s}^{2T+s} ||Y(\gamma_n(t - s) + s) - Y(t)\|_E^p \, dtds
\]

Since \( \gamma_n(t - s) + s \) is within \( 2^{-n} \) of \( t \) and \( Y(t) \) vanishes if \( t \notin [0, T] \), this reduces to

\[
\int_{\mathbb{R}} \int_{-2T}^{2T} ||Y(\gamma_n(t - s) + s) - Y(t)\|_E^p \, dtds.
\]

This converges to 0 as \( n \to \infty \) as was shown above. Therefore,

\[
\int_0^T \int_0^T ||Y(\gamma_n(t - s) + s) - Y(t)\|_E^p \, dtds
\]

also converges to 0 as \( n \to \infty \). The only problem is that \( \gamma_n(t - s) + s \geq t - 2^{-n} \) and so \( \gamma_n(t - s) + s \) could be less than 0 for \( t \in [0, 2^{-n}] \). Since this is an interval whose measure converges to 0 it follows

\[
\int_0^T \int_0^T \| Y((\gamma_n(t - s) + s)^+) - Y(t) \|_E^p \, dtds
\]

converges to 0 as \( n \to \infty \). Let

\[
m_n(s) = \int_0^T \| Y((\gamma_n(t - s) + s)^+) - Y(t) \|_E^p \, dt
\]
Then
\[ P((m_n(s) > \lambda)) \leq \frac{1}{X} \int_0^T m_n(s) \, ds. \]

It follows there exists a subsequence \( n_k \) such that
\[ P\left( \left[ m_{n_k}(s) > \frac{1}{k} \right] \right) < 2^{-k} \]

Hence by the Borel Cantelli lemma, there exists a set of measure zero \( N \) such that for \( s \notin N \),
\[ m_{n_k}(s) \leq \frac{1}{k} \]
for all \( k \) sufficiently large. Picking \( s_k \notin N \),
\[ Y_k(t) = Y\left( (\gamma_{n_k}(t - s_k) + s_k)^+ \right) \]

Then \( t \to Y\left( (\gamma_{n_k}(t - s_k) + s_k)^+ \right) \) is a step function of the sort described above. Of course you can always simply define \( Y_k(0) = 0 \). This is because the interval affected has length which converges to 0 as \( k \to \infty \). The jumps in \( t \to \gamma_{n_k}(t - s_k) \) determine the mesh points of the partition. By picking \( s_k \) appropriately, you can have each of these mesh points miss a given set of measure zero except for the first and last point. This is because when you slide \( s_k \) it just moves the mesh points of \( P_k \) except for the first point and last point. Let \( N_1 \) be a set of measure zero and let \( (a, b) \subseteq (0, T] \). Now let \( s \) move through \( (a, b) \) and denote by \( A_j \) the corresponding set of points obtained by the \( j^{th} \) mesh point. Thus \( A_j \) has positive measure and so it is not contained in \( N_1 \). Let \( S_j \) be the points of \( (a, b) \) which correspond to \( A_j \cap N_1 \). Thus \( S_j \) has measure 0. Just pick \( s_k \in (a, b) \setminus \cup_j S_j \). You can also choose \( s_k \) such that
\[ T - s_k - \gamma_{n_k}(T - s_k) > 2^{-(n_k+1)} \]
which will cause the last condition mentioned above to hold.

To get the other sequence of step functions, just use a similar argument with \( \delta_n \) in place of \( \gamma_n \).

**Theorem 41.2.2** Let \( V \subseteq H = H' \subseteq V' \) be a Gelfand triple and suppose \( Y \in L^p(0,T;V') \equiv K' \) and
\[ X(t) = X_0 + \int_0^t Y(s) \, ds \text{ in } V' \quad (41.2.8) \]
where \( X_0 \in H \), and it is known that \( X \in L^p(0,T,V) \equiv K \) for \( p > 1 \). Then \( t \to X(t) \) is in \( C([0,T],H) \) and also
\[ \frac{1}{2} |X(t)|_H^2 = \frac{1}{2} |X_0|_H^2 + \int_0^t (Y(s),X(s)) \, ds \]
41.2. AN IMPORTANT FORMULA

Proof: By Lemma 41.2.1 there exists a sequence of uniform partitions \( \{ t^n_k \}_{k=0}^{m_n} = \mathcal{P}_n, \mathcal{P}_n \subseteq \mathcal{P}_{n+1} \), of \([0, T]\) such that the step functions

\[
\sum_{k=0}^{m_n-1} X \left( t^n_k \right) \mathcal{X}_{(t^n_k, t^n_{k+1})} (t) = X^l (t)
\]

\[
\sum_{k=0}^{m_n-1} X \left( t^n_{k+1} \right) \mathcal{X}_{(t^n_k, t^n_{k+1})} (t) = X^r (t)
\]

certify to \( X \) in \( K \) and in \( L^2 ([0, T], H) \).

Lemma 41.2.3 Let \( s < t \). Then for \( X, Y \) satisfying (41.2.8)

\[
|X (t)|^2 = |X (s)|^2 + 2 \int_s^t \langle Y (u), X (t) \rangle du - |X (t) - X (s)|^2 \quad (41.2.9)
\]

Proof: It follows from the following computations

\[
X (t) - X (s) = \int_s^t Y (u) du
\]

\[
- |X (t) - X (s)|^2 = - |X (t)|^2 + 2 \langle X (t), X (s) \rangle - |X (s)|^2
\]

\[
= - |X (t)|^2 + 2 \left( X (t), X (t) - \int_s^t Y (u) du \right) - |X (s)|^2
\]

\[
= - |X (t)|^2 + 2 |X (t)|^2 - 2 \left( \int_s^t Y (u) du, X (t) \right) - |X (s)|^2
\]

Hence

\[
|X (t)|^2 = |X (s)|^2 + 2 \int_s^t \langle Y (u), X (t) \rangle du - |X (t) - X (s)|^2 \quad \blacksquare
\]

Lemma 41.2.4 In the above situation,

\[
\sup_{t \in [0, T]} |X (t)|_H \leq C (\| Y \|_{K'}, \| X \|_K)
\]

Also, \( t \rightarrow X (t) \) is weakly continuous with values in \( H \).

Proof: From the above formula applied to the \( k^{th} \) partition of \([0, T]\) described above,

\[
|X (t_m)|^2 - |X_0|^2 = \sum_{j=0}^{m-1} |X (t_{j+1})|^2 - |X (t_j)|^2
\]
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) \rangle \, du - |X(t_{j+1}) - X(t_j)|_H^2

= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(u), X_k(u) \rangle \, du - |X(t_{j+1}) - X(t_j)|_H^2

Thus, discarding the negative terms and denoting by \( P_k \) the \( k \)th of these partitions,

\[
\sup_{t_j \in P_k} |X(t_j)|_H^2 \leq |X_0|^2 + 2 \int_0^T \|Y(u)\|_V \cdot \|X_k(u)\|_V \, du
\]

\[
\leq |X_0|^2 + 2 \left( \int_0^T \|Y(u)\|_V^{p'}, \, du \right)^{1/p'} \left( \int_0^T \|X_k(u)\|_V^p \, du \right)^{1/p} \leq C \left( \|Y\|_{K'}, \|X\|_K \right)
\]

because these partitions are chosen such that

\[
\lim_{k \to \infty} \left( \int_0^T \|X_k(u)\|_V^p \, du \right)^{1/p} = \left( \int_0^T \|X(u)\|_V^p \, du \right)^{1/p}
\]

and so these are bounded. This has shown that for the dense subset of \([0, T]\),

\[
D = \bigcup_k P_k,
\]

\[
\sup_{t \in D} |X(t)| < C \left( \|Y\|_{K'}, \|X\|_K \right)
\]

Now let \( \{g_k\}_{k=1}^\infty \) be linearly independent vectors of \( V \) whose span is dense in \( V \). This is possible because \( V \) is separable. Then let \( \{e_j\}_{j=1}^\infty \) be an orthonormal basis for \( H \) such that \( e_k \in \text{span}(g_1, \ldots, g_k) \) and each \( g_k \in \text{span}(e_1, \ldots, e_k) \). This is done with the Gram Schmidt process. Then it follows that \( \text{span}(\{e_k\}_{k=1}^\infty) \) is dense in \( V \).

I claim

\[
|y|_H^2 = \sum_{j=1}^\infty |\langle y, e_j \rangle|^2.
\]

This is certainly true if \( y \in H \) because

\[
\langle y, e_j \rangle = \langle y, e_j \rangle_H
\]

If \( y \notin H \), then the series must diverge since otherwise, you could consider the infinite sum

\[
\sum_{j=1}^\infty \langle y, e_j \rangle e_j \in H
\]

because

\[
\left| \sum_{j=p}^{q} \langle y, e_j \rangle e_j \right|^2 - \sum_{j=p}^{q} |\langle y, e_j \rangle|^2 \to 0 \text{ as } p, q \to \infty.
\]
41.2. AN IMPORTANT FORMULA

Letting \( z = \sum_{j=1}^{\infty} \langle y, e_j \rangle e_j \), it follows that \( \langle y, e_j \rangle \) is the \( j^{th} \) Fourier coefficient of \( z \) and that

\[
\langle z - y, v \rangle = 0
\]

for all \( v \in \text{span} \{ e_k \}_{k=1}^{\infty} \) which is dense in \( V \). Therefore, \( z = y \) in \( V' \) and so \( y \in H \).

It follows that

\[
\langle y, e_j \rangle = \text{the } j^{th} \text{ Fourier coefficient of } z
\]

and that \( \langle z, y, v \rangle = 0 \) for all \( v \). Therefore, \( z = y \) in \( V' \) and so \( y \in H \).

It follows

\[
|X(t)|^2 = \sup_n \sum_{j=1}^{n} |\langle X(t), e_j \rangle|^2
\]

which is just the sup of continuous functions of \( t \). Therefore, \( t \to |X(t)|^2 \) is lower semicontinuous. It follows that for any \( t \), letting \( t_j \to t \) for \( t_j \in D \),

\[
|X(t)|^2 \leq \lim \inf_{j \to \infty} |X(t_j)|^2 \leq C \|Y\|_{K'}, \|X\|_K
\]

This proves the first claim of the lemma.

Consider now the claim that \( t \to X(t) \) is weakly continuous. Letting \( v \in V \),

\[
\lim_{t \to s} \langle X(t), v \rangle = \lim_{t \to s} \langle X(t), v \rangle = \langle X(s), v \rangle = \langle X(s), v \rangle
\]

Since it was shown that \( |X(t)| \) is bounded independent of \( t \), and since \( V \) is dense in \( H \), the claim follows.

Now

\[
- \sum_{j=0}^{m-1} |X(t_{j+1}) - X(t_j)|_H^2 = |X(t_m)|^2 - |X_0|^2 - \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(u), X_k^r(u) \rangle \, du
\]

\[
= |X(t_m)|^2 - |X_0|^2 - 2 \int_0^{t_m} \langle Y(u), X_k^r(u) \rangle \, du
\]

Thus, since the partitions are nested, eventually \( |X(t_m)|^2 \) is constant for all \( k \) large enough and the integral term converges to

\[
\int_0^{t_m} \langle Y(u), X(u) \rangle \, du
\]

It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by \( X \),

\[
X(t_{j+1}) - X(t_j) = \int_{t_j}^{t_{j+1}} Y(u) \, du
\]

Therefore, this term is dominated by an expression of the form

\[
\sum_{j=0}^{m-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) - X(t_j) \rangle \, du
\]
\[ \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) \rangle - \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_j) \rangle \]

\[ = \int_0^T \langle Y(u), X^r(u) \rangle \, du - \int_0^T \langle Y(u), X^l(u) \rangle \, du \]

However, both \( X^r \) and \( X^l \) converge to \( X \) in \( K = L^p(0,T;V) \). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \( t \in D \), the desired formula holds. Thus, for such \( t \),

\[ |X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds \]

It remains to verify that this holds for all \( t \). Let \( t \notin D \) and let \( t(k) \in \mathcal{P}_k \) be the largest point of \( \mathcal{P}_k \) which is less than \( t \). Suppose \( t(m) \leq t(k) \) so that \( m \leq k \). Then

\[ X(t(m)) = X_0 + \int_{t(m)}^{t(k)} Y(s) \, ds, \]

a similar formula for \( X(t(k)) \). Thus for \( t > t(m) \),

\[ X(t) - X(t(m)) = \int_{t(m)}^{t(k)} Y(s) \, ds \]

which is the same sort of thing already looked at except that it starts at \( t(m) \) rather than at 0 and \( X_0 = 0 \). Therefore,

\[ |X(t(k)) - X(t(m))|^2 = 2 \int_{t(m)}^{t(k)} \langle Y(s), X(s) - X(t(m)) \rangle \, ds \]

Thus, for \( m \leq k \)

\[ \lim_{m,k \to \infty} |X(t(k)) - X(t(m))|^2 = 0 \]

Hence \( \{X(t(k))\}_{k=1}^\infty \) is a convergent sequence in \( H \). Does it converge to \( X(t) \)? Let \( \xi(t) \in H \) be what it does converge to. Let \( v \in V \). Then

\[ \langle \xi(t), v \rangle = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \langle X(t), v \rangle = \langle X(t), v \rangle \]

because it is known that \( t \to X(t) \) is continuous into \( V' \) and it is also known that \( X(t) \in H \) and that the \( X(t) \) for \( t \in [0,T] \) are uniformly bounded. Therefore, since \( V \) is dense in \( H \), it follows that \( \xi(t) = X(t) \).

Now for every \( t \in D \), it was shown above that

\[ |X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds \]
Thus, using what was just shown, if $t \notin D$ and $t_k \to t$,

$$|X(t)|^2 = \lim_{k \to \infty} |X(t_k)|^2 = \lim_{k \to \infty} \left( |X_0|^2 + 2 \int_0^{t_k} \langle Y(s), X(s) \rangle \, ds \right)$$

$$= |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds$$

which proves the desired formula. From this it follows right away that $t \to X(t)$ is continuous into $H$ because it was just shown that $t \to |X(t)|$ is continuous and $t \to X(t)$ is weakly continuous. Since Hilbert space is uniformly convex, this implies the $t \to X(t)$ is continuous. To see this in the special case of Hilbert space,

$$|X(t) - X(s)|^2 = |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2$$

Then $\lim_{t \to s} \left( |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2 \right) = 0$ by weak convergence of $X(t)$ to $X(s)$ and the convergence of $|X(t)|^2$ to $|X(s)|^2$.

### 41.3 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

$$BX(t) = BX_0 + \int_0^t Y(s) \, ds$$

This involves an operator $B \in \mathcal{L}(W, W')$ and $B$ satisfies

$$\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle$$

for $V \subseteq W, W' \subseteq V'$

Where $V$ is dense in the Hilbert space $W$. Before giving the theorem, here is a technical lemma.

**Lemma 41.3.1** Suppose $V, W$ are separable Banach spaces, $W$ also a Hilbert space such that $V$ is dense in $W$ and $B \in \mathcal{L}(W, W')$ satisfies

$$\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle, \quad B \neq 0.$$

Then there exists a countable set $\{e_i\}$ of vectors in $V$ such that

$$\langle Be_i, e_j \rangle = \delta_{ij}$$

and for each $x \in W$,

$$\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,$$
and also
\[ Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i, \]
the series converging in \( W' \).

**Proof:** Let \( \{g_k\}_{k=1}^{\infty} \) be linearly independent vectors of \( V \) whose span is dense in \( V \). This is possible because \( V \) is separable. Thus, their span is also dense in \( W \). Let \( n_1 \) be the first index such that \( \langle Bg_{n_1}, g_{n_1} \rangle \neq 0 \).

**Claim:** If there is no such index, then \( B = 0 \).

**Proof of claim:** First note that if there is no such first index, then if \( x = \sum_{i=1}^{k} a_i g_i \)

\[
|\langle Bx, x \rangle| = \left| \sum_{i \neq j} a_i a_j \langle Bg_i, g_j \rangle \right| \leq \sum_{i \neq j} |a_i| |a_j| |\langle Bg_i, g_j \rangle| \\
\leq \sum_{i \neq j} |a_i| |a_j| |\langle Bg_i, g_i \rangle^{1/2} \langle Bg_j, g_j \rangle^{1/2}| = 0
\]

Therefore, if \( x \) is given, you could take \( x_k \) in the span of \( \{g_1, \ldots, g_k\} \) such that
\( \|x_k - x\|_W \to 0 \). Then
\[
|\langle Bx, y \rangle| = \lim_{k \to \infty} |\langle Bx_k, y \rangle| \leq \lim_{k \to \infty} \langle Bx_k, x_k \rangle^{1/2} \langle By, y \rangle^{1/2} = 0
\]
because \( \langle Bx_k, x_k \rangle \) is zero by what was just shown.

Thus assume there is such a first index. Let
\[
e_1 := \frac{g_{n_1}}{\langle Bg_{n_1}, g_{n_1} \rangle^{1/2}}
\]
Then \( \langle Be_1, e_1 \rangle = 1 \). Now if you have constructed \( e_j \) for \( j \leq k \),
\[ e_j \in \text{span} \{g_{n_1}, \ldots, g_n\}, \quad \langle Be_i, e_j \rangle = \delta_{ij}, \]
g_{n_j+1} being the first for which
\[
\left\langle Bg_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j+1}}, e_i \rangle Be_i, g_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j}}, e_i \rangle e_i \right\rangle \neq 0,
\]
and
\[
\text{span} \{g_{n_1}, \ldots, g_n\} = \text{span} \{e_1, \ldots, e_k\},
\]
let \( g_{n_{k+1}} \) be such that \( g_{n_{k+1}} \) is the first in the list \( \{g_n\} \) such that
\[
\left\langle Bg_{n_{k+1}} - \sum_{i=1}^{k} \langle Bg_{n_{k+1}}, e_i \rangle Be_i, g_{n_{k+1}} - \sum_{i=1}^{k} \langle Bg_{n_{k+1}}, e_i \rangle e_i \right\rangle \neq 0
\]
Note the difference between this and the Gram Schmidt process. Here you don’t necessarily use all of the \(g_k\) due to the possible degeneracy of \(B\).

**Claim:** If there is no such first \(g_{n_k+1}\), then \(B(\text{span}(e_1, \cdots, e_k)) = BW\) so in this case, \(\{Be_i\}_{i=1}^k\) is actually a basis for \(BW\).

**Proof:** Let \(x \in W\). Let \(x_r \in \text{span}(g_1, \cdots, g_r), r > n_k\) such that \(\lim_{r \to \infty} x_r = x\) in \(W\). Then

\[
x_r = \sum_{i=1}^k c_i^r e_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^r d_i^r g_i \equiv y_r + z_r \tag{41.3.10}
\]

If \(l \notin \{n_1, \cdots, n_k\}\), then by the construction and the above assumption, for some \(j \leq k\)

\[
\left\langle Bg_l - \sum_{i=1}^j \langle Bg_l, e_i \rangle Be_i, g_l - \sum_{i=1}^j \langle Bg_l, e_i \rangle e_i \right\rangle = 0 \tag{41.3.11}
\]

If \(l < n_k\), this follows from the construction. If the above is nonzero all \(j \leq k\) then \(l\) would have been chosen but it wasn’t. Thus

\[
Bg_l = \sum_{i=1}^j \langle Bg_l, e_i \rangle Be_i
\]

If \(l > n_k\), then by assumption, \(41.3.11\) holds for \(j = k\). Thus, in any case, it follows that for each \(l \notin \{n_1, \cdots, n_k\}\),

\[
Bg_l \in B(\text{span}(e_i, \cdots, e_k)).
\]

Now it follows from \(41.3.11\) that

\[
Bx_r = \sum_{i=1}^k c_i^r Be_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^r d_i^r Bg_i
\]

\[
= \sum_{i=1}^k c_i^r Be_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^r d_i^r \sum_{j=1}^k c_j^r Be_j
\]

and so \(Bx_r \in B(\text{span}(e_i, \cdots, e_k))\). Then \(Bx = \lim_{r \to \infty} Bx_r = \lim_{r \to \infty} By_r\) where \(y_r \in \text{span}(e_i, \cdots, e_k)\). Say

\[
Bx_r = \sum_{i=1}^k a_i^r Be_i
\]

It follows easily that \(\langle Bx_r, e_j \rangle = a_j^r\). (Act on \(e_j\) by both sides and use \(\langle Be_i, e_j \rangle = \delta_{ij}\).) Now since \(x_r\) is bounded, it follows that these \(a_j^r\) are also bounded. Hence, defining \(y_r \equiv \sum_{i=1}^k a_i^r e_i\), it follows that \(y_r\) is bounded in \(\text{span}(e_i, \cdots, e_k)\) and so, there exists a subsequence, still denoted by \(r\) such that \(y_r \to y \in \text{span}(e_i, \cdots, e_k)\). Therefore, \(Bx = \lim_{r \to \infty} By_r = By\). In other words, \(BW = B(\text{span}(e_i, \cdots, e_k))\) as claimed. This proves the claim.
If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

As long as the process does not stop, let

\[ e_{k+1} = \frac{g_{n_{k+1}} - \sum_{i=1}^{k} \langle B g_{n_{k+1}}, e_i \rangle e_i}{\left( B \left( g_{n_{k+1}} - \sum_{i=1}^{k} \langle B g_{n_{k+1}}, e_i \rangle e_i \right), g_{n_{k+1}} - \sum_{i=1}^{k} \langle B g_{n_{k+1}}, e_i \rangle e_i \right)^{1/2}} \]

Thus, as in the usual argument for the Gram Schmidt process, \( \langle B e_i, e_j \rangle = \delta_{ij} \) for \( i, j \leq k + 1 \). This is already known for \( i, j \leq k \). Letting \( l \leq k \), and using the orthogonality already shown,

\[
\langle B e_{k+1}, e_l \rangle = C \left( B \left( g_{n_{k+1}} - \sum_{i=1}^{k} \langle B g_{n_{k+1}}, e_i \rangle e_i \right), e_l \right) = C \left( \langle B g_{k+1}, e_l \rangle - \langle B g_{n_{k+1}}, e_l \rangle \right) = 0
\]

Consider

\[
\left. \langle B g_p - B \left( \sum_{i=1}^{k} \langle B g_{p}, e_i \rangle e_i \right), g_p - \sum_{i=1}^{k} \langle B g_{p}, e_i \rangle e_i \right) \right. 
\]

Either this equals 0 because \( p \) is never one of the \( n_k \) or eventually it equals 0 for some \( k \) because \( g_p = g_{n_k} \) for some \( n_k \) and so, from the construction, \( g_{n_k} = g_p \in \text{span}(e_1, \ldots, e_k) \) and therefore,

\[ g_p = \sum_{j=1}^{k} a_j e_j \]

which requires easily that

\[ B g_p = \sum_{i=1}^{k} \langle B g_{p}, e_i \rangle B e_i, \]

the above holding for all \( k \) large enough. It follows that for any \( x \in \text{span}(\{g_k\}_{k=1}^{\infty}) \), (finite linear combination of vectors in \( \{g_k\}_{k=1}^{\infty} \))

\[ B x = \sum_{i=1}^{\infty} \langle B x, e_i \rangle B e_i \quad (41.3.12) \]

because for all \( k \) large enough,

\[ B x = \sum_{i=1}^{k} \langle B x, e_i \rangle B e_i \]
Also note that for such \( x \in \text{span} \left( \{g_k\}_{k=1}^\infty \right) \),

\[
\langle Bx, x \rangle = \sum_{i=1}^k \langle Bx, e_i \rangle B e_i, x = \sum_{i=1}^k \langle Bx, e_i \rangle \langle Bx, e_i \rangle
\]

\[
= \sum_{i=1}^k \langle Bx, e_i \rangle |^2 = \sum_{i=1}^\infty \langle Bx, e_i \rangle |^2
\]

Now for \( x \) arbitrary, let \( x_k \to x \) in \( W \) where \( x_k \in \text{span} \left( \{g_k\}_{k=1}^\infty \right) \). Then by Fatou’s lemma,

\[
\sum_{i=1}^\infty \langle Bx, e_i \rangle |^2 \leq \liminf_{k \to \infty} \sum_{i=1}^\infty \langle Bx_k, e_i \rangle |^2
\]

\[
= \liminf_{k \to \infty} \langle Bx_k, x_k \rangle = \langle Bx, x \rangle \quad (41.3.13)
\]

\[
\leq \|Bx\|_W \|x\|_W \leq \|B\| \|x\|_W^2
\]

Thus the series on the left converges. Then also, from the above inequality,

\[
\left| \sum_{i=p}^q \langle Bx, e_i \rangle B e_i, y \right| \leq \sum_{i=p}^q \langle Bx, e_i \rangle | \langle Be_i, y \rangle | \leq \sum_{i=p}^q \langle Bx, e_i \rangle \left( \sum_{i=p}^q \langle Bx, e_i \rangle \right)^{1/2}
\]

\[
\leq \left( \sum_{i=p}^q \langle Bx, e_i \rangle \right)^{1/2} \left( \sum_{i=p}^q \langle By, e_i \rangle \right)^{1/2}
\]

By \[\text{HILB.13}\],

\[
\leq \left( \sum_{i=p}^q \langle Bx, e_i \rangle \right)^{1/2} \left( \|B\| \|y\|_W^2 \right)^{1/2}
\]

\[
\leq \left( \sum_{i=p}^q \langle Bx, e_i \rangle \right)^{1/2} \|B\|^{1/2} \|y\|_W
\]

It follows that

\[
\sum_{i=1}^\infty \langle Bx, e_i \rangle B e_i \quad (41.3.14)
\]
converges in $W'$ because it was just shown that
\[
\left\| \sum_{i=p}^{q} \langle Bx, e_i \rangle B e_i \right\|_{W'} \leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2}
\]
and it was shown above that $\sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 < \infty$, so the partial sums of the series $\sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i$ are a Cauchy sequence in $W'$. Also, the above estimate shows that for $\|y\| = 1$,
\[
\left| \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i, y \right| \leq \left( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2}
\]
and so
\[
\left\| \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i \right\|_{W'} \leq \left( \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2} \tag{41.3.15}
\]

Now for $x$ arbitrary, let $x_k \in \text{span} \left\{ \{g_j\}_{j=1}^{\infty} \right\}$ and $x_k \to x$ in $W$. Then for a fixed $k$ large enough,
\[
\left\| Bx - \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i \right\| \leq \|Bx - Bx_k\|
\]
\[
+ \left\| Bx_k - \sum_{i=1}^{\infty} \langle Bx_k, e_i \rangle B e_i \right\| + \left\| \sum_{i=1}^{\infty} \langle Bx_k, e_i \rangle B e_i - \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i \right\|
\]
\[
\leq \varepsilon + \left\| \sum_{i=1}^{\infty} \langle B(x_k - x), e_i \rangle B e_i \right\|
\]
the term
\[
\left\| Bx_k - \sum_{i=1}^{\infty} \langle Bx_k, e_i \rangle B e_i \right\|
\]
equaling 0 by Hahn-Banach and Hahn-Banach.
\[
\leq \varepsilon + \|B\|^{1/2} \left( \sum_{i=1}^{\infty} |\langle B(x_k - x), e_i \rangle|^2 \right)^{1/2}
\]
\[
\leq \varepsilon + \|B\|^{1/2} \langle B(x_k - x), x_k - x \rangle^{1/2} < 2\varepsilon
\]
whenever $k$ is large enough. Therefore,
\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i
\]
in \( W' \). It follows that
\[
(Bx, x) = \lim_{k \to \infty} \left( \sum_{i=1}^{k} (Bx, e_i) Be_i, x \right) = \lim_{k \to \infty} \sum_{i=1}^{k} |(Bx, e_i)|^2 \equiv \sum_{i=1}^{\infty} |(Bx, e_i)|^2 \tag{41.3.16}
\]

**Theorem 41.3.2** Let \( V \subseteq W, W' \subseteq V' \) be separable Banach spaces, \( W \) a separable Hilbert space, and let \( Y \in L^p (0, T; V') \equiv K' \) and
\[
BX(t) = BX_0 + \int_{0}^{t} Y(s) \, ds \text{ in } V'
\]
where \( X_0 \in W, \) and it is known that \( X \in L^p (0, T, V) \equiv K \) for \( p > 1 \). Also assume \( X \in L^2(0, T, W) \). Then \( t \to BX(t) \) is in \( C([0,T], W') \) and also
\[
\frac{1}{2} \langle BX(t), X(t) \rangle = \frac{1}{2} \langle BX_0, X_0 \rangle + \int_{0}^{t} \langle Y(s), X(s) \rangle \, ds
\]

**Proof:** By Lemma [H.2](#) there exists a sequence of uniform partitions \( \{t^n_k\}_{k=0}^{m_n} = P_n, P_n \subseteq P_{n+1} \) of \([0, T]\) such that the step functions
\[
\sum_{k=0}^{m_n-1} X(t^n_k) \chi_{(t^n_k, t^n_{k+1}]}(t) = X^l(t)
\]
\[
\sum_{k=0}^{m_n-1} X(t^n_{k+1}) \chi_{(t^n_k, t^n_{k+1}]}(t) = X^r(t)
\]
converge to \( X \) in \( K \) and also \( BX^l, BX^r \to BX \) in \( L^2(\[0, T\], W') \).

**Lemma 41.3.3** Let \( s < t \). Then for \( X, Y \) satisfying [41.3.17]
\[
\langle BX(t), X(t) \rangle = \langle BX(s), X(s) \rangle + 2 \int_{s}^{t} \langle Y(u), X(t) \rangle \, du - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]

**Proof:** It follows from the following computations
\[
B(X(t) - X(s)) = \int_{s}^{t} Y(u) \, du
\]
and so
\[
2 \int_{s}^{t} \langle Y(u), X(t) \rangle \, du - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]
\[
= 2 \langle B(X(t) - X(s)), X(t) \rangle - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]
\[
= 2 \langle BX(t), X(t) \rangle - 2 \langle BX(s), X(t) \rangle - \langle BX(t), X(t) \rangle
\]
\[
+ 2 \langle BX(s), X(t) \rangle - \langle BX(s), X(s) \rangle
\]
\[ = \langle BX (t) , X (t) \rangle - \langle BX (s) , X (s) \rangle \]

Thus
\[ \langle BX (t) , X (t) \rangle - \langle BX (s) , X (s) \rangle \]
\[ = 2 \int_s^t \langle Y (u) , X (t) \rangle \, du - \langle B (X (t) - X (s)) , (X (t) - X (s)) \rangle \]

**Lemma 41.3.4** In the above situation,
\[
\sup_{t \in [0,T]} \langle BX (t) , X (t) \rangle \leq C (\|Y\|_{K'} , \|X\|_K)
\]

Also, \( t \to BX (t) \) is weakly continuous with values in \( W' \).

**Proof:** From the above formula applied to the \( k \)-th partition of \([0,T]\) described above,
\[
\langle BX (t_m) , X (t_m) \rangle - \langle BX_0 , X_0 \rangle = \sum_{j=0}^{m-1} \langle BX (t_{j+1}) , X (t_{j+1}) \rangle - \langle BX (t_j) , X (t_j) \rangle
\]
\[
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y (u) , X (t_{j+1}) \rangle \, du - \langle B (X (t_{j+1}) - X (t_j)) , (X (t_{j+1}) - X (t_j)) \rangle
\]
\[
= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y (u) , X_k^r (u) \rangle \, du - \langle B (X (t_{j+1}) - X (t_j)) , (X (t_{j+1}) - X (t_j)) \rangle
\]

Thus, discarding the negative terms and denoting by \( P_k \) the \( k \)-th of these partitions,
\[
\sup_{t_j \in P_k} \langle BX (t_j) , X (t_j) \rangle \leq \langle BX_0 , X_0 \rangle + 2 \int_0^T \|Y (u) \|_{V'} \|X_k^r (u)\|_V \, du
\]
\[
\leq \langle BX_0 , X_0 \rangle + 2 \int_0^T \|Y (u) \|_{V'} \|X_k^r (u)\|_V \, du
\]
\[
\leq \langle BX_0 , X_0 \rangle + 2 \left( \int_0^T \|Y (u) \|_{V'}^{p'} \, du \right)^{1/p'} \left( \int_0^T \|X_k^r (u)\|_V^p \, du \right)^{1/p}
\]
\[
\leq C (\|Y\|_{K'} , \|X\|_K)
\]

because these partitions are chosen such that
\[
\lim_{k \to \infty} \left( \int_0^T \|X_k^r (u)\|_V^p \right)^{1/p} = \left( \int_0^T \|X (u)\|_{V'}^p \right)^{1/p}
\]
and so these are bounded. This has shown that for the dense subset of $[0,T]$, $D \equiv \cup_k P_k$, 

$$\sup_{t \in D} \langle BX(t), X(t) \rangle < C(\|Y\|_{K'}, \|X\|_K)$$

From Lemma 41.3.1 above, there exists $\{e_j\} \subseteq V$ such that $\langle Be_i, e_j \rangle = \delta_{ij}$ and

$$\langle BX(t), X(t) \rangle = \sum_{k=1}^{\infty} |\langle BX(t), e_i \rangle|^2 = \sup_m \sum_{k=1}^{m} |\langle BX(t), e_i \rangle|^2$$

Since each $e_i \in V$, and since $t \to BX(t)$ is continuous into $V'$ thanks to the formula 41.3.17, it follows that $t \to \sum_{k=1}^{m} |\langle BX(t), e_i \rangle|$ is continuous and so $t \to \langle BX(t), X(t) \rangle$ is the sup of continuous functions. Therefore, this function of $t$ is lower semicontinuous. Since $D$ is dense in $[0,T]$, it follows that for all $t$,

$$\langle BX(t), X(t) \rangle \leq C(\|Y\|_{K'}, \|X\|_K)$$

It only remains to verify the claim about weak continuity.

Consider now the claim that $t \to BX(t)$ is weakly continuous. Letting $v \in V$,

$$\lim_{t \to s} \langle BX(t), v \rangle = \langle BX(s), v \rangle = \langle BX(s), v \rangle \quad (41.3.18)$$

The limit follows from the formula 41.3.17 which implies $t \to BX(t)$ is continuous into $V'$. Now

$$\|BX(t)\| = \sup_{\|v\| \leq 1} |\langle BX(t), v \rangle| \leq \|Bv, v\|^{1/2} \|BX(t), X(t)\|^{1/2}$$

which was shown to be bounded for $t \in [0,T]$. Now let $w \in W$. Then

$$|\langle BX(t), w \rangle - \langle BX(s), w \rangle| \leq |\langle BX(t) - BX(s), w - v \rangle| + |\langle BX(t) - BX(s), v \rangle|$$

Then the first term is less than $\varepsilon$ if $v$ is close enough to $w$ and the second converges to 0 so 41.3.18 holds for all $v \in W$ and so this shows the weak continuity. \end{proof}

Now pick $t \in D$, the union of all the mesh points. Then for all $k$ large enough, $t \in P_k$. Say $t = t_m$. From Lemma 41.3.3,

$$- \sum_{j=0}^{m-1} \langle B(X(t_{j+1}) - X(t_j)), (X(t_{j+1}) - X(t_j)) \rangle =$$

$$\langle BX(t_m), X(t_m) \rangle - \langle BX_0, X_0 \rangle - 2 \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X'_k(u) \rangle du$$

Thus, $\langle BX(t_m), X(t_m) \rangle$ is constant for all $k$ large enough and the integral term converges to

$$\int_0^{t_m} \langle Y(u), X(u) \rangle du$$
It follows that the term on the left does converge to something as \( k \to \infty \). It just remains to consider what it does converge to. However, from the equation solved by \( X \),

\[
BX (t_{j+1}) - BX (t_j) = \int_{t_j}^{t_{j+1}} Y (u) \, du
\]

Therefore, this term is dominated by an expression of the form

\[
\sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y (u) \, du, X (t_{j+1}) - X (t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y (u) \, du, X (t_{j+1}) - X (t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} Y (u) \, du, X (t_{j+1}) - X (t_j) \right) du
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y (u), X (t_{j+1}) - X (t_j) \rangle du
\]

\[
= \int_0^T \langle Y (u), X^r (u) \rangle \, du - \int_0^T \langle Y (u), X^l (u) \rangle \, du
\]

However, both \( X^r \) and \( X^l \) converge to \( X \) in \( K = L^p (0, T, V) \). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \( t \in D \), the desired formula holds. Thus, for such \( t \in D \),

\[
\langle BX (t), X (t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y (u), X (u) \rangle \, du
\]

It remains to verify that this holds for all \( t \). Let \( t \notin D \) and let \( t (k) \in \mathcal{P}_k \) be the largest point of \( \mathcal{P}_k \) which is less than \( t \). Suppose \( t (m) \leq t (k) \) so that \( m \leq k \). Then

\[
BX (t (m)) = BX_0 + \int_{0}^{t (m)} Y (s) \, ds,
\]

a similar formula for \( X (t (k)) \). Thus for \( t > t (m) \),

\[
BX (t) - BX (t (m)) = \int_{t (m)}^{t} Y (s) \, ds
\]

which is the same sort of thing already looked at except that it starts at \( t (m) \) rather than at 0 and \( X_0 = 0 \). Therefore,

\[
\langle B (X (t (k)) - X (t (m))), X (t (k)) - X (t (m)) \rangle = 2 \int_{t (m)}^{t (k)} \langle Y (s), X (s) - X (t (m)) \rangle \, ds
\]
Thus, for $m \leq k$

$$\lim_{m,k \to \infty} \langle B \left( X \left( t (k) \right) - X \left( t (m) \right) \right), X \left( t (k) \right) - X \left( t (m) \right) \rangle = 0 \quad (41.3.19)$$

Hence $\{BX \left( t (k) \right)\}_{k=1}^\infty$ is a convergent sequence in $W'$ because

$$|\langle B \left( X \left( t (k) \right) - X \left( t (m) \right) \right), y \rangle| \leq \langle B \left( X \left( t (k) \right) - X \left( t (m) \right) \right), X \left( t (k) \right) - X \left( t (m) \right) \rangle^{1/2} \langle By, y \rangle^{1/2}$$

$$\leq \langle B \left( X \left( t (k) \right) - X \left( t (m) \right) \right), X \left( t (k) \right) - X \left( t (m) \right) \rangle^{1/2} \|B\|^{1/2} \|y\|_W$$

Does it converge to $BX \left( t \right)$? Let $\xi \left( t \right) \in W'$ be what it does converge to. Let $v \in V$. Then

$$\langle \xi \left( t \right), v \rangle = \lim_{k \to \infty} \langle BX \left( t (k) \right), v \rangle = \lim_{k \to \infty} \langle BX \left( t (k) \right), v \rangle = \langle BX \left( t \right), v \rangle$$

because it is known that $t \to BX \left( t \right)$ is continuous into $V'$. It is also known that $BX \left( t \right) \in W' \subseteq V'$ and that the $BX \left( t \right)$ for $t \in [0, T]$ are uniformly bounded in $W'$. Therefore, since $V$ is dense in $W$, it follows that $\xi \left( t \right) = BX \left( t \right)$.

Now for every $t \in D$, it was shown above that

$$\langle BX \left( t \right), X \left( t \right) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y \left( u \right), X \left( u \right) \rangle du$$

Also it was just shown that $BX \left( t (k) \right) \to BX \left( t \right)$. Then

$$\|\langle BX \left( t (k) \right), X \left( t (k) \right) \rangle - \langle BX \left( t \right), X \left( t \right) \rangle\|$$

$$\leq \|\langle BX \left( t (k) \right), X \left( t (k) \right) - X \left( t \right) \rangle\| + \|\langle BX \left( t (k) \right) - BX \left( t \right), X \left( t \right) \rangle\|$$

Then the second term converges to 0. The first equals

$$\|\langle BX \left( t \right) - BX \left( t \right), X \left( t (k) \right) \rangle\|$$

$$\leq \langle B \left( X \left( t \right) - X \left( t \right) \right), X \left( t (k) \right) - X \left( t \right) \rangle^{1/2} \langle BX \left( t (k) \right), X \left( t (k) \right) \rangle^{1/2}$$

From the above, this is dominated by an expression of the form

$$\langle B \left( X \left( t \right) - X \left( t \right) \right), X \left( t (k) \right) - X \left( t \right) \rangle^{1/2} C$$

Then using the lower semicontinuity of $t \to \langle B \left( X \left( t \right) - X \left( t \right) \right), X \left( t (k) \right) - X \left( t \right) \rangle$ which follows from the above, this is no larger than

$$\liminf_{m \to \infty} \langle B \left( X \left( t \right) - X \left( t (m) \right) \right), X \left( t (k) \right) - X \left( t (m) \right) \rangle^{1/2} C < \epsilon$$

provided $k$ is large enough. This follows from $\|\xi\|_{V'}$. Since $\epsilon$ is arbitrary, it follows that

$$\lim_{k \to \infty} \|\langle BX \left( t (k) \right), X \left( t (k) \right) \rangle - \langle BX \left( t \right), X \left( t \right) \rangle\| = 0$$
Then from the formula,
\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(u) \rangle \, du
\]
valid for \( t \in D \), it follows that the same formula holds for all \( t \). This formula implies \( t \to \langle BX(t), X(t) \rangle \) is continuous. Also recall that \( t \to BX(t) \) was shown to be weakly continuous into \( W' \). Then
\[
\langle B(X(t) - X(s)), X(t) - X(s) \rangle = \langle BX(t), X(t) \rangle - 2 \langle BX(t), X(s) \rangle + \langle BX(s), X(s) \rangle
\]
From this, it follows that \( t \to BX(t) \) is continuous into \( W' \) because \( \lim_{t \to s} \) of the right side gives 0 and so the same is true of the left. Hence,
\[
\left\| \langle B(X(t) - X(s)), y \rangle \right\| \\
\leq \langle B y, y \rangle^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \\
\leq \| B \|^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \| y \|
\]
so
\[
\| B(X(t) - X(s)) \|_{W'} \leq \| B \|^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2}
\]
which converges to 0 as \( t \to s \).

### 41.4 Some Implicit Inclusions

Let \( B \in \mathcal{L}(W, W') \) and \( B \) satisfies
\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle
\]
for
\[
V \subseteq W, \quad W' \subseteq V'
\]
Where \( V \) is dense in the Hilbert space \( W \). Now let
\[
D(L) \equiv \{ u \in V : (Bu)' \in V', Bu(0) = 0 \}, \quad Lu \equiv (Bu)'
\]
Then clearly \( D(L) \) is dense in \( V \). Here \( V \equiv L^p ([0, T], V) \) where \( p \geq 2 \) for simplicity. Now let
\[
D(T) \equiv \{ u \in V : u' \in V \text{ and } u(T) = 0 \}, \quad Tu \equiv -B(u')
\]
The idea is to show that \( L = T^* \) and that \( T \) is monotone. Then this will imply using Proposition 23.8.2 that \( L^* \) is monotone. This is done by showing that \( \mathcal{G}(L^*) = \mathcal{G}(T) \).

**Lemma 41.4.1** \( T \) is monotone, \( T^* = L \) and \( L^*, L \) are both monotone.
Proof: First, why is $T$ monotone?

$$\int_0^T \langle -B u', u \rangle \, dt = \int_0^T -\langle Bu, u' \rangle \, dt = -\langle Bu, u \rangle |_0^T + \int_0^T \langle (Bu)', u \rangle \, dt$$

$$= \langle Bu(0), u(0) \rangle + \int_0^T \langle Bu', u \rangle \, dt$$

and so

$$2 \langle Tu, u \rangle = 2 \int_0^T \langle -Bu', u \rangle \, dt = \langle Bu(0), u(0) \rangle \geq 0$$

Next, why is $T^* = L$? Let $u \in D(L)$. Then for $v \in D(T)$,

$$\langle Tv, u \rangle = \int_0^T \langle -B v', u \rangle \, dt = \int_0^T \langle Bu, v' \rangle \, dt = -\langle Bu, v \rangle |_0^T + \int_0^T \langle (Bu)', v \rangle \, ds$$

$$= \langle Lu, v \rangle$$

Hence $u \in D(T^*)$ and $T^* u = Lu$ since $D(T)$ is dense. Thus $D(L) \subseteq D(T^*)$ and on $D(L)$, these two are equal. Next suppose $u \in D(T^*)$. Then for all $v \in D(T)$,

$$\langle Tv, u \rangle \leq C \|v\|_\mathcal{V}$$

Thus, by density and the Riesz representation theorem, there exists a unique $g^* \in \mathcal{V}'$ such that

$$\langle Tv, u \rangle = \int_0^T \langle g^*, v \rangle \, dt = \int_0^T \langle -Bu, u' \rangle \, dt = -\int_0^T \langle Bu, v' \rangle \, dt$$

In particular, it follows from the definition of weak $\mathcal{V}'$ valued distributions that $g^* = (Bu)'$. Simply specialize to letting $v(t) = v \phi(t)$ where $\phi \in C_c^\infty(0, T)$. Thus in particular $(Bu)' \in \mathcal{V}'$ and the above reduces to

$$\langle Tv, u \rangle = \int_0^T \langle (Bu)', v \rangle \, dt$$

Thus also $(Bu)(0) = 0$. Hence $D(T^*) \subseteq D(L)$ and this shows that $L = T^*$ as claimed.

Why is $L$ monotone? From the material on weak derivatives,

$$Bu(t) = \int_0^t (Bu)'(s) \, ds$$
and now use Theorem 41.3.2 to obtain

\[
0 \leq \langle Bu(t), u(t) \rangle = 2 \int_0^t \langle Bu', u \rangle \, ds.
\]

In particular, this holds for \( t = T \) and so \( \langle Lu, u \rangle \geq 0 \).

Why is \( L^* \) monotone? This follows from Proposition 23.8.2 and the fact that \( L = T^* \) shown above.

If \( G(L) = (G(T))^{\perp} \) Then \( (\tau S)^{\perp} \) is to say that if \( (a, b^*) \in S \), then \( \langle (a, b^*), (-b^*, a) \rangle = 0 \) or in other words, \( \langle x, b^* \rangle = \langle y, a \rangle \). To say that \( (x, y^*) \in \tau \left( S^{\perp} \right) \) is to say that \( (x, y^*) = (-c, d^*) \) where

\[
\langle (d^*, c), (a, b^*) \rangle = 0
\]

for all \( (a, b^*) \in S \). That is, \( \langle (y^*, -x), (a, b^*) \rangle = 0 \) for all \( (a, b^*) \in S \). In other words \( \langle y, a \rangle = \langle x, b^* \rangle \) for all \( (a, b^*) \in S \). Thus \( (\tau S)^{\perp} = \tau \left( S^{\perp} \right) \). Now \( \tau M = M \) if \( M \) is a subspace. and \( (M^{\perp})^{\perp} = M \) if \( M \) is a subspace. Hence

\[
G(L^*) = (\tau G(T))^{\perp} = \tau \left( G(L)^{\perp} \right) = \tau \left( \left( \tau (G(T))^{\perp} \right)^{\perp} \right) = \tau \left( G(T)^{\perp} \right)^{\perp} = G(T)
\]

Now it follows that, since \( T \) is monotone, it follows that \( L^* \) is also monotone. \( \blacksquare \)

Note that as part of this argument, we have proved that for \( T \) a densely defined linear operator, \( G(T^{**}) = G(T) \).

Now recall Theorem 23.8.8 on Page 904 which is listed next.

**Theorem 41.4.2** Let \( L : D(L) \subseteq V \to V' \) where \( D(L) \) is dense, \( L \) is monotone, \( L \) is closed, and \( L^* \) is monotone, \( L \) a linear map. Let \( T : V \to \mathcal{P}(V') \) be \( L \) pseudomonotone, bounded, coercive. Then \( L + T \) is onto. Here \( V \) is a reflexive Banach space such that the norms for \( V \) and \( V' \) are strictly convex.

To apply this theorem, let \( B \) be as above and \( V \to V \equiv L^p(\{0, T\}, V) \). Letting \( u_0 \in V \), let

\[
T(u) \equiv A(u + u_0)
\]

where \( A : V \to \mathcal{P}(V') \). Suppose that \( T \) just defined is set valued pseudomonotone and coercive. Let \( Lu = (Bu)' \) as described above in 41.4.20. Then from Theorem 41.3.2 and if \( f \in V' \), there exists a solution \( u \) to

\[
Lu + A(u + u_0) \ni f
\]

Thus there exists \( \xi \in A(u + u_0) \) such that

\[
Lu + \xi = f \text{ in } V'
\]
Then letting $w = u + u_0$, it follows that $\xi \in A(w)$ and
\[ L(w - w_0) + \xi = f \]
Thus,
\[ (Bw)' + \xi = f, \quad (Bw)(0) = Bu_0 \]
Written in terms of $A$,
\[ (Bw)' + A(w) \ni f \text{ in } V', \quad (Bw)(0) = Bu_0. \]
This proves the following theorem about the existence of solutions to implicit evolution inclusions.

**Theorem 41.4.3** Suppose $u \to A(u + u_0)$ is set valued pseudomonotone and coercive for $u_0 \in V$. Also let
\[ V \subseteq W, \ W' \subseteq V' \]
where $W$ is a Hilbert space, $V$ is a reflexive Banach space dense in $W$. Suppose $B : W \to W'$ is self adjoint and nonnegative. Then there exists a solution $w \in V$ to the implicit evolution equation
\[ (Bw)' + A(w) \ni f \text{ in } V', \quad (Bw)(0) = Bu_0. \]

### 41.5 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling’s lemma.

**Definition 41.5.1** Let $E, W$ be Banach spaces such that $E \subseteq W$ and the injection map from $E$ into $W$ is continuous. The injection map is said to be compact if every bounded set in $E$ has compact closure in $W$. In other words, if a sequence is bounded in $E$ it has a convergent subsequence converging in $W$. This is also referred to by saying that bounded sets in $E$ are precompact in $W$.

**Theorem 41.5.2** Let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Then for every $\varepsilon > 0$ there exists a constant, $C_\varepsilon$ such that for all $u \in E$,
\[ ||u||_W \leq \varepsilon ||u||_E + C_\varepsilon ||u||_X \]

**Proof:** Suppose not. Then there exists $\varepsilon > 0$ and for each $n \in \mathbb{N}$, $u_n$ such that
\[ ||u_n||_W > \varepsilon ||u_n||_E + n ||u_n||_X \]
Now let $v_n = u_n/||u_n||_E$. Therefore, $||v_n||_E = 1$ and
\[ ||v_n||_W > \varepsilon + n ||v_n||_X \]
It follows there exists a subsequence, still denoted by $v_n$ such that $v_n$ converges to $v$ in $W$. However, the above inequality shows that $||v_n||_X \to 0$. Therefore, $v = 0$. But then the above inequality would imply that $||v_n|| > \varepsilon$ and passing to the limit yields $0 > \varepsilon$, a contradiction.
**Definition 41.5.3** Define \( C ([a, b]; X) \) the space of functions continuous at every point of \([a, b]\) having values in \(X\).

You should verify that this is a Banach space with norm

\[
\| u \|_{\infty, X} = \max \{ \| u_n(t) - u(t) \|_X : t \in [a, b] \} .
\]

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem.

**Theorem 41.5.4** Let \( q > 1 \) and let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Let \( S \) be defined by

\[
\{ u \text{ such that } \| u(t) \|_E + \| u'' \|_{L^q([a, b]; X)} \leq R \text{ for all } t \in [a, b] \}.
\]

Then \( S \subseteq C ([a, b]; W) \) and if \( \{ u_n \} \subseteq S \), there exists a subsequence, \( \{ u_{n_k} \} \) which converges to a function \( u \in C ([a, b]; W) \) in the following way.

\[
\lim_{k \to \infty} \| u_{n_k} - u \|_{\infty, W} = 0.
\]

**Proof:** First consider the issue of \( S \) being a subset of \( C ([a, b]; W) \). By Theorem 41.1.9 on Page 1443 the following holds in \( X \) for \( u \in S \):

\[
u(t) - u(s) = \int_s^t u'(r) \, dr.
\]

Thus \( S \subseteq C ([a, b]; X) \). Let \( \varepsilon > 0 \) be given. Then by Theorem 41.5.2 there exists a constant, \( C_\varepsilon \) such that for all \( u \in W \)

\[
\| u \|_W \leq \frac{\varepsilon}{4R} \| u \|_E + C_\varepsilon \| u \|_X.
\]

Therefore, for all \( u \in S \),

\[
\| u(t) - u(s) \|_W \leq \frac{\varepsilon}{6R} \| u(t) - u(s) \|_E + C_\varepsilon \| u(t) - u(s) \|_X
\leq \frac{\varepsilon}{3} + C_\varepsilon \int_s^t \| u'(r) \|_X \, dr
\leq \frac{\varepsilon}{3} + C_\varepsilon \int_s^t \| u'(r) \|_X \, dr \leq \frac{\varepsilon}{3} + C_\varepsilon R | t - s |^{1/q} (41.5.22)
\]

Since \( \varepsilon \) is arbitrary, it follows \( u \in C ([a, b]; W) \).

Let \( D = \mathbb{Q} \cap [a, b] \) so \( D \) is a countable dense subset of \([a, b]\). Let \( D = \{ t_n \}_{n=1}^\infty \). By compactness of the embedding of \( E \) into \( W \), there exists a subsequence \( u_{(n,1)} \) such that as \( n \to \infty \), \( u_{(n,1)}(t_1) \) converges to a point in \( W \). Now take a subsequence of this, called \( (n,2) \) such that as \( n \to \infty \), \( u_{(n,2)}(t_2) \) converges to a point in \( W \). It follows that \( u_{(n,2)}(t_1) \) also converges to a point of \( W \). Continue this way. Now
41.5. SOME IMBEDDING THEOREMS

consider the diagonal sequence, \( u_k \equiv u_{(k,k)} \). This sequence is a subsequence of \( u_{(n,t)} \) whenever \( k > l \). Therefore, \( u_k \) converges for all \( t_j \in D \).

**Claim:** Let \( \{u_k\} \) be as just defined, converging at every point of \( D \equiv \mathbb{Q} \cap [a, b] \). Then \( \{u_k\} \) converges at every point of \( [a, b] \).

**Proof of claim:** Let \( \varepsilon > 0 \) be given. Let \( t \in [a, b] \). Pick \( t_m \in D \cap [a, b] \) such that in \( H.5.22 \) \( C_R |t - t_m| < \varepsilon /3 \). Then there exists \( N \) such that if \( l, n > N \), then
\[
||u_l (t_m) - u_n (t_m)||_X < \varepsilon /3.
\]
It follows that for \( l, n > N \),
\[
||u_l (t) - u_n (t)||_X \leq ||u_l (t) - u_l (t_m)|| + ||u_l (t_m) - u_n (t_m)||
+ ||u_n (t_m) - u_n (t)||
\leq \frac{2\varepsilon}{3} + \frac{2\varepsilon}{3} < 2\varepsilon
\]
Since \( \varepsilon \) was arbitrary, this shows \( \{u_k(t)\}_{k=1}^{\infty} \) is a Cauchy sequence. Since \( W \) is complete, this shows this sequence converges.

Now let \( s \neq t \). Then
\[
||u_n (s) - u_m (s)|| \leq ||u_n (s) - u_n (t)|| + ||u_n (t) - u_m (t)|| + ||u_m (t) - u_m (s)||
\]
From \( H.5.22 \)
\[
||u_n (s) - u_m (s)|| \leq 2 \left( \frac{\varepsilon}{3} + C_R |t - s|^{1/q} \right) + ||u_n (t) - u_m (t)||
\]
and so it follows that if \( \delta \) is sufficiently small and \( s \in B(t, \delta) \), then when \( n, m > N_t \)
\[
||u_n (s) - u_m (s)|| < \varepsilon.
\]
Since \([a, b] \) is compact, there are finitely many of these balls, \( \{B(t_i, \delta)\}_{i=1}^{p} \), such that for \( s \in B(t_i, \delta) \) and \( n, m > N_{t_i} \), the above inequality holds. Let \( N > \max \{N_{t_1}, \ldots, N_{t_p} \} \). Then if \( m, n > N \) and \( s \in [a, b] \) is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

**Claim:** Let \( \varepsilon > 0 \) be given. Then there exists \( N \) such that if \( m, n > N \), then
\[
||u_n - u_m||_W < \varepsilon.
\]
Now let \( u(t) = \lim_{k \to \infty} u_k (t) \).
\[
||u (t) - u (s)||_W \leq ||u (t) - u_n (t)||_W + ||u_n (t) - u_m (s)||_W + ||u_m (s) - u (s)||_W
\]
(41.5.23)
Let \( N \) be in the above claim and fix \( n > N \). Then
\[
||u (t) - u_n (t)||_W = \lim_{m \to \infty} ||u_m (t) - u_n (t)||_W \leq \varepsilon
\]
and similarly, \( ||u_n (s) - u (s)||_W \leq \varepsilon \). Then if \( |t - s| \) is small enough, \( H.5.22 \) shows the middle term in \( H.5.22 \) is also smaller than \( \varepsilon \). Therefore, if \( |t - s| \) is small enough,
\[
||u (t) - u (s)||_W < 3\varepsilon.
\]
Thus \( u \) is continuous. Finally, let \( N \) be as in the above claim. Then letting \( m, n > N \), it follows that for all \( t \in [a, b] \),
\[
\| u_m (t) - u_n (t) \| < \varepsilon .
\]
Therefore, letting \( m \to \infty \), it follows that for all \( t \in [a, b] \),
\[
\| u (t) - u_n (t) \| \leq \varepsilon .
\]
and so \( \| u - u_n \|_{\infty, W} \leq \varepsilon \). Since \( \varepsilon \) is arbitrary, this proves the theorem.

The next theorem is another such imbedding theorem found in \[ 126 \]. It is often used in partial differential equations.

**Theorem 41.5.5** Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Let \( p \geq 1 \), let \( q > 1 \), and define
\[
S \equiv \{ u \in L^p ([a, b]; E) : u' \in L^q ([a, b]; X) \text{ and } \| u \|_{L^p([a, b]; E)} + \| u' \|_{L^q([a, b]; X)} \leq R \}.
\]
Then \( S \) is precompact in \( L^p ([a, b]; W) \). This means that if \( \{ u_n \}_{n=1}^\infty \subseteq S \), it has a subsequence \( \{ u_{n_k} \} \) which converges in \( L^p ([a, b]; W) \).

**Proof:** By Proposition 126 on Page 121 it suffices to show \( S \) has an \( \eta \) net in 
\[ L^p ([a, b]; W) \] for each \( \eta > 0 \).

If not, there exists \( \eta > 0 \) and a sequence \( \{ u_n \} \subseteq S \), such that
\[
\| u_n - u_m \| \geq \eta \quad (41.5.24)
\]
for all \( n \neq m \) and the norm refers to \( L^p ([a, b]; W) \). Let
\[
a = t_0 < t_1 < \cdots < t_k = b, \ t_i - t_{i-1} = (b - a) / k.
\]
Now define
\[
\overline{u}_n (t) \equiv \sum_{i=1}^k \overline{u}_n X_{[t_{i-1}, t_i]} (t), \ \overline{u}_n \equiv \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n (s) \, ds.
\]
The idea is to show that \( \overline{u}_n \) approximates \( u_n \) well and then to argue that a subsequence of the \( \{ \overline{u}_n \} \) is a Cauchy sequence yielding a contradiction to (41.5.24).

Therefore,
\[
\begin{align*}
\overline{u}_n (t) - u_n (t) &= \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \, X_{[t_{i-1}, t_i]} (t) .
\end{align*}
\]
It follows from Jensen's inequality that
\[
\begin{align*}
\| u_n (t) - \overline{u}_n (t) \|_W^p &= \sum_{i=1}^k \left\| \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n (t) - u_n (s)) \, ds \right\|_W^p \, X_{[t_{i-1}, t_i]} (t) \\
&\leq \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \| u_n (t) - u_n (s) \|_W^p \, ds \, X_{[t_{i-1}, t_i]} (t)
\end{align*}
\]
and so
\[ \int_a^b \| (u_n(t) - \bar{u}_n(s)) \|_W^p \, ds \]
\[ \leq \int_a^b \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \| u_n(t) - u_n(s) \|_W^p \, ds \, \chi_{[t_{i-1}, t_i]}(t) \, dt \]
\[ = \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} \| u_n(t) - u_n(s) \|_W^p \, ds \, dt. \quad (41.5.25) \]

From Theorems 41.4 and 41.5, if \( \varepsilon > 0 \), there exists \( C_\varepsilon \) such that
\[ \| u_n(t) - u_n(s) \|_W^p \leq \varepsilon \| u_n(t) - u_n(s) \|_X^p + C_\varepsilon \| u_n(t) - u_n(s) \|_X^p \]
\[ \leq 2^{p-1} \varepsilon (\| u_n(t) \|_W^p + \| u_n(s) \|_W^p) + C_\varepsilon \left( \int_s^t \| u_n'(r) \|_X^p \, dr \right) \]
\[ \leq 2^{p-1} \varepsilon (\| u_n(t) \|_W^p + \| u_n(s) \|_W^p) \]
\[ + C_\varepsilon \left( \left( \int_s^t \| u_n'(r) \|_X^{q/p} \, dr \right)^{1/q} |t - s|^{1/q'} \right)^p \]
\[ = 2^{p-1} \varepsilon (\| u_n(t) \|_W^p + \| u_n(s) \|_W^p) + C_\varepsilon R^{p/q} |t - s|^{p/q'}. \]

This is substituted in to (41.5.25) to obtain
\[ \int_a^b \| (u_n(t) - \bar{u}_n(s)) \|_W^p \, ds \leq \]
\[ \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \left( 2^{p-1} \varepsilon (\| u_n(t) \|_W^p + \| u_n(s) \|_W^p) \right) \]
\[ + C_\varepsilon R^{p/q} |t - s|^{p/q'} \, ds \, dt \]
\[ = \sum_{i=1}^k 2^p \varepsilon \int_{t_{i-1}}^{t_i} \| u_n(t) \|_W^p \, ds \, \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} |t - s|^{p/q'} \, ds \, dt \]
\[ = 2^p \varepsilon \int_a^b \| u_n(t) \|_W^p \, dt \, + C_\varepsilon R^{p/q} \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \sum_{j=1}^{t_i} \int_{t_{i-1}}^{t_i} (t_i - t_{i-1})^{p/q'} \, ds \, dt \]
\[ = 2^p \varepsilon \int_a^b \| u_n(t) \|_W^p \, dt \, + C_\varepsilon R^{p/q} \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \sum_{j=1}^{t_i} \int_{t_{i-1}}^{t_i} (t_i - t_{i-1})^{p/q'} (t_i - t_{i-1})^2 \]
\[ \leq 2^p \varepsilon R^p + C_\varepsilon R^{p/q} \sum_{i=1}^k (t_i - t_{i-1})^{1+p/q'} = 2^p \varepsilon R^p + C_\varepsilon R^{p/q} k \left( \frac{b - a}{k} \right)^{1+p/q'}. \]
Taking $\varepsilon$ so small that $2^p\varepsilon R^p < \eta^p/8^p$ and then choosing $k$ sufficiently large, it follows
\[ \|u_n - \overline{u}_n\|_{L^p([a,b];W)} < \frac{\eta}{4}. \]

Now use compactness of the embedding of $E$ into $W$ to obtain a subsequence such that $\{\overline{u}_n\}$ is Cauchy in $L^p(a,b;W)$ and use this to contradict $41.5.24$. The details follow.

Suppose $\overline{u}_n(t) = \sum_{i=1}^k u_i^n \mathcal{X}_i(t_{i-1}, t_i)(t)$. Thus
\[ \|\overline{u}_n(t)\|_E = \sum_{i=1}^k \|u_i^n\|_E \mathcal{X}_i(t_{i-1}, t_i)(t) \]
and so
\[ R \geq \int_a^b \|\overline{u}_n(t)\|^p_E \, dt = \frac{T}{k} \sum_{i=1}^k \|u_i^n\|^p_E. \]

Therefore, the $\{u_i^n\}$ are all bounded. It follows that after taking subsequences $k$ times there exists a subsequence $\{u_{nk}\}$ such that $u_{nk}$ is a Cauchy sequence in $L^p(a,b;W)$. You simply get a subsequence such that $u_i^{nk}$ is a Cauchy sequence in $W$ for each $i$. Then denoting this subsequence by $n$,
\[ \|u_n - u_m\|_{L^p(a,b;W)} \leq \|u_n - \overline{u}_n\|_{L^p(a,b;W)} + \|\overline{u}_n - u_m\|_{L^p(a,b;W)} + \|u_m - u_m\|_{L^p(a,b;W)} \]
\[ \leq \frac{\eta}{4} + \|\overline{u}_n - u_m\|_{L^p(a,b;W)} + \frac{\eta}{4} < \eta \]
provided $m, n$ are large enough, contradicting $41.5.24$. This proves the theorem.

### 41.6 The $K$ Method

This considers the problem of interpolating Banach spaces. The idea is to build a Banach space between two others in a systematic way, thus constructing a new Banach space from old ones. The first method of defining intermediate Banach spaces is called the $K$ method. For more on this topic as well as the other topics on interpolation see $[13]$ which is what I am following. See also $[14]$. There is far more on these subjects in these books than what I am presenting here! My goal is to present only enough to give an introduction to the topic and to use it in presenting more theory of Sobolev spaces.

In what follows a topological vector space is a vector space in which vector addition and scalar multiplication are continuous. That is $\cdot : F \times X \to X$ is continuous and $+: X \times X \to X$ is also continuous.

A common example of a topological vector space is the dual space, $X'$ of a Banach space, $X$ with the weak * topology. For $S \subseteq X$ a finite set, define
\[ B_S(x^*, r) \equiv \{y^* \in X' : |y^*(x) - x^*(x)| < r \text{ for all } x \in S\} \]
Then the $B_S(x^*,r)$ for $S$ a finite subset of $X$ and $r > 0$ form a basis for the topology on $X'$ called the weak * topology. You can check that the vector space operations are continuous.

**Definition 41.6.1** Let $A_0$ and $A_1$ be two Banach spaces with norms $\|\cdot\|_0$ and $\|\cdot\|_1$ respectively, also written as $\|\cdot\|_{A_0}$ and $\|\cdot\|_{A_1}$ and let $X$ be a topological vector space such that $A_i \subseteq X$ for $i = 1, 2$, and the identity map from $A_i$ to $X$ is continuous. For each $t > 0$, define a norm on $A_0 + A_1$ by

$$K(t, a) \equiv \|a\|_t \equiv \inf \{\|a_0\|_0 + t \|a_1\|_1 : a_0 + a_1 = a\}.$$

This is short for $K(t, a, A_0, A_1)$. Thus $K(t, a, A_1, A_0)$ will mean

$$K(t, a, A_1, A_0) \equiv \inf \{\|a_1\|_{A_1} + t \|a_0\|_{A_0} : a_0 + a_1 = a\}$$

but the default is $K(t, a, A_0, A_1)$ if $K(t, a)$ is written.

The following lemma is an interesting exercise.

**Lemma 41.6.2** $(A_0 + A_1, K(t, \cdot))$ is a Banach space and all the norms, $K(t, \cdot)$ are equivalent.

**Proof:** First, why is $K(t, \cdot)$ a norm? It is clear that $K(t, a) \geq 0$ and that if $a = 0$ then $K(t, a) = 0$. Is this the only way this can happen? Suppose $K(t, a) = 0$. Then there exist $a_{0n} \in A_0$ and $a_{1n} \in A_1$ such that $\|a_{0n}\|_0 \to 0$, $\|a_{1n}\|_1 \to 0$, and $a = a_{0n} + a_{1n}$. Since the embedding of $A_1$ into $X$ is continuous and since $X$ is a topological vector space,

$$a = a_{0n} + a_{1n} \to 0$$

and so $a = 0$.

Let $\alpha$ be a nonzero scalar. Then

$$K(t, \alpha a) = \inf \{\|a_0\|_0 + t \|a_1\|_1 : a_0 + a_1 = \alpha a\} = \inf \{|\alpha| \left(\|a_0\|_0 + t \|a_1\|_1\right) : \frac{a_0}{\alpha} + \frac{a_1}{\alpha} = a\} = |\alpha| \inf \{\|a_0\|_0 + t \|a_1\|_1 : a_0 + a_1 = a\} = |\alpha| K(t, a)\,.$$

It remains to verify the triangle inequality. Let $\varepsilon > 0$ be given. Then there exist $a_0, a_1, b_0,$ and $b_1$ in $A_0, A_1, A_0,$ and $A_1$ respectively such that $a_0 + a_1 = a, b_0 + b_1 = b$ and

$$\varepsilon + K(t, a) + K(t, b) > \|a_0\|_0 + t \|a_1\|_1 + \|b_0\|_0 + t \|b_1\|_1 \geq \|a_0 + b_0\|_0 + t \|b_1 + a_1\|_1 \geq K(t, a + b).$$

---

1Vector addition is continuous is the property which is used here.
Let \( f \) all these norms are equivalent, it suffices to only consider the norm, \( K \). Theorem 41.6.4 denotes elements of \( A \) between 0.

Then \( x \) converges to 0.

Hence it follows there exist \( \epsilon > 0 \) such that for every \( m, n \) large enough,

\[
K(1, a_0 + a_n - (a_0 + a_1)) < \epsilon.
\]

It follows there exist \( x_n \in A_0 \) and \( y_n \in A_1 \) such that \( x_n + y_n = 0 \) for every \( n \) and whenever \( m, n \) are large enough,

\[
||a_0 + x_n - (a_0 + x_m)|| + ||a_1 + y_n - (a_1 + y_m)||_1 < \epsilon.
\]

Hence \( \{a_1 + y_n\} \) is a Cauchy sequence in \( A_1 \) and \( \{a_0 + x_n\} \) is a Cauchy sequence in \( A_0 \). Let

\[
a_0 + x_n \to a_0 \in A_0,
\]

\[
a_1 + y_n \to a_1 \in A_1.
\]

Then

\[
K(1, a_0 + a_1 - (a_0 + a_1)) = K(1, a_0 + x_n + a_1 + y_n - (a_0 + a_1)) \leq ||a_0 + x_n - a_0||_1 + ||a_1 + y_n - a_1||_1
\]

which converges to 0. Thus \( A_0 + A_1 \) is a Banach space as claimed.

With this, there exists a method for constructing a Banach space which lies between \( A_0 \cap A_1 \) and \( A_0 + A_1 \).

**Definition 41.6.3** Let \( 1 \leq q < \infty, 0 < \theta < 1 \). Define \( (A_0, A_1)_{\theta, q} \) to be those elements of \( A_0 + A_1, a \), such that

\[
||a||_{\theta, q} = \left[ \int_0^\infty \left( t^{-\theta} K(t, a, A_0, A_1) \right)^q \frac{dt}{t} \right]^{1/q} < \infty.
\]

**Theorem 41.6.4** \( (A_0, A_1)_{\theta, q} \) is a normed linear space satisfying

\[
A_0 \cap A_1 \subseteq (A_0, A_1)_{\theta, q} \subseteq A_0 + A_1,
\]

(41.6.26)
41.6. THE K METHOD

with the inclusion maps continuous, and

\[
\left( (A_0, A_1)_{\theta,q}, \| \cdot \|_{\theta,q} \right) \text{ is a Banach space.} \tag{41.6.27}
\]

If \( a \in A_0 \cap A_1 \), then

\[
\| a \|_{\theta,q} \leq \left( \frac{1}{\theta (1 - \theta)} \right)^{1/q} \| a \|_1^\theta \| a \|_0^{1 - \theta}. \tag{41.6.28}
\]

If \( A_0 \subseteq A_1 \) with \( \| \cdot \|_0 \geq \| \cdot \|_1 \), then

\[
A_0 \cap A_1 = A_0 \subseteq (A_0, A_1)_{\theta,q} \subseteq A_1 = A_0 + A_1.
\]

Also, if bounded sets in \( A_0 \) have compact closures in \( A_1 \) then the same is true if \( A_1 \) is replaced with \( (A_0, A_1)_{\theta,q} \). Finally, if

\[
T \in \mathcal{L}(A_0, B_0), T \in \mathcal{L}(A_1, B_1), \tag{41.6.29}
\]

and \( T \) is a linear map from \( A_0 + A_1 \) to \( B_0 + B_1 \) where the \( A_i \) and \( B_i \) are Banach spaces with the properties described above, then it follows

\[
T \in \mathcal{L} \left( (A_0, A_1)_{\theta,q}, (B_0, B_1)_{\theta,q} \right) \tag{41.6.30}
\]

and if \( M \) is its norm, and \( M_0 \) and \( M_1 \) are the norms of \( T \) as a map in \( \mathcal{L}(A_0, B_0) \) and \( \mathcal{L}(A_1, B_1) \) respectively, then

\[
M \leq M_0^{1 - \theta} M_1^\theta. \tag{41.6.31}
\]

**Proof:** Suppose first \( a \in A_0 \cap A_1 \). Then

\[
\| a \|_{\theta,q}^q = \int_0^r (t^{-\theta} K(t, a))^q \frac{dt}{t} + \int_r^\infty (t^{-\theta} K(t, a))^q \frac{dt}{t} \tag{41.6.32}
\]

\[
\leq \int_0^r (t^{-\theta} \| a \|_1 t)^q \frac{dt}{t} + \int_r^\infty (t^{-\theta} \| a \|_0)^q \frac{dt}{t}
\]

\[
= \| a \|_1^q \int_0^r t^{\theta(1 - \theta) - 1} dt + \| a \|_0^q \int_r^\infty t^{-1 - \theta q} dt
\]

\[
= \| a \|_1^q \frac{r^{\theta q - \theta} - 1}{\theta q - 1} + \| a \|_0^q \frac{r^{-\theta q}}{\theta q - \theta} < \infty \tag{41.6.33}
\]

Which shows the first inclusion of (41.6.26). The above holds for all \( r > 0 \) and in particular for the value of \( r \) which minimizes the expression on the right in (41.6.33), \( r = \| a \|_0 / \| a \|_1 \). Therefore, doing some calculus,

\[
\| a \|_{\theta,q}^q \leq \frac{1}{\theta q (1 + \theta)} \| a \|_0^q (1 - \theta) \| a \|_1^\theta
\]

which shows (41.6.26). This also verifies that the first inclusion map is continuous in (41.6.26) because if \( a_n \to 0 \) in \( A_0 \cap A_1 \), then \( a_n \to 0 \) in \( A_0 \) and in \( A_1 \) and so the above shows \( a_n \to 0 \) in \( (A_0, A_1)_{\theta,q} \).
Now consider the second inclusion in \(A_0, A_1\). The inclusion is obvious because 
\((A_0, A_1)_{\theta, q}\) is given to be a subset of \(A_0 + A_1\) defined by 
\[
\left( \int_0^\infty \left( t^{-\theta} K(t, a) \right)^q \frac{dt}{t} \right)^{1/q} < \infty
\]

It remains to verify the inclusion map is continuous. Therefore, suppose \(a_n \to a\) in 
\((A_0, A_1)_{\theta, q}\). Since \(a_n \to 0\) in \((A_0, A_1)_{\theta, q}\), it follows the function, 
\(t \to t^{-\theta} K(t, a_n)\) converges to zero in \(L^q(0, \infty)\) with respect to the measure, 
\(dt/t\). Therefore, taking another subsequence, still denoted as \(a_n\), you can assume this function converges 
to 0 a.e. Pick such a \(t\) where this convergence takes place. Then \(K(t, a_n) \to 0\) as 
\(n \to \infty\) and so \(a_n \to 0\) in \(A_0 + A_1\). (Recall all these norms \(K(t, \cdot)\) are equivalent.) 
This shows that if \(a_n \to 0\) in \((A_0, A_1)_{\theta, q}\), then there exists a subsequence \(\{a_{n_k}\}\) 
such that \(a_{n_k} \to 0\) in \(A_0 + A_1\). It follows that if \(a_n \to 0\) in \((A_0, A_1)_{\theta, q}\), then \(a_n \to 0\) 
in \(A_0 + A_1\). This proves the continuity of the embedding.

What about \((A_0, A_1)_{\theta, q}\)? Suppose \(\{a_n\}\) is a Cauchy sequence in 
\((A_0, A_1)_{\theta, q}\). Then 
from what was just shown this is a Cauchy sequence in \(A_0 + A_1\) and so there exists 
a \(a \in A_0 + A_1\) such that \(a_n \to a\) in \(A_0 + A_1\) because \(A_0 + A_1\) is a Banach space. Thus, 
\(K(t, a_n) \to K(t, a)\) for all \(t > 0\). (Recall all these norms \(K(t, \cdot)\) are equivalent.) 
Therefore, by Fatou’s lemma, 
\[
\left( \int_0^\infty \left( t^{-\theta} K(t, a) \right)^q \frac{dt}{t} \right)^{1/q} \leq \lim \inf_{n \to \infty} \left( \int_0^\infty \left( t^{-\theta} K(t, a_n) \right)^q \frac{dt}{t} \right)^{1/q} 
\leq \max \left\{ ||a_n||_{\theta, q} : n \in \mathbb{N} \right\} < \infty
\]

and so \(a \in (A_0, A_1)_{\theta, q}\). Now 
\[
||a - a_n||_{\theta, q} \leq \lim \inf_{m \to \infty} \left( \int_0^\infty \left( t^{-\theta} K(t, a_n - a_m) \right)^q \frac{dt}{t} \right)^{1/q} 
= \lim \inf_{m \to \infty} ||a_n - a_m||_{\theta, q} < \varepsilon
\]
whenever \(n\) is large enough. Thus \((A_0, A_1)_{\theta, q}\) is complete as claimed.

Next suppose \(A_0 \subseteq A_1\) and the inclusion map is compact. In this case, \(A_0 \cap A_1 = A_0\) 
and so it has been shown above that \(A_0 \subseteq (A_0, A_1)_{\theta, q}\). It remains to show that 
every bounded subset, \(S\), contained in \(A_0\) has an \(\eta\) net in \((A_0, A_1)_{\theta, q}\). Recall the 
equality, \(\frac{1}{q \theta (1 - \theta)}\) 
\[
||a||_{\theta, q} \leq \left( \frac{1}{q \theta (1 - \theta)} \right)^{1/q} ||a||_1^{\theta} ||a||_0^{1-\theta} 
= \frac{C}{\varepsilon} ||a||_1^{\theta} ||a||_0^{1-\theta}.
\]
Now this implies 
\[
||a||_{\theta, q} \leq \left( \frac{C}{\varepsilon} \right)^{1/\theta} \theta ||a||_1 + \varepsilon^{1/(1-\theta)} (1 - \theta) ||a||_0.
\]
41.6. THE $K$ METHOD

By compactness of the embedding of $A_0$ into $A_1$, it follows there exists an $\varepsilon^{(1+\theta)/\theta}$ net for $S$ in $A_1, \{a_1, \ldots, a_p\}$. Then for $a \in S$, there exists $k$ such that $||a - a_k||_1 < \varepsilon^{(1+\theta)/\theta}$. It follows

$$||a - a_k||_{\theta,q} \leq \left( \frac{C}{\varepsilon} \right)^{1/\theta} \theta ||a - a_k||_1 + \varepsilon^{1/(1-\theta)} (1 - \theta) ||a - a_k||_0$$

$$\leq \left( \frac{C}{\varepsilon} \right)^{1/\theta} \theta \varepsilon^{(1+\theta)/\theta} + \varepsilon^{1/(1-\theta)} (1 - \theta) 2M$$

$$= C^{1/\theta} \theta \varepsilon + \varepsilon^{1/(1-\theta)} (1 - \theta) 2M$$

where $M$ is large enough that $||a||_0 \leq M$ for all $a \in S$. Since $\varepsilon$ is arbitrary, this shows the existence of a $\eta$ net and proves the compactness of the embedding into $(A_0, A_1)_{\theta,q}$.

It remains to verify the assertions $41.6.29$ $41.6.31$. Let $T \in \mathcal{L}(A_0, B_0), T \in \mathcal{L}(A_1, B_1)$ with $T$ a linear map from $A_0 + A_1$ to $B_0 + B_1$. Let $a \in (A_0, A_1)_{\theta,q} \subseteq A_0 + A_1$ and consider $Ta \in B_0 + B_1$. Denote by $K(t, \cdot)$ the norm described above for both $A_0 + A_1$ and $B_0 + B_1$ since this will cause no confusion. Then

$$||Ta||_{\theta,q} \equiv \left( \int_0^\infty (t^{-\theta}K(t, Ta))^q \frac{dt}{t} \right)^{1/q} \quad (41.6.34)$$

Now let $a_0 + a_1 = a$ and so $Ta_0 +Ta_1 = Ta$

$$K(t, Ta) \leq ||Ta_0||_0 + t ||Ta_1||_1 \leq M_0 ||a_0||_0 + M_1 t ||a_1||_1$$

and so, taking $\inf$ for all $a_0 + a_1 = a$, yields

$$K(t, Ta) \leq M_0 K \left( t \left( \frac{M_1}{M_0} \right), a \right)$$

It follows from $41.6.30$ that

$$||Ta||_{\theta,q} \equiv \left( \int_0^\infty (t^{-\theta}K(t, Ta))^q \frac{dt}{t} \right)^{1/q}$$

$$\leq \left( \int_0^\infty (t^{-\theta}M_0 K \left( t \left( \frac{M_1}{M_0} \right), a \right))^q \frac{dt}{t} \right)^{1/q}$$

$$= M_0 \left( \int_0^\infty (t^{-\theta}K \left( t \left( \frac{M_1}{M_0} \right), a \right))^q \frac{dt}{t} \right)^{1/q}$$

$$= M_0 \left( \int_0^\infty \left( \frac{M_0}{M_1 s} \right)^{-\theta} K(s, a) \right)^q \frac{ds}{s} \right)^{1/q}$$

$$= M_0^\theta M_0^{(1-\theta)} \left( \int_0^\infty \left( s^{-\theta}K(s, a) \right)^q \frac{ds}{s} \right)^{1/q} = M_0^\theta M_0^{(1-\theta)} ||a||_{\theta,q}.$$
This shows $T \in L \left( (A_0, A_1)_{\theta,q}, (B_0, B_1)_{\theta,q} \right)$ and if $M$ is the norm of $T$, $M \leq M_1^{1-\theta} M_1^\theta$ as claimed. This proves the theorem.

### 41.7 The $J$ Method

There is another method known as the $J$ method. Instead of 

$$K(t,a) \equiv \inf \left\{ \|a_0\|_{A_0} + t \|a_1\|_{A_1} : a_0 + a_1 = a \right\}$$

for $a \in A_0 + A_1$, this method considers $a \in A_0 \cap A_1$ and $J(t,a)$ defined below gives a norm on $A_0 \cap A_1$.

**Definition 41.7.1** For $A_0$ and $A_1$ Banach spaces as described above, and $a \in A_0 \cap A_1$,

$$J(t,a) \equiv \max \left( \|a\|_{A_0}, t \|a\|_{A_1} \right).$$

(41.7.35)

This is short for $J(t,a,A_0,A_1)$. Thus 

$$J(t,a,A_0,A_1) \equiv \max \left( \|a\|_{A_1}, t \|a\|_{A_0} \right)$$

but unless indicated otherwise, $A_0$ will come first. Now for $\theta \in (0,1)$ and $q \geq 1$, define a space, $(A_0,A_1)_{\theta,q,J}$ as follows. The space, $(A_0,A_1)_{\theta,q,J}$ will consist of those elements, $a$, of $A_0 + A_1$ which can be written in the form

$$a = \int_0^\infty u(t) \frac{dt}{t} \equiv \lim_{\epsilon \rightarrow 0^+} \int_\epsilon^1 u(t) \frac{dt}{t} + \lim_{r \rightarrow \infty} \int_1^r u(t) \frac{dt}{t}$$

(41.7.36)

the limits taking place in $A_0 + A_1$ with the norm 

$$K(1,a) \equiv \inf_{a = a_0 + a_1} \left( \|a_0\|_{A_0} + \|a_1\|_{A_1} \right),$$

where $u(t)$ is strongly measurable with values in $A_0 \cap A_1$ and bounded on every compact subset of $(0, \infty)$ such that

$$\left( \int_0^\infty (t^{-\theta} J(t,u(t),A_0,A_1))^q \frac{dt}{t} \right)^{1/q} < \infty.$$  

(41.7.37)

For such $a \in A_0 + A_1$, define 

$$\|a\|_{\theta,q,J} \equiv \inf_u \left\{ \left( \int_0^\infty (t^{-\theta} J(t,u(t),A_0,A_1))^q \frac{dt}{t} \right)^{1/q} \right\}$$

(41.7.38)

where the infimum is taken over all $u$ satisfying (41.7.36) and (41.7.37).

Note that a norm on $A_0 \times A_1$ would be 

$$\|(a_0,a_1)\| \equiv \max \left( \|a_0\|_{A_0}, t \|a_1\|_{A_1} \right)$$
and so $J(t, \cdot)$ is the restriction of this norm to the subspace of $A_0 \times A_1$ defined by $\{(a, a) : a \in A_0 \cap A_1\}$. Also for each $t > 0$ $J(t, \cdot)$ is a norm on $A_0 \cap A_1$ and furthermore, any two of these norms are equivalent. In fact, for $0 < t < s$,

$$J(t, a) = \max (\|a\|_{A_0}, t \|a\|_{A_1}) \geq \max (\|a\|_{A_0}, s \|a\|_{A_1}) = J(s, a) \geq \max (\frac{s}{t} \|a\|_{A_0}, s \|a\|_{A_1}) = \frac{s}{t} \max (\|a\|_{A_0}, t \|a\|_{A_1}) \geq \frac{s}{t} J(t, a).$$

The following lemma is significant and follows immediately from the above definition.

**Lemma 41.7.2** Suppose $a \in (A_0, A_1)_{\theta, q, J}$ and $a = \int_0^\infty u(t) \frac{dt}{t}$ where $u$ is described above. Then letting $r > 1$,

$$u_r(t) \equiv \begin{cases} u(t) & \text{if } t \in \left(\frac{1}{r}, r\right) \\ 0 & \text{otherwise} \end{cases}.$$  

it follows that

$$\int_0^\infty u_r(t) \frac{dt}{t} \in A_0 \cap A_1.$$

**Proof:** The integral equals $\int_{1/r}^r u(t) \frac{dt}{t} \int_{1/r}^r \frac{1}{t} dt = 2 \ln r < \infty$. Now $u_r$ is measurable in $A_0 \cap A_1$ and bounded. Therefore, there exists a sequence of measurable simple functions, $\{s_n\}$ having values in $A_0 \cap A_1$ which converges pointwise and uniformly to $u_r$. It can also be assumed $J(r, s_n(t)) \leq J(r, u_r(t))$ for all $t \in [1/r, r]$. Therefore,

$$\lim_{n, m \to \infty} \int_{1/r}^r J(r, s_m - s_n) \frac{dt}{t} = 0.$$  

It follows from the definition of the Bochner integral that

$$\lim_{n \to \infty} \int_{1/r}^r s_n \frac{dt}{t} = \int_{1/r}^r u_r \frac{dt}{t} \in A_0 \cap A_1.$$

This proves the lemma.

The remarkable thing is that the two spaces, $(A_0, A_1)_{\theta, q}$ and $(A_0, A_1)_{\theta, q, J}$ coincide and have equivalent norms. The following important lemma, called the fundamental lemma of interpolation theory in $[\mathbb{L}]$ is used to prove this. This lemma is really incredible.
**Lemma 41.7.3** Suppose for $a \in A_0 + A_1$, $\lim_{t \to 0^+} K(t, a) = 0$ and $\lim_{t \to \infty} \frac{K(t, a)}{t} = 0$. Then for any $\varepsilon > 0$, there is a representation,

$$a = \sum_{i=-\infty}^{\infty} u_i = \lim_{n,m \to \infty} \sum_{i=-m}^{n} u_i, \ u_i \in A_0 \cap A_1,$$

(41.7.39)

the convergences taking place in $A_0 + A_1$, such that

$$J \left( 2^i, u_i \right) \leq 3 \left( 1 + \varepsilon \right) K \left( 2^i, a \right).$$

(41.7.40)

**Proof:** For each $i$, there exist $a_{0,i} \in A_0$ and $a_{1,i} \in A_1$ such that

$$a = a_{0,i} + a_{1,i},$$

and

$$(1 + \varepsilon) K \left( 2^i, a \right) \geq \|a_{0,i}\|_{A_0} + 2^i \|a_{1,i}\|_{A_1}.$$  

(41.7.41)

This follows directly from the definition of $K(t, a)$. From the assumed limit conditions on $K(t, a)$,

$$\lim_{i \to \infty} \|a_{1,i}\|_{A_1} = 0, \ \lim_{i \to -\infty} \|a_{0,i}\|_{A_0} = 0.$$  

(41.7.42)

Then let $u_i \equiv a_{0,i} - a_{0,i-1} = a_{1,i-1} - a_{1,i}$. The reason these are equal is $a = a_{0,i} + a_{1,i} = a_{0,i-1} + a_{1,i-1}$. Then

$$\sum_{i=-m}^{n} u_i = a_{0,n} - a_{0,-(m+1)} = a_{1,-(m+1)} - a_{1,n}.$$  

It follows $a - \sum_{i=-m}^{n} u_i = a - (a_{0,n} - a_{0,-(m+1)}) = a_{0,-(m+1)} + a_{1,n}$, and both terms converge to zero as $m$ and $n$ converge to $\infty$ by (41.7.42). Therefore,

$$K \left( 1, a - \sum_{i=-m}^{n} u_i \right) \leq \|a_{0,-(m+1)}\| + \|a_{1,n}\|$$

(41.7.43)

and so this shows $a = \sum_{i=-\infty}^{\infty} u_i$ which is one of the claims of the lemma. Also

$$J \left( 2^i, u_i \right) \equiv \max \left( \|u_i\|_{A_0}, 2^i \|u_i\|_{A_1} \right) \leq \|u_i\|_{A_0} + 2^i \|u_i\|_{A_1}$$

$$\leq 2 \left( \|a_{0,i-1}\|_{A_0} + 2^{i-1} \|a_{1,i-1}\|_{A_1} \right)$$

$$\leq \|a_{0,i}\|_{A_0} + 2^i \|a_{1,i}\|_{A_1} + \|a_{0,i-1}\|_{A_0} + 2^{i-1} \|a_{1,i-1}\|_{A_1}$$

$$\leq (1 + \varepsilon) K \left( 2^i, a \right) + 2 \left( 1 + \varepsilon \right) K \left( 2^{i-1}, a \right) \leq 3 \left( 1 + \varepsilon \right) K \left( 2^i, a \right)$$

because $t \to K(t, a)$ is nondecreasing. This proves the lemma.

**Lemma 41.7.4** If $a \in A_0 \cap A_1$, then $K(t, a) \leq \min \left( 1, \frac{1}{t} \right) J(s, a)$. 

41.7. THE J METHOD

Proof: If \( s \geq t \), then \( \min \left( \frac{1}{s}, \frac{t}{s} \right) = \frac{t}{s} \) and so

\[
\min \left( 1, \frac{t}{s} \right) J(s, a) = \frac{t}{s} \max \left( \|a\|_{A_0}, s \|a\|_{A_1} \right) \geq \left( \frac{t}{s} \right) s \|a\|_{A_1}
\]

\[
= t \|a\|_{A_1} \geq K(t, a).
\]

Now in case \( s < t \), then \( \min \left( \frac{1}{s}, \frac{t}{s} \right) = 1 \) and so

\[
\min \left( 1, \frac{t}{s} \right) J(s, a) = \max \left( \|a\|_{A_0}, s \|a\|_{A_1} \right) \geq \|a\|_{A_0}
\]

\[
\geq K(t, a).
\]

This proves the lemma.

Theorem 41.7.5 Let \( A_0, A_1, K \) and \( J \) be as described above. Then for all \( q \geq 1 \) and \( \theta \in (0, 1) \),

\[
(A_0, A_1)_{\theta, q} = (A_0, A_1)_{\theta, q, t}
\]

and furthermore, the norms are equivalent.

Proof: Begin with \( a \in (A_0, A_1)_{\theta, q} \). Thus

\[
\|a\|_{\theta, q}^q = \int_0^\infty \left( t^{-\theta} \frac{1}{t} J(t, a) \right)^q \frac{dt}{t} < \infty \quad (41.7.43)
\]

and it is necessary to produce \( u(t) \) as described above,

\[
a = \int_0^\infty u(t) \frac{dt}{t} \quad \text{where} \quad \int_0^\infty \left( t^{-\theta} \frac{1}{t} J(t, u(t)) \right)^q \frac{dt}{t} < \infty.
\]

From \( 41.7.43 \), \( \lim_{t \to 0+} K(t, a) = 0 \) since \( t \to K(t, a) \) is nondecreasing and so if its limit is positive, the integrand would have a non integrable singularity like \( t^{-\theta q - 1} \).

Next consider what happens to \( \frac{K(t, a)}{t} \) as \( t \to \infty \).

Claim: \( t \to \frac{K(t, a)}{t} \) is decreasing.

Proof of the claim: Choose \( a_0 \in A_0 \) and \( a_1 \in A_1 \) such that \( a_0 + a_1 = a \) and

\[
K(t, a) + \varepsilon t > \|a_0\|_{A_0} + t \|a_1\|_{A_1}
\]

let \( s > t \). Then

\[
\frac{K(t, a) + \varepsilon t}{t} \geq \frac{\|a_0\|_{A_0} + t \|a_1\|_{A_1}}{t} \geq \frac{\|a_0\|_{A_0} + s \|a_1\|_{A_1}}{s} \geq \frac{K(s, a)}{s}.
\]

Since \( \varepsilon \) is arbitrary, this proves the claim.

Let \( r \equiv \lim_{t \to \infty} \frac{K(t, a)}{t} \). Is \( r = 0 \)? Suppose to the contrary that \( r > 0 \). Then the integrand of \( 41.7.43 \), is at least as large as

\[
t^{-\theta q - 1} \frac{K(t, a)}{t} \geq t^{-\theta q} K(t, a)^{\theta q - 1} r
\]
whose integral is infinite. Therefore, \( r = 0 \).

Lemma 41.7.3 implies there exist \( u_i \in A_0 \cap A_1 \) such that \( a = \sum_{i=-\infty}^{\infty} u_i \), the convergence taking place in \( A_0 + A_1 \) with the inequality of that Lemma holding,

\[
J (2^i, u_i) \leq 3 (1 + \varepsilon) K (2^i, a).
\]

For \( i \) an integer and \( t \in [2^{i-1}, 2^i) \), let

\[
u(t) \equiv u_i / \ln 2.
\]

Then

\[
a = \sum_{i=-\infty}^{\infty} u_i = \int_{0}^{\infty} u(t) \frac{dt}{t}.
\]  

(41.7.44)

Now

\[
\|a\|_{\theta, q, J}^q \leq \int_{0}^{\infty} (t^{-\theta} J(t, u(t)))^q \frac{dt}{t}
\]

\[
= \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^i} (t^{-\theta} J(t, u_i))^q \frac{dt}{t}
\]

\[
\leq \left( \frac{1}{\ln 2} \right)^q \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^i} (t^{-\theta} 3 (1 + \varepsilon) K (2^i, a))^q \frac{dt}{t}
\]

Using the above claim, \( K(2^i, a) \leq K(2^{i-1}, a) / 2^{2i} \) and so \( K (2^i, a) \leq 2K (2^{i-1}, a) \). Therefore, the above is no larger than

\[
\leq 2 \left( \frac{3 (1 + \varepsilon)}{\ln 2} \right)^q \sum_{i=-\infty}^{\infty} \int_{2^{i-1}}^{2^i} (t^{-\theta} K(t, a))^q \frac{dt}{t}
\]

\[
= 2 \left( \frac{3 (1 + \varepsilon)}{\ln 2} \right)^q \int_{0}^{\infty} (t^{-\theta} K(t, a))^q \frac{dt}{t} = 2 \left( \frac{3 (1 + \varepsilon)}{\ln 2} \right)^q \|a\|_{\theta, q, J}^q \quad (41.7.45)
\]

This has shown that if \( a \in (A_0, A_1)_{\theta, q} \), then by 41.7.3 and 41.7.4, \( a \in (A_0, A_1)_{\theta, q, J} \) and

\[
\|a\|_{\theta, q, J}^q \leq 2 \left( \frac{3 (1 + \varepsilon)}{\ln 2} \right)^q \|a\|_{\theta, q}^q.
\]  

(41.7.46)
It remains to prove the other inclusion and norm inequality, both of which are much easier to obtain. Thus, let
\[ a = \int_0^\infty u(t) \frac{dt}{t} \] (41.7.47)
where \( u \) is a strongly measurable function having values in \( A_0 \cap A_1 \) and for which
\[ \int_0^\infty (t^{-\theta} J(t, u(t)))^q dt < \infty. \] (41.7.48)
\[ K(t, a) = K\left(t, \int_0^\infty u(s) \frac{ds}{s}\right) \leq \int_0^\infty K(t, u(s)) \frac{ds}{s}. \] (41.7.49)
Now by Lemma 41.7.3, this is dominated by an expression of the form
\[ \leq \int_0^\infty \min \left(1, \frac{t}{s}\right) J(s, u(s)) \frac{ds}{s} = \int_0^\infty \min \left(1, \frac{1}{s}\right) J(ts, u(ts)) \frac{ds}{s} \] (41.7.50)
where the equation follows from a change of variable. From Minkowski’s inequality and 41.7.50, we have
\[ |a|_{\theta,q} \equiv \left( \int_0^\infty (t^{-\theta} K(t, a))^q \frac{dt}{t} \right)^{1/q} \leq \left( \int_0^\infty \left( t^{-\theta} \int_0^\infty \min \left(1, \frac{1}{s}\right) J(ts, u(ts)) \frac{ds}{s} \right)^q \frac{dt}{t} \right)^{1/q} \leq \int_0^\infty \left( \int_0^\infty \left( t^{-\theta} \min \left(1, \frac{1}{s}\right) J(ts, u(ts)) \right)^q \frac{dt}{t} \right) \frac{ds}{s}. \]
Now change the variable in the inside integral to obtain, letting \( t = \tau s \),
\[ \leq \int_0^\infty \min \left(1, \frac{1}{s}\right) \left( \int_0^\infty (t^{-\theta} J(ts, u(ts)))^q \frac{dt}{t} \right)^{1/q} \frac{ds}{s} = \int_0^\infty \min \left(1, \frac{1}{s}\right) s^{-\theta} \frac{ds}{s} \left( \int_0^\infty (\tau^{-\theta} J(\tau, u(\tau)))^q \frac{d\tau}{\tau} \right)^{1/q} = \left( \frac{1}{(1-\theta)\theta} \right) \left( \int_0^\infty (\tau^{-\theta} J(\tau, u(\tau)))^q \frac{d\tau}{\tau} \right)^{1/q} . \]
This has shown that
\[ \|a\|_{\theta,q} \leq \left( \frac{1}{(1-\theta)\theta} \right) \left( \int_0^\infty (\tau^{-\theta} J(\tau, u(\tau)))^q \frac{d\tau}{\tau} \right)^{1/q} < \infty \]
for all \( u \) satisfying 41.7.47 and 41.7.48. Therefore, taking the infimum it follows \( a \in (A_0, A_1)_{\theta,q} \) and
\[ \|a\|_{\theta,q} \leq \left( \frac{1}{(1-\theta)\theta} \right) \|a\|_{\theta,q,J}. \]
This proves the theorem.
41.8 Duality And Interpolation

In this section it will be assumed that \( A_0 \cap A_1 \) is dense in \( A_i \) for \( i = 0, 1 \). This is done so that \( A_i'[\mathbb{C}] \subseteq (A_0 \cap A_1)' \) and the inclusion map is continuous. Thus it makes sense to add something in \( A_0' \) to something in \( A_1' \).

What is the dual space of \( (A_0, A_1)_{\theta,q} \)? The answer is based on the following lemma, [15]. Remember that

\[
J(t,a) = \max(||a||_{A_0}, t||a||_{A_1})
\]

and this is a norm on \( A_0 \cap A_1 \) and

\[
K(t,a) = \inf \{||a||_{A_0} + t||a||_{A_1} : a = a_0 + a_1\}.
\]

As mentioned above, \( A_0' + A_1' \subseteq (A_0 \cap A_1)' \). In fact these two are equal. This is the first part of the following lemma.

**Lemma 41.8.1** Suppose \( A_0 \cap A_1 \) is dense in \( A_i \), \( i = 0, 1 \). Then

\[
A_0' + A_1' = (A_0 \cap A_1)', \tag{41.8.51}
\]

and for \( a' \in A_0' + A_1' = (A_0 \cap A_1)' \),

\[
K(t, a') = \sup_{a \in A_0 \cap A_1} \frac{|a'(a)|}{J(t^{-1}, a)}. \tag{41.8.52}
\]

Thus \( K(t, \cdot) \) is an equivalent norm to the usual operator norm on \( (A_0 \cap A_1)' \) taken with respect to \( J(t^{-1}, \cdot) \). If, in addition to this, \( A_i \) is reflexive, then for \( a' \in A_0' \cap A_1' \), and \( a \in A_0 \cap A_1 \),

\[
J(t, a') K(t^{-1}, a) \geq |a'(a)|. \tag{41.8.53}
\]

**Proof:** First consider the claim that \( A_0' + A_1' = (A_0 \cap A_1)' \). As noted above, \( \subseteq \) is clear. Define a norm on \( A_0 \times A_1 \) as follows.

\[
|| (a_0, a_1) ||_{A_0 \times A_1} \equiv \max \left( ||a_0||_{A_0}, t^{-1} ||a_1||_{A_1} \right). \tag{41.8.54}
\]

Let \( a' \in (A_0 \cap A_1)' \). Let

\[
E \equiv \{(a, a) : a \in A_0 \cap A_1 \}
\]

with the norm \( J(t^{-1}, a) \equiv \max \left( ||a||_{A_0}, t^{-1} ||a||_{A_1} \right) \). Now define \( \lambda \) on \( E \), the subspace of \( A_0 \times A_1 \) by

\[
\lambda((a, a)) \equiv a'(a).
\]

Thus \( \lambda \) is a continuous linear map on \( E \) and in fact,

\[
|\lambda((a, a))| = |a'(a)| \leq ||a'|| J(t^{-1}, a).
\]
By the Hahn Banach theorem there exists an extension of \( \lambda \) to all of \( A_0 \times A_1 \). This extension is of the form \((a'_0, a'_1) \in A'_0 \times A'_1\). Thus
\[
(a'_0, a'_1)((a, a)) = a'_0(a) + a'_1(a) = a'(a)
\]
and therefore, \( a'_0 + a'_1 = a' \) provided \( a'_0 + a'_1 \) is continuous. But
\[
|(|a'_0 + a'_1)(a)| = |a'_0(a) + a'_1(a)| \leq |a'_0(a)| + |a'_1(a)| 
\]
\[
\leq \|a'_0\| \|a\|_{A_0} + \|a'_1\| \|a\|_{A_1} 
\]
\[
\leq \|a'_0\| \|a\|_{A_0} + t \|a'_1\| t^{-1} \|a\|_{A_1} 
\]
\[
\leq (\|a'_0\| + t \|a'_1\|) J(t^{-1}, a)
\]
which shows that \( a'_0 + a'_1 \) is continuous and in fact
\[
\|a'_0 + a'_1\|_{(A_0 \times A_1)'} \leq (\|a'_0\| + t \|a'_1\|).
\]
This proves the first part of the lemma.

\textbf{Claim:} With this definition of the norm in (41.8.39), the operator norm of \((a'_0, a'_1) \in (A_0 \times A_1)', A'_0 \times A'_1\) is
\[
\|((a'_0, a'_1))_{(A_0 \times A_1)'} = \|a'_0\|_{A'_0} + t \|a'_1\|_{A'_1}.
\]

\textbf{Proof of the claim:} \(\| (a'_0, a'_1)(a, 0) \| \leq \|a'_0\| \|a_0\| + \|a'_1\| \|a_1\| \). Now suppose that \( \|a_0\| = \max (\|a_0\|, t^{-1} \|a_1\|) \). Then this is no larger than
\[
(\|a'_0\| + t \|a'_1\|) \|a_0\| = (\|a'_0\| + t \|a'_1\|) \max (\|a_0\|, t^{-1} \|a_1\|).
\]
The other case is that \( t^{-1} \|a_1\| = \max (\|a_0\|, t^{-1} \|a_1\|) \). In this case,
\[
|(|a'_0, a'_1)(0, a_1)| \leq |\|a'_0\|| |a_0| + |\|a'_1\|| |a_1|
\]
\[
\leq |\|a'_0\|| t^{-1} |a_1| + |\|a'_1\|| |a_1|
\]
\[
= (\|a'_0\| + t \|a'_1\|) t^{-1} |a_1|
\]
\[
= (\|a'_0\| + t \|a'_1\|) \max (\|a_0\|, t^{-1} \|a_1\|).
\]
This shows \(\| (a'_0, a'_1))_{(A_0 \times A_1)'} \leq (\|a'_0\| + t \|a'_1\|) \). Is equality achieved? Let \( a_{0n} \) and \( a_{1n} \) be points of \( A_0 \) and \( A_1 \) respectively such that \( \|a_{0n}\|, \|a_{1n}\| \leq 1 \) and \( \lim_{n \to \infty} a_{0}'(a_{1n}) = \|a'_1\| \). Then
\[
(a'_0, a'_1)(a_{0n}, ta_{1n}) \rightarrow \|a'_0\| + t \|a'_1\|
\]
and also, \(\| (a_{0n}, ta_{1n})\|_{(A_0 \times A_1)} \leq \max (\|a_{0n}\|, t^{-1} t \|a_{1n}\|_{A_1}) \leq 1 \). Therefore, equality is indeed achieved and this proves the claim.

Consider (41.8.39). Take \( a' \in A'_0 + A'_1 = (A_0 \cap A_1)' \) and let
\[
E = \{(a, a) \in A_0 \times A_1 : a \in A_0 \cap A_1\}.
\]
Now define a linear map, λ on \( E \) as before.

\[
\lambda ((a, a)) \equiv a'(a).
\]

If \( a' = \tilde{a}_0' + \tilde{a}_1' \),

\[
|\lambda ((a, a))| \leq ||\tilde{a}_0'||_{A_0'} ||a||_{A_0} + ||\tilde{a}_1'||_{A_1'} ||a||_{A_1}
= ||\tilde{a}_0'||_{A_0'} ||a||_{A_0} + t ||\tilde{a}_1'||_{A_1'} t^{-1} ||a||_{A_1}
\leq (||\tilde{a}_0'|| + t ||\tilde{a}_1'||) ||(a, a)||_{A_0 \times A_1}
\]

so \( \lambda \) is continuous on the subspace, \( E \) of \( A_0 \times A_1 \) and

\[
||\lambda||_{E'} \leq ||\tilde{a}_0'|| + t ||\tilde{a}_1'||.
\] (41.8.56)

By the Hahn Banach theorem, there exists an extension of \( \lambda \) defined on all of \( A_0 \times A_1 \) with the same norm. Thus, from 41.8.53, there exists \( (a_0', a_1') \in (A_0 \times A_1)' \) which is an extension of \( \lambda \) such that

\[
||(a_0', a_1')||_{(A_0 \times A_1)'} = ||a_0'||_{A_0'} + t ||a_1'||_{A_1'} = ||\lambda||_{E'}
\]

and for all \( a \in A_0 \cap A_1 \),

\[
a_0'(a) + a_1'(a) = \lambda ((a, a)) = a'(a).
\]

It follows that \( a_0' + a_1' = a' \) in \( (A_0 \cap A_1)' \). Therefore, from 41.8.50,

\[
||\lambda||_{E'} \leq \inf \{ ||\tilde{a}_0'||_{A_0'} + t ||\tilde{a}_1'||_{A_1'} : a' = \tilde{a}_0' + \tilde{a}_1' \} \equiv K(t, a') \] (41.8.57)

\[
\leq ||a_0'||_{A_0'} + t ||a_1'||_{A_1'} = ||\lambda||_{E'} = \sup_{a \in A_0 \cap A_1} |a'(a)| J(t^{-1}, a') \] (41.8.58)

because on \( E, J(t^{-1}, a) = ||(a, a)||_{A_0 \times A_1} \) which proves 41.8.52.

To obtain 41.8.54 in the case that \( A_i \) is reflexive, apply 41.8.50 to the case where \( A_i'' \) plays the role of \( A_i \) in 41.8.54. Thus, for \( a'' \in A_0'' + A_1'' \),

\[
K(t, a'') = \sup_{a' \in A_0' \cap A_1'} |a''(a')| J(t^{-1}, a').
\]

Now \( a'' = a''_0 + a''_0 = \eta_1 a_1 + \eta_0 a_0 \) where \( \eta_i \) is the map from \( A_i \) to \( A_i'' \) which is onto and preserves norms, given by \( \eta(a') \equiv a'(a) \). Therefore, letting \( a_1 + a_0 = a \)

\[
K(t, a) = K(t, a'') = \sup_{a' \in A_0' \cap A_1'} |a''(a')| J(t^{-1}, a')
= \sup_{a' \in A_0' \cap A_1'} \frac{|(\eta_1 a_1 + \eta_0 a_0)(a')|}{J(t^{-1}, a')} = \sup_{a' \in A_0' \cap A_1'} \frac{|(a'(a_1 + a_0))|}{J(t^{-1}, a')}
\]

and so

\[
K(t, a) = \sup_{a' \in A_0' \cap A_1'} \frac{|a'(a)|}{J(t^{-1}, a')}
\]
41.8. DUALITY AND INTERPOLATION

Changing \( t \to t^{-1} \),

\[
K \left( t^{-1}, a \right) J \left( t, a' \right) \geq |a' (a)|.
\]

which proves the lemma.

Consider \((A_0, A_1)_{\theta, q}'\).

**Definition 41.8.2** Let \( q \geq 1 \). Then \( \lambda^{\theta, q} \) will denote the sequences, \( \{\alpha_i\}_{i=-\infty}^{\infty} \) such that

\[
\sum_{i=-\infty}^{\infty} (|\alpha_i| \cdot 2^{-i \theta})^q < \infty.
\]

For \( \alpha \in \lambda^{\theta, q} \),

\[
\|\alpha\|_{\lambda^{\theta, q}} \equiv \left( \sum_{i=-\infty}^{\infty} (|\alpha_i| \cdot 2^{-i \theta})^q \right)^{1/q}.
\]

Thus \( \alpha \in \lambda^{\theta, q} \) means \( \{\alpha_i 2^{-i \theta}\} \in l_q \).

**Lemma 41.8.3** Let \( f (t) \geq 0 \), and let \( f (t) = \alpha_i \) for \( t \in [2^i, 2^{i+1}) \) where \( \alpha \in \lambda^{\theta, q} \). Then there exists a constant, \( C \), such that

\[
\|t^{-\theta} f\|_{L^q (0, \infty; \frac{dt}{t})} \leq C \|\alpha\|_{\lambda^{\theta, q}}.
\]

(41.8.59)

Also, if whenever \( \alpha \in \lambda^{\theta, q} \), and \( \alpha_i \geq 0 \) for all \( i \),

\[
\sum_{i} f (2^i) 2^{-i \alpha_i} \leq C \|\alpha\|_{\lambda^{\theta, q}},
\]

(41.8.60)

then

\[
\{f (2^i)\}_{i=-\infty}^{\infty} \overline{l}_{\lambda^{1-i, q'}} \leq C.
\]

(41.8.61)

**Proof:** Consider \( l_{L^q \overline{\phi}} \).

\[
\int_{0}^{\infty} (t^{-\theta} f(t))^q \frac{dt}{t} = \sum_i \int_{2^i}^{2^{i+1}} t^{-\theta q} \alpha_i^q \frac{dt}{t} \\
\leq \sum_i \int_{2^i}^{2^{i+1}} (2^{-i \alpha_i})^q \frac{dt}{t} = \ln 2 \sum_i (2^{-i \alpha_i})^q = \ln 2 \|\alpha\|^q_{\lambda^{\theta, q}}.
\]

(41.8.59) is next. By \( l_{L^q \overline{\phi}} \), whenever \( \alpha \in \lambda^{\theta, q} \),

\[
\left| \sum_{i} (f (2^i) 2^{-(1-\theta)i}) 2^{-i \alpha_i} \right| \leq C \|\{2^{-i \alpha_i}\}\|_{l_q}.
\]

It follows from the Riesz representation theorem that \( \{f (2^i) 2^{-(1-\theta)i}\} \) is in \( l_{q'} \) and

\[
\left\| \{f (2^i) 2^{-(1-\theta)i}\} \right\|_{l_{q'}} = \left\| \{f (2^i)\} \right\|_{\lambda^{1-i, q'}} \leq C.
\]

This proves the lemma.

The dual space of \((A_0, A_1)_{\theta, q, \phi} \) is discussed next.
Lemma 41.8.4 Let $\theta \in (0, 1)$ and let $q \geq 1$. Then,

$$(A_0, A_1)'_{\theta, q, J} \subseteq (A_1', A_0')_{1-\theta, q}$$

and the inclusion map is continuous.

Proof: Let $a' \in (A_0, A_1)'_{\theta, q, J}$. Now

$$a_0 \cap A_1 \subseteq (A_0, A_1)'_{\theta, q, J}$$

and if

$$a \in (A_0, A_1)'_{\theta, q, J},$$

then $a$ has a representation of the form

$$a = \int_0^\infty u(t) \frac{dt}{t}$$

where

$$\int_0^\infty \left( t^{-\theta} J(t, u(t)) \right)^q \frac{dt}{t} < \infty$$

where

$$J(t, u(t)) = \max \left( \|u(t)\|_{A_0}, t \|u(t)\|_{A_1} \right)$$

for $u(t) \in A_0 \cap A_1$. Now let

$$u_r(t) = \begin{cases} u(t) & \text{if } t \in \left( \frac{1}{r}, r \right) \\ 0 & \text{otherwise} \end{cases}.$$ 

Then

$$\int_0^\infty \left( t^{-\theta} J(t, u_r(t)) \right)^q \frac{dt}{t} < \infty$$

and

$$a_r = \int_0^\infty u_r(t) \frac{dt}{t} \in A_0 \cap A_1$$

by Lemma 41.7.2. Also

$$\|a - a_r\|_{\theta, q, J}^q \leq \int_0^{1/r} \left( t^{-\theta} J(t, u(t)) \right)^q \frac{dt}{t} + \int_r^\infty \left( t^{-\theta} J(t, u(t)) \right)^q \frac{dt}{t}$$

which is small whenever $r$ is large enough thanks to the dominated convergence theorem. Therefore, $A_0 \cap A_1$ is dense in $(A_0, A_1)'_{\theta, q, J}$ and so

$$(A_0, A_1)'_{\theta, q, J} \subseteq (A_0 \cap A_1)' = A_0' + A_1',$$

the equality following from Lemma 41.8.1.
41.8. DUALITY AND INTERPOLATION

It follows $a' \in A'_0 + A'_1$ and so, by Lemma 41.8.1 there exists $b_i \in A_0 \cap A_1$ such that
\[
K (2^{-i}, a', A'_0, A'_1) - \varepsilon \min (1, 2^{-i}) \leq \frac{a' (b_i)}{J (2^i, b_i, A'_0, A'_1)}.
\]
Now let $\alpha \in \mathbb{X}^{\theta, q}$ with $\alpha_i \geq 0$ for all $i$ and let
\[
a_\infty \equiv \sum_i J (2^i, b_i, A'_0, A'_1)^{-1} b_i \alpha_i.
\] (41.8.62)
Consider first whether $a_\infty$ makes sense before proceeding further.
\[
a_\infty \equiv \sum_i \max \left( \left\| b_i \right\|_{A_0}, 2^i \left\| b_i \right\|_{A_1} \right) 2^{-i \theta} \alpha_i.
\]
Now
\[
\left\| \frac{b_i 2^{i \theta}}{\max \left( \left\| b_i \right\|_{A_0}, 2^i \left\| b_i \right\|_{A_1} \right)} \right\|_{A_0 + A_1} \leq \begin{cases} 2^{i \theta} & \text{if } i < 0 \\ 2^{-i (1 - \theta)} & \text{if } i \geq 0 \end{cases}.
\] (41.8.63)
This is fairly routine to verify. Consider the case where $i \geq 0$. Then
\[
\left\| \frac{b_i 2^{i \theta}}{\max \left( \left\| b_i \right\|_{A_0}, 2^i \left\| b_i \right\|_{A_1} \right)} \right\|_{A_0 + A_1} \leq \left\| \frac{b_i 2^{i \theta}}{2^i \left\| b_i \right\|_{A_1}} \right\|_{A_0 + A_1} \leq 2^{-i (1 - \theta)}
\]
because $\left\| b_i \right\|_{A_1} \geq \left\| b_i \right\|_{A_0 + A_1}$. Therefore,
\[
\sum_{i=0}^{M} \left\| \frac{b_i 2^{i \theta}}{\max \left( \left\| b_i \right\|_{A_0}, 2^i \left\| b_i \right\|_{A_1} \right)} 2^{-i \theta} \alpha_i \right\|_{A_0 + A_1} \leq \sum_{i=0}^{M} 2^{-i (1 - \theta)} 2^{-i \theta} \alpha_i \leq \left( \sum_{i=0}^{\infty} 2^{-i (1 - \theta) q'} \right)^{1/q'} \left( \sum_{i=0}^{\infty} 2^{-i \theta} \alpha_i^q \right)^{1/q} < \infty
\]
and similarly,
\[
\sum_{i=0}^{M} \left\| \frac{b_i 2^{i \theta}}{\max \left( \left\| b_i \right\|_{A_0}, 2^i \left\| b_i \right\|_{A_1} \right)} 2^{-i \theta} \alpha_i \right\|_{A_0 + A_1} \leq \left( \sum_{i=-\infty}^{\infty} 2^{-i (1 - \theta) q'} \right)^{1/q'} \left( \sum_{i=-\infty}^{\infty} 2^{-i \theta} \alpha_i^q \right)^{1/q} < \infty
\]
converges. Therefore, $a_\infty$ makes sense in $A_0 + A_1$ and also from Lemma 41.8.5 we see that
\[
\left\{ \frac{\left\| b_i \right\|_{A_0 + A_1} 2^{i \theta}}{J (2^i, b_i)} \right\} \in \mathbb{X}^{(1 - \theta) q'}
\]
Now let
\[
u (t) = \frac{\alpha_i b_i}{J (2^i, b_i) \ln 2} \quad \text{on } [2^{i-1}, 2^i].
\]
Then
\[
\int_0^\infty u(t) \frac{dt}{t} = \sum_i \int_{2^{i-1}}^{2^i} \frac{\alpha_i b_i}{J(2^i, b_i) \ln 2} \, dt
\]
\[= \sum_i \frac{\alpha_i b_i}{J(2^i, b_i)} = a_\infty.
\]
Also
\[
\int_0^\infty (t^{-\theta} J(t, u(t)))^q \frac{dt}{t} \leq \sum_i \int_{2^{i-1}}^{2^i} \left( 2^{(1-i)\theta} J(2^i, u(2^{i-1})) \right) \frac{dt}{t}
\]
\[\leq \sum_i \left[ 2^{-((i-1)\theta)} J(2^i, u(2^{i-1})) \right]^q \ln 2
\]
\[= \sum_i \left[ 2^{-((i-1)\theta)} J(2^i, b_i) \alpha_i \right]^{\frac{q}{\theta}} \ln 2
\]
\[= C \sum_i \left( 2^{-i\theta} |\alpha_i| \right)^q < \infty \quad (41.8.64)
\]
and so \( \|a_\infty\|_{\theta, q, J} < \infty \). Now for \( a' \) as above, \( a' \in (A_0, A_1)'_{\theta, q, J} \subseteq (A_0 + A_1)' \), and so since the sum for \( a_\infty \) converges in \( A_0 + A_1 \), we have
\[a'(a_\infty) = \sum_i J(2^i, b_i)^{-1} \alpha_i a'(b_i).
\]
Therefore,
\[
a'(a_\infty) \geq \sum_i \left[ K \left( 2^{-i}, a' \right) - \varepsilon \min \left( 1, 2^{-i} \right) \right] \alpha_i
\]
\[= \sum_i K \left( 2^{-i}, a' \right) \alpha_i - \sum_i \varepsilon \min \left( 1, 2^{-i} \right) \alpha_i
\]
\[= \sum_i K \left( 2^{-i}, a' \right) \alpha_i - O(\varepsilon) \quad (41.8.65)
\]
The reason for this is that \( \alpha \in \lambda^{\theta,q} \) so \( \{ \alpha_i 2^{-i \theta} \} \in l_q \). Therefore,

\[
\sum_i \varepsilon \min \left( 1, 2^{-i} \right) \alpha_i = \varepsilon \left\{ \sum_{i=0}^{\infty} 2^{-i} \alpha_i + \sum_{i=-\infty}^{-1} \alpha_i \right\} = \varepsilon \left\{ \sum_{i=0}^{\infty} 2^{-i \theta} 2^{i(\theta-1)} \alpha_i + \sum_{i=-\infty}^{-1} \alpha_i 2^{-i \theta} 2^i \right\} \leq \varepsilon \left\{ \left( \sum_i |\alpha_i 2^{-i \theta}|^q \right)^{1/q} \left( \sum_{i=0}^{\infty} \left( 2^{i(\theta-1)} \right) q' \right)^{1/q'} + \left( \sum_i |\alpha_i 2^{-i \theta}|^q \right)^{1/q} \left( \sum_{i=0}^{\infty} \left( 2^i \right) q' \right)^{1/q'} \right\} < C\varepsilon.
\]

Also

\[
|a'(a')| \leq \|a'||_{(A_0,A_1)_{\theta,q,J}} \|a\|_{(A_0,A_1)_{\theta,q,J}}.
\]

Now from the definition of \( K \),

\[
K \left( 2^{-i}, a', A'_0, A'_1 \right) = 2^{-i} K \left( 2^i, a', A'_1, A'_0 \right)
\]

and so from Lemma \ref{lem:41.8.3}:

\[
\sum_i 2^{-i} K \left( 2^i, a', A'_1, A'_0 \right) \alpha_i = O(\varepsilon) \leq a'(a_{\infty}) \leq \|a'||_{(A_0,A_1)_{\theta,q,J}} C_\theta \|\alpha\|_{\lambda^{\theta,q}}.
\]

Since \( \varepsilon \) is arbitrary, it follows that whenever, \( \alpha \in \lambda^{\theta,q}, \alpha_i \geq 0, \)

\[
\sum_i 2^{-i} K \left( 2^i, a', A'_1, A'_0 \right) \alpha_i \leq \|a'||_{(A_0,A_1)_{\theta,q,J}} C_\theta \|\alpha\|_{\lambda^{\theta,q}}.
\]

By Lemma \ref{lem:41.8.3}, \( \{ K \left( 2^i, a', A'_1, A'_0 \right) \} \in \lambda^{1-\theta,q'} \) and

\[
\|\{ K \left( 2^i, a', A'_1, A'_0 \right) \}\|_{\lambda^{1-\theta,q'}} \leq \|a'||_{(A_0,A_1)_{\theta,q,J}} C_\theta.
\]
Therefore,
\[
\left( \frac{1}{\ln 2} \int_0^\infty \left( K(t, a', A_1', A_0) t^{-(1-\theta)} \right)^{q'} \frac{dt}{t} \right)^{1/q'} = \left( \sum_i \frac{1}{\ln 2} \int_{2^i}^{2^{i+1}} \left( K(t, a', A_1', A_0) t^{-(1-\theta)} \right)^{q'} \frac{dt}{t} \right)^{1/q'} 
\]
\[
\leq \left( \sum_i \left( 2^{-i(1-\theta)} K(2^i, a', A_1', A_0) \right)^{q'} \right)^{1/q'} 
\]
\[
\leq \|a'\|_{(A_0, A_1)^{\theta,q,J}} C_\theta. 
\]

Thus
\[
\|a'\|_{(A_1', A_0)^{1-\theta,q'}} = \left\| t^{-(1-\theta)} K(t, a', A_1', A_0) \right\|_{L^{q'}(0, \infty, \frac{dt}{t})} 
\]
\[
\leq C \|a'\|_{(A_0, A_1)^{\theta,q,J}} 
\]
which shows that \((A_0, A_1)^{\theta,q,J}_{\theta,q,J} \subseteq (A_1', A_0)^{1-\theta,q'}\) with the inclusion map continuous. This proves the lemma.

**Lemma 41.8.5** If \(A_i\) is reflexive for \(i = 0, 1\) and if \(A_0 \cap A_1\) is dense in \(A_i\), then
\[
(A_1', A_0')_{1-\theta,q'} \subseteq (A_0, A_1)^{\theta,q}_{\theta,q,J}
\]
and the inclusion map is continuous.

**Proof:** Let \(a' \in (A_1', A_0')_{1-\theta,q'}\). Thus, there exists \(u^*\) bounded on compact subsets of \((0, \infty)\) and measurable with values in \(A_0 \cap A_1\) and
\[
a' = \int_0^\infty u^* (t) \frac{dt}{t}, \quad (41.8.66)
\]
\[
\int_0^\infty \left( t^{-(1-\theta)} J(t, u^*(t)) \right) \frac{dt}{t} < \infty.
\]
Then
\[
a' = \sum_{i=-\infty}^{\infty} \int_{2^i}^{2^{i+1}} u^* (t) \frac{dt}{t} = \sum_{i=-\infty}^{\infty} a'_i
\]
where \(a'_i \in A_1' \cap A_0'\), the convergence taking place in \(A_1' + A_0'\). Now let \(a \in A_0 \cap A_1\).
From Lemma 41.8.1

\[ |a'(a)| \leq \sum_{i=-\infty}^{\infty} |a'_i(a)| \]

\[ \leq \sum_{i=-\infty}^{\infty} J(2^{-i}, a'_i, A'_0, A'_1) K(2^i, a, A_0, A_1) \]

\[ = \sum_{i=-\infty}^{\infty} 2^{-i} J(2^i, a'_i, A'_0, A'_1) K(2^i, a, A_0, A_1) \]

\[ \leq \left( \sum_i \left( 2^{-(1-\theta)i} J(2^i, a'_i, A'_1, A'_0) \right)^q \right)^{1/q'} \cdot \left( \sum_i \left( 2^{-\theta i} K(2^i, a, A_0, A_1) \right)^q \right)^{1/q}. \]

\[ \leq C \left[ \int_0^\infty \left( t^{(1-\theta)} J(t, u^*(t), A'_1, A'_0) \right)^{q'} \frac{dt}{t} \right]^{1/q'} \cdot \left[ \int_0^\infty \left( t^{-\theta} K(t, a, A_0, A_1) \right)^{q} \frac{dt}{t} \right]^{1/q}. \]

In going from the sums to the integrals, express the first sum as a sum of integrals on \([2^i, 2^{i+1})\) and the second sum as a sum of integrals on \([2^{i-1}, 2^i]\).

Taking the infimum over all \(u^*\) representing \(a'\),

\[ |a'(a)| \leq C \|a'\|_{(A'_1, A'_0)_{1-\theta, q'}, J} \|a\|_{\theta, q}. \]

It follows \(a' \in (A_0, A_1)'_{\theta, q}\) and \(\|a'\|_{(A_0, A_1)_{\theta, q}} \leq C \|a'\|_{(A'_1, A'_0)_{1-\theta, q'}, J}\) which proves the lemma.

With these two lemmas the main result follows.

**Theorem 41.8.6** Suppose \(A_0 \cap A_1\) is dense in \(A_i\) and \(A_i\) is reflexive. Then

\[ (A'_1, A'_0)_{1-\theta, q'} = (A_0, A_1)'_{\theta, q} \]

and the norms are equivalent.

**Proof:** By Theorem 41.7.6, and the last two lemmas,

\[ (A_0, A_1)'_{\theta, q} = (A_0, A_1)'_{\theta, q,J} \subseteq (A'_1, A'_0)_{1-\theta, q'} \]

\[ = (A'_1, A'_0)_{1-\theta, q', J} \subseteq (A_0, A_1)'_{\theta, q}. \]

This proves the theorem.
Chapter 42

Trace Spaces

42.1 Definition And Basic Theory Of Trace Spaces

Another approach to these sorts of problems is to use trace spaces. This allows the consideration of fractional order Sobolev spaces. In so far as the subject of Sobolev spaces is concerned, I will present this material in a manner which is essentially independent of the previous material on interpolation spaces.

As in the case of interpolation spaces, suppose $A_0$ and $A_1$ are two Banach spaces which are continuously embedded in some topological vector space, $X$.

**Definition 42.1.1** Define a norm on $A_0 + A_1$ as follows.

$$
||a||_{A_0 + A_1} \equiv \inf \{||a_0||_{A_0} + ||a_1||_{A_1} : a_0 + a_1 = a \} \quad (42.1.1)
$$

**Lemma 42.1.2** $A_0 + A_1$ with the norm just described is a Banach space.

**Proof:** This was already explained in the treatment of the $K$ method of interpolation. It is just $K(1,a)$.

**Definition 42.1.3** Take $f'$ in the sense of distributions for any $f \in L^1_{loc}(0, \infty; A_0 + A_1)$ as follows.

$$
f'(\phi) = \int_0^\infty -f(t) \phi'(t) \, dt
$$

whenever $\phi \in C_c^\infty(0, \infty)$. Define a Banach space, $W(A_0, A_1, p, \theta) = W$ where $p \geq 1, \theta \in (0, 1)$. Let

$$
||f||_W \equiv \max \left( ||t^\theta f||_{L^p(0, \infty; \frac{dt}{t}; A_0)} \cdot ||t^\theta f'||_{L^p(0, \infty; \frac{dt}{t}; A_1)} \right) \quad (42.1.2)
$$

and let $W$ consist of $f \in L^1_{loc}(0, \infty; A_0 + A_1)$ such that $||f||_W < \infty$.  

1499
Note that to be in $W$, $f(t) \in A_0$ and $f'(t) \in A_1$.

**Lemma 42.1.4** If $f \in W$, then

$$\text{Trace} (f) \equiv f(0) \equiv \lim_{t \to 0} f(t)$$

exists in $A_0 + A_1$. Also $Z \equiv \{f \in W : f(0) = 0\}$ is a closed subspace of $W$. In addition to this, for every $f \in W$ and $\varepsilon > 0$ there exists a $g \in W$ such that $\|f - g\|_W < \varepsilon$ and $g \in C^\infty (0, \infty; A_0)$ while $g' \in C^\infty (0, \infty; A_1)$.

**Proof:** Let $0 < s < t$. Let $\nu + \frac{1}{p} = \theta$. Then for a generic $g$,

$$\int_0^\infty ||\tau^\nu g(\tau)||^p d\tau = \int_0^\infty ||\tau^{\theta} g(\tau)||^p \frac{d\tau}{\tau}$$

so that $t' f' \in L^p (0, \infty; A_1)$, the measure in this case being usual Lebesgue measure. Then

$$f(t) - f(s) = \int_s^t f'(\tau) d\tau = \int_s^t \tau^{\nu} f'(\tau) \tau^{-\nu} d\tau.$$ 

For $\frac{1}{p} + \frac{1}{p'} = 1$, $\nu p' = (\theta - \frac{1}{p}) p' < 1$ because $\theta < 1 = \frac{1}{p'} + \frac{1}{p}$. Therefore,

$$||f(t) - f(s)||_{A_0 + A_1}$$

$$\leq \int_s^t ||f'(\tau)||_{A_0 + A_1} d\tau$$

$$\leq \int_s^t ||f'(\tau)||_{A_1} d\tau = \int_s^t ||\tau^{\nu} f'(\tau)||_{A_1} \tau^{-\nu} d\tau$$

$$\leq \left( \int_s^t ||\tau^{\nu} f'(\tau)||_{A_1}^p d\tau \right)^{\frac{1}{p}} \left( \int_s^t \tau^{-\nu p'} d\tau \right)^{\frac{1}{p'}}$$

$$\leq ||f||_W \left( t^{1-\nu p'} + s^{1-\nu p'} \right)^{\frac{1}{p'}}$$

(42.1.3)

which converges to 0 as $t \to 0$. This shows that $\lim_{t \to 0} f(t)$ exists in $A_0 + A_1$.

Clearly $Z$ is a subspace. Let $f_n \to f$ in $W$ and suppose $f_n \in Z$. Then since $f \in W$, **[2.1.3]** implies $f$ is continuous. Using **[2.1.3]** and replacing $f$ with $f_n - f_m$ and then taking a limit as $s \to 0$,

$$||f_n(t) - f_m(t)||_{A_0 + A_1} \leq ||f_n - f_m||_W C_\nu t^{1-\nu p'}$$

Taking a subsequence, it can be assumed $f_n(t)$ converges to $f(t)$ a.e. But the above inequality shows that $f_n(t)$ is a Cauchy sequence in $C([0, \beta]; A_0 + A_1)$ for all $\beta < \infty$. Therefore, $f_n(t) \to f(t)$ for all $t$. Also,

$$||f_n(t)||_{A_0 + A_1} \leq C_\nu ||f_n||_W t^{1-\nu p'} \leq K t^{1-\nu p'}$$
for some $K$ depending on $\max \{ \|f_n\| : n \geq 1 \}$ and so

$$\|f(t)\|_{A_0 + A_1} \leq K t^{1-\nu'p}$$

which implies $f(0) = 0$. Thus $Z$ is closed.

Consider the last claim. For a generic $t^\theta g \in L^p \left( 0, \infty, \frac{dt}{t}; A \right),$ changing variables $t = e^\tau,$

$$\int_0^\infty t^\theta_p |g(t)|^p \frac{dt}{t} = \int_{-\infty}^\infty e^{\theta \tau_p} |g(e^\tau)|^p d\tau$$

Let $\bar{g}(\tau) \equiv g(e^\tau).$ Thus $\tau \to e^{\tau \theta_p} \bar{g}(\tau)$ is $L^p(\mathbb{R}; A)$ and $\bar{g} \in L^1_{loc}(\mathbb{R}).$ Now let $\psi_\delta$ be a mollifier and consider

$$e^{\theta \tau_p} \bar{g}_\delta(\tau) \equiv \int_{-\infty}^\infty e^{\theta \sigma_p} \bar{g}(\sigma) \psi_\delta(\tau - \sigma) d\sigma$$

$$= \int_{-\infty}^\infty e^{\theta(\tau - \sigma)} \bar{g}(\tau - \sigma) \psi_\delta(\sigma) d\sigma$$

so that

$$\bar{g}_\delta(\tau) = \int_{-\infty}^\infty e^{-\theta \sigma_p} \bar{g}(\tau - \sigma) \psi_\delta(\sigma) d\sigma$$

$$= \int_{-\infty}^\infty e^{-\theta(\tau - \sigma)} \bar{g}(\sigma) \psi_\delta(\tau - \sigma) d\sigma$$

Thus $\bar{g}_\delta \in C^\infty(\mathbb{R}; A)$ and using Minkowski’s inequality,

$$\left( \int_{-\infty}^\infty \left\| e^{\theta \tau_p} \bar{g}_\delta(\tau) - e^{\theta \tau_p} \bar{g}(\tau) \right\|^p d\tau \right)^{1/p} =$$

$$\left( \int_{-\infty}^\infty \left\| \int_{-\infty}^\infty \left( e^{\theta(\tau - \sigma)} \bar{g}(\tau - \sigma) - e^{\theta \tau_p} \bar{g}(\tau) \right) \psi_\delta(\sigma) d\sigma \right\|^p d\tau \right)^{1/p}$$

$$\leq \int_{-\delta}^\delta \psi_\delta(\sigma) \left( \int_{-\infty}^\infty \left\| e^{\theta(\tau - \sigma)} \bar{g}(\tau - \sigma) - e^{\theta \tau_p} \bar{g}(\tau) \right\|^p d\tau \right)^{1/p} d\sigma$$

$$\leq \varepsilon \int_{-\infty}^\infty \psi_\delta(\sigma) d\sigma = \varepsilon$$

provided $\delta$ is small enough due to continuity of translation in $L^p$. Thus changing variables in $\int_{-\infty}^\infty$, letting $\tau = \ln(t)$ and $g_\delta(t) \equiv \bar{g}_\delta(\ln(t)),$ it follows $g_\delta \in C^\infty(0, \infty; A)$ and this integral equals

$$\left( \int_0^\infty e^{\theta \tau_p} |g_\delta(t) - g(t)|^p \frac{dt}{t} \right)^{1/p}$$

This result applied to $f$ and $f'$ with $A = A_0$ and then $A = A_1$ shows the last claim. This proves the lemma.
**Definition 42.1.5** Let $W$ be a Banach space and let $Z$ be a closed subspace. Then the quotient space, denoted by $W/Z$ consists of the set of equivalence classes $[x]$ where the equivalence relation is defined by $x \sim y$ means $x - y \in Z$. Then $W/Z$ is a vector space if the operations are defined by $\alpha[x] \equiv [\alpha x]$ and $[x] + [y] \equiv [x + y]$ and these vector space operations are well defined. The norm on the quotient space is defined as $\|[x]\| \equiv \inf \{\|x + z\| : z \in Z\}$.

The verification of the algebraic claims made in the above definition is left to the reader. It is routine. What is not as routine is the following lemma. However, it is similar to some topics in the presentation of the $K$ method of interpolation.

**Lemma 42.1.6** Let $W$ be a Banach space and let $Z$ be a closed subspace of $W$. Then $W/Z$ with the norm described above is a Banach space.

**Proof:** That $W/Z$ is a vector space is left to the reader. Why is $\|\cdot\|$ a norm? Suppose $\alpha \neq 0$. Then

\[
\|\alpha[x]\| = \|\alpha x\| = \inf \{\|\alpha x + z\| : z \in Z\} = \inf \{\|\alpha x + \alpha z\| : z \in Z\} = |\alpha| \inf \{\|x + z\| : z \in Z\} = |\alpha| \|x\|.
\]

Now let $\|[x]\| \geq |x + z_1| - \varepsilon$ and let $\|[y]\| \geq |y + z_2| - \varepsilon$ where $z_i \in Z$. Then

\[
\|[x] + [y]\| \equiv \|[x + y]\| \leq |x + y + z_1 + z_2| \\
\leq \|x + z_1\| + \|y + z_2\| \leq \|x\| + \|y\| + 2\varepsilon.
\]

Since $\varepsilon$ is arbitrary, this shows the triangle inequality. Clearly, $\|[x]\| \geq 0$. It remains to show that the only way $\|[x]\| = 0$ is for $x \in Z$. Suppose then that $\|[x]\| = 0$. This means there exist $z_n \in Z$ such that $\|x + z_n\| \to 0$. Therefore, $-x$ is a limit of a sequence of points of $Z$ and since $Z$ is closed, this requires $-x \in Z$ also because $Z$ is a subspace. This shows $\|\cdot\|$ is a norm on $W/Z$. It remains to verify that $W/Z$ is a Banach space.

Suppose $\{[x_n]\}$ is a Cauchy sequence in $W/Z$ and suppose $\|[x_n] - [x_{n+1}]\| < \frac{1}{2^n}$. Let $x'_1 = x_1$. If $x'_n$ has been chosen let $x'_{n+1} = x_{n+1} + z_{n+1}$ where $z_{n+1} \in Z$ be such that

\[
\|[x'_{n+1} - x'_n]\| \leq \|[x_{n+1} - x_n]\| + \frac{1}{2^{n+1}} = \|[x_{n+1}] - [x_n]\| + \frac{1}{2^{n+1}} < \frac{1}{2^n}.
\]

It follows $\{x'_n\}$ is a Cauchy sequence in $W$ and so it must converge to some $x \in W$. Now

\[
\|[x] - [x_n]\| = \|[x - x_n]\| = \|[x - x'_n]\| \leq \|x - x'_n\|
\]

which converges to 0. Now if $\{[x_n]\}$ is just a Cauchy sequence, there exists a subsequence satisfying $\|[x_{n_k}] - [x_{n_{k+1}}]\| < \frac{1}{2^{n_k}}$ and so from the first part, the subsequence converges to some $[x] \in W/Z$ and so the original Cauchy sequence also converges. Therefore, $W/Z$ is a Banach space as claimed.
42.1. DEFINITION AND BASIC THEORY OF TRACE SPACES

**Definition 42.1.7** Define $T(A_0, A_1, p, \theta) = T$, to consist of
\[
\left\{ a \in A_0 + A_1 : a = \lim_{t \to 0^+} f(t) \text{ for some } f \in W(A_0, A_1, p, \theta) \right\},
\]

the limit taking place in $A_0 + A_1$. Let $\gamma f$ be defined for $f \in W$ by $\gamma f \equiv \lim_{t \to 0^+} f(t)$. Thus $T = \gamma (W)$. As above $Z \equiv \{ f \in W : \gamma f = 0 \} = \ker (\gamma)$.

**Lemma 42.1.8** $T$ is a Banach space with norm given by
\[
||a||_T \equiv \inf \{ ||f||_W : f(0) = a \}.
\]

**Proof:** Define a mapping, $\psi : W/Z \to T$ by
\[
\psi([f]) \equiv \gamma f.
\]
Then $\psi$ is one to one and onto. Also
\[
||[f]|| \equiv \inf \{ ||f + g|| : g \in Z \} = \inf \{ ||h||_W : \gamma h = \gamma f \} = ||\gamma (f)||_T.
\]
Therefore, the Banach space, $W/Z$ and $T$ are isometric and so $T$ must be a Banach space since $W/Z$ is.

The following is an important interpolation inequality.

**Theorem 42.1.9** If $a \in T$, then
\[
||a||_T = \inf \left\{ ||t^\theta f||_{L^p(0, \infty, \frac{d}{d\theta}; A_0)} ||t^\theta f'||_{L^p(0, \infty, \frac{d}{d\theta}; A_1)} \right\}
\]
where the infimum is taken over all $f \in W$ such that $a = f(0)$. Also, if $a \in A_0 \cap A_1$, then $a \in T$ and
\[
||a||_T \leq K ||a||_{A_1}^{1-\theta} ||a||_{A_0}^\theta
\]
for some constant $K$. Also
\[
A_0 \cap A_1 \subseteq T(A_0, A_1, p, \theta) \subseteq A_0 + A_1
\]
and the inclusion maps are continuous.

**Proof:** First suppose $f(0) = a$ where $f \in W$. Then letting $f_\lambda(t) \equiv f(\lambda t)$, it follows that $f_\lambda(0) = a$ also and so
\[
||a||_T \leq \max \left( ||t^\theta f_\lambda||_{L^p(0, \infty, \frac{d}{d\theta}; A_0)} , ||t^\theta f_\lambda'||_{L^p(0, \infty, \frac{d}{d\theta}; A_1)} \right)
\]
\[
= \max \left( \lambda^{-\theta} ||t^\theta f||_{L^p(0, \infty, \frac{d}{d\theta}; A_0)} , \lambda^{1-\theta} ||t^\theta f'||_{L^p(0, \infty, \frac{d}{d\theta}; A_1)} \right)
\]
\[
= \max \left( \lambda^{-\theta} R, \lambda^{1-\theta} S \right).
\]
Now choose $\lambda = R/S$ to obtain
\[
||a||_T \leq R^{1-\theta} S^\theta = ||t^\theta f||_{L^p(0, \infty, \frac{d}{d\theta}; A_0)} ||t^\theta f'||_{L^p(0, \infty, \frac{d}{d\theta}; A_1)}.
\]
Thus
\[ ||a||_T \leq \inf \left\{ ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)}^\theta \left\| t^\theta f \right\|_{L^p(0, \infty; \mathbb{A}_1)}^\theta \right\}. \]

Next choose \( f \in W \) such that \( f(0) = a \) and \( ||f||_W \approx ||a||_T \). More precisely, pick \( f \in W \) such that \( f(0) = a \) and \( ||a||_T > -\varepsilon + ||f||_W \). Also let
\[ R = \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)} \right\|, \quad S = \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_1)} \right\|. \]

Then as before,
\[ \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)} \right\| = \lambda^{-\theta}R, \quad \left\| ||t^\theta (f \lambda)'||_{L^p(0, \infty; \mathbb{A}_0)} \right\| = \lambda^{1-\theta}S. \] (42.1.9)
so that \( ||f||_W = \max (R, S) \). Then, changing the variables, letting \( \lambda = R/S \),
\[ \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)} \right\| = \left\| ||t^\theta (f \lambda)'||_{L^p(0, \infty; \mathbb{A}_0)} \right\| = R^{1-\theta} S^\theta \] (42.1.10)

Since \( f_\lambda(0) = a, f_\lambda \in W \), and it is always the case that for positive \( R, S, R^{1-\theta} S^\theta \leq \max (R, S) \), this shows that
\[ ||a||_T \leq \max \left( \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)} \right\|, \left\| ||t^\theta (f \lambda)'||_{L^p(0, \infty; \mathbb{A}_0)} \right\| \right) \]
\[ = R^{1-\theta} S^\theta \leq \max (R, S) = ||f||_W < ||a||_T + \varepsilon, \]
the first inequality holding because \( ||a||_T \) is the infimum of such things on the right.

This shows \( \text{(42.1.4)} \).

It remains to verify \( \text{(42.1.5)} \). To do this, let \( \psi \in C^\infty ([0, \infty)) \), with \( \psi(0) = 1 \) and \( \psi(t) = 0 \) for all \( t > 1 \). Then consider the special \( f \in W \) which is given by \( f(t) = a \psi(t) \) where \( a \in \mathbb{A}_0 \cap \mathbb{A}_1 \). Thus \( f \in W \) and \( f(0) = a \) so \( a \in T (\mathbb{A}_0, \mathbb{A}_1, \rho, \theta) \).

From the first part, there exists a constant, \( K \) such that
\[ ||a||_T \leq \left\| ||t^\theta f||_{L^p(0, \infty; \mathbb{A}_0)} \right\| + \left\| ||t^\theta (f \lambda)'||_{L^p(0, \infty; \mathbb{A}_0)} \right\| \]
\[ \leq K \left( ||a||_{\mathbb{A}_0} + \theta ||a||_{\mathbb{A}_1} \right). \]
This shows \( \text{(42.1.5)} \) and the first inclusion in \( \text{(42.1.7)} \). From the inequality just obtained,
\[ ||a||_T \leq K \left( (1 - \theta) ||a||_{\mathbb{A}_0} + \theta ||a||_{\mathbb{A}_1} \right) \]
\[ \leq K ||a||_{\mathbb{A}_0 \cap \mathbb{A}_1} \cdot \]

This shows the first inclusion map of \( \text{(42.1.7)} \) is continuous.

Now take \( a \in T \). Let \( f \in W \) be such that \( a = f(0) \) and
\[ ||a||_T + \varepsilon > ||f||_W \geq ||a||_T. \]
By \( \text{(42.1.6)} \),
\[ ||a - f(t)||_{\mathbb{A}_0 + \mathbb{A}_1} \leq C_\rho t^{1-\nu'} ||f||_W \]
where \( \frac{1}{p} + \nu = \theta \), and so

\[
||a||_{A_0 + A_1} \leq ||f(t)||_{A_0 + A_1} + C_{\nu} t^{1-\nu p'} ||f||_W.
\]

Now \( ||f(t)||_{A_0 + A_1} \leq ||f(t)||_{A_0} \cdot \)

\[
||a||_{A_0 + A_1} \leq t^\nu ||f(t)||_{A_0 + A_1} t^{-\nu} + C_{\nu} t^{1-\nu p'} ||f||_W
\]

\[
\leq C_{\nu} t^{1-\nu p'} ||f||_W.
\]

Therefore, recalling that \( \nu p' < 1 \), and integrating both sides from 0 to 1,

\[
||a||_{A_0 + A_1} \leq C_{\nu} ||f||_W \leq C_{\nu} (||a||_T + \varepsilon).
\]

To see this,

\[
\int_0^1 t^\nu ||f(t)||_{A_0} t^{-\nu} dt \leq \left( \int_0^1 (t^\nu ||f(t)||_{A_0})^p dt \right)^{1/p} \left( \int_0^1 t^{-\nu p'} dt \right)^{1/p'}
\]

\[
\leq C ||f||_W.
\]

Since \( \varepsilon > 0 \) is arbitrary, this verifies the second inclusion and continuity of the inclusion map completing the proof of the theorem.

The interpolation inequality is very significant. The next result concerns bounded linear transformations.

**Theorem 42.1.10** Now suppose \( A_0, A_1 \) and \( B_0, B_1 \) are pairs of Banach spaces such that \( A_i \) embeds continuously into a topological vector space, \( X \) and \( B_i \) embeds continuously into a topological vector space, \( Y \). Suppose also that \( L \in \mathcal{L}(A_0, B_0) \) and \( L \in \mathcal{L}(A_1, B_1) \) where the operator norm of \( L \) in these spaces is \( K_i, i = 0, 1 \). Then

\[
L \in \mathcal{L}(A_0 + A_1, B_0 + B_1) \tag{42.1.11}
\]

with

\[
||La||_{B_0 + B_1} \leq \max (K_0, K_1) ||a||_{A_0 + A_1} \tag{42.1.12}
\]

and

\[
L \in \mathcal{L}(T(A_0, A_1, p, \theta), T(B_0, B_1, p, \theta)) \tag{42.1.13}
\]

and for \( K \) the operator norm,

\[
K \leq K_0^1 - \theta K_1^\theta. \tag{42.1.14}
\]

**Proof:** To verify let \( a \in A_0 + A_1 \) and pick \( a_0 \in A_0 \) and \( a_1 \in A_1 \) such that

\[
||a||_{A_0 + A_1} + \varepsilon > ||a_0||_{A_0} + ||a_1||_{A_1}.
\]

Then

\[
||L(a)||_{B_0 + B_1} = ||La_0 + La_1||_{B_0 + B_1} \leq ||La_0||_{B_0} + ||La_1||_{B_1}
\]
\[ \leq K_0 \|a_0\|_{A_0} + K_1 \|a_1\|_{A_1} \leq \max(K_0, K_1) \left( \|a\|_{A_0+A_1} + \varepsilon \right). \]

This establishes (42.1.12). Now consider the other assertions.

Let \( a \in T(A_0, A_1, p, \theta) \) and pick \( f \in W(A_0, A_1, p, \theta) \) such that \( \gamma f = a \) and

\[ \|a\|_{T(A_0, A_1, p, \theta)} + \varepsilon > \|\sigma^\theta f\|_{L^p(0, \infty, \phi, A_0)} \|\sigma^\theta f'\|_{L^p(0, \infty, \phi, A_1)}^\theta. \]

Then consider \( Lf \). Since \( L \) is continuous on \( A_0 + A_1 \),

\[ Lf(0) = La \]

and \( Lf \in W(B_0, B_1, p, \theta) \). Therefore, by Theorem (42.1.13),

\[ \|La\|_{T(B_0, B_1, p, \theta)} \leq \|\sigma^\theta Lf\|_{L^p(0, \infty, \phi, B_0)} \|\sigma^\theta Lf'\|_{L^p(0, \infty, \phi, B_1)}^\theta \]
\[ \leq K_0^{1-\theta} K_1^\theta \|\sigma^\theta f\|_{L^p(0, \infty, \phi, A_0)} \|\sigma^\theta f'\|_{L^p(0, \infty, \phi, A_1)}^\theta \]
\[ \leq K_0^{1-\theta} K_1^\theta \left( \|a\|_{T(A_0, A_1, p, \theta)} + \varepsilon \right). \]

and since \( \varepsilon > 0 \) is arbitrary, this proves the theorem.

### 42.2 Trace And Interpolation Spaces

Trace spaces are equivalent to interpolation spaces. In showing this, a more general sort of trace space than that presented earlier will be used.

**Definition 42.2.1** Define for \( m \) a positive integer, \( V^m = V^m(A_0, A_1, p, \theta) \) to be the set of functions, \( u \) such that

\[ t \to t^\theta u(t) \in L^p \left( 0, \infty, \frac{dt}{t}; A_0 \right) \]

and

\[ t \to t^\theta + m - 1 u^{(m)}(t) \in L^p \left( 0, \infty, \frac{dt}{t}; A_1 \right). \]

\( V^m \) is a Banach space with the norm

\[ \|u\|_{V^m} \equiv \max \left( \|t^\theta u(t)\|_{L^p(0, \infty, \phi; A_0)}, \|t^\theta + m - 1 u^{(m)}(t)\|_{L^p(0, \infty, \phi; A_1)} \right). \]

Thus \( V^m \) equals \( W \) in the case when \( m = 1 \). More generally, as in \( \mathbb{R}^2 \) different exponents are used for the two \( L^p \) spaces, \( p_0 \) in place of \( p \) for the space corresponding to \( A_0 \) and \( p_1 \) in place of \( p \) for the space corresponding to \( A_1 \).

**Definition 42.2.2** Denote by \( T^m(A_0, A_1, p, \theta) \) the set of all \( a \in A_0 + A_1 \) such that for some \( u \in V^m \),

\[ a = \lim_{t \to 0+} u(t) \equiv \text{trace}(u), \]

the limit holding in \( A_0 + A_1 \). For the norm

\[ \|a\|_{T^m} \equiv \inf \{ \|u\|_{V^m} : \text{trace}(u) = a \}. \]
The case when \( m = 1 \) was discussed in Section 42.1. Note it is not known at this point whether \( \lim_{t \to 0^+} u(t) \) even exists for every \( u \in V^m \). Of course, if \( m = 1 \) this was shown earlier but it has not been shown for \( m > 1 \). The following theorem is absolutely amazing. Note the lack of dependence on \( m \) of the right side!

**Theorem 42.2.3** The following hold.

\[
T^m (A_0, A_1, p, \theta) = (A_0, A_1)_{\theta, p, J} = (A_0, A_1)_{\theta, p}.
\] (42.2.19)

**Proof:** It is enough to show the first equality because of Theorem [12.7.5] which identifies \( (A_0, A_1)_{\theta, p, J} \) and \( (A_0, A_1)_{\theta, p} \). Let \( a \in T^m \). Then there exists \( u \in V^m \) such that

\[
a = \lim_{t \to 0^+} u(t) \text{ in } A_0 + A_1.
\]

The first task is to modify this \( u(t) \) to get a better one which is more usable in order to show \( a \in (A_0, A_1)_{\theta, p, J} \). Remember, it is required to find \( w(t) \in A_0 \cap A_1 \) for all \( t \in (0, \infty) \) and \( a = \int_0^\infty w(t) \frac{dt}{t} \), a representation which is not known at this time. To get such a thing, let

\[
\phi \in C_c^\infty (0, \infty), \text{spt} (\phi) \subseteq [\alpha, \beta]
\] (42.2.20)

with \( \phi \geq 0 \) and

\[
\int_0^\infty \phi(t) \frac{dt}{t} = 1.
\] (42.2.21)

Then define

\[
\bar{u}(t) = \int_0^\infty \phi\left( \frac{t}{\tau} \right) u(\tau) \frac{d\tau}{\tau} = \int_0^\infty \phi(s) u\left( \frac{t}{s} \right) \frac{ds}{s}.
\] (42.2.22)

**Claim:** \( \lim_{t \to 0^+} \bar{u}(t) = a \) and \( \lim_{t \to \infty} \bar{u}^{(k)}(t) = 0 \) in \( A_0 + A_1 \) for all \( k \leq m \).

**Proof of the claim:** From (42.2.22) and (42.2.21) it follows that for \( ||\cdot|| \) referring to \( ||\cdot||_{A_0 + A_1} \),

\[
||\bar{u}(t) - a|| \leq \int_0^\infty \left| u\left( \frac{t}{s} \right) - a \right| \phi(s) \frac{ds}{s}
\]

\[
= \int_0^\infty ||u(\tau) - a|| \phi\left( \frac{t}{\tau} \right) \frac{d\tau}{\tau}
\]

\[
= \int_{t/\beta}^{t/\alpha} ||u(\tau) - a|| \phi\left( \frac{t}{\tau} \right) \frac{d\tau}{\tau}
\]

\[
\leq \int_{t/\beta}^{t/\alpha} \varepsilon \phi\left( \frac{t}{\tau} \right) \frac{d\tau}{\tau} = \varepsilon \int_{\alpha}^{\beta} \phi(s) \frac{ds}{s} = \varepsilon
\]

whenever \( t \) is small enough due to the convergence of \( u(t) \) to \( a \) in \( A_0 + A_1 \).

Now consider what occurs when \( t \to \infty \). For \( ||\cdot|| \) referring to the norm in \( A_0 \),

\[
\bar{u}^{(k)}(t) = \int_0^\infty \phi^{(k)}\left( \frac{t}{\tau} \right) \frac{1}{\tau^k} u(\tau) \frac{d\tau}{\tau}
\]
and so
\[ \|\tilde{u}(k)(t)\|_{A_0} \leq C_k \int_{t/\beta}^{t/\alpha} \|u(\tau)\|_{A_0} \frac{d\tau}{\tau} \]
\leq C \left( \int_{t/\beta}^{t/\alpha} \frac{d\tau}{\tau} \right)^{1/p'} \left( \int_{t/\beta}^{t/\alpha} \|u(\tau)\|^p_{A_0} \frac{d\tau}{\tau} \right)^{1/p}.

Now \( \left( \frac{\beta}{\tau} \right)^{\theta \tau} \geq 1 \) for \( \tau \geq t/\beta \) and so the above expression
\[ \leq C \left( \ln \frac{\beta}{\alpha} \right)^{1/p'} \left( \frac{\beta}{\tau} \right)^{\theta} \left( \int_{t/\beta}^{\infty} (\tau^\theta \|u(\tau)\|^p_{A_0})^p \frac{d\tau}{\tau} \right)^{1/p} \]
and so \( \lim_{\tau \to \infty} \|\tilde{u}(k)(t)\|_{A_0} = 0 \) and therefore, this also holds in \( A_0 + A_1 \). This proves the claim.

Thus \( \tilde{u} \) has the same properties as \( u \) in terms of having \( a \) as its trace. \( \tilde{u} \) is used to build the desired \( v \), representing \( a \) as an integral. Define
\[ v(t) = \frac{(-1)^m}{(m-1)!} \tilde{u}^{(m)}(t) = \frac{(-1)^m}{(m-1)!} \int_0^\infty \frac{t^m}{\tau^m} \phi^{(m)}(t) u(\tau) \frac{d\tau}{\tau} \]
\[ = \frac{(-1)^m}{(m-1)!} \int_0^\infty s^m \phi^{(m)}(s) \left( \frac{1}{s} \right) u(\frac{1}{s}) \frac{ds}{s}. \] (42.2.23)

Then from the claim, and integration by parts in the last step,
\[ \int_0^\infty v \left( \frac{1}{t} \right) \frac{dt}{t} = \int_0^\infty v(t) \frac{dt}{t} = \frac{(-1)^m}{(m-1)!} \int_0^\infty t^{m-1} \tilde{u}^{(m)}(t) \ dt = a. \] (42.2.24)

Thus \( v \left( \frac{1}{t} \right) \) represents \( a \) in the way desired for \( (A_0, A_1)_{\delta, p, J} \) if it is also true that \( v \left( \frac{1}{t} \right) \in A_0 \cap A_1 \) and \( t \to t^{-\theta} v \left( \frac{1}{t} \right) \) is in \( L^p \left( 0, \infty, \frac{dt}{\tau}; A_0 \right) \) and \( t \to t^{1-\theta} v \left( \frac{1}{t} \right) \) is in \( L^p \left( 0, \infty, \frac{dt}{\tau}; A_1 \right) \). First consider whether \( v(t) \in A_0 \cap A_1 \). \( v(t) \in A_0 \) for each \( t \) from [42.2.24] and the assumption that \( u \in L^p \left( 0, \infty, \frac{dt}{\tau}; A_0 \right) \). To verify \( v(t) \in A_1 \), integrate by parts in [42.2.24] to obtain
\[ v(t) = \frac{(-1)^m}{(m-1)!} \int_0^\infty \phi^{(m)}(s) \left( s^{m-1} u \left( \frac{t}{s} \right) \right) \frac{ds}{s} \] (42.2.25)
\[ = \frac{1}{(m-1)!} \int_0^\infty \phi(s) \frac{dt^m}{ds^m} \left( s^{m-1} u \left( \frac{t}{s} \right) \right) \frac{ds}{s} \]
\[ = \frac{(-1)^m}{(m-1)!} \int_0^\infty \phi(s) \frac{t^m}{s^{m+1}} u^{(m)} \left( \frac{t}{s} \right) \frac{ds}{s} \in A_1 \]
The last step may look very mysterious. If so, consider the case where $m = 2$.

$$
\phi(s) \left( su \left( \frac{t}{s} \right) \right)^{''} \\
= \phi(s) \left( -\frac{t}{s} u' \left( \frac{t}{s} \right) + u \left( \frac{t}{s} \right) \right)' \\
= \phi(s) \left( \left( -\frac{t}{s} u'' \left( \frac{t}{s} \right) - \frac{t}{s^2} u' \left( \frac{t}{s} \right) \right) + \frac{t}{s^2} u' \left( \frac{t}{s} \right) - \frac{t}{s^2} u' \left( \frac{t}{s} \right) \right) \\
= \phi(s) \frac{t^2}{s^3} u'' \left( \frac{t}{s} \right).
$$

You can see the same pattern will take place for other values of $m$.

Now

$$
\|a\|_{\ell_{p}, J} \leq \left( \int_{0}^{\infty} \left( t^{-\theta} J(t, v \left( \frac{1}{t} \right)) \right)^{p} \frac{dt}{t} \right)^{1/p}
$$

\[
\leq C_{p} \left\{ \int_{0}^{\infty} \left[ \left( t^{-\theta} \| v \left( \frac{1}{t} \|_{A_{0}} \right) \right)^{p} \frac{dt}{t} \right]^{1/p} \\
+ \left( \int_{0}^{\infty} \left( t^{\theta} \| v \left( \frac{1}{t} \|_{A_{1}} \right) \right)^{p} \frac{dt}{t} \right)^{1/p} \right\}. \quad (42.2.26)
\]

The first term equals

$$
\left( \int_{0}^{\infty} \left( t^{-\theta} \| v \left( \frac{1}{t} \|_{A_{0}} \right) \right)^{p} \frac{dt}{t} \right)^{1/p}
$$

\[
= \left( \int_{0}^{\infty} \left( t^{\theta} \| v (t) \|_{A_{0}} \right)^{p} \frac{dt}{t} \right)^{1/p}
\]

\[
= \left( \int_{0}^{\infty} \left( t^{\theta} \left( \int_{0}^{\infty} s^{m} \phi^{(m)} (s) u \left( \frac{t}{s} \right) \frac{ds}{s} \right) \right)^{p} \frac{dt}{t} \right)^{1/p}
\]

\[
\leq \left( \int_{0}^{\infty} \left( t^{\theta} \left( \int_{0}^{\infty} s^{m} \phi^{(m)} (s) u \left( \frac{t}{s} \right) \frac{ds}{s} \right) \right)^{p} \frac{dt}{t} \right)^{1/p} \frac{ds}{s}
\]

\[
\leq \left( \int_{0}^{\infty} s^{m} \phi^{(m)} (s) \left( \int_{0}^{\infty} t^{\theta} \left( \int_{0}^{\infty} \frac{ds}{s} \right)^{p} \frac{dt}{t} \right)^{1/p} \frac{ds}{s} \right)
\]
\[ = \int_0^\infty s^{\theta + m} \phi^{(m)}(s) \frac{ds}{s} \left( \int_0^\infty (\tau^\theta \|u(\tau)\|_{A_0})^p d\tau \right)^{1/p} \]

\[ = C \left( \int_0^\infty (\tau^\theta \|u(\tau)\|_{A_0})^p d\tau \right)^{1/p} \]  

(42.2.27)

The second term equals

\[ \left( \int_0^\infty \left( t^{1-\theta} \left\| v \left( \frac{1}{t} \right) \right\|_{A_1} \right)^p dt \right)^{1/p} \]

\[ = \left( \int_0^\infty \left( \frac{1}{(m-1)!} \int_0^\infty \phi(s) \frac{t^m}{s^m} u^{(m)} \left( \frac{t}{s} \right) \frac{ds}{s} \right)^p dt \right)^{1/p} \]

\[ \leq \int_0^\infty \phi(s) \frac{1}{s^m} \left( \int_0^\infty t^{\theta+m-1} \left\| u^{(m)} \left( \frac{t}{s} \right) \right\|_{A_1} \right)^p \frac{dt}{t} \frac{ds}{s} \]

\[ \leq \int_0^\infty \phi(s) \frac{1}{s^m} \left( \int_0^\infty t^{\theta+m-1} \left\| u^{(m)} (\tau) \right\|_{A_1} \right)^p \frac{d\tau}{\tau} \frac{ds}{s} \]

\[ = C \left( \int_0^\infty (\tau^\theta \|u^{(m)}(\tau)\|_{A_1})^p d\tau \right)^{1/p} . \]  

(42.2.28)

Now from the estimates on the two terms in \[42.2.26\] found in \[42.2.27\] and \[42.2.28\], and the simple estimate,

\[ 2 \max (\alpha, \beta) \geq \alpha + \beta, \]

it follows

\[ \|a\|_{\theta,p,J} \geq \max \left( \left( \int_0^\infty (\tau^\theta \|u(\tau)\|_{A_0})^p d\tau \right)^{1/p} \right) \]  

(42.2.29)

\[ \leq C \max \left( \left( \int_0^\infty (\tau^\theta \|u(\tau)\|_{A_0})^p d\tau \right)^{1/p} \right) \]  

(42.2.30)

\[ \cdot \left( \int_0^\infty (\tau^\theta \|u^{(m)}(\tau)\|_{A_1})^p d\tau \right)^{1/p} \]  

(42.2.31)

which shows that after taking the infimum over all \( u \) whose trace is \( a \), it follows

\[ a \in (A_0, A_1)_{\theta,p,J} \implies \|a\|_{\theta,p,J} \leq C \|a\|_{T^m} \]  

(42.2.32)

Thus \( T^m (A_0, A_1, \theta, p) \subseteq (A_0, A_1)_{\theta,p,J} \).
42.2. TRACE AND INTERPOLATION SPACES

Is \((A_0, A_1)_{\theta, p, J} \subseteq T^m (A_0, A_1, \theta, p)\)? Let \(a \in (A_0, A_1)_{\theta, p, J}\). There exists \(u\) having values in \(A_0 \cap A_1\) and such that
\[
a = \int_0^\infty u(t) \frac{dt}{t} = \int_0^\infty u \left( \frac{1}{t} \right) \frac{dt}{t},
\]
in \(A_0 + A_1\) such that
\[
\int_0^\infty (t^{-\theta} J(t, u(t)))^p \, dt < \infty, \quad \text{where} \quad J(t, a) = \max \left( ||a||_{A_0}, t ||a||_{A_1} \right).
\]

Then let
\[
w(t) = \int_t^\infty \left( 1 - \frac{t}{\tau} \right)^{m-1} u \left( \frac{1}{\tau} \right) \frac{d\tau}{\tau} \tag{42.2.33}
\]
\[
\int_0^{1/t} (1 - st)^{m-1} u(s) \frac{ds}{s} = \int_0^1 (1 - \tau)^{m-1} u \left( \frac{\tau}{t} \right) \frac{d\tau}{\tau}. \tag{42.2.34}
\]

It is routine to verify from (42.2.33) that
\[
w^{(m)}(t) = (m-1)! (-1)^m \frac{u \left( \frac{1}{t} \right)}{t^m}. \tag{42.2.35}
\]

For example, consider the case where \(m = 2\).
\[
\left( \int_t^\infty \left( 1 - \frac{t}{\tau} \right)^{m-1} u \left( \frac{1}{\tau} \right) \frac{d\tau}{\tau} \right)'' = \left( 0 + \int_t^\infty \left( - \frac{1}{\tau} \right) u \left( \frac{1}{\tau} \right) \frac{d\tau}{\tau} \right)'
\]
\[
= \frac{1}{t^2} u \left( \frac{1}{t} \right).
\]

Also from (42.2.33), it follows that \(\text{trace} (w) = a\). It remains to verify \(w \in V^m\).

From (42.2.35)
\[
\left( \int_0^\infty \left( t^{\theta - 1} \frac{\left( t^{m+1} \right)^p}{||w^{(m)}(t)||_{A_1}} \right) \frac{dt}{t} \right)^{1/p} =
\]
\[
C_m \left( \int_0^\infty \left( t^{\theta - 1} \frac{\left( t^{m+1} \right)^p}{||w^{(m)}(t)||_{A_1}} \right) \frac{dt}{t} \right)^{1/p} = C_m \left( \int_0^\infty \left( t^{\theta - 1} ||u(t)||_{A_1} \right)^p \frac{dt}{t} \right)^{1/p}
\]
\[
\leq C_m \left( \int_0^\infty \left( t^{\theta - 1} J(t, u(t)) \frac{dt}{t} \right)^{1/p} < \infty. \tag{42.2.36}
\]

It remains to consider \(\left( \int_0^\infty \left( t^{\theta - 1} ||u(t)||_{A_1} \right)^p \frac{dt}{t} \right)^{1/p} \). From (42.2.33)
\[
\left( \int_0^\infty \left( t^{\theta - 1} ||u(t)||_{A_1} \right)^p \frac{dt}{t} \right)^{1/p} =
\]
\[
\left( \int_0^\infty \left( t^{\theta - 1} \frac{\left( t^{m+1} \right)^p}{||w^{(m)}(t)||_{A_1}} \right) \frac{dt}{t} \right)^{1/p}
\]
\[
= \left( \int_0^\infty \left( t^{\theta - 1} \frac{\left( t^{m+1} \right)^p}{||w^{(m)}(t)||_{A_1}} \right) \frac{dt}{t} \right)^{1/p}
\]
It follows that
\[
\|w\|_{V_m} = \max \left( \left( \int_0^\infty \left( t^{-\theta} \|w(t)\|_{A_0} \right)^p \frac{dt}{t} \right)^{1/p}, \left( \int_0^\infty \left( t^{-\theta} \|w(t)^{(m)}\|_{A_1} \right)^p \frac{dt}{t} \right)^{1/p} \right)
\]
\[
\leq C \left( \int_0^\infty \left( s^{-\theta} \|u(s)\|_{A_0} \right)^p \frac{ds}{s} \right)^{1/p}
\]
\[
\leq C \left( \int_0^\infty \left( t^{-\theta} J(t, u(t)) \right)^p \frac{dt}{t} \right)^{1/p} < \infty.
\] (42.2.37)

This together with 42.2.32 proves the theorem.

By Theorem 42.2.3 and Theorem 41.8.6, we obtain the following important corollary describing the dual space of a trace space.

**Corollary 42.2.4** Let \( A_0 \cap A_1 \) be dense in \( A_i \) for \( i = 0, 1 \) and suppose that \( A_i \) is reflexive for \( i = 0, 1 \). Then for \( \infty > p \geq 1 \),

\[
T^m (A_0, A_1, \theta, p) = T^m (A_1', A_0', 1 - \theta, p')
\]
Chapter 43

Traces Of Sobolev Spaces And Fractional Order Spaces

43.1 Traces Of Sobolev Spaces On The Boundary Of A Half Space

In this section consider the trace of $W^{m,p}(\mathbb{R}^n_+)$ onto a Sobolev space of functions defined on $\mathbb{R}^{n-1}$. This latter Sobolev space will be defined in terms of the following theory in such a way that the trace map is continuous. The trace map is continuous as a map from $W^{m,p}(\mathbb{R}^n_+)$ to $W^{m-1,p}(\mathbb{R}^{n-1})$ but here I will give a better conclusion using the above theory.

**Definition 43.1.1** Let $\theta \in (0,1)$ and let $\Omega$ be an open subset of $\mathbb{R}^m$. We define

$$W^{\theta,p}(\Omega) \equiv T(\Omega \oplus \mathbb{R}^{n-1}, p, 1-\theta).$$

Thus, from the above general theory, $W^{1,p}(\Omega) \hookrightarrow W^{\theta,p}(\Omega) \hookrightarrow L^p(\Omega) = L^p(\Omega) + W^{1,p}(\Omega)$. Now we consider the trace map for Sobolev space.

**Lemma 43.1.2** Let $\phi \in C^\infty(\mathbb{R}^n_+)$. Then $\gamma \phi(x') \equiv \phi(x',0)$. Then $\gamma : C^\infty(\mathbb{R}^n_+) \rightarrow L^p(\mathbb{R}^{n-1})$ is continuous as a map from $W^{1,p}(\mathbb{R}^n_+)$ to $L^p(\mathbb{R}^{n-1})$.

**Proof:** We know

$$\phi(x',x_n) = \gamma \phi(x') + \int_0^{x_n} \frac{\partial \phi(x',t)}{\partial t} \, dt$$

1513
Then by Jensen’s inequality,
\[
\int_{\mathbb{R}^{n-1}} |\gamma \phi (x')|^p dx'
= \int_0^1 \int_{\mathbb{R}^{n-1}} |\gamma \phi (x')|^p dx' dx_n
\leq C \int_0^1 \int_{\mathbb{R}^{n-1}} |\phi (x',x_n)|^p dx' dx_n
+ C \int_0^1 \int_{\mathbb{R}^{n-1}} \left| \int_0^x \frac{\partial \phi (x',t)}{\partial t} dt \right|^p dx' dx_n
\leq C \|\phi\|_{0,p,\mathbb{R}^n_+}^p + C \int_0^1 x_n^{p-1} \int_{\mathbb{R}^{n-1}} \left| \int_0^x \frac{\partial \phi (x',t)}{\partial t} dt \right|^p dx' dx_n
\leq C \|\phi\|_{0,p,\mathbb{R}^n_+}^p + C \int_0^1 x_n^{p-1} \int_{\mathbb{R}^{n-1}} \left| \int_0^\infty \frac{\partial \phi (x',t)}{\partial t} dt \right|^p dx' dx_n
\leq C \|\phi\|_{0,p,\mathbb{R}^n_+}^p + C \|\phi\|_{1,p,\mathbb{R}^n_+}^p + C \frac{1}{p} \int_{\mathbb{R}^{n-1}} \int_0^\infty \left| \frac{\partial \phi (x',t)}{\partial t} \right|^p dt dx'
\leq C \|\phi\|_{1,p,\mathbb{R}^n_+}^p.
\]
This proves the lemma.

**Definition 43.1.3** We define the trace, \( \gamma : W^{1,p} (\mathbb{R}^n_+) \to L^p (\mathbb{R}^{n-1}) \) as follows. \( \gamma \phi (x') = \phi (x',0) \) whenever \( \phi \in C^\infty (\mathbb{R}^n_+) \). For \( u \in W^{1,p} (\mathbb{R}^n_+) \), we define \( \gamma u \equiv \lim_{k \to \infty} \gamma \phi_k \) in \( L^p (\mathbb{R}^{n-1}) \) where \( \phi_k \to u \) in \( W^{1,p} (\mathbb{R}^n_+) \). Then the above lemma shows this is well defined.

Also from this lemma we obtain a constant, \( C \) such that
\[
\|\phi\|_{0,p,\mathbb{R}^n_+} \leq C \|\phi\|_{1,p,\mathbb{R}^n_+}
\]
and the same constant holds for all \( u \in W^{1,p} (\mathbb{R}^n_+) \).

From the definition of the norm in the trace space, if \( f \in C^\infty (\mathbb{R}^n_+) \), and letting \( \theta = 1 - \frac{1}{p} \), it follows from the definition
\[
\|f\|_{1-\frac{1}{p},p,\mathbb{R}^n_+}
\leq \max \left( \left( \int_0^\infty \left( t^{1/p} \|f (t)\|_{1,p,\mathbb{R}^n_+} \right)^p \frac{dt}{t} \right)^{1/p}, \left( \int_0^\infty \left( t^{1/p} \|f' (t)\|_{0,p,\mathbb{R}^n_+} \right)^p \frac{dt}{t} \right)^{1/p} \right)
\leq C \|f\|_{1,p,\mathbb{R}^n_+}.
\]
Thus, if \( f \in W^{1,p} (\mathbb{R}^n_+) \), define \( \gamma f \in W^{1-\frac{1}{p},p} (\mathbb{R}^{n-1}) \) according to the rule,
\[
\gamma f = \lim_{k \to \infty} \gamma \phi_k.
\]
43.1. TRACES OF SOBOLEV SPACES ON THE BOUNDARY OF A HALF SPACE

where \( \phi_k \to f \) in \( W^{1,p}(\mathbb{R}^n_+) \) and \( \phi_k \in C^\infty(\overline{\mathbb{R}^n_+}) \). This shows the continuity part of the following lemma.

**Lemma 43.1.4** The trace map, \( \gamma \), is a continuous map from \( W^{1,p}(\mathbb{R}^n_+) \) onto 
\[ W^{1-\frac{1}{p},p}(\mathbb{R}^{n-1}). \]

Furthermore, for \( f \in W^{1,p}(\mathbb{R}^n_+) \),
\[ \gamma f = f(0) = \lim_{t \to 0+} f(t) \]
the limit taking place in \( L^p(\mathbb{R}^{n-1}) \).

**Proof:** It remains to verify it is onto along with the displayed equation. But by definition, things in \( W^{1-\frac{1}{p},p}(\mathbb{R}^{n-1}) \) are of the form \( \lim_{t \to 0+} f(t) \) where \( f \in L^p(0,\infty; W^{1,p}(\mathbb{R}^{n-1})) \), and \( f' \in L^p(0,\infty; L^p(\mathbb{R}^{n-1})) \), the limit taking place in 
\[ W^{1,p}(\mathbb{R}^{n-1}) + L^p(\mathbb{R}^{n-1}) = L^p(\mathbb{R}^{n-1}), \]
and
\[ \left( \int_0^\infty ||f(t)||_{1,p,\mathbb{R}^{n-1}}^p dt \right)^{1/p} + \left( \int_0^\infty ||f'(t)||_{0,p}^p dt \right)^{1/p} < \infty. \]
Then taking a measurable representative, we see \( f \in W^{1,p}(\mathbb{R}^n_+) \) and \( f_{x_n} = f' \). Also, as an equation in \( L^p(\mathbb{R}^{n-1}) \), the following holds for all \( t > 0 \).
\[ f(\cdot, t) = f(0) + \int_0^t f_{x_n}(\cdot, s) ds \]
But also, for a.e. \( x' \), the following equation holds for a.e. \( t > 0 \).
\[ f(x', t) = \gamma f(x') + \int_0^t f_{x_n}(x', s) ds, \quad (43.1.1) \]
showing that
\[ \gamma f = f(0) \in W^{1-\frac{1}{p},p}(\mathbb{R}^{n-1}) \equiv T \left( W^{1,p}(\Omega), L^p(\Omega), p, \frac{1}{p} \right). \]

To see that \( (43.1.1) \) holds, approximate \( f \) with a sequence from \( C^\infty(\mathbb{R}^n_+) \) and finally obtain an equation of the form
\[ \int_{\mathbb{R}^{n-1}} \int_0^\infty \left[ f(x', t) - \gamma f(x') - \int_0^t f_{x_n}(x', s) ds \right] \psi(x', t) \, dt \, dx' = 0, \]
which holds for all \( \psi \in C^\infty_c(\mathbb{R}^n_+) \). This proves the lemma.

Thus taking the trace on the boundary loses exactly \( \frac{1}{p} \) derivatives.
43.2 A Right Inverse For The Trace For A Half Space

It is also important to show there is a continuous linear function,

\[ R : W^{1,\frac{1}{2}}(\mathbb{R}^{n-1}) \rightarrow W^{1,\frac{1}{2}}(\mathbb{R}^n_+) \]

which has the property that \( \gamma(Rg) = g \). Define this function as follows.

\[
Rg(x',x_n) \equiv \int_{\mathbb{R}^{n-1}} g(y') \phi \left( \frac{x' - y'}{x_n} \right) \frac{1}{x_n^{n-1}} dy'
\]

(43.2.2)

where \( \phi \) is a mollifier having support in \( B(0,1) \).

**Lemma 43.2.1** Let \( R \) be defined in (43.2.2). Then \( Rg \in W^{1,\frac{1}{2}}(\mathbb{R}^n_+) \) and is a continuous linear map from \( W^{1,\frac{1}{2}}(\mathbb{R}^{n-1}) \) to \( W^{1,\frac{1}{2}}(\mathbb{R}^n_+) \) with the property that \( \gamma Rg = g \).

**Proof:** Let \( f \in W^{1,\frac{1}{2}}(\mathbb{R}^n_+) \) be such that \( \gamma f = g \). Let \( \psi(x_n) \equiv (1-x_n)_+ \) and assume \( f \) is Borel measurable by taking a Borel measurable representative. Then for a.e. \( x' \) we have the following formula holding for a.e. \( x_n \).

\[
Rg(x',x_n) = \int_{\mathbb{R}^{n-1}} \left[ \psi(x_n) f(y', \psi(x_n)) - \int_0^{\psi(x_n)} (\psi f)_{n} (y', t) dt \right] \phi \left( \frac{x' - y'}{x_n} \right) x_n^{1-n} dy'.
\]

Using the repeated index summation convention to save space, we obtain that in terms of weak derivatives,

\[
Rg_n(x',x_n) = \int_{\mathbb{R}^{n-1}} \left[ \psi(x_n) f(y', \psi(x_n)) - \int_0^{\psi(x_n)} (\psi f)_{n} (y', t) dt \right] \cdot \phi \left( \frac{x' - y'}{x_n} \right) \left( \frac{y_k - x_k}{x_n} \right) + \phi \left( \frac{x' - y'}{x_n} \right) \left( \frac{1-n}{x_n} \right) dy'.
\]

\[
= \int_{\mathbb{R}^{n-1}} \left[ \psi(x_n) f(x' - x_n z', \psi(x_n)) - \int_0^{\psi(x_n)} (\psi f)_{n} (x' - x_n z', t) dt \right] \cdot \phi \left( \frac{z'}{x_n} \right) \left( \frac{y_k - x_k}{x_n} \right) + \phi \left( \frac{z'}{x_n} \right) \left( \frac{1-n}{x_n} \right) x_n^{2n} dz'.
\]

and so

\[
|Rg_n(x',x_n)| \leq C(\phi) \int_{B(0,1)} \left| \psi(x_n) f(x' - x_n z', \psi(x_n)) - \int_0^{\psi(x_n)} (\psi f)_{n} (x' - x_n z', t) dt \right|
\]
Therefore, we have shown that whenever $f$

\[ \int_{B(0,x_n)} \left| \psi \left( x_n \right) f \left( x' + y', \psi \left( x_n \right) \right) \right| dy' \]

\[ + \int_{B(0,x_n)} \psi^{(x_n)} \left| \left( \psi f \right)^{,n} \left( x' + y', t \right) \right| dt dy' \]

Therefore,

\[ \left( \int_{R^n} \int_{R^n-1} |Rg_n (x', x_n)|^p dx' dx_n \right)^{1/p} \leq \]

\[ C \left( \int_{R^n} \int_{R^n-1} \left| \frac{1}{x_n^{n-1}} \int_{B(0,x_n)} \left| \psi \left( x_n \right) f \left( x' + y', \psi \left( x_n \right) \right) \right| dy' \right|^{p} dx' dx_n \right)^{1/p} \]

\[ + C \left( \int_{R^n} \int_{R^n-1} \left| \frac{1}{x_n^{n-1}} \int_{B(0,x_n)} \int_{0}^{\psi(x_n)} \left| \left( \psi f \right)^{,n} \left( x' + y', t \right) \right| dt dy' \right|^{p} dx' dx_n \right)^{1/p} \]

Consider the first term on the right. We change variables, letting $y' = z' x_n$. Then this term becomes

\[ C \left( \int_{0}^{1} \int_{R^n-1} \left| \psi \left( x_n \right) f \left( x' + z_n x_n \psi \left( x_n \right) \right) \right| dz' \right|^{p} dx' dx_n \right)^{1/p} \]

\[ \leq C \left( \int_{B(0,1)} \int_{0}^{1} \left| \psi \left( x_n \right) f \left( x' + z_n x_n \psi \left( x_n \right) \right) \right|^{p} dx' dx_n \right)^{1/p} \]

Now we change variables, letting $t = \psi \left( x_n \right)$. This yields

\[ = C \left( \int_{B(0,1)} \int_{0}^{1} \left| t \psi \left( x' + z_n x_n \psi \left( x_n \right) \right) \right|^{p} dx' dt \right)^{1/p} \]

\[ dz' \leq C \left( \phi \right) \left| f \right|_{1,p,R^n_+}. \]

Now we consider the second term on the right in \ref{43.2.3}. Using the same arguments which were used on the first term involving Minkowski’s inequality and changing the variables, we obtain the second term

\[ \leq C \left( \phi \right) \left| f \right|_{1,p,R^n_+}. \]

\[ (43.2.4) \]

It is somewhat easier to verify that

\[ \left| Rg \right|_{0,p,R^n_+} \leq C \left( \phi \right) \left| f \right|_{1,p,R^n_+}. \]

Therefore, we have shown that whenever $\gamma f = f \left( 0 \right) = g$,

\[ \left| Rg \right|_{1,p,R^n_+} \leq C \left( \phi \right) \left| f \right|_{1,p,R^n_+}. \]
Taking the infimum over all such \( f \) and using the definition of the norm in 
\[
W^{1 - \frac{1}{p}, \frac{1}{p}}(\mathbb{R}^{n-1}),
\]
it follows
\[
\|Rg\|_{1, p, \mathbb{R}^{n+}} \leq C(\phi) \|g\|_{1 - \frac{1}{p}, p, \mathbb{R}^{n-1}},
\]
showing that this map, \( R \), is continuous as claimed. It is obvious that
\[
\lim_{x_n \to 0} Rg(x_n) = g,
\]
the convergence taking place in \( L^p(\mathbb{R}^{n-1}) \) because of general results about convolution with mollifiers. This proves the lemma.

### 43.3 Intrinsic Norms

The above presentation is very abstract, involving the trace of a function in 
\[
W(A_0, A_1, p, \theta)
\]
and a norm which was the infimum of norms of functions in \( W \) which have trace equal to the given function. It is very useful to have a description of the norm in these fractional order spaces which is defined in terms of the function itself rather than functions which have the given function as trace. This leads to something called an intrinsic norm. I am following Adams [3].

The following interesting lemma is called Young’s inequality. It holds more generally than stated.

**Lemma 43.3.1** Let \( g = f * h \) where \( f \in L^1(\mathbb{R}), h \in L^p(\mathbb{R}), \) and \( f, h \) are all Borel measurable, \( p \geq 1 \). Then \( g \in L^p(\mathbb{R}) \) and
\[
\|g\|_{L^p(\mathbb{R})} \leq \|f\|_{L^1(\mathbb{R})} \|h\|_{L^p(\mathbb{R})}
\]

**Proof:** First of all it is good to show \( g \) is well defined. Using Minkowski’s inequality
\[
\left( \int \left( \int |h(t-s)f(s)| ds \right)^p dt \right)^{1/p}
\]
\[
\leq \int \left( \int |h(t-s)|^p |f(s)|^p dt \right)^{1/p} ds
\]
\[
= \int |f(s)| \left( \int |h(t-s)|^p dt \right)^{1/p} ds
\]
\[
= \|f\|_{L^1} \|h\|_{L^p}
\]
Therefore, for a.e. \( t \),

\[
\int |h(t - s) f(s)| ds = \int |h(s) f(t - s)| ds < \infty
\]

and so for all such \( t \) the convolution \( f * h(t) \) makes sense. The above also shows

\[
\|g\|_{L^p} = \left( \int \left( \int f(t - s) h(s) ds \right)^p dt \right)^{1/p} \leq \|f\|_{L^1} \|h\|_{L^p}
\]

and this proves the lemma.

The following is a very interesting inequality of Hardy Littlewood and Pólya.

**Lemma 43.3.2** Let \( f \) be a real valued function defined a.e. on \([0, \infty)\) and let \( \alpha \in (-\infty, 1) \) and

\[
g(t) = \frac{1}{t} \int_0^t f(\xi) d\xi
\]

For \( 1 \leq p < \infty \)

\[
\int_0^\infty t^{\alpha p} |g(t)|^p \frac{dt}{t} \leq \frac{1}{(1-\alpha)^p} \int_0^\infty t^{\alpha p} |f(t)|^p \frac{dt}{t}
\]

**Proof:** First it can be assumed the right side of (43.3.7) is finite since otherwise there is nothing to show. Changing the variables letting \( t = e^\tau \), the above inequality takes the form

\[
\int_{-\infty}^\infty e^{\tau p\alpha} |g(e^\tau)|^p d\tau \leq \frac{1}{(1-\alpha)^p} \int_{-\infty}^\infty e^{\tau p\alpha} |f(e^\tau)|^p d\tau
\]

Now from the definition of \( g \) it follows

\[
g(e^\tau) = e^{-\tau} \int_{-\infty}^{e^\tau} f(\xi) d\xi
\]

\[
= e^{-\tau} \int_{-\infty}^0 f(e^\sigma) e^{\sigma} d\sigma
\]

and so the left side equals

\[
\int_{-\infty}^\infty e^{\tau(p\alpha - 1)} \left| \int_{-\infty}^{e^\tau} f(e^\sigma) e^{\sigma} d\sigma \right|^p d\tau
\]

\[
= \int_{-\infty}^\infty \left| \int_{-\infty}^{\tau} e^{\sigma f(e^\sigma) e^{-\sigma} d\sigma} \right|^p d\tau
\]

\[
= \int_{-\infty}^\infty \left| \int_{-\infty}^{\tau} e^{(\tau - \sigma) \alpha} e^{-\sigma} f(e^\sigma) d\sigma \right|^p d\tau
\]
\[
\int_{-\infty}^{\infty} \left| \int_{-\infty}^{\infty} X_{(-\infty,0)} (\tau - \sigma) e^{(\tau - \sigma)(\alpha - 1)} e^{\sigma \alpha} f (e^\sigma) \, d\sigma \right|^p \, d\tau
\]

and by Lemma 43.3.1,
\[
\leq \left( \int_{-\infty}^{0} e^{(\alpha - 1)u} \, du \right)^p \int_{-\infty}^{\infty} e^{\sigma \alpha} \left| f (e^\sigma) \right|^p \, d\sigma
\]
\[
= \left( \frac{1}{1 - \alpha} \right)^p \int_{-\infty}^{\infty} e^{\sigma \alpha} \left| f (e^\sigma) \right|^p \, d\sigma
\]

which was to be shown. This proves the lemma.

Next consider the case where \( G (t), t > 0 \) is a continuous semigroup on \( A_1 \) and \( A_0 \equiv D (\Lambda) \) where \( \Lambda \) is the generator of this semigroup. Recall that from Proposition 43.4.7 on Page 1520, \( A_0 \) is a closed densely defined operator and so \( A_0 \) is a Banach space if the norm is given by
\[
\| u \|_{A_0} \equiv \| u \|_{A_1} + \| \Lambda u \|_{A_1}
\]

Also assume \( \| G (t) \| \) is uniformly bounded for \( t \in [0, \infty) \). I have in mind the case where \( A_1 = L^p (\mathbb{R}^n) \) and \( G (t) u (x) = u (x + te_i) \) but it is notationally easier to discuss this in the general case. First here is a simple lemma.

**Lemma 43.3.3** Let \( A_0 = D (\Lambda) \) as just described. Then for \( u \in A_1 \)
\[
\| u \|_{A_1 + A_0} = \| u \|_{A_1}
\]

**Proof:** \( D (\Lambda) \subseteq A_1 \). Now let \( u \in A_1 \).
\[
\| u \|_{A_0 + A_1} \equiv \inf \left\{ \| u_0 \|_{A_1} + \| \Lambda u_0 \|_{A_1} + \| u_1 \|_{A_1} : u = u_0 + u_1 \right\}
\]

To make this as small as possible you should clearly take \( u_1 = u \) because
\[
\| u_0 \|_{A_1} + \| \Lambda u_0 \|_{A_1} + \| u_1 \|_{A_1} \geq \| u_0 + u_1 \|_{A_1} + \| \Lambda u_0 \| = \| u \|_{A_1} + \| \Lambda u_0 \|
\]

Therefore, the result of the lemma follows.

**Lemma 43.3.4** Let \( \Lambda \) be the generator of \( G (t) \) and let \( t \to g (t) \) be in \( C^1 (0, \infty; A_1) \). Then there exists a unique solution to the initial value problem
\[
y' - \Lambda y = g, \ y (0) = y_0 \in D (\Lambda)
\]
and it is given by
\[
y (t) = G (t) y_0 + \int_0^t G (t - s) g (s) \, ds. \quad (43.3.8)
\]

This solution is continuous having continuous derivative and has values in \( D (\Lambda) \).
**Proof:** First I show the following claim.

**Claim:** \( \int_0^t G(t - s) g(s) \, ds \in D(\Lambda) \) and

\[
\Lambda \left( \int_0^t G(t - s) g(s) \, ds \right) = G(t) g(0) - g(t) + \int_0^t G(t - s) g'(s) \, ds
\]

**Proof of the claim:**

\[
\frac{1}{h} \left( G(h) \int_0^t G(t - s) g(s) \, ds - \int_0^t G(t - s) g(s) \, ds \right)
\]
\[
= \frac{1}{h} \left( \int_0^{t-h} G(t - s + h) g(s) \, ds - \int_0^t G(t - s) g(s) \, ds \right)
\]
\[
= \frac{1}{h} \left( \int_{t-h}^t G(t - s) g(s + h) \, ds - \int_0^t G(t - s) g(s) \, ds \right)
\]
\[
= \frac{1}{h} \int_{t-h}^t G(t - s) g(s + h) \, ds + \int_0^{t-h} G(t - s) \frac{g(s + h) - g(s)}{h} \, ds
\]
\[
- \frac{1}{h} \int_{t-h}^t G(t - s) g(s) \, ds
\]

Using the estimate in Theorem 72.12.3 on Page 555 and the dominated convergence theorem the limit as \( h \to 0 \) of the above equals

\[
G(t) g(0) - g(t) + \int_0^t G(t - s) g'(s) \, ds
\]

which proves the claim.

Since \( y_0 \in D(\Lambda) \),

\[
G(t) \Lambda y_0 = G(t) \lim_{h \to 0} \frac{G(h) y_0 - y_0}{h}
\]
\[
= \lim_{h \to 0} \frac{G(t + h) - G(t)}{h} y_0
\]
\[
= \lim_{h \to 0} \frac{G(h) G(t) y_0 - G(t) y_0}{h}
\]

Since this limit exists, the last limit in the above exists and equals

\[
\Lambda G(t) y_0
\]

(43.3.10)

and \( G(t) y_0 \in D(\Lambda) \). Now consider \( y(43.3.9) \),

\[
\frac{y(t + h) - y(t)}{h} = \frac{G(t + h) - G(t)}{h} y_0 +
\]
\[
\frac{1}{h} \left( \int_0^{t+h} G(t-s+h)g(s)\,ds - \int_0^t G(t-s)g(s)\,ds \right)
\]
\[=
\frac{G(t+h) - G(t)}{h} y_0 + \frac{1}{h} \left( \int_0^t G(t-s)g(s)\,ds - \int_0^t G(t-s)g(s)\,ds \right)
\]
\[+ \frac{1}{h} \left( G(h) \int_0^t G(t-s)g(s)\,ds - \int_0^t G(t-s)g(s)\,ds \right)
\]

From the claim and \[43.3.9, 43.3.10\] the limit of the right side is
\[
\Lambda G(t) y_0 + g(t) + \Lambda \left( \int_0^t G(t-s)g(s)\,ds \right)
\]
\[=
\Lambda \left( G(t) y_0 + \int_0^t G(t-s)g(s)\,ds \right) + g(t)
\]

Hence
\[
y'(t) = \Lambda y(t) + g(t)
\]
and from the formula, \(y'\) is continuous since by the claim and \[43.3.10\] it also equals
\[
G(t) \Lambda y_0 + g(t) + G(t)g(0) - g(t) + \int_0^t G(t-s)g'(s)\,ds
\]
which is continuous. The claim and \[43.3.10\] also shows \(y(t) \in D(\Lambda)\). This proves the existence part of the lemma.

It remains to prove the uniqueness part. It suffices to show that if
\[
y' - \Lambda y = 0, \ y(0) = 0
\]
and \(y\) is \(C^1\) having values in \(D(\Lambda)\), then \(y = 0\). Suppose then that \(y\) is this way. Letting \(0 < s < t\),
\[
\frac{d}{ds} \left( G(t-s) y(s) \right)
\]
\[=
\lim_{h \to 0} \frac{G(t-s-h) y(s+h) - y(s)}{h}
\]-
\[\frac{G(t-s) y(s) - G(t-s-h) y(s)}{h}
\]
provided the limit exists. Since \(y'\) exists and \(y(s) \in D(\Lambda)\), this equals
\[
G(t-s) y'(s) - G(t-s) \Lambda y(s) = 0.
\]

Let \(y^* \in A_1\). This has shown that on the open interval \((0, t)\) the function \(s \to y^* (G(t-s) y(s))\) has a derivative equal to 0. Also from continuity of \(G\) and \(y\), this function is continuous on \([0, t]\). Therefore, it is constant on \([0, t]\) by the mean value theorem. At \(s = 0\), this function equals 0. Therefore, it equals 0 on \([0, t]\). Thus for fixed \(s > 0\) and letting \(t > s\), \(y^* (G(t-s) y(s)) = 0\). Now let \(t\) decrease toward \(s\). Then \(y^* (y(s)) = 0\) and since \(y^*\) was arbitrary, it follows \(y(s) = 0\). This proves uniqueness.
Definition 43.3.5 Let $G(t)$ be a uniformly bounded continuous semigroup defined on $A_1$ and let $\Lambda$ be its generator. Let the norm on $D(\Lambda)$ be given by

$$||u||_{D(\Lambda)} \equiv ||u||_{A_1} + ||\Lambda u||_{A_1}$$

so that by Lemma 43.3.3 the norm on $A_1 + D(\Lambda)$ is just $||\cdot||_{A_1}$. Let

$$T_0 \equiv \left\{ u \in A_1 : ||u||^p_{A_1} + \int_0^\infty e^{\theta p} \left| \frac{G(t) u - u}{t} \right|^p \frac{dt}{t} \equiv ||u||^p_{T_0} < \infty \right\}$$

Theorem 43.3.6 $T_0 = T(D(\Lambda), A_1, p, \theta) \equiv T$ and the two norms are equivalent.

Proof: Take $u \in T(D(\Lambda), A_1, p, \theta)$. I will show $||u||_{T_0} \leq C(\theta, p) ||u||_T$. By the definition of the norm in $T$, there exists $f \in W(D(\Lambda), A_1, p, \theta)$ such that

$$||u||^p_T + \delta > ||f||^p_W, \quad f(0) = u.$$ 

Now by Lemma 43.3.3 there exists $g_r \in W$ such that $||g_r - f||_W < r$ and $g_r \in C^\infty(0, \infty; D(\Lambda))$ and $g_r' \in C^\infty(0, \infty; A_1)$. Thus for each $\varepsilon > 0, g_r(\varepsilon) \in D(\Lambda)$ although possibly $g_r(0) \notin D(\Lambda)$. Then letting $h_r(t)$ be defined by

$$g_r'(t) - \Lambda g_r(t) = h_r(t)$$

it follows $h_r \in C^1(0, \infty; A_1)$ and applying Lemma 43.3.3 on $[\varepsilon, \infty)$ it follows

$$g_r(t) = G(t - \varepsilon) g_r(\varepsilon) + \int_\varepsilon^t G(t - s) h_r(s) ds.$$  \hspace{1cm} (43.3.11)

By Lemma 43.3.3 again, $g_r(\varepsilon)$ converges to $g_r(0)$ in $A_1$. Thus

$$\int_\varepsilon^t \left| G(t - s) h_r(s) \right|_{A_1} ds \leq C$$

for some constant independent of $\varepsilon$. Thus $s \to G(t - s) h_r(s)$ is in $L^1(0, t; A_1)$ and it is possible to pass to the limit in $43.3.11$ as $\varepsilon \to 0$ to conclude

$$g_r(t) = G(t) g_r(0) + \int_0^t G(t - s) h_r(s) ds$$

Now

$$\frac{G(t) g_r(0) - g_r(0)}{t} = \frac{1}{t} \int_0^t g_r'(s) ds - \frac{1}{t} \int_0^t G(t - s) h_r(s) ds$$

and so using the assumption that $G(t)$ is uniformly bounded,

$$\left| \left| \frac{G(t) g_r(0) - g_r(0)}{t} \right| \right| \leq \frac{1}{t} \int_0^t |g_r'|_{A_1} + M ||h_r||_{A_1}$$
\[ 0 \leq \frac{1}{t} \int_0^t \left| g_r' \right| (M + 1) + M \left| \Delta g_r \right| ds \]
\[ \leq \frac{M + 1}{t} \int_0^t \left| g_r' \right|_{A_1} + \left| g_r \right|_{D(A)} ds \]

Therefore, from Lemma 43.3.2

\[ \int_1^0 t^{p \theta - p} \left| G(t) g_r(0) - g_r(0) \right|_{A_1}^p \frac{dt}{t} \]
\[ = \int_0^\infty t^{p \theta} \left| \frac{G(t) g_r(0) - g_r(0)}{t} \right|_{A_1}^p \frac{dt}{t} \]
\[ \leq \int_0^\infty t^{p \theta} \left| \frac{M + 1}{t} \right| \int_0^t \left| g_r' \right|_{A_1} + \left| g_r \right|_{D(A)} ds \right|^p dt/t \]
\[ \leq (M + 1)^p 2^{p-1} \left( \frac{1}{1 - \theta} \right)^p \int_0^\infty t^{p \theta} \left( \left| g_r' \right|_{A_1}^p + \left| g_r \right|_{D(A)}^p \right) \]

Now since \( g_r \to f \) in \( W \), it follows from Lemma 42.1.8 that \( g_r(0) \to u \) in \( T \) and hence by Theorem 42.1.9 this also in \( A_1 \). Therefore, using Fatou's lemma in the above along with the convergence of \( g_r \) to \( f \),

\[ \int_0^\infty t^{p \theta - p} \left| G(t) u - u \right|_{A_1}^p \frac{dt}{t} \]
\[ \leq (M + 1)^p 2^{p-1} \left( \frac{1}{1 - \theta} \right)^p \int_0^\infty t^{p \theta} \left( \left| f' \right|_{A_1} + \left| f \right|_{D(A)}^p \right) \]
\[ \leq (M + 1)^p 2^{p-1} \left( \frac{1}{1 - \theta} \right)^p \left( \left| u \right|_{T}^p + \delta \right) \]

Since \( u \in T \), Theorem 42.1.9 implies \( u \in A_1 \) and \( \left| u \right|_{A_1} \leq C \left| u \right|_{T} \). Therefore, since \( \delta \) was arbitrary, this has shown that \( u \in T_0 \) and

\[ \left| u \right|_{T_0} \leq C(\theta, p) \left| u \right|_{T} . \]

This shows \( T \subseteq T_0 \) with continuous inclusion.

Now it is necessary to take \( u \in T_0 \) and show it is in \( T \). Since \( u \in T_0 \)

\[ \infty > \left| u \right|_{A_1}^p + \int_0^\infty t^{p \theta} \left| G(t) u - u \right|_{A_1}^p \frac{dt}{t} \]
\[ \equiv \left| u \right|_{T_0}^p \]

Let \( \phi \) be a nonnegative decreasing infinitely differentiable function such that \( \phi(0) = 1 \) and \( \phi(t) = 0 \) for all \( t > 1 \). Then define

\[ f(t) \equiv \phi(t) \frac{1}{t} \int_0^t G(\tau) u \, d\tau . \]
It is easy to see that \( f(t) \in D(\Lambda) \). In fact, changing variables as needed,
\[
\frac{1}{h} \left( G(h) \int_0^t G(\tau) u d\tau - \int_0^t G(\tau) u d\tau \right)
\]
\[
= \frac{1}{h} \int_0^{t+h} G(\tau) u d\tau - \frac{1}{h} \int_0^t G(\tau) u d\tau
\]
\[
= \frac{1}{h} \int_0^{t+h} G(\tau) u d\tau - \frac{1}{h} \int_0^h G(\tau) u d\tau
\]
which converges to \( G(t) u - u \) and so
\[
\Lambda \int_0^t G(\tau) u d\tau = G(t) u - u. \tag{43.3.12}
\]
Thus
\[
\int_0^\infty t^{p\theta} \|A f\|_{A_1}^p \frac{dt}{t} \leq \int_0^\infty t^{p\theta} \left\| G(t) u - u \right\|_{A_1}^p \frac{dt}{t} \leq \|u\|_{T_0}^p.
\]
Next it is necessary to consider
\[
\int_0^\infty t^{p\theta} \|f'\|_{A_1}^p \frac{dt}{t}.
\]
\[
f'(t) = \phi'(t) \frac{1}{t} \int_0^t G(\tau) u d\tau + \phi(t) \left( -\frac{1}{t^2} \int_0^t G(\tau) u d\tau + \frac{1}{t} G(t) u \right)
\]
\[
= \phi'(t) \frac{1}{t} \int_0^t G(\tau) u d\tau + \phi(t) \left( \frac{1}{t^2} \int_0^t (G(t) u - G(\tau) u) d\tau \right)
\]
and so there is a constant \( C \) depending on \( \phi \) and the uniform bound on \( \|G(t)\| \) such that
\[
\|f'(t)\|_{A_1} \leq C \chi_{[0,1]}(t) \left( ||u||_{A_1} + \frac{1}{t^2} \int_0^t ||G(t - \tau) u - u|| d\tau \right)
\]
\[
= C \chi_{[0,1]}(t) \left( ||u||_{A_1} + \frac{1}{t^2} \int_0^t ||G(\tau) u - u|| d\tau \right)
\]
Now
\[
\int_0^\infty \chi_{[0,1]}(t) t^{p\theta} \|u\|_{A_1}^p \frac{dt}{t} \leq C (p, \theta) \|u\|_{T_0}^p.
\]
and using Lemma 43.3.2,

\[ \int_0^\infty \mathcal{X}_{[0,1]}(t) \left| \frac{1}{t^2} \int_0^t |G(\tau) u - u| \, d\tau \right|^p \frac{dt}{t^\theta} \]

\[ \leq \int_0^\infty \frac{1}{t} \int_0^t |G(\tau) u - u| \, d\tau \left| \frac{dt}{t^{\theta(\theta-1)}} \right|^p \]

\[ \leq \frac{1}{(1-(\theta-1))^{\theta}} \int_0^\infty |G(\tau) u - u|^{p(\theta-1)} \frac{dt}{t} \]

\[ = \frac{1}{(2-\theta)^p} \int_0^\infty \left| \frac{G(\tau) u - u}{t} \right|^{p \theta} \frac{dt}{t} \leq C(\theta, p) \|u\|_{T_0}^p \]

This proves the theorem.

Of course the case of most interest here is where \( A_1 = L^p(\mathbb{R}^n) \) and

\[ G(t) u(x) \equiv u(x + te_i) \]

Thus \( \Lambda u = \partial u/\partial x_i \), the weak derivative. The trace space \( T(D(A), L^p(\mathbb{R}^n), p, 1-\theta) \)
then is a space of functions in \( L^p(\mathbb{R}^n) \) which have a fractional order partial derivative with respect to \( x_i \).

Recall from Definition 43.1.1 that for \( \theta \in (0, 1) \),

\[ W^{\theta,p}(\mathbb{R}^n) \equiv T\left(W^{1,p}(\mathbb{R}^n), L^p(\mathbb{R}^n), p, 1-\theta\right) \]

Let \( f \in W\left(W^{1,p}(\mathbb{R}^n), L^p(\mathbb{R}^n), p, 1-\theta\right) \). Then

\[ \|f\|_W = \max \left( \int_0^\infty t^{(1-\theta)p} \left| f(t) \right|^p dt \right) \left( \int_0^\infty t^{(1-\theta)p} \left| f'(t) \right|^p dt \right)^{1/p} \]

Letting \( G_i(t) u(x) \equiv u(x + te_i) \) and \( \Lambda_i \) its generator,

\[ W^{1,p}(\Omega) = \cap_i^n DA_i \cap L^p(\mathbb{R}^n) \]

with the norm given by

\[ \|u\|^p = \|u\|_{L^p}^p + \sum_{i=1}^n \|\Lambda_i u\|_{L^p}^p \]

which is equivalent to the norm

\[ \|u\|^p = \sum_{i=1}^n \|u\|_{L^p(\Lambda_i)}^p \cdot \]

Then by considering each of the \( G_i \) and repeating the above argument in Theorem 43.3.10, it follows an equivalent intrinsic norm is

\[ \|u\|_{W^{\theta,p}(\mathbb{R}^n)}^p = \|u\|_{L^p(\mathbb{R}^n)}^p + \sum_{i=1}^n \int_0^\infty t^{(1-\theta)p} \left| \frac{G_i(t) u - u}{t} \right|^p dt \]

\[ \leq C(\theta, p) \|u\|_{T_0}^p \]

This completes the proof.
\[
\|u\|_{L^p(\mathbb{R}^n)}^p + \sum_{i=1}^{n} \int_0^\infty \frac{t^{(1-\theta)p}}{t^p} \left\| \frac{u(\cdot + te_i) - u(\cdot)}{t^p} \right\|_{L^p} \, dt
\]

and \( u \in W^{\theta,p}(\mathbb{R}^n) \) when this norm is finite. The only new detail is that in showing that for \( u \in T_0 \) it follows it is in \( T \), you use the function

\[
f(t) \equiv \phi(t) \frac{1}{t} \int_0^t \cdots \int_0^t G_1(\tau_1)G_2(\tau_2)\cdots G_n(\tau_n) \, d\tau_1 \cdots d\tau_n
\]

and the fact that these semigroups commute. To get this started, note that

\[
g(t) \equiv \int_0^t \cdots \int_0^t G_1(\tau_1)G_2(\tau_2)\cdots G_n(\tau_n) \, d\tau_1 \cdots d\tau_n \in D(\Lambda_i)
\]

for each \( i \). This follows from writing it as

\[
\int_0^t G_i(\tau_i)(w_i) \, d\tau_i
\]

for \( w_i \in L^p \) coming from the other integrals and then repeating the earlier argument to get

\[
\Lambda_i g(t) = G_i(t) w_i - w_i
\]

and then

\[
\int_0^\infty t^{p(1-\theta)} \left\| \Lambda_i f \right\|_{L^p}^p \, \frac{dt}{t} \leq C \int_0^\infty t^{p(1-\theta)} \left\| G_i(t) u - u \right\|_{L^p}^p \, \frac{dt}{t} \leq C \|u\|^p_{T_0}
\]

Thus all is well as far as \( f \) is concerned and the proof will work as it did earlier in Theorem 43.3.6. What about \( f' \)? As before, the only term which is problematic is

\[
\phi(t) \left( \frac{1}{t} \int_0^t \cdots \int_0^t G_1(\tau_1)G_2(\tau_2)\cdots G_n(\tau_n) \, d\tau_1 \cdots d\tau_n \right)'
\]

After enough massaging, it becomes

\[
\sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{t} \int_0^t G_j(\tau_j) \, d\tau_j \frac{1}{t^2} \int_0^t (G_i(t) u - G_i(\tau_i) u) \, d\tau_i
\]

where the operator \( \sum_{i=1}^{n} \prod_{j \neq i} \frac{1}{t} \int_0^t G_j(\tau_j) \, d\tau_j \) is bounded. Thus similar arguments to those of Theorem 43.3.6 will work, the only difference being a sum.
Theorem 43.3.7  An equivalent norm for \( W^{\theta,p}(\mathbb{R}^n) \) for \( \theta \in (0,1) \) is

\[
\|u\|_{W^{\theta,p}(\mathbb{R}^n)}^p = \|u\|_{L^p(\mathbb{R}^n)}^p + \sum_{i=1}^n \int_0^\infty t^{(1-\theta)p} \left\| \frac{G_i(t)(u-u)}{t} \right\|_{L^p}^p \frac{dt}{t} \\
= \|u\|_{L^p(\mathbb{R}^n)}^p + \sum_{i=1}^n \int_0^\infty t^{(1-\theta)p} \left\| \frac{u(\cdot+te_i) - u(\cdot)}{t} \right\|_{L^p}^p \frac{dt}{t} \tag{43.3.14}
\]

Note it is obvious from (43.3.13) that a Lipschitz map takes \( W^{\theta,p}(\mathbb{R}^n) \) to \( W^{\theta,p}(\mathbb{R}^n) \) and is continuous.

The above description in Theorem 43.3.7 also makes possible the following corollary.

Corollary 43.3.8  \( W^{\theta,p}(\mathbb{R}^n) \) is reflexive.

**Proof:**  Let \( u \in W^{\theta,p}(\mathbb{R}^n) \). For each \( i = 1, 2, \cdots, n \), define for \( t > 0 \),

\[
\Delta_i u(t)(x) = \frac{u(x+te_i) - u(x)}{t}
\]

Then by Theorem 43.3.7,

\[
\Delta_i u \in L^p((0,\infty);L^p(\mathbb{R}^n), \mu) \equiv Y
\]

where

\[
\mu(E) = \int_E t^{(1-\theta)p} t^{-1} dt.
\]

Clearly the measure space is \( \sigma \)-finite and so \( Y \) is reflexive by Corollary 43.3.4 on Page 173. Also \( \Delta_i \) is a closed operator whose domain is \( W^{\theta,p}(\mathbb{R}^n) \). To see this, suppose \( u_n \in W^{\theta,p}(\mathbb{R}^n) \) and \( u_n \to u \) in \( L^p(\mathbb{R}^n) \) while \( \Delta_i u_n \to g \) in \( Y \). Then in particular \( \|\Delta_i u_n\|_Y \) is bounded. Now by Fatou’s lemma,

\[
\liminf_{n \to \infty} \int_0^\infty t^{(1-\theta)p} \left\| \frac{u_n(\cdot+te_i) - u_n(\cdot)}{t} \right\|_{L^p(\mathbb{R}^n)}^p \frac{dt}{t} < \infty.
\]

Letting \( \tilde{\Delta} \equiv (\Delta_1, \Delta_2, \cdots, \Delta_n) \), it follows from similar reasoning that \( \tilde{\Delta} \) is a closed operator mapping \( W^{\theta,p}(\mathbb{R}^n) \) to \( Y^n \). Therefore

\[
\left( \text{id}, \tilde{\Delta} \right) (W^{\theta,p}(\mathbb{R}^n)) \subseteq L^p(\mathbb{R}^n) \times Y^n
\]

and is a closed subspace of the reflexive space \( L^p(\mathbb{R}^n) \times Y^n \). With the norm in \( L^p(\mathbb{R}^n) \times Y^n \) given as the sum of the norms of the components, it follows the
mapping \((\text{id}, \Delta)\) is a norm preserving isomorphism between \(W^{\theta,p}(\mathbb{R}^n)\) and this closed subspace of \(L^p(\mathbb{R}^n) \times Y^n\). Since \(L^p(\mathbb{R}^n)\) and \(Y^n\) are reflexive, their product is reflexive. By Lemma 19.2.7 on Page 639 it follows \((\text{id}, \Delta)(W^{\theta,p}(\mathbb{R}^n))\) and hence \(W^{\theta,p}(\mathbb{R}^n)\) is reflexive. This proves the theorem.

One can generalize this to find an intrinsic norm for \(W^{\theta,p}(\Omega)\). The version given above will not do because it requires the function to be defined on all of \(\mathbb{R}^n\) in order to make sense of the shift operators \(G_i\). However, you can give a different version of this intrinsic norm which will make sense for \(\Omega \neq \mathbb{R}^n\).

**Lemma 43.3.9** Let \(t \neq 0\) be a number. Then there is a constant \(C(n, \theta, p)\) depending on the indicated quantities such that

\[
\int_{\mathbb{R}^{n-1}} \frac{1}{(t^2 + |s|^2)^{\frac{n+p\theta}{2}}} ds = C(n, \theta, p) \frac{1}{|t|^{1+p\theta}}
\]

**Proof:** Change the integral to polar coordinates. Thus the integral equals

\[
\int_{S^{n-1}} \int_0^\infty \frac{\rho^{n-2}}{(t^2 + \rho^2)^{\frac{n+p\theta}{2}}} d\rho d\sigma
\]

Now change the variables, \(\rho = |t| u\). Then the above integral becomes

\[
C_n \int_0^\infty \frac{|t|^{n-2} u^{n-2} |t|}{|t|^{n+p\theta} (1 + u^2)^{\frac{n+p\theta}{2}}} du
= C_n \frac{1}{|t|^{1+p\theta}} \int_0^\infty \frac{u^{n-2}}{(1 + u^2)^{\frac{n+p\theta}{2}}} du = C(n, \theta, p) \frac{1}{|t|^{1+p\theta}}.
\]

This proves the lemma.

Now let \(u \in W^{\theta,p}(\mathbb{R}^n)\). This means the norm of \(||u||^{\theta,p}_{W^{\theta,p}}\) can be taken as

\[
||u||^{\theta,p}_{L^p} + \sum_{i=1}^n \int_0^\infty |t|^{(1-\theta)p} \int_{\mathbb{R}^n} \frac{|u(x + te_i) - u(x)|^p}{t} \frac{dx \, dt}{|t|}
= ||u||^{\theta,p}_{L^p} + \frac{1}{2} \sum_{i=1}^n \int_0^\infty |t|^{(1-\theta)p} \int_{\mathbb{R}^n} \frac{|u(x + te_i) - u(x)|^p}{t} \frac{dx \, dt}{|t|}
\]

That integral over \(\mathbb{R}^n\) can be massaged and one obtains the above equal to

\[
||u||^{\theta,p}_{L^p} + \frac{1}{2} \sum_{i=1}^n \int_{\mathbb{R}^{n-i}} \int_{\mathbb{R}^{i-1}} \frac{1}{t^{1+p\theta}} |u(x_1, \cdots, x_i + t, y_{i+1}, \cdots, y_n) - u(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n)|^p \, dx_i \, dy_{n-i} \, dt
\]
where \( dx_i \) refers to the first \( i \) entries and \( dy_{n-i} \) refers to the remaining entries. From Lemma 15.3, the complicated expression above equals

\[
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{-\infty}^{\infty} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}} \int_{\mathbb{R}^{n-1}} \frac{1}{(t^2 + |s|^2)^{\frac{1}{2}(n+p)}} |u(x_1, \ldots, x_i-1, x_i, y_{i+1}, \ldots, y_n) - u(x_1, \ldots, x_i, y_{i+1}, \ldots, y_n)|^p \, ds \, dx_i \, dy_{n-i} \, dt
\]

Now Fubini this to get

\[
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{(t^2 + |s|^2)^{\frac{1}{2}(n+p)}} |u(x_1, \ldots, x_i-1, x_i, y_{i+1}, \ldots, y_n) - u(x_1, \ldots, x_i, y_{i+1}, \ldots, y_n)|^p \, dt \, ds \, dx_i \, dy_{n-i}
\]

Changing the variable in the inside integral to \( t = y_i - x_i \), this equals

\[
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{((y_i - x_i)^2 + |s|^2)^{\frac{1}{2}(n+p)}} |u(x_1, \ldots, x_i-1, y_i, y_{i+1}, \ldots, y_n) - u(x_1, \ldots, x_i, y_{i+1}, \ldots, y_n)|^p \, dy_i \, ds \, dx_i \, dy_{n-i}
\]

Next let

\[
(s_1, \ldots, s_{n-1}) \equiv (y_1 - x_1, \ldots, y_{i-1} - x_{i-1}, x_{i+1} - y_{i+1}, \ldots, x_n - y_n)
\]

where the new variables of integration in the integral corresponding to \( ds \) are \( y_1, \ldots, y_{i-1} \) and \( x_{i+1}, \ldots, x_n \). Then changing the variables, the above reduces to

\[
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{\mathbb{R}^{n-1}} \int_{-\infty}^{\infty} \frac{1}{|(x - y)^{(n+p)}} |u(x_1, \ldots, x_{i-1}, y_i, y_{i+1}, \ldots, y_n) - u(x_1, \ldots, x_i, y_{i+1}, \ldots, y_n)|^p \, dy_i \, dx_i \, dy_{n-i} \, dx_n \, dx \, dy_j \, dy_{j+1} \, \ldots \, dy_n
\]

Then if you Fubini again, it reduces to the expression

\[
\frac{1}{C(n, \theta, p)} \frac{1}{2} \sum_{i=1}^{n} \int_{\mathbb{R}^{n}} \int_{\mathbb{R}^{n}} \frac{|u(x_1, \ldots, x_i-1, y_i, y_{i+1}, \ldots, y_n) - u(x_1, \ldots, x_i, y_{i+1}, \ldots, y_n)|^p}{|(x - y)^{(n+p)}} \, dx \, dy
\]
43.3. INTRINSIC NORMS

Now taking the sum inside and adjusting the constants yields

\[ \geq C(n, \theta, p) \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+p\theta)}} \, dx \, dy \]

Thus there exists a constant \( C(n, \theta, p) \) such that

\[ ||u||_{W^{\theta,p}(\mathbb{R}^n)} \geq C(n, \theta, p) \left( ||u||_{L^p}^p + \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+p\theta)}} \, dx \, dy \right)^{1/p} \]

Next start with the right side of the above. It suffices to consider only the complicated term. First note that for a a vector,

\[ \left( \sum_{i=1}^{n} a_i^2 \right)^{p/2} \geq |a_i|^p \]

and so

\[ \sum_{i=1}^{n} |a_i|^p \leq n \left( \sum_{i=1}^{n} a_i^2 \right)^{p/2} = n |a|^p \]

from which it follows

\[ \frac{1}{n} \sum_{i=1}^{n} |a_i|^p \leq |a|^p \]

Then it follows

\[ \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(x_1, \cdots, x_{i-1}, y_i, y_{i+1}, \cdots, y_n) - u(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n)|^p}{|x - y|^{(n+p\theta)}} \, dx \, dy \geq \frac{1}{n} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \sum_{i=1}^{n} \frac{|u(y_1, \cdots, x_{i-1}, y_i, y_{i+1}, \cdots, y_n) - u(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n)|^p}{|x - y|^{(n+p\theta)}} \, dx \, dy \]

Consider the \( i^{th} \) term. By Fubini's theorem it equals

\[ \frac{1}{n} \int_{\cdots} \int_{\cdots} \frac{1}{(y_i - x_i)^2 + \sum_{j \neq i} (y_j - x_j)^2} \frac{1}{4(n+p\theta)} \]

\[ |u(x_1, \cdots, x_{i-1}, y_i, y_{i+1}, \cdots, y_n) - u(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n)|^p \]

\[ dy_1 dx_1 \cdots dx_{i-1} dy_{i+1} \cdots dy_n dy_1 \cdots dy_{i-1} dx_1 \cdots dx_n \]

Let \( t = y_i - x_1 \). Then it reduces to

\[ \frac{1}{n} \int_{\cdots} \int_{\cdots} \frac{1}{(t^2 + \sum_{j \neq i} (y_j - x_j)^2} \frac{1}{4(n+p\theta)} \]

\[ |u(x_1, \cdots, x_{i-1}, x_i + t, y_{i+1}, \cdots, y_n) - u(x_1, \cdots, x_i, y_{i+1}, \cdots, y_n)|^p \]

\[ dt dx_1 \cdots dx_{i-1} dy_{i+1} \cdots dy_n dy_1 \cdots dy_{i-1} dx_1 \cdots dx_n \]
Now let 
\[
(s_1, \ldots, s_{n-1}) = (x_1 - y_1, \ldots, x_{i-1} - y_{i-1}, y_{i+1} - x_{i+1}, \ldots, y_n - x_n)
\]
on the next \(n-1\) iterated integrals. Then using Fubini’s theorem again and changing
the variables, it equals
\[
\frac{1}{n} \int \cdots \int \frac{1}{(t^2 + |s|^2)^{\frac{1}{2}(n+p\theta)}} . \\
|u(s_1 + y_1, \ldots, y_{i-1} + s_{i-1}, x_i + t, x_{i+1} + s_i, \ldots, x_n + s_{n-1}) - u(s_1 + y_1, \ldots, y_{i-1} + s_{i-1}, x_i, x_{i+1} + s_i, \ldots, x_n + s_{n-1})|^p \\
dy_1 \cdots dy_{i-1} dx_i \cdots dx_n ds_1 \cdots ds_{i-1} ds_i \cdots ds_{n-1} dt
\]
By translation invariance of the measure, the inside integrals corresponding to
d\(dy_1 \cdots dy_{i-1} dx_i \cdots dx_n\)
simplify and the expression can be written as
\[
\frac{1}{n} \int \cdots \int \frac{1}{(t^2 + |s|^2)^{\frac{1}{2}(n+p\theta)}} . \\
|u(x_1, \ldots, x_{i-1}, x_i + t, x_{i+1}, \ldots, x_n) - u(x_1, \ldots, x_{i-1}, x_i, x_{i+1}, \ldots, x_n)|^p \\
dx_1 \cdots dx_{i-1} dx_i \cdots dx_n ds_1 \cdots ds_{i-1} ds_i \cdots ds_{n-1} dt
\]
where I just renamed the variables. Use Fubini’s theorem again to get
\[
\frac{1}{n} \int \cdots \int \frac{1}{(t^2 + |s|^2)^{\frac{1}{2}(n+p\theta)}} . \\
|u(x_1, \ldots, x_{i-1}, x_i + t, x_{i+1}, \ldots, x_n) - u(x_1, \ldots, x_{i-1}, x_i, x_{i+1}, \ldots, x_n)|^p \\
ds_1 \cdots ds_{i-1} ds_i \cdots ds_{n-1} dx_1 \cdots dx_{i-1} dx_i \cdots dx_n dt
\]
Now from Lemma 43.3.9, the inside \(n-1\) integrals corresponding to \(ds_1 \cdots ds_{i-1} ds_i \cdots ds_{n-1}\) can be replaced with
\[
\frac{C(n, \theta, p)}{|t|^{1+p\theta}}
\]
and this yields
\[
C(n, \theta, p) \int_\mathbb{R} \frac{1}{|t|^{p\theta}} \int_\mathbb{R}^n |u(x + te) - u(x)|^p dx \frac{dt}{t}
\]
\[
= \frac{1}{2} C(n, \theta, p) \int_0^\infty \|u (\cdot + te) - u (\cdot)|^p_{L^p(\mathbb{R}^n)} \frac{dt}{t}
\]
43.3. INTRINSIC NORMS

Applying this to each term of the sum in (43.3.15) and adjusting the constant, it follows

\[ \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+\theta p)}} \, dx \, dy \geq C(n, \theta, p) \sum_{i=1}^{n} \int_{0}^{\infty} t^{p(1-\theta)} \frac{|u(\cdot + t\mathbf{e}_i) - u(\cdot)||_{L^p(\mathbb{R}^n)}}{t^p} \, dt \]

Therefore,

\[ \|u\|_{W^{\theta,p}(\mathbb{R}^n)} \geq C(n, \theta, p) \left( \|u\|_{L^p(\mathbb{R}^n)}^p + \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+\theta p)}} \, dx \, dy \right)^{1/p} \]

This has proved most of the following theorem about the intrinsic norm.

**Theorem 43.3.10** An equivalent norm for \( W^{\theta,p}(\mathbb{R}^n) \) is

\[ \|u\| = \left( \|u\|_{L^p(\mathbb{R}^n)}^p + \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+\theta p)}} \, dx \, dy \right)^{1/p} \]

Also for any open subset of \( \mathbb{R}^n \)

\[ \|u\| = \left( \|u\|_{L^p(\Omega)}^p + \int_{\Omega} \int_{\Omega} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+\theta p)}} \, dx \, dy \right)^{1/p} \]  \hspace{1cm} (43.3.16)

is a norm.

**Proof:** It only remains to verify this is a norm. Recall the \( l_p \) norm on \( \mathbb{R}^2 \) given by

\[ |(x, y)|_{l^p} = (|x|^p + |y|^p)^{1/p} \]

For \( u, v \in W^{\theta,p} \) denote by \( \rho(u) \) the expression

\[ \left( \int_{\Omega} \int_{\Omega} \frac{|u(y) - u(x)|^p}{|x - y|^{(n+\theta p)}} \, dx \, dy \right)^{1/p} \]

a similar definition holding for \( v \). Then it follows from the usual Minkowski inequality that \( \rho(u + v) \leq \rho(u) + \rho(v) \). Then from (43.3.17)

\[ \|u + v\| = (\|u + v\|_{L^p} + \rho(u + v)^p)^{1/p} \]

\[ \leq (\|u\|_{L^p} + \|v\|_{L^p} + (\rho(u) + \rho(v))^p)^{1/p} \]
\[
\begin{align*}
&= \|u\|_{L^p(U)} + \|v\|_{L^p(U)} \\
&\leq \|u\|_{L^p(U)} + \|v\|_{L^p(U)} \\
&= (\|u\|_{L^p}^p + \rho(u)^p)^{1/p} + (\|v\|_{L^p}^p + \rho(v)^p)^{1/p} \\
&= \|u\| + \|v\|
\end{align*}
\]

The other properties of a norm are obvious. This proves the theorem.

As pointed out in the above theorem, this is a norm in $W^{\theta,p}(\mathbb{R}^d)$. One could define a set of functions for which this norm is finite. In the case where $\Omega = \mathbb{R}^n$ the conclusion of Theorem 43.3.10 is that this space of functions is the same as $W^{\theta,p}(\mathbb{R}^n)$ and the norms are equivalent. Does this happen for other open subsets of $\mathbb{R}^n$?

**Definition 43.3.11** Denote by $\tilde{W}^{\theta,p}(U)$ the functions in $L^p(U)$ for which the norm of Theorem 43.3.10 is finite. Here $\theta \in (0, 1)$.

**Proposition 43.3.12** Let $U$ be a bounded open set which has Lipschitz boundary and $\theta \in (0, 1)$. Then for each $p \geq 1$, there exists $E \in L^p \left( W^{\theta,p}(U), W^{\theta,p}(\mathbb{R}^n) \right)$ such that $Eu(x) = u(x)$ a.e. $x \in U$.

**Proof:** In proving this, I will use the equivalent norm of Theorem 43.3.10 as the norm of $W^{\theta,p}(\mathbb{R}^n)$ Consider the following picture.

![Diagram](image)

The wavy line signifies a part of the boundary of $U$ and $\text{spt}(u)$ is contained in the circle as shown. It is drawn as a circle but this is not important. Denote by $U^+$ the region above the part of the boundary which is shown. Also let the boundary be given by $x_n = g(\bar{x})$ for $\bar{x} \in B \equiv B(\bar{y}_0, r) \subseteq \mathbb{R}^{n-1}$. Of course $u$ is only defined on $U$ so actually the support of $u$ is contained in the intersection of the circle with $U$.

Let the Lipschitz constant for $g$ be very small and denote it by $K$. Of course, assume $8K^2 < 1$. I will first show how to extend when this condition holds and then I will remove it with a simple trick. Define

\[
Eu(\bar{x}, x_n) = \begin{cases} 
    u(\bar{x}, x_n) & \text{if } x_n \leq g(\bar{x}) \\
    u(\bar{x}, 2g(\bar{x}) - x_n) & \text{if } x_n > g(\bar{x}) \\
    0 & \text{if } \bar{x} \notin B
\end{cases}
\]
I will write $U$ instead of $U \cap B \times (a, b)$ to save space but this does not matter because $u$ is assumed to be zero outside the indicated region. Then

\[
\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|Eu(\hat{x}, x_n) - Eu(\hat{y}, y_n)|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dx \, dy
\]

\[
= \int_\mathcal{U} \int_\mathcal{U} \frac{|u(\hat{x}, x_n) - u(\hat{y}, y_n)|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dx \, dy + \int_{\mathcal{U}^+} \int_{\mathcal{U}^+} \frac{|Eu(\hat{x}, x_n) - u(\hat{y}, y_n)|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dx \, dy + \int_{\mathcal{U}^+} \int_{\mathcal{U}^+} \frac{|Eu(\hat{x}, x_n) - Eu(\hat{y}, y_n)|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dx \, dy 
\]

Consider the second of the integrals on the right of the equal sign. Using Fubini’s theorem, it equals

\[
\int_\mathcal{U} \int_{\mathcal{U}^+} \frac{|u(\hat{x}, x_n) - 2g(\hat{y}) - y_n|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dy \, dx
\]

\[
= \int_\mathcal{U} \int_{\mathcal{U}^+} \frac{|u(\hat{x}, x_n) - g(\hat{y})|^p}{|\hat{x} - \hat{y}|^2 + (x_n - y_n)^2} \, dy \, dx
\]

\[
= \int_\mathcal{U} \int_{\mathcal{U}^+} \frac{|u(\hat{x}, x_n) - u(\hat{y}, z_n)|^p}{|\hat{x} - \hat{y}|^2 + (x_n - (2g(\hat{y}) - z_n))^2} \, dz \, dy
\]

I need to estimate $|x_n - z_n|$.

\[
|x_n - z_n| \leq |x_n - g(\hat{x})| + |g(\hat{x}) - g(\hat{y})| + |g(\hat{y}) - z_n|
\]

\[
\leq g(\hat{x}) - x_n + K |\hat{x} - \hat{y}| + y_n - g(\hat{y})
\]

\[
\leq |y_n - x_n| + 2K |\hat{x} - \hat{y}|
\]

and so

\[
|x_n - z_n|^2 \leq 8K^2 |\hat{x} - \hat{y}|^2 + 2 |y_n - x_n|^2
\]

\[
\leq |\hat{x} - \hat{y}|^2 + 2 |y_n - x_n|^2
\]
Thus,
\[(y_n - x_n)^2 \geq \frac{1}{2} |x_n - z_n|^2 - \frac{1}{2} |\hat{x} - \hat{y}|^2\]
and so, the above change of variables results in an expression which is dominated by
\[
\int_U \int_U \frac{|u(\hat{x}, x_n) - u(\hat{y}, z_n)|^p}{\left|\frac{1}{2} |\hat{x} - \hat{y}|^2 + \frac{1}{2} (x_n - z_n)^2\right|^{(1/2)(n+\theta)}} dy dx
\]
where \(y\) refers to \((\hat{y}, z_n)\) in the above formula. Hence there is a constant \(C(n, \theta)\) such that \(33.3.17\) is dominated by \(C(n, \theta) \|u\|^p_{W^{\theta, p}(U)}\). A similar inequality holds for the third term. Finally consider \(33.3.18\). This equals
\[
\int_{U^+} \int_{U^+} \frac{|u(\hat{x}, 2g(\hat{x}) - x_n) - u(\hat{y}, 2g(\hat{y}) - y_n)|^p}{\left|\frac{1}{2} |\hat{x} - \hat{y}|^2 + (x_n - y_n)^2\right|^{(1/2)(n+\theta)}} dx dy
\]
Changing variables, \(x' = 2g(\hat{x}) - x_n\), \(y' = 2g(\hat{y}) - y_n\), it equals
\[
\int_{U^+} \int_{U^+} \frac{|u(\hat{x}, x') - u(\hat{y}, y')|^p}{\left|\frac{1}{2} |\hat{x} - \hat{y}|^2 + (x_n - y_n)^2\right|^{(1/2)(n+\theta)}} dx' dy', \tag{43.3.20}
\]
each of \(x_n, y_n\) being a function of \(x'_n, y'_n\) where an estimate needs to be obtained on \(|x'_n - y'_n|\) in terms of \(|x_n - y_n|\).

\[
(x'_n - y'_n)^2 = (2(g(\hat{x}) - g(\hat{y})) + y_n - x_n)^2
\]
\[
= (y_n - x_n)^2 + 4(g(\hat{x}) - g(\hat{y})) (y_n - x_n) + 4(g(\hat{x}) - g(\hat{y}))^2
\]
\[
\leq (y_n - x_n)^2 + 2(g(\hat{x}) - g(\hat{y}))^2 + 2(y_n - x_n)^2 + 4(g(\hat{x}) - g(\hat{y}))^2
\]
and so
\[
(x'_n - y'_n)^2 \leq 3(y_n - x_n)^2 + 6K^2 |\hat{x} - \hat{y}|^2
\]
which implies
\[
(y_n - x_n)^2 \geq \frac{1}{3} (x'_n - y'_n)^2 - 2K^2 |\hat{x} - \hat{y}|^2.
\]
Then substituting this in to \(33.3.20\), a short computation shows \(33.3.19\) is dominated by an expression of the form \(C(n, \theta) \|u\|^p_{W^{\theta, p}(U)}\) and this proves the existence of an extension operator provided the Lipschitz constant is small enough. It is clear \(E\) is linear where \(E\) is defined above.

Now this assumption on the smallness of the Lipschitz constant is needed. For \((\hat{x}, x_n) \in U\) define
\[
U' \equiv \{\hat{x} = \lambda (\hat{x} - \hat{b}_0) : \hat{x} \in U\}
\]
43.3. INTRINSIC NORMS

here this is centering at 0 and stretching $B$ since $\lambda$ will be large. Let $h$ be the name of this mapping. Thus

$$h(\tilde{x}) = \lambda (\tilde{x} - \hat{b}_0),$$

$$k(\tilde{x}) = h^{-1}(\tilde{x}) = \frac{1}{\lambda} \tilde{x} + \hat{b}_0$$

These mappings are defined on all of $\mathbb{R}^n$. Now let $u'$ be defined on $U'$ as follows.

$$u'(\tilde{x}, x_n) \equiv k^*u(\tilde{x}, x_n).$$

Also let

$$g'(\tilde{x}) = k^*g(\tilde{x}).$$

Thus $g'(\tilde{x}) = g(\frac{1}{\lambda} \tilde{x} + \hat{b}_0) = g(k(\tilde{x}))$. Then choosing $\lambda$ large enough the Lipschitz condition for $g'$ is as small as desired. Always assume $\lambda$ has been chosen this large and also $\lambda \geq 1$. Furthermore, $g'(\tilde{x}) = x_n'$ describes the boundary in the same way as $x_n = g(\tilde{x})$. Now I need to consider whether

$$u''(\tilde{x}, x_n) \in W^{\theta, p}(U').$$

Consider

$$\int_{U'} \int_{U'} |u'(\tilde{x}', x_n) - u'(\tilde{y}', y_n)|^p \left( |\tilde{x}' - \tilde{y}'|^2 + (x_n - y_n)^2 \right)^{p+n\theta} d\tilde{x}' d\tilde{y}'$$

$$= \int_{U'} \int_{U'} |k^*u(\tilde{x}', x_n) - k^*u(\tilde{y}', y_n)|^p \left( |\tilde{x}' - \tilde{y}'|^2 + (x_n - y_n)^2 \right)^{p+n\theta} d\tilde{x}' d\tilde{y}'$$

Then change the variables $\tilde{x}' = \lambda (\tilde{x} - \hat{b}_0) = h(\tilde{x})$ with a similar change for $\tilde{y}'$, the above expression equals

$$(\lambda^{n-1})^2 \int_U \int_U \frac{|u(\tilde{x}, x_n) - u(\tilde{y}, y_n)|^p}{(\lambda^2 |\tilde{x} - \tilde{y}|^2 + (x_n - y_n)^2)^{p+n\theta}} d\tilde{x} d\tilde{y}$$

Thus

$$||u'||_{W^{\theta, p}(U')} \leq \lambda^{n-1} ||u||_{\overset{\rightarrow}{W^{\theta, p}(U)}} < \infty \quad (43.3.21)$$

and $k^* : W^{\theta, p}(U) \to W^{\theta, p}(U')$ is continuous and linear. Similar reasoning shows that $h^*$ is continuous and linear mapping $W^{\theta, p}(\mathbb{R}^n)$ to $W^{\theta, p}(\mathbb{R}^n)$. By the first part of the argument there exists a continuous linear map

$$E' : W^{\theta, p}(U') \to W^{\theta, p}(\mathbb{R}^n)$$
CHAPTER 43. TRACES OF SOBOLEV SPACES AND FRACTIONAL ORDER SPACES

Now define 
\[ Eu \equiv h^* E' (k^* u) \]
Say \( x_n \leq g(\xi) \). Then \( (\xi, x_n) \in U \) and so \( (h(\xi), x_n) \in U' \). Thus
\[
Eu(\xi, x_n) = h^* E'(k^* u)(\xi, x_n)
\]
\[
= E'(k^* u)(h(\xi), x_n)
\]
(43.3.22)
Now \( g(\xi) \geq x_n \) and so \( g'(h(\xi)) \geq x_n \) because
\[
g'(h(\xi)) = k^* g(h(\xi)) = g(\xi)
\]
and so (43.3.22) equals
\[
= (k^* u)(h(\xi), x_n) = u(\xi, x_n)
\]
Thus \( E \) leaves \( u \) unchanged at points \((\xi, x_n)\) where \( x_n \leq g(\xi) \). Also
\[
||Eu||_{W^{s,p}(\mathbb{R}^n)} = ||h^* E'k^* u||_{W^{s,p}(\mathbb{R}^n)} \leq ||h^*|| ||E'k^* u||_{W^{s,p}(\mathbb{R}^n)}
\]
\[
\leq ||h^*|| ||E'|| ||k^*|| ||u||_{W^{s,p}(\mathbb{R}^n)} = C ||u||_{W^{\theta,p}(U)}
\]
To complete the proof, cover \( U \) with finitely many sets of this sort oriented with respect to one of the coordinate axes as this one was along with an open set whose closure is contained in \( U \) and then use a smooth partition of unity to localize the function to the situation of the sort just discussed and one whose support is contained in \( U \). Extend that one to equal zero off its support and treat the others as above. This proves the proposition.

Recall Theorem 43.3.12 which provides an extension operator from \( W^{1,p}(U) \) to \( W^{1,p}(\mathbb{R}^n) \) also denoted by \( E \). Now it is not hard to see that \( \tilde{W}^{\theta,p}(U) = W^{\theta,p}(U) \) and the two norms are equivalent.

**Theorem 43.3.13** Let \( U \) be a bounded open set which has Lipschitz boundary and \( \theta \in (0, 1) \). Then \( \tilde{W}^{\theta,p}(U) = W^{\theta,p}(U) \) and the two norms are equivalent.

**Proof:** Let \( u \in \tilde{W}^{\theta,p}(U) \). Letting \( E \) be the extension operator of Lemma 43.3.12, there is a constant \( C \) such that
\[
C ||u||_{W^{\theta,p}(U)} \geq ||Eu||_{W^{\theta,p}(\mathbb{R}^n)} = ||Eu||_{W^{s,p}(\mathbb{R}^n)} \geq ||u||_{W^{\theta,p}(U)}
\]
Thus if \( u \in \tilde{W}^{\theta,p}(U) \), then \( u \in W^{\theta,p}(U) \) and the inclusion map is continuous.

Next suppose \( u \in W^{\theta,p}(U) \) and let \( \gamma f = u \) for
\[
f \in W \left(W^{1,p}(U), L^p(U), p, 1 - \theta \right) \equiv W_U
\]
Then from Theorem 43.3.7 and the definition of the norm in \( W_U \)
\[
Ef \in W \left(W^{1,p}(\mathbb{R}^n), L^p(\mathbb{R}^n), p, 1 - \theta \right) \equiv W
\]
43.4. FRACTIONAL ORDER SOBOLEV SPACES

where this $E$ pertains to extending $W^{1,p}(U)$.

$$C_1 \|f\|_{W^1} \geq \|Ef\|_{W^{1,p}(\mathbb{R}^n)} \geq \|u\|_{W^{s,p}(U)}$$

Since this is true for every $f \in W^1$, it follows $u \in \widetilde{W^{s,p}(U)}$ and

$$\|u\|_{\widetilde{W^{s,p}(U)}} \leq C_1 \|u\|_{W^{s,p}(U)}.$$

This proves the theorem.

Corollary 43.3.14 Let $U$ be a bounded open set with Lipschitz boundary. Then $W^{\theta,p}(U)$ is reflexive.

**Proof:** From Proposition 43.3.12 and Theorem 43.3.13, there exists an extension operator $E: W^{\theta,p}(U) \to W^{\theta,p}(\mathbb{R}^n)$ which is continuous. This operator is one to one and continuous. Furthermore, $\|Ef\|_{W^{\theta,p}(\mathbb{R}^n)} \geq \|u\|_{W^{\theta,p}(U)}$ and so $E(W^{\theta,p}(U))$ is closed. Therefore, by Corollary 19.2.8 on Page 639 and the fact $W^{\theta,p}(\mathbb{R}^n)$ is reflexive which was shown in Corollary 43.3.8, it follows $W^{\theta,p}(U)$ is reflexive. This proves the corollary.

There may be other sets $U$ for which the intrinsic norm is an equivalent norm for $W^{\theta,p}(U)$ but this much will suffice. It should be routine to verify that this works for $U$ a half space for example and the extension argument should be much easier than that presented above. More generally, the assumption that $U$ was bounded in the above extension argument of Proposition 43.3.12 was never needed except for giving finitely many of those special sets covering the boundary. If you just assumed this at the outset instead of an assumption the set is bounded, the same sort of extension would work.

43.4 Fractional Order Sobolev Spaces

Now it is time to define fractional order Sobolev spaces between $W^{m,p}$ and $W^{m+1,p}$.

**Definition 43.4.1** Let $m$ be a nonnegative integer and let $s = m + \sigma$ where $\sigma \in (0,1)$. Then $W^{s,p}(\Omega)$ will consist of those elements of $W^{m,p}(\Omega)$ for which $D^\alpha u \in W^{\sigma,p}(\Omega)$ for all $|\alpha| = m$. The norm is given by the following.

$$\|u\|_{s,p,\Omega} \equiv \left( \|u\|_{m,p,\Omega}^p + \sum_{|\alpha| = m} \|D^\alpha u\|_{\sigma,p,\Omega}^p \right)^{1/p}.$$

**Corollary 43.4.2** The space, $W^{s,p}(\Omega)$ is a reflexive Banach space whenever $p > 1$.

**Proof:** From the theory of interpolation spaces, $W^{\sigma,p}(\Omega)$ is reflexive. This is because it is an interpolation space for the two reflexive spaces, $L^p(\Omega)$ and $W^{1,p}(\Omega)$. (Alternatively, you could use Corollary 19.2.14 in the case where $\Omega$ is a bounded...
open set with Lipschitz boundary or you could use Corollary 43.3.8 in case \( \Omega = \mathbb{R}^n \). In addition, the same ideas would work if \( \Omega \) were any space for which there was a continuous extension map from \( W^{\sigma,p}(\Omega) \) to \( W^{\sigma,p}(\mathbb{R}^n) \). Now the formula for the norm of an element in \( W^{\sigma,p}(\Omega) \) shows this space is isometric to a closed subspace of \( W^{m,p}(\Omega) \times W^{\sigma,p}(\Omega)^k \) for suitable \( k \). Therefore, from Corollary 19.2.8 on Page 639, \( W^{\sigma,p}(\Omega) \) is also reflexive.

**Theorem 43.4.3** The trace map, \( \gamma : W^{m,p}(\mathbb{R}^n) \to W^{m-\frac{1}{p},p}(\mathbb{R}^{n-1}) \) is continuous.

**Proof:** Let \( f \in \mathcal{S} \), the Schwartz class. Let \( \sigma = 1 - \frac{1}{p} \) so that \( m - \left( \frac{1}{p} \right) = m - 1 + \sigma \). Then from the definition and using \( f \in \mathcal{S} \),

\[
||\gamma f||_{m-\frac{1}{p},p,\mathbb{R}^{n-1}} = \left( ||\gamma f||_{m-1,p,\mathbb{R}^{n-1}}^p + \sum_{|\alpha|=m-1} ||D^\alpha \gamma f||_{1,\frac{1}{p},p,\mathbb{R}^{n-1}}^p \right)^{1/p} = \left( ||\gamma f||_{m-1,p,\mathbb{R}^{n-1}}^p + \sum_{|\alpha|=m-1} ||D^\alpha f||_{1,\frac{1}{p},p,\mathbb{R}^{n-1}}^p \right)^{1/p}
\]

and from Lemma 19.1.31, and the fact that the trace is continuous as a map from \( W^{m,p}(\mathbb{R}^n) \) to \( W^{m-1,1,p}(\mathbb{R}^{n-1}) \),

\[
||\gamma f||_{m-\frac{1}{p},p,\mathbb{R}^{n-1}} \leq \left( C_1||f||_{m,p,\mathbb{R}^n}^p + C_2 \sum_{|\alpha|=m-1} ||D^\alpha f||_{1,p,\mathbb{R}^n} \right)^{1/p} \leq C||f||_{m,p,\mathbb{R}^n + p}.
\]

Then using density of \( \mathcal{S} \) this implies the desired result.

With the definition of \( W^{s,p}(\Omega) \) for \( s \) not an integer, here is a generalization of an earlier theorem.

**Theorem 43.4.4** Let \( h : U \to V \) where \( U \) and \( V \) are two open sets and suppose \( h \) is bilipschitz and that \( D^s h \) and \( D^s h^{-1} \) exist and are Lipschitz continuous if \( |\alpha| \leq m \) where \( m = 0, 1, \ldots \) and \( s = m + \sigma \) where \( \sigma \in (0, 1) \). Then \( h^* : W^{s,p}(V) \to W^{s,p}(U) \) is continuous, linear, one to one, and has an inverse with the same properties, the inverse being \( (h^{-1})^* \).

**Proof:** In case \( m = 0 \), the conclusion of the theorem is immediate from the general theory of trace spaces. Therefore, assume \( m \geq 1 \). It follows from the definition that

\[
||h^* u||_{m+s,p,U} = \left[ ||h^* u||_{m,p,U}^p + \sum_{|\alpha|=m} ||D^\alpha (h^* u)||_{\sigma,p,U}^p \right]^{1/p}
\]
Consider the case when \( m = 1 \). Then it is routine to verify that
\[
D_j h^\ast u (x) = u_k (h (x)) h_{k,j} (x) .
\]
Let \( L_k : W^{1,p} (V) \to W^{1,p} (U) \) be defined by
\[
L_k v = h^\ast (v) h_{k,j}.
\]
Then \( L_k \) is continuous as a map from \( W^{1,p} (V) \) to \( W^{1,p} (U) \) and as a map from \( L^p (V) \) to \( L^p (U) \) and therefore, it follows that \( L_k \) is continuous as a map from \( W^{\sigma,p} (V) \) to \( W^{\sigma,p} (U) \). Therefore,
\[
|| L_k (v) ||_{\sigma,p,U} \leq C_k || v ||_{\sigma,p,U}
\]
and so
\[
|| D_j (h^\ast u) ||_{\sigma,p,U} \leq \sum_k || L_k (u_k) ||_{\sigma,p,U}
\]
\[
\leq \sum_k C_k || D_k u ||_{\sigma,p,V}
\]
\[
\leq C \left( \sum_k || D_k u ||_{\sigma,p,V}^p \right)^{1/p} .
\]
Therefore, it follows that
\[
|| h^\ast u ||_{1+\sigma,p,U} \leq \left[ || h^\ast u ||_{1,p,U}^p + \sum_j C^p \sum_k || D_k u ||_{\sigma,p,V}^p \right]^{1/p}
\]
\[
\leq C \left[ || u ||_{1,p,V}^p + \sum_k || D_k u ||_{\sigma,p,V}^p \right]^{1/p} = C || u ||_{1+\sigma,p,V} .
\]
The general case is similar except for the use of a more complicated linear operator in place of \( L_k \). This proves the theorem.

It is interesting to prove this theorem using Theorem 43.3.13 and the intrinsic norm.

Now we prove an important interpolation inequality for Sobolev spaces.

**Theorem 43.4.5** Let \( \Omega \) be an open set in \( \mathbb{R}^n \) which has the segment property and let \( f \in W^{m+1,p} (\Omega) \) and \( \sigma \in (0,1) \). Then for some constant, \( C \), independent of \( f \),
\[
|| f ||_{m+\sigma,p,\Omega} \leq C || f ||_{m+1,p,\Omega}^{1-\sigma} || f ||_{m,p,\Omega}^{\sigma} .
\]
Also, if \( L \in \mathcal{L} (W^{m,p} (\Omega), W^{m,p} (\Omega)) \), then \( L \) is continuous as a map from \( W^{\sigma,p} (\Omega) \) to \( W^{\sigma,p} (\Omega) \) for any \( m = 0,1,\cdots \).
Proof: Recall from above, $W^{1-\theta,p}(\Omega) \equiv T \left( W^{1,p}(\Omega), L^p(\Omega), p, \theta \right)$. Therefore, from Theorem 42.1.9, if $f \in W^{1,p}(\Omega)$,

$$
\|f\|_{1-\theta,p,\Omega} \leq K \|f\|_p^{\theta} \|f\|_{0,p,\Omega}^{1-\theta}
$$

Therefore,

$$
\|f\|_{m+\sigma,p,\Omega} \leq \left( \|f\|_{m,p,\Omega}^p + \sum_{|\alpha|=m} K \left( \|D^\alpha f\|_{1,p,\Omega}^{1-\sigma} \|D^\alpha f\|_{0,p,\Omega}^\sigma \right)^p \right)^{1/p}
$$

$$
\leq C \left( \|f\|_{m,p,\Omega}^p + \left( \|f\|_{m+1,p,\Omega}^{1-\sigma} \|f\|_{m,p,\Omega}^\sigma \right)^p \right)^{1/p}
$$

$$
\leq C \left( \|f\|_{m+1,p,\Omega}^{1-\sigma} \|f\|_{m,p,\Omega}^\sigma + \left( \|f\|_{m+1,p,\Omega}^{1-\sigma} \|f\|_{m,p,\Omega}^\sigma \right)^p \right)^{1/p}
$$

$$
\leq C \|f\|_{m+1,p,\Omega}^{1-\sigma} \|f\|_{m,p,\Omega}^\sigma .
$$

This proves the first part. Now consider the second. Let $\phi \in C^\infty(\Omega)$

$$
\|L\phi\|_{m+\sigma,p,\Omega} = \left( \|L\phi\|_{m,p,\Omega}^p + \sum_{|\alpha|=m} \|D^\alpha L\phi\|_{\sigma,p,\Omega}^p \right)^{1/p}
$$

$$
= \left( \|L\phi\|_{m,p,\Omega}^p + \sum_{|\alpha|=m} \left[ \inf \left( \|t^{1-\sigma} Lf_\alpha\|_{1}^\sigma \|t^{1-\sigma} Lf'_\alpha\|_{2}^{1-\sigma} \right) \right] \right)^{1/p}
$$

$$
(43.4.23)
$$

where

$$
\inf \left( \|t^{1-\sigma} Lf_\alpha\|_{1}^\sigma \|t^{1-\sigma} Lf'_\alpha\|_{2}^{1-\sigma} \right) =
$$

$$
\inf \left( ||t^{1-\sigma} Lf_\alpha||_{L^p(0,\infty;W^{1,\rho}(\Omega))}^\sigma ||t^{1-\sigma} Lf'_\alpha||_{L^p(0,\infty;L^p(\Omega))}^{1-\sigma} \right),
$$

$f_\alpha(t) \equiv \lim_{t \to 0} f_\alpha(t) = D^\alpha \phi$ in $W^{1,p}(\Omega) + L^p(\Omega)$, and the infimum is taken over all such functions. Therefore, from [43.4.24], and letting $\|L\|_1$ denote the operator.
norm of $L$ in $W^{1,p}(\Omega)$ and $\|L\|_2$ denote the operator norm of $L$ in $L^p(\Omega)$, 

$$
\|L\phi\|_{m+\sigma,p,\Omega} \\
\leq \left(\|L\phi\|_{m,p,\Omega}^p + \sum_{|\alpha|=m} \inf \left(\|L\|^q \|L\|^{1-\sigma}_2 \left\|t^{1-\sigma} f_\alpha\right\|_{1}^{\sigma} \left\|t^{1-\sigma} f'_\alpha\right\|_{2}^{1-\sigma}\right)^p\right)^{1/p} \\
\leq \left(\|L\phi\|_{m,p,\Omega}^p + \left(\|L\|^q \|L\|^{1-\sigma}_2\right)^p \sum_{|\alpha|=m} \inf \left(\left\|t^{1-\sigma} f_\alpha\right\|_{1}^{\sigma} \left\|t^{1-\sigma} f'_\alpha\right\|_{2}^{1-\sigma}\right)^p\right)^{1/p} \\
\leq C \left(\|\phi\|_{m,p,\Omega}^p + \sum_{|\alpha|=m} \left[\|D\phi\|_{\sigma,p,\Omega}\right]^p\right)^{1/p} = C \|\phi\|_{m+\sigma,p,\Omega}.
$$

Since $C^\infty(\bar{\Omega})$ is dense in all the Sobolev spaces, this inequality establishes the desired result.

**Definition 43.4.6** Define for $s \geq 0$, $W^{-s,p'}(\mathbb{R}^n)$ to be the dual space of $W^{s,p}(\mathbb{R}^n)$.

Here $\frac{1}{p} + \frac{1}{p'} = 1$.

Note that in the case of $m = 0$ this is consistent with the Riesz representation theorem for the $L^p$ spaces.
Chapter 44

Sobolev Spaces On Manifolds

44.1 Basic Definitions

Consider the following situation. There exists a set, $\Gamma \subseteq \mathbb{R}^m$ where $m > n$, mappings, $h_i : U_i \rightarrow \Gamma_i = \Gamma \cap W_i$ for $W_i$ an open set in $\mathbb{R}^m$ with $\Gamma \subseteq \bigcup_{i=1}^d W_i$ and $U_i$ is an open subset of $\mathbb{R}^n$ which $h_i$ one to one and onto. Assume $h_i$ is of the form

$$h_i(x) = H_i(x, 0)$$

(44.1.1)

where for some open set, $O_i$, $H_i : U_i \times O_i \rightarrow W_i$ is bilipschitz having bilipschitz inverse such that for $G = H_i$ or $H_i^{-1}$, $D^\alpha G$ is Lipschitz for $|\alpha| \leq k$.

For example, let $m = n + 1$ and let

$$H_i(x,y) = \left( \begin{array}{c} x \\ \phi(x) + y \end{array} \right)$$

where $\phi$ is a Lipschitz function having $D^\alpha \phi$ Lipschitz for all $|\alpha| \leq k$. This is an example of the sort of thing just described if $x \in U_i \subseteq \mathbb{R}^n$ and $O_i = \mathbb{R}$, because it is obvious the inverse of $H_i$ is given by

$$H_i^{-1}(x,y) = \left( \begin{array}{c} x \\ y - \phi(x) \end{array} \right).$$

Also let $\{\psi_i\}_{i=1}^d$ be a partition of unity subordinate to the open cover $\{W_i\}$ satisfying $\psi_i \in C^\infty_c(W_i)$. Then the definition of $W^{s,p}(\Gamma)$ follows.

**Definition 44.1.1** $u \in W^{s,p}(\Gamma)$ if whenever $\{W_i, \psi_i, \Gamma_i, U_i, h_i, H_i\}_{i=1}^d$ is described above with $h_i \in C^{k,1}$, $h_i^* (u \psi_i) \in W^{s,p}(U_i)$. The norm is given by

$$\|u\|_{s,p,\Gamma} \equiv \sum_{i=1}^d \|h_i^* (u \psi_i)\|_{s,p,U_i}.$$
It is not at all obvious this norm is well defined. What if

\( \{ W'_i, \phi_i, \Gamma_i, V_i, g_i, G_i \}_{i=1}^r \)

is as described above. Would the two norms be equivalent? To begin with consider
the following lemma which involves a particular choice for \( \{ W'_i, \phi_i, \Gamma_i, U_i, h_i, H_i \}_{i=1}^r \).

**Lemma 44.1.2** \( W^{s,p}(\Gamma) \) as just described, is a Banach space. If \( p > 1 \) then it is
reflexive.

**Proof:** Let \( L : W^{s,p}(\Gamma) \to \prod_{i=1}^r W^{s,p}(U_i) \) be defined by \( \{ L u \}_{i=1}^r = h_i^*(u \psi_i) \).
Let \( \{ u_j \}_{j=1}^\infty \) be a Cauchy sequence in \( W^{s,p}(\Gamma) \). Then \( \{ h_i^*(u_j \psi_i) \}_{j=1}^\infty \) is a Cauchy
sequence in \( W^{s,p}(U_i) \) for each \( i \). Therefore, for each \( i \), there exists \( w_i \in W^{s,p}(U_i) \)
such that

\[ \lim_{j \to \infty} h_i^*(u_j \psi_i) = w_i \text{ in } W^{s,p}(U_i). \]

But also, there exists a subsequence, still denoted by \( j \) such that for each \( i \)
\( \{ h_i^*(u_j \psi_i)(x) \}_{j=1}^\infty \) is a Cauchy
sequence for a.e. \( x \). Since \( h_i \) is given to be Lipschitz, it maps sets of
measure 0 to sets of \( n \) dimensional Hausdorff measure zero. Therefore,
\( \{ u_j \psi_i(y) \}_{j=1}^\infty \)
is a Cauchy sequence for \( \mu \) a.e. \( y \in W_i \cap \Gamma \) where \( \mu \) denotes the \( n \) dimensional
Hausdorff measure. It follows that for \( \mu \) a.e. \( y \), \( \{ u_j(y) \}_{j=1}^\infty \) is a Cauchy
sequence and so it converges to a function denoted as \( u(y) \).

\[ u_j(y) \to u(y) \text{ } \mu \text{ a.e.} \]

Therefore, \( w_i(x) = h_i^*(u \psi_i)(x) \text{ a.e.} \) and this shows \( h_i^*(u \psi_i) \in W^{s,p}(U_i) \). Thus
\( u \in W^{s,p}(\Gamma) \) showing completeness. It is clear \( ||\cdot||_{s,p,\Gamma} \) is a norm. Thus \( L \) is an
isometry of \( W^{s,p}(\Gamma) \) and a closed subspace of \( \prod_{i=1}^r W^{s,p}(U_i) \). By Corollary 34.2.1,
\( W^{s,p}(U_i) \) is reflexive which implies the product is reflexive. Closed subspaces
of reflexive spaces are reflexive by Lemma 19.2.7 on Page 639 and so \( W^{s,p}(\Gamma) \) is also
reflexive. This proves the lemma.

I now show that any two such norms are equivalent.

Suppose \( \{ W'_j, \phi_j, \Gamma_j, V_j, g_j, G_j \}_{j=1}^r \) and \( \{ W_i, \psi_i, \Gamma_i, U_i, h_i, H_i \}_{i=1}^l \) both satisfy
the conditions described above. Let \( ||\cdot||_{s,p,\Gamma} \) denote the norm defined by

\[ ||u||_{s,p,\Gamma}^1 = \sum_{j=1}^r ||g_j^*(u \phi_j)||_{s,p,V_j} \]

\[ \leq \sum_{j=1}^r \left| g_j^* \left( \sum_{i=1}^l u \phi_j \psi_i \right) \right|_{s,p,V_j} \leq \sum_{j,i} ||g_j^*(u \phi_j \psi_i)||_{s,p,V_j} \]
44.2. THE TRACE ON THE BOUNDARY OF AN OPEN SET

\[ \sum_{j,i} \left\| g^*_j \left( \phi_j \psi_i \right) \right\|_{s,p} \mathbb{g}^{-1}_j(W_i \cap W'_i) \]  

(44.1.2)

Now define a new norm \( \| u \|_{s,p,\Gamma} \) by the formula \[ \left\{ W'_i \cap W_i, \psi_i, \phi_j, \Gamma_j \cap \Gamma_i, V_j, g_{i,j}, G_{i,j} \right\} \] This norm is determined by \[ \{ W'_i \cap W_i, \psi_i, \phi_j, \Gamma_j \cap \Gamma_i, V_j, g_{i,j}, G_{i,j} \} \] where \( g_{i,j} = g_j \). Thus the identity map is continuous from \( (W_{s,p}) \) to \( (W_{s,p}) \). It follows the two norms, \( \| \cdot \|_{s,p,\Gamma}^1 \) and \( \| \cdot \|_{s,p,\Gamma}^2 \), are equivalent by the open mapping theorem. In a similar way, the norms, \( \| \cdot \|_{s,p,\Gamma}^2 \) and \( \| \cdot \|_{s,p,\Gamma}^1 \) are equivalent where

\[ \| u \|_{s,p,\Gamma}^1 = \sum_{j=1}^l \| h_j^* (u \psi_i) \|_{s,p,U_i} \]

and

\[ \| u \|_{s,p,\Gamma}^2 = \sum_{j=1}^l \| h_j^* (u \phi_j \psi_i) \|_{s,p,U_i} = \sum_{j=1}^l \| h_j^* (u \phi_j \psi_i) \|_{s,p,h^{-1}_j(W_i \cap W'_i)} \]

But from the assumptions on \( h \) and \( g \), in particular the assumption that these are restrictions of functions which are defined on open subsets of \( \mathbb{R}^m \) which have Lipschitz derivatives up to order \( k \) along with their inverses, Theorem 44.3.4 implies, there exist constants \( C_i \), independent of \( u \) such that

\[ \| h_j^* (u \phi_j \psi_i) \|_{s,p,h^{-1}_j(W_i \cap W'_i)} \leq C_1 \| g^*_j (u \phi_j \psi_i) \|_{s,p,\mathbb{g}^{-1}_j(W_i \cap W'_i)} \]

and

\[ \| g^*_j (u \phi_j \psi_i) \|_{s,p,\mathbb{g}^{-1}_j(W_i \cap W'_i)} \leq C_2 \| h_j^* (u \phi_j \psi_i) \|_{s,p,h^{-1}_j(W_i \cap W'_i)} \]

Therefore, the two norms, \( \| \cdot \|_{s,p,\Gamma}^1 \) and \( \| \cdot \|_{s,p,\Gamma}^2 \) are equivalent. It follows that the norms, \( \| \cdot \|_{s,p,\Gamma}^1 \) and \( \| \cdot \|_{s,p,\Gamma}^2 \) are equivalent. This proves the following theorem.

**Theorem 44.1.3** Let \( \Gamma \) be described above. Then any two norms for \( W^{s,p} (\Gamma) \) as in Definition 37.6.3 are equivalent.

44.2 The Trace On The Boundary Of An Open Set

Next is a generalization of earlier theorems about the loss of \( \frac{1}{p} \) derivatives on the boundary.

**Definition 44.2.1** Define

\[ \mathbb{R}^{n-1}_k = \{ x \in \mathbb{R}^n : x_k = 0 \} \]

An open set, \( \Omega \) is \( C^{m,1} \) if there exist open sets, \( W_i, i = 0, 1, \ldots, l \) such that

\[ \Omega = \bigcup_{i=0}^l W_i \]
CHAPTER 44. SOBOLEV SPACES ON MANIFOLDS

with \( W_0 \subseteq \Omega \), open sets \( U_i \subseteq \mathbb{R}^{n-1} \) for some \( k \), and open intervals, \((a_i, b_i)\) containing 0 such that for \( i \geq 1 \),

\[
\partial \Omega \cap W_i = \{ \mathbf{x}_k + \phi_i (\mathbf{x}_k) \mathbf{e}_k : \mathbf{x}_k \in U_i \},
\]

\[
\Omega \cap W_i = \{ \mathbf{x}_k + (\phi_i (\mathbf{x}_k) + x_k) \mathbf{e}_k : (\mathbf{x}_k, x_k) \in U_i \times I_i \},
\]

where \( \phi_i \) is Lipschitz with partial derivatives up to order \( m \) also Lipschitz. Here \( I_i = (a_i, 0) \) or \( (0, b_i) \). The case of \((a_i, 0)\) is shown in the picture.

Assume \( \Omega \) is \( C^{m-1,1} \). Define

\[
h_i (\mathbf{x}_k) = \mathbf{x}_k + \phi_i (\mathbf{x}_k) \mathbf{e}_k, H_i (\mathbf{x}) \equiv \mathbf{x}_k + (\phi_i (\mathbf{x}_k) + x_k) \mathbf{e}_k,
\]

and let \( \psi_i \in C^\infty (W_i) \) with \( \sum_{i=0}^l \psi_i (\mathbf{x}) = 1 \) on \( \overline{\Omega} \). Thus

\[
\{ W_i, \psi_i, \partial \Omega \cap W_i, U_i, h_i, H_i \}_{i=1}^l
\]

satisfies all the conditions for defining \( W^{s,p} (\partial \Omega) \) for \( s \leq m \). Let \( u \in C^\infty (\overline{\Omega}) \) and let \( h_i \) be as just described. The trace, denoted by \( \gamma \) is that operator which evaluates functions in \( C^\infty (\overline{\Omega}) \) on \( \partial \Omega \). Thus for \( u \in C^\infty (\overline{\Omega}) \), and \( y \in \partial \Omega \),

\[
u(y) = \sum_{i=1}^l (u \psi_i) (y)
\]

and so using the notation to suppress the reference to \( y \),

\[
\gamma u = \sum_{i=1}^l \gamma (u \psi_i)
\]

It is necessary to show this is a continuous map. Letting \( u \in W^{m,p} (\Omega) \), it follows from Theorem 43.4.3, and Theorem 36.0.14.

\[
\| \gamma u \|_{m-\frac{1}{p}, p, \partial \Omega} = \sum_{i=1}^l \| h_i^* (\gamma (\psi_i u)) \|_{m-\frac{1}{p}, p, U_i}
\]
44.2. THE TRACE ON THE BOUNDARY OF AN OPEN SET

\[ \sum_{i=1}^{l} \| h_i^* (\psi_i u) \|_{m-\frac{1}{p}, p, \mathbb{R}^{n-1}} \leq C \sum_{i=1}^{l} \| H_i^* (\psi_i u) \|_{m, p, \mathbb{R}^n} \]

\[ \leq C \sum_{i=1}^{l} \| H_i^* (\psi_i u) \|_{m, p, U_i \cap \{a_i, 0\}} \leq C \sum_{i=1}^{l} \| (\psi_i u) \|_{m, p, W_i \cap \Omega} \]

\[ \leq C \sum_{i=1}^{l} \| (\psi_i u) \|_{m, p, \Omega} \leq C \sum_{i=1}^{l} \| u \|_{m, p, \Omega} \leq C \| u \|_{m, p, \Omega}. \]

Now use the density of \( C^\infty (\overline{\Omega}) \) in \( W^{m, p} (\Omega) \) to see that \( \gamma \) extends to a continuous linear map defined on \( W^{m, p} (\Omega) \) still called \( \gamma \) such that for all \( u \in W^{m, p} (\Omega) \),

\[ \| \gamma u \|_{m-\frac{1}{p}, p, \partial \Omega} \leq C \| u \|_{m, p, \Omega}. \] (44.2.3)

Also, it can be shown that \( \gamma \) maps \( W^{m, p} (\Omega) \) onto \( W^{m-\frac{1}{p}} (\partial \Omega) \). Let \( g \in W^{m-\frac{1}{p}} (\partial \Omega) \). By definition, this means

\[ h_i^* (\psi_i g) \in W^{m-\frac{1}{p}} (U_i), \] each \( i \)

and so, using a cutoff function, there exists \( w_i \in W^{m, p} (U_i \times I_i) \) such that

\[ \gamma w_i = h_i^* (\psi_i g) = h_i^* (\gamma \psi_i g) \]

Thus \( (H_i^{-1})^* w_i \in W^{mp} (\Omega \cap W_i) \). Let

\[ w \equiv \sum_{i=1}^{l} \psi_i (H_i^{-1})^* w_i \in W^{mp} (\Omega) \]

then

\[ \gamma w = \sum_{i=1}^{l} \gamma \psi_j (H_i^{-1})^* w_i = \sum_{i=1}^{l} \gamma \psi_j (H_i^{-1})^* \gamma w_i = \sum_{i=1}^{l} \gamma \psi_j (H_i^{-1})^* h_i^* (\gamma \psi_i g) = g \]

In addition to this, in the case where \( m = 1 \), Lemma [XXX] implies there exists a linear map, \( R \), from \( W^{1-\frac{1}{p}, p} (\partial \Omega) \) to \( W^{1, p} (\Omega) \) which has the property that \( \gamma R g = g \) for every \( g \in W^{1-\frac{1}{p}, p} (\partial \Omega) \). I show this now. Letting \( g \in W^{1-\frac{1}{p}, p} (\partial \Omega) \),

\[ g = \sum_{i=1}^{l} \psi_i g. \]

Then also,

\[ h_i^* (\psi_i g) \in W^{1-\frac{1}{p}, p} (\mathbb{R}^{n-1}) \]
if extended to equal 0 off $U_i$. From Lemma 43.2.1, there exists an extension of this to $W^{1,p}(\mathbb{R}^n)$. Without loss of generality, assume that $Rh_i^*(\psi_i g) \in W^{1,p}(U_i \times (a_i, 0))$. If not so, multiply by a suitable cut off function in the definition of $R$. Then the extension is

$$Rg = \sum_{i=1}^l \left(H_i^{-1}\right)^* Rh_i^*(\psi_i g).$$

This works because from the definition of $\gamma$ on $C^\infty(\overline{\Omega})$ and continuity of the map established above, $\gamma$ and $(H_i^{-1})^*$ commute and so

$$\gamma Rg = \sum_{i=1}^l \gamma (H_i^{-1})^* Rh_i^*(\psi_i g)$$

$$= \sum_{i=1}^l \left(H_i^{-1}\right)^* \gamma Rh_i^*(\psi_i g)$$

$$= \sum_{i=1}^l \left(H_i^{-1}\right)^* h_i^*(\psi_i g) = g.$$

This proves the following theorem about the trace.

**Theorem 44.2.2** Let $\Omega \in C^{m-1,1}$. Then there exists a constant, $C$ independent of $u \in W^{m,p}(\Omega)$ and a continuous linear map, $\gamma : W^{m,p}(\Omega) \to W^{m-\frac{1}{p},p}(\partial \Omega)$ such that $L_{4.2.2}$ holds. This map satisfies $\gamma u(x) = u(x)$ for all $u \in C^\infty(\overline{\Omega})$ and $\gamma$ is onto. In the case where $m = 1$, there exists a continuous linear map, $R : W^{1,\frac{n}{n-1}p}(\partial \Omega) \to W^{1,p}(\Omega)$ which has the property that $\gamma Rg = g$ for all $g \in W^{1,\frac{n}{n-1}p}(\partial \Omega)$.

Of course more can be proved but this is all to be presented here.
Part IV

Multifunctions
Chapter 45

The Yankov von Neumann Aumann theorem

The Yankov von Neumann Aumann theorem deals with the projection of a product measurable set. It is a very difficult but interesting theorem. The material of this chapter is taken from [28], [29], [9], and [63]. We use the standard notation that for $S$ and $F$ $\sigma$ algebras, $S \times F$ is the $\sigma$ algebra generated by the measurable rectangles, the product measure $\sigma$ algebra. The next result is fairly easy and the proof is left for the reader.

**Lemma 45.0.1** Let $(X,d)$ be a metric space. Then if $d_1(x,y) = \frac{d(x,y)}{1+d(x,y)}$, it follows that $d_1$ is a metric on $X$ and the basis of open balls taken with respect to $d_1$ yields the same topology as the basis of open balls taken with respect to $d$.

**Theorem 45.0.2** Let $(X_i,d_i)$ denote a complete metric space and let $X = \prod_{i=1}^{\infty} X_i$. Then $X$ is also a complete metric space with the metric

$$
\rho(x,y) = \sum_{i=1}^{\infty} 2^{-i} \frac{d_i(x_i,y_i)}{1+d_i(x_i,y_i)}.
$$

Also, if $X_i$ is separable for each $i$ then so is $X$.

**Proof:** It is clear from the above lemma that $\rho$ is a metric on $X$. We need to verify $X$ is complete with this metric. Let $\{x^n\}$ be a Cauchy sequence in $X$. Then it is clear from the definition that $\{x^n_i\}$ is a Cauchy sequence for each $i$ and converges to $x_i \in X_i$. Therefore, letting $\varepsilon > 0$ be given, we choose $N$ such that

$$
\sum_{k=N}^{\infty} 2^{-k} < \frac{\varepsilon}{2},
$$

we choose $M$ large enough that for $n > M$,

$$
2^{-i} \frac{d_i(x^n_i,x_i)}{1+d_i(x^n_i,x_i)} < \frac{\varepsilon}{2(N+1)}
$$

1553
A complete separable metric space is called a polish space.

Let \( k \) accomplished by finding \( \varepsilon \) to the metric, \( \rho \).

Therefore, both \( B \) and each of \( D \) can see \( \varepsilon \) above theorem. Thus for \( m \):

\[
\exists \ v \in X \quad \text{such that} \quad \rho(x, m) < \varepsilon.
\]

Thus \( D \) is onto and continuous. Here \( \rho \) is very small. Therefore, obtaining \( D \) close to \( x \in X \) may be accomplished by finding \( d \in D \) such that \( d \) is close to \( x \) in the first \( k \) components for \( k \) large enough. Note that we do not use \( \prod_{k=1}^{\infty} D_k! \).

**Definition 45.0.3** A complete separable metric space is called a polish space.

**Theorem 45.0.4** Let \( X \) be a polish space. Then there exists \( f : \mathbb{N}^N \to X \) which is onto and continuous. Here \( \mathbb{N}^N \equiv \prod_{i=1}^{\infty} \mathbb{N} \) and a metric is given according to the above theorem. Thus for \( n, m \in \mathbb{N}^N \),

\[
\rho(n, m) = \sum_{i=1}^{\infty} 2^{-i} \frac{|n_i - m_i|}{1 + |n_i - m_i|}.
\]

**Proof:** Since \( X \) is polish, there exists a countable covering of \( X \) by closed sets having diameters no larger than \( 2^{-i} \), \( \{B(i)\}_{i=1}^{\infty} \). Each of these closed sets is also a polish space and so there exists a countable covering of \( B(i) \) by a countable collection of closed sets, \( \{B(i, j)\}_{j=1}^{\infty} \) each having diameter no larger than \( 2^{-2} \) where \( B(i, j) \subseteq B(i) \neq \emptyset \) for all \( j \). Continue this way. Thus

\[
B(n_1, n_2, \ldots, n_m) = \bigcup_{i=1}^{\infty} B(n_1, n_2, \ldots, n_m, i)
\]

and each of \( B(n_1, n_2, \ldots, n_m, i) \) is a closed set contained in \( B(n_1, n_2, \ldots, n_m) \) whose diameter is at most half of the diameter of \( B(n_1, n_2, \ldots, n_m) \). Now we define our mapping from \( \mathbb{N}^N \) to \( X \). If \( n = \{n_k\}_{k=1}^{\infty} \in \mathbb{N}^N \), we let \( f(n) \equiv \cap_{m=1}^{\infty} B(n_1, n_2, \ldots, n_m) \). Since the diameters of these sets converge to \( 0 \), there exists a unique point in this countable intersection and this is \( f(n) \).

We need to verify \( f \) is continuous. Let \( n \in \mathbb{N}^N \) be given and suppose \( m \) is very close to \( n \). The only way this can occur is for \( n_k \) to coincide with \( m_k \) for many \( k \). Therefore, both \( f(n) \) and \( f(m) \) must be contained in \( B(n_1, n_2, \ldots, n_m) \) for some fairly large \( m \). This implies, from the above construction that \( f(m) \) is as close to \( f(n) \) as \( 2^{-m} \), proving \( f \) is continuous. To see that \( f \) is onto, note that from the construction, if \( x \in X \), then \( x \in B(n_1, n_2, \ldots, n_m) \) for some choice of \( n_1 \), \( \ldots \), \( n_m \) for each \( m \). Note nothing is said about \( f \) being one to one. It probably is not one to one.
Definition 45.0.5 We call a topological space $X$ a Suslin space if $X$ is a Hausdorff space and there exists a polish space, $Z$ and a continuous function $f$ which maps $Z$ onto $X$.

$Z \xrightarrow{f \text{ onto}} X$

These Suslin spaces are also called analytic sets in some contexts but we will use the term Suslin space in referring to them.

Corollary 45.0.6 $X$ is a Suslin space, if and only if there exists a continuous mapping from $\mathbb{N}^\mathbb{N}$ onto $X$.

Proof: We know there exists a polish space $Z$ and a continuous function, $h : Z \to X$ which is onto. By the above theorem there exists a continuous map, $g : \mathbb{N}^\mathbb{N} \to Z$ which is onto. Then $h \circ g$ is a continuous map from $\mathbb{N}^\mathbb{N}$ onto $X$. The “if” part of this theorem is accomplished by noting that $\mathbb{N}^\mathbb{N}$ is a polish space.

Lemma 45.0.7 Let $X$ be a Suslin space and suppose $X_i$ is a subspace of $X$ which is also a Suslin space. Then $\bigcup_{i=1}^\infty X_i$ and $\bigcap_{i=1}^\infty X_i$ are also Suslin spaces. Also every Borel set in $X$ is a Suslin space.

Proof: Let $f_i : Z_i \to X_i$ where $Z_i$ is a polish space and $f_i$ is continuous and onto. Without loss of generality we may assume the spaces $Z_i$ are disjoint because if not, we could replace $Z_i$ with $Z_i \times \{i\}$. Now we define a metric, $\rho$, for $Z \equiv \bigcup_{i=1}^\infty Z_i$ as follows.

$$\rho(x, y) = 1 \text{ if } x \in Z_i, y \in Z_k, i \neq k$$

$$\rho(x, y) = \frac{d_i(x, y)}{1 + d_i(x, y)} \text{ if } x, y \in Z_i.$$  

Here $d_i$ is the metric on $Z_i$. It is easy to verify $\rho$ is a metric and that $(Z, \rho)$ is a polish space. Now we define $f : Z \to \bigcup_{i=1}^\infty X_i$ as follows. For $x \in Z_i$, $f(x) \equiv f_i(x)$. This is well defined because the $Z_i$ are disjoint. If $y$ is very close to $x$ it must be that $x$ and $y$ are in the same $Z_i$, otherwise this could not happen. Therefore, continuity of $f$ follows from continuity of $f_i$. This shows countable unions of Suslin subspaces of a Suslin space are Suslin spaces.

If $H \subseteq X$ is a closed subset, then, letting $f : Z \to X$ be onto and continuous, it follows $f : f^{-1}(H) \to H$ is onto and continuous. Since $f^{-1}(H)$ is closed, it follows $f^{-1}(H)$ is a polish space. Therefore, $H$ is a Suslin space.

Now we show countable intersections of Suslin spaces are Suslin. It is clear that $\theta : \prod_{i=1}^\infty Z_i \to \prod_{i=1}^\infty X_i$ given by $\theta(z) \equiv x = \{x_i\}$ where $x_i = f_i(z_i)$ is continuous and onto, this with respect to the usual product topology. Note that $\prod_{i=1}^\infty Z_i$ is a polish space because of the assumption that each $Z_i$ is and the above considerations. Therefore, $\prod_{i=1}^\infty X_i$ is a Suslin space. Now let $P \equiv \{y \in \prod_{i=1}^\infty f_i(Z_i) : y_i = y_j \text{ for all } i, j\}$ (This is how you get it on the intersection. I guess this must be the case where each $X_i \subseteq X$). Then $P$ is a closed subspace of a Suslin space and so it is Suslin. Then we define $h : P \to \bigcap_{i=1}^\infty X_i$ by $h(y) \equiv f_i(y_i)$. This shows $\bigcap_{i=1}^\infty X_i$ is Suslin because $h$ is continuous and onto.
(h ◦ θ : θ−1 (P) → ∩_{i=1}^{∞} X_i is continuous and θ−1 (P) being a closed subset of a polish space is polish.)

Next let U be an open subset of X. Then f−1 (U), being an open subset of a polish space, can be obtained as an increasing limit of closed sets, Kn. Therefore, U = ∪_{n=1}^{∞} f (Kn). Each f (Kn) is a Suslin space because it is the continuous image of a polish space, Kn. Therefore, by the first part of the lemma, U is a Suslin space. Now let

\[ F \equiv \{ E \subseteq X : \text{both } E^c \text{ and } E \text{ are Suslin} \} . \]

We see that F is closed with respect to taking complements. The first part of this lemma shows F is closed with respect to countable unions. Therefore, F is a σ algebra and so, since it contains the open sets, must contain the Borel sets.

It turns out that Suslin spaces tend to be measurable sets. In order to develop this idea, we need a technical lemma.

**Lemma 45.0.8** Let (Ω, F, μ) be a measure space and denote by μ* the outer measure generated by μ. Thus

\[ μ^*(S) \equiv \inf \{ μ(E) : E \supseteq S, E \in F \} . \]

Then μ* is regular, meaning that for every S, there exists E ∈ F such that E ⊇ S and μ (E) = μ* (S). If Sn ↑ S, it follows that μ* (Sn) ↑ μ* (S). Also if μ (Ω) < ∞, then a set, E is measurable if and only if

\[ μ^*(Ω) \geq μ^*(E) + μ^*(Ω \setminus E) . \]

**Proof:** First we verify that μ* is regular. If μ* (S) = ∞, let E = Ω. Then μ* (S) = μ (E) and E ⊇ S. On the other hand, if μ* (S) < ∞, then we can obtain En ∈ F such that μ* (S) + \frac{1}{n} ≥ μ (En) and En ⊇ S. Now let Fn = \cap_{i=1}^{n} Ei. Then Fn ⊇ S and so μ* (S) + \frac{1}{n} ≥ μ (Fn) ≥ μ* (S). Therefore, letting F = \cap_{k=1}^{∞} Fk ∈ F it follows μ (F) = \lim_{n \to ∞} μ (Fn) = μ* (S).

Let En ⊇ Sn be such that En ∈ F and μ (En) = μ* (Sn). Also let E∞ ⊇ S such that μ (E∞) = μ* (S) and E∞ ∈ F. Now consider Bn = \bigcup_{k=1}^{n} Ek. We claim

\[ μ (B_n) = μ (S_n) \]  \hspace{1cm} (45.0.1)

Here is why:

\[ μ (E_1 \setminus E_2) = μ (E_1) - μ (E_1 \cap E_2) = μ^* (S_1) - μ^* (S_1) = 0 . \]

Therefore,

\[ μ (B_2) = μ (E_1 \cup E_2) = μ (E_1 \setminus E_2) + μ (E_2) = μ (E_2) = μ^* (S_2) . \]

Continuing in this way we see that (45.0.1) holds. Now let B_n \cap E∞ = C_n. Then C_n ↑ C = \bigcup_{k=1}^{∞} C_n ∈ F and μ (C_n) = μ* (Sn). Since Sn ↑ S and each C_n ⊇ S_n, it follows C ⊇ S and therefore,

\[ μ^* (S) \leq μ (C) = \lim_{n \to ∞} μ (C_n) = \lim_{n \to ∞} μ^* (S_n) \leq μ^* (S) . \]
Now we verify the second claim of the lemma. It is clear the formula holds whenever $E$ is measurable. Suppose now that the formula holds. Let $S$ be an arbitrary set. We need to verify that

$$
\mu^*(S) \geq \mu^*(S \cap E) + \mu^*(S \setminus E).
$$

Let $F \supseteq S$, $F \in \mathcal{F}$, and $\mu(F) = \mu^*(S)$. Then since $\mu^*$ is subadditive,

$$
\mu^*(\Omega \setminus F) \leq \mu^*(E \setminus F) + \mu^*(\Omega \cap E^C \cap F^C).
$$

(45.0.2)

Since $F$ is measurable,

$$
\mu^*(E) = \mu^*(E \cap F) + \mu^*(E \setminus F)
$$

(45.0.3)

and

$$
\mu^*(\Omega \setminus E) = \mu^*(F \setminus E) + \mu^*(\Omega \cap E^C \cap F^C)
$$

(45.0.4)

and by the hypothesis,

$$
\mu^*(\Omega) \geq \mu^*(E) + \mu^*(\Omega \setminus E).
$$

(45.0.5)

Therefore,

$$
\mu(\Omega) \geq \mu^*(E) + \mu^*(\Omega \setminus E)
$$

$$
= \mu^*(E \cap F) + \mu^*(E \setminus F) + \mu^*(\Omega \setminus E)
$$

$$
= \mu^*(E \cap F) + \mu^*(E \setminus F) + \mu^*(F \setminus E) + \mu^*(\Omega \cap E^C \cap F^C)
$$

$$
\geq \mu^*(\Omega \setminus F) + \mu^*(F \setminus E) + \mu^*(E \cap F)
$$

$$
\geq \mu^*(\Omega \setminus F) + \mu^*(F) = \mu(\Omega)
$$

showing that all the inequalities must be equal signs. Hence, referring to the top and fourth lines above,

$$
\mu(\Omega) = \mu^*(\Omega \setminus F) + \mu^*(F \setminus E) + \mu^*(E \cap F).
$$

Subtracting $\mu^*(\Omega \setminus F) = \mu(\Omega \setminus F)$ from both sides gives

$$
\mu^*(S) = \mu(F) = \mu^*(F \setminus E) + \mu^*(E \cap F) \geq \mu^*(S \setminus E) + \mu^*(E \cap S),
$$

This proves the lemma.

The next theorem is a major result. It states that the Suslin subsets are measurable under appropriate conditions. This is sort of interesting because something being a Suslin subset has to do with topology and this topological condition implies that the set is measurable.

**Theorem 45.0.9** Let $\Omega$ be a metric space and let $(\Omega, \mathcal{F}, \mu)$ be a complete Borel measure space with $\mu(\Omega) < \infty$. Denote by $\mu^*$ the outer measure generated by $\mu$. Then if $A$ is a Suslin subset of $\Omega$, it follows that $A$ is $\mu^*$ measurable. Since the original measure space is complete, it follows that the completion produces nothing new and so in fact $A$ is in $\mathcal{F}$. See Proposition [10.1.5].
**Proof:** We need to verify that

\[ \mu^* (\Omega) \geq \mu^* (A) + \mu^* (\Omega \setminus A). \]

We know from Corollary 45.0.6, there exists a continuous map, \( f : \mathbb{N}^\mathbb{N} \to A \) which is onto. Let

\[ E (k) = \{ n \in \mathbb{N}^\mathbb{N} : n_1 \leq k \}. \]

Then \( E (k) \uparrow \mathbb{N}^\mathbb{N} \) and so from Lemma 45.0.8 we know \( \mu^* (f (E (k))) \uparrow \mu^* (A) \). Therefore, there exists \( m_1 \) such that

\[ \mu^* (f (E (m_1))) > \mu^* (A) - \frac{\varepsilon}{2}. \]

Now \( E (k) \) is clearly not compact but it is trying to be as far as the first component is concerned. Now we let

\[ E (m_1, k) = \{ n \in \mathbb{N}^\mathbb{N} : n_1 \leq m_1 \text{ and } n_2 \leq k \}. \]

Thus \( E (m_1, k) \uparrow E (m_1) \) and so we can pick \( m_2 \) such that

\[ \mu^* (f (E (m_1, m_2))) > \mu^* (f (E (m_1))) - \frac{\varepsilon}{2^2}. \]

We continue in this way obtaining a decreasing list of sets, \( f (E (m_1, m_2, \ldots, m_{k-1}, m_k)) \), such that

\[ \mu^* (f (E (m_1, m_2, \ldots, m_{k-1}, m_k))) > \mu^* (f (E (m_1, m_2, \ldots, m_{k-1}))) - \frac{\varepsilon}{2^k}. \]

Therefore,

\[ \mu^* (f (E (m_1, m_2, \ldots, m_{k-1}, m_k))) - \mu^* (A) > \sum_{l=1}^{k} - \left( \frac{\varepsilon}{2^l} \right) > -\varepsilon. \]

Now define a closed set,

\[ C = \bigcap_{k=1}^{\infty} f (E (m_1, m_2, \ldots, m_{k-1}, m_k)). \]

The sets \( f (E (m_1, m_2, \ldots, m_{k-1}, m_k)) \) are decreasing as \( k \to \infty \) and so

\[ \mu^* (C) = \lim_{k \to \infty} \mu^* (f (E (m_1, m_2, \ldots, m_{k-1}, m_k))) \geq \mu^* (A) - \varepsilon. \]

We wish to verify that \( C \subseteq A \). If we can do this we will be done because \( C \), being a closed set, is measurable and so

\[ \mu^* (\Omega) = \mu^* (C) + \mu^* (\Omega \setminus C) \geq \mu^* (A) - \varepsilon + \mu^* (\Omega \setminus A). \]

Since \( \varepsilon \) is arbitrary, this will conclude the proof. Therefore, we only need to verify that \( C \subseteq A \).
What we know is that each \( f \left( E (m_1, m_2, \cdots, m_k, m_k) \right) \) is contained in \( A \). We do not know their closures are contained in \( A \). We let \( m \equiv \{ m_i \}_{i=1}^\infty \) where the \( m_i \) are defined above. Then letting

\[
K \equiv \{ n \in \mathbb{N}^\mathbb{N} : n_i \leq m_i \text{ for all } i \},
\]

we see that \( K \) is a closed, hence complete subset of \( \mathbb{N}^\mathbb{N} \) which is also totally bounded due to the definition of the distance. Therefore, \( K \) is compact and so \( f (K) \) is also compact, hence closed due to the assumption that \( \Omega \) is a Hausdorff space and we know that \( f (K) \subseteq A \). We know \( f (K) \subseteq C \). Suppose therefore, \( p \in C \). From the definition of \( C \), we know there exists \( r^k \in E (m_1, m_2, \cdots, m_k, m_k) \) such that \( d \left( f \left( r^k \right), p \right) < \frac{1}{2^k} \). Denote by \( \tilde{r}^k \) the element of \( \mathbb{N}^\mathbb{N} \) which consists of modifying \( r^k \) by taking all components after the \( k \)-th equal to one. Thus \( \tilde{r}^k \in K \). Now \( \{ \tilde{r}^k \} \) is in a compact set and so taking a subsequence we can have \( \tilde{r}^k \to r \in K \). But from the metric on \( \mathbb{N}^\mathbb{N} \), it follows that \( \rho \left( \tilde{r}^k, r^k \right) < \frac{1}{2^{k-1}} \). Therefore, \( r^k \to r \) also and so \( f \left( r^k \right) \to f (r) = p \). Therefore, \( p \in f (K) \) and this proves the theorem.

Note we could have proved this under weaker assumptions. If we had assumed only that every point has a countable basis (first axiom of countability) and \( \Omega \) is Hausdorff, the same argument would work. We will need the following definition.

**Definition 45.0.10** Let \( F \) be a \( \sigma \)-algebra of sets from \( \Omega \) and let \( \mu \) denote a finite measure defined on \( F \). We let \( F_\mu \) denote the completion of \( F \) with respect to \( \mu \). Thus we let \( \mu^* \) be the outer measure determined by \( \mu \) and \( F_\mu \) will be the \( \sigma \)-algebra of \( \mu^* \)-measurable subsets of \( \Omega \). We also define \( \tilde{F} \) by

\[
\tilde{F} \equiv \cap \{ F_\mu : \mu \text{ is a finite measure defined on } F \}.
\]

Also, if \( X \) is a topological space, we will denote by \( B (X) \) the Borel sets of \( X \).

With this notation, we can give the following simple corollary of Theorem 45.0.9.

This is really quite amazing.

**Corollary 45.0.11** Let \( \Omega \) be a compact metric space and let \( A \) be a Suslin subset of \( \Omega \). Then \( A \in B (\tilde{\Omega}) \).

**Proof:** Let \( \mu \) be a finite measure defined on \( B (\Omega) \). By Theorem 45.0.9, \( A \in B (\tilde{\Omega}) \). Since this is true for every finite measure, \( \mu \), it follows \( A \in B (\tilde{\Omega}) \) as claimed. This proves the corollary.

We give another technical lemma about the completion of measure spaces.

**Lemma 45.0.12** Let \( \mu \) be a finite measure on a \( \sigma \)-algebra, \( \Sigma \). Then \( A \in \Sigma_\mu \) if and only if there exists \( A_1 \in \Sigma \) and \( N_1 \) such that \( A = A_1 \cup N_1 \) where there exists \( N \in \Sigma \) such that \( \mu (N) = 0 \) and \( N_1 \subseteq N \).
Let $\Omega$.

Lemma 45.0.14 to a very simple sort of measure space in which topology plays a significant role.

Definition 45.0.13 with $A$ separable if there exists a sequence $\{A_n\}$ such that $\sigma (\{A_n\}) \subseteq \Sigma$ and if $w \neq w'$, then there exists $A \in \Sigma$ such that $X_A (w) \neq X_A (w')$. This last condition is referred to by saying $\{A_n\}$ separates the points of $\Omega$. Given two measure spaces, $(\Omega, \Sigma)$ and $(\Omega', \Sigma')$, we say they are isomorphic if there exists a function, $f : \Omega \to \Omega'$ which is one to one and $f (E) \in \Sigma'$ whenever $E \in \Sigma$ and $f^{-1} (F) \in \Sigma$ whenever $F \in \Sigma'$.

The interesting thing about separable measure spaces is that they are isomorphic to a very simple sort of measure space in which topology plays a significant role.

Lemma 45.0.14 Let $(\Omega, \Sigma)$ be separable. Then there exists $E \in \{0, 1\}^N$ such that $(\Omega, \Sigma)$ and $(E, B (E))$ are isomorphic.

Proof: First we show $\{A_n\}$ separates the points. Here $\sigma (\{A_n\}) = \Sigma$. We already know $\Sigma$ separates the points but now we show the smaller set does so also.
If this is not so, there exists \( \omega, \omega_1 \in \Omega \) such that for all \( n \), \( \mathcal{X}_{A_n}(\omega) = \mathcal{X}_{A_n}(\omega_1) \).

Then let

\[
\mathcal{F} \equiv \{ F \in \Sigma : \mathcal{X}_F(\omega) = \mathcal{X}_F(\omega_1) \}
\]

Thus \( A_n \in \mathcal{F} \) for all \( n \). It is also clear that \( \mathcal{F} \) is a \( \sigma \)-algebra and so \( \mathcal{F} = \Sigma \) contradicting the assumption that \( \Sigma \) separates points. Now we define a function from \( \Omega \) to \( \{0, 1\}^\mathbb{N} \) as follows.

\[
f(\omega) \equiv \{ \mathcal{X}_{A_n}(\omega) \}_{n=1}^{\infty}
\]

We also let \( E \equiv f(\Omega) \). Since the \( \{A_n\} \) separate the points, we see that \( f \) is one to one. A subbasis for the topology of \( \{0, 1\}^\mathbb{N} \) consists of sets of the form \( \prod_{i=1}^\infty H_i \) where \( H_i = \{0, 1\} \) for all \( i \) except one, when \( i = j \) and \( H_j \) equals either \( \{0\} \) or \( \{1\} \).

Therefore, \( f^{-1}(\text{subbasic open set}) \in \Sigma \) because if \( H_j \) is the exceptional set then this equals \( A_j \) if \( H_j = \{1\} \) and \( A_j^c \) if \( H_j = \{0\} \). Intersections of these subbasic sets with \( E \) gives a countable subbasis for \( E \) and so the inverse image of all sets in a countable subbasis for \( E \) are in \( \Sigma \), showing that \( f^{-1}(\text{open set}) \in \Sigma \). Now we consider \( f(A_n) \).

\[
f(A_n) \equiv \{ \lambda_k \}_{k=1}^{\infty} : \lambda_n = 1 \} \cap E,
\]

an open set in \( E \). Hence \( f(A_n) \in B(E) \). Now letting

\[
\mathcal{F} \equiv \{ G \subseteq \Omega : f(G) \in B(E) \}.
\]

we see that \( \mathcal{F} \) is a \( \sigma \)-algebra which contains \( \{A_n\}_{n=1}^{\infty} \) and so \( \mathcal{F} \supseteq \sigma(\{A_n\}) \equiv \Sigma \). Thus \( f(F) \in B(E) \) for all \( A \in \Sigma \). This proves the lemma.

**Lemma 45.0.15** Let \( \phi : (\Omega_1, \Sigma_1) \to (\Omega_2, \Sigma_2) \) where \( \phi^{-1}(U) \in \Sigma_1 \) for all \( U \in \Sigma_2 \). Then if \( F \in \Sigma_2 \), it follows \( \phi^{-1}(F) \in \Sigma_1 \).

**Proof:** Let \( \mu \) be a finite measure on \( \Sigma_1 \) and define a measure \( \phi(\mu) \) on \( \Sigma_2 \) by the rule

\[
\phi(\mu)(F) \equiv \mu(\phi^{-1}(F)).
\]

Now let \( A \in \Sigma_{2\phi(\mu)} \). Then by Lemma [**LMAUX**], \( A = A_1 \cup N_1 \) where there exists \( N \in \Sigma_2 \) with \( \phi(\mu)(N) = 0 \) and \( A_1 \in \Sigma_2 \). Therefore, from the definition of \( \phi(\mu) \), we have \( \mu(\phi^{-1}(N)) = 0 \) and therefore, \( \phi^{-1}(A) = \phi^{-1}(A_1) \cup \phi^{-1}(N_1) \) where \( \phi^{-1}(N_1) \subseteq \phi^{-1}(N) \in \Sigma_1 \) and \( \mu(\phi^{-1}(N)) = 0 \). Therefore, \( \phi^{-1}(A) \in \Sigma_{1\mu} \) and so if \( F \in \Sigma_2 \), then

\[
F \in \cap \{ \Sigma_{2\nu} : \nu \text{ is a finite measure on } \Sigma_2 \} \subseteq \cap \{ \Sigma_{2\phi(\mu)} : \mu \text{ is a finite measure on } \Sigma_1 \},
\]

and so \( \phi^{-1}(F) \in \Sigma_{1\mu} \). Since \( \mu \) is arbitrary, this shows \( \phi^{-1}(F) \in \Sigma_1 \).

The next lemma is a special case of the Yankov von Neumann Aumann projection theorem. It contains the main idea of the proof of the more general theorem.

**Definition 45.0.16** Let \( (\Omega, \Sigma) \) be a measurable space and let \( G \in \Sigma \times B(X) \) the product measurable sets resulting from the Borel sets \( B(X) \) for \( X \) a Suslan space. Then

\[
\text{proj}_\Omega(G) \equiv \{ \omega \in \Omega : \text{there exists } x \in X \text{ with } (\omega, x) \in G \}
\]
What if you had $G = \cup \{ \omega \times A(\omega) : \omega \in \Omega \}$ where $A(\omega)$ is in $Y$ some polish space and $A(\omega)$ is, for example, a closed nonempty set? Then

$$\text{proj}_\Omega (G) = \{ \omega \in \Omega : A(\omega) \cap X \neq \emptyset \}$$

Of course, you might ask whether this particular $G$ is in $\Sigma \times B(X)$. For fixed $\omega$ the $\omega$ section is closed which is Borel. To say that $\text{proj}_\Omega (G) \in \Sigma$ would be to say that each $y$ section is in $\Sigma$ so this $G$ is in $\Sigma \times B(X)$ exactly when $\text{proj}_\Omega (G) \in \Sigma$. Later this will be defined as saying that $A$ is a measurable multifunction. It will be measurable when $X$ is open, strongly measurable when $X$ is closed.

**Lemma 45.0.17** Let $(\Omega, \Sigma)$ be separable and let $X$ be a Suslin space. Let $G \in \Sigma \times B(X)$. (Recall $\Sigma \times B(X)$ is the $\sigma$ algebra of product measurable sets, the smallest $\sigma$ algebra containing the measurable rectangles.) Then

$$\text{proj}_\Omega (G) \in \bar{\Sigma}.$$ 

**Proof:** Let $f : (\Omega, \Sigma) \to (E, B(E))$ be the isomorphism of Lemma 45.14. We have the following claim.

Claim: $f \times \text{id}_X$ maps $\Sigma \times B(X)$ to $B(E) \times B(X)$.

**Proof of the claim:** First of all, assume $A \times B$ is a measurable rectangle where $A \in \Sigma$ and $B \in B(X)$. Then by the assumption that $f$ is an isomorphism, $f(A) \in B(E)$ and so

$$f \times \text{id}_X (A \times B) \in B(E) \times B(X).$$

Now let

$$\mathcal{F} = \{ P \in \Sigma \times B(X) : f \times \text{id}_X (P) \in B(E) \times B(X) \}.$$

Then we see that $\mathcal{F}$ is a $\sigma$ algebra and contains the elementary sets. ($\mathcal{F}$ is closed with respect to complements because $f$ is one to one.) Therefore, $\mathcal{F} \subseteq \Sigma \times B(X)$ and this proves the claim.

Therefore, since $G \in \Sigma \times B(X)$, we see

$$f \times \text{id}_X (G) \in B(E) \times B(X) \subseteq B(E \times X).$$

The set inclusion follows from the observation that if $A \in B(E)$ and $B \in B(X)$ then $A \times B$ is in $B(E \times X)$ and the collection of sets in $B(E) \times B(X)$ which are in $B(E \times X)$ is a $\sigma$ algebra.

Therefore, there exists $D$, a Borel set in $E \times X$ such that $f \times \text{id}_X (G) = D \cap (E \times X)$. Now from this it follows from Lemma 16.14 that $D$ is a Suslin space. Letting $Y$ be $\{0,1\}^\mathbb{N}$, it follows that $\text{proj}_Y(D)$ is a Suslin space in $Y$. By Corollary 15.10, we see that $\text{proj}_Y(D) \in B(Y)$. Now

$$\text{proj}_\Omega (G) = \{ \omega \in \Omega : \text{there exists } x \in X \text{ with } (\omega, x) \in G \}$$

$$= \{ \omega \in \Omega : \text{there exists } x \in X \text{ with } (\omega, x) \in f \times \text{id}_X (G) \}$$
\[ f^{-1} (\{ y \in Y : \text{there exists } x \in X \text{ with } (y, x) \in D \}) \]
\[ = f^{-1} (\text{proj}_Y (D)) . \]

Now \( \text{proj}_Y (D) \in B(Y) \) and so Lemma 45.0.15 shows \( f^{-1} (\text{proj}_Y (D)) \in \tilde{\Sigma} \). This proves the lemma.

Now we are ready to prove the Yankov von Neumann Aumann projection theorem. First we must present another technical lemma.

**Lemma 45.0.18** Let \( X \) be a Hausdorff space and let \( G \in \Sigma \times B(X) \) where \( \Sigma \) is a \( \sigma \) algebra of sets of \( \Omega \). Then there exists \( \Sigma_0 \subseteq \Sigma \) a countably generated \( \sigma \) algebra such that \( G \in \Sigma_0 \times B(X) \).

**Proof:** First suppose \( G \) is a measurable rectangle, \( G = A \times B \) where \( A \in \Sigma \) and \( B \in B(X) \). Letting \( \Sigma_0 \) be the finite \( \sigma \) algebra, \( \{ \emptyset, A, A^c, \Omega \} \), we see that \( G \in \Sigma_0 \times B(X) \). Similarly, if \( G \) equals an elementary set, then the conclusion of the lemma holds for \( G \). Let

\[ \mathcal{F} = \{ H \in \Sigma \times B(X) : H \in \Sigma_0 \times B(X) \} \]

for some countably generated \( \sigma \) algebra, \( \Sigma_0 \). We just saw that \( \mathcal{F} \) contains the elementary sets. If \( H \in \mathcal{F} \), then \( H^c \in \Sigma_0 \times B(X) \) for the same \( \Sigma_0 \) and so \( \mathcal{F} \) is closed with respect to complements. Now suppose \( H_n \in \mathcal{F} \). Then for each \( n \), there exists a countably generated \( \sigma \) algebra, \( \Sigma_{0n} \) such that \( H_n \in \Sigma_{0n} \times B(X) \). Then

\[ \bigcup_{n=1}^\infty H_n \in \sigma (\{ \Sigma_{0n} \times B(X) \}) \]

We will be done when we show

\[ \sigma (\{ \Sigma_{0n} \times B(X) \}_{n=1}^\infty) \subseteq \sigma (\{ \Sigma_{0n} \}_{n=1}^\infty) \times B(X) \]

because it is clear that \( \sigma (\{ \Sigma_{0n} \}_{n=1}^\infty) \) is countably generated. We see that

\[ \sigma (\{ \Sigma_{0n} \times B(X) \}_{n=1}^\infty) \]

is generated by sets of the form \( A \times B \) where \( A \in \Sigma_{0n} \) and \( B \in B(X) \). But each such set is also contained in \( \sigma (\{ \Sigma_{0n} \}_{n=1}^\infty) \times B(X) \) and so the desired inclusion is obtained. Therefore, \( \mathcal{F} \) is a \( \sigma \) algebra and so since \( \mathcal{F} \) was shown to contain the measurable rectangles, this verifies \( \mathcal{F} = \Sigma \times B(X) \) and this proves the lemma.

**Theorem 45.0.19** Let \( (\Omega, \Sigma) \) be a measure space and let \( G \in \tilde{\Sigma} \times B(X) \) where \( X \) is a Suslin space. Then

\[ \text{proj}_{\Omega} (G) \in \tilde{\Sigma} . \]

**Proof:** By the previous lemma, \( G \in \Sigma_0 \times B(X) \) where \( \Sigma_0 \) is countably generated. If \( (\Omega, \Sigma_0) \) were separable, we could then apply Lemma 45.0.17 and be done. Unfortunately, we don’t know \( \Sigma_0 \) separates the points of \( \Omega \). Therefore, we define an equivalence class on the points of \( \Omega \) as follows. We say \( \omega \sim \omega_1 \) if and only if \( \mathcal{X}_A (\omega) = \mathcal{X}_A (\omega_1) \) for all \( A \in \Sigma_0 \). Now the nice thing to notice about this equivalence relation is that if \( \omega \in A \in \Sigma_0 \), and if \( \omega \sim \omega_1 \), then \( 1 = \mathcal{X}_A (\omega) = \mathcal{X}_A (\omega_1) \) implying \( \omega_1 \in A \) also. Therefore, every set of \( \Sigma_0 \) is the union of equivalence classes.
It follows that for $A \in \Sigma_0$, and $\pi$ the map given by $\pi \omega = [\omega]$ where $[\omega]$ is the equivalence class determined by $\omega$,

$$\pi (A) \cap \pi (\Omega \setminus A) = \emptyset.$$  

Suppose now that $H_n \in \Sigma_0 \times B(X)$. If $([\omega], x) \in \cap_{n=1}^{\infty} \pi \times \text{id}_X (H_n)$, then for each $n$,

$$([\omega], x) = (\pi w_n, x)$$

for some $(\omega_n, x) \in H_n$. But this implies $\omega \sim \omega_n$ and so from the above observation that the sets of $\Sigma_0$ are unions of equivalence classes, it follows that $(\omega, x) \in H_n$. Therefore, $([\omega], x) \in \cap_{n=1}^{\infty} H_n$ and so $([\omega], x) = \pi \times \text{id}_X (\omega, x)$ where $(\omega, x) \in \cap_{n=1}^{\infty} H_n$. This shows that

$$\pi \times \text{id}_X (\cap_{n=1}^{\infty} H_n) \supseteq \cap_{n=1}^{\infty} \pi \times \text{id}_X (H_n).$$

In fact these two sets are equal because the other inclusion is obvious. We will denote by $\Omega_1$ the set of equivalence classes and $\Sigma_1$ will be the subsets, $S_1$, of $\Omega_1$ such that $S_1 = \{[\omega] : \omega \in S \in \Sigma_0\}$. Then $(\Omega_1, \Sigma_1)$ is clearly a measure space which is separable. Let

$$\mathcal{F} \equiv \left\{ H \in \Sigma_0 \times B(X) : \pi \times \text{id}_X (H), \pi \times \text{id}_X (H^C) \in \Sigma_1 \times B(X) \right\}.$$  

We see that the measurable rectangles, $A \times B$ where $A \in \Sigma_0$ and $B \in B(X)$ are in $\mathcal{F}$, that from the above observation on countable intersections, $\mathcal{F}$ is closed with respect to countable unions and closed with respect to complements. Therefore, $\mathcal{F}$ is a $\sigma$ algebra and so $\mathcal{F} = \Sigma_0 \times B(X)$. By Lemma 45.0.14 $(\Omega_1, \Sigma_1)$ is isomorphic to $(E, B(E))$ where $E$ is a subspace of $\{0,1\}^N$. Denoting the isomorphism by $h$, it follows as in Lemma 45.0.17 that $h \times \text{id}_X$ maps $\Sigma_1 \times B(X)$ to $B(E) \times B(X)$. Therefore, we see $f \equiv h \circ \pi$ is a mapping from $\Omega$ to $E$ which has the property that $f \times \text{id}_X$ maps $\Sigma_0 \times B(X)$ to $B(E) \times B(X)$. Now from the proof of Lemma 45.0.17 starting with the claim, we see that $G \in \widehat{\Sigma}_0$. However, if $\mu$ is a finite measure on $\widehat{\Sigma}$, then $\widehat{\Sigma}_0 = \Sigma_\mu$ and so $\widehat{\Sigma}_0 \subseteq \widehat{\Sigma} \subseteq \widehat{\Lambda}$. This proves the theorem.
Chapter 46

Multifunctions And Their Measurability

46.1 The General Case

Let $X$ be a separable complete metric space and let $(\Omega, \mathcal{C}, \mu)$ be a set, a $\sigma$ algebra of subsets of $\Omega$, and a measure $\mu$ such that this is a complete $\sigma$ finite measure space. Also let $\Gamma : \Omega \rightarrow \mathcal{P}_F(X)$, the closed subsets of $X$.

**Definition 46.1.1** We define $\Gamma^-(S) \equiv \{\omega \in \Omega : \Gamma(\omega) \cap S \neq \emptyset\}$

We will consider a theory of measurability of set valued functions. The following theorem is the main result in the subject. In this theorem the third condition is what we will refer to as measurable.

**Theorem 46.1.2** The following are equivalent in case of a complete $\sigma$ finite measure space. However 3 and 4 are equivalent for any measurable space consisting only of a set $\Omega$ and a $\sigma$ algebra $\mathcal{C}$.

1. For all $B$ a Borel set in $X$, $\Gamma^-(B) \in \mathcal{C}$.
2. For all $F$ closed in $X$, $\Gamma^-(F) \in \mathcal{C}$
3. For all $U$ open in $X$, $\Gamma^-(U) \in \mathcal{C}$
4. There exists a sequence, $\{\sigma_n\}$ of measurable functions satisfying $\sigma_n(\omega) \in \Gamma(\omega)$ such that for all $\omega \in \Omega$,

$$\Gamma(\omega) = \{\sigma_n(\omega) : n \in \mathbb{N}\}$$

These functions are called measurable selections.
5. For all $x \in X$, $\omega \rightarrow \text{dist}(x, \Gamma(\omega))$ is a measurable real valued function.
6. \( \mathcal{G}(\Gamma) \equiv \{(\omega, x) : x \in \Gamma(\omega)\} \subseteq C \times B(X) \).

**Proof:** It is obvious that 1.) \( \Rightarrow \) 2.). To see that 2.) \( \Rightarrow \) 3.) note that \( \Gamma^- (\bigcup_{i=1}^{\infty} F_i) = \bigcup_{i=1}^{\infty} \Gamma^- (F_i) \). Since any open set in \( X \) can be obtained as a countable union of closed sets, this implies 2.) \( \Rightarrow \) 3.).

Now we verify that 3.) \( \Rightarrow \) 4.). For convenience, drop the assumption that \( \Gamma(\omega) \) is closed in this part of the argument. It will just be set valued and satisfy the measurability condition. A measurable selection will be obtained in \( \Gamma(\omega) \). Let \( \{x_n\}_{n=1}^{\infty} \) be a countable dense subset of \( X \). For \( \omega \in \Omega \), let \( \psi_1(\omega) = x_n \) where \( n \) is the smallest integer such that \( \Gamma(\omega) \cap B(x_n, 1) \neq \emptyset \). Therefore, \( \psi_1(\omega) \) has countably many values, \( x_{n_1}, x_{n_2}, \cdots \) where \( n_1 < n_2 < \cdots \). Now

\[
\{\omega : \psi_1 = x_n\} = \{\omega : \Gamma(\omega) \cap B(x_n, 1) \neq \emptyset\} \cap \Omega \setminus \bigcup_{k<n} \{\omega : \Gamma(\omega) \cap B(x_k, 1) \neq \emptyset\} \in \mathcal{C}.
\]

Thus we see that \( \psi_1 \) is measurable and \( \text{dist}(\psi_1(\omega), \Gamma(\omega)) < 1 \). Let

\[ \Omega_n \equiv \{\omega \in \Omega : \psi_1(\omega) = x_n\}. \]

Then \( \Omega_n \in \mathcal{C} \) and \( \Omega_n \cap \Omega_m = \emptyset \) for \( n \neq m \) and \( \bigcup_{n=1}^{\infty} \Omega_n = \Omega \). Let

\[ D_n \equiv \{x_k : x_k \in B(x_n, 1)\}. \]

Now for each \( n \), \( \omega \in \Omega_n \), let \( \psi_2(\omega) = x_k \) where \( k \) is the smallest index such that \( x_k \in D_n \) and \( B(x_k, \frac{1}{2}) \cap \Gamma(\omega) \neq \emptyset \). Thus \( \text{dist}(\psi_2(\omega), \Gamma(\omega)) < \frac{1}{2} \) and

\[ d(\psi_2(\omega), \psi_1(\omega)) < 1. \]

Continue this way obtaining \( \psi_k \) a measurable function such that

\[ \text{dist}(\psi_k(\omega), \Gamma(\omega)) < \frac{1}{2^{k-1}}, d(\psi_k(\omega), \psi_{k+1}(\omega)) < \frac{1}{2^{k-2}}. \]

Then for each \( \omega \), \( \{\psi_k(\omega)\} \) is a Cauchy sequence converging to a point, \( \sigma(\omega) \in \overline{\Gamma(\omega)} \).

This has shown that if \( \Gamma \) is measurable, there exists a measurable selection, \( \sigma(\omega) \in \overline{\Gamma(\omega)} \). Of course, if \( \Gamma(\omega) \) is closed, then \( \sigma(\omega) \in \Gamma(\omega) \). Note that this had nothing to do with the measure. It remains to show there exists a sequence of these measurable selections \( \sigma_n \) such that the conclusion of 4.) holds. To do this we define for \( \Gamma(\omega) \) closed and measurable,

\[ \Gamma_{ni}(\omega) \equiv \begin{cases} \Gamma(\omega) \cap B(x_n, 2^{-i}) & \text{if } \Gamma(\omega) \cap B(x_n, 2^{-i}) \neq \emptyset \\ \Gamma(\omega) & \text{otherwise.} \end{cases} \]

Thus

\[ \Gamma(\omega) \cap B(x_n, 2^{-i+1}) \subseteq \Gamma_{ni}(\omega) \subseteq \Gamma(\omega) \cap B(x_n, 2^{-i}) \]

First we show that \( \Gamma_{ni} \) is measurable. Let \( U \) be open. Then

\[ \{\omega : \Gamma_{ni}(\omega) \cap U \neq \emptyset\} = \{\omega : \Gamma(\omega) \cap B(x_n, 2^{-i}) \cap U \neq \emptyset\} \cup \]
46.1. THE GENERAL CASE

\[
\left\{ \omega : \Gamma (\omega) \cap B \left( x_n, 2^{-i} \right) = \emptyset \right\} \cap \left\{ \omega : \Gamma (\omega) \cap U \neq \emptyset \right\}
\]

\[
= \left\{ \omega : \Gamma (\omega) \cap B \left( x_n, 2^{-i} \right) \cap U \neq \emptyset \right\} \cup
\]

\[
\left( \Omega \setminus \left\{ \omega : \Gamma (\omega) \cap B \left( x_n, 2^{-i} \right) \neq \emptyset \right\} \right) \cap \left\{ \omega : \Gamma (\omega) \cap U \neq \emptyset \right\},
\]

a measurable set. By what was just shown, there exists \( \sigma_{ni} \), a measurable function such that \( \sigma_{ni} (\omega) \in \Gamma_{ni} (\omega) \subseteq \Gamma (\omega) \) for all \( \omega \in \Omega \). If \( x \in \Gamma (\omega) \), then

\[
x \in \overline{B \left( x_n, 2^{-i+2} \right)}
\]

whenever \( x_n \) is close enough to \( x \). Thus both \( x, \sigma_{ni+2} (\omega) \) are in \( B \left( x_n, 2^{-i+2} \right) \) and so \( |\sigma_{ni+1} (\omega) - x| < 2^{-i} \). It follows that condition 4.) holds. Note that this had nothing to do with the measure.

Now we verify that 4.) \( \Rightarrow \) 3.). Suppose there exist measurable selections \( \sigma_n (\omega) \in \Gamma (\omega) \) satisfying condition 4.). Let \( U \) be open. Then

\[
\left\{ \omega : \Gamma (\omega) \cap U \neq \emptyset \right\} = \bigcup_{n=1}^{\infty} \sigma_n^{-1} (U) \in \mathcal{C}.
\]

Now we verify that 4.) \( \Rightarrow \) 5.). Let \( F (\omega) = \text{dist} \left( x, \Gamma (\omega) \right) \). Then letting \( U \) be an open set in \([0, \infty)\), \( F (\omega) \in U \) if and only if \( d \left( x, \sigma_n (\omega) \right) \in U \) for some \( \sigma_n (\omega) \). Let

\[
h_n (\omega) = d \left( x, \sigma_n (\omega) \right).
\]

Then \( h_n \) is measurable and \( F^{-1} (U) = \bigcup_{n=1}^{\infty} h_n^{-1} (U) \in \mathcal{C} \). This shows that for all \( x \in X \), \( \omega \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) is measurable and this proves 5.).

Now we verify that 5.) \( \Rightarrow \) 4.). We know \( \text{dist} \left( x, \Gamma (\cdot) \right) \) is measurable and we show

\[
\left\{ \omega : \Gamma (\omega) \cap U \neq \emptyset \right\} \in \mathcal{C}
\]

whenever \( U \) is open and then use 3.) \( \Rightarrow \) 4.). Since \( X \) is separable, there exists \( B \left( x_i, r_i \right) \) such that \( U = \bigcup_{i=1}^{\infty} B \left( x_i, r_i \right) \). Then

\[
\left\{ \omega : \Gamma (\omega) \cap U \neq \emptyset \right\} = \bigcup_{i=1}^{\infty} \left\{ \omega : \Gamma (\omega) \cap B \left( x_i, r_i \right) \neq \emptyset \right\}
\]

\[
= \bigcup_{i=1}^{\infty} \left\{ \omega : \text{dist} \left( x_i, \Gamma (\omega) \right) < r_i \right\} \in \mathcal{C}.
\]

Therefore, 5.) \( \Rightarrow \) 4.) as claimed.

Now we must prove 5.) \( \Rightarrow \) 6.). We note that \( \omega \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) is measurable and \( x \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) is continuous. Also, the graph of \( \Gamma, \mathcal{G} (\Gamma) \) is given by

\[
\mathcal{G} (\Gamma) = \left\{ \left( \omega, x \right) : \text{dist} \left( x, \Gamma (\omega) \right) = 0 \right\}.
\]

We wish to show that \( (\omega, x) \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) is product measurable because then \( \mathcal{G} (\Gamma) \), being the inverse image of \( \{0\} \) will be product measurable. Let \( \{x_k\} \) be a countable dense set in \( X \) and let

\[
\phi_k (\omega, x) = \text{dist} \left( x_n, \Gamma (\omega) \right)
\]

where \( n \) is the first index such that \( x \in B \left( x_n, 2^{-k} \right) \). Then \( \phi_k (\omega, x) \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) due to the continuity of \( x \rightarrow \text{dist} \left( x, \Gamma (\omega) \right) \) and so we must argue that \( \phi_k \) is product measurable. On

\[
E_n = \Omega \times \left( B \left( x_n, 2^{-k} \right) \setminus \bigcup_{m<n} B \left( x_m, 2^{-k} \right) \right),
\]
The following are equivalent for any measurable space consisting
of a set $\Omega$ and a $\sigma$ algebra $\mathcal{C}$. Here nothing is known about $\Gamma(\omega)$ other than
that is a nonempty set.

1. For all $U$ open in $X$, $\Gamma^{-}(U) \in \mathcal{C}$
   \[ \Gamma^{-}(U) \equiv \{ \omega : \Gamma(\omega) \cap U \neq \emptyset \} \]

2. There exists a sequence, $\{\sigma_n\}$ of measurable functions satisfying $\sigma_n(\omega) \in \Gamma(\omega)$ such that for all $\omega \in \Omega$,
   \[ \Gamma(\omega) = \{ \sigma_n(\omega) : n \in \mathbb{N} \} \]
   These functions are called measurable selections.

Proof: First 1.) $\Rightarrow$ 2.). A measurable selection will be obtained in $\overline{\Gamma(\omega)}$. Let $\{x_n\}_{n=1}^{\infty}$ be a countable dense subset of $X$. For $\omega \in \Omega$, let $\psi_1(\omega) = x_n$ where $n$ is the smallest integer such that $\Gamma(\omega) \cap B(x_n, 1) \neq \emptyset$. Therefore, $\psi_1(\omega)$ has countably many values, $x_{n_1}, x_{n_2}, \ldots$ where $n_1 < n_2 < \cdots$. Now
   \[ \{ \omega : \psi_1 = x_n \} \]
   \[ \{ \omega : \Gamma(\omega) \cap B(x_n, 1) \neq \emptyset \} \cap [\Omega \setminus \bigcup_{k<n} \{ \omega : \Gamma(\omega) \cap B(x_k, 1) \neq \emptyset \}] \in \mathcal{C}. \]
   Thus we see that $\psi_1$ is measurable and $\text{dist}(\psi_1(\omega), \Gamma(\omega)) < 1$. Let
   \[ \Omega_n \equiv \{ \omega \in \Omega : \psi_1(\omega) = x_n \}. \]
   Then $\Omega_n \in \mathcal{C}$ and $\Omega_n \cap \Omega_m = \emptyset$ for $n \neq m$ and $\bigcup_{n=1}^{\infty} \Omega_n = \Omega$. Let
   \[ D_n \equiv \{ x_k : x_k \in B(x_n, 1) \}. \]
Now for each \( n \), and \( \omega \in \Omega_n \), let \( \psi_2 (\omega ) = x_k \) where \( k \) is the smallest index such that \( x_k \in D_n \) and \( B \ (x_k, \frac{1}{2}) \cap \Gamma (\omega) \neq \emptyset \). Thus \( \text{dist} (\psi_2 (\omega ), \Gamma (\omega)) < \frac{1}{2} \) and
\[
\text{dist} (\psi_2 (\omega ), \psi_1 (\omega)) < 1.
\]
Continue this way obtaining \( \psi_k \), a measurable function such that
\[
\text{dist} (\psi_k (\omega), \Gamma (\omega)) < \frac{1}{2^{k-1}}, \text{dist} (\psi_k (\omega), \psi_{k+1} (\omega)) < \frac{1}{2^{k-2}}.
\]
Then for each \( \omega \), \( \{ \psi_k (\omega) \} \) is a Cauchy sequence converging to a point, \( \sigma (\omega) \in \overline{\Gamma (\omega)} \).

This has shown that if \( \Gamma \) is measurable, there exists a measurable selection, \( \sigma (\omega) \in \overline{\Gamma (\omega)} \). Of course, if \( \Gamma (\omega) \) is closed, then \( \sigma (\omega) \in \Gamma (\omega) \). Note that this had nothing to do with a measure.

It remains to show there exists a sequence of these measurable selections \( \sigma_n \) such that the conclusion of 2.) holds. To do this we define
\[
\Gamma_{ni} (\omega) \equiv \begin{cases}
\Gamma (\omega) \cap B (x_n, 2^{-i}) & \text{if } \Gamma (\omega) \cap B (x_n, 2^{-i}) \neq \emptyset \\
\Gamma (\omega) & \text{otherwise}
\end{cases}
\]
First we show that \( \Gamma_{ni} \) is measurable. Let \( U \) be open. Then
\[
\{ \omega : \Gamma_{ni} (\omega) \cap U \neq \emptyset \} = \{ \omega : \Gamma (\omega) \cap B (x_n, 2^{-i}) \cap U \neq \emptyset \} \cup
\[
\{ \omega : \Gamma (\omega) \cap B (x_n, 2^{-i}) = \emptyset \} \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}
\]
\[
= \{ \omega : \Gamma (\omega) \cap B (x_n, 2^{-i}) \cap U \neq \emptyset \} \cup
\]
\[
\{ \omega : \Gamma (\omega) \cap B (x_n, 2^{-i}) = \emptyset \} \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}
\]
a measurable set. By what was just shown, there exists \( \sigma_{ni} \), a measurable function such that \( \sigma_{ni} (\omega) \in \Gamma_{ni} (\omega) \subseteq \Gamma (\omega) \) for all \( \omega \in \Omega \). If \( x \in \Gamma (\omega) \), then
\[
x \in B (x_n, 2^{-(i+2)})
\]
whenever \( x_n \) is close enough to \( x \). Thus both \( x, \sigma_{n(i+2)} (\omega) \) are in \( B (x_n, 2^{-(i+2)}) \) and so \( | \sigma_{n(i+1)} (\omega) - x | < 2^{-i} \). It follows that condition 2.) holds. Note that this had nothing to do with a measure.

Now consider why 2.) \( \Rightarrow \) 1.). We have \( \{ \sigma_n (\omega) \} \subseteq \Gamma (\omega) \) and \( \sigma_n \) is measurable and \( \cup_n \sigma_n (\omega) \) equals \( \Gamma (\omega) \). Why is \( \Gamma \) a measurable multifunction? Let \( U \) be an open set
\[
\Gamma^{-} (U) \equiv \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}
\]
\[
= \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}
\]
\[
= \cup_n \sigma_n^{-1} (U) \in \mathcal{C} \quad \square
\]

For much more on multifunctions, you should see the book by Hu and Papageorgiou. The above proof follows the presentation in this book.
46.1.1 A Special Case Which Is Easier

The above is a pretty long and difficult argument to show that $\Gamma^-(U) \in \mathcal{C}$ for all $U$ open is equivalent to $\Gamma^-(F)$ for all $F$ closed. However, there is a special case for which this is much easier to show. Suppose $\Gamma(\omega)$ is not just closed but is also compact. Then as above, if $\Gamma^-(F) \in \mathcal{C}$ for all $F$ closed, then $\Gamma^-(U) = \bigcup_n \Gamma^-(F_n)$ where $F_n$ is an increasing sequence of closed sets whose union is $U$. This follows from the observation that

$$\Gamma(\omega) \cap U = \bigcup_n \Gamma(\omega) \cap F_n$$

and so to say the set on the left is nonempty is to say that at least one of the sets on the right is nonempty. Thus if $\Gamma^-(F) \in \mathcal{C}$ for all $F$ closed, then $\Gamma^-(U) \in \mathcal{C}$ for all $U$ open. This requires no special considerations.

Now suppose $\Gamma(\omega)$ is compact for every $\omega$ and that $\Gamma^-(U) \in \mathcal{C}$ for every $U$ open. Then let $F$ be a closed set and let $\{U_n\}$ be a decreasing sequence of open sets whose intersection equals $F$ such that also, for all $n, U_n \supseteq \overline{U_{n+1}}$. Then

$$\Gamma(\omega) \cap F = \bigcap_n \Gamma(\omega) \cap U_n = \bigcap_n \Gamma(\omega) \cap \overline{U_n}$$

Now because of compactness, the set on the left is nonempty if and only if each set on the right is also nonempty. Thus $\Gamma^-(F) = \bigcap_n \Gamma^-(U_n) \in \mathcal{C}$. Thus in this special case, it is much easier to see that these two conditions for measurability are equivalent. Note that there is no condition on measures or completeness or any such thing. This proves the following proposition.

**Proposition 46.1.4** Let $X$ be a Polish space and let $\Gamma : X \to \mathcal{P}(X)$ have compact values. Then $\Gamma$ is measurable if and only if it is strongly measurable, the latter being the statement that $\Gamma^-(C)$ is measurable whenever $C$ is closed.

Let $\Gamma$ be strongly measurable. Let $\mathcal{G}$ be the sets $G$ such that $\Gamma^-(G)$ and $\Gamma^-(G^C)$ are both in $\mathcal{C}$. Then clearly $\mathcal{G}$ is closed with respect to complements. If $G \in \mathcal{G}$ is $G^C$? Is $\Gamma^-(G^C)$ and $\Gamma^-(G^C)^C$ in $\mathcal{C}$? I guess this is just the definition of what it means to be in $\mathcal{G}$. Also if you have $\{G_i\} \subseteq \mathcal{G}$, Then

$$\Gamma^-(\bigcup_i G_i) = \bigcup_i \Gamma^-(G_i) \in \mathcal{C}$$

and so $\mathcal{G}$ is closed with respect to countable unions. Hence $\mathcal{G}$ must contain the Borel sets because the strong measurability implies that the closed sets and hence open sets are in $\mathcal{G}$. Thus $\Gamma^-(G) \in \mathcal{C}$ whenever $G$ is Borel.

46.1.2 Other Measurability Considerations

Here are some general considerations about measurable multifunctions.

**Lemma 46.1.5** Suppose $f : K \times \Omega \to X, K \subseteq X$. Here $X$ is Polish space, separable complete metric space, and $(\Omega, \mathcal{F})$ is a measurable space. Also suppose $\omega \to f(x, \omega)$ is measurable and $x \to f(x, \omega)$ is continuous. Also suppose that $K(\omega) := f(K, \omega)$ is a compact set for each $\omega$. Then you can conclude that $\omega \to K(\omega)$ is a strongly measurable multifunction.
**Proof:** Let \( \{ x_n \} \) be a countable dense subset of \( X \). Then if \( U \) is open,
\[
\{ \omega : \mathcal{K}(\omega) \cap U \neq \emptyset \} = \bigcup_{n=1}^{\infty} f(\{x_n, \cdot\})^{-1}(U)
\]
and each of the sets in the union is assumed to be measurable. The reason for the equality is as follows. It is clear that the right side is contained in the left. Now if \( \mathcal{K}(\omega) \cap U \neq \emptyset \), then by definition, \( f(x, \omega) \in U \) for some \( x \) but then by continuity, \( f(x_n, \omega) \in U \) also for some \( x_n \) close to \( x \). Thus the two sets are actually equal. \( \mathcal{K}(\omega) \) has compact values and is measurable so it will be strongly measurable. 

Then from standard results on measurable multifunctions, there is a countable dense \( \{ f(\{x_n, \omega\}, \omega) \} \) such that these are measurable functions of \( \omega \) and for each \( \omega \), this sequence of measurable selections is dense in \( \mathcal{K}(\omega) \).

This lemma gives an easy example of a measurable multifunction having compact values. In fact this is the one of most interest in what follows. However, we also have the following general result. It gives the existence of a measurable \( \varepsilon \) net. This is formulated in Banach space because it is convenient to add. It could also be formulated in Polish space with a little more difficulty. One just defines things a little differently.

**Proposition 46.1.6** Let \( \omega \to \mathcal{K}(\omega) \) be a measurable multifunction where \( \mathcal{K}(\omega) \) is a compact set. Then for each \( \varepsilon > 0 \), there exists \( N(\omega) \) and measurable functions \( y_j, j = 1, 2, \cdots, N(\omega), y_j(\omega) \in \mathcal{K}(\omega) \), such that
\[
\bigcup_{j=1}^{N} B(y_j(\omega), \varepsilon) \supseteq \mathcal{K}(\omega)
\]
for each \( \omega \). Also \( \omega \to N(\omega) \) is measurable.

**Proof:** Suppose that \( \omega \to \mathcal{K}(\omega) \) is a measurable multifunction having compact values in \( X \) a Banach space. Let \( \{ \sigma_n(\omega) \} \) be the measurable selections such that for each \( \omega, \{ \sigma_n(\omega) \}_{n=1}^{\infty} \) is dense in \( \mathcal{K}(\omega) \). Let \( y_1(\omega) := \sigma_1(\omega) \). Now let \( 2(\omega) \) be the first index after 1 such that \( \| \sigma_{2(\omega)}(\omega) - \sigma_1(\omega) \| > \frac{\varepsilon}{2} \). Thus \( 2(\omega) = k \) on the measurable set
\[
\left\{ \omega \in \Omega : \| \sigma_k(\omega) - \sigma_1(\omega) \| > \frac{\varepsilon}{2} \right\} \cap \left\{ \omega \in \Omega : \bigcap_{j=1}^{k-1} \| \sigma_j(\omega) - \sigma_1(\omega) \| \leq \frac{\varepsilon}{2} \right\}
\]
Suppose \( 1(\omega), 2(\omega), \cdots, (m-1)(\omega) \) have been chosen such that this is a strictly increasing sequence for each \( \omega \), each is a measurable function, and for \( i, j \leq m-1 \),
\[
\| \sigma_{i(\omega)}(\omega) - \sigma_{j(\omega)}(\omega) \| > \frac{\varepsilon}{2}.
\]
Each \( \omega \to \sigma_{i(\omega)}(\omega) \) is measurable because it equals
\[
\sum_{k=1}^{\infty} \chi_{[i(\omega) = k]}(\omega) \sigma_k(\omega).
\]
Then \( m(\omega) \) will be the first index larger than \( (m-1)(\omega) \) such that
\[
\| \sigma_{m(\omega)}(\omega) - \sigma_{j(\omega)}(\omega) \| > \frac{\varepsilon}{2}
\]
for all \( j(\omega) < m(\omega) \). Thus \( \omega \to m(\omega) \) is also measurable because it equals \( k \) on the measurable set
\[
\left( \cap \left\{ \omega : \| \sigma_k(\omega) - \sigma_{j(\omega)}(\omega) \| > \frac{\varepsilon}{2}, \ j \leq m - 1 \right\} \right) \cap \{ \omega : (m - 1)(\omega) < k \}
\]
\[
\cap \left( \cup \left\{ \omega : \| \sigma_{k-1}(\omega) - \sigma_{j(\omega)}(\omega) \| \leq \frac{\varepsilon}{2}, \ j \leq m - 1 \right\} \cup \{ \omega : (m - 1)(\omega) \geq k - 1 \} \right)
\]
The top line says it does what is wanted and the second says it is the first after \( (m - 1)(\omega) \) which does so. Since \( K(\omega) \) is a compact set, it follows that the above measurable set will be empty for all \( m(\omega) \) sufficiently large called \( N(\omega) \), also a measurable function, and so the process ends. Let \( y_i(\omega) := \sigma_i(\omega) \). Then this gives the desired measurable \( \varepsilon \) net. The fact that
\[
\bigcup_{i=1}^{N(\omega)} B(y_i(\omega), \varepsilon) \supseteq K(\omega)
\]
follows because if there exists \( z \in K(\omega) \setminus \left( \bigcup_{i=1}^{N(\omega)} B(y_i(\omega), \varepsilon) \right) \), then \( B(z, \frac{\varepsilon}{2}) \) would have empty intersection with all of the balls \( B(y_i(\omega), \frac{\varepsilon}{2}) \) and by density of the \( \sigma_i(\omega) \) in \( K(\omega) \), there would be some \( \sigma_l(\omega) \) contained in \( B(z, \frac{\varepsilon}{2}) \) for arbitrarily large \( l \) and so the process would not have ended as shown above. 

The existence of such measurable nets allows the generalization of Kuratowski’s theorem to the following. The proof goes the same way.

Recall the Kuratowski theorem. We can give a generalization to the following theorem in which \( E \) is replaced with \( E(\omega) \) where \( \omega \to E(\omega) \) is measurable.

**Theorem 46.1.7** Let \( E(\omega) \) be a compact metric space and let \((\Omega, \mathcal{F})\) be a measure space. Suppose \( \psi : E \times \Omega \to \mathbb{R} \) has the property that \( x \to \psi(x, \omega) \) is continuous and \( \omega \to \psi(x, \omega) \) is measurable. Then there exists a measurable function, \( f \) having values in \( E(\omega) \) such that
\[
\psi(f(\omega), \omega) = \sup_{x \in E} \psi(x, \omega).
\]
Furthermore, \( \omega \to \psi(f(\omega), \omega) \) is measurable.

**Proof:** Let \( C_1(\omega) \) be a \( 2^{-1} \) net of \( E(\omega) \). Suppose \( C_1, \cdots, C_m(\omega) \) is measurable have been chosen such that \( C_k(\omega) \) is a \( 2^{-k} \) net and \( C_{i+1}(\omega) \supseteq C_i(\omega) \) for all \( i \). Say \( C_i(\omega) = \{ y_i(\omega) \}_{i=1}^{r_i(\omega)} \) where \( \omega \to r_i(\omega) \) is measurable. That such exists follows from Proposition 10.15. Then consider \( E(\omega) \setminus \bigcup \{ B(x, 2^{-(m+1)}) : x \in C_m(\omega) \} \). If this set is empty, let \( C_{m+1}(\omega) = C_m(\omega) \). If it is nonempty, let \( \{ y_i(\omega) \}_{i=1}^{r(\omega)} \) be a \( 2^{-(m+1)} \) net for this compact set, \( r(\omega) \) measurable. Then let \( C_{m+1}(\omega) = C_m(\omega) \cup \{ y_i \}_{i=1}^{r(\omega)} \). It follows \( \{ C_m(\omega) \}_{m=1}^{\infty} \) satisfies \( C_m(\omega) \) is a \( 2^{-m} \) net and \( C_m(\omega) \subseteq C_{m+1}(\omega) \).

Let \( \{ x_k \}_{k=1}^{m(\omega)} \) equal \( C_1, \omega \to m(1, \omega) \) measurable. Let
\[
A_1^k = \left\{ \omega : \psi(x_k^1, \omega) = \max_k \psi(x_k^1, \omega) \right\}
\]
46.1. THE GENERAL CASE

For $\omega \in A_1^1$, define $s_1 (\omega) \equiv x_1^1$. Next let

$$\begin{align*}
A_1^1 &= \left\{ \omega \notin A_1^1 : \psi (x_2^1, \omega) = \max_k \psi (x_k^1, \omega) \right\}
\end{align*}$$

and let $s_1 (\omega) \equiv x_1^1$ on $A_1^1$. Continue in this way to obtain a simple function, $s_1$
such that

$$\psi (s_1 (\omega), \omega) = \max \{ \psi (x, \omega) : x \in C_1 (\omega) \}$$

and $s_1$ has values in $C_1 (\omega)$.

Suppose $s_1 (\omega), s_2 (\omega), \cdots, s_m (\omega)$ are simple functions with the property that
if $m > 1$,

$$d (s_k (\omega), s_{k+1} (\omega)) < 2^{-k},$$

$$\psi (s_k (\omega), \omega) = \max \{ \psi (x, \omega) : x \in C_k (\omega) \}$$

for each $k + 1 \leq m$, only the second and third assertions holding if $m = 1$. Letting
$C_m (\omega) = \{ x_k (\omega) \}_{k=1}^N (\omega)$, it follows $s_m (\omega)$ is of the form

$$s_m (\omega) = \sum_{k=1}^N x_k (\omega) \chi_{A_k} (\omega), \ A_i \cap A_j = \emptyset. \quad (46.1.1)$$

meaning that $s_m (\omega)$ has value $x_k (\omega)$ on $A_k$. Denote by $\{ y_{1i} (\omega) \}_{i=1}^{n_1 (\omega)}$
those points of $C_{m+1} (\omega)$ which are contained in $B (x_1 (\omega), 2^{-m})$. Letting $A_k$
play the role of $\Omega$ in the first step in which $s_1$ was constructed, for each $\omega \in A_1$
let $s_{m+1} (\omega)$ be a simple function which has one of the values $y_{1i}$ and satisfies

$$\psi (s_{m+1} (\omega), \omega) = \max_{i \leq n_1} \psi (y_{1i} (\omega), \omega)$$

for each $\omega \in A_1$. Next let $\{ y_{2i} (\omega) \}_{i=1}^{n_2 (\omega)}$ be those points of $C_{m+1} (\omega)$
different than $\{ y_{1i} (\omega) \}_{i=1}^{n_1 (\omega)}$ which are contained in $B (x_2 (\omega), 2^{-m})$. Then define $s_{m+1} (\omega)$ on $A_2$
to have values taken from $\{ y_{2i} (\omega) \}_{i=1}^{n_2 (\omega)}$ and

$$\psi (s_{m+1} (\omega), \omega) = \max_{i \leq n_2 (\omega)} \psi (y_{2i} (\omega), \omega)$$

for each $\omega \in A_2$. Continuing this way defines $s_{m+1}$ on all of $\Omega$ and it satisfies

$$d (s_m (\omega), s_{m+1} (\omega)) < 2^{-m} \text{ for all } \omega \in \Omega \quad (46.1.2)$$

It remains to verify

$$\psi (s_{m+1} (\omega), \omega) = \max \{ \psi (x, \omega) : x \in C_{m+1} (\omega) \}. \quad (46.1.3)$$

To see this is so, pick $\omega \in \Omega$. Let

$$\max \{ \psi (x, \omega) : x \in C_{m+1} (\omega) \} = \psi (y_{rj} (\omega), \omega) \quad (46.1.4)$$
where \( y_{rj}(\omega) \in \{ y_{ri}(\omega) \}_{i=1}^{n_r(\omega)} \subseteq C_{m+1}(\omega) \) and out of all the balls \( B(x_i(\omega), 2^{-m}) \), let the first one which contains \( y_{rj}(\omega) \) be \( B(x_k(\omega), 2^{-m}) \). Then by the construction, \( s_{m+1}(\omega) = y_{rj}(\omega) \) because \( \psi(y_{rj}(\omega), \omega) \) is at least as large as \( \psi(y_{kj}(\omega), \omega) \) for all the other \( y_{kj}(\omega) \). This and Proposition 46.1.3 verifies Proposition 46.1.2.

From Proposition 46.1.2 it follows \( s_m(\omega) \) converges uniformly on \( \Omega \) to a measurable function, \( f(\omega) \). Then from the construction, \( \psi(f(\omega), \omega) \geq \psi(s_m(\omega), \omega) \) for all \( m \) and \( \omega \). Now pick \( \omega \in \Omega \) and let \( z(\omega) \) be such that \( \psi(z(\omega), \omega) = \max_{x \in E(\omega)} \psi(x, \omega) \). Letting \( y_{k(\omega)}(\omega) \to z(\omega) \) where \( y_{k(\omega)}(\omega) \in C_k(\omega) \), it follows from continuity of \( \psi \) in the first argument that

\[
\max_{x \in E(\omega)} \psi(x, \omega) = \psi(z(\omega), \omega) = \lim_{k \to \infty} \psi(y_{k(\omega)}(\omega), \omega) \\
\leq \lim_{m \to \infty} \psi(s_m(\omega), \omega) = \psi(f(\omega), \omega) \leq \max_{x \in E} \psi(x, \omega).
\]

To show \( \omega \to \psi(f(\omega), \omega) \) is measurable, note that since \( E(\omega) \) is compact, there exists a countable dense subset, \( D(\omega) \) consisting of the union of measurable nets as in Proposition 46.1.6. Then using continuity of \( \psi \) in the first argument,

\[
\psi(f(\omega), \omega) = \sup_{x \in E(\omega)} \psi(x, \omega) \\
= \sup_{x \in D(\omega)} \psi(x, \omega)
\]

which equals a measurable function of \( \omega \) because \( D(\omega) \) is countable. 

### 46.2 Existence Of Measurable Fixed Points

#### 46.2.1 Simplices And Labeling

First define an \( n \) simplex, denoted by \([x_0, \ldots, x_n]\), to be the convex hull of the \( n+1 \) points, \( \{x_0, \ldots, x_n\} \) where \( \{x_i - x_0\}_{i=1}^{n} \) are independent. Thus

\[
[x_0, \ldots, x_n] = \left\{ \sum_{i=0}^{n} t_i x_i : \sum_{i=0}^{n} t_i = 1, \; t_i \geq 0 \right\}.
\]

Since \( \{x_i - x_0\}_{i=1}^{n} \) is independent, the \( t_i \) are uniquely determined. If two of them are

\[
\sum_{i=0}^{n} t_i x_i = \sum_{i=0}^{n} s_i x_i
\]

Then

\[
\sum_{i=0}^{n} t_i (x_i - x_0) = \sum_{i=0}^{n} s_i (x_i - x_0)
\]

so \( t_i = s_i \) for \( i \geq 1 \). Since the \( s_i \) and \( t_i \) sum to 1, it follows that also \( s_0 = t_0 \). If \( n \leq 2 \), the simplex is a triangle, line segment, or point. If \( n \leq 3 \), it is a
tetrahedron, triangle, line segment or point. To say that \( \{ x_i - x_0 \}_{i=1}^n \) are independent is to say that \( \{ x_i - x_r \}_{j \neq r} \) are independent for each fixed \( r \). Indeed, if \( x_i - x_r = \sum_{j \neq i, r} c_j (x_j - x_r) \), then you would have

\[
x_i - x_0 + x_0 - x_r = \sum_{j \neq i, r} c_j (x_j - x_0) + \left( \sum_{j \neq i, r} c_j \right) x_0
\]

and it follows that \( x_i - x_0 \) is a linear combination of the \( x_j - x_0 \) for \( j \neq i \), contrary to assumption.

A simplex \( S \) can be triangulated. This means it is the union of smaller sub-simplices such that if \( S_1, S_2 \) are two simplices in the triangulation, with

\[
S_1 \equiv [z_0^0, \ldots, z_m^0], \quad S_2 \equiv [z_0^1, \ldots, z_p^1]
\]

then

\[
S_1 \cap S_2 = [x_{k_0}, \ldots, x_{k_r}]
\]

where \( [x_{k_0}, \ldots, x_{k_r}] \) is in the triangulation and

\[
\{x_{k_0}, \ldots, x_{k_r}\} = \{z_0^1, \ldots, z_m^1\} \cap \{z_0^2, \ldots, z_p^2\}
\]

or else the two simplices do not intersect. Does there exist a triangulation in which all sub-simplices have diameter less than \( \varepsilon \)? This is obvious if \( n \leq 2 \). Supposing it to be true for \( n - 1 \), is it also so for \( n \)? The barycenter \( b \) of a simplex \([x_0, \ldots, x_n]\) is just \( \frac{1}{i=1} x_i \). This point is not in the convex hull of any of the faces, those simplices of the form \([x_0, \ldots, \hat{x}_k, \ldots, x_n]\) where the hat indicates \( x_k \) has been left out. Thus \([x_0, \ldots, b, \ldots, x_n]\) is a \( n \) simplex also. Now in general, if you have an \( n \) simplex \([x_0, \ldots, x_n]\), its diameter is the maximum of \( |x_k - x_i| \) for all \( k \neq l \). Consider \( |b - x_j| \). It equals \( \sum_{i=0}^n \frac{1}{n+1} (x_i - x_j) = \sum_{i \neq j} \frac{1}{n+1} (x_i - x_j) \leq \frac{n}{n+1} \text{diam}(S) \).

Next consider the \( k^{th} \) face of \( S = [x_0, \ldots, x_k, \ldots, x_n] \). By induction, it has a triangulation into simplices which each have diameter no more than \( \frac{n}{n+1} \text{diam}(S) \). Let these \( n - 1 \) simplices be denoted by \( \{ S_i^{k}, \ldots, S_i^{m_k} \} \). Then the simplices \( \{ [S_i^{k}, b] \}_{i=1}^{m_k, n+1} \) are a triangulation of \( S \) such that \( \text{diam}(S_i^{k}, b) \leq \frac{n}{n+1} \text{diam}(S) \). Do for \( S_i^{k}, b \) what was just done for \( S \) obtaining a triangulation of \( S \) as the union of what is obtained such that each simplex has diameter no more than \( \left( \frac{n}{n+1} \right)^2 \text{diam}(S) \). Continuing this way shows the existence of the desired triangulation.

### 46.2.2 Labeling Vertices

Next is a way to label the vertices. Let \( p_0, \ldots, p_n \) be the first \( n + 1 \) prime numbers. All vertices of a simplex \( S = [x_0, \ldots, x_n] \) having \( \{x_k - x_0\}_{k=1}^n \) independent will be labeled with one of these primes. In particular, the vertex \( x_k \) will be labeled as \( p_k \) if the simplex is \([x_0, \ldots, x_n]\). The value of a simplex will be the product of its labels. Triangulate this \( S \). Consider a 1 simplex coming from the original simplex
[\mathbf{x}_k, \mathbf{x}_n]$, label one end as $p_k$, and the other as $p_{k+1}$. Then label all other vertices of this triangulation which occur on $[\mathbf{x}_k, \mathbf{x}_n]$ either $p_k$, or $p_{k+1}$. Then obviously there will be an odd number of simplices in this triangulation having value $p_k p_{k+1}$, that is a $p_k$ at one end and a $p_{k+1}$ at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on $[\mathbf{x}_j, \mathbf{x}_{j+1}]$, 

$$\{\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}\} \subseteq \{\mathbf{x}_0, \ldots, \mathbf{x}_n\}$$

any $k$ simplex for $k \leq n-1$, and there is an odd number of simplices from the triangulation having value equal to $\prod_{i=1}^{k+1} p_{i,j}$. Consider $\hat{S} = [\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}, \mathbf{x}_{j+2}]$. Then by induction, there is an odd number of $k$ simplices on the $k^{th}$ face $[\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}, \mathbf{x}_{j+2}]$ having value $\prod_{i \notin S} p_{i,j}$. In particular the face $[\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}, \mathbf{x}_{j+2}]$ has an odd number of simplices with value $\prod_{i \leq k+1} p_{i,j}$. Now no simplex in any other face of $\hat{S}$ can have this value by uniqueness of prime factorization. Lable the “interior” vertices, those $u$ having all $s_i > 0$ in $u = \sum_{i=1}^{k+2} s_i \mathbf{x}_i$, (These have not yet been labeled.) with any of the $p_{i,j}, \ldots, p_{j+2}$. Pick a simplex on the face $[\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}, \mathbf{x}_{j+2}]$ which has value $\prod_{i \leq k+1} p_{i,j}$ and cross this simplex into $\hat{S}$. Continue crossing simplices having value $\prod_{i \leq k+1} p_{i,j}$ which have not been crossed till the process ends. It must end because there are an odd number of these simplices having value $\prod_{i \leq k+1} p_{i,j}$, if the process leads to the outside of $\hat{S}$, then one can always enter it again because there are an odd number of simplices with value $\prod_{i \leq k+1} p_{i,j}$ available and you will have used up an even number. When the process ends, the value of the simplex must be $\prod_{i=1}^{k+2} p_{i,j}$ because it will have the additional label $p_{j+2}$ on a vertex since if not, there will be another way out of the simplex. This identifies a simplex in the triangulation with value $\prod_{i=1}^{k+2} p_{i,j}$. Then repeat the process with $\prod_{i \leq k+1} p_{i,j}$ valued simplices on $[\mathbf{x}_j, \ldots, \mathbf{x}_{j+1}, \mathbf{x}_{j+2}]$ which have not been crossed. Repeating the process, entering from the outside, cannot deliver a $\prod_{i=1}^{k+2} p_{i,j}$ valued simplex encountered earlier. This is because you cross faces labeled $\prod_{i \leq k+1} p_{i,j}$. If the remaining vertex is labeled $p_{i,j}$ where $i \neq k+2$, then this yields exactly one other face to cross. There are two, the one with the first vertex $p_{i,j}$ and the next one with the new vertex labeled $p_{i,j}$, substituted for the first vertex having this label. Thus there is either one route in to a simplex or two. Thus, starting at a simplex labeled $\prod_{i \leq k+1} p_{i,j}$, one can cross faces having this value till one is led to the $\prod_{i \leq k+1} p_{i,j}$ valued simplex on the selected face of $\hat{S}$. In other words, the process is one to one in selecting a $\prod_{i \leq k+1} p_{i,j}$ vertex from crossing such a vertex on the selected face of $\hat{S}$.

Continue doing this, crossing a $\prod_{i \leq k+1} p_{i,j}$ simplex on the face of $\hat{S}$ which has not been crossed previously. This identifies an odd number of simplices having value $\prod_{i=1}^{k+2} p_{i,j}$. These are the ones which are “accessible” from the outside using this process. If there are any which are not accessible from outside, applying the same process starting inside one of these, leads to exactly one other inaccessible simplex with value $\prod_{i=1}^{k+2} p_{i,j}$. Hence these inaccessible simplices occur in pairs and so there are an odd number of simplices in the triangulation having value $\prod_{i=1}^{k+2} p_{i,j}$. We refer to this procedure of labeling as Sperner’s lemma. The system of labeling is well defined thanks to the assumption that $\{\mathbf{x}_k - \mathbf{x}_0\}_{k=1}^n$ is independent which implies
that \(\{x_k - x_i\}_{k \neq i}\) is also linearly independent. The following is a description of the system of labeling the vertices.

**Lemma 46.2.1** Let \([x_0, \ldots, x_n]\) be an \(n\) simplex with \(\{x_k - x_0\}_{k=1}^n\) independent, and let the first \(n+1\) primes be \(p_0, p_1, \ldots, p_n\). Label \(x_k\) as \(p_k\) and consider a triangulation of this simplex. Labeling the vertices of this triangulation which occur on \([x_{k_1}, \ldots, x_{k_s}]\) with any of \(p_{k_1}, \ldots, p_{k_s}\), beginning with all \(1\) simplices \([x_{k_1}, x_{k_2}]\) and then \(2\) simplices and so forth, there are an odd number of simplices \([y_{k_1}, \ldots, y_{k_s}]\) of the triangulation contained in \([x_{k_1}, \ldots, x_{k_s}]\) which have value \(p_{k_1}, \ldots, p_{k_s}\). This for \(s = 1, 2, \ldots, n\).

Another way To Explain The Labeling

We now give a brief discussion of the system of labeling for Sperner’s lemma from the point of view of counting numbers of faces rather than obtaining them with an algorithm. Let \(p_0, \ldots, p_n\) be the first \(n+1\) prime numbers. All vertices of a simplex \(S = [x_0, \ldots, x_n]\) having \(\{x_k - x_0\}_{k=1}^n\) independent will be labeled with one of these primes. In particular, the vertex \(x_k\) will be labeled as \(p_k\). The value of a simplex will be the product of its labels. Triangulate this \(S\). Consider a \(1\) simplex coming from the original simplex \([x_{k_1}, x_{k_2}]\), label one end as \(p_{k_1}\) and the other as \(p_{k_2}\). Then label all other vertices of this triangulation which occur on \([x_{k_1}, x_{k_2}]\) either \(p_{k_1}\) or \(p_{k_2}\). Then obviously there will be an odd number of simplices in this triangulation having value \(p_{k_1}p_{k_2}\), that is a \(p_k\) at one end and a \(p_{k'}\) at the other. Suppose that the labeling has been done for all vertices of the triangulation which are on \([x_{j_1}, \ldots, x_{j_{k+1}}]\),

\[
\{x_{j_1}, \ldots, x_{j_{k+1}}\} \subseteq \{x_0, \ldots, x_n\}
\]

any \(k\) simplex for \(k \leq n - 1\), and there is an odd number of simplices from the triangulation having value equal to \(\prod_{i=1}^{k+1} p_{j_i}\). Consider \(\tilde{S} = [x_{j_1}, \ldots, x_{j_{k+1}}, x_{j_{k+2}}]\). Then by induction, there is an odd number of \(k\) simplices on the \(s^{th}\) face

\[
[x_{j_1}, \ldots, \hat{x}_{j_s}, \ldots, x_{j_{k+1}}]
\]

having value \(\prod_{i \neq s} p_{j_i}\). In particular the face \([x_{j_1}, \ldots, x_{j_{k+1}}, \hat{x}_{j_{k+2}}]\) has an odd number of simplices with value \(\prod_{i=1}^{k+2} p_{j_i} := \hat{P}_k\). We want to argue that some simplex in the triangulation which is contained in \(\tilde{S}\) has value \(\hat{P}_{k+1} := \prod_{i=1}^{k+2} p_{j_i}\). Let \(Q\) be the number of \(k+1\) simplices from the triangulation contained in \(\tilde{S}\) which have two faces with value \(\hat{P}_k\) (A \(k+1\) simplex has either 1 or 2 \(\hat{P}_k\) faces.) and let \(R\) be the number of \(k+1\) simplices from the triangulation contained in \(\tilde{S}\) which have exactly one \(\hat{P}_k\) face. These are the ones we want because they have value \(\hat{P}_{k+1}\). Thus the number of faces having value \(\hat{P}_k\) which is described here is \(2Q + R\). All interior \(\hat{P}_k\) faces being counted twice by this number. Now we count the total number of \(\hat{P}_k\) faces another way. There are \(P\) of them on the face \([x_{j_1}, \ldots, x_{j_{k+1}}, \hat{x}_{j_{k+2}}]\) and by induction, \(P\) is odd. Then there are \(O\) of them which are not on this face. These faces got counted twice. Therefore,

\[2Q + R = P + 2O\]
and so, since $P$ is odd, so is $R$. Thus there is an odd number of $\hat{P}_{k+1}$ simplices in $\hat{S}$.

We refer to this procedure of labeling as Spener’s lemma. The system of labeling is well defined thanks to the assumption that $\{x_k - x_0\}^n_{k=1}$ is independent which implies that $\{x_k - x_i\}_{k \neq i}$ is also linearly independent. Spener’s lemma is now a consequence of this discussion.

### 46.2.3 Measurability Of Brouwer Fixed Points

First, here is a nice measurable selection theorem.

**Lemma 46.2.2** Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\{u_j(\omega)\}^\infty_{j=1}$ in $U$, where each $\omega \to u_j(\omega)$ is measurable and for each $\omega$, $\sup_j \|u_i(\omega)\| < \infty$. Then, there exists $u(\omega) \in U$ such that $\omega \to u(\omega)$ is measurable, and a subsequence $n(\omega)$, that depends on $\omega$, such that the weak limit

$$
\lim_{n(\omega) \to \infty} u_n(\omega)(\omega) = u(\omega)
$$

holds.

**Proof:** Let $\{z_i\}^\infty_{i=1}$ be a countable dense subset of $U'$. Let $h : U \to \prod_{i=1}^\infty \mathbb{R}$ be defined by

$$
h(u) = \prod_{i=1}^\infty \langle z_i, u \rangle.
$$

Let $X = \prod_{i=1}^\infty \mathbb{R}$ with the product topology. Then, this is a Polish space with the metric defined as $d(x, y) = \sum_{i=1}^\infty \frac{|x_i - y_i|}{1 + |x_i - y_i|} 2^{-i}$. By compactness, for a fixed $\omega$, the $h(u_n(\omega))$ are contained in a compact subset of $X$. Next, define

$$
\Gamma_n(\omega) = \bigcup_{k \geq n} h(u_k(\omega)),
$$

which is a nonempty compact subset of $X$. Moreover, $\Gamma_n(\omega)$ is a measurable multifunction into $X$.

Next, we claim that $\omega \to \Gamma_n(\omega)$ is a measurable multifunction.

The proof of the claim is as follows. It is necessary to show that $\Gamma_n^{-}(O)$ defined as $\{\omega : \Gamma_n(\omega) \cap O \neq \emptyset\}$ is measurable whenever $O$ is open. It suffices to verify this for $O$ a basic open set in the topology of $X$. Thus let $O = \bigcap_{i=1}^\infty O_i$ where each $O_i$ is a proper open subset of $\mathbb{R}$ only for $i \in \{j_1, \cdots, j_m\}$. Then,

$$
\Gamma_n^{-}(O) = \bigcup_{k \geq n} \bigcap_{i=1}^m \{\omega : \langle z_{j_i}, u_k(\omega) \rangle \in O_{j_i}\},
$$

which is a measurable set since $u_k$ is measurable.

Then, it follows that $\omega \to \Gamma_n(\omega)$ is strongly measurable because it has compact values in $X$, thanks to Tychonoff's theorem. Thus $\Gamma_n^{-}(H) = \{\omega : H \cap \Gamma_n(\omega) \neq \emptyset\}$ is measurable whenever $H$ is a closed set. Now, let $\Gamma(\omega)$ be defined as $\bigcap_n \Gamma_n(\omega)$ and then for $H$ closed,

$$
\Gamma^{-}(H) = \bigcap_n \Gamma_n^{-}(H)
$$
and each set in the intersection is measurable, so this shows that $\omega \to \Gamma(\omega)$ is also measurable. Therefore, it has a measurable selection $g(\omega)$. It follows from the definition of $\Gamma(\omega)$ that there exists a subsequence $n(\omega)$ such that

$$g(\omega) = \lim_{n(\omega) \to \infty} h(u_{n(\omega)}(\omega))$$

in $X$.

In terms of components, we have

$$g_i(\omega) = \lim_{n(\omega) \to \infty} \langle z_i, u_{n(\omega)}(\omega) \rangle.$$

Furthermore, there is a further subsequence, still denoted with $n(\omega)$, such that $u_{n(\omega)}(\omega) \to u(\omega)$ weakly. This means that for each $i$,

$$g_i(\omega) = \lim_{n(\omega) \to \infty} \langle z_i, u_{n(\omega)}(\omega) \rangle = \langle z_i, u(\omega) \rangle.$$

Thus, for each $z_i$ in a dense set, $\omega \to \langle z_i, u(\omega) \rangle$ is measurable. Since the $z_i$ are dense, this implies $\omega \to \langle z, u(\omega) \rangle$ is measurable for every $z \in U'$ and so by the Pettis theorem, $\omega \to u(\omega)$ is measurable. \qed

Now we consider the case of fixed points for simplices.

Suppose $f(\cdot, \omega) : S \to S$ for $S$ a simplex. Then from the Brouwer fixed point theorem, there is a fixed point $x(\omega)$ provided $f(\cdot, \omega)$ is continuous. Can it be arranged to have $\omega \to x(\omega)$ also measurable? In fact, it can, and this is shown here. In other words, if $P(\omega)$ are the fixed points of $f(\cdot, \omega)$, there exists a measurable selection in $P(\omega)$.

$S \equiv [x_0, \cdots, x_n]$ is a simplex in $\mathbb{R}^n$. Assume $\{x_i - x_0\}_{i=1}^n$ are linearly independent. Thus a typical point of $S$ is of the form

$$\sum_{i=0}^n t_i x_i$$

where the $t_i$ are uniquely determined and the map $x \to t$ is continuous from $S$ to the compact set $\{t \in \mathbb{R}^{n+1} : \sum t_i = 1, t_i \geq 0\}$.

To see this, suppose $x^t \to x$ in $S$. Let $x^k \equiv \sum_{i=0}^n t_i^k x_i$ with $x$ defined similarly with $t_i^k$ replaced with $t_i$, $x \equiv \sum_{i=0}^n t_i x_i$. Then

$$x^k - x_0 = \sum_{i=0}^n t_i^k x_i - \sum_{i=0}^n t_i^k x_0 = \sum_{i=0}^n t_i^k (x_i - x_0)$$

Thus

$$x^k - x_0 = \sum_{i=1}^n t_i^k (x_i - x_0), \quad x - x_0 = \sum_{i=1}^n t_i (x_i - x_0)$$

Say $t_i^k$ fails to converge to $t_i$ for all $i \geq 1$. Then there exists a subsequence, still denoted with superscript $k$ such that for each $i = 1, \cdots, n$, it follows that $t_i^k \to s_i$ where $s_i \geq 0$ and some $s_i \neq t_i$. But then, taking a limit, it follows that

$$x - x_0 = \sum_{i=1}^n s_i (x_i - x_0) = \sum_{i=1}^n t_i (x_i - x_0)$$
which contradicts independence of the \(x_i - x_0\). It follows that for all \(i \geq 1, t_i^k \to t_i\). Since they all sum to 1, this implies that also \(t_i^k \to t_0\). Thus the claim about continuity is verified.

Let \(f(\cdot, \omega): S \to S\) be continuous such that \(\omega \to f(x, \omega)\) is measurable. When doing \(f(\cdot, \omega)\) to a point \(\sum_{i=0}^n t_i x_i\), one obtains another point of \(S\) denoted as \(\sum_{i=0}^n s_i(\omega) x_i\). The coefficients \(s_i\) must be measurable functions. This is because

\[
\omega \to f(x, \omega) = \sum_{i=0}^n s_i(\omega) x_i
\]

and the left side is measurable so it follows the right is also. Now as noted above, the map which takes a point of \(S\) to its coefficients is continuous and so each \(s_i\) is measurable as a function of \(\omega\). Note also that this new method of labeling does not contradict the original labels placed on the vertices of \(S\).

Label \(x_j\) as \(p_j\) where \(p_0, \ldots, p_n\) are the first \(n + 1\) prime numbers. Thus the vertices of \(S\) have been labeled. Next triangulate \(S\) so that all simplices have diameter less than \(\varepsilon\). If \([y_0, \ldots, y_n]\) is one of these small vertices, each is of the form \(\sum_{i=0}^n t_i x_i\), where \(t_i \geq 0\) and \(\sum t_i = 1\). Define \(r_k(\omega) \equiv s_k(\omega) / t_k\) if \(t_k > 0\) and \(\infty\) if \(t_k = 0\). Thus this is a measurable function.

\[
E_k = \cap_{j \neq k} [\omega : r_k(\omega) \leq r_j(\omega)], \quad F_0 \equiv E_0, F_1 \equiv E_1 \setminus E_0, \ldots, F_n \equiv E_n \setminus \cup_{i=0}^{n-1} E_i
\]

Then \(p(y_i, \omega)\) will be the label placed on \(y_i\). It equals

\[
p(y_i, \omega) = \sum_{k=0}^n p_k x_{F_k}(\omega)
\]

obviously a measurable function. Note also that this new method of labeling does not contradict the original labels placed on the vertices \(x_i\). This is because for \(x_i, t_i = 1\) and all other \(t_j = 0\) so the only ratio that is finite will be \(s_i/t_i\). All others are \(\infty\) by definition. As for the vertices which are on the \(k\)th face \([x_0, \ldots, x_k, \ldots, x_n]\), these will be labeled from the list \(\{p_0, \ldots, p_k, \ldots, p_n\}\) because \(t_k = 0\) for each of these and so \(r_k(\omega) = \infty\). By the Sperner’s lemma procedure described above, there are an odd number of simplices having value \(\prod_{i \neq k} p_i\) on the \(k\)th face and an odd number of simplices in the triangulation of \(S\) for which the product of the labels on their vertices equals \(p_0 p_1 \cdots p_n \equiv P_n\). We call this the value of the simplex. Thus if \([y_0, \ldots, y_n]\) is one of these simplices, and \(p(y_i, \omega)\) is the label for \(y_i\), a measurable function of \(\omega\),

\[
\prod_{i=0}^n p(y_i, \omega) = \prod_{i=0}^n p_i \equiv P_n
\]

For \(\omega \in F_k\), what is \(r_k(\omega)\)? Could it be larger than 1? \(r_k(\omega)\) is certainly finite because at least some \(t_j \neq 0\) since they sum to 1. Thus, if \(r_k(\omega) > 1\), you would
have $s_k(\omega) > t_k$. The $s_i$ sum to 1 and so some $s_i(\omega) < t_j$ since otherwise, the sum of the $t_j$ equalling 1 would require the sum of the $s_j$ to be larger than 1. Hence $r_k(\omega)$ was not really the smallest so $\omega \notin F_k$. Thus $r_k(\omega) \leq 1$. Hence $s_k(\omega) \leq t_k$.

Let $S$ denote those simplices whose value is $P_n$ for some $\omega$. In other words, if $\{y_0, \cdots, y_n\}$ are the vertices of one of these simplices, and

$$y_s = \sum_{i=0}^{n} t_i^s x_i$$

then for some $\omega$, $r_{k_s}(\omega) \leq r_j(\omega)$ for all $j \neq k_s$ and $\{k_0, \cdots, k_n\} = \{0, \cdots, n\}$. There are finitely many of these simplices, so $S \equiv \{S_1, \cdots, S_m\}$. Let $F_1 \subseteq \Omega$ be defined by

$$F_1 \equiv \{\omega : \prod_{i=0}^{n} p(y_i, \omega) = P_n\} : [y_0, \cdots, y_n] = S_1$$

If $F_1 = \Omega$, then stop. If not, let

$$F_2 \equiv \{\omega \notin F_1 : \prod_{i=0}^{n} p(y_i, \omega) = P_n\} : [y_0, \cdots, y_n] = S_2$$

Continue this way obtaining disjoint measurable sets $F_j$ whose union is all of $\Omega$. The union is $\Omega$ because every $\omega$ is associated with at least one of the $S_i$. Now for $\omega \in F_k$ and $[y_0, \cdots, y_n] = S_k$, it follows that $\prod_{i=0}^{n} p(y_i, \omega) = P_n$. For $\omega \in F_k$, let $b(\omega)$ denote the barycenter of $S_k$. Thus $\omega \rightarrow b(\omega)$ is a measurable function, being constant on a measurable set. Thus we let $b(\omega) = \sum_{i=1}^{m} X_{F_i}(\omega) b_i$ where $b_i$ is the barycenter of $S_i$.

Now do this for a sequence $\varepsilon_k \rightarrow 0$ where $b_k(\omega)$ is a barycenter as above. By Lemma 46.2.2 there exists $x(\omega)$ such that $\omega \rightarrow x(\omega)$ is measurable and a sequence $\{b_k(\omega)\}_{k(\omega)=1}^{\infty}, \lim_{k(\omega) \rightarrow \infty} b_k(\omega) = x(\omega)$. This $x(\omega)$ is also a fixed point.

Consider this last claim. $x(\omega) = \sum_{i=0}^{n} t_i(\omega) x_i$ and after applying $f(\cdot, \omega)$, the result is $\sum_{i=0}^{n} s_i(\omega) x_i$. Then $b_k(\omega) \in \sigma_k(\omega)$ where $\sigma_k(\omega)$ is a simplex having vertices $\{y_{0_k}^k(\omega), \cdots, y_n^k(\omega)\}$ and the value of $[y_{0_k}^k(\omega), \cdots, y_n^k(\omega)]$ is $P_n$. Re ordering these if necessary, we can assume that the label for $y_k^i(\omega) = p_i$ which implies that, as noted above,

$$\frac{s_i(\omega)}{t_i(\omega)} \leq 1, \ s_i(\omega) \leq t_i(\omega)$$

the $i^{th}$ coordinate of $f(y_k^i(\omega), \omega)$ with respect to the original vertices of $S$ decreases and each $i$ is represented for $i = \{0, 1, \cdots, n\}$. Thus

$$y_k^i(\omega) \rightarrow x(\omega)$$

and so the $i^{th}$ coordinate of $y_k^i(\omega)$, $t_k^i(\omega)$ must converge to $t_i(\omega)$. Hence if the $i^{th}$ coordinate of $f(y_k^i(\omega), \omega)$ is denoted by $s_k^i(\omega)$,

$$s_k^i(\omega) \leq t_k^i(\omega)$$
By continuity of $f$, it follows that $s_i^k(\omega) \to s_i(\omega)$. Thus the above inequality is preserved on taking $k \to \infty$ and so

$$0 \leq s_i(\omega) \leq t_i(\omega)$$

this for each $i$. But these $s_i$ add to 1 as do the $t_i$ and so in fact, $s_i(\omega) = t_i(\omega)$ for each $i$ and so $f(x(\omega), \omega) = x(\omega)$. This proves the following theorem which gives the existence of a measurable fixed point.

Theorem 46.2.3 Let $S$ be a simplex $[x_0, \ldots, x_n]$ such that $\{x_i - x_0\}_{i=1}^n$ are independent. Also let $f(\cdot, \omega) : S \to S$ be continuous for each $\omega$ and $\omega \to f(x, \omega)$ is measurable, meaning inverse images of sets open in $S$ are in $\mathcal{F}$ where $(\Omega, \mathcal{F})$ is a measurable space. Then there exists $x(\omega) \in S$ such that $\omega \to x(\omega)$ is measurable and $f(x(\omega), \omega) = x(\omega)$.

Corollary 46.2.4 Let $K$ be a closed convex bounded subset of $\mathbb{R}^n$. Let $f(\cdot, \omega) : K \to K$ be continuous for each $\omega$ and $\omega \to f(x, \omega)$ is measurable, meaning inverse images of sets open in $K$ are in $\mathcal{F}$ where $(\Omega, \mathcal{F})$ is a measurable space. Then there exists $x(\omega) \in K$ such that $\omega \to x(\omega)$ is measurable and $f(x(\omega), \omega) = x(\omega)$.

Proof: Let $S$ be a large simplex containing $K$ and let $P$ be the projection map onto $K$. Consider $g(x(\omega)) \equiv f(P(x), \omega)$. Then $g$ satisfies the necessary conditions for Theorem 46.2.3 and so there exists $x(\omega) \in S$ such that $\omega \to x(\omega)$ is measurable and $g(x(\omega), \omega) = x(\omega)$. But this says $x(\omega) \in K$ and so $g(x(\omega), \omega) = f(x(\omega), \omega)$.

Much shorter proof

The above gives a proof of a measurable fixed point as part of a proof of the Brouwer fixed point theorem directly but it is a lot easier if you simply begin with the existence of the Brouwer fixed point and show it is measurable. We sent the above to be considered for publication and the referee pointed this out. I totally missed it because I had forgotten about the Kuratowski selection theorem. The functions $f : \Omega \times E \to \mathbb{R}$ in which $f(\cdot, \omega)$ is continuous are called Caratheodory functions.

Kuratowski [2] which is presented next. It is Theorem 46.2.3 in this collection.

Theorem 46.2.5 Let $E$ be a compact metric space and let $(\Omega, \mathcal{F})$ be a measure space. Suppose $\psi : E \times \Omega \to \mathbb{R}$ has the property that $x \to \psi(x, \omega)$ is continuous and $\omega \to \psi(x, \omega)$ is measurable. Then there exists a measurable function, $f$ having values in $E$ such that

$$\psi(f(\omega), \omega) = \sup_{x \in E} \psi(x, \omega).$$

Furthermore, $\omega \to \psi(f(\omega), \omega)$ is measurable.

Theorem 46.2.6 Let $K$ be a closed convex bounded subset of $\mathbb{R}^n$. Let $f(\cdot, \omega) : K \to K$ be continuous for each $\omega$ and $\omega \to f(x, \omega)$ is measurable, meaning inverse images of sets open in $K$ are in $\mathcal{F}$ where $(\Omega, \mathcal{F})$ is a measurable space. Then there exists $x(\omega) \in K$ such that $\omega \to x(\omega)$ is measurable and $f(x(\omega), \omega) = x(\omega)$. 
46.2. EXISTENCE OF MEASURABLE FIXED POINTS

Proof: Simply consider $E = K$ and $\psi(x, \omega) \equiv -|x - f(x, \omega)|$. It has a maximum $x(\omega)$ for each $\omega$ thanks to continuity of $f(\cdot, \omega)$. Thanks to the Brouwer fixed point theorem, this $x(\omega)$ must be a fixed point. By the above Kuratowski theorem, one of these $x(\omega)$ is measurable. Obviously, by continuity of $f(\cdot, \omega)$, $\omega \rightarrow f(x(\omega), \omega)$ is measurable. ■

46.2.4 Measurability Of Schauder Fixed Points

Now we consider the Schauder fixed point theorem. Let $\omega \rightarrow K(\omega)$ be a measurable multifunction having compact convex values. Here $K(\omega) \subseteq X$ a separable Banach space. Also assume

\[ f(\cdot, \omega) \text{ be continuous, } f(\cdot, \omega) : K(\omega) \rightarrow K(\omega), \]

$\omega \rightarrow f(x, \omega)$ is measurable

Lemma 46.2.7 $K(\omega) = \overline{f(K(\omega), \omega)}$ is compact valued and measurable.

Proof: It is given to be compact valued since $f$ is continuous. We need to check that it is measurable. For $U$ open, is

\[ \{ \omega : f(K(\omega), \omega) \cap U \neq \emptyset \} \]

a measurable set? Since $U$ is open and $x \rightarrow f(x, \omega)$ is continuous, the set is the same as

\[ \{ \omega : f(K(\omega), \omega) \cap U \neq \emptyset \} \]

Let $\{k_j(\omega)\}$ be a dense countable subset of $K(\omega)$ where $\omega \rightarrow k_j(\omega)$ is measurable. Then this last set is of the form

\[ \{ \omega : f(K(\omega), \omega) \cap U \neq \emptyset \} = \bigcup_{i=1}^{\infty} f(k_i(\cdot), \cdot)^{-1}(U) \] which is measurable. ■

Next we have the following approximation result.

Lemma 46.2.8 Let $f$ be as above and $f(K(\omega), \omega) \subseteq K(\omega)$ for $K(\omega)$ compact and $\omega \rightarrow K(\omega)$ a measurable multifunction. For each $r > 0$ and $\omega$, there exists a finite set of points

\[ \{y_1(\omega), \cdots, y_{n(\omega)}(\omega)\} \subseteq f(K(\omega), \omega), \omega \rightarrow y_i(\omega) \text{ measurable} \]

and continuous functions $\psi_i(\cdot, \omega)$ defined on $f(K(\omega), \omega)$ such that for $y \in f(K(\omega), \omega)$,

\[ \sum_{i=1}^{n(\omega)} \psi_i(y, \omega) = 1, \quad (46.2.5) \]

$\psi_i(y, \omega) = 0$ if $y \notin B(y_i(\omega), r)$, $\psi_i(y, \omega) > 0$ if $y \in B(y_i(\omega), r)$. 
If
\[ f_r(x, \omega) \equiv \sum_{i=1}^{n(\omega)} y_i(\omega) \psi_i(f(x, \omega), \omega), \]  
(46.2.6)
then whenever \( x \in K(\omega) \),
\[ \| f(x, \omega) - f_r(x, \omega) \| \leq r. \]

**Proof:** Using the compactness of \( \overline{f(K(\omega), \omega)} \), Proposition 46.1.6 says there exist measurable functions \( y_i(\omega) \)
\[ \{ y_1(\omega), \ldots, y_n(\omega) \} \subseteq \overline{f(K(\omega), \omega)} \subseteq K(\omega) \]
such that
\[ \{ B(y_i(\omega), r) \}_{i=1}^n \]
covers \( \overline{f(K, \omega)} \). Let
\[ \phi_i(y, \omega) \equiv (r - \| y - y_i(\omega) \|)^+ \]
Thus \( \phi_i \) is continuous in \( y \) and measurable in \( \omega \) for fixed \( y \). Also \( \phi_i(y, \omega) > 0 \) if \( y \in B(y_i(\omega), r) \) and \( \phi_i(y, \omega) = 0 \) if \( y \notin B(y_i(\omega), r) \). For \( y \in \overline{f(K, \omega)} \), let
\[ \psi_i(y, \omega) \equiv \phi_i(y, \omega) \left( \sum_{j=1}^{n(\omega)} \phi_j(y, \omega) \right)^{-1}. \]
From the formula, \( \omega \rightarrow \psi_i(y, \omega) \) is measurable. Also 46.2.5 is satisfied. Indeed the denominator is not zero because \( y \) is in one of the \( B(y_i(\omega), r) \). Thus it is obvious that the sum of these equals 1 on \( f(K, \omega) \). Now let \( f_r \) be given by 46.2.6 for \( x \in K \). For such \( x \),
\[ f(x, \omega) - f_r(x, \omega) = \sum_{i=1}^{n} (f(x, \omega) - y_i(\omega)) \psi_i(f(x, \omega), \omega) \]
Thus
\[ f(x, \omega) - f_r(x, \omega) = \sum_{\{i : f(x) \in B(y_i(\omega), r) \}} (f(x, \omega) - y_i(\omega)) \psi_i(f(x, \omega), \omega) \]
\[ + \sum_{\{i : f(x) \notin B(y_i(\omega), r) \}} (f(x, \omega) - y_i(\omega)) \psi_i(f(x, \omega), \omega) \]
\[ = \sum_{\{i : f(x) - y_i(\omega) \in B(0, r) \}} (f(x, \omega) - y_i(\omega)) \psi_i(f(x, \omega), \omega) \in B(0, r) \]
46.2. EXISTENCE OF MEASURABLE FIXED POINTS

because \(0 \in B(0, r)\), \(B(0, r)\) is convex, and \(f(x, \omega) - f_r(x, \omega)\) is a convex combination of vectors in \(B(0, r)\). ■

We think of \(f_r(\cdot, \omega)\) as an approximation to \(f(\cdot, \omega)\). In fact it is uniformly within \(r\) of \(f(\cdot, \omega)\) on \(K(\omega)\). The next lemma shows that this \(f_r(\cdot, \omega)\) has a fixed point. This is the main result and comes from the Brouwer fixed point theorem in \(\mathbb{R}^n\). It is an approximate fixed point.

**Lemma 46.2.9** For each \(r > 0\), there exists \(x_r(\omega) \in \text{convex hull of } f(K(\omega), \omega) \subseteq K(\omega)\) such that

\[
f_r(x_r(\omega), \omega) = x_r(\omega), \quad \|f_r(x, \omega) - f(x, \omega)\| < r \quad \text{for all } x \in K(\omega)
\]

and \(\omega \rightarrow x_r(\omega)\) is measurable.

**Proof:** The upper limit in the sum of the above lemma \(n(\omega)\) is a measurable function. One can partition the measure space according to the value of \(n(\omega)\). This gives a countable set of disjoint measurable subsets \(\{\Omega_n\}_{n=1}^{\infty}\) in the partition such that on the measurable set \(\Omega_n\), \(n(\omega) = n\). Specializing to the measurable space consisting of \(\Omega_n\), we will assume here that \(n(\omega) = n\) and show that there exists a measurable fixed point \(x_r(\omega) \in K(\omega)\) for \(\omega \in \Omega_n\). Then the result follows by letting \(x_r(\omega)\) be that which has been obtained on \(\Omega_n\). Thus, from now on, simply denote as \(n\) the upper limit and let \(\omega \in \Omega_n\). If \(f_r(x_r, \omega) = x_r\) and

\[
x_r = \sum_{i=1}^{n} a_i y_i(\omega)
\]

for \(\sum_{i=1}^{n} a_i = 1\) and the \(y_i\) described in the above lemma, we need

\[
f_r(x_r, \omega) = \sum_{i=1}^{n} y_i(\omega) \psi_i(f(x_r, \omega), \omega) = \sum_{j=1}^{n} y_j(\omega) \psi_j(f(\sum_{i=1}^{n} a_i y_i, \omega), \omega) = \sum_{j=1}^{n} a_j y_j(\omega) = x_r.
\]

Also, if this is satisfied, then we have the desired fixed point.

This will be satisfied if for each \(j = 1, \ldots, n\),

\[
a_j = \psi_j(f(\sum_{i=1}^{n} a_i y_i, \omega), \omega)
\]

so, let

\[
\Sigma_{n-1} = \left\{ \mathbf{a} \in \mathbb{R}^n : \sum_{i=1}^{n} a_i = 1, \ a_i \geq 0 \right\}
\]

and let \(h(\cdot, \omega) : \Sigma_{n-1} \rightarrow \Sigma_{n-1}\) be given by

\[
h(\mathbf{a}, \omega)_j = \psi_j(f(\sum_{i=1}^{n} a_i y_i, \omega), \omega)
\]
Can we obtain a fixed point \( a(\omega) \) such that \( \omega \rightarrow a(\omega) \) is measurable? Since \( h(\cdot,\omega) \) is a continuous function of \( a \) and \( \omega \rightarrow h(x,\omega) \) is measurable, such a measurable fixed point exists thanks to Theorem \[46.2.10\] above. Then \( x_r(\omega) = \sum_{i=1}^n a_i(\omega) y_i(\omega) \) so \( x_r \) is measurable. \[ \blacksquare \]

The following is the Schauder fixed point theorem for measurable fixed points.

**Theorem 46.2.10** Let \( \omega \rightarrow K(\omega) \) be a measurable multifunction which has convex and compact values in a separable Banach space. Let \( f(\cdot,\omega) : K(\omega) \rightarrow K(\omega) \) be continuous and \( \omega \rightarrow f(x,\omega) \) is measurable. Then \( f(\cdot,\omega) \) has a fixed point \( x(\omega) \) such that \( \omega \rightarrow x(\omega) \) is measurable.

**Proof:** Recall that \( f(x_r(\omega),\omega) - f_r(x_r(\omega),\omega) \in B(0,r) \) and \( f_r(x_r(\omega),\omega) = x_r(\omega) \) with \( x_r(\omega) \in \text{conv} h(K(\omega),\omega) \subseteq K(\omega) \). Here \( x_r \) is measurable. By Lemma \[46.2.10\] there is a measurable function \( x(\omega) \) which equals the weak \( \lim_{r(\omega) \rightarrow 0} x_r(\omega) \). However, since \( h(K(\omega),\omega) \) is compact, there is a subsequence still denoted with \( r(\omega) \) such that \( f(x_r(\omega),\omega) \) converges strongly to some \( x \in h(K(\omega),\omega) \). It follows that \( f_r(x_r(\omega),\omega) \) also converges to \( x \) strongly. But this equals \( x_r(\omega) \) which shows that \( x_r(\omega) \) converges strongly to the measurable \( x(\omega) \). Therefore,

\[
\begin{align*}
    f(x(\omega),\omega) &= \lim_{r(\omega) \rightarrow 0} f(x_r(\omega),\omega) = \lim_{r(\omega) \rightarrow 0} f_r(x_r(\omega),\omega) \\
    &= \lim_{r(\omega) \rightarrow 0} x_r(\omega) = x(\omega). \quad \blacksquare
\end{align*}
\]

As a special case of the above, here is a corollary which generalizes the earlier result on the Brouwer fixed point theorem.

**Corollary 46.2.11** Let \((\Omega,\mathcal{F})\) be a measurable space and let \( K(\omega) \) be a convex and compact set in \( \mathbb{R}^n \) and \( \omega \rightarrow K(\omega) \) is a measurable multifunction. Also let \( f(\cdot,\omega) : K(\omega) \rightarrow K(\omega) \) be continuous and for fixed \( x \in \mathbb{R}^n, \omega \rightarrow f(x,\omega) \) is measurable. Then there exists a fixed point \( x(\omega) \) for \( f(\cdot,\omega) \) such that \( \omega \rightarrow x(\omega) \) is measurable.

Note that in all of these considerations, there is no loss of generality in assuming \( f(\cdot,\omega) \) is defined on the whole space \( X \) thanks to the theorem which says that a continuous function defined on a convex closed set can be extended to a continuous function defined on the whole space.

In the case of a single set, the following corollary is also obtained.

**Corollary 46.2.12** Let \( X \) be a Banach space and let \( K \) be a compact convex subset. Let \( f : K \times \Omega \rightarrow K \) satisfy

\[
\begin{align*}
    x &\rightarrow f(x,\omega) \text{ is continuous} \\
    \omega &\rightarrow f(x,\omega) \text{ is measurable}
\end{align*}
\]

Then \( f(\cdot,\omega) \) has a fixed point \( x(\omega) \) such that \( \omega \rightarrow x(\omega) \) is measurable.
46.3. A Set Valued Browder Lemma With Measurability

**Proof:** The set $K$ has a countable dense subset $\{k_i\}$. You could consider $Y$ as the closure in $X$ of the span of these $k_i$. Thus $Y$ is a separable Banach space which contains $K$. Now apply the above result. ■

If $X$ is only a normed linear space, you could just consider its completion and apply the above result. Since $K$ is compact, it is automatically complete with respect to the norm on $X$.

**46.3 A Set Valued Browder Lemma With Measurability**

A simple application is a measurable version of the Browder lemma which is also valid for upper semicontinuous set valued maps. In what follows, we do not assume that $A(\cdot, \omega)$ is a set valued measurable multifunction, only that it has a measurable selection which is a weaker assumption. First is a general result on upper set valued maps ($V$ valued maps ($u; c$) selection which is a weaker assumption. First is a general result on upper semicontinuous set valued maps. In what follows, we do not assume $A$ is upper semicontinuous from the strong topology of $V$. We can assume that $A(u, \omega)$ is upper-semicontinuous from the strong topology of $V$ to the weak topology of $V'$. That is, if $u_n \to u$ in $V$ strongly, then if $O$ is a weakly open set containing $A(u, \omega)$, it follows that $A(u_n, \omega) \in O$ for all $n$ large enough. **Conclusion:** Then, whenever $\omega \to u(\omega)$ is measurable into $V$ there is a measurable selection for $\omega \to A(u, \omega)$ into $V'$.

**Proof:** Let $\omega \to u(\omega)$ be measurable into $V$, and let $u_n(\omega) \to u(\omega)$ in $V$ where $u_n$ is a simple function

$$u_n(\omega) = \sum_{k=1}^{m_n} c_k^n X_{E_k^n}(\omega)$$

the $E_k^n$ disjoint, $\Omega = \cup_k E_k^n$,

each $c_k^n$ being in $V$. We can assume that $\|u_n(\omega)\| \leq 2 \|u(\omega)\|$ for all $\omega$. Then, by assumption, there is a measurable selection for $\omega \to A(c_k^n, \omega)$ denoted as $\omega \to y_k^n(\omega)$. Thus, $\omega \to y_k^n(\omega)$ is measurable into $V'$ and $y_k^n(\omega) \in A(c_k^n, \omega)$ for all $\omega \in \Omega$. Consider now,

$$y^n(\omega) = \sum_{k=1}^{m_n} y_k^n(\omega) X_{E_k^n}(\omega).$$

It is measurable and for $\omega \in E_k^n$ it equals $y_k^n(\omega) \in A(c_k^n, \omega) = A(u_n(\omega), \omega)$. Thus, $y^n$ is a measurable selection of $\omega \to A(u_n(\omega), \omega)$. By the assumption $A(\cdot, \omega)$ is bounded, for each $\omega$ these $y^n(\omega)$ lie in a bounded subset of $V'$. The bound might depend on $\omega$ of course. It follows now from Lemma [1587] that there is a subsequence $\{y^{n(\omega)}\}$ that converges weakly to $y(\omega)$, where $\omega \to y(\omega)$ is measurable. But,

$$y^{n(\omega)}(\omega) \in A(u_n(\omega), \omega).$$
is a convex closed set for which $u \rightarrow A(u, \omega)$ is upper-semicontinuous and $u_n(\omega) \rightarrow u$, hence, $y(\omega) \in A(u(\omega), \omega)$. This is the claimed measurable selection. ■

The next lemma is about the projection map onto a set valued map whose values are closed convex sets.

**Lemma 46.3.2** Let $\omega \rightarrow \mathcal{K}(\omega)$ be measurable into $\mathbb{R}^n$ where $\mathcal{K}(\omega)$ is closed and convex. Then $\omega \rightarrow P_{\mathcal{K}(\omega)}(u(\omega))$ is also measurable into $\mathbb{R}^n$ if $\omega \rightarrow u(\omega)$ is measurable. Here $P_{\mathcal{K}(\omega)}$ is the projection map giving the closest point.

**Proof:** It follows from standard results on measurable multi-functions also in Theorem 46.3.1 above that there is a countable collection \{w_n(\omega)\}, $\omega \rightarrow w_n(\omega)$ being measurable and $w_n(\omega) \in \mathcal{K}(\omega)$ for each $\omega$ such that for each $\omega$, $\mathcal{K}(\omega) = \bigcup_n w_n(\omega)$. Let

$$d_n(\omega) \equiv \min \{ \|u(\omega) - w_k(\omega)\|, k \leq n \}$$

Let $u_1(\omega) \equiv w_1(\omega)$. Let

$$u_2(\omega) = w_1(\omega)$$

on the set

$$\{ \omega : \|u(\omega) - w_1(\omega)\| < \|u(\omega) - w_2(\omega)\| \}$$

and

$$u_2(\omega) \equiv w_2(\omega)$$

off the above set.

Thus $\|u_2(\omega) - u(\omega)\| = d_2$. Let

\[
\begin{align*}
  u_3(\omega) &= w_1(\omega) \text{ on } \left\{ \omega : \|u(\omega) - w_1(\omega)\| < \|u(\omega) - w_j(\omega)\|, j = 2, 3 \right\} \equiv S_1 \\
  u_3(\omega) &= w_2(\omega) \text{ on } S_1 \cap \left\{ \omega : \|u(\omega) - w_1(\omega)\| < \|u(\omega) - w_j(\omega)\|, j = 3 \right\} \\
  u_3(\omega) &= w_3(\omega) \text{ on the remainder of } \Omega
\end{align*}
\]

Thus $\|u_3(\omega) - u(\omega)\| = d_3$. Continue this way, obtaining $u_n(\omega)$ such that

$$\|u_n(\omega) - u(\omega)\| = d_n(\omega)$$

and $u_n(\omega) \in \mathcal{K}(\omega)$ with $u_n$ measurable. Thus, in effect one picks the closest of all the $w_k(\omega)$ for $k \leq n$ as the value of $u_n(\omega)$ and $u_n$ is measurable and by density in $\mathcal{K}(\omega)$ of $\{w_n(\omega)\}$ for each $\omega$, \{u_n(\omega)\} must be a minimizing sequence for

$$\lambda(\omega) \equiv \inf \{ \|u(\omega) - z\| : z \in \mathcal{K}(\omega) \}$$

Then it follows that $u_n(\omega) \rightarrow P_{\mathcal{K}(\omega)}(u(\omega)$ weakly in $\mathbb{R}^n$. Here is why: Suppose it fails to converge to $P_{\mathcal{K}(\omega)}(u(\omega)$. Since it is minimizing, it is a bounded sequence. Thus there would be a subsequence, still denoted as $u_n(\omega)$ which converges to some $q(\omega) \neq P_{\mathcal{K}(\omega)}(u(\omega)$. Then

$$\lambda(\omega) = \lim_{n \rightarrow \infty} \|u(\omega) - u_n(\omega)\| \geq \|u(\omega) - q(\omega)\|$$
because convex and lower semicontinuous is weakly lower semicontinuous. But this implies \( q(\omega) = P_{\mathcal{K}(\omega)}(u(\omega)) \) because the projection map is well defined thanks to strict convexity of the norm used. This is a contradiction. Hence \( P_{\mathcal{K}(\omega)}u(\omega) = \lim_{n \to \infty} u_n(\omega) \) and so is a measurable function. It follows that \( \omega \to P_{\mathcal{K}(\omega)}(u(\omega), \omega) \) is measurable into \( \mathbb{R}^n \).

One way to prove the following Theorem in simpler cases is to use a measurable version of the Kakutani fixed point theorem. It is done this way in [47] without the dependence on \( \omega \). See also [48] for a measurable version of this fixed point theorem. However, one can also prove it by a generalization of the proof Browder gave for a single valued case and this is summarized here. We want to include the case where \( A \) is a sum of two set valued operators and this involves careful consideration of the details. Such a situation occurs when one considers operators which are a sum, one dependent on the boundary of a region, and the other from a partial differential inclusion. Also, we will need to consider finite dimensional subspaces which depend on \( \omega \) which further complicates the considerations.

**Theorem 46.3.3 Assumptions:** Let \( B(\cdot, \omega) : V \to \mathcal{P}(V'), C(\cdot, \omega) : V \to \mathcal{P}(V') \) for \( V \) a separable Banach space. Suppose that \( \omega \to B(x, \omega), \omega \to C(x, \omega) \) each has a measurable selection and \( x \to B(x, \omega), x \to C(x, \omega) \) each is upper semicontinuous from strong to weak topologies. Also let \( E(\omega) \) be an \( n \) dimensional subspace of \( V \) which has a basis \( \{b_1(\omega), \ldots, b_n(\omega)\} \) each of which is a measurable function into \( V \), and that \( K(\omega) \subseteq E(\omega) \) where \( K(\omega) \) is a measurable multifunction which has convex closed bounded values. Also let \( y(\omega) \) be given, a measurable function into \( V' \). **Conclusion:** There exist measurable functions \( w_B(\omega), w_C(\omega) \) and \( x(\omega) \) with \( w_B(\omega) \in B(x(\omega), \omega), w_C(\omega) \in C(x(\omega), \omega) \), and \( x(\omega) \in K(\omega) \) such that for all \( z \in K(\omega), \)

\[
\langle y(\omega) - (w_B(\omega) + w_C(\omega)), z - x(\omega) \rangle \leq 0
\]

**Proof:** The argument will refer to the following commutative diagram.

\[
\begin{array}{ccc}
E(\omega) & \xrightarrow{\theta(\omega)^*} & \mathbb{R}^n \\
i(\omega)^* \downarrow & & \uparrow \theta(\omega)^* \downarrow & \theta(\omega)^* A (\cdot, \omega) \\
E(\omega) & \xleftarrow{\theta(\omega)} & \mathbb{R}^n \\
\end{array}
\]

where \( A(\cdot, \omega) \) will be either \( B(\cdot, \omega) \) or \( C(\cdot, \omega) \). Here \( \theta(\omega) e_i \equiv b_i(\omega) \) and extended linearly. Then it is clear that \( \theta(\omega) \) maps measurable functions to measurable functions.

What of \( \theta(\omega)^{-1} \)? Does it map measurable functions to measurable functions? Let \( h(\omega) \) have values in \( E(\omega) \) and be measurable into \( V \). Thus

\[
h(\omega) = \sum_i a_i(\omega) b_i(\omega)
\]

The question reduces to whether the \( a_i(\omega) \) are measurable. To see that this is the case, consider first \( \|h(\omega)\| < M \) for all \( \omega \). Let \( S_r \equiv \)

\[
\left\{ \omega : \inf_{|a|>r} \left| \sum_i a_i b_i(\omega) \right| > M \right\} = \left\{ \omega : \inf_{|a|>r, a \in \mathbb{Q}^n} \left| \sum_i a_i b_i(\omega) \right| > M \right\}
\]
Thus this is a measurable set. Also every $\omega$ is in some $S_r$ because if not, you could get a sequence $|a^r| \to \infty$ and yet $\| \sum_i a^r b_i (\omega) \| \leq M$. But then, dividing by $|a^r|$ and taking a suitable subsequence, one can obtain $\sum_i a_i b_i (\omega) = 0$ for some $|a| = 1$. Also the $S_r$ are increasing in $r$. Now for $\omega \in S_r$, define $\Phi (a, \omega) = - \| \sum_i a_i b_i (\omega) - h (\omega) \|$ where we will let $|a| \leq r + 1$. Since $\{b_i (\omega)\}$ is a basis, there exists $a (\omega)$ such that $\Phi (a (\omega), \omega) = 0$. This $a$ must satisfy $|a| \leq r + 1$ because if not, then you would have $\| \sum_i a_i b_i (\omega) \| \geq M$ since $\omega \in S_r$. But $\| \sum_i a_i b_i (\omega) \| = \| h (\omega) \| < M$. Thus the maximum of $a \to \Phi (a, \omega)$ occurs on the compact set $|a| \leq r + 1$ and is 0. (The function cannot get any larger than 0 under any circumstances.) By Kuratowski’s theorem, we have $\omega \to a (\omega)$ is measurable where $h (\omega) = \sum_i a_i (\omega) b_i (\omega)$ on $S_r$. Thus, since every $\omega$ is in some $S_r$, we must have $\omega \to a_i (\omega)$ is measurable in case $\| h (\omega) \| \leq M$ for all $\omega$. In the general case, let $a^m (\omega)$ be the measurable function which goes with $h_m (\omega)$ where $h_m (\omega)$ is given by a truncation of $h$ so that $\| h_m (\omega) \| \leq m$. For each $\omega, h_m (\omega)$ is eventually smaller than $m$. Thus if $a^m_i (\omega)$ go with $h_m (\omega)$, these are constant for all $m$ large enough. Thus letting $a_i (\omega) = \lim_{m \to \infty} a^m_i (\omega)$, $a_i$ is measurable and

$$h (\omega) = \lim_{m \to \infty} h_m (\omega) = \lim_{m \to \infty} \sum_i a^m_i (\omega) b_i (\omega) = \sum_i a_i (\omega) b_i (\omega)$$

and so the $a_i$ are indeed measurable. Thus the $\theta (\omega)^{-1} h (\omega) = \sum_i a_i (\omega) e_i$, which shows that $\theta (\omega)^{-1}$ does map measurable functions to measurable functions. In particular, $\theta (\omega)^{-1} K (\omega)$ is indeed a closed, bounded, convex, and measurable multifunction which can be seen by considering $\{k_i (\omega)\}_{i=1}^{\infty}$, a countable dense subset of $K (\omega)$.

Define for $A = B$ or $C$,

$$\hat{A} (\cdot, \omega) = \theta (\omega)^* i (\omega)^* A (\theta (\omega) \cdot, \omega), \ y (\omega) = \theta (\omega)^* i (\omega)^* y (\omega). \quad (46.3.8)$$

We claim that $\omega \to \hat{A} (x, \omega)$ has a measurable selection and for fixed $\omega$ this is upper semicontinuous in $x$. The second condition for fixed $\omega$ is obvious. Consider the first. It was shown above that $\theta (\omega) x$ is measurable into $V$. Thus, by Theorem 46.3.1, it follows that $\omega \to A (\theta (\omega) x, \omega)$ has a measurable selection into $V'$. Therefore, it suffices to show that if $z (\omega)$ is measurable into $V'$ then $\theta (\omega)^* i (\omega)^* z (\omega)$ is measurable into $\mathbb{R}^n$. Let $w \in \mathbb{R}^n$. Then

$$\left( \theta (\omega)^* i (\omega)^* z (\omega), w \right)_{\mathbb{R}^n} \equiv \left\langle i (\omega)^* z (\omega), \theta (\omega) w \right\rangle$$

$$= \left\langle i (\omega)^* z (\omega), \sum_i w_i b_i (\omega) \right\rangle$$

$$= \left\langle z (\omega), \sum_i w_i b_i (\omega) \right\rangle_{V', V}$$

which is measurable. By the Pettis theorem, $\omega \to \theta (\omega)^* i (\omega)^* z (\omega)$ is measurable. Thus $\hat{A} (\cdot, \omega)$ has the properties claimed.
46.3. A SET VALUED BROWER LEMMA WITH MEASURABILITY

Now tile \( \mathbb{R}^n \) with \( n \) simplices, each having diameter less than \( \varepsilon < 1 \), the set of simplices being locally finite. Define for \( A = B \) or \( C \) the single valued function \( \hat{A}_\varepsilon \) on all of \( \mathbb{R}^n \) by the following rule. If
\[
x \in [x_0, \ldots, x_n],
\]
so \( x = \sum_{i=0}^n t_i x_i, t_i \geq 0, \sum t_i = 1 \), then let \( \hat{A}_\varepsilon (x_k, \omega) \) be a measurable selection from \( \hat{A} (x_k, \omega) \) for each \( x_k \) a vertex of the simplex. However, we chose \( \hat{A}_\varepsilon (x_k, \omega) \) in the obvious way. It is \( \theta (\omega)^* i (\omega)^* w_k^B (\omega) \) where \( w_k^B (\omega) \) is a measurable selection of \( B (\theta (\omega) x_k, \omega) \), measurable into \( V_B \) when \( A = B \) and \( \theta (\omega)^* i (\omega)^* w_k^C (\omega) \) where \( w_k^C (\omega) \) is a measurable selection of \( C (\theta (\omega) x_k, \omega) \), measurable into \( V_B \) when \( A = C \). Then
\[
\hat{B}_\varepsilon (x_k, \omega) = \theta (\omega)^* i (\omega)^* w_k^B (\omega), \omega \rightarrow w_k^B (\omega) \text{ measurable} \quad (46.3.9)
\]
with a similar definition holding for \( \hat{C}_\varepsilon \).

Define the single valued map for \( x \in [x_0, \ldots, x_n], x = \sum_{i=0}^n t_i x_i \) as follows. For \( A = B, C, \)
\[
\hat{A}_\varepsilon (x, \omega) \equiv \sum_{k=0}^n t_k \hat{A}_\varepsilon (x_k, \omega)
\]
when
\[
(46.3.10)
\]
Thus \( \hat{A}_\varepsilon (\cdot, \omega) \) is a continuous map defined on \( \mathbb{R}^n \) thanks to the local finiteness of the tiling, and \( \omega \rightarrow \hat{A}_\varepsilon (x, \omega) \) is measurable.

Let \( P_{\theta (\omega)^{-1} K (\omega)} \) denote the projection onto the closed convex set \( \theta (\omega)^{-1} K (\omega) \). This is a continuous mapping by Hilbert space considerations. Therefore,
\[
x \rightarrow P_{\theta (\omega)^{-1} K (\omega)} \left( y (\omega) - \hat{A}_\varepsilon (x, \omega) + x \right)
\]
is continuous and by Lemma \( \text{46.3.10} \),
\[
\omega \rightarrow P_{\theta (\omega)^{-1} K (\omega)} \left( y (\omega) - \hat{A}_\varepsilon (x, \omega) + x \right)
\]
is measurable, and for each \( \omega \), this function of \( x \) maps into \( \theta (\omega)^{-1} K (\omega) \). Therefore by Corollary \( \text{46.3.11} \), there exists a fixed point \( x_\varepsilon (\omega) \in \theta (\omega)^{-1} K (\omega) \) such that
\[
\omega \rightarrow x_\varepsilon (\omega)
\]
is measurable and
\[
P_{\theta (\omega)^{-1} K (\omega)} \left( y (\omega) - \left( \hat{B}_\varepsilon (x_\varepsilon (\omega), \omega) + \hat{C}_\varepsilon (x_\varepsilon (\omega), \omega) \right) + x_\varepsilon (\omega) \right) = x_\varepsilon (\omega).
\]
This requires
\[
\left( y (\omega) - \left( \hat{B}_\varepsilon (x_\varepsilon (\omega), \omega) + \hat{C}_\varepsilon (x_\varepsilon (\omega), \omega) \right), z - x_\varepsilon (\omega) \right)_{\mathbb{R}^n} \leq 0 \quad (46.3.11)
\]
for all \( z \in \theta (\omega)^{-1} K (\omega) \). Note that this implies \( \omega \rightarrow \hat{A}_\varepsilon (x_\varepsilon (\omega), \omega) \) is measurable for \( A = B \) or \( C \).

We have
\[
x_\varepsilon (\omega) = \sum_{k=0}^n t_k^\varepsilon (\omega) x_k^\varepsilon (\omega) \quad (46.3.12)
\]
where the $x_k^x(\omega)$ are vertices of the tiling corresponding to $\varepsilon$.

**Claim:** The vertices $x_k^x(\omega)$ and coordinates $t_k^x(\omega)$ can be considered measurable.

**Proof of claim:** Let the simplices in the tiling be $\{\sigma_k\}_k$ and let the vertices of simplices in the tiling be $\{z_j\}_j$. Let $F_k$ and $E_k$ be defined as follows.

$$F_k \equiv x_k^{-1}(\sigma_k), E_1 \equiv F_1, \ldots, E_k \equiv F_k \setminus \bigcup_{i=1}^k F_i$$

Then $\omega$ is in exactly one of these measurable sets $E_k$ which partition $\Omega$. Let $\sigma_k(\omega)$ be the unique simplex for $\omega \in E_k$. Thus $x_k^x(\omega) \in \sigma_k(\omega)$ for $\omega$ on the measurable set $E_k$. Denote its vertices by $z_{i_0}(\omega), z_{i_1}(\omega), \ldots, z_{i_{n}}(\omega)$. These vertices are $x_{0}^x(\omega), \ldots, x_{n}^x(\omega)$ in the order of an enumeration of the vertices of simplices in the tiling. They are determined this way on a measurable set and so they must be measurable $\mathbb{R}^n$ valued functions. Then $\omega \to t_k^x(\omega)$ is also measurable because there is a continuous mapping to these scalars from $x_k^x(\omega)$ which was obtained measurable. This shows the claim.

Recall $\text{En.44}$ Let $W^\varepsilon(\omega)$ be defined as follows.

$$W^\varepsilon(\omega) \equiv \left( t_0^x(\omega), \ldots, t_n^x(\omega), x_0^x(\omega), \ldots, x_n^x(\omega), \right) \in \mathbb{R}^{2(n+1)} \times (V)^{2(n+1)}$$

This is in $\mathbb{R}^{2(n+1)} \times (V)^{2(n+1)}$. Then by Lemma $\text{En.44}$ since $W^\varepsilon(\omega)$ is bounded in a reflexive separable Banach space, there is a subsequence $\varepsilon(\omega) \to 0$ such that $W^{\varepsilon(\omega)}(\omega) \to W(\omega)$ weakly and given by

$$W(\omega) \equiv \left( t_0(\omega), \ldots, t_n(\omega), x_0(\omega), \ldots, x_n(\omega), \right)$$

where each of these components is measurable into the appropriate space. Of course, in the finite dimensional components, the convergence is strong because strong and weak convergence is the same in finite dimensions. Since the diameter of the simplex containing the fixed point $x_{\varepsilon(\omega)}(\omega)$ converges to 0, it follows that

$$\lim_{\varepsilon(\omega) \to 0} x_{k}^{\varepsilon(\omega)}(\omega) = x(\omega)$$

By upper semicontinuity, for $A = B, C$, it follows that $\hat{A}\left(x_k^{\varepsilon(\omega)}(\omega), \omega\right) \subseteq \hat{A}\left(x(\omega), \omega\right) + B(0, r)$ for all $\varepsilon(\omega)$ small enough. Since, by the construction,

$$\hat{B}(x_k^{\varepsilon(\omega)}(\omega), \omega) = \theta(\omega)^* i(\omega)^* w_k^{\varepsilon(\omega)}(\omega) \in \hat{B}\left(x_k^{\varepsilon(\omega)}(\omega), \omega\right),$$

a similar statement for $\hat{C}$, it follows that $\hat{B}(x_k^{\varepsilon(\omega)}(\omega), \omega) = \theta(\omega)^* i(\omega)^* w_k^{\varepsilon(\omega)}(\omega)$ is within $r$ of the closed convex bounded set $\hat{B}(x(\omega), \omega)$ whenever $\varepsilon(\omega)$ is small enough, similar for $\hat{C}$. Thus

$$\theta(\omega)^* i(\omega)^* w_k^B(\omega) \in \hat{B}(x(\omega), \omega),$$
similar for \( \check{C} \). Since this last set is convex, it follows that
\[
\theta (\omega)^* i (\omega)^* \sum_{k} t_k (\omega) w_k^B (\omega) \in \check{B} (x (\omega), \omega)
\]
similar for \( \check{C} \).

Now recall and the inequality which imply that for \( z \in \theta (\omega)^{-1} K (\omega),
\[
\left( y (\omega) - \theta (\omega)^* i (\omega)^* \left( \sum_{k=0}^{n} t_k (\omega) w_k^B (\omega) + \sum_{k=0}^{n} t_k (\omega) w_k^C (\omega) \right), z - x (\omega) \right) = \lim_{\varepsilon (\omega) \to 0} \left( y (\omega) - \left( \sum_{k=0}^{n} t_k (\omega) \theta (\omega)^* i (\omega)^* w_k^{B(\omega)} (\omega) + \sum_{k=0}^{n} t_k (\omega) \theta (\omega)^* i (\omega)^* w_k^{C(\omega)} (\omega) \right), z - x_{\varepsilon (\omega)} (\omega) \right)
\]
(46.3.13)
\[
= \lim_{\varepsilon (\omega) \to 0} \left( y (\omega) - \left( \sum_{k=0}^{n} t_k (\omega) \theta (\omega)^* i (\omega)^* w_k^{B(\omega)} (\omega) + \sum_{k=0}^{n} t_k (\omega) \theta (\omega)^* i (\omega)^* w_k^{C(\omega)} (\omega) \right), z - x_{\varepsilon (\omega)} (\omega) \right)
\]
Recall and which imply from the above conventions that the sum in the above equals \( \check{B}_\varepsilon (x_{\varepsilon (\omega)}, \omega) + \check{C}_\varepsilon (x_{\varepsilon (\omega)}, \omega) \). Thus the above equals
\[
\lim_{\varepsilon (\omega) \to 0} \left( y (\omega) - \left( \check{B}_\varepsilon (x_{\varepsilon (\omega)}, \omega) + \check{C}_\varepsilon (x_{\varepsilon (\omega)}, \omega) \right), z - x_{\varepsilon (\omega)} (\omega) \right) \leq 0
\]
Now \( w_k^{B(\omega)} (\omega) \in B \left( \theta (\omega)^* x_{\varepsilon (\omega)} (\omega), \omega \right) \) and the weak uppersemicontinuity must then imply that \( w_k^B (\omega) \in B \left( \theta (\omega) x (\omega), \omega \right), \) a similar statement holding for \( C \). By convexity,
\[
w_B (\omega) = \sum_{k=0}^{n} t_k (\omega) w_k^B (\omega) \in B \left( \theta (\omega) x (\omega), \omega \right),
\]
similar for \( C \). Then from
\[
\left( y (\omega) - \theta (\omega)^* i (\omega)^* \left( \sum_{k=0}^{n} t_k (\omega) w_k^B (\omega) + \sum_{k=0}^{n} t_k (\omega) w_k^C (\omega) \right), z - x (\omega) \right) = \left( \theta (\omega)^* i (\omega)^* \left( y (\omega) - (w_B (\omega) + w_C (\omega)) \right), z - x (\omega) \right) \leq 0
\]
It follows that if \( x (\omega) = \theta (\omega) x (\omega), \)
\[
\langle y (\omega) - (w_B (\omega) + w_C (\omega)), \theta (\omega) z - x (\omega) \rangle \leq 0
\]
each of \( x (\omega), w_B (\omega), w_C (\omega) \) are measurable and \( w_B (\omega) \in B \left( x (\omega), \omega \right), w_C (\omega) \in C \left( x (\omega), \omega \right). \) Since \( \theta (\omega) z \) is a generic element of \( K (\omega), \) this proves the theorem.

Obviously one could have any finite sum of operators having the same properties as \( B, C \) above and one could get a similar result.
46.4 A Measurable Kakutani Theorem

Recall the Kakutani theorem, Theorem 46.3.1.

**Theorem 46.4.1** Let $K$ be a compact convex subset of $\mathbb{R}^n$ and let $A : K \to \mathcal{P}(K)$ such that $A x$ is a closed convex subset of $K$ and $A$ is upper semicontinuous. Then there exists $x$ such that $x \in A x$. This is the “fixed point”.

Here is a measurable version of this theorem. It is just like the proof of the above Browder lemma.

**Theorem 46.4.2** Let $K(\omega)$ be compact, convex, and $\omega \to K(\omega)$ a measurable multifunction. Let $A(\cdot, \omega) : K(\omega) \to K(\omega)$ be upper semicontinuous, and let $\omega \to A(x, \omega)$ have a measurable selection for each $x \in \mathbb{R}^n$. Then there exists $x(\omega) \in K(\omega) \cap A(K(\omega), \omega)$ such that $\omega \to x(\omega)$ is measurable.

**Proof:** Tile $\mathbb{R}^n$ with $n$ simplices such that the collection is locally finite and each simplex has diameter less than $\varepsilon < 1$. This collection of simplices is determined by a countable collection of vertices so there exists a one to one and onto map from $\mathbb{N}$ to the collection of vertices. By assumption, for each vertex $x$, there exists $A_\varepsilon(x, \omega) \in A(P_{K(\omega)} x, \omega)$. By Lemma 46.3.1 $\omega \to P_{K(\omega)} x$ is measurable and by Theorem 46.3.1 there is a measurable selection for $\omega \to A(P_{K(\omega)} x, \omega)$ which is denoted as $A_\varepsilon(x, \omega)$. By local finiteness, this function is continuous in $x$ on the set of vertices. Define $A_\varepsilon$ on all of $\mathbb{R}^n$ by the following rule. If $x \in [x_0, \ldots, x_n]$, so $x = \sum_{i=0}^n t_i x_i$, then

$$A_\varepsilon(x, \omega) = \sum_{k=0}^n t_k A_\varepsilon(x_k, \omega).$$

By local finiteness, this function satisfies $\omega \to A_\varepsilon(x, \omega)$ is measurable and also $x \to A_\varepsilon(x, \varepsilon)$ is continuous. It also maps $\mathbb{R}^n$ to $K(\omega)$. By Corollary 46.3.1 there is a measurable fixed point $x_\varepsilon(\omega)$ satisfying $x_\varepsilon(\omega) \in K(\omega)$ and $A_\varepsilon(x_\varepsilon(\omega), \omega) = x_\varepsilon(\omega)$.

Suppose $x_\varepsilon(\omega) \in [x_0(\omega), \ldots, x_n(\omega)]$ so $x_\varepsilon(\omega) = \sum_{k=0}^n t_k^\varepsilon(\omega) x_k^\varepsilon(\omega)$.

**Claim:** The vertices $x_k^\varepsilon(\omega)$ can be considered measurable also as is $t_k^\varepsilon(\omega)$.

**Proof of claim:** Let the simplices in the tiling be $\{\sigma_k\}_{k=1}^\infty$ and let the vertices of simplices in the tiling be $\{z_j\}_{j=1}^\infty$. Let

$$F_k := x_k^{-1} (\sigma_k), E_1 := F_1, \ldots, E_k := F_k \setminus \bigcup_{i=1}^{k-1} F_i$$

Then $\omega$ is in exactly one of these measurable sets $E_k$. These measurable sets partition $\Omega$. Let $\sigma_k(\omega)$ be the unique simplex for $\omega \in E_k$. Thus $x_\varepsilon(\omega) \in \sigma_k(\omega)$ on the measurable set $E_k$. Its vertices, are $z_{i_0}(\omega), z_{i_1}(\omega), \ldots, z_{i_n}(\omega)$. These are $x_0^\varepsilon(\omega), \ldots, x_n^\varepsilon(\omega)$ in order. They are determined in this way on a measurable set so they are measurable $\mathbb{R}^n$ valued functions. Then $\omega \to t_k^\varepsilon(\omega)$ is also measurable because there is a continuous mapping to these scalars from $x_\varepsilon(\omega)$. 

Then since \( x_\varepsilon (\omega) \) is contained in \( K (\omega) \), a compact set, and the diameter of each simplex is less than 1, it follows that \( A_\varepsilon (x_k^\varepsilon (\omega), \omega) \) is contained in 

\[
A(\overline{K (\omega)} + B(0,1), \omega)
\]

which is a compact set. Let \( W^\varepsilon (\omega) \in \mathbb{R}^{2n+2n^2} \) be defined as follows.

\[
W^\varepsilon (\omega) := \left( t_1^\varepsilon (\omega), \ldots, t_n^\varepsilon (\omega), x_0^\varepsilon (\omega), \ldots, x_n^\varepsilon (\omega), x_\varepsilon (\omega), \right)
\]

Therefore, \( P \left( x_k^\varepsilon (\omega), \omega \right) \) converges to \( P \left( x_\varepsilon (\omega), \omega \right) \) as \( \varepsilon (\omega) \to 0 \). Recall also that

\[
A_\varepsilon (x_k^\varepsilon (\omega), \omega) \subseteq A \left( P_K (\omega) x_k^\varepsilon, \omega \right)
\]

Now

\[
|P_{K(\omega)} x_k^\varepsilon (\omega) - x_\varepsilon (\omega)| = |P_{K(\omega)} x_k^\varepsilon (\omega) - P_{K(\omega)} x_\varepsilon (\omega)| \leq |x_k^\varepsilon - x_\varepsilon| < \varepsilon
\]

Both \( x_k^\varepsilon (\omega) \) and \( x_\varepsilon (\omega) \) converge to \( x (\omega) \) and so the above shows that also, \( P_{K(\omega)} x_k^\varepsilon (\omega) \to x (\omega) \). Therefore,

\[
A_\varepsilon \left( x_k^\varepsilon (\omega), \omega \right) \subseteq A \left( x (\omega), \omega \right) + B(0,r)
\]

whenever \( \varepsilon (\omega) \) is small enough. Since \( A \left( x (\omega), \omega \right) \) is closed, this implies \( y_k (\omega) \in A \left( x (\omega), \omega \right) \). Since \( A \left( x (\omega), \omega \right) \) is convex,

\[
\sum_{k=1}^{n} t_k (\omega) y_k (\omega) \in A \left( x (\omega), \omega \right).
\]

Also, from the construction,

\[
x_\varepsilon (\omega) = A_\varepsilon \left( x_\varepsilon (\omega), \omega \right) = \sum_{k=0}^{n} t_k^\varepsilon (\omega) A_\varepsilon \left( x_k^\varepsilon (\omega), \omega \right)
\]

so passing to the limit as \( \varepsilon (\omega) \to 0 \), we get

\[
x (\omega) = \sum_{k=0}^{n} t_k (\omega) y_k (\omega) \in A \left( x (\omega), \omega \right)
\]

and this is the measurable fixed point. \( \blacksquare \)
46.5 Some Variational Inequalities

In the following, \( V \) will be a reflexive separable Banach space. Following \[46.5\], here is a definition of a pseudomonotone operator. Actually, we will consider a slight generalization of the usual definition in \[23.4.17\] which involves an assumption that there exists a subsequence such that the \( \lim \inf \) condition holds rather than use the original sequence.

**Definition 46.5.1** Let \( V \) be a reflexive Banach space. Then \( A : V \to \mathcal{P}(V') \) is pseudomonotone if the following conditions hold.

\[
Au \text{ is closed, nonempty, convex.} \tag{46.5.14}
\]

If \( F \) is a finite dimensional subspace of \( V \), then if \( u \in F \) and \( W \supseteq Au \) for \( W \) a weakly open set in \( V' \), then there exists \( \delta > 0 \) such that

\[
v \in B(u, \delta) \cap F \text{ implies } Av \subseteq W. \tag{46.5.15}
\]

If \( u_k \rightharpoonup u \) and if \( u_k^* \in Au_k \) is such that

\[
\limsup_{k \to \infty} \langle u_k^*, u_k - u \rangle \leq 0,
\]

Then there exists a subsequence still denoted with \( k \) such that for all \( v \in V \), there exists \( u^*(v) \in Au \) such that

\[
\liminf_{k \to \infty} \langle u_k^*, u_k - v \rangle \geq \langle u^*(v), (u - v) \rangle. \tag{46.5.16}
\]

We say \( A \) is coercive if

\[
\lim_{\|v\| \to \infty} \inf \left\{ \frac{\langle z^*, v \rangle}{\|v\|} : z^* \in Av \right\} = \infty. \tag{46.5.17}
\]

If one assumes \( A \) is bounded, then the weak upper semicontinuity condition \[46.5.15\] can be proved from the other conditions. It has been known for a long time that these operators are useful in the study of variational inequalities. In this section, we give a short example to show how one can obtain measurable solutions to variational inequalities from the measurable Browder lemma given above. This is the following theorem which gives a measurable version of old results of Brezis dating from the late 1960s. This will involve the following assumptions.

1. **Measurability condition**
   For each \( u \in V \), there is a measurable selection \( z(\omega) \) such that
   \[ z(\omega) \in A(u, \omega). \]

2. **Values of \( A \)**
   \( A(\cdot, \omega) : V \to \mathcal{P}(V') \) has bounded, closed, nonempty, convex values. \( A(\cdot, \omega) \) maps bounded sets to bounded sets.
3. Limit conditions

If \( u_n \to u \) and \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0, \) \( z_n \in A(u_n, \omega) \)

then for given \( v \), there exists \( z(v) \in A(u, \omega) \) such that

\[
\liminf_{k \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle
\]

Thus, for fixed \( \omega, A(\cdot, \omega) \) is a set valued bounded pseudomonotone operator. Recall that the sum of two of these is also a set valued bounded pseudomonotone operator.

By Theorem 46.3.1 if \( \omega \to u(\omega) \) is measurable, then \( A(u(\omega), \omega) \) has a measurable selection. Also, the limit condition implies that \( A(\cdot, \omega) \) is upper semicontinuous from the strong to the weak topology. The overall approach to the following theorem is well known. The new ingredients are Lemma 46.2.2 and Theorem 46.3.3 which are what allows us to obtain measurable solutions. First is a standard result on the sum of two pseudomonotone bounded operators. See Theorem 23.5.1 on Page 833.

Theorem 46.5.2 Say \( A, B \) are set valued bounded pseudomonotone operators. Then their sum is also a set valued bounded pseudomonotone operator. Also, if \( u_n \to u \) weakly, \( z_n \to z, \) \( z_n \in A(u_n), \) and \( w_n \to w \) weakly with \( w_n \in A(u_n) \), then if

\[
\limsup_{n \to \infty} \langle z_n + w_n, u_n - u \rangle \leq 0,
\]

it follows that

\[
\liminf_{n \to \infty} \langle z_n + w_n, u_n - v \rangle \geq \langle z(v) + w(v), u - v \rangle, \quad z(v) \in A(u), w(v) \in B(u),
\]

and \( z \in A(u), w \in B(u) \).

Theorem 46.5.3 Let \( V \) be a reflexive separable Banach space. Let \( \omega \to K(\omega) \) be a measurable multifunction, \( K(\omega) \) convex, closed, and bounded. Also for \( A = B, C \) let \( A(\cdot, \cdot) \) satisfy 4. Let \( \omega \to f(\omega) \) be measurable with values in \( V' \). Then there exists measurable \( \omega \to u(\omega) \in K(\omega) \) and \( \omega \to w_B(\omega), \omega \to w_C(\omega) \) with \( w_B(\omega) \in B(u(\omega), \omega), w_C(\omega) \in C(u(\omega), \omega) \) such that

\[
\langle f(\omega) - (w_B(\omega) + w_C(\omega)), z - u(\omega) \rangle \leq 0
\]

for all \( z \in K(\omega) \). If it is only known that \( K(\omega) \) is closed and convex, the same conclusion can be obtained if it is also known that for some \( z(\omega) \in K(\omega), B(\cdot, \omega) + C(\cdot, \omega) \) is coercive meaning

\[
\lim_{\|v\| \to \infty} \inf \left\{ \frac{\langle z^*, v - z \rangle}{\|v\|} : z^* \in B(v, \omega) + C(v, \omega) \right\} = \infty.
\]
Proof: Let \( V_n = V_n(\omega) \) denote an increasing sequence of finite dimensional subspaces whose union is dense in \( V \). Let \( V_n(\omega) \) contain the first \( n \) vectors of \( \{d_k(\omega)\}_{k=1}^\infty \) where the closure of this sequence equals \( K(\omega) \) for each \( \omega \), each function being measurable. Let

\[
V_n(\omega) = \text{span}(v_1, \cdots, v_n, d_1(\omega), \cdots, d_n(\omega)).
\]

where \( \{v_k\}_{k=1}^\infty \) is dense in \( V \). Also let

\[
\gamma_n(\omega) = \max\{\|d_1(\omega)\|, \cdots, \|d_n(\omega)\|, \|v_1\|, \cdots, \|v_n\|\}
\]

and \( B_n(\omega) \) defined as \( B(0, \gamma_n(\omega)) \). Then let

\[
K_n(\omega) = V_n(\omega) \cap K(\omega) \cap B_n(\omega) \neq \emptyset \quad \forall_n K_n(\omega) \quad \text{dense in } K(\omega)
\]

Now each \( K_n(\omega) \) is a set valued compact convex subset of \( V_n(\omega) \) which is a measurable multifunction. It is a measurable multifunction because the linear combinations of the measurable functions \( \{v_1, \cdots, v_n, d_1(\omega), \cdots, d_n(\omega)\} \) having a subset of the rational numbers as coefficients is a dense subset of \( K_n(\omega) \). Then by Theorem 4.6.3.3, there exist measurable functions

\[
u_n(\omega) \in K_n(\omega), w_n^B(\omega) \in B(u_n(\omega), \omega), w_n^C(\omega) \in C(u_n(\omega), \omega)
\]

such that

\[
\langle f(\omega) - (w_n^B(\omega) + w_n^C(\omega)), z - u_n(\omega) \rangle \leq 0 \quad (*)
\]

for all \( z \in K_n(\omega) \).

Thus for all \( w \in K_n(\omega) \),

\[
\langle w_n^B(\omega) + w_n^C(\omega), u_n(\omega) - w \rangle \leq \langle f(\omega), u_n(\omega) - w \rangle.
\]

These \( u_n(\omega) \) are bounded because \( K(\omega) \) is a bounded set or in the other case, one can pick the special \( z(\omega) \) in the definition for coercivity to obtain that these \( u_n(\omega) \) are bounded. Thus, since \( A(\cdot, \omega) \) is assumed to be bounded for \( A = B, C \), each of \( u_n(\omega) \) and \( w_n^B(\omega), w_n^C(\omega) \) are bounded for each \( \omega \).

By Lemma 4.6.3.3, there is a subsequence \( n(\omega) \) such that

\[
\left( u_n(\omega), w_n^B(\omega), w_n^C(\omega) \right)
\]

converges weakly to \( (u(\omega), w_B(\omega), w_C(\omega)) \) in \( V \times V' \times V' \) and

\[
\omega \rightarrow (u(\omega), w_B(\omega), w_C(\omega))
\]

is measurable into \( V \times V' \times V' \). It is now only a matter of verifying the desired variational inequality for each \( \omega \).

By convexity, \( u(\omega) \in K(\omega) \). Now for fixed \( \omega \), let \( \hat{u}_n(\omega) \rightarrow u(\omega) \) strongly in \( V \) where \( \hat{u}_n(\omega) \in K_n(\omega) \). Then

\[
\lim_{n(\omega) \rightarrow \infty} \sup_{n(\omega)} \left( w_n^B(\omega) + w_n^C(\omega), u_n(\omega) - u(\omega) \right) = \lim_{n(\omega) \rightarrow \infty} \left( w_n^B(\omega) + w_n^C(\omega), u_n(\omega) - \hat{u}_n(\omega) \right)
\]
46.5. SOME VARIATIONAL INEQUALITIES

\[ \leq \lim_{n(\omega) \to \infty} \sup \langle f(\omega), u_{n(\omega)}(\omega) - \hat{u}_{n(\omega)} \rangle \leq 0. \]

By Theorem 46.5.3.1,

\[ w_B(\omega) \in B(u(\omega), \omega), w_C(\omega) \in C(u(\omega), \omega). \]

Also, there is a subsequence, still denoted with \( n(\omega) \) such that

\[ \lim \inf_{n(\omega) \to \infty} \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle \]

\[ \geq \langle w(u(\omega)), u(\omega) - u(\omega) \rangle = 0 \]

for some \( w(u(\omega)) \in B(u(\omega), \omega) + C(u(\omega), \omega) \) because the sum of pseudomonotone operators is pseudomonotone. Thus for this subsequence, since

\[ \lim \sup_{n(\omega) \to \infty} \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle \]

\[ \leq 0 \leq \lim \inf_{n(\omega) \to \infty} \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle, \]

it follows that

\[ \lim_{n(\omega) \to \infty} \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle = 0. \]

We will consider this subsequence or a further subsequence. Then since the lim sup condition holds for this subsequence, there exists for any \( v \in V \), \( w_B(v) \in B(u(\omega), \omega), w_C(v) \in C(u(\omega), \omega) \) such that

\[ \langle w_B(\omega) + w_C(\omega), u(\omega) - v \rangle \]

\[ \geq \lim \inf_{n(\omega) \to \infty} \left( \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle + \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u(\omega) - v \rangle \right) \]

\[ = \lim \inf_{n(\omega) \to \infty} \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - v \rangle \]

\[ \geq \langle w_B(v) + w_C(v), u(\omega) - v \rangle \]

Finally, let \( v \in K(\omega) \). Then it follows that there exists a sequence \( \{\hat{v}_n\} \) such that \( \hat{v}_n \in K_n(\omega) \) which converges strongly to \( v \). Thus

\[ \langle w_n^B(\omega) + w_n^C(\omega), u_n(\omega) - \hat{v}_n \rangle \leq \langle f(\omega), u_n(\omega) - \hat{v}_n \rangle \]

Then

\[ \langle w_B(\omega) + w_C(\omega), u(\omega) - v \rangle = \]

\[ \lim_{n(\omega) \to \infty} \sup_{n(\omega) \to \infty} \left( \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u_{n(\omega)}(\omega) - u(\omega) \rangle \right. \]

\[ + \left. \langle w_{n(\omega)}^B(\omega) + w_{n(\omega)}^C(\omega), u(\omega) - v \rangle \right) \]
We can let

\[ \lim \sup_{n(\omega) \to \infty} \left\langle w_{n(\omega)}^B (\omega) + w_{n(\omega)}^C (\omega), u_{n(\omega)} (\omega) - v \right\rangle \]

\[ = \lim \sup_{n(\omega) \to \infty} \left\langle w_{n(\omega)}^B (\omega) + w_{n(\omega)}^C (\omega), u_{n(\omega)} (\omega) - \hat{v}_{n(\omega)} \right\rangle \]

\[ \leq \lim \sup_{n(\omega) \to \infty} \left\langle f (\omega), u_{n(\omega)} (\omega) - \hat{v}_{n(\omega)} \right\rangle = \langle f (\omega), u (\omega) - v \rangle \]

Note that from standard results, in the case of coercivity and \( V = K (\omega) \), the above shows that for \( f \) measurable there is a measurable \( u \) such that \( f (\omega) \in B (u (\omega), \omega) + C (u (\omega), \omega) \). Specifically, there are measurable functions \( w_B (\omega) \in B (u (\omega), \omega) \) and \( w_C (\omega) \in C (u (\omega), \omega) \) such that \( f (\omega) = w_C (\omega) + w_B (\omega) \).

**Example 46.5.4** We can let \( \Omega = [0, T] \) and let the measurable sets be the Lebesgue measurable sets, \( t \to f (t) \) measurable into \( V' \). Then for \( A (\cdot, \cdot) \) satisfying \( \mathbb{H} \) the above theorem gives the solution \( u, w(t), u(t) \in K(t) \) to variational inequalities of the form

\[ \langle f (t) - w (t), z - u (t) \rangle \leq 0, \ w (t) \in A (u (t), t) \]

for all \( z \in K (t) \) where \( K (t) \) is a closed bounded convex subset of \( V \) for \( t \to K (t) \) a measurable multifunction. Here both \( u \) and \( w \) are measurable. If \( u \to A (u, t) \) is coercive, this allows for \( K (t) \) only closed and convex. If \( A \) is the sum of \( B, C \) and \( u \to B (u, t) \) and \( u \to C (u, t) \), these each satisfying the conditions \( \mathbb{H} \), \( w (t) = w_B (t) + w_C (t) \) where both of these summands are measurable and \( w_B (t) \in B (u (t), t) \), \( w_C (t) \in C (u (t), t) \). If suitable estimates hold, and \( f \in L^p ([0, T]; V') \) then one can conclude that \( w \in L^p ([0, T]; V') \) and \( u \in L^p ([0, T]; V) \). This paper has resolved the only difficult issue which is existence of a measurable solution with no monotonicity or uniqueness assumptions on the problem for fixed \( t \).

**Example 46.5.5** We can let \( \Omega \) be of the form \( [0, T] \times \Omega \) where \( (\Omega, \mathcal{F}) \) is a measurable space. In this case, we could let the \( \sigma \) algebra be \( \mathcal{B} \times \mathcal{F} \) the product measurable sets and obtain product measurable solutions to the same variational inequalities.

**Example 46.5.6** In the case of a filtration \( \{ \mathcal{F}_t \} \), one could let the \( \sigma \) algebra consist of the progressively measurable sets and obtain the same conclusions. Thus the variational inequality would be of the form

\[ \langle f (t, \omega) - w (t, \omega), z - u (t, \omega) \rangle \leq 0, \ w (t, \omega) \in A (u (t, \omega), t, \omega), z \in K (t, \omega) \]

This result is quite interesting because it is describing a situation where there is no uniqueness or monotonicity and all that is required are conditions of measurability on \( f \). Also, one only needs to check the limit conditions on \( u \to A (u, \omega) \) for fixed \( \omega \) so all Sobolev embedding theorems are available. Nor is it necessary to assume that \( \omega \to A (u, \omega) \) is a measurable multifunction as is often done. It suffices to check that it has a measurable selection. This is a strictly more general condition.
46.6 An Example

Let \( r \to \sigma (r, t) \) be a continuous function of \( r \) which satisfies

\[
\begin{align*}
  r & \to \sigma (r, t) \text{ is continuous, } t \to \sigma (r, t) \text{ is measurable,} \\
  0 & < \delta (t) \leq \sigma (r, t) \leq 1/\delta (t)
\end{align*}
\]

There is no uniform lower bound needed for \( \delta (t) \). Then we will let \( V \) be a closed subspace of \( H^1 (\Omega) \) where \( \Omega \) is a bounded open set with Lipschitz boundary.

\[
V \equiv \left\{ u \in H^1 (\omega) : \gamma u = 0 \text{ on } \Sigma_0 \right\}
\]

where \( \alpha (\Sigma_0) > 0 \) for \( \alpha \) the surface measure, \( \Sigma_0 \) a closed subset of \( \partial \Omega \) and \( \gamma \) is the trace map. Thus an equivalent norm for \( V \) is

\[
\| u \|_V^2 = \int_\Omega |\nabla u|^2 \, dx
\]

Also let \( H = L^2 (\Omega) \) and let \( H = H' \) so that \( V \subseteq H = H' \subseteq V' \). Then let \( A (\cdot, t) : V \to V' \) be defined by

\[
\langle A (u, t), v \rangle = \int_\Omega \sigma (u, t) \nabla u \cdot \nabla v
\]

Is this a bounded pseudomonotone map? It is clearly bounded thanks to the bounds on \( \sigma \). Suppose then that \( u_n \to u \) weakly in \( V \) and

\[
\limsup_{n \to \infty} \langle A (u_n, t), u_n - u \rangle \leq 0
\]

Does the \( \liminf \) condition hold? If not, then there exists a subsequence and \( v \in V \) such that

\[
\lim_{n \to \infty} \langle A (u_n, t), u_n - v \rangle < \langle A (u, t), u - v \rangle
\]

By compactness, there is a further subsequence still denoted with \( n \) such that \( u_n \to u \) strongly in \( L^2 (\Omega) \) and pointwise. Consider

\[
\int_\Omega \sigma (u_n, t) \nabla u_n \cdot (\nabla u_n - \nabla v)
\]

Now by the dominated convergence theorem,

\[
\int_\Omega |\sigma (u_n, t) - \sigma (u, t)|^2 \to 0
\]

and so in fact \( \sigma (u_n, t) \nabla u_n \to \sigma (u, t) \nabla u \) weakly in \( H^3 \). Then

\[
\int_\Omega \sigma (u_n, t) \nabla u_n \cdot (\nabla u_n - \nabla v) = \int_\Omega \sigma (u_n, t) \nabla u_n \cdot (\nabla u_n - \nabla u) + \int_\Omega \sigma (u_n, t) \nabla u_n \cdot (\nabla u - \nabla v)
\]
\[ \geq \int_{\Omega} \sigma(u_n, t) \nabla u \cdot (\nabla u_n - \nabla u) + \int_{\Omega} \sigma(u_n, t) \nabla u_n \cdot (\nabla u - \nabla v) \]

and so, taking lim inf of both sides using the estimates to justify the use of Fatou’s lemma,

\[ \lim_{n \to \infty} \int_{\Omega} \sigma(u_n, t) \nabla u_n \cdot (\nabla u_n - \nabla v) \geq \int_{\Omega} \sigma(u, t) \nabla u \cdot (\nabla u - \nabla v) \]

This is a contradiction. Thus the lim inf condition must hold.

Next consider another operator. Let \( \Sigma_1 \) be \( \partial \Omega \setminus \Sigma_0 \) and has positive surface measure. Let \( r \to a(r, t) \) be lower semicontinuous and \( r \to b(r, t) \) be upper semicontinuous. Let \( 0 < \delta(t) \leq a(r, t) \leq b(r, t) \leq \frac{1}{\delta(t)} \). Also let both of these functions be measurable in \( t \). Now \( \gamma : V \to L^2(\Sigma_1) \) and so \( \gamma^* : L^2(\Sigma_1) \to V' \) defined in the usual way. Then \( z \in B(u, t) \) will mean \( z = \gamma^* w \) for some \( w \in L^2(\Sigma_1) \) with

\[ w(x) \in [a(\gamma u(x), t), b(\gamma u(x), t)] \]

for a.e. \( x \) such that

\[ \langle z, v \rangle = \int_{\Sigma_1} w(x) \gamma v(x) \]

Using Sobolev embedding theorems, if \( u_n \to u \) weakly in \( V \), then from the Sobolev embedding theorem \( u_n \to u \) strongly in a suitable Sobolev space of fractional order such that the embedding of \( V \) into this space is compact and the trace map is still continuous. Thus there is a subsequence such that \( \gamma u_n(x) \to \gamma u(x) \) pointwise a.e. and \( w_n \to w \) in \( L^2(\Sigma_1) \). Then by the semicontinuity properties of \( a, b \) we obtain from routine considerations that \( w(x) \in [a(\gamma u(x), t), b(\gamma u(x), t)] \) a.e. To see how you can do this, let

\[ E = \left\{ x : w(x) \geq b(\gamma u(x), t) + \frac{1}{k} \right\} . \]

Then

\[ \int_{\Sigma_1} \mathcal{X}_E(x) (-b(\gamma u_n(x), t)) \leq \int_{\Sigma_1} \mathcal{X}_E(x) (-w_n(x)) \to \int_{\Sigma_1} \mathcal{X}_E(x) (-w(x)) \]

\[ \leq \int_{\Sigma_1} \mathcal{X}_E(x) \left( -b(\gamma u(x), t) - \frac{1}{k} \right) \]

By lower semicontinuity of \(-b(\cdot, t)\) and the boundedness assumption, we can use Fatou’s lemma to take lim inf of both sides and conclude that

\[ \int_{\Sigma_1} \mathcal{X}_E(x) (-b(\gamma u(x), t)) \leq \int_{\Sigma_1} \mathcal{X}_E(x) \left( -b(\gamma u(x), t) - \frac{1}{k} \right) \]

an obvious contradiction unless \( \alpha(E) = 0 \). Then taking the union of the exceptional sets for all \( k \), it follows that \( w(x) \leq b(\gamma u(x), t) \) a.e. The other side of the inequality can be shown similarly. Letting \( z_n \in B(u_n, t) \) and \( v \in V \), it is true that

\[ \lim \inf_{n \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u_n - v \rangle \]
for some $z (v) \in B (u, t)$. Suppose not. Then from the above, there is a subsequence such that the limit equals the lim inf but which has the inequality turned around for some $v$ and all $z \in B (u, t)$. Then from what was just shown, letting $w_n$ go with $z_n$, there is a further subsequence such that $w_n \to w$ weakly in $L^2 (\Sigma_1)$ and $\gamma u_n \to \gamma u$ strongly in $L^2 (\Sigma_1)$ and

$$w (x) \in [a (\gamma u (x), t), b (\gamma u (x), t)] \text{ a.e. } x$$

Then

$$\int_{\Sigma_1} w_n (x) (\gamma u_n (x) - \gamma v (x)) \to \int_{\Sigma_1} w (x) (\gamma u (x) - \gamma v (x)) = (z, u - v)$$

where $w \in B (u, t)$ and $z = \gamma^* w$ so the lim inf condition holds. Thus this second operator is pseudomonotone.

Do these have measurable selections? This is obvious. Letting $u \in V$, $t \to \gamma^* a (\gamma u (x), t)$ is measurable into $V'$ and is in $B (u, t)$. Similarly $t \to A (u, t)$ is measurable into $V'$. Note that on the second operator, it was really only necessary to assume that there exists $t \to c (r, t)$ measurable with $c (r, t) \in [a (r, t), b (r, t)]$ and totally eliminate the assumption that either $a$ or $b$ is measurable in $t$.

Now let $t \to f (t)$ be measurable into $V'$. Say

$$\langle f (t), v \rangle = \int_{\Omega} h (t) v dx + \int_{\Sigma_1} \beta (t) v d\alpha$$

and let $K (t) \subseteq V$ be a closed convex subset of $V$. There is obviously a coercivity condition holding for the sum of these two operators $A (u, t) + B (u, t)$ and so there exists $u (t) \in K (t)$ such that for all $v \in K (t)$

$$\langle f (t) - (A (u (t), t) + z (t)), v - u (t) \rangle \leq 0$$

(*)

where $t \to u (t)$ is measurable into $V$, $t \to z (t)$ measurable into $V'$, $t \to A (u (t), t)$ measurable into $V'$. Is $t \to w (t)$ measurable where $z (t) = \gamma^* w (t)$? Let $\phi \in V$. Then

$$\langle z (t), \phi \rangle_{V', V} = (w (t), \gamma \phi)_{L^2 (\Sigma_1)}$$

and is given to be a measurable function of $t$. However, since $\Sigma_1$ is open, the image of the trace is dense in $L^2 (\Sigma_1)$ and so by this density and Pettis theorem, $t \to w (t)$ must be measurable into $L^2 (\Sigma_1)$. Thus the variational inequality * is of the form

$$\left( \langle h (t), v - u (t) \rangle_H + \langle \beta (t) - w (t), \gamma v - \gamma u (t) \rangle_{L^2 (\Sigma_1)} - (\sigma (u (t), t) \nabla u (t), \nabla v)_{H^3} \right) \leq 0$$

for all $v \in K (t)$. If the inequality which gives coercivity were eliminated, we would still have the above if $K (t)$ were assumed bounded.

What equation is satisfied if $K (t) = V$? We would have

$$\int_{\Omega} \sigma (u (t), t) \nabla u (t) \cdot \nabla v dx + \int_{\Sigma_1} w (t) v dx = \int_{\Omega} \langle f (t), v \rangle dx,$$
Let of those points of $K$ convex sets $h$ either the desired solutions. Also note that nothing is needed about the integrability of $\max (\sigma (u(t),t)\nabla u(t))$. Then a formal application of the divergence theorem yields the boundary conditions

$$\sigma (u(t),t)\nabla u(t) \cdot \mathbf{n} + w(t) = \beta(t) \text{ on } \Sigma_1$$
$$u(t) = 0 \text{ on } \Sigma_0$$

where $w(t) \in [a(\gamma u(t),t), b(\gamma u(t),t)]$ along with the partial differential equation

$$-\nabla \cdot (\sigma (u(t),t)\nabla u(t)) = h(t)$$

Note that if either $a(\cdot, t)$ or $b(\cdot, t)$ were continuous, there would have been no point in considering the second operator as a set valued map. One could simply replace the closed interval $[a(r,t), b(r,t)]$ with either $a(r,t)$ or $b(r,t)$ and obtain the desired solutions. Also note that nothing is needed about the integrability of either $t \to h(t)$ or $t \to \beta(t)$. The following lemma is convenient in considering the convex sets $K(t)$.

**Lemma 46.6.1** Let $F$ be those points where $u = 0$. Then for a.e. $x \in F, \nabla u(x) = 0$.

**Proof:** Suppose $u = 0$ on $F \subseteq \Omega$, $F$ Borel measurable. Then $u_{x_n} = 0$ a.e. Here $u \in W^{1,p}(\Omega)$.

$$\frac{u(t_1, \ldots, t_{n-1}, t_n) - u(t_1, \ldots, t_{n-1}, t_n - h)}{h} = \frac{1}{h} \int_{t_n-h}^{t_n} u_{x_n}(t_1, \ldots, t_{n-1}, s) \, ds$$

Then a.e. $t_n$ is a Lebesgue point of $u_{x_n}$ for $F(t_1, \ldots, t_{n-1})$ where $F(t_1, \ldots, t_{n-1})$ consists of those points of $F$ where $(t_1, \ldots, t_{n-1})$ is fixed. Also let $t_n$ be a point of density of $F(t_1, \ldots, t_{n-1})$. Of course $m_1$ a.e. points of $F(t_1, \ldots, t_{n-1})$ are points of density. Therefore, there exists a sequence $h_k \to 0$ such that $t_n - h_k \to t_n$ as $k \to \infty$ and $(t_n - h_k) \in F(t_1, \ldots, t_{n-1})$. Otherwise there would be some open set about $t_n$ which excludes points of $F(t_1, \ldots, t_{n-1})$ which would imply that $t_n$ is not actually a point of density. Then using the fundamental theorem of calculus, we get for such points which are points of $F(t_1, \ldots, t_{n-1})$ the fact that $u_{x_n}(t_1, \ldots, t_{n-1}, t_n) = 0$. Thus for a.e. $t_n \in F(t_1, \ldots, t_{n-1}), u_{x_n}(t_1, \ldots, t_{n-1}, t_n) = 0$. Thus $u_{x_n}(t_1, \ldots, t_{n-1}, t_n) = 0$ for a.e. $t_n$ in $F(t_1, \ldots, t_{n-1})$. Similar reasoning holds for differentiation with respect to the other variables. Thus $\nabla u = 0$ a.e. on $F$.

**Lemma 46.6.2** Let $V$ be a closed subset of $W^{1,p}(\Omega), p > 1$ and let $k \in V$. Then max $(k, u) \in V$ and if $u_n \to u$ in $V$, then max $(u_n, k) \to \max (u, k)$ in $V$. 
46.6. AN EXAMPLE

Proof: We consider \( \psi (r) = |r|, \psi_\varepsilon (r) = \sqrt{\varepsilon + r^2} \). Then for \( \phi \in C^\infty_c (\Omega), \)

\[
\int_\Omega \psi (u) \phi_{x_k} (x) = \lim_{\varepsilon \to 0} \int_\Omega \psi_\varepsilon (u) \phi_{x_k} (x) \]

\[
= - \lim_{\varepsilon \to 0} \int_\Omega \frac{u(x)}{\sqrt{\varepsilon + u^2}} \phi (x) \]

\[
= - \int_\Omega \xi (u) \phi (x)
\]

where \( \xi (r) = 1 \) if \( r > 0 \), \(-1 \) if \( r < 0 \) and \( 0 \) if \( r = 0 \). Thus \( \psi (u) \phi_{x_k} = \xi (u) \phi_{x_k} \) a.e. and this is clearly in \( W^{1,p} (\Omega) \). Of course \( \max(u, k) = \frac{|k-u|+(k+u)}{2} \) so this shows that \( \max(u, k) \) is in \( W^{1,p} (\Omega) \).

Next suppose \( u_n \to u \) in \( W^{1,p} (\Omega) \). Does

\[
\xi (u_n) u_{n,x_k} \to \xi (u) u_{x_k} \text{ ?}
\]

Let \( G = \{ x : u(x) \neq 0 \} \). A subsequence, still denoted by \( u_n \), converges pointwise a.e. to \( u \) and \( u_{n,x_k} \to u_{x_k} \) pointwise a.e. Therefore, off a set of measure zero, \( \xi (u_n (x)) = \xi (u (x)) \) for all \( n \) large enough. Thus

\[
\left( \int_\Omega |\xi (u_n) u_{n,x_k} - \xi (u) u_{x_k} |^p \right)^{1/p} \leq \left( \int_\Omega |\xi (u_n) u_{n,x_k} - \xi (u_n) u_{x_k} |^p \right)^{1/p} \]

\[
+ \left( \int_\Omega |\xi (u_n) - \xi (u) |^p u_{x_k} |^p \right)^{1/p}
\]

That second term on the right converges to 0. It equals

\[
\left( \int_G |\xi (u_n) - \xi (u) |^p u_{x_k} |^p \right)^{1/p}
\]

Now on \( G \), \( u_{x_k} (x) = 0 \) a.e. by the above lemma and so the first term in the parentheses is 0. The second converges to 0 by the dominated convergence theorem. Then this shows that the second term in * converges to 0. The first obviously converges to 0 from the convergence of \( u_{n,x_k} \) to \( u_{x_k} \). Now consider whether \( \psi (u_n) \phi_{x_k} \) converges to \( \psi (u) \phi_{x_k} \). Those functions \( \psi (u_n) \phi_{x_k} \) are bounded in \( L^p (\Omega) \) from the above description and so if it fails to converge to \( \psi (u) \phi_{x_k} \) in \( L^p \) a subsequence converges weakly to \( \zeta \neq \psi (u) \phi_{x_k} \). But then, the above argument shows that a further subsequence does converge strongly to \( \psi (u) \phi_{x_k} \) contrary to \( \zeta \neq \psi (u) \phi_{x_k} \).

Now, from the description of the maximum of two functions given above, we obtain that \( \max (u_n, k) \to \max (u, k) \) in \( V \) provided \( u_n \to u \) in \( V \). ■

What of the convex set \( K (t) \)? Consider \( k (t, x) \) where \( k (t, \cdot) \) is continuous into \( V \). Thus \( k (t, \cdot) \) is clearly measurable into \( V \). Also \( C ([0, T]; V) \) is separable, hence completely separable. It follows that

\[
\{ u \in C ([0, T]; V) : \text{ for all } t, u(t, x) \geq k(t, x) \text{ a.e. } x \}
\]
is also separable. Let \( \{ b_i(t) \}_{i=1}^{\infty} \) be a dense countable subset of \( K(t) \), each \( b_i \) measurable. One could obtain such by letting \( b_i(t, x) = \max (k(t, x), d_i(t, x)) \) where \( \{ d_i \}_{i=1}^{\infty} \) is a countable dense subset of \( C([0, T]; V) \). Then let \( K(t) \) be the closure of \( b_i(t) \) in \( V \). It follows that \( t \to K(t) \) is a measurable multifunction with values in \( V \). If \( u \in K(t) \), there exists a sequence \( b_{i_k}(t) \to u \) in \( V \). Therefore, a subsequence converges to \( u \) pointwise a.e. and it follows that \( u(x) \geq k(t, x) \) a.e. \( x \). On the other hand, if \( u(x) \geq k(t, x) \) for a.e. \( x \), does it follow that it is the limit of a subsequence of the \( b_i(t) \) in \( V \)? Consider \( \max (u(x), k(s, x)) \equiv l(s, x) \). Then \( l \) is in \( C([0, T]; V) \) and is always as large as \( k(s, x) \) for all \( s \). Therefore, there is a subsequence \( b_{i_k}(t, \cdot) \) which converges to \( l(t, \cdot) \) pointwise a.e. and in \( V \). Thus \( b_{i_k}(t) \) converges to \( u \) pointwise also for a.e. \( x \). It follows that \( t \to K(t) \) is measurable into \( V \) and \( K(t) = \{ u \in V : u(x) \geq k(t, x) \text{ a.e.} \} \). As an example, you could simply take \( k \) to be the restriction to \( \Omega \times [0, T] \) of a smooth function. This is an example of an obstacle problem in which the obstacle changes in \( t \) and there is no uniqueness even though there exists a measurable solution to the variational inequality for each \( t \).

One could also replace \( \sigma(u, t) \) with a graph having a jump as in the second of the two operators and get similar results by beginning with the above solutions and then using Lemma 46.22, and the arguments used in the second operator to pass to a limit.

The next section is an interesting result on the pseudomonotone condition for Nemytskii operators defined in this section.

### 46.7 Limit Conditions For Nemytskii Operators

This is about the following problem. You know

\[
u \to A(u, t)\]

is pseudomonotone. You can also define \( \hat{A} : V \to V' \) by

\[
\hat{A}(u)(t) \equiv A(u(t), t) \text{ a.e.}
\]

Then when can you obtain a useable limit condition for \( \hat{A} \)? I think the earliest solution to this problem was given in [16]. These ideas were extended to set valued maps in [17] and to another situation in [18].

Define \( V \equiv V_p \) by

\[
V = L^p([0, T]; V), \quad p > 1,
\]

where \( V \) is a separable Banach space and \( H \) is a Hilbert space such that

\[
V \subseteq H = H' \subseteq V'
\]

with each space dense in the following one. The measure space is chosen to be \( ([0, T], \mathcal{B}([0, T]), m) \) where \( m \) is the Lebesgue measure and \( \mathcal{B}([0, T]) \) consists of all the Borel sets, although one could use the \( \sigma \) algebra of Lebesgue measurable sets as
well. We denote by $V$ or $\mathcal{V}$ the above space. If $U$ is a Banach space, $U_r$ will denote $L^r([0, T], U)$.

We will assume the following measurability condition. For each $u \in V$,

$$t \to A(u(t), t)$$

is a measurable multifunction \((46.7.18)\)

In the case when $A(\cdot, t)$ is single-valued, bounded and pseudomonotone, this measurability condition is satisfied and so it is measurable. Thus, this definition is a generalization of what would be expected for single-valued operators. We use the following lemma.

**Lemma 46.7.1** Let $U$ be a separable reflexive Banach space. Suppose there is a sequence $\{u_j(\omega)\}_{j=1}^{\infty}$ in $U$, where each $\omega \to u_j(\omega)$ is measurable and for each $\omega$, $\sup_i \|u_i(\omega)\| < \infty$. Then, there exists $u(\omega) \in U$ such that $\omega \to u(\omega)$ is measurable, and a subsequence $n(\omega)$, that depends on $\omega$, such that the weak limit

$$\lim_{n(\omega) \to \infty} u_n(\omega) = u(\omega)$$

holds.

**Proof.** Let $\{z_i\}_{i=1}^{\infty}$ be a countable dense subset of $U'$. Let $h : U \to \prod_{i=1}^{\infty} \mathbb{R}$ be defined by

$$h(u) = \prod_{i=1}^{\infty} \langle z_i, u \rangle.$$

Let $X = \prod_{i=1}^{\infty} \mathbb{R}$ with the product topology. Then, this is a Polish space with the metric defined as $d(x, y) = \sum_{i=1}^{\infty} \frac{|x_i - y_i|}{1 + |x_i - y_i|} 2^{-i}$. By compactness, for a fixed $\omega$, the $h(u_n(\omega))$ are contained in a compact subset of $X$. Next, define

$$\Gamma_n(\omega) = \bigcup_{k \geq n} h(u_k(\omega)),$$

which is a nonempty compact subset of $X$.

Next, we claim that $\omega \to \Gamma_n(\omega)$ is a measurable multifunction.

The proof of the claim is as follows. It is necessary to show that $\Gamma_n(\omega)$ defined as $\{\omega : \Gamma_n(\omega) \cap O \neq \emptyset\}$ is measurable whenever $O$ is open. It suffices to verify this for $O$ a basic open set in the topology of $X$. Thus let $O = \prod_{i=1}^{\infty} O_i$ where each $O_i$ is a proper open subset of $\mathbb{R}$ only for $i \in \{j_1, \cdots, j_m\}$. Then,

$$\Gamma_n(\omega) = \bigcup_{k \geq n} \bigcap_{i=1}^{m} \{\omega : \langle z_{j_i}, u_k(\omega) \rangle \in O_{j_i}\},$$

which is a measurable set since $u_k$ is measurable.

Then, it follows that $\omega \to \Gamma_n(\omega)$ is strongly measurable because it has compact values in $X$, thanks to Tychonoff’s theorem. Thus $\Gamma_n^-(H) = \{\omega : H \cap \Gamma_n(\omega) \neq \emptyset\}$ is measurable whenever $H$ is a closed set. Now, let $\Gamma(\omega)$ be defined as $\cap_n \Gamma_n(\omega)$ and then for $H$ closed,

$$\Gamma^-(H) = \cap_n \Gamma_n^-(H)$$
and each set in the intersection is measurable, so this shows that \( \omega \to \Gamma(\omega) \) is also measurable. Therefore, it has a measurable selection \( g(\omega) \). It follows from the definition of \( \Gamma(\omega) \) that there exists a subsequence \( n(\omega) \) such that

\[
g(\omega) = \lim_{n(\omega) \to \infty} h \left( u_{n(\omega)}(\omega) \right) \quad \text{in } X.
\]

In terms of components, we have

\[
g_i(\omega) = \lim_{n(\omega) \to \infty} \langle z_i, u_{n(\omega)}(\omega) \rangle.
\]

Furthermore, there is a further subsequence, still denoted with \( n(\omega) \), such that

\[
u_{n(\omega)}(\omega) \to \nu(\omega) \quad \text{weakly}.
\]

This means that for each \( i; g_i(\omega) = \lim_{n(\omega) \to \infty} \langle z_i, u_{n(\omega)}(\omega) \rangle = \langle z_i, u(\omega) \rangle \).

Thus, for each \( z_i \) in a dense set, \( \omega \to \langle z_i, u(\omega) \rangle \) is measurable. Since the \( z_i \) are dense, this implies \( \omega \to \langle z, u(\omega) \rangle \) is measurable for every \( z \in U' \) and so by the Pettis theorem, \( \omega \to u(\omega) \) is measurable.

Also is a definition.

**Definition 46.7.2** Let \( A(\cdot, t): V \to \mathcal{P}(V') \). Then, the Nemitskii operator associated with \( A \),

\[
\hat{A}: \mathcal{L}^p([0,T]; V) \to \mathcal{P} \left( \mathcal{L}^p([0,T]; V') \right),
\]

is given by

\[
z \in \hat{A}(u) \quad \text{if and only if } z \in \mathcal{L}^{p'}([0,T]; V') \text{ and } z(t) \in A(u(t), t) \text{ a.e. } t.
\]

**Growth and coercivity**

The next three conditions on the operator \( A \) are similar to the conditions proposed by Bian and Webb. See also Berkovitz and Mustonen which seems to be the paper where these ideas originated. These specific and reasonable conditions, together with a fourth one we add below, allow us to prove an appropriate limit condition that is based on the assumption that \( u \to A(u, t) \) is a set-valued, bounded and pseudomonotone map from \( V \) to \( \mathcal{P}(V') \) and \( t \to A(u, t) \) has a measurable selection.

Our aim is to provide reasonable conditions under which an assumption of pseudomonotonicity on \( u \to A(u, t) \) transfers to a usable limit condition for the operator \( \hat{A} \) defined on \( V = \mathcal{L}^p([0,T]; V) \).

It is obvious that \( \hat{A}u \) is convex because this is true of \( A(u, t) \). It is also closed. To see this, suppose \( z_n \in \hat{A}(u) \). Then \( z_n(t) \in A(u(t), t) \) for a.e.t. Taking the union of the exceptional sets, we can assume this inclusion holds off a single set of measure zero for all \( n \). If you have \( z_n \to w \) strongly in \( V' \), then a subsequence converges pointwise a.e. Therefore, by upper semicontinuity of the pointwise operator \( u \to A(u, t) \), it follows that \( w(t) \in A(u(t), t) \) for a.e. \( t \). Thus \( \hat{A}u \) is convex and strongly closed.

We assume the following conditions on \( A \).
1. \( A(\cdot, t) : V \to \mathcal{P}(V') \) is pseudomonotone and bounded: \( A(u, t) \) is a closed convex set for each \( t, u \to A(u, t) \) is bounded, and if
\[
\limsup_{n \to \infty} \langle A(u_n, t), u_n - u \rangle \leq 0
\]
then for any \( v \in V \),
\[
\liminf_{n \to \infty} \langle A(u_n, t), u_n - v \rangle \geq \langle z(v), u - v \rangle \text{ some } z(v) \in A(u, t)
\]

2. \( A(\cdot, t) \) satisfies the estimates: There exists \( b_1 \geq 0 \) and \( b_2 \geq 0 \), such that
\[
\|z\|_{V'} \leq b_1 \|u\|_{V'}^{-1} + b_2 (t), \quad (46.7.19)
\]
for all \( z \in A(u, t) \), \( b_2 (\cdot) \in L^p ([0, T]) \).

3. There exist a positive constant \( b_3 \) and a nonnegative function \( b_4 \) that is \( B([0, T]) \) measurable and also \( b_4 (\cdot) \in L^1 ([0, T]) \), such that
\[
\inf_{z \in A(u, t)} \langle z, u \rangle \geq b_3 \|u\|_{V'}^2 - b_4 (t) - \lambda |u|_H^2 . \quad (46.7.20)
\]

4. The operators \( t \to A(u(t), t) \) are measurable in the sense that
\[
t \to A(u(t), t)
\]
is a measurable multifunction with respect to \( \mathcal{F} \) where \( \mathcal{F} \) will be the \( \sigma \) algebra of Lebesgue measurable sets whenever \( t \to u(t) \) is in \( V_p \).

5. For \( u \in V_p \), we define \( \hat{A}(u) \in \mathcal{P}(V'_p) \) as follows: \( z \in \hat{A}(u) \) means that \( z(t) \in A(u(t), t) \) a.e. \( t \). Thus this is the Nemytskii operator for \( A(\cdot, t) \).

In the following theorem and in arguments which take place below, \( U \) will be a Hilbert space dense in \( V \) with the inclusion map compact. Such a Hilbert space always exists and is important in probability theory where \((i, U, V)\) is an abstract Wiener space. However, in most applications from partial differential equations, it suffices to take \( U \) as a suitable Sobolev space.

**Theorem 46.7.3** Suppose conditions \( \[\] - \[\] \) hold. Also, suppose
\[
V \subseteq H = H' \subseteq V', \text{ where } V \text{ is dense in } H,
\]
Then, the operator \( \hat{A} \) satisfies the following.

**Hypotheses:**
\[
\mu_n \to u \text{ weakly in } V, \limsup_{n \to \infty} \langle z_n, u_n - u \rangle_{V'_p, V} \leq 0,
\]
for \( z_n \in \hat{A}u_n \), and there exists a set of zero measure \( \Sigma \) such that for \( t \notin \Sigma \), every subsequence of \( \{u_n\} \) has a further subsequence, possibly depending on \( t \notin \Sigma \) such that
\[
u_n(t) \to u(t) \text{ weakly in } U',
\]
where $U$ is a Banach space dense in $V$. In (4.3), if $\lambda > 0$, then assume also that
\[
\sup_n \sup_{t \in [0, T]} |u_n(t)| < \infty. \tag{46.7.21}
\]

**Conclusion:** If the above conditions hold, then there exists $z(v)$ with
\[
\lim \inf_{n \to \infty} \langle z_n, u_n - v \rangle_{V', V} \geq \langle z(v), u - v \rangle_{V', V}.
\]
where $z(v) \in \hat{A}(v)$. Furthermore, $\hat{A}$ is a nonempty, closed and convex set in $V'$.

**Proof:** It was argued above that $\hat{A}(u)$ is closed and convex.
Enlarge the set of measure zero $\Sigma$, if needed, so that for each $n$,
\[
z_n(t) \in A(u_n(t), t)
\]
for each $t \notin \Sigma$.
Next, we claim that if $t \notin \Sigma$, then
\[
\lim \inf_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle \geq 0.
\]

**Proof of the claim:** Let $t \notin \Sigma$ be fixed and suppose to the contrary that
\[
\lim \inf_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle < 0. \tag{46.7.22}
\]
Then, there exists a subsequence $\{n_k\}$, which may depend on $t$, such that
\[
\lim_{k \to \infty} \langle z_{n_k}(t), u_{n_k}(t) - u(t) \rangle = \lim \inf_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle < 0. \tag{46.7.23}
\]
Now, condition (3) implies that for all $k$ large enough,
\[
b_2 \|u_{n_k}(t)\|^p_{V'} - b_k(t) - \lambda \|u_{n_k}(t)\|^2_H < \|z_{n_k}(t)\|_{V'} \|u(t)\|_{V'}
\]
\[
\leq \left( b_1 \|u_{n_k}(t)\|^{p-1}_{V'} + b_2(t) \right) \|u(t)\|_{V'},
\]
therefore, $\|u_{n_k}(t)\|_{V'}$ and consequently $\|z_{n_k}(t)\|_{V'}$ are bounded. This follows from
(46.7.24) in case $\lambda > 0$. Note that $\|z_{n_k}(t)\|_{V'}$ is bounded independently of $n_k$ because of
the assumption that $A(\cdot, t)$ is bounded and we just showed that $\|u_{n_k}(t)\|_{V'}$ is
bounded.
Taking a further subsequence if necessary, let $u_{n_k}(t) \to u(t)$ weakly in $U'$ and
$u_{n_k}(t) \to \xi$ weakly in $V$. Thus, by density considerations, $\xi = u(t)$. Now, (16.7.29)
and the limit conditions for pseudomonotone operators imply that the limit condition holds.
There exists $z_\infty \in A(u(t), t)$ such that
\[
\lim_{k \to \infty} \langle z_{n_k}(t), u_{n_k}(t) - u(t) \rangle \geq \langle z_\infty, u(t) - u(t) \rangle = 0
\]
\[
> \lim_{k \to \infty} \langle z_{n_k}(t), u_{n_k}(t) - u(t) \rangle,
\]

which is a contradiction. This completes the proof of the claim.

We continue with the proof of the theorem. It follows from this claim that for every \( t \not\in \Sigma \),

\[
\lim_{n \to \infty} \inf \langle z_n(t), u_n(t) - u(t) \rangle \geq 0. \tag{46.7.24}
\]

Also, it is assumed that

\[
\lim_{n \to \infty} \sup \langle z_n, u_n - u \rangle_V \leq 0.
\]

Then from the estimates,

\[
\int_0^T \left( b_3 \|u_n(t)\|_V^p - b_4(t) - \lambda \|u_n(t)\|_H^2 \right) dt \leq \int_0^T \|u(t)\|_V \left( \|u_n\|_V^{-1} b_1 + b_2 \right) dt,
\]

so it is routine to get \( \|u_n\|_V \) is bounded. This follows from the assumptions, in particular \([46.7.24]\).

Now, the coercivity condition \( \text{b} \) shows that if \( y \in L^p([0, T]; V) \), then

\[
\langle z_n(t), u_n(t) - y(t) \rangle \geq b_3 \|u_n(t)\|_V^p - b_4(t) - \lambda \|u_n(t)\|_H^2
\]

\[
- \left( b_1 \|u_n(t)\|_V^{-1} + b_2(t) \right) \|y(t)\|_V.
\]

Using \( p - 1 = \frac{p}{p'} \), where \( \frac{1}{p} + \frac{1}{p'} = 1 \), the right-hand side of this inequality equals

\[
b_3 \|u_n(t)\|_V^p - b_4(t) - b_1 \|u_n(t)\|_V^{p/p'} \|y(t)\|_V - b_2(t) \|y(t)\|_V - \lambda \|u_n(t)\|_H^2,
\]

the last term being bounded independent of \( t, n \) by assumption. Thus there exists \( c \in L^1(0, T) \) and a positive constant \( C \) such that

\[
\langle z_n(t), u_n(t) - y(t) \rangle \geq -c(t) - C \|y(t)\|_V^p. \tag{46.7.25}
\]

Letting \( y = u \), we use Fatou's lemma to write

\[
\lim_{n \to \infty} \inf \int_0^T (\langle z_n(t), u_n(t) - u(t) \rangle + c(t) + C \|u(t)\|_V^p) dt \geq
\]

\[
\int_0^T \lim_{n \to \infty} \inf \langle z_n(t), u_n(t) - u(t) \rangle + (c(t) + C \|u(t)\|_V^p) dt
\]

\[
\geq \int_0^T (c(t) + C \|u(t)\|_V^p) dt.
\]

Here, we added the term \( c(t) + C \|u(t)\|_V^p \) to make the integrand nonnegative in order to apply Fatou’s lemma. Thus,

\[
\lim_{n \to \infty} \inf \int_0^T \langle z_n(t), u_n(t) - u(t) \rangle dt \geq 0.
\]
Consequently, using the claim in the last inequality,

\[
0 \geq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle_{\mathcal{V}', \mathcal{V}} \\
\geq \liminf_{n \to \infty} \int_0^T \langle z_n(t), u_n(t) - u(t) \rangle dt \\
= \liminf_{n \to \infty} \langle z_n, u_n - u \rangle_{\mathcal{V}', \mathcal{V}} \\
\geq \int_0^T \liminf_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle dt \geq 0,
\]

hence, we find that

\[
\lim_{n \to \infty} \langle z_n, u_n - u \rangle_{\mathcal{V}', \mathcal{V}} = 0. \quad (46.7.26)
\]

We need to show that if \( y \) is given in \( \mathcal{V} \) then

\[
\liminf_{n \to \infty} \langle z_n, u_n - y \rangle_{\mathcal{V}', \mathcal{V}} \geq (z, u - y)_{\mathcal{V}', \mathcal{V}}, \quad z(y) \in \mathcal{A}u
\]

Suppose to the contrary that there exists \( y \) such that

\[
\eta = \liminf_{n \to \infty} \langle z_n, u_n - y \rangle_{\mathcal{V}', \mathcal{V}} < (z, u - y)_{\mathcal{V}', \mathcal{V}}, \quad (46.7.27)
\]

for all \( z \in \mathcal{A}u \). Take a subsequence, denoted still with subscript \( n \) such that

\[
\eta = \lim_{n \to \infty} \langle z_n, u_n - y \rangle_{\mathcal{V}', \mathcal{V}}
\]

Thus

\[
\lim_{n \to \infty} \langle z_n, u_n - y \rangle_{\mathcal{V}', \mathcal{V}} < (z, u - y)_{\mathcal{V}', \mathcal{V}} \quad (46.7.28)
\]

We will obtain a contradiction to this. In what follows we continue to use the subsequence just described which satisfies the above inequality.

The estimate (46.7.24) implies,

\[
0 \leq \langle z_n(t), u_n(t) - u(t) \rangle^- \leq c(t) + C \|u(t)\|^p_{\mathcal{V}'} \quad (46.7.29)
\]

where \( c \) is a function in \( L^1(0, T) \). Thanks to (46.7.24),

\[
\liminf_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle \geq 0,
\]

and, therefore, the following pointwise limit exists,

\[
\lim_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle^- = 0,
\]

and so we may apply the dominated convergence theorem using (46.7.24) and conclude

\[
\lim_{n \to \infty} \int_0^T \langle z_n(t), u_n(t) - u(t) \rangle^- dt = \int_0^T \lim_{n \to \infty} \langle z_n(t), u_n(t) - u(t) \rangle^- dt = 0
\]
Thus, it was shown above that this $G$ that $S$ let which then satisfies $F$ ding on $t$.

From the above, it follows that there exists a further subsequence $F$ such that

$$\lim_{n \to \infty} \int_0^T (z_n(t), u_n(t) - u(t))^+ \, dt = 0$$

$$\lim_{n \to \infty} \langle z_n, u_n - u \rangle_{V', V} = 0.$$

Therefore, both $\int_0^T (z_n(t), u_n(t) - u(t))^+ \, dt$ and $\int_0^T (z_n(t), u_n(t) - u(t))^+ \, dt$ converge to 0, thus,

$$\lim_{n \to \infty} \int_0^T |\langle z_n(t), u_n(t) - u(t) \rangle| \, dt = 0 \quad (46.7.30)$$

$$\lim_{n \to \infty} \langle z_n, u_n - u \rangle_{V', V} = 0$$

From the above, it follows that there exists a further subsequence $\{n_k\}$ not depending on $t$ such that

$$|\langle z_{n_k}(t), u_{n_k}(t) - u(t) \rangle| \to 0 \quad a.e. \ t. \quad (46.7.31)$$

Therefore, by the pseudomonotone limit condition for $A$ there exists $w_t \in A(u(t), t)$ such that for a.e. $t$,

$$\alpha(t) \equiv \lim_{k \to \infty} \inf \langle z_{n_k}(t), u_{n_k}(t) - y(t) \rangle$$

$$= \lim_{k \to \infty} \inf \langle z_{n_k}(t), u(t) - y(t) \rangle \geq \langle w_t, u(t) - y(t) \rangle.$$

Then on the exceptional set, let $\alpha(t) \equiv \infty$, and consider the set

$$F(t) \equiv \{ w \in A(u(t), t) : \langle w, u(t) - y(t) \rangle \leq \alpha(t) \},$$

which then satisfies $F(t) \neq \emptyset$. Now $F(t)$ is closed and convex in $V'$.

**Claim:** $t \to F(t)$ has a measurable selection off a set of measure zero.

**Proof of claim:** Letting $B(0, C (t))$ contain $A(u(t), t)$, we can assume $t \to C(t)$ is measurable by using the estimates and the measurability of $u$. For $p \in \mathbb{N}$, let $S_p \equiv \{ t : C(t) < p \}$. If it is shown that $F$ has a measurable selection on $S_p$, then it follows that it has a measurable selection. Thus in what follows, assume that $t \in S_p$.

Define

$$G(t) \equiv \left\{ w : \langle w, u(t) - y(t) \rangle < \alpha(t) + \frac{1}{n}, t \notin \Sigma \right\} \cap B(0, p)$$

Thus, it was shown above that this $G(t) \neq \emptyset$. For $U$ open,

$$G^-(U) \equiv \left\{ t \in S_p : \text{ for some } w \in U \cap B(0, p), \langle w, u(t) - y(t) \rangle < \alpha(t) + \frac{1}{n} \right\} \ (*)$$
Let \( \{ w_j \} \) be a dense subset of \( U \cap B(0, p) \). This is possible because \( V' \) is separable. The expression in \( \ast \) equals

\[
\cup_{k=1}^{\infty} \left\{ t \in S_p : \langle w_k, u(t) - y(t) \rangle < \alpha(t) + \frac{1}{n} \right\}
\]

which is measurable. Thus \( G \) is a measurable multifunction.

Since \( t \to G(t) \) is measurable, there is a sequence \( \{ w_n(t) \} \) of measurable functions such that \( \cup_{n=1}^{\infty} w_n(t) \) equals

\[
\overline{G(t)} = \left\{ w : \langle w, u(t) - y(t) \rangle \leq \alpha(t) + \frac{1}{n}, t \notin \Sigma \right\} \cap B(0, p)
\]

As shown above, there exists \( w_t \) in \( A(u(t), t) \) as well as \( G(t) \). Thus there is a sequence of \( w_r(t) \) converging to \( w_t \). Since \( t \to A(u(t), t) \) is a measurable multifunction, it has a countable subset of measurable functions \( \{ z_m(t) \} \) which is dense in \( A(u(t), t) \). Let

\[
U_k(t) = \cup_m B \left( z_m(t), \frac{1}{k} \right) \subseteq A(u(t), t) + B(0, \frac{2}{k})
\]

Now define \( A_{1k} = \{ t : w_1(t) \in U_k(t) \} \). Then let \( A_{2k} = \{ t \notin A_{1k} : w_2(t) \in U_k(t) \} \) and \( A_{3k} = \{ t \notin \cup_{i=1}^{2} A_{ik} : w_3(t) \in U_k(t) \} \) and so forth. Any \( t \in S_p \) must be contained in one of these \( A_{rk} \) for some \( r \) since if not so, there would not be a sequence \( w_r(t) \) converging to \( w_t \in A(u(t), t) \). These \( A_{rp} \) partition \( S_p \) and each is measurable since the \( \{ z_k(t) \} \) are measurable. Let

\[
\hat{w}_k(t) = \sum_{r=1}^{\infty} A_{rk}(t) w_r(t)
\]

Thus \( \hat{w}_k(t) \) is in \( U_k(t) \) for all \( t \in S_p \) and equals exactly one of the \( w_m(t) \in \overline{G(t)} \).

Also, by construction, the \( \hat{w}_k(\cdot) \) are bounded in \( L^\infty(S_p, V') \). Therefore, there is a subsequence of these, still called \( \hat{w}_k \) which converges weakly to a function \( w \) in \( L^2(S_p, V') \). Thus \( w \) is a weak limit point of \( \cup_{j=k}^{\infty} \hat{w}_j \) for each \( k \). Therefore, in the open ball \( B(w, \frac{1}{k}) \subseteq L^2(S_p; V') \) with respect to the strong topology, there is a convex combination \( \sum_{j=k}^{\infty} c_{jk} \hat{w}_j \) (the \( c_{jk} \) add to 1 and only finitely many are nonzero). Since \( \overline{G(t)} \) is convex and closed, this convex combination is in \( \overline{G(t)} \). Off a set of measure zero, we can assume this convergence of \( \sum_{j=k}^{\infty} c_{jk} \hat{w}_j \) as \( k \to \infty \) happens pointwise for a suitable subsequence. However,

\[
\sum_{j=k}^{\infty} c_{jk} \hat{w}_j(t) \in U_k(t) \subseteq A(u(t), t) + B(0, \frac{2}{k})
\]

Thus \( w(t) \in A(u(t), t) \) a.e. \( t \) because \( A(u(t), t) \) is a closed set. Since \( w \) is the pointwise limit of measurable functions off a set of measure zero, it can be assumed
measurable and for a.e. \( t, w(t) \in A(u(t), t) \cap G(t) \). Now, denote this measurable function \( w_n \). Then
\[
w_n(t) \in A(u(t), t), \langle w_n(t), u(t) - y(t) \rangle \leq \alpha(t) + \frac{1}{n} \text{ a.e. } t
\]
These \( w_n(t) \) are bounded for each \( t \) off a set of measure zero and so by Lemma 10.7.3, there is a measurable function \( t \to z(t) \) and a subsequence \( w_{n(t)}(t) \to z(t) \) weakly as \( n(t) \to \infty \). Now \( A(u(t), t) \) is closed and convex, hence weakly closed as well. Thus \( z(t) \in A(u(t), t) \) and
\[
\langle z(t), u(t) - y(t) \rangle \leq \alpha(t) = \liminf_{k \to \infty} \langle z_{n_k}(t), u_{n_k}(t) - y(t) \rangle \quad (**)
\]
Therefore, \( t \to F(t) \) has a measurable selection on \( S_p \) excluding a set of measure zero, namely \( z(t) \) which will be called \( z_p(t) \) in what follows.

It follows that \( F(t) \) has a measurable selection on \( [0, T] \) other than a set of measure zero. To see this, enlarge \( \Sigma \) to include the exceptional sets of measure zero in the above argument for each \( p \). Then partition \( [0, T] \setminus \Sigma \) as follows. For \( p = 1, 2, \ldots \), consider \( S_p \setminus S_{p-1}, p = 1, 2, \ldots \) for \( S_0 \) defined as \( \emptyset \). Then letting \( z_p \) be the selection for \( t \in S_p \), let \( z(t) = \sum_{p=1}^{\infty} z_p(t) \chi_{S_p \setminus S_{p-1}}(t) \). The estimates imply \( z \in V' \) and so \( z \in \hat{A}(u) \).

From the estimates, there exists \( h \in L^1(0, T) \) such that \( \langle z(t), u(t) - y(t) \rangle \geq -|h(t)| \). Thus, from the above inequality,
\[
\|h\|_{L^1} + \langle z, u - y \rangle_{V', V} \leq \int_0^T \liminf_{k \to \infty} \langle z_{n_k}(t), u_{n_k}(t) - y(t) \rangle + |h(t)| dt
\]
\[
\leq \liminf_{k \to \infty} \langle z_{n_k}, u_{n_k} - y \rangle_{V', V} + \|h\|_{L^1} = \lim_{n \to \infty} \langle z_n, u_n - y \rangle_{V', V} + \|h\|_{L^1}
\]
which contradicts Lemma 10.7.3. \( \blacksquare \)

This all works for progressively measurable operators. These are discussed more later in the material on probability. A filtration is \( \{F_t\}, t \in [0, T] \) where each \( F_t \) is a \( \sigma \) algebra of sets in \( \Omega \) usually a probability space and these are increasing in \( t \). Then the progressively measurable sets \( P \) are \( S \subseteq \Omega \) such that
\[
S \cap [0, t] \times \Omega = B([0, t]) \times F_t \text{ measurable}
\]
You can verify that this is indeed a \( \sigma \) algebra of sets in \( [0, T] \times \Omega \). Now here is a generalization of the above which will work for this situation.

In what follows, \( P \) will be the \( \sigma \) algebra of progressively measurable sets. Thus there is a filtration \( \{F_t\} \) and a set \( S \in P \) measurable means that
\[
(t, \omega) \to \chi_{[0, t] \times \Omega} (t, \omega) \chi_S (t, \omega) \text{ is a } B([0, t]) \times F_t
\]
measurable function.

We assume the following conditions on \( A \).
1. \( A(\cdot, t, \omega) : V \rightarrow \mathcal{P}(V') \) is pseudomonotone and bounded: \( A(u, t, \omega) \) is a closed convex set for each \((t, \omega)\), \( u \rightarrow A(u, t, \omega) \) is bounded, and if \( u_n \rightarrow u \) weakly and

\[
\lim \sup_{n \to \infty} \langle A(u_n, t, \omega), u_n - u \rangle \leq 0
\]

then for any \( v \in V \),

\[
\lim \inf_{n \to \infty} \langle A(u_n, t, \omega), u_n - v \rangle \geq \langle z(v), u - v \rangle \text{ some } z(v) \in A(u, t, \omega)
\]

2. \( A(\cdot, t, \omega) \) satisfies the estimates: There exists \( b_1 \geq 0 \) and \( b_2 \geq 0 \), such that

\[
\| z \|_{V'} \leq b_1 \| u \|_{V}^{p-1} + b_2(t, \omega), \tag{46.7.32}
\]

for all \( z \in A(u, t, \omega) \), \( b_2(\cdot, \cdot) \in L^p([0, T] \times \Omega) \).

3. There exist a positive constant \( b_3 \) and a nonnegative function \( b_4 \) that is \( B([0, T]) \times \mathcal{F}_T \) measurable and also \( b_4(\cdot, \cdot) \in L^1([0, T] \times \Omega) \), such that for some \( \lambda \geq 0 \),

\[
\inf_{z \in A(u, t, \omega)} \langle z, u \rangle \geq b_3 \| u \|_V^p - b_4(t, \omega) - \lambda \| u \|_H^2. \tag{46.7.33}
\]

4. The mapping \((t, \omega) \rightarrow A(u(t, \omega), t, \omega)\) is measurable in the sense that

\[
(t, \omega) \rightarrow A(u(t, \omega), t, \omega)
\]

is a measurable multifunction with respect to \( \mathcal{P} \) whenever \((t, \omega) \rightarrow u(t, \omega)\) is in \( V \equiv V_p \equiv L^p([0, T] \times \Omega; V, \mathcal{P}) \).

5. For \( u \in V_p \), we define \( \hat{A}(u) \in \mathcal{P}(V_p') \) as follows: \( z \in \hat{A}(u) \) means that \( z(t, \omega) \in A(u(t, \omega), t, \omega) \) a.e. \((t, \omega)\). Thus this is the Nemytskii operator for \( A(\cdot, t, \omega) \).

In the following theorem and in arguments which take place below, \( U \) will be a Hilbert space dense in \( V \) with the inclusion map compact. Such a Hilbert space always exists and is important in probability theory where \((i, U, V)\) is an abstract Wiener space. However, in most applications from partial differential equations, it suffices to take \( U \) as a suitable Sobolev space. Also for \( S \) a set in \([0, T] \times \Omega, S_\omega \) will denote \( \{ t : (t, \omega) \in S \} \).

**Theorem 46.7.4** Suppose conditions 1 - 5 hold. Also, suppose \( U \) is a separable Hilbert space dense in \( V \), a reflexive separable Banach space with the inclusion map compact and \( V \) is dense in a Hilbert space \( H \). Thus

\[
U \subseteq V \subseteq H = H' \subseteq V' \subseteq U',
\]

Then, the operator \( \hat{A} \) in the definition 2 satisfies the following.
Hypotheses:

\[ u_n \to u \text{ weakly in } \mathcal{V}, \quad \limsup_{n \to \infty} \langle z_n, u_n - u \rangle_{\mathcal{V}', \mathcal{V}} \leq 0, \]

for \( z_n \in \hat{A} u_n \). For each \( \omega \), off a set of \( P \) measure zero \( N \), every subsequence of \( u_n (t, \omega) \) has a further subsequence, possibly depending on \( t, \omega \) such that

\[ u_n (t, \omega) \to u (t, \omega) \text{ weakly in } \mathcal{U}', \]

Assume also that

\[ \sup_{\omega \in \Omega \setminus N} \sup_n \sup_{t \in [0, T]} \lambda |u_n (t, \omega)|_H < \infty. \]  

(46.7.34)

Conclusion: If the above conditions hold, then there exists \( z (v) \) with

\[ \liminf_{n \to \infty} \langle z_n, u_n - v \rangle_{\mathcal{V}', \mathcal{V}} \geq \langle z (v), u - v \rangle_{\mathcal{V}', \mathcal{V}}. \]

where \( z (v) \in \hat{A} (u) \).

Proof: It was argued above that \( \hat{A} (u) \) is closed and convex. Let \( \Sigma \) have measure zero and for each \( (t, \omega) \notin \Sigma \), \( z_n (t, \omega) \in A (u_n (t, \omega), t, \omega) \) for each \( n \). Now \( \Sigma_{\omega} \) has measure zero for a.e. \( \omega \) since otherwise \( \Sigma \) would not have measure zero. These are the \( \omega \) of interest in the following argument, and we can simply include the exceptional \( \omega \) in the set of measure zero \( N \) which is being ignored since it has measure zero.

First we claim that if \( t \notin \Sigma_{\omega} \), then

\[ \liminf_{n \to \infty} \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle \geq 0. \]

Proof of the claim: Let \( t \notin \Sigma_{\omega} \) be fixed and suppose to the contrary that

\[ \liminf_{n \to \infty} \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle < 0. \]  

(46.7.35)

Then, there exists a subsequence \( \{n_k\} \), which may depend on \( t, \omega \), such that

\[ \lim_{k \to \infty} \langle z_{n_k} (t, \omega), u_{n_k} (t, \omega) - u (t, \omega) \rangle = \liminf_{n \to \infty} \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle < 0. \]  

(46.7.37)

Now, condition 4 implies that for all \( k \) large enough,

\[ b_3 ||u_{n_k} (t, \omega)||_{\mathcal{V}}^p - b_4 (t, \omega) - \lambda ||u_{n_k} (t, \omega)||_H^2 < ||z_{n_k} (t, \omega)||_{\mathcal{V}}, ||u (t, \omega)||_{\mathcal{V}}, \]

\[ \leq \left(b_1 ||u_{n_k} (t, \omega)||_V^{p-1} + b_2 (t, \omega)\right) ||u (t, \omega)||_{\mathcal{V}}, \]

therefore, \( ||u_{n_k} (t, \omega)||_{\mathcal{V}} \) and consequently \( ||z_{n_k} (t, \omega)||_{\mathcal{V}}, \) are bounded. This follows from 46.7.32. Note that \( ||z_{n_k} (t, \omega)||_{\mathcal{V}} \) is bounded independently of \( n_k \) because of
the assumption that $A(\cdot, t, \omega)$ is bounded and we just showed that $\|u_{n_k}(t, \omega)\|_V$ is bounded.

Taking a further subsequence if necessary, let $u_{n_k}(t, \omega) \to u(t, \omega)$ weakly in $U'$ and $u_{n_k}(t, \omega) \to \xi$ weakly in $V$. Thus, by density considerations, $\xi = u(t, \omega)$. Now, (46.7.34) and the limit conditions for pseudomonotone operators imply that the $\lim \inf$ condition holds. There exists $z_\infty \in A(u(t, \omega), t, \omega)$ such that

$$\lim \inf_{k \to \infty} \langle z_{n_k}(t, \omega), u_{n_k}(t, \omega) - u(t, \omega) \rangle \geq \langle z_\infty, u(t, \omega) - u(t, \omega) \rangle = 0$$

$$> \lim_{k \to \infty} \langle z_{n_k}(t, \omega), u_{n_k}(t, \omega) - u(t, \omega) \rangle,$$

which is a contradiction. This completes the proof of the claim.

We continue with the proof of the theorem. It follows from this claim that for given $\omega$, every $t \notin \Sigma_\omega$,

$$\lim_{n \to \infty} \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle \geq 0. \quad (46.7.38)$$

Also, it is assumed that

$$\limsup_{n \to \infty} \langle z_n, u_n - u \rangle_V \leq 0.$$

Then from the estimates,

$$\int_\Omega \int_0^T \left( b_3 \|u_n(t, \omega)\|^p_V - b_4(t, \omega) - \lambda \|u_n(t, \omega)\|^2_H \right) \, dt \, dP$$

$$\leq \int_\Omega \int_0^T \|u(t, \omega)\|^p_V \left( \|u_n(t, \omega)\|^{p-1} b_1 + b_2 \right) \, dt \, dP$$

so it is routine to get $\|u_n\|_V$ is bounded. This follows from the assumptions, in particular (46.7.29).

Now, the coercivity condition $\mathfrak{c}$ shows that if $y \in V$, then

$$\langle z_n(t, \omega), u_n(t, \omega) - y(t, \omega) \rangle \geq b_3 \|u_n(t, \omega)\|^p_V - b_4(t, \omega) - \lambda \|u_n(t, \omega)\|^2_H$$

$$- \left( b_1 \|u_n(t, \omega)\|^{p-1} + b_2(t, \omega) \right) \|y(t, \omega)\|_V.$$

Using $p - 1 = \frac{p}{p'}$, where $\frac{1}{p} + \frac{1}{p'} = 1$, the right-hand side of this inequality equals

$$b_3 \|u_n(t, \omega)\|^p_V - b_4(t, \omega) - b_1 \|u_n(t, \omega)\|^{p/p'} \|y(t, \omega)\|_V$$

$$- b_2(t, \omega) \|y(t, \omega)\|_V - \lambda \|u_n(t, \omega)\|^2_H,$$

the last term being bounded independent of $t, n$ by assumption. Thus there exists $c(\cdot, \cdot) \in L^1([0, T] \times \Omega)$ and a positive constant $C$ such that

$$\langle z_n(t, \omega), u_n(t, \omega) - y(t, \omega) \rangle \geq -c(t, \omega) - C \|y(t, \omega)\|^p_V. \quad (46.7.39)$$
Letting $y = u$, we use Fatou’s lemma to write
\[
\liminf_{n \to \infty} \int_0^T \left( \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle + c(t, \omega) + C\|u(t, \omega)\|_{V'}^p \right) \, dt \, dP \geq \\
\int_0^T \liminf_{n \to \infty} \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle + (c(t, \omega) + C\|u(t, \omega)\|_{V'}^p) \, dt \, dP \geq \\
\int_0^T (c(t, \omega) + C\|u(t, \omega)\|_{V'}^p) \, dt \, dP.
\]
Here, we added the term $c(t, \omega) + C\|u(t, \omega)\|_{V'}^p$ to make the integrand nonnegative in order to apply Fatou’s lemma. Thus,
\[
\liminf_{n \to \infty} \int_0^T \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle \, dt \, dP \geq 0.
\]
Consequently, using the claim in the last inequality,
\[
0 \geq \limsup_{n \to \infty} \langle z_n, u_n - u \rangle_{V', V} \\
\geq \liminf_{n \to \infty} \int_0^T \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle \, dt \, dP \\
= \liminf_{n \to \infty} \langle z_n, u_n - u \rangle_{V', V} \\
\geq \int_0^T \liminf_{n \to \infty} \langle z_n(t, \omega), u_n(t, \omega) - u(t, \omega) \rangle \, dt \, dP \geq 0,
\]

hence, we find that
\[
\lim_{n \to \infty} \langle z_n, u_n - u \rangle_{V', V} = 0. \tag{46.7.40}
\]

We need to show that if $y$ is given in $V'$ then
\[
\liminf_{n \to \infty} \langle z_n, u_n - y \rangle_{V', V} \geq \langle z(y), u - y \rangle_{V', V}, \quad z(y) \in \hat{A}u
\]

Suppose to the contrary that there exists $y$ such that
\[
\eta = \liminf_{n \to \infty} \langle z_n, u_n - y \rangle_{V', V} < \langle z, u - y \rangle_{V', V}, \tag{46.7.41}
\]

for all $z \in \hat{A}u$. Take a subsequence, denoted still with subscript $n$ such that
\[
\eta = \lim_{n \to \infty} \langle z_n, u_n - y \rangle_{V', V}
\]

Note that this subsequence does not depend on $(t, \omega)$. Thus
\[
\lim_{n \to \infty} \langle z_n, u_n - y \rangle_{V', V} < \langle z, u - y \rangle_{V', V} \tag{46.7.42}
\]

We will obtain a contradiction to this. In what follows, we continue to use the subsequence just described which satisfies the above inequality.
The estimate (46.7.39) implies,
\[
0 \leq \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^- \leq c (t, \omega) + C \| u (t, \omega) \|^p_V, \tag{46.7.43}
\]
where \( c \) is a function in \( L^1 (0, T) \). Thanks to (46.7.38),
\[
\lim \inf_{n \to \infty} \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle \geq 0, \text{ a.e.}
\]
and, therefore, the following pointwise limit exists,
\[
\lim_{n \to \infty} \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^- = 0, \text{ a.e.}
\]
and so we may apply the dominated convergence theorem using (46.7.43) and conclude
\[
\lim_{n \to \infty} \int_\Omega \int_0^T \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^- dt dP = 0
\]
Now, it follows from (46.7.40) and the above equation, that
\[
\lim_{n \to \infty} \int_\Omega \int_0^T \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^+ dt dP
\]
\[
= \lim_{n \to \infty} \int_\Omega \int_0^T \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^+ dt dP
\]
\[
+ \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^- dt dP
\]
\[
= \lim_{n \to \infty} (z_n, u_n - u)_{V', V} = 0.
\]
Therefore, both
\[
\int_\Omega \int_0^T \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^+ dt dP
\]
and
\[
\int_\Omega \int_0^T \langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle^- dt dP
\]
converge to 0, thus,
\[
\lim_{n \to \infty} \int_\Omega \int_0^T |\langle z_n (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle| dt dP = 0 \tag{46.7.44}
\]
From the above, it follows that there exists a further subsequence \( \{n_k\} \) not depending on \( t, \omega \) such that
\[
|\langle z_{n_k} (t, \omega), u_{n_k} (t, \omega) - u (t, \omega) \rangle| \to 0 \quad \text{a.e.} \quad (t, \omega). \tag{46.7.45}
\]
46.7. LIMIT CONDITIONS FOR NEMYTSKII OPERATORS

Therefore, by the pseudomonotone limit condition for \( A \) there exists \( w_{t,\omega} \in A(u(t,\omega),t,\omega) \) such that for a.e. \((t,\omega)\)

\[
\alpha(t,\omega) \equiv \liminf_{k \to \infty} \langle z_{n_k}(t,\omega), u_{n_k}(t,\omega) - y(t,\omega) \rangle
\]

\[
= \liminf_{k \to \infty} \langle z_{n_k}(t,\omega), u(t,\omega) - y(t,\omega) \rangle \geq \langle w_{t,\omega}, u(t,\omega) - y(t,\omega) \rangle.
\]

Then on the exceptional set, let \( \alpha(t,\omega) \equiv \infty \), and consider the set

\[
F(t,\omega) \equiv \{ w \in A(u(t,\omega),t,\omega) : \langle w, u(t,\omega) - y(t,\omega) \rangle \leq \alpha(t,\omega) \},
\]

which then satisfies \( F(t,\omega) \neq \emptyset \). Now \( F(t,\omega) \) is closed and convex in \( V' \).

**Claim**: \( (t,x) \to F(t,\omega) \) has a measurable selection off a set of measure zero.

**Proof of claim**: Letting \( B(0,C(t,\omega)) \) contain \( A(u(t,\omega),t,\omega) \), we can assume \((t,\omega) \to C(t,\omega) \) is \( \mathcal{P} \) measurable by using the estimates and the measurability of \( u \).

For \( \gamma \in \mathbb{N} \), let \( S_{\gamma} \equiv \{ (t,\omega) : C(t,\omega) < \gamma \} \). If it is shown that \( F \) has a measurable selection on \( S_{\gamma} \), then it follows that it has a measurable selection. Thus in what follows, assume that \((t,\omega) \in S_{\gamma}\).

Define

\[
G(t,\omega) \equiv \left\{ w : \langle w, u(t,\omega) - y(t,\omega) \rangle < \alpha(t,\omega) + \frac{1}{n}, (t,\omega) \notin \Sigma \right\} \cap B(0,\gamma)
\]

Thus, it was shown above that this \( G(t,\omega) \neq \emptyset \) at least for large enough \( \gamma \). For \( U \) open,

\[
G^-(U) \equiv \left\{ (t,\omega) \in S_{\gamma} : \text{for some } w \in U \cap B(0,\gamma), \right\}
\]

\[
\langle w, u(t,\omega) - y(t,\omega) \rangle < \alpha(t,\omega) + \frac{1}{n} \}
\]

\((*)\)

Let \( \{ w_j \} \) be a dense subset of \( U \cap B(0,\gamma) \). This is possible because \( V' \) is separable.

The expression in \( * \) equals

\[
\bigcup_{k=1}^{\infty} \left\{ (t,\omega) \in S_{\gamma} : \langle w_k, u(t,\omega) - y(t,\omega) \rangle < \alpha(t,\omega) + \frac{1}{n} \right\}
\]

which is measurable. Thus \( G \) is a measurable multifunction.

Since \((t,\omega) \to G(t,\omega) \) is measurable, there is a sequence \( \{ w_n(t,\omega) \} \) of measurable functions such that \( \bigcup_{n=1}^{\infty} w_n(t,\omega) \) equals

\[
G(t,\omega) = \left\{ w : \langle w, u(t,\omega) - y(t,\omega) \rangle \leq \alpha(t,\omega) + \frac{1}{n}, t \notin \Sigma \right\} \cap B(0,\gamma)
\]

As shown above, there exists \( w_{t,\omega} \) in \( A(u(t,\omega),t,\omega) \) as well as \( G(t,\omega) \). Thus there is a sequence of \( w_r(t,\omega) \) converging to \( w_{t,\omega} \). Of course \( r \) will need to depend on \( t,\omega \). Since \((t,\omega) \to A(u(t,\omega),t,\omega) \) is a measurable multifunction, it has a countable subset of \( \mathcal{P} \) measurable functions \( \{ z_k(t,\omega) \} \) which is dense in \( A(u(t,\omega),t,\omega) \). Let

\[
U_k(t,\omega) \equiv \bigcup_{m} B \left( z_m(t,\omega), \frac{1}{k} \right) \subseteq A(u(t,\omega),t,\omega) + B \left( 0, \frac{2}{k} \right)
\]
Now define $A_{1k} = \{(t, \omega) : w_1(t, \omega) \in U_k(t, \omega)\}$. Then let
\[ A_{2k} = \{(t, \omega) \notin A_{1k} : w_2(t, \omega) \in U_k(t, \omega)\} \]
and
\[ A_{3k} = \{(t, \omega) \notin \bigcup_{i=1}^{2} A_{ik} : w_3(t, \omega) \in U_k(t, \omega)\} \]
and so forth. Any $(t, \omega) \in S_\gamma$ must be contained in one of these $A_{rk}$ for some $r$ since if not so, there would not be a sequence $w_r(t, \omega)$ converging to $w_{t,\omega} \in A(u(t, \omega), t, \omega)$. These $A_{rk}$ partition $S_\gamma$ and each is measurable since the $\{z_{k}(t, \omega)\}$ are measurable. Let
\[ \hat{w}_k(t, \omega) = \sum_{r=1}^{\infty} A_{r, k}(t, \omega) w_r(t, \omega) \]
Thus $\hat{w}_k(t, \omega)$ is in $U_k(t, \omega)$ for all $(t, \omega) \in S_\gamma$ and equals exactly one of the $w_m(t, \omega) \in G(t, \omega)$.

Also, by construction, the $\hat{w}_k(\cdot, \cdot)$ are bounded in $L^\infty(S_\gamma; V')$. Therefore, there is a subsequence of these, still called $\hat{w}_k$ which converges weakly to a function $w$ in $L^2(S_\gamma; V')$. Thus $w$ is a weak limit point of $\text{co}\left(\bigcup_{k=0}^{\infty} \hat{w}_j\right)$ for each $k$. Therefore, in the open ball $B\left(w, \frac{1}{k}\right) \subseteq L^2(S_\gamma; V')$ with respect to the strong topology, there is a convex combination $\sum_{j=k}^{\infty} c_{jk} \hat{w}_j$ (the $c_{jk}$ add to 1 and only finitely many are nonzero). Since $G(t, \omega)$ is convex and closed, this convex combination is in $G(t, \omega)$. Off a set of $\mathcal{P}$ measure zero, we can assume this convergence of $\sum_{j=k}^{\infty} c_{jk} \hat{w}_j$ as $k \to \infty$ happens pointwise a.e. for a suitable subsequence. However,
\[ \sum_{j=k}^{\infty} c_{jk} \hat{w}_j(t, \omega) \in U_k(t, \omega) \subseteq A(u(t, \omega), t, \omega) + B\left(0, \frac{2}{k}\right). \]
Thus $w(t, \omega) \in A(u(t, \omega), t, \omega)$ a.e. $(t, \omega)$ because $A(u(t, \omega), t, \omega)$ is a closed set. Since $w$ is the pointwise limit of measurable functions off a set of measure zero, it can be assumed measurable and for a.e. $(t, \omega)$, $w(t, \omega) \in A(u(t, \omega), t, \omega) \cap \overline{G(t, \omega)}$. Now denote this measurable function $w_n$. Then
\[ w_n(t, \omega) \in A(u(t, \omega), t, \omega), \langle w_n(t, \omega), u(t, \omega) - y(t, \omega)\rangle \leq \alpha(t, \omega) + \frac{1}{n} \text{ a.e. } (t, \omega) \]
These $w_n(t, \omega)$ are bounded for each $(t, \omega)$ off a set of measure zero and so by Lemma 10.7.9, there is a $\mathcal{P}$ measurable function $(t, \omega) \to z(t, \omega)$ and a subsequence $w_{n(t,\omega)}(t, \omega) \to z(t, \omega)$ weakly as $n(t, \omega) \to \infty$. Now $A(u(t, \omega), t, \omega)$ is closed and convex, and $w_{n(t,\omega)}(t, \omega)$ is in $A(u(t, \omega), t, \omega)$, and so $z(t, \omega) \in A(u(t, \omega), t, \omega)$ and
\[ \langle z(t, \omega), u(t, \omega) - y(t, \omega)\rangle \leq \alpha(t, \omega) = \lim_{k \to \infty} \inf_{k} \langle z_{nk}(t, \omega), u_{nk}(t, \omega) - y(t, \omega)\rangle \quad (**) \]
Therefore, $t \to F(t, \omega)$ has a measurable selection on $S_\gamma$ excluding a set of measure zero, namely $z_{\gamma}(t, \omega)$ which will be called $z_{\gamma}(t, \omega)$ in what follows.
46.7. LIMIT CONDITIONS FOR NEMYTSKII OPERATORS

Then $F(t, \omega)$ has a measurable selection on $[0, T] \times \Omega$ other than a set of measure zero. To see this, enlarge $\Sigma$ to include the exceptional sets of measure zero in the above argument for each $\gamma$. Then partition $[0, T] \times \Omega \setminus \Sigma$ as follows. For $\gamma = 1, 2, \cdots$, consider $S_\gamma \setminus S_{\gamma-1}, \gamma = 1, 2, \cdots$ for $S_0$ defined as $\emptyset$. Then letting $z_\gamma$ be the selection for $(t, \omega) \in S_\gamma$, let $z(t, \omega) = \sum_{\gamma=1}^{\infty} z_\gamma(t, \omega) \chi_{S_\gamma \setminus S_{\gamma-1}}(t, \omega)$. The estimates imply $z \in \mathcal{V}'$ and so $z \in \mathcal{A}(u)$.

From the estimates, there exists $h \in L^1([0, T] \times \Omega)$ such that

$$
(z(t, \omega), u(t, \omega) - y(t, \omega)) \geq -|h(t, \omega)|
$$

Thus, from the above inequality,

$$
\|h\|_{L^1} + \langle z, u - y \rangle_{\mathcal{V}', \mathcal{V}}
\leq \int_0^T \liminf_{k \to \infty} \langle z_{n_k}(t, \omega), u_{n_k}(t, \omega) - y(t, \omega) \rangle + |h(t, \omega)| \, dt \, dP
\leq \liminf_{k \to \infty} \langle z_{n_k}, u_{n_k} - y \rangle_{\mathcal{V}', \mathcal{V}} + \|h\|_{L^1}
= \lim_{n \to \infty} \langle z_n, u_n - y \rangle_{\mathcal{V}', \mathcal{V}} + \|h\|_{L^1}
$$

which contradicts $|h|_{L^1}$. ■

The difficulty with this, is that it is hard to get the hypotheses holding. If you have $u_n \to u$ weakly in $\mathcal{V}$, then how do you get $u_n(t, \omega) \to u(t, \omega)$ weakly in $\mathcal{U}'$, for a subsequence, this for each $\omega$ not in a set of measure zero? The weak convergence does not seem to give pointwise weak convergence of the sort you need. More precisely, the pointwise convergence you get, might not be the right thing because in $u_n$, it will be $u_{n(\omega)}$. This is the problem with this theorem. It seems correct but not very useful.
CHAPTER 46. MULTIFUNCTIONS AND THEIR MEASURABILITY
Part V

Complex Analysis
Chapter 47

The Complex Numbers

The reader is presumed familiar with the algebraic properties of complex numbers, including the operation of conjugation. Here a short review of the distance in \( \mathbb{C} \) is presented.

The length of a complex number, referred to as the modulus of \( z \) and denoted by \( |z| \) is given by

\[
|z| = (x^2 + y^2)^{1/2} = (z\overline{z})^{1/2},
\]

Then \( \mathbb{C} \) is a metric space with the distance between two complex numbers, \( z \) and \( w \) defined as

\[
d(z, w) = |z - w|.
\]

This metric on \( \mathbb{C} \) is the same as the usual metric of \( \mathbb{R}^2 \). A sequence, \( z_n \to z \) if and only if \( x_n \to x \) in \( \mathbb{R} \) and \( y_n \to y \) in \( \mathbb{R} \) where \( z = x + iy \) and \( z_n = x_n + iy_n \). For example if \( z_n = \frac{n}{n+1} + i \frac{1}{n} \), then \( z_n \to 1 + 0i = 1 \).

**Definition 47.0.1** A sequence of complex numbers, \( \{z_n\} \) is a Cauchy sequence if for every \( \varepsilon > 0 \) there exists \( N \) such that \( n, m > N \) implies \( |z_n - z_m| < \varepsilon \).

This is the usual definition of Cauchy sequence. There are no new ideas here.

**Proposition 47.0.2** The complex numbers with the norm just mentioned forms a complete normed linear space.

**Proof:** Let \( \{z_n\} \) be a Cauchy sequence of complex numbers with \( z_n = x_n + iy_n \). Then \( \{x_n\} \) and \( \{y_n\} \) are Cauchy sequences of real numbers and so they converge to real numbers, \( x \) and \( y \) respectively. Thus \( z_n = x_n + iy_n \to x + iy \). \( \mathbb{C} \) is a linear space with the field of scalars equal to \( \mathbb{C} \). It only remains to verify that \( |\cdot| \) satisfies the axioms of a norm which are:

\[
|z + w| \leq |z| + |w|
\]

\[
|z| \geq 0 \text{ for all } z
\]
The only one of these axioms of a norm which is not completely obvious is the first one, the triangle inequality. Let \( z = x + iy \) and \( w = u + iv \)

\[
|z + w|^2 = (z + w) (\overline{z} + \overline{w}) = |z|^2 + |w|^2 + 2 \text{Re} (zw)
\]

\[
\leq |z|^2 + |w|^2 + 2 |zw| = (|z| + |w|)^2
\]

and this verifies the triangle inequality.

**Definition 47.0.3** An infinite sum of complex numbers is defined as the limit of the sequence of partial sums. Thus,

\[
\sum_{k=1}^{\infty} a_k \equiv \lim_{n \to \infty} \sum_{k=1}^{n} a_k.
\]

Just as in the case of sums of real numbers, an infinite sum converges if and only if the sequence of partial sums is a Cauchy sequence.

From now on, when \( f \) is a function of a complex variable, it will be assumed that \( f \) has values in \( X \), a complex Banach space. Usually in complex analysis courses, \( f \) has values in \( \mathbb{C} \) but there are many important theorems which don’t require this so I will leave it fairly general for a while. Later the functions will have values in \( \mathbb{C} \). If you are only interested in this case, think \( \mathbb{C} \) whenever you see \( X \).

**Definition 47.0.4** A sequence of functions of a complex variable, \( \{f_n\} \) converges uniformly to a function, \( g \) for \( z \in S \) if for every \( \varepsilon > 0 \) there exists \( N_\varepsilon \) such that if \( n > N_\varepsilon \), then

\[
||f_n (z) - g (z)|| < \varepsilon
\]

for all \( z \in S \). The infinite sum \( \sum_{k=1}^{\infty} f_n \) converges uniformly on \( S \) if the partial sums converge uniformly on \( S \). Here ||·|| refers to the norm in \( X \), the Banach space in which \( f \) has its values.

The following proposition is also a routine application of the above definition. Neither the definition nor this proposition say anything new.

**Proposition 47.0.5** A sequence of functions, \( \{f_n\} \) defined on a set \( S \), converges uniformly to some function, \( g \) if and only if for all \( \varepsilon > 0 \) there exists \( N_\varepsilon \) such that whenever \( m, n > N_\varepsilon \),

\[
||f_n - f_m||_\infty < \varepsilon.
\]

Here ||\( f ||_\infty \equiv \sup \{ ||f (z)|| : z \in S \} \).

Just as in the case of functions of a real variable, one of the important theorems is the Weierstrass M test. Again, there is nothing new here. It is just a review of earlier material.
Theorem 47.0.6 Let \( \{f_n\} \) be a sequence of complex valued functions defined on \( S \subseteq \mathbb{C} \). Suppose there exists \( M_n \) such that \( \|f_n\|_\infty < M_n \) and \( \sum M_n \) converges. Then \( \sum f_n \) converges uniformly on \( S \).

Proof: Let \( z \in S \). Then letting \( m < n \)

\[
\left\| \sum_{k=1}^{n} f_k(z) - \sum_{k=1}^{m} f_k(z) \right\| \leq \sum_{k=m+1}^{n} \|f_k(z)\| \leq \sum_{k=m+1}^{\infty} M_k < \varepsilon
\]

whenever \( m \) is large enough. Therefore, the sequence of partial sums is uniformly Cauchy on \( S \) and therefore, converges uniformly to \( \sum_{k=1}^{\infty} f_k(z) \) on \( S \).

47.1 The Extended Complex Plane

The set of complex numbers has already been considered along with the topology of \( \mathbb{C} \) which is nothing but the topology of \( \mathbb{R}^2 \). Thus, for \( z_n = x_n + iy_n \), \( z_n \rightarrow z \equiv x + iy \) if and only if \( x_n \rightarrow x \) and \( y_n \rightarrow y \). The norm in \( \mathbb{C} \) is given by

\[
|x + iy| \equiv ((x + iy)(x - iy))^{1/2} = (x^2 + y^2)^{1/2}
\]

which is just the usual norm in \( \mathbb{R}^2 \) identifying \( (x, y) \) with \( x + iy \). Therefore, \( \mathbb{C} \) is a complete metric space topologically like \( \mathbb{R}^2 \) and so the Heine Borel theorem that compact sets are those which are closed and bounded is valid. Thus, as far as topology is concerned, there is nothing new about \( \mathbb{C} \).

The extended complex plane, denoted by \( \mathbb{C}' \), consists of the complex plane, \( \mathbb{C} \) along with another point not in \( \mathbb{C} \) known as \( 1 \): For example, \( 1 \) could be any point in \( \mathbb{R}^3 \)

A sequence of complex numbers, \( z_n \), converges to \( 1 \) if, whenever \( K \) is a compact set in \( \mathbb{C} \), there exists a number, \( N \) such that for all \( n > N \), \( z_n \notin K \). Since compact sets in \( \mathbb{C} \) are closed and bounded, this is equivalent to saying that for all \( R > 0 \), there exists \( N \) such that if \( n > N \), then \( z_n \notin B(0, R) \) which is the same as saying \( \lim_{n \rightarrow \infty} |z_n| = \infty \) where this last symbol has the same meaning as it does in calculus.

A geometric way of understanding this in terms of more familiar objects involves a concept known as the Riemann sphere.

Consider the unit sphere, \( S^2 \) given by \((z - 1)^2 + y^2 + x^2 = 1\). Define a map from the complex plane to the surface of this sphere as follows. Extend a line from the point, \( p \) in the complex plane to the point \((0,0,2)\) on the top of this sphere and let \( \theta(p) \) denote the point of this sphere which the line intersects. Define \( \theta(\infty) \equiv (0,0,2) \).
Then $\theta^{-1}$ is sometimes called stereographic projection. The mapping $\theta$ is clearly continuous because it takes converging sequences, to converging sequences. Furthermore, it is clear that $\theta^{-1}$ is also continuous. In terms of the extended complex plane, $\mathbb{C}$, a sequence, $z_n$ converges to $\infty$ if and only if $\theta z_n$ converges to $(0, 0, 2)$ and a sequence, $z_n$ converges to $z \in \mathbb{C}$ if and only if $\theta (z_n) \to \theta (z)$.

In fact this makes it easy to define a metric on $\mathbb{C}$.

**Definition 47.1.1** Let $z, w \in \mathbb{C}$ including possibly $w = \infty$. Then let $d (x, w) \equiv |\theta (z) - \theta (w)|$ where this last distance is the usual distance measured in $\mathbb{R}^3$.

**Theorem 47.1.2** $(\mathbb{C}, d)$ is a compact, hence complete metric space.

**Proof:** Suppose $\{z_n\}$ is a sequence in $\mathbb{C}$. This means $\{\theta (z_n)\}$ is a sequence in $S^2$ which is compact. Therefore, there exists a subsequence, $\{\theta z_{n_k}\}$ and a point, $z \in S^2$ such that $\theta z_{n_k} \to \theta z$ in $S^2$ which implies immediately that $d (z_{n_k}, z) \to 0$. A compact metric space must be complete.

### 47.2 Exercises

1. Prove the root test for series of complex numbers. If $a_k \in \mathbb{C}$ and $r \equiv \limsup_{n \to \infty} |a_n|^{1/n}$ then
   \[
   \sum_{k=0}^{\infty} a_k \left\{ \begin{array}{ll}
   \text{converges absolutely if } r < 1 \\
   \text{diverges if } r > 1 \\
   \text{test fails if } r = 1.
   \end{array} \right.
   \]

2. Does $\lim_{n \to \infty} n \left( \frac{2+1}{3} \right)^n$ exist? Tell why and find the limit if it does exist.

3. Let $A_0 = 0$ and let $A_n = \sum_{k=1}^{n} a_k$ if $n > 0$. Prove the partial summation formula,
   \[
   \sum_{k=p}^{q} a_k b_k = A_q b_q - A_{p-1} b_p + \sum_{k=p}^{q-1} A_k (b_k - b_{k+1}).
   \]
   Now using this formula, suppose $\{b_n\}$ is a sequence of real numbers which converges to 0 and is decreasing. Determine those values of $\omega$ such that $|\omega| = 1$ and $\sum_{k=1}^{\infty} b_k \omega^k$ converges.
4. Let \( f : U \subseteq \mathbb{C} \to \mathbb{C} \) be given by \( f(x + iy) = u(x, y) + iv(x, y) \). Show \( f \) is continuous on \( U \) if and only if \( u : U \to \mathbb{R} \) and \( v : U \to \mathbb{R} \) are both continuous.
Chapter 48

Riemann Stieltjes Integrals

In the theory of functions of a complex variable, the most important results are those involving contour integration. I will base this on the notion of Riemann Stieltjes integrals as in [41], [86], and [59]. The Riemann Stieltjes integral is a generalization of the usual Riemann integral and requires the concept of a function of bounded variation.

Definition 48.0.1 Let \( \gamma : [a, b] \to \mathbb{C} \) be a function. Then \( \gamma \) is of bounded variation if

\[
\sup \left\{ \sum_{i=1}^{n} |\gamma(t_i) - \gamma(t_{i-1})| : a = t_0 < \cdots < t_n = b \right\} \equiv V(\gamma, [a, b]) < \infty
\]

where the sums are taken over all possible lists, \( \{a = t_0 < \cdots < t_n = b\} \). The set of points \( \gamma([a, b]) \) will also be denoted by \( \gamma^* \).

The idea is that it makes sense to talk of the length of the curve \( \gamma([a, b]) \), defined as \( V(\gamma, [a, b]) \). For this reason, in the case that \( \gamma \) is continuous, such an image of a bounded variation function is called a rectifiable curve.

Definition 48.0.2 Let \( \gamma : [a, b] \to \mathbb{C} \) be of bounded variation and let \( f : \gamma^* \to X \). Letting \( P \equiv \{t_0, \cdots, t_n\} \) where \( a = t_0 < t_1 < \cdots < t_n = b \), define

\[
||P|| \equiv \max \{|t_j - t_{j-1}| : j = 1, \cdots, n\}
\]

and the Riemann Steiltjes sum by

\[
S(P) \equiv \sum_{j=1}^{n} f(\gamma(t_j))(\gamma(t_j) - \gamma(t_{j-1}))
\]

where \( \tau_j \in [t_{j-1}, t_j] \). (Note this notation is a little sloppy because it does not identify the specific point, \( \tau_j \) used. It is understood that this point is arbitrary.) Define
\[ \int_{\gamma} fd\gamma \text{ as the unique number which satisfies the following condition. For all } \varepsilon > 0 \text{ there exists a } \delta > 0 \text{ such that if } ||P|| \leq \delta, \text{ then} \]

\[ \left| \int_{\gamma} fd\gamma - S(P) \right| < \varepsilon. \]

Sometimes this is written as

\[ \int_{\gamma} fd\gamma \equiv \lim_{||P|| \to 0} S(P). \]

The set of points in the curve, \(\gamma([a,b])\) will be denoted sometimes by \(\gamma^*\).

Then \(\gamma^*\) is a set of points in \(\mathbb{C}\) and as \(t\) moves from \(a\) to \(b\), \(\gamma(t)\) moves from \(\gamma(a)\) to \(\gamma(b)\). Thus \(\gamma^*\) has a first point and a last point. If \(\phi : [c,d] \to [a,b]\) is a continuous nondecreasing function, then \(\gamma \circ \phi : [c,d] \to \mathbb{C}\) is also of bounded variation and yields the same set of points in \(\mathbb{C}\) with the same first and last points.

**Theorem 48.0.3** Let \(\phi\) and \(\gamma\) be as just described. Then assuming that

\[ \int_{\gamma} fd\gamma \]

exists, so does

\[ \int_{\gamma \circ \phi} fd(\gamma \circ \phi) \]

and

\[ \int_{\gamma} fd\gamma = \int_{\gamma \circ \phi} fd(\gamma \circ \phi). \quad (48.0.1) \]

**Proof:** There exists \(\delta > 0\) such that if \(P\) is a partition of \([a,b]\) such that \(||P|| < \delta\), then

\[ \left| \int_{\gamma} fd\gamma - S(P) \right| < \varepsilon. \]

By continuity of \(\phi\), there exists \(\sigma > 0\) such that if \(Q\) is a partition of \([c,d]\) with \(||Q|| < \sigma\), \(Q = \{s_0, \ldots, s_n\}\), then \(|\phi(s_j) - \phi(s_{j-1})| < \delta\). Thus letting \(P\) denote the points in \([a,b]\) given by \(\phi(s_j)\) for \(s_j \in Q\), it follows that \(||P|| < \delta\) and so

\[ \left| \int_{\gamma} fd\gamma - \sum_{j=1}^{n} f(\gamma(\phi(\tau_j))) (\gamma(\phi(s_j)) - \gamma(\phi(s_{j-1}))) \right| < \varepsilon \]

where \(\tau_j \in [s_{j-1}, s_j]\). Therefore, from the definition \(48.0.1\) holds and

\[ \int_{\gamma \circ \phi} fd(\gamma \circ \phi) \]

exists.
This theorem shows that \( \int f \, d\gamma \) is independent of the particular \( \gamma \) used in its computation to the extent that if \( \phi \) is any nondecreasing continuous function from another interval, \([c, d]\), mapping to \([a, b]\), then the same value is obtained by replacing \( \gamma \) with \( \gamma \circ \phi \).

The fundamental result in this subject is the following theorem. We have in mind functions which have values in \( \mathbb{C} \) but there is no change if the functions have values in any complete normed vector space.

**Theorem 48.0.4** Let \( f : \gamma^* \to X \) be continuous and let \( \gamma : [a, b] \to \mathbb{C} \) be continuous and of bounded variation. Then \( \int f \, d\gamma \) exists. Also letting \( \delta_m > 0 \) be such that \( |t - s| < \delta_m \) implies \( |f(\gamma(t)) - f(\gamma(s))| < \frac{1}{m} \),

\[
\left| \int f \, d\gamma - S(P) \right| \leq \frac{2V(\gamma, [a, b])}{m}
\]

whenever \( ||P|| < \delta_m \).

**Proof:** The function, \( f \circ \gamma \), is uniformly continuous because it is defined on a compact set. Therefore, there exists a decreasing sequence of positive numbers, \( \{\delta_m\} \) such that if \( |s - t| < \delta_m \), then

\[
|f(\gamma(t)) - f(\gamma(s))| < \frac{1}{m}.
\]

Let

\[
F_m = \{S(P) : ||P|| < \delta_m\}.
\]

Thus \( F_m \) is a closed set. (The symbol, \( S(P) \) in the above definition, means to include all sums corresponding to \( P \) for any choice of \( \tau_j \).) It is shown that

\[
diam(F_m) \leq \frac{2V(\gamma, [a, b])}{m} \tag{48.0.2}
\]

and then it will follow there exists a unique point, \( I \in \bigcap_{m=1}^{\infty} F_m \). This is because \( X \) is complete. It will then follow \( I = \int f \, d\gamma(t) \). To verify this, it suffices to verify that whenever \( P \) and \( Q \) are partitions satisfying \( ||P|| < \delta_m \) and \( ||Q|| < \delta_m \),

\[
|S(P) - S(Q)| \leq \frac{2}{m}V(\gamma, [a, b]) \tag{48.0.3}
\]

Suppose \( ||P|| < \delta_m \) and \( Q \supseteq P \). Then also \( ||Q|| < \delta_m \). To begin with, suppose that \( P \equiv \{t_0, \cdots, t_p, \cdots, t_n\} \) and \( Q \equiv \{t_0, \cdots, t_{p-1}, t^*, t_p, \cdots, t_n\} \). Thus \( Q \) contains only one more point than \( P \). Letting \( S(Q) \) and \( S(P) \) be Riemann Steiltjes sums, \( S(Q) \equiv \sum_{j=1}^{p-1} f(\gamma(\sigma_j))(\gamma(t_j) - \gamma(t_{j-1})) + f(\gamma(\sigma^*))((t^*) - \gamma(t_{p-1})) \)

\[
S(Q) = \sum_{j=1}^{p-1} f(\gamma(\sigma_j))(\gamma(t_j) - \gamma(t_{j-1})) + f(\gamma(\sigma^*))((t^*) - \gamma(t_{p-1}))
\]
+ f (\gamma (\sigma^*)) (\gamma (t_p) - \gamma (t^*)) + \sum_{j=p+1}^{n} f (\gamma (\sigma_j)) (\gamma (t_j) - \gamma (t_{j-1})),
\begin{align*}
S (P) & = \sum_{j=1}^{p-1} f (\gamma (\tau_j)) (\gamma (t_j) - \gamma (t_{j-1})) + \\
& \quad \frac{f (\gamma (\tau_p)) (\gamma (t^*) - \gamma (t_{p-1})) + f (\gamma (\tau_p)) (\gamma (t_p) - \gamma (t^*))}{f (\gamma (\tau_p)) (\gamma (t^*) - \gamma (t_{p-1})) + f (\gamma (\tau_p)) (\gamma (t_p) - \gamma (t^*))} + \\
& \quad + \sum_{j=p+1}^{n} f (\gamma (\tau_j)) (\gamma (t_j) - \gamma (t_{j-1})).
\end{align*}

Therefore,
\begin{align*}
|S (P) - S (Q)| & \leq \sum_{j=1}^{p-1} \frac{1}{m} |\gamma (t_j) - \gamma (t_{j-1})| + \frac{1}{m} |\gamma (t^*) - \gamma (t_{p-1})| + \\
& \quad + \sum_{j=p+1}^{n} \frac{1}{m} |\gamma (t_j) - \gamma (t_{j-1})| \leq \frac{1}{m} V (\gamma, [a, b]). 
\end{align*}

Clearly the extreme inequalities would be valid if \( Q \) had more than one extra point. You simply do the above trick more than one time. Let \( S (P) \) and \( S (Q) \) be Riemann Steiltjes sums for which \( ||P|| \) and \( ||Q|| \) are less than \( \delta_m \) and let \( R \equiv P \cup Q \). Then from what was just observed,
\begin{align*}
|S (P) - S (Q)| & \leq |S (P) - S (R)| + |S (R) - S (Q)| \leq \frac{2}{m} V (\gamma, [a, b]).
\end{align*}
and this shows which proves Therefore, there exists a unique complex number, \( I \in \cap_{m=1}^{\infty} F_m \) which satisfies the definition of \( \int_{\gamma} f d\gamma \). This proves the theorem.

The following theorem follows easily from the above definitions and theorem.

**Theorem 48.0.5** Let \( f \in C (\gamma^*) \) and let \( \gamma : [a, b] \to \mathbb{C} \) be of bounded variation and continuous. Let
\[ M \geq \max \{ ||f \circ \gamma (t)|| : t \in [a, b] \} \tag{48.0.5} \]
Then
\[ \left\| \int_{\gamma} f d\gamma \right\| \leq MV (\gamma, [a, b]). \tag{48.0.6} \]
Also if \( \{ f_n \} \) is a sequence of functions of \( C (\gamma^*) \) which is converging uniformly to the function, \( f \) on \( \gamma^* \), then
\[ \lim_{n \to \infty} \int_{\gamma} f_n d\gamma = \int_{\gamma} f d\gamma. \tag{48.0.7} \]
Proof: Let \( \|P\| < \delta_m \) hold. From the proof of the above theorem, when \( \|P\| < \delta_m \),

\[
\left\| \int_{\gamma} f d\gamma - S(P) \right\| \leq \frac{2}{m} V(\gamma, [a, b])
\]

and so

\[
\left\| \int_{\gamma} f d\gamma \right\| \leq \|S(P)\| + \frac{2}{m} V(\gamma, [a, b])
\]

\[
\leq \sum_{j=1}^{n} M |\gamma(t_j) - \gamma(t_{j-1})| + \frac{2}{m} V(\gamma, [a, b])
\]

\[
\leq MV(\gamma, [a, b]) + \frac{2}{m} V(\gamma, [a, b]).
\]

This proves \(4.5.\) since \(m\) is arbitrary. To verify \(4.6.\) use the above inequality to write

\[
\left\| \int_{\gamma} f d\gamma - \int_{\gamma} f_n d\gamma \right\| = \left\| \int_{\gamma} (f - f_n) d\gamma(t) \right\|
\]

\[
\leq \max \{ ||f \circ \gamma(t) - f_n \circ \gamma(t)|| : t \in [a, b] \} V(\gamma, [a, b]).
\]

Since the convergence is assumed to be uniform, this proves \(4.6.\)

It turns out to be much easier to evaluate such integrals in the case where \(\gamma\) is also \(C^1([a, b])\). The following theorem about approximation will be very useful but first here is an easy lemma.

Lemma 48.0.6 Let \(\gamma : [a, b] \to \mathbb{C}\) be in \(C^1([a, b])\). Then \(V(\gamma, [a, b]) < \infty\) so \(\gamma\) is of bounded variation.

Proof: This follows from the following

\[
\sum_{j=1}^{n} |\gamma(t_j) - \gamma(t_{j-1})| = \sum_{j=1}^{n} \left| \int_{t_{j-1}}^{t_j} \gamma'(s) \, ds \right|
\]

\[
\leq \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} |\gamma'(s)| \, ds
\]

\[
\leq \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} ||\gamma'||_{\infty} \, ds
\]

\[
= ||\gamma'||_{\infty} (b-a).
\]

Therefore it follows \(V(\gamma, [a, b]) \leq ||\gamma'||_{\infty} (b-a)\). Here \(||\gamma||_{\infty} = \max \{ |\gamma(t)| : t \in [a, b] \}||.

Theorem 48.0.7 Let \(\gamma : [a, b] \to \mathbb{C}\) be continuous and of bounded variation. Let \(\Omega\) be an open set containing \(\gamma^*\) and let \(f : \Omega \times K \to X\) be continuous for \(K\) a
compact set in \(\mathbb{C}\), and let \(\varepsilon > 0\) be given. Then there exists \(\eta : [a, b] \to \mathbb{C}\) such that \(\eta (a) = \gamma (a)\), \(\eta (b) = \eta (b)\), \(\eta \in C^1 ([a, b])\), and

\[
||\gamma - \eta|| < \varepsilon, \tag{48.0.8}
\]

\[
\left| \int_{\gamma} f (\cdot, z) d\gamma - \int_{\eta} f (\cdot, z) d\eta \right| < \varepsilon, \tag{48.0.9}
\]

\[
V (\eta, [a, b]) \leq V (\gamma, [a, b]), \tag{48.0.10}
\]

where \(||\gamma - \eta|| \equiv \max \{|\gamma (t) - \eta (t)| : t \in [a, b]\}\).

**Proof:** Extend \(\gamma\) to be defined on all \(\mathbb{R}\) according to \(\gamma (t) = \gamma (a)\) if \(t < a\) and \(\gamma (t) = \gamma (b)\) if \(t > b\). Now define

\[
\gamma_h (t) = \frac{1}{2h} \int_{-2h + t}^{t + 2h} \gamma (s) ds.
\]

where the integral is defined in the obvious way. That is,

\[
\int_{a}^{b} \alpha (t) + i \beta (t) dt = \int_{a}^{b} \alpha (t) dt + i \int_{a}^{b} \beta (t) dt.
\]

Therefore,

\[
\gamma_h (b) = \frac{1}{2h} \int_{b}^{b + 2h} \gamma (s) ds = \gamma (b),
\]

\[
\gamma_h (a) = \frac{1}{2h} \int_{a - 2h}^{a} \gamma (s) ds = \gamma (a).
\]

Also, because of continuity of \(\gamma\) and the fundamental theorem of calculus,

\[
\gamma'_h (t) = \frac{1}{2h} \left\{ \gamma \left( t + \frac{2h}{b - a} (t - a) \right) \left( 1 + \frac{2h}{b - a} \right) - \\
\gamma \left( -2h + t + \frac{2h}{b - a} (t - a) \right) \left( 1 + \frac{2h}{b - a} \right) \right\}
\]

and so \(\gamma_h \in C^1 ([a, b])\). The following lemma is significant.

**Lemma 48.0.8** \(V (\gamma_h, [a, b]) \leq V (\gamma, [a, b])\).

**Proof:** Let \(a = t_0 < t_1 < \cdots < t_n = b\). Then using the definition of \(\gamma_h\) and changing the variables to make all integrals over \([0, 2h]\),

\[
\sum_{j=1}^{n} |\gamma_h (t_j) - \gamma_h (t_{j-1})| =
\]

\[
\sum_{j=1}^{n} \frac{1}{2h} \int_{0}^{2h} \gamma \left( s - 2h + t_j + \frac{2h}{b - a} (t_j - a) \right) -
\]
\[ \gamma \left( s - 2h + t_{j-1} + \frac{2h}{b-a} (t_{j-1} - a) \right) \]

\[ \leq \frac{1}{2h} \int_0^{2h} \sum_{j=1}^n \gamma \left( s - 2h + t_j + \frac{2h}{b-a} (t_j - a) \right) - \]

\[ \gamma \left( s - 2h + t_{j-1} + \frac{2h}{b-a} (t_{j-1} - a) \right) ds. \]

For a given \( s \in [0, 2h] \), the points, \( s - 2h + t_j + \frac{2h}{b-a} (t_j - a) \) for \( j = 1, \ldots, n \) form an increasing list of points in the interval \([a - 2h, b + 2h]\) and so the integrand is bounded above by \( V (\gamma, [a - 2h, b + 2h]) = V (\gamma, [a, b]) \). It follows

\[ \sum_{j=1}^n |\gamma_h (t_j) - \gamma_h (t_{j-1})| \leq V (\gamma, [a, b]) \]

which proves the lemma.

With this lemma the proof of the theorem can be completed without too much trouble. Let \( H \) be an open set containing \( \gamma^* \) such that \( \overline{H} \) is a compact subset of \( \Omega \). Let \( 0 < \varepsilon < \text{dist} (\gamma^*, H^c) \). Then there exists \( \delta_1 \) such that if \( h < \delta_1 \), then for all \( t \),

\[ |\gamma (t) - \gamma_h (t)| \leq \frac{1}{2h} \int_{-2h + t + \frac{2h}{b-a} (t_a)}^{t + \frac{2h}{b-a} (t-a)} |\gamma (s) - \gamma (t)| ds \]

\[ < \frac{1}{2h} \int_{-2h + t + \frac{2h}{b-a} (t-a)}^{t + \frac{2h}{b-a} (t-a)} \varepsilon ds = \varepsilon \quad (48.0.11) \]

due to the uniform continuity of \( \gamma \). This proves \( 48.0.8 \).

From \( 48.0.8 \) and the above lemma, there exists \( \delta_2 \) such that if \( ||P|| < \delta_2 \), then for all \( z \in K \),

\[ \left| \int f (\cdot, z) d\gamma (t) - S (P) \right| < \frac{\varepsilon}{3}, \left| \int f (\cdot, z) d\gamma_h (t) - S_h (P) \right| < \frac{\varepsilon}{3} \]

for all \( h \). Here \( S (P) \) is a Riemann Steiltjes sum of the form

\[ \sum_{i=1}^n f (\gamma (\tau_i), z) (\gamma (t_i) - \gamma (t_{i-1})) \]

and \( S_h (P) \) is a similar Riemann Steiltjes sum taken with respect to \( \gamma_h \) instead of \( \gamma \). Because of \( 48.0.11 \), \( \gamma_h (t) \) has values in \( H \subseteq \Omega \). Therefore, fix the partition, \( P \), and choose \( h \) small enough that in addition to this, the following inequality is valid for all \( z \in K \).

\[ |S (P) - S_h (P)| < \frac{\varepsilon}{3} \]
CHAPTER 48. RIEMANN STIELTJES INTEGRALS

This is possible because of \[48.0.11\] and the uniform continuity of \(f\) on \(\bar{H} \times K\). It follows

\[
\left| \int_{\gamma} f(\cdot, z) \, d\gamma(t) - \int_{\gamma_h} f(\cdot, z) \, d\gamma_h(t) \right| \leq \\
\left| \int_{\gamma} f(\cdot, z) \, d\gamma(t) - S(P) \right| + \left| S(P) - S_h(P) \right| \\
+ \left| S_h(P) - \int_{\gamma_h} f(\cdot, z) \, d\gamma_h(t) \right| < \varepsilon.
\]

Formula \[48.0.10\] follows from the lemma. This proves the theorem.

Of course the same result is obtained without the explicit dependence of \(f\) on \(z\):

This is a very useful theorem because if \(\gamma \in C^1([a,b])\), it is easy to calculate \(\int f \, d\gamma\) and the above theorem allows a reduction to the case where \(\gamma \in C^1\). The next theorem shows how easy it is to compute these integrals in the case where \(\gamma \in C^1\):

First note that if \(f\) is continuous and \(f \in C^1([a,b])\), then by Lemma \[48.0.6\] and the fundamental existence theorem, Theorem \[48.0.4\],

\[48.0.9\]

\[
\int f \, d\gamma = \int_a^b f(\gamma(t)) \gamma'(t) \, dt.
\]

**Proof:** Let \(P\) be a partition of \([a,b]\), \(P = \{t_0, \cdots, t_n\}\) and \(\|P\|\) is small enough that whenever \(|t - s| < \|P\|\),

\[
|f(\gamma(t)) - f(\gamma(s))| < \varepsilon \tag{48.0.13}
\]

and

\[
\left| \int_{\gamma} \int_a^b f(t) \, dt - \sum_{j=1}^n f(\gamma(t_j)) (\gamma(t_j) - \gamma(t_{j-1})) \right| < \varepsilon.
\]

Now

\[
\sum_{j=1}^n f(\gamma(t_j)) (\gamma(t_j) - \gamma(t_{j-1})) = \int_a^b \sum_{j=1}^n f(\gamma(t_j)) \mathcal{X}_{[t_{j-1}, t_j]}(s) \gamma'(s) \, ds
\]

where here

\[
\mathcal{X}_{[a,b]}(s) \equiv \begin{cases} 
1 & \text{if } s \in [p, q] \\
0 & \text{otherwise}
\end{cases}
\]

Also,

\[
\int_a^b f(\gamma(s)) \gamma'(s) \, ds = \int_a^b \sum_{j=1}^n f(\gamma(s)) \mathcal{X}_{[t_{j-1}, t_j]}(s) \gamma'(s) \, ds
\]
and thanks to
\[ = \sum_{j=1}^{n} f(\gamma(t_j))(\gamma(t_j) - \gamma(t_{j-1})) \]
\[ \int_a^b \sum_{j=1}^{n} f(\gamma(t_j)) \mathcal{X}_{[t_{j-1}, t_j]}(s) \gamma'(s) \, ds - \int_a^b \sum_{j=1}^{n} f(\gamma(s)) \mathcal{X}_{[t_{j-1}, t_j]}(s) \gamma'(s) \, ds \]
\[ \leq \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} ||f(\gamma(t_j)) - f(\gamma(s))|| |\gamma'(s)| \, ds \leq ||\gamma'||\infty \sum_j \varepsilon (t_j - t_{j-1}) \]
\[ = \varepsilon ||\gamma'||\infty (b - a). \]

It follows that
\[ \left| \int_{\gamma} f \, dz - \int_a^b f(\gamma(s)) \gamma'(s) \, ds \right| \leq \left| \int_{\gamma} f \, dz - \sum_{j=1}^{n} f(\gamma(t_j))(\gamma(t_j) - \gamma(t_{j-1})) \right| \]
\[ + \left| \sum_{j=1}^{n} f(\gamma(t_j))(\gamma(t_j) - \gamma(t_{j-1})) - \int_a^b f(\gamma(s)) \gamma'(s) \, ds \right| \leq \varepsilon ||\gamma'||\infty (b - a) + \varepsilon. \]

Since \( \varepsilon \) is arbitrary, this verifies

**Definition 48.0.10** Let \( \Omega \) be an open subset of \( \mathbb{C} \) and let \( \gamma : [a, b] \to \Omega \) be a continuous function with bounded variation \( f : \Omega \to X \) be a continuous function. Then the following notation is more customary.

\[ \int_{\gamma} f(z) \, dz \equiv \int_{\gamma} f \, dz. \]

The expression, \( \int_{\gamma} f(z) \, dz \), is called a contour integral and \( \gamma \) is referred to as the contour. A function \( f : \Omega \to X \) for \( \Omega \) an open set in \( \mathbb{C} \) has a primitive if there exists a function, \( F \), the primitive, such that \( F'(z) = f(z) \). Thus \( F \) is just an antiderivative. Also if \( \gamma_k : [a_k, b_k] \to \mathbb{C} \) is continuous and of bounded variation, for \( k = 1, \cdots, m \) and \( \gamma_k(b_k) = \gamma_{k+1}(a_k) \), define

\[ \int_{\sum_{k=1}^{m} \gamma_k} f(z) \, dz \equiv \sum_{k=1}^{m} \int_{\gamma_k} f(z) \, dz. \quad (48.0.14) \]

In addition to this, for \( \gamma : [a, b] \to \mathbb{C} \), define \( -\gamma : [a, b] \to \mathbb{C} \) by \( -\gamma(t) \equiv \gamma(b + a - t) \). Thus \( \gamma \) simply traces out the points of \( \gamma^* \) in the opposite order.

The following lemma is useful and follows quickly from Theorem

\[ \text{Lemma} \]
Lemma 48.0.11  In the above definition, there exists a continuous bounded variation function, \( \gamma \) defined on some closed interval, \([c,d]\), such that \( \gamma ([c,d]) = \bigcup_{k=1}^{m} \gamma_k ([a_k,b_k]) \) and \( \gamma (c) = \gamma_1 (a_1) \) while \( \gamma (d) = \gamma_m (b_m) \). Furthermore,

\[
\int_{\gamma} f (z) \, dz = \sum_{k=1}^{m} \int_{\gamma_k} f (z) \, dz.
\]

If \( \gamma : [a,b] \to \mathbb{C} \) is of bounded variation and continuous, then

\[
\int_{\gamma} f (z) \, dz = - \int_{-\gamma} f (z) \, dz.
\]

Re stating Theorem 48.0.7 with the new notation in the above definition,

Theorem 48.0.12  Let \( K \) be a compact set in \( \mathbb{C} \) and let \( f : \Omega \times K \to X \) be continuous for \( \Omega \) an open set in \( \mathbb{C} \). Also let \( \gamma : [a,b] \to \Omega \) be continuous with bounded variation. Then if \( r > 0 \) is given, there exists \( \eta : [a,b] \to \Omega \) such that \( \eta (a) = \gamma (a) \), \( \eta (b) = \gamma (b) \), \( \eta \) is \( C^1 ([a,b]) \), and

\[
\left| \int_{\gamma} f (z,w) \, dz - \int_{\eta} f (z,w) \, dz \right| < r, \quad ||\eta - \gamma|| < r.
\]

It will be very important to consider which functions have primitives. It turns out, it is not enough for \( f \) to be continuous in order to possess a primitive. This is in stark contrast to the situation for functions of a real variable in which the fundamental theorem of calculus will deliver a primitive for any continuous function. The reason for the interest in such functions is the following theorem and its corollary.

Theorem 48.0.13  Let \( \gamma : [a,b] \to \mathbb{C} \) be continuous and of bounded variation. Also suppose \( F' (z) = f (z) \) for all \( z \in \Omega \), an open set containing \( \gamma^* \) and \( f \) is continuous on \( \Omega \). Then

\[
\int_{\gamma} f (z) \, dz = F (\gamma (b)) - F (\gamma (a)).
\]

Proof: By Theorem 48.0.12 there exists \( \eta \in C^1 ([a,b]) \) such that \( \gamma (a) = \eta (a) \), and \( \gamma (b) = \eta (b) \) such that

\[
\left| \int_{\gamma} f (z) \, dz - \int_{\eta} f (z) \, dz \right| < \varepsilon.
\]

Then since \( \eta \) is in \( C^1 ([a,b]) \),

\[
\int_{\eta} f (z) \, dz = \int_{a}^{b} f (\eta (t)) \eta' (t) \, dt = \int_{a}^{b} dF (\eta (t)) \, dt = F (\eta (b)) - F (\eta (a)) = F (\gamma (b)) - F (\gamma (a)).
\]

Therefore,

\[
\left| (F (\gamma (b)) - F (\gamma (a))) - \int_{\gamma} f (z) \, dz \right| < \varepsilon
\]

and since \( \varepsilon > 0 \) is arbitrary, this proves the theorem.
Corollary 48.0.14 If $\gamma : [a, b] \to \mathbb{C}$ is continuous, has bounded variation, is a closed curve, $\gamma (a) = \gamma (b)$, and $\gamma^* \subseteq \Omega$ where $\Omega$ is an open set on which $F' (z) = f (z)$, then
\[ \int_{\gamma} f (z) \, dz = 0. \]

48.1 Exercises

1. Let $\gamma : [a, b] \to \mathbb{R}$ be increasing. Show $V (\gamma, [a, b]) = \gamma (b) - \gamma (a)$.

2. Suppose $\gamma : [a, b] \to \mathbb{C}$ satisfies a Lipschitz condition, $|\gamma (t) - \gamma (s)| \leq K |s - t|$. Show $\gamma$ is of bounded variation and that $V (\gamma, [a, b]) \leq K |b - a|$.  

3. $\gamma : [c_0, c_m] \to \mathbb{C}$ is piecewise smooth if there exist numbers, $c_k, k = 1, \ldots, m$ such that $c_0 < c_1 < \cdots < c_{m-1} < c_m$ such that $\gamma$ is continuous and $\gamma : [c_k, c_{k+1}] \to \mathbb{C}$ is $C^1$. Show that such piecewise smooth functions are of bounded variation and give an estimate for $V (\gamma, [c_0, c_m])$.

4. Let $\gamma : [0, 2\pi] \to \mathbb{C}$ be given by $\gamma (t) = r (\cos mt + i \sin mt)$ for $m$ an integer. Find $\int_{\gamma} \frac{dz}{z}$.

5. Show that if $\gamma : [a, b] \to \mathbb{C}$ then there exists an increasing function $h : [0, 1] \to [a, b]$ such that $\gamma \circ h ([0, 1]) = \gamma^*$.

6. Let $\gamma : [a, b] \to \mathbb{C}$ be an arbitrary continuous curve having bounded variation and let $f, g$ have continuous derivatives on some open set containing $\gamma^*$. Prove the usual integration by parts formula.
\[ \int_{\gamma} fg' \, dz = f (\gamma (b)) g (\gamma (b)) - f (\gamma (a)) g (\gamma (a)) - \int_{\gamma} f' g \, dz. \]

7. Let $f (z) = |z| - (1/2) e^{-iz^2}$ where $z = |z| e^{i\theta}$. This function is called the principle branch of $z^{-(1/2)}$. Find $\int_{\gamma} f (z) \, dz$ where $\gamma$ is the semicircle in the upper half plane which goes from $(1, 0)$ to $(-1, 0)$ in the clockwise direction. Next do the integral in which $\gamma$ goes in the counterclockwise direction along the semicircle in the lower half plane.

8. Prove an open set, $U$ is connected if and only if for every two points in $U$, there exists a $C^1$ curve having values in $U$ which joins them.

9. Let $P, Q$ be two partitions of $[a, b]$ with $P \subseteq Q$. Each of these partitions can be used to form an approximation to $V (\gamma, [a, b])$ as described above. Recall the total variation was the supremum of sums of a certain form determined by a partition. How is the sum associated with $P$ related to the sum associated with $Q$? Explain.
10. Consider the curve,

\[ \gamma(t) = \begin{cases} 
  t + it^2 \sin \left( \frac{1}{t} \right) & \text{if } t \in (0, 1] \\
  0 & \text{if } t = 0 
\end{cases} \]

Is \( \gamma \) a continuous curve having bounded variation? What if the \( t^2 \) is replaced with \( t \)? Is the resulting curve continuous? Is it a bounded variation curve?

11. Suppose \( \gamma : [a, b] \to \mathbb{R} \) is given by \( \gamma(t) = t \). What is \( \int_{\gamma} f(t) \, d\gamma \)? Explain.
Chapter 49

Fundamentals Of Complex Analysis

49.1 Analytic Functions

Definition 49.1.1 Let $\Omega$ be an open set in $\mathbb{C}$ and let $f : \Omega \rightarrow X$. Then $f$ is analytic on $\Omega$ if for every $z \in \Omega$,

$$
\lim_{h \to 0} \frac{f(z+h) - f(z)}{h} = f'(z)
$$

exists and is a continuous function of $z \in \Omega$. Here $h \in \mathbb{C}$.

Note that if $f$ is analytic, it must be the case that $f$ is continuous. It is more common to not include the requirement that $f'$ is continuous but it is shown later that the continuity of $f'$ follows.

What are some examples of analytic functions? In the case where $X = \mathbb{C}$, the simplest example is any polynomial. Thus

$$
p(z) \equiv \sum_{k=0}^{n} a_k z^k
$$

is an analytic function and

$$
p'(z) = \sum_{k=1}^{n} a_k k z^{k-1}.
$$

More generally, power series are analytic. This will be shown soon but first here is an important definition and a convergence theorem called the root test.

Definition 49.1.2 Let $\{a_k\}$ be a sequence in $X$. Then $\sum_{k=1}^{\infty} a_k = \lim_{n \to \infty} \sum_{k=1}^{n} a_k$ whenever this limit exists. When the limit exists, the series is said to converge.
Theorem 49.1.3 Consider \( \sum_{k=1}^{\infty} a_k \) and let \( \rho \equiv \limsup_{k \to \infty} ||a_k||^{1/k} \). Then if \( \rho < 1 \), the series converges absolutely and if \( \rho > 1 \) the series diverges spectacularly in the sense that \( \lim_{k \to \infty} a_k \neq 0 \). If \( \rho = 1 \) the test fails. Also \( \sum_{k=1}^{\infty} a_k (z-a)^k \) converges on some disk \( B(a, R) \). It converges absolutely if \( |z-a| < R \) and uniformly on \( B(a, r_1) \) whenever \( r_1 < R \). The function \( f(z) = \sum_{k=1}^{\infty} a_k (z-a)^k \) is continuous on \( B(a, R) \).

**Proof:** Suppose \( \rho < 1 \). Then there exists \( r \in (\rho, 1) \). Therefore, \( ||a_k|| \leq r^k \) for all \( k \) large enough and so by a comparison test, \( \sum_k ||a_k|| \) converges because the partial sums are bounded above. Therefore, the partial sums of the original series form a Cauchy sequence in \( X \) and so they also converge due to completeness of \( X \).

Now suppose \( \rho > 1 \). Then letting \( \rho > r > 1 \), it follows \( ||a_k||^{1/k} \geq r \) infinitely often. Thus \( ||a_k|| \geq r^k \) infinitely often. Thus there exists a subsequence for which \( ||a_{n_k}|| \) converges to \( \infty \). Therefore, the series cannot converge.

Now consider \( \sum_{k=1}^{\infty} a_k (z-a)^k \). This series converges absolutely if

\[
\limsup_{k \to \infty} ||a_k||^{1/k} |z-a| < 1
\]

which is the same as saying \( |z-a| < 1/\rho \) where \( \rho \equiv \limsup_{k \to \infty} ||a_k||^{1/k} \). Let \( R = 1/\rho \).

Now suppose \( r_1 < R \). Consider \( |z-a| \leq r_1 \). Then for such \( z \),

\[
||a_k|| |z-a|^k \leq ||a_k|| r_1^k
\]

and

\[
\limsup_{k \to \infty} (||a_k|| r_1^k)^{1/k} = \limsup_{k \to \infty} ||a_k||^{1/k} r_1 = \frac{r_1}{R} < 1
\]

so \( \sum_{k=1}^{\infty} ||a_k|| r_1^k \) converges. By the Weierstrass M test, \( \sum_{k=1}^{\infty} a_k (z-a)^k \) converges uniformly for \( |z-a| \leq r_1 \). Therefore, \( f \) is continuous on \( B(a, R) \) as claimed because it is the uniform limit of continuous functions, the partial sums of the infinite series.

What if \( \rho = 0? \) In this case,

\[
\limsup_{k \to \infty} ||a_k||^{1/k} |z-a| = 0 \cdot |z-a| = 0
\]

and so \( R = \infty \) and the series, \( \sum ||a_k|| |z-a|^k \) converges everywhere.

What if \( \rho = \infty? \) Then in this case, the series converges only at \( z = a \) because if \( z \neq a \),

\[
\limsup_{k \to \infty} ||a_k||^{1/k} |z-a| = \infty.
\]

Theorem 49.1.4 Let \( f(z) = \sum_{k=1}^{\infty} a_k (z-a)^k \) be given in Theorem [49.1.3] where \( R > 0 \). Then \( f \) is analytic on \( B(a, R) \). So are all its derivatives.
49.1. ANALYTIC FUNCTIONS

**Proof:** Consider \( g(z) = \sum_{k=2}^{\infty} a_k z^{k-1} \) on \( B(a, R) \) where \( R = \rho^{-1} \) as above. Let \( r_1 < r < R \). Then letting \( |z-a| < r_1 \) and \( h < r - r_1 \),

\[
\left| \frac{f(z+h) - f(z)}{h} - g(z) \right| \\
\leq \sum_{k=2}^{\infty} |a_k| \left| \frac{(z+h-a)^k - (z-a)^k}{h} - k(z-a)^{k-1} \right| \\
\leq \sum_{k=2}^{\infty} |a_k| \left| 1 \frac{\sum_{i=0}^{k} \binom{k}{i} (z-a)^{k-i} h^i - (z-a)^k}{h} - k(z-a)^{k-1} \right| \\
= \sum_{k=2}^{\infty} |a_k| \left| \frac{\sum_{i=1}^{k} \binom{k}{i} (z-a)^{k-i} h^i}{h} - k(z-a)^{k-1} \right| \\
\leq \sum_{k=2}^{\infty} |a_k| \left| \frac{1}{k} \sum_{i=1}^{k} \binom{k}{i} (z-a)^{k-i} h^{i-1} \right| \\
= \left| h \sum_{k=2}^{\infty} \sum_{i=2}^{\infty} \frac{\binom{k-2}{i-2}}{i+2} |z-a|^{k-2-i} |h|^i \right| \\
= \left| h \sum_{k=2}^{\infty} \sum_{i=0}^{\infty} \frac{\binom{k-2}{i}}{i+2} |z-a|^{k-2-i} |h|^i \right| \\
\leq \left| h \sum_{k=2}^{\infty} \frac{k(k-1)}{2} \left( \sum_{i=0}^{\infty} \frac{k-2}{i} |z-a|^{k-2-i} |h|^i \right) \right| \\
= \left| h \sum_{k=2}^{\infty} \frac{k(k-1)}{2} (|z-a| + |h|)^{k-2} \right| < |h| \sum_{k=2}^{\infty} |a_k| \frac{k(k-1)}{2} r^{k-2}.
\]

Then

\[
\lim_{k \to \infty} \sup \left( \sum_{k=2}^{\infty} |a_k| \frac{k(k-1)}{2} r^{k-2} \right)^{1/k} = \rho r < 1
\]

and so

\[
\left| \frac{f(z+h) - f(z)}{h} - g(z) \right| \leq C |h|.
\]

Therefore, \( g(z) = f'(z) \). Now by Theorem 49.1.1 it also follows that \( f' \) is continuous. Since \( r_1 < R \) was arbitrary, this shows that \( f'(z) \) is given by the differentiated series above for \( |z-a| < R \). Now a repeat of the argument shows all the derivatives of \( f \) exist and are continuous on \( B(a, R) \).

### 49.1.1 Cauchy Riemann Equations

Next consider the very important Cauchy Riemann equations which give conditions under which complex valued functions of a complex variable are analytic.
Theorem 49.1.5  Let $\Omega$ be an open subset of $\mathbb{C}$ and let $f : \Omega \to \mathbb{C}$ be a function, such that for $z = x + iy \in \Omega$, 
\[ f(z) = u(x, y) + iv(x, y). \]
Then $f$ is analytic if and only if $u, v$ are $C^1(\Omega)$ and 
\[ \frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \]
Furthermore, 
\[ f'(z) = \frac{\partial u}{\partial x}(x, y) + i\frac{\partial v}{\partial x}(x, y). \]

Proof: Suppose $f$ is analytic first. Then letting $t \in \mathbb{R}$, 
\[ f'(z) = \lim_{t \to 0} \frac{f(z + t) - f(z)}{t} = \lim_{t \to 0} \left( \frac{u(x + t, y) + iv(x + t, y)}{t} - \frac{u(x, y) + iv(x, y)}{t} \right) = \frac{\partial u}{\partial x}(x, y) + i\frac{\partial v}{\partial x}(x, y). \]
But also 
\[ f'(z) = \lim_{t \to 0} \frac{f(z + it) - f(z)}{it} = \lim_{t \to 0} \left( \frac{u(x, y + t) + iv(x, y + t)}{it} - \frac{u(x, y) + iv(x, y)}{it} \right) = \frac{1}{i} \left( \frac{\partial u}{\partial y}(x, y) + i\frac{\partial v}{\partial y}(x, y) \right) = \frac{\partial v}{\partial y}(x, y) - i\frac{\partial u}{\partial y}(x, y). \]
This verifies the Cauchy Riemann equations. We are assuming that $z \to f'(z)$ is continuous. Therefore, the partial derivatives of $u$ and $v$ are also continuous. To see this, note that from the formulas for $f'(z)$ given above, and letting $z_1 = x_1 + iy_1$ 
\[ \left| \frac{\partial u}{\partial y}(x, y) - \frac{\partial v}{\partial y}(x_1, y_1) \right| \leq |f'(z) - f'(z_1)|, \]
showing that $(x, y) \to \frac{\partial v}{\partial y}(x, y)$ is continuous since $(x_1, y_1) \to (x, y)$ if and only if $z_1 \to z$. The other cases are similar.

Now suppose the Cauchy Riemann equations hold and the functions, $u$ and $v$ are $C^1(\Omega)$. Then letting $h = h_1 + ih_2$, 
\[ f(z + h) - f(z) = u(x + h_1, y + h_2) \]
49.1. ANALYTIC FUNCTIONS

\[ +iv (x + h_1, y + h_2) - (u (x, y) + iv (x, y)) \]

We know \( u \) and \( v \) are both differentiable and so

\[ f (z + h) - f (z) = \frac{\partial u}{\partial x} (x, y) h_1 + \frac{\partial u}{\partial y} (x, y) h_2 + \]

\[ i \left( \frac{\partial v}{\partial x} (x, y) h_1 + \frac{\partial v}{\partial y} (x, y) h_2 \right) + o (h). \]

Dividing by \( h \) and using the Cauchy Riemann equations,

\[ \frac{f (z + h) - f (z)}{h} = \frac{\partial u}{\partial x} (x, y) h_1 + \frac{\partial v}{\partial y} (x, y) h_2 + \]

\[ i \left( \frac{\partial v}{\partial x} (x, y) h_1 + \frac{\partial v}{\partial y} (x, y) h_2 \right) + o (h) \]

\[ = \frac{\partial u}{\partial x} (x, y) \frac{h_1 + \frac{ih_2}{h}}{h} + \frac{\partial v}{\partial y} (x, y) \frac{h_1 + \frac{ih_2}{h}}{h} + o (h) \]

Taking the limit as \( h \to 0 \),

\[ f' (z) = \frac{\partial u}{\partial x} (x, y) + i \frac{\partial v}{\partial x} (x, y). \]

It follows from this formula and the assumption that \( u, v \) are \( C^1 (\Omega) \) that \( f' \) is continuous.

It is routine to verify that all the usual rules of derivatives hold for analytic functions. In particular, the product rule, the chain rule, and quotient rule.

49.1.2 An Important Example

An important example of an analytic function is \( e^z \equiv \exp (z) \equiv e^x \cos (y) + ie^x \sin (y) \) where \( z = x + iy \). You can verify that this function satisfies the Cauchy Riemann equations and that all the partial derivatives are continuous. Also from the above discussion, \( (e^z)' = e^x \cos (y) + ie^x \sin (y) = e^z \). Later I will show that \( e^z \) is given by the usual power series. An important property of this function is that it can be used to parameterize the circle centered at \( z_0 \) having radius \( r \).

Lemma 49.1.6 Let \( \gamma \) denote the closed curve which is a circle of radius \( r \) centered at \( z_0 \). Then a parameterization this curve is \( \gamma (t) = z_0 + re^{it} \) where \( t \in [0, 2\pi] \).

Proof: \( |\gamma (t) - z_0|^2 = |re^{it}re^{-it}| = r^2 \). Also, you can see from the definition of the sine and cosine that the point described in this way moves counter clockwise over this circle.
49.2 Exercises

1. Verify all the usual rules of differentiation including the product and chain rules.

2. Suppose \( f \) and \( f' : U \to \mathbb{C} \) are analytic and \( f(z) = u(x, y) + iv(x, y) \). Verify \( u_{xx} + u_{yy} = 0 \) and \( v_{xx} + v_{yy} = 0 \). This partial differential equation satisfied by the real and imaginary parts of an analytic function is called Laplace’s equation. We say these functions satisfying Laplace’s equation are harmonic functions. If \( u \) is a harmonic function defined on \( B(0, r) \) show that \( v(x, y) = \int_0^r u_x(x, t) \, dt - \int_0^r u_y(t, 0) \, dt \) is such that \( u + iv \) is analytic.

3. Let \( f : U \to \mathbb{C} \) be analytic and \( f(z) = u(x, y) + iv(x, y) \). Show \( u, v \) and \( uv \) are all harmonic although it can happen that \( u^2 \) is not. Recall that a function, \( w \) is harmonic if \( w_{xx} + w_{yy} = 0 \).

4. Define a function \( f(z) = \Re \equiv x - iy \) where \( z = x + iy \). Is \( f \) analytic?

5. If \( f(z) = u(x, y) + iv(x, y) \) and \( f \) is analytic, verify that

\[
\det \begin{pmatrix} u_x & u_y \\ v_x & v_y \end{pmatrix} = |f'(z)|^2.
\]

6. Show that if \( u(x, y) + iv(x, y) = f(z) \) is analytic, then \( \nabla u \cdot \nabla v = 0 \). Recall

\[
\nabla u(x, y) = \langle u_x(x, y), u_y(x, y) \rangle.
\]

7. Show that every polynomial is analytic.

8. If \( \gamma(t) = x(t) + iy(t) \) is a \( C^1 \) curve having values in \( U \), an open set of \( \mathbb{C} \), and if \( f : U \to \mathbb{C} \) is analytic, we can consider \( f \circ \gamma \), another \( C^1 \) curve having values in \( \mathbb{C} \). Also, \( \gamma'(t) \) and \( (f \circ \gamma)'(t) \) are complex numbers so these can be considered as vectors in \( \mathbb{R}^2 \) as follows. The complex number, \( x + iy \) corresponds to the vector, \( (x, y) \). Suppose that \( \gamma \) and \( \eta \) are two such \( C^1 \) curves having values in \( U \) and that \( \gamma(t_0) = \eta(s_0) = z \) and suppose that \( f : U \to \mathbb{C} \) is analytic. Show that the angle between \( (f \circ \gamma)'(t_0) \) and \( (f \circ \eta)'(s_0) \) is the same as the angle between \( \gamma'(t_0) \) and \( \eta'(s_0) \) assuming that \( f'(z) \neq 0 \). Thus analytic mappings preserve angles at points where the derivative is nonzero. Such mappings are called isogonal. . Hint: To make this easy to show, first observe that \( \langle x, y \rangle \cdot \langle a, b \rangle = \frac{1}{2} \langle z\overline{w} + \overline{z}w \rangle \) where \( z = x + iy \) and \( w = a + ib \).

9. Analytic functions are even better than what is described in Problem 8. In addition to preserving angles, they also preserve orientation. To verify this show that if \( z = x + iy \) and \( w = a + ib \) are two complex numbers, then \( \langle x, y, 0 \rangle \) and \( \langle a, b, 0 \rangle \) are two vectors in \( \mathbb{R}^3 \). Recall that the cross product, \( \langle x, y, 0 \rangle \times \langle a, b, 0 \rangle \), yields a vector normal to the two given vectors such that the triple, \( \langle x, y, 0 \rangle, \langle a, b, 0 \rangle \), and \( \langle x, y, 0 \rangle \times \langle a, b, 0 \rangle \) satisfies the right hand rule.
and has magnitude equal to the product of the sine of the included angle times the product of the two norms of the vectors. In this case, the cross product either points in the direction of the positive $z$ axis or in the direction of the negative $z$ axis. Thus, either the vectors $(x, y, 0), (a, b, 0), k$ form a right handed system or the vectors $(a, b, 0), (x, y, 0), k$ form a right handed system. These are the two possible orientations. Show that in the situation of Problem 8 the orientation of $f'(t_0), f'(s_0), k$ is the same as the orientation of the vectors $(f \circ \gamma)'(t_0), (f \circ \eta)'(s_0), k$. Such mappings are called conformal. If $f$ is analytic and $f'(z) \neq 0$, then we know from this problem and the above that $f$ is a conformal map. Hint: You can do this by verifying that $(f \circ \gamma)'(t_0) \times (f \circ \eta)'(s_0) = (f'(\gamma(t_0)))^2(\gamma(t_0) \times \eta'(s_0))$. To make the verification easier, you might first establish the following simple formula for the cross product where here $x + iy = z$ and $a + ib = w$.

$$(x, y, 0) \times (a, b, 0) = \text{Re}(ziw)k.$$ 

10. Write the Cauchy Riemann equations in terms of polar coordinates. Recall the polar coordinates are given by

$$x = r \cos \theta, \quad y = r \sin \theta.$$ 

This means, letting $u(x, y) = u(r, \theta), v(x, y) = v(r, \theta)$, write the Cauchy Riemann equations in terms of $r$ and $\theta$. You should eventually show the Cauchy Riemann equations are equivalent to

$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta}, \quad \frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}.$$ 

11. Show that a real valued analytic function must be constant.

### 49.3 Cauchy’s Formula For A Disk

The Cauchy integral formula is the most important theorem in complex analysis. It will be established for a disk in this chapter and later will be generalized to much more general situations but the version given here will suffice to prove many interesting theorems needed in the later development of the theory. The following are some advanced calculus results.

**Lemma 49.3.1** Let $f : [a, b] \to \mathbb{C}$. Then $f'(t)$ exists if and only if $\text{Re} f'(t)$ and $\text{Im} f'(t)$ exist. Furthermore,

$$f'(t) = \text{Re} f'(t) + i \text{Im} f'(t).$$

**Proof:** The if part of the equivalence is obvious.

Now suppose $f'(t)$ exists. Let both $t$ and $t + h$ be contained in $[a, b]$

$$\left| \frac{\text{Re} f(t + h) - \text{Re} f(t)}{h} - \text{Re} (f'(t)) \right| \leq \left| \frac{f(t + h) - f(t)}{h} - f'(t) \right|$$
and this converges to zero as $h \to 0$. Therefore, $\text{Re} f'(t) = \text{Re} (f'(t))$. Similarly, $\text{Im} f'(t) = \text{Im} (f'(t))$.

**Lemma 49.3.2** If $g : [a, b] \to \mathbb{C}$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g'(t) = 0$, then $g(t)$ is a constant.

**Proof:** From the above lemma, you can apply the mean value theorem to the real and imaginary parts of $g$.

Applying the above lemma to the components yields the following lemma.

**Lemma 49.3.3** If $g : [a, b] \to \mathbb{C}^n = X$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g'(t) = 0$, then $g(t)$ is a constant.

If you want to have $X$ be a complex Banach space, the result is still true.

**Lemma 49.3.4** If $g : [a, b] \to X$ and $g$ is continuous on $[a, b]$ and differentiable on $(a, b)$ with $g'(t) = 0$, then $g(t)$ is a constant.

**Proof:** Let $\Lambda \in X'$. Then $\Lambda g : [a, b] \to \mathbb{C}$, Therefore, from Lemma [Lemma 49.3.2], for each $\Lambda \in X'$, $\Lambda g(s) = \Lambda g(t)$ and since $X'$ separates the points, it follows $g(s) = g(t)$ so $g$ is constant.

**Lemma 49.3.5** Let $\phi : [a, b] \times [c, d] \to \mathbb{R}$ be continuous and let

$$g(t) \equiv \int_a^b \phi(s, t) \, ds. \quad (49.3.1)$$

Then $g$ is continuous. If $\frac{\partial \phi}{\partial t}$ exists and is continuous on $[a, b] \times [c, d]$, then

$$g'(t) = \int_a^b \frac{\partial \phi(s, t)}{\partial t} \, ds. \quad (49.3.2)$$

**Proof:** The first claim follows from the uniform continuity of $\phi$ on $[a, b] \times [c, d]$, which uniform continuity results from the set being compact. To establish [Lemma 49.3.5], let $t$ and $t + h$ be contained in $[c, d]$ and form, using the mean value theorem,

$$\frac{g(t + h) - g(t)}{h} = \frac{1}{h} \int_a^b [\phi(s, t + h) - \phi(s, t)] \, ds$$

$$= \frac{1}{h} \int_a^b \frac{\partial \phi(s, t + \theta h)}{\partial t} \, ds$$

$$= \int_a^b \frac{\partial \phi(s, t + \theta h)}{\partial t} \, ds,$$

where $\theta$ may depend on $s$ but is some number between 0 and 1. Then by the uniform continuity of $\frac{\partial \phi}{\partial t}$, it follows that [Lemma 49.3.5] holds.
Corollary 49.3.6 Let \( \phi : [a, b] \times [c, d] \to \mathbb{C} \) be continuous and let
\[
g(t) = \int_a^b \phi(s, t) \, ds. \tag{49.3.3}
\]
Then \( g \) is continuous. If \( \frac{\partial \phi}{\partial t} \) exists and is continuous on \([a, b] \times [c, d] \), then
\[
g'(t) = \int_a^b \frac{\partial \phi(s, t)}{\partial t} \, ds. \tag{49.3.4}
\]

**Proof:** Apply Lemma 49.3.5 to the real and imaginary parts of \( \phi \).

Applying the above corollary to the components, you can also have the same result for \( \phi \) having values in \( \mathbb{C}^n \).

Corollary 49.3.7 Let \( \phi : [a, b] \times [c, d] \to \mathbb{C}^n \) be continuous and let
\[
g(t) = \int_a^b \phi(s, t) \, ds. \tag{49.3.5}
\]
Then \( g \) is continuous. If \( \frac{\partial \phi}{\partial t} \) exists and is continuous on \([a, b] \times [c, d] \), then
\[
g'(t) = \int_a^b \frac{\partial \phi(s, t)}{\partial t} \, ds. \tag{49.3.6}
\]

If you want to consider \( \phi \) having values in \( X \), a complex Banach space a similar result holds.

Corollary 49.3.8 Let \( \phi : [a, b] \times [c, d] \to X \) be continuous and let
\[
g(t) = \int_a^b \phi(s, t) \, ds. \tag{49.3.7}
\]
Then \( g \) is continuous. If \( \frac{\partial \phi}{\partial t} \) exists and is continuous on \([a, b] \times [c, d] \), then
\[
g'(t) = \int_a^b \frac{\partial \phi(s, t)}{\partial t} \, ds. \tag{49.3.8}
\]

**Proof:** Let \( \Lambda \in X' \). Then \( \Lambda \phi : [a, b] \times [c, d] \to \mathbb{C} \) is continuous and \( \frac{\partial \Lambda \phi}{\partial t} \) exists and is continuous on \([a, b] \times [c, d] \). Therefore, from 49.3.5,
\[
\Lambda (g'(t)) = (\Lambda g)'(t) = \int_a^b \frac{\partial \Lambda \phi(s, t)}{\partial t} \, ds = \Lambda \int_a^b \frac{\partial \phi(s, t)}{\partial t} \, ds
\]
and since \( X' \) separates the points, it follows 49.3.5 holds.

You can give a different proof of this.
Theorem 49.3.9 Let \( \phi : [a, b] \times [c, d] \to X \) be continuous and suppose \( \phi_t \) is continuous. Then
\[
\left( \int_a^b \phi(s, t) \, ds \right)_{t = t} = \int_a^b \frac{\partial \phi}{\partial t}(s, t) \, ds
\]
Here \( X \) is a complex Banach space.

**Proof:** Consider the following set \( P \) which is where the ordered pair \((t, h)\) will be.

This is so that both \( t \) and \( t + h \) are in \([a, b]\). Then for such an ordered pair, consider
\[
\Delta(s, t, h) = \begin{cases} 
\frac{\phi(s, t + h) - \phi(s, t)}{h} & \text{if } h \neq 0 \\
\phi_t(s, t) & \text{if } h = 0
\end{cases}
\]

Claim: \( \Delta \) is continuous on the compact set \([a, b] \times P\).

**Proof of claim:** It is obvious unless \( h = 0 \). Therefore, consider the point \((s, t, 0)\).

\[
\|\Delta(s', t', h) - \Delta(s, t, 0)\| = \left\| \frac{\phi(s', t' + h) - \phi(s', t')}{h} - \phi_t(s, t) \right\|
\]

\[
= \left\| \frac{1}{h} \int_{t'}^{t' + h} \phi_t(s', r) \, dr - \phi_t(s, t) \right\| \leq \frac{1}{h} \int_{t'}^{t' + h} \|\phi_t(s', r) - \phi_t(s, t)\| \, dr < \varepsilon
\]
provided \(|(s', t', h) - (s, t, 0)|\) is small enough, this by continuity of \( \phi_t \). Therefore, \( \Delta(s, t, h) \) is uniformly continuous.

\[
\left\| \frac{1}{h} \left( \int_a^b \phi(s, t + h) \, ds - \int_a^b \phi(s, t) \, ds \right) - \int_a^b \phi_t(s, t) \, ds \right\|
\]

\[
\leq \int_a^b \left\| \frac{\phi(s, t + h) - \phi(s, t)}{h} - \phi_t(s, t) \right\| \, ds = \int_a^b \|\Delta(s, t, h) - \phi_t(s, t)\| \, ds
\]

Then by uniform continuity, if \( h \) is small enough, the integrand on the right is smaller than \( \varepsilon \). ■

The following is Cauchy’s integral formula for a disk.

Theorem 49.3.10 Let \( f : \Omega \to X \) be analytic on the open set, \( \Omega \) and let
\[
\overline{B(z_0, r)} \subseteq \Omega.
\]
Let \( \gamma(t) \equiv z_0 + re^{it} \) for \( t \in [0, 2\pi] \). Then if \( z \in B(z_0, r) \),

\[
f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{w-z} \, dw.
\]

(49.3.9)

**Proof:** Consider for \( \alpha \in [0, 1] \),

\[
g(\alpha) = \int_0^{2\pi} \frac{f(z + \alpha(z_0 + re^{it} - z))}{re^{it} + z_0 - z} \, rie^{it} \, dt.
\]

If \( \alpha \) equals one, this reduces to the integral in (49.3.9). The idea is to show \( g \) is a constant and that \( g(0) = f(z) \frac{2\pi}{2}i \). First consider the claim about \( g(0) \):

\[
g(0) = \left( \int_0^{2\pi} \frac{re^{it}}{re^{it} + z_0 - z} \, dt \right) i f(z)
\]

\[
= i f(z) \left( \int_0^{2\pi} \frac{1}{1 - \frac{z-z_0}{re^{it}}} \, dt \right)
\]

\[
= i f(z) \left( \int_0^{2\pi} \sum_{n=0}^{\infty} r^{-n} e^{-int} (z-z_0)^n \, dt \right)
\]

because \(|\frac{z-z_0}{re^{it}}| < 1\). Since this sum converges uniformly you can interchange the sum and the integral to obtain

\[
g(0) = i f(z) \sum_{n=0}^{\infty} r^{-n} (z-z_0)^n \int_0^{2\pi} e^{-int} \, dt
\]

\[
= 2\pi i f(z)
\]

because \( \int_0^{2\pi} e^{-int} \, dt = 0 \) if \( n > 0 \).

Next consider the claim that \( g \) is constant. By Corollary (49.3.3), for \( \alpha \in (0, 1) \),

\[
g'(\alpha) = \int_0^{2\pi} \frac{f'(z + \alpha(z_0 + re^{it} - z))}{re^{it} + z_0 - z} \, rie^{it} \, dt
\]

\[
= \int_0^{2\pi} f'(z + \alpha(z_0 + re^{it} - z)) \, rie^{it} \, dt
\]

\[
= \int_0^{2\pi} \frac{d}{dt} \left( f(z + \alpha(z_0 + re^{it} - z)) \frac{1}{\alpha} \right) \, dt
\]

\[
= f(z + \alpha(z_0 + re^{it} - z)) \frac{1}{\alpha} - f(z + \alpha(z_0 + re^{it} - z)) \frac{1}{\alpha} = 0.
\]

Now \( g \) is continuous on \([0, 1]\) and \( g'(t) = 0 \) on \((0, 1)\) so by Lemma (49.3.3), \( g \) equals a constant. This constant can only be \( g(0) = 2\pi if(z) \). Thus,

\[
g(1) = \int_{\gamma} \frac{f(w)}{w-z} \, dw = g(0) = 2\pi if(z).
\]

This proves the theorem.

This is a very significant theorem. A few applications are given next.
**Theorem 49.3.11** Let \( f : \Omega \to X \) be analytic where \( \Omega \) is an open set in \( \mathbb{C} \). Then \( f \) has infinitely many derivatives on \( \Omega \). Furthermore, for all \( z \in B(z_0, r) \),

\[
f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\gamma} \frac{f(w)}{(w - z)^{n+1}} dw \tag{49.3.10}
\]

where \( \gamma(t) \equiv z_0 + re^{it}, t \in [0, 2\pi] \) for \( r \) small enough that \( B(z_0, r) \subseteq \Omega \).

**Proof:** Let \( z \in B(z_0, r) \subseteq \Omega \) and let \( \Omega = \overline{B(z_0, r)} \subseteq \Omega \). Then, letting \( \gamma(t) \equiv z_0 + re^{it}, t \in [0, 2\pi] \), and \( h \) small enough,

\[
f(z) = \frac{1}{2\pi i} \int_{\gamma} f(w) \frac{dw}{w - z}, \quad f(z + h) = \frac{1}{2\pi i} \int_{\gamma} f(w) \frac{dw}{w - z - h}
\]

Now

\[
\frac{1}{w - z - h} - \frac{1}{w - z} = \frac{h}{(-w + z + h)(-w + z)}
\]

and so

\[
\frac{f(z + h) - f(z)}{h} = \frac{1}{2\pi i} \int_{\gamma} \frac{hf(w)}{(-w + z + h)(-w + z)} dw
\]

\[
= \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{(-w + z + h)(-w + z)} dw.
\]

Now for all \( h \) sufficiently small, there exists a constant \( C \) independent of such \( h \) such that

\[
\left| \frac{1}{(-w + z + h)(-w + z)} - \frac{1}{(-w + z)(-w + z)} \right| = \left| \frac{h}{(w - z - h)(w - z)^2} \right| \leq C|h|
\]

and so, the integrand converges uniformly as \( h \to 0 \) to

\[
= \frac{f(w)}{(w - z)^2}
\]

Therefore, the limit as \( h \to 0 \) may be taken inside the integral to obtain

\[
f'(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{(w - z)^2} dw.
\]

Continuing in this way, yields (49.3.10).

This is a very remarkable result. It shows the existence of one continuous derivative implies the existence of all derivatives, in contrast to the theory of functions of a real variable. Actually, more than what is stated in the theorem was shown. The above proof establishes the following corollary.
Corollary 49.3.12 Suppose $f$ is continuous on $\partial B(z_0, r)$ and suppose that for all $z \in B(z_0, r)$,

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(w)}{w-z} \, dw,$$

where $\gamma(t) \equiv z_0 + re^{it}$, $t \in [0, 2\pi]$. Then $f$ is analytic on $B(z_0, r)$ and in fact has infinitely many derivatives on $B(z_0, r)$.

Another application is the following lemma.

Lemma 49.3.13 Let $\gamma(t) = z_0 + re^{it}$, for $t \in [0, 2\pi]$, suppose $f_n \to f$ uniformly on $B(z_0, r)$, and suppose

$$f_n(z) = \frac{1}{2\pi i} \int_\gamma \frac{f_n(w)}{w-z} \, dw$$

(49.3.11)

for $z \in B(z_0, r)$. Then

$$f(z) = \frac{1}{2\pi i} \int_\gamma \frac{f(w)}{w-z} \, dw,$$

(49.3.12)

implying that $f$ is analytic on $B(z_0, r)$.

Proof: From (49.3.11) and the uniform convergence of $f_n$ to $f$ on $\gamma([0, 2\pi])$, the integrals in (49.3.11) converge to

$$\frac{1}{2\pi i} \int_\gamma \frac{f(w)}{w-z} \, dw.$$

Therefore, the formula (49.3.12) follows.

Uniform convergence on a closed disk of the analytic functions implies the target function is also analytic. This is amazing. Think of the Weierstrass approximation theorem for polynomials. You can obtain a continuous nowhere differentiable function as the uniform limit of polynomials.

The conclusions of the following proposition have all been obtained earlier in Theorem 49.1.4 but they can be obtained more easily if you use the above theorem and lemmas.

Proposition 49.3.14 Let $\{a_n\}$ denote a sequence in $X$. Then there exists $R \in [0, \infty]$ such that

$$\sum_{k=0}^{\infty} a_k (z-z_0)^k$$

converges absolutely if $|z-z_0| < R$, diverges if $|z-z_0| > R$ and converges uniformly on $B(z_0, r)$ for all $r < R$. Furthermore, if $R > 0$, the function,

$$f(z) = \sum_{k=0}^{\infty} a_k (z-z_0)^k$$

is analytic on $B(z_0, R)$. 
**Proof:** The assertions about absolute convergence are routine from the root test if

\[ R \equiv \left( \limsup_{n \to \infty} |a_n|^{1/n} \right)^{-1} \]

with \( R = \infty \) if the quantity in parenthesis equals zero. The root test can be used to verify absolute convergence which then implies convergence by completeness of \( X \).

The assertion about uniform convergence follows from the Weierstrass M test and \( M_n = |a_n| r^n \). (\( \sum_{n=0}^{\infty} |a_n| r^n < \infty \) by the root test). It only remains to verify the assertion about \( f(z) \) being analytic in the case where \( R > 0 \).

Let \( 0 < r < R \) and define \( f_n(z) = \sum_{k=0}^{n} a_k (z - z_0)^k \). Then \( f_n \) is a polynomial and so it is analytic. Thus, by the Cauchy integral formula above,

\[
f_n(z) = \frac{1}{2\pi i} \int_{\gamma} f_n(w) \frac{dw}{w - z}
\]

where \( \gamma(t) = z_0 + re^{it}, \) for \( t \in [0,2\pi] \). By Lemma [49.3.12] and the first part of this proposition involving uniform convergence,

\[
f(z) = \frac{1}{2\pi i} \int_{\gamma} f(w) \frac{dw}{w - z}.
\]

Therefore, \( f \) is analytic on \( B(z_0, r) \) by Corollary [49.3.12]. Since \( r < R \) is arbitrary, this shows \( f \) is analytic on \( B(z_0, R) \).

This proposition shows that all functions having values in \( X \) which are given as power series are analytic on their circle of convergence, the set of complex numbers, \( z \), such that \( |z - z_0| < R \). In fact, every analytic function can be realized as a power series.

**Theorem 49.3.15** If \( f: \Omega \to X \) is analytic and if \( B(z_0, r) \subseteq \Omega \), then

\[
f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n \tag{49.3.13}
\]

for all \( |z - z_0| < r \). Furthermore,

\[
a_n = \frac{f^{(n)}(z_0)}{n!}. \tag{49.3.14}
\]

**Proof:** Consider \( |z - z_0| < r \) and let \( \gamma(t) = z_0 + re^{it}, \) \( t \in [0,2\pi] \). Then for \( w \in \gamma([0,2\pi]) \),

\[
\frac{|z - z_0|}{|w - z_0|} < 1
\]
and so, by the Cauchy integral formula,

\[ f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{w-z} \, dw \]

\[ = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{(w-z_0) \left(1 - \frac{z-z_0}{w-z_0}\right)} \, dw \]

\[ = \frac{1}{2\pi i} \int_{\gamma} f(w) \sum_{n=0}^{\infty} \left(\frac{z-z_0}{w-z_0}\right)^n \, dw. \]

Since the series converges uniformly, you can interchange the integral and the sum to obtain

\[ f(z) = \sum_{n=0}^{\infty} \left(\frac{1}{2\pi i} \int_{\gamma} f(w) \left(\frac{w-z_0}{z-z_0}\right)^{n+1} \, dw\right) (z-z_0)^n \]

\[ = \sum_{n=0}^{\infty} a_n (z-z_0)^n \]

By Theorem 49.3.11, 49.3.14 holds.

Note that this also implies that if a function is analytic on an open set, then all of its derivatives are also analytic. This follows from Theorem 49.1.4 which says that a function given by a power series has all derivatives on the disk of convergence.

### 49.4 Exercises

1. Show that if \(|e_k| \leq \varepsilon\), then \(\left|\sum_{k=m}^{\infty} e_k (r^k - r^{k+1})\right| < \varepsilon\) if \(0 \leq r < 1\). **Hint:** Let \(|\theta| = 1\) and verify that

\[ \theta \sum_{k=m}^{\infty} e_k (r^k - r^{k+1}) = \sum_{k=m}^{\infty} e_k (r^k - r^{k+1}) = \sum_{k=m}^{\infty} \text{Re} (\theta e_k) (r^k - r^{k+1}) \]

where \(-\varepsilon < \text{Re}(\theta e_k) < \varepsilon\).

2. Abel’s theorem says that if \(\sum_{n=0}^{\infty} a_n (z-a)^n\) has radius of convergence equal to 1 and if \(A = \sum_{n=0}^{\infty} a_n\), then \(\lim_{r \to 1^-} \sum_{n=0}^{\infty} a_n r^n = A\). **Hint:** Show \(\sum_{k=0}^{\infty} a_k r^k = \sum_{k=0}^{\infty} A_k (r^k - r^{k+1})\) where \(A_k\) denotes the \(k^{th}\) partial sum of \(\sum a_j\). Thus

\[ \sum_{k=0}^{\infty} a_k r^k = \sum_{k=m+1}^{\infty} A_k (r^k - r^{k+1}) + \sum_{k=0}^{m} A_k (r^k - r^{k+1}), \]

where \(|A_k - A| < \varepsilon\) for all \(k \geq m\). In the first sum, write \(A_k = A + e_k\) and use Problem 3. **Hint:** Use this theorem to verify that \(\arctan(1) = \sum_{k=0}^{\infty} (-1)^k \frac{1}{2k+1}\).
3. Find the integrals using the Cauchy integral formula.

(a) \[ \int_\gamma \frac{\sin z}{z-i} \, dz \] where \( \gamma(t) = 2e^{it} : t \in [0, 2\pi] \).

(b) \[ \int_\gamma \frac{1}{z-a} \, dz \] where \( \gamma(t) = a + re^{it} : t \in [0, 2\pi] \).

(c) \[ \int_\gamma \frac{\cos z}{z^2-1} \, dz \] where \( \gamma(t) = e^{it} : t \in [0, 2\pi] \).

(d) \[ \int_\gamma \frac{\log(z)}{z-a} \, dz \] where \( \gamma(t) = 1 + \frac{1}{2} e^{it} : t \in [0, 2\pi] \) and \( n = 0, 1, 2 \). In this problem, \( \log(z) \equiv \ln|z| + i \arg(z) \) where \( \arg(z) \in (-\pi, \pi) \) and \( z = |z|e^{i\arg(z)} \). Thus \( e^{\log(z)} = z \) and \( \log(z)' = \frac{1}{z} \).

4. Let \( \gamma(t) = 4e^{it} : t \in [0, 2\pi] \) and find \( \int_\gamma \frac{z^2 + 4}{z(z^2 + 1)} \, dz \).

5. Suppose \( f(z) = \sum_{n=0}^{\infty} a_n z^n \) for all \( |z| < R \). Show that then

\[
\frac{1}{2\pi} \int_0^{2\pi} |f(re^{i\theta})|^2 \, d\theta = \sum_{n=0}^{\infty} |a_n|^2 r^{2n}
\]

for all \( r \in [0, R] \). \textbf{Hint:} Let

\[
f_n(z) = \sum_{k=0}^{n} a_k z^k,
\]

show

\[
\frac{1}{2\pi} \int_0^{2\pi} |f_n(re^{i\theta})|^2 \, d\theta = \sum_{k=0}^{n} |a_k|^2 r^{2k}
\]

and then take limits as \( n \to \infty \) using uniform convergence.

6. The Cauchy integral formula, marvelous as it is, can actually be improved upon. The Cauchy integral formula involves representing \( f \) by the values of \( f \) on the boundary of the disk, \( B(a, r) \). It is possible to represent \( f \) by using only the values of \( \Re f \) on the boundary. This leads to the Schwarz formula.

Supply the details in the following outline.

Suppose \( f \) is analytic on \( |z| < R \) and

\[
f(z) = \sum_{n=0}^{\infty} a_n z^n \quad (49.4.15)
\]

with the series converging uniformly on \( |z| = R \). Then letting \( |w| = R \),

\[ 2u(w) = f(w) + \overline{f(w)} \]

and so

\[ 2u(w) = \sum_{k=0}^{\infty} a_k w^k + \sum_{k=0}^{\infty} \overline{a_k} \overline{w}^k. \quad (49.4.16) \]
49.4. EXERCISES

Now letting \( \gamma(t) = \Re e^{it}, t \in [0, 2\pi] \)
\[
\int_\gamma \frac{2u(w)}{w} \, dw = (a_0 + \overline{a_0}) \int_\gamma \frac{1}{w} \, dw = 2\pi i (a_0 + \overline{a_0}).
\]

Thus, multiplying \(49.4.16\) by \(w^{-1}\),
\[
\frac{1}{\pi i} \int_\gamma \frac{u(w)}{w} \, dw = a_0 + \overline{a_0}.
\]

Now multiply \(49.4.16\) by \(w^{-(n+1)}\) and integrate again to obtain
\[
a_n = \frac{1}{\pi i} \int_\gamma \frac{u(w)}{w^{n+1}} \, dw.
\]

Using these formulas for \(a_n\) in \(49.4.18\), we can interchange the sum and the integral (Why can we do this?) to write the following for \(|z| < R\).
\[
f(z) = \frac{1}{2\pi i} \int_\gamma \frac{1}{z} \sum_{k=0}^{\infty} \left( \frac{z}{w} \right)^{k+1} u(w) \, dw - \overline{a_0}
\]
\[
= \frac{1}{\pi i} \int_\gamma \frac{u(w)}{w-z} \, dw - \overline{a_0},
\]
which is the Schwarz formula. Now \(\Re a_0 = \frac{1}{2\pi i} \int_\gamma \frac{u(w)}{w} \, dw\) and \(\overline{a_0} = \Re a_0 - i \Im a_0\). Therefore, we can also write the Schwarz formula as
\[
f(z) = \frac{1}{2\pi i} \int_\gamma \frac{u(w)(w+z)}{(w-z)w} \, dw + i \Im a_0. \quad (49.4.17)
\]

7. Take the real parts of the second form of the Schwarz formula to derive the Poisson formula for a disk,
\[
u \left( r e^{i\alpha} \right) = \frac{1}{2\pi} \int_0^{2\pi} \frac{u \left( Re^{i\theta} \right) \left( R^2 - r^2 \right)}{R^2 + r^2 - 2R r \cos (\theta - \alpha)} \, d\theta. \quad (49.4.18)
\]

8. Suppose that \(u(w)\) is a given real continuous function defined on \(\partial B(0, R)\) and define \(f(z)\) for \(|z| < R\) by \(49.4.17\). Show that \(f\), so defined is analytic. Explain why \(u\) given in \(49.4.18\) is harmonic. Show that
\[
\lim_{r \to R^-} u \left( r e^{i\alpha} \right) = u \left( \Re e^{i\alpha} \right).
\]

Thus \(u\) is a harmonic function which approaches a given function on the boundary and is therefore, a solution to the Dirichlet problem.
9. Suppose \( f(z) = \sum_{k=0}^{\infty} a_k (z - z_0)^k \) for all \( |z - z_0| < R \). Show that \( f'(z) = \sum_{k=0}^{\infty} k a_k (z - z_0)^{k-1} \) for all \( |z - z_0| < R \). \textbf{Hint:} Let \( f_n(z) \) be a partial sum of \( f \). Show that \( f_n' \) converges uniformly to some function, \( g \) on \( |z - z_0| \leq r \) for any \( r < R \). Now use the Cauchy integral formula for a function and its derivative to identify \( g \) with \( f' \).

10. Use Problem 4 to find the exact value of \( \sum_{k=0}^{\infty} k^2 (\frac{1}{3})^k \).

11. Prove the binomial formula,
\[
(1 + z)^\alpha = \sum_{n=0}^{\infty} \binom{\alpha}{n} z^n
\]
where
\[
\binom{\alpha}{n} = \frac{\alpha \cdot (\alpha - n + 1)}{n!}.
\]
Can this be used to give a proof of the binomial formula,
\[
(a + b)^n = \sum_{k=0}^{n} \binom{n}{k} a^n b^k?
\]
Explain.

12. Suppose \( f \) is analytic on \( B(z_0, r) \) and continuous on \( \overline{B(z_0, r)} \) and \( |f(z)| \leq M \) on \( \overline{B(z_0, r)} \). Show that then \( |f^{(n)}(a)| \leq \frac{M n!}{r^n} \).

49.5 Zeros Of An Analytic Function

In this section we give a very surprising property of analytic functions which is in stark contrast to what takes place for functions of a real variable.

\textbf{Definition 49.5.1} A region is a connected open set.

It turns out the zeros of an analytic function which is not constant on some region cannot have a limit point. This is also a good time to define the order of a zero.

\textbf{Definition 49.5.2} Suppose \( f \) is an analytic function defined near a point, \( \alpha \) where \( f(\alpha) = 0 \). Thus \( \alpha \) is a zero of the function, \( f \). The zero is of order \( m \) if \( f(z) = (z - \alpha)^m g(z) \) where \( g \) is an analytic function which is not equal to zero at \( \alpha \).

\textbf{Theorem 49.5.3} Let \( \Omega \) be a connected open set (region) and let \( f : \Omega \to X \) be analytic. Then the following are equivalent.

1. \( f(z) = 0 \) for all \( z \in \Omega \)
2. There exists \( z_0 \in \Omega \) such that \( f^{(n)}(z_0) = 0 \) for all \( n \).
3. There exists \( z_0 \in \Omega \) which is a limit point of the set,

\[ Z \equiv \{ z \in \Omega : f(z) = 0 \} . \]

**Proof:** It is clear the first condition implies the second two. Suppose the third holds. Then for \( z \) near \( z_0 \)

\[ f(z) = \sum_{n=k}^{\infty} \frac{f^{(n)}(z_0)}{n!} (z - z_0)^n \]

where \( k \geq 1 \) since \( z_0 \) is a zero of \( f \). Suppose \( k < \infty \). Then,

\[ f(z) = (z - z_0)^k \ g(z) \]

where \( g(z_0) \neq 0 \). Letting \( z_n \to z_0 \) where \( z_n \in Z, z_n \neq z_0 \), it follows

\[ 0 = (z_n - z_0)^k \ g(z_n) \]

which implies \( g(z_n) = 0 \). Then by continuity of \( g \), we see that \( g(z_0) = 0 \) also, contrary to the choice of \( k \). Therefore, \( k \) cannot be less than \( \infty \) and so \( z_0 \) is a point satisfying the second condition.

Now suppose the second condition and let

\[ S \equiv \{ z \in \Omega : f^{(n)}(z) = 0 \text{ for all } n \} . \]

It is clear that \( S \) is a closed set which by assumption is nonempty. However, this set is also open. To see this, let \( z \in S \). Then for all \( w \) close enough to \( z \),

\[ f(w) = \sum_{k=0}^{\infty} \frac{f^{(k)}(z)}{k!} (w - z)^k = 0. \]

Thus \( f \) is identically equal to zero near \( z \in S \). Therefore, all points near \( z \) are contained in \( S \) also, showing that \( S \) is an open set. Now \( \Omega = S \cup (\Omega \setminus S) \), the union of two disjoint open sets, \( S \) being nonempty. It follows the other open set, \( \Omega \setminus S \), must be empty because \( \Omega \) is connected. Therefore, the first condition is verified. This proves the theorem. (See the following diagram.)

Note how radically different this is from the theory of functions of a real variable. Consider, for example the function

\[ f(x) = \begin{cases} \ x^2 \sin \left( \frac{1}{x} \right) \text{ if } x \neq 0 \\ 
0 \text{ if } x = 0 \end{cases} \]
which has a derivative for all \( x \in \mathbb{R} \) and for which 0 is a limit point of the set, \( Z \), even though \( f \) is not identically equal to zero.

Here is a very important application called Euler’s formula. Recall that

\[
e^z \equiv e^x (\cos(y) + i \sin(y))\]  

(49.5.19)

Is it also true that

\[
e^z = \sum_{k=0}^{\infty} \frac{z^k}{k!}.
\]

**Theorem 49.5.4 (Euler’s Formula)** Let \( z = x + iy \). Then

\[
e^z = \sum_{k=0}^{\infty} \frac{z^k}{k!}.
\]

**Proof:** It was already observed that \( e^z \) given by (49.5.19) is analytic. So is \( \exp(z) = \sum_{k=0}^{\infty} \frac{z^k}{k!} \). In fact the power series converges for all \( z \in \mathbb{C} \). Furthermore the two functions, \( e^z \) and \( \exp(z) \) agree on the real line which is a set which contains a limit point. Therefore, they agree for all values of \( z \in \mathbb{C} \).

This formula shows the famous two identities,

\[
e^{i\pi} = -1 \quad \text{and} \quad e^{2\pi i} = 1.
\]

### 49.6 Liouville’s Theorem

The following theorem pertains to functions which are analytic on all of \( \mathbb{C} \), “entire” functions.

**Definition 49.6.1** A function, \( f : \mathbb{C} \to \mathbb{C} \) or more generally, \( f : \mathbb{C} \to X \) is entire means it is analytic on \( \mathbb{C} \).

**Theorem 49.6.2 (Liouville’s theorem)** If \( f \) is a bounded entire function having values in \( X \), then \( f \) is a constant.

**Proof:** Since \( f \) is entire, pick any \( z \in \mathbb{C} \) and write

\[
f'(z) = \frac{1}{2\pi i} \int_{\gamma_R} \frac{f(w)}{(w-z)^2} \, dw
\]

where \( \gamma_R(t) = z + Re^{it} \) for \( t \in [0, 2\pi] \). Therefore,

\[||f'(z)|| \leq C \frac{1}{R},\]

where \( C \) is some constant depending on the assumed bound on \( f \). Since \( R \) is arbitrary, let \( R \to \infty \) to obtain \( f'(z) = 0 \) for any \( z \in \mathbb{C} \). It follows from this that \( f \) is constant for if \( z_j, j = 1, 2 \) are two complex numbers, let \( h(t) = f(z_1 + t(z_2 - z_1)) \) for \( t \in [0, 1] \). Then \( h'(t) = f'(z_1 + t(z_2 - z_1))(z_2 - z_1) = 0 \). By Lemmas 49.3.2 - 49.3.4 \( h \) is a constant on \([0, 1]\) which implies \( f(z_1) = f(z_2) \).
With Liouville’s theorem it becomes possible to give an easy proof of the fundamental theorem of algebra. It is ironic that all the best proofs of this theorem in algebra come from the subjects of analysis or topology. Out of all the proofs that have been given of this very important theorem, the following one based on Liouville’s theorem is the easiest.

**Theorem 49.6.3 (Fundamental theorem of Algebra)** Let

$$p(z) = z^n + a_{n-1}z^{n-1} + \cdots + a_1z + a_0$$

be a polynomial where \( n \geq 1 \) and each coefficient is a complex number. Then there exists \( z_0 \in \mathbb{C} \) such that \( p(z_0) = 0 \).

**Proof:** Suppose not. Then \( p(z)^{-1} \) is an entire function. Also

$$|p(z)| \geq |z|^n - \left( |a_{n-1}| |z|^{n-1} + \cdots + |a_1||z| + |a_0| \right)$$

and so \( \lim_{z \to \infty} |p(z)| = \infty \) which implies \( \lim_{z \to \infty} \left| p(z)^{-1} \right| = 0 \). It follows that, since \( p(z)^{-1} \) is bounded for \( z \) in any bounded set, we must have that \( p(z)^{-1} \) is a bounded entire function. But then it must be constant. However since \( p(z)^{-1} \to 0 \) as \( |z| \to \infty \), this constant can only be 0. However, \( \frac{1}{p(z)} \) is never equal to zero. This proves the theorem.

### 49.7 The General Cauchy Integral Formula

#### 49.7.1 The Cauchy Goursat Theorem

This section gives a fundamental theorem which is essential to the development which follows and is closely related to the question of when a function has a primitive. First of all, if you have two points in \( \mathbb{C} \), \( z_1 \) and \( z_2 \), you can consider \( \gamma(t) = z_1 + t (z_2 - z_1) \) for \( t \in [0,1] \) to obtain a continuous bounded variation curve from \( z_1 \) to \( z_2 \). More generally, if \( z_1, \ldots, z_m \) are points in \( \mathbb{C} \) you can obtain a continuous bounded variation curve from \( z_1 \) to \( z_m \) which consists of first going from \( z_1 \) to \( z_2 \) and then from \( z_2 \) to \( z_3 \) and so on, till in the end one goes from \( z_{m-1} \) to \( z_m \). We denote this piecewise linear curve as \( \gamma(z_1, \ldots, z_m) \). Now let \( T \) be a triangle with vertices \( z_1, z_2 \) and \( z_3 \) encountered in the counter clockwise direction as shown.

![Triangle](image)

Denote by \( \int_{\partial T} f(z) \, dz \), the expression, \( \int_{\gamma(z_1, z_2, z_3)} f(z) \, dz \). Consider the follo-
CHAPTER 49. FUNDAMENTALS OF COMPLEX ANALYSIS

wing picture.

\[
\int_{\partial T} f(z) \, dz = \sum_{k=1}^{4} \int_{\partial T_k} f(z) \, dz. \quad (49.7.20)
\]

On the "inside lines" the integrals cancel as claimed in Lemma 48.0.11 because there are two integrals going in opposite directions for each of these inside lines.

**Theorem 49.7.1 (Cauchy Goursat)** Let \( f : \Omega \to X \) have the property that \( f'(z) \) exists for all \( z \in \Omega \) and let \( T \) be a triangle contained in \( \Omega \). Then

\[
\int_{\partial T} f(w) \, dw = 0.
\]

**Proof:** Suppose not. Then

\[
\left\| \int_{\partial T} f(w) \, dw \right\| = \alpha \neq 0.
\]

From (49.7.1) it follows

\[
\alpha \leq \sum_{k=1}^{4} \left\| \int_{\partial T_k} f(w) \, dw \right\|
\]

and so for at least one of these \( T_k \), denoted from now on as \( T_1 \),

\[
\left\| \int_{\partial T_1} f(w) \, dw \right\| \geq \frac{\alpha}{4}.
\]

Now let \( T_1 \) play the same role as \( T \), subdivide as in the above picture, and obtain \( T_2 \) such that

\[
\left\| \int_{\partial T_2} f(w) \, dw \right\| \geq \frac{\alpha}{4^2}.
\]

Continue in this way, obtaining a sequence of triangles,

\[
T_k \supseteq T_{k+1}, \text{diam}(T_k) \leq \text{diam}(T) \cdot 2^{-k},
\]
and

\[ \left| \int_{\partial T_k} f(w) \, dw \right| \geq \frac{\alpha}{4^k}. \]

Then let \( z \in \cap_{k=1}^{\infty} T_k \) and note that by assumption, \( f'(z) \) exists. Therefore, for all \( k \) large enough,

\[ \int_{\partial T_k} f(w) \, dw = \int_{\partial T_k} f(z) + f'(z)(w-z) + g(w) \, dw \]

where \( ||g(w)|| < \varepsilon |w-z| \). Now observe that \( w \to f(z) + f'(z)(w-z) \) has a primitive, namely,

\[ F(w) = f(z)w + f'(z)(w-z)^2/2. \]

Therefore, by Corollary 48.0.14,

\[ \int_{\partial T_k} f(w) \, dw = \int_{\partial T_k} g(w) \, dw. \]

From the definition, of the integral,

\[ \frac{\alpha}{4^k} \leq \left| \int_{\partial T_k} g(w) \, dw \right| \leq \varepsilon \text{diam}(T_k) \text{(length of } \partial T_k) \]

\[ \leq \varepsilon 2^{-k} \text{(length of } T) \text{diam}(T) 2^{-k}, \]

and so

\[ \alpha \leq \varepsilon \text{(length of } T) \text{diam}(T). \]

Since \( \varepsilon \) is arbitrary, this shows \( \alpha = 0 \), a contradiction. Thus \( \int_{\partial T} f(w) \, dw = 0 \) as claimed.

This fundamental result yields the following important theorem.

**Theorem 49.7.2 (Morera)** Let \( \Omega \) be an open set and let \( f'(z) \) exist for all \( z \in \Omega \). Let \( D \equiv \overline{B(z_0,r)} \subseteq \Omega \). Then there exists \( \varepsilon > 0 \) such that \( f \) has a primitive on \( B(z_0,r+\varepsilon) \).

**Proof:** Choose \( \varepsilon > 0 \) small enough that \( B(z_0,r+\varepsilon) \subseteq \Omega \). Then for \( w \in B(z_0,r+\varepsilon) \), define

\[ F(w) \equiv \int_{\gamma(z_0,w)} f(u) \, du. \]

Then by the Cauchy Goursat theorem, and \( w \in B(z_0,r+\varepsilon) \), it follows that for \( |h| \) small enough,

\[ \frac{F(w+h) - F(w)}{h} = \frac{1}{h} \int_{\gamma(w,w+h)} f(u) \, du \]

\[ = \frac{1}{h} \int_{0}^{1} f(w+th) \, hdt = \int_{0}^{1} f(w+th) \, dt \]

\[ ^{1}\text{Giancinto Morera 1856-1909. This theorem or one like it dates from around 1886} \]
which converges to \( f(w) \) due to the continuity of \( f \) at \( w \). This proves the theorem.

The following is a slight generalization of the above theorem which is also referred to as Morera’s theorem.

**Corollary 49.7.3** Let \( \Omega \) be an open set and suppose that whenever

\[
\gamma (z_1, z_2, z_3, z_1)
\]

is a closed curve bounding a triangle \( T \), which is contained in \( \Omega \), and \( f \) is a continuous function defined on \( \Omega \), it follows that

\[
\int_{\gamma(z_1, z_2, z_3, z_1)} f(z) \, dz = 0,
\]

then \( f \) is analytic on \( \Omega \).

**Proof:** As in the proof of Morera’s theorem, let \( B(z_0, r) \subseteq \Omega \) and use the given condition to construct a primitive, \( F \) for \( f \) on \( B(z_0, r) \). Then \( F \) is analytic and so by Theorem 49.3.11, it follows that \( F \) and hence \( f \) have infinitely many derivatives, implying that \( f \) is analytic on \( B(z_0, r) \). Since \( z_0 \) is arbitrary, this shows \( f \) is analytic on \( \Omega \).

### 49.7.2 A Redundant Assumption

Earlier in the definition of analytic, it was assumed the derivative is continuous. This assumption is redundant.

**Theorem 49.7.4** Let \( \Omega \) be an open set in \( \mathbb{C} \) and suppose \( f : \Omega \rightarrow X \) has the property that \( f'(z) \) exists for each \( z \in \Omega \). Then \( f \) is analytic on \( \Omega \).

**Proof:** Let \( z_0 \in \Omega \) and let \( B(z_0, r) \subseteq \Omega \). By Morera’s theorem \( f \) has a primitive, \( F \) on \( B(z_0, r) \). It follows that \( F \) is analytic because it has a derivative, \( f' \), and this derivative is continuous. Therefore, by Theorem 49.3.11, \( F \) has infinitely many derivatives on \( B(z_0, r) \) implying that \( f \) also has infinitely many derivatives on \( B(z_0, r) \). Thus \( f \) is analytic as claimed.

It follows a function is analytic on an open set, \( \Omega \) if and only if \( f'(z) \) exists for \( z \in \Omega \). This is because it was just shown the derivative, if it exists, is automatically continuous.

The same proof used to prove Theorem 49.7.4 implies the following corollary.

**Corollary 49.7.5** Let \( \Omega \) be a convex open set and suppose that \( f'(z) \) exists for all \( z \in \Omega \). Then \( f \) has a primitive on \( \Omega \).

Note that this implies that if \( \Omega \) is a convex open set on which \( f'(z) \) exists and if \( \gamma : [a, b] \rightarrow \Omega \) is a closed, continuous curve having bounded variation, then letting \( F \) be a primitive of \( f \) Theorem 49.3.11 implies

\[
\int_{\gamma} f(z) \, dz = F(b) - F(a) = 0.
\]
Notice how different this is from the situation of a function of a real variable! It is possible for a function of a real variable to have a derivative everywhere and yet the derivative can be discontinuous. A simple example is the following.

\[ f(x) = \begin{cases} 
  x^2 \sin \left(\frac{1}{x}\right) & \text{if } x \neq 0 \\
  0 & \text{if } x = 0
\end{cases} \]

Then \( f'(x) \) exists for all \( x \in \mathbb{R} \). Indeed, if \( x \neq 0 \), the derivative equals \( 2x \sin \frac{1}{x} - \cos \frac{1}{x} \) which has no limit as \( x \to 0 \). However, from the definition of the derivative of a function of one variable, \( f'(0) = 0 \).

### 49.7.3 Classification Of Isolated Singularities

First some notation.

**Definition 49.7.6** Let \( B'(a;r) = \{ z \in \mathbb{C} \text{ such that } 0 < |z - a| < r \} \). Thus this is the usual ball without the center. A function is said to have an isolated singularity at the point \( a \in \mathbb{C} \) if \( f \) is analytic on \( B'(a;r) \) for some \( r > 0 \).

It turns out isolated singularities can be neatly classified into three types, removable singularities, poles, and essential singularities. The next theorem deals with the case of a removable singularity.

**Definition 49.7.7** An isolated singularity of \( f \) is said to be removable if there exists an analytic function, \( g \) analytic at \( a \) and near \( a \) such that \( f = g \) at all points near \( a \).

**Theorem 49.7.8** Let \( f : B'(a;r) \to X \) be analytic. Thus \( f \) has an isolated singularity at \( a \). Suppose also that

\[ \lim_{z \to a} f(z)(z - a) = 0. \]

Then there exists a unique analytic function, \( g : B(a;r) \to X \) such that \( g = f \) on \( B'(a;r) \). Thus the singularity at \( a \) is removable.

**Proof:** Let \( h(z) = (z - a)^2 f(z), h(a) = 0 \). Then \( h \) is analytic on \( B(a;r) \) because it is easy to see that \( h'(a) = 0 \). It follows \( h \) is given by a power series,

\[ h(z) = \sum_{k=2}^{\infty} a_k (z - a)^k \]

where \( a_0 = a_1 = 0 \) because of the observation above that \( h'(a) = h(a) = 0 \). It follows that for \( |z - a| > 0 \)

\[ f(z) = \sum_{k=2}^{\infty} a_k (z - a)^{k-2} \equiv g(z). \]

This proves the theorem.

What of the other case where the singularity is not removable? This situation is dealt with by the amazing Casorati Weierstrass theorem.
Theorem 49.7.9 (Casorati Weierstrass) Let \( a \) be an isolated singularity and suppose for some \( r > 0 \), \( f(B'(a,r)) \) is not dense in \( \mathbb{C} \). Then either \( a \) is a removable singularity or there exist finitely many \( b_1, \cdots, b_M \) for some finite number, \( M \) such that for \( z \) near \( a \),

\[
f(z) = g(z) + \sum_{k=1}^{M} \frac{b_k}{(z-a)^k} \tag{49.7.21}
\]

where \( g(z) \) is analytic near \( a \).

**Proof:** Suppose \( B(z_0, \delta) \) has no points of \( f(B'(a,r)) \). Such a ball must exist if \( f(B'(a,r)) \) is not dense. Then for \( z \in B'(a,r) \), \(|f(z) - z_0| \geq \delta > 0 \). It follows from Theorem 49.7.8 that \( \frac{1}{f(z) - z_0} \) has a removable singularity at \( a \). Hence, there exists \( h \) an analytic function such that for \( z \) near \( a \),

\[
h(z) = \frac{1}{f(z) - z_0}. \tag{49.7.22}
\]

There are two cases. First suppose \( h(a) = 0 \). Then \( \sum_{k=1}^{\infty} a_k (z-a)^k = \frac{1}{f(z) - z_0} \) for \( z \) near \( a \). If all the \( a_k = 0 \), this would be a contradiction because then the left side would equal zero for \( z \) near \( a \) but the right side could not equal zero. Therefore, there is a first \( m \) such that \( a_m \neq 0 \). Hence there exists an analytic function, \( k(z) \) which is not equal to zero in some ball, \( B(a, \varepsilon) \) such that

\[
k(z)(z-a)^m = \frac{1}{f(z) - z_0}.
\]

Hence, taking both sides to the \(-1\) power,

\[
f(z) - z_0 = \frac{1}{(z-a)^m} \sum_{k=0}^{\infty} b_k (z-a)^k
\]

and so \( 49.7.21 \) holds.

The other case is that \( h(a) \neq 0 \). In this case, raise both sides of \( 49.7.22 \) to the \(-1\) power and obtain

\[
f(z) - z_0 = h(z)^{-1},
\]

a function analytic near \( a \). Therefore, the singularity is removable. This proves the theorem.

This theorem is the basis for the following definition which classifies isolated singularities.

**Definition 49.7.10** Let \( a \) be an isolated singularity of a complex valued function, \( f \). When \( 49.7.21 \) holds for \( z \) near \( a \), then \( a \) is called a pole. The order of the pole in \( 49.7.21 \) is \( M \). If for every \( r > 0 \), \( f(B'(a,r)) \) is dense in \( \mathbb{C} \) then \( a \) is called an essential singularity.

In terms of the above definition, isolated singularities are either removable, a pole, or essential. There are no other possibilities.
**Theorem 49.7.11** Suppose \( f : \Omega \to \mathbb{C} \) has an isolated singularity at \( a \in \Omega \). Then \( a \) is a pole if and only if
\[
\lim_{z \to a} d(f(z), \infty) = 0
\]
in \( \hat{\mathbb{C}} \).

**Proof:** Suppose first \( f \) has a pole at \( a \). Then by definition, \( f(z) = g(z) + \sum_{k=1}^{M} \frac{b_k}{z-a} \) for \( z \) near \( a \) where \( g \) is analytic. Then
\[
|f(z)| \geq \frac{|b_M|}{|z-a|^M} - |g(z)| - \sum_{k=1}^{M-1} \frac{|b_k|}{|z-a|^k}
\]
\[
= \frac{1}{|z-a|^M} \left( |b_M| - \left( |g(z)| |z-a|^M + \sum_{k=1}^{M-1} |b_k| |z-a|^{M-k} \right) \right) .
\]
Now \( \lim_{z \to a} \left( |g(z)| |z-a|^M + \sum_{k=1}^{M-1} |b_k| |z-a|^{M-k} \right) = 0 \) and so the above inequality proves \( \lim_{z \to a} |f(z)| = \infty \). Referring to the diagram on Page [1630], you see this is the same as saying
\[
\lim_{z \to a} |\theta f(z) - (0,0,2)| = \lim_{z \to a} |\theta f(z) - \theta(\infty)| = \lim_{z \to a} d(f(z), \infty) = 0
\]

Conversely, suppose \( \lim_{z \to a} d(f(z), \infty) = 0 \). Then from the diagram on Page [1630], it follows \( \lim_{z \to a} |f(z)| = \infty \) and in particular, \( a \) cannot be either removable or an essential singularity by the Casorati Weierstrass theorem, Theorem [49.7.9]. The only case remaining is that \( a \) is a pole. This proves the theorem.

**Definition 49.7.12** Let \( f : \Omega \to \mathbb{C} \) where \( \Omega \) is an open subset of \( \mathbb{C} \). Then \( f \) is called meromorphic if all singularities are isolated and are either poles or removable and this set of singularities has no limit point. It is convenient to regard meromorphic functions as having values in \( \hat{\mathbb{C}} \) where if \( a \) is a pole, \( f(a) \equiv \infty \). From now on, this will be assumed when a meromorphic function is being considered.

The usefulness of the above convention about \( f(a) \equiv \infty \) at a pole is made clear in the following theorem.

**Theorem 49.7.13** Let \( \Omega \) be an open subset of \( \mathbb{C} \) and let \( f : \Omega \to \hat{\mathbb{C}} \) be meromorphic. Then \( f \) is continuous with respect to the metric, \( d \) on \( \hat{\mathbb{C}} \).

**Proof:** Let \( z_n \to z \) where \( z \in \Omega \). Then if \( z \) is a pole, it follows from Theorem [49.7.11] that
\[
d(f(z_n), \infty) \equiv d(f(z_n), f(z)) \to 0.
\]
If \( z \) is not a pole, then \( f(z_n) \to f(z) \) in \( \mathbb{C} \) which implies \( |\theta(f(z_n)) - \theta(f(z))| = d(f(z_n), f(z)) \to 0 \). Recall that \( \theta \) is continuous on \( \mathbb{C} \).
CHAPTER 49. FUNDAMENTALS OF COMPLEX ANALYSIS

49.7.4 The Cauchy Integral Formula

This section presents the general version of the Cauchy integral formula valid for arbitrary closed rectifiable curves. The key idea in this development is the notion of the winding number. This is the number also called the index, defined in the following theorem. This winding number, along with the earlier results, especially Liouville’s theorem, yields an extremely general Cauchy integral formula.

**Definition 49.7.14** Let \( \gamma : [a, b] \to \mathbb{C} \) and suppose \( z \notin \gamma^* \). The winding number, \( n(\gamma, z) \), is defined by

\[
 n(\gamma, z) = \frac{1}{2\pi i} \int_{\gamma} \frac{dw}{w - z}.
\]

The main interest is in the case where \( \gamma \) is a closed curve. However, the same notation will be used for any such curve.

**Theorem 49.7.15** Let \( \gamma : [a, b] \to \mathbb{C} \) be continuous and have bounded variation with \( \gamma(a) = \gamma(b) \). Also suppose that \( z \notin \gamma^* \). Define

\[
 n(\gamma, z) = \frac{1}{2\pi i} \int_{\gamma} \frac{dw}{w - z}.
\]

Then \( n(\gamma, \cdot) \) is continuous and integer valued. Furthermore, there exists a sequence, \( \eta_k : [a, b] \to \mathbb{C} \) such that \( \eta_k \in C^1([a, b]) \),

\[
 ||\eta_k - \gamma|| < \frac{1}{k}, \quad \eta_k(a) = \eta_k(b) = \gamma(a) = \gamma(b),
\]

and \( n(\eta_k, z) = n(\gamma, z) \) for all \( k \) large enough. Also \( n(\gamma, \cdot) \) is constant on every connected component of \( \mathbb{C}\setminus\gamma^* \) and equals zero on the unbounded component of \( \mathbb{C}\setminus\gamma^* \).

**Proof:** First consider the assertion about continuity.

\[
 |n(\gamma, z) - n(\gamma, z_1)| \leq C \left| \int_{\gamma} \left( \frac{1}{w - z} - \frac{1}{w - z_1} \right) dw \right| \leq \tilde{C} \text{ (Length of } \gamma \text{)} |z_1 - z|
\]

whenever \( z_1 \) is close enough to \( z \). This proves the continuity assertion. Note this did not depend on \( \gamma \) being closed.

Next it is shown that for a closed curve the winding number equals an integer. To do so, use Theorem 48.0.12 to obtain \( \eta_k \), a function in \( C^1([a, b]) \) such that \( \eta_k \notin [a, b] \) for all \( k \) large enough, \( \eta_k(x) = \gamma(x) \) for \( x = a, b, \) and

\[
 \left| \frac{1}{2\pi i} \int_{\gamma} \frac{dw}{w - z} - \frac{1}{2\pi i} \int_{\eta_k} \frac{dw}{w - z} \right| < \frac{1}{k}, \quad ||\eta_k - \gamma|| < \frac{1}{k}.
\]

It is shown that each of \( \frac{1}{2\pi i} \int_{\eta_k} \frac{dw}{w - z} \) is an integer. To simplify the notation, write \( \eta \) instead of \( \eta_k \):

\[
 \int_{\eta} \frac{dw}{w - z} = \int_{a}^{b} \frac{\eta'(s) ds}{\eta(s) - z}.
\]
Define
\[ g(t) = \int_a^t \frac{\eta'(s)}{\eta(s) - z} \, ds. \] (49.7.24)

Then
\[
\left( e^{-g(t)} (\eta(t) - z) \right)' = e^{-g(t)} \eta'(t) - e^{-g(t)} g'(t) (\eta(t) - z) \\
= e^{-g(t)} \eta'(t) - e^{-g(t)} \eta'(t) = 0.
\]

It follows that \( e^{-g(t)} (\eta(t) - z) \) equals a constant. In particular, using the fact that \( \eta(a) = \eta(b) \),
\[
e^{-g(b)} (\eta(b) - z) = e^{-g(a)} (\eta(a) - z) = (\eta(a) - z) = (\eta(b) - z)
\]
and so \( e^{-g(b)} = 1 \). This happens if and only if \( -g(b) = 2m\pi i \) for some integer \( m \).

Therefore, \( \frac{e^{-g(t)}}{\eta(s) - z} \) is an integer where \( \frac{e^{-g(t)}}{\eta(s) - z} \) is continuous and integer valued, it follows from Corollary 49.7.2
on Page 174 that it must be constant on every connected component of \( \mathbb{C} \setminus \gamma^* \). It is clear that \( n(\gamma, z) \) equals zero on the unbounded component because from the formula,
\[
\lim_{z \to \infty} |n(\gamma, z)| \leq \lim_{z \to \infty} V(\gamma, [a, b]) \left( \frac{1}{|z| - c} \right)
\]
where \( c \geq \max \{|w| : w \in \gamma^*\} \). This proves the theorem.

**Corollary 49.7.16** Suppose \( \gamma : [a, b] \to \mathbb{C} \) is a continuous bounded variation curve and \( n(\gamma, z) \) is an integer where \( z \notin \gamma^* \). Then \( \gamma(a) = \gamma(b) \). Also \( z \to n(\gamma, z) \) for \( z \notin \gamma^* \) is continuous.

**Proof:** Letting \( \eta \) be a \( C^1 \) curve for which \( \eta(a) = \gamma(a) \) and \( \eta(b) = \gamma(b) \) and which is close enough to \( \gamma \) that \( n(\eta, z) = n(\gamma, z) \), the argument is similar to the above. Let
\[ g(t) = \int_a^t \frac{\eta'(s)}{\eta(s) - z} \, ds. \] (49.7.25)

Then
\[
\left( e^{-g(t)} (\eta(t) - z) \right)' = e^{-g(t)} \eta'(t) - e^{-g(t)} g'(t) (\eta(t) - z) \\
= e^{-g(t)} \eta'(t) - e^{-g(t)} \eta'(t) = 0.
\]

Hence
\[ e^{-g(t)} (\eta(t) - z) = c \neq 0. \] (49.7.26)
By assumption
\[ g(b) = \int_{\eta} \frac{1}{w-z} \, dw = 2\pi m \]
for some integer, \( m \). Therefore, from \(49.7.26\)
\[ 1 = e^{2\pi mi} = \frac{\eta(b) - z}{c}. \]
Thus \( c = \eta(b) - z \) and letting \( t = a \) in \(49.7.26\),
\[ 1 = \frac{\eta(a) - z}{\eta(b) - z} \]
which shows \( \eta(a) = \eta(b) \). This proves the corollary since the assertion about continuity was already observed.

It is a good idea to consider a simple case to get an idea of what the winding number is measuring. To do so, consider \( \gamma : [a, b] \to \mathbb{C} \) such that \( \gamma \) is continuous, closed and bounded variation. Suppose also that \( \gamma \) is one to one on \( (a, b) \). Such a curve is called a simple closed curve. It can be shown that such a simple closed curve divides the plane into exactly two components, an “inside” bounded component and an “outside” unbounded component. This is called the Jordan Curve theorem. This is a difficult theorem which requires some very hard topology such as homology theory or degree theory. It won’t be used here beyond making reference to it. For now, it suffices to simply assume that \( \gamma \) is such that this result holds. This will usually be obvious anyway. Also assume that it is possible to change the parameter to be in \([0, 2\pi]\) in such a way that \( \gamma(t) + \lambda (z + re^{it} - \gamma(t)) - z \neq 0 \) for all \( t \in [0, 2\pi] \) and \( \lambda \in [0, 1] \). (As \( t \) goes from 0 to \( 2\pi \) the point \( \gamma(t) \) traces the curve \( \gamma([0, 2\pi]) \) in the counter clockwise direction.) Suppose \( z \in D \), the inside of the simple closed curve and consider the curve \( \delta(t) = z + re^{it} \) for \( t \in [0, 2\pi] \) where \( r \) is chosen small enough that \( B(z, r) \subseteq D \). Then it happens that \( n(\delta, z) = n(\gamma, z) \).

**Proposition 49.7.17** Under the above conditions,
\[ n(\delta, z) = n(\gamma, z) \]
and \( n(\delta, z) = 1. \)

**Proof:** By changing the parameter, assume that \([a, b] = [0, 2\pi]\). From Theorem \(49.7.16\) it suffices to assume also that \( \gamma \) is \( C^1 \). Define \( h_\lambda(t) \equiv \gamma(t) + \lambda (z + re^{it} - \gamma(t)) \) for \( \lambda \in [0, 1] \). (This function is called a homotopy of the curves \( \gamma \) and \( \delta \).) Note that for each \( \lambda \in [0, 1] \), \( t \to h_\lambda(t) \) is a closed \( C^1 \) curve. Also,
\[ \frac{1}{2\pi i} \int_{h_\lambda} \frac{1}{w-z} \, dw = \frac{1}{2\pi i} \int_0^{2\pi} \frac{\gamma'(t) + \lambda (r\text{e}^{it} - \gamma'(t))}{\gamma(t) + \lambda (z + re^{it} - \gamma(t)) - z} \, dt. \]
This number is an integer and it is routine to verify that it is a continuous function of \( \lambda \). When \( \lambda = 0 \) it equals \( n(\gamma, z) \) and when \( \lambda = 1 \) it equals \( n(\delta, z) \). Therefore,
n(δ, z) = n(γ, z). It only remains to compute n(δ, z).

\[ n(δ, z) = \frac{1}{2\pi i} \int_0^{2\pi} \frac{r e^{it}}{e^{it}} dt = 1. \]

This proves the proposition.

Now if γ was not one to one but caused the point, γ(t) to travel around γ* twice, you could modify the above argument to have the parameter interval, [0, 4π] and still find n(δ, z) = n(γ, z) only this time, n(δ, z) = 2. Thus the winding number is just what its name suggests. It measures the number of times the curve winds around the point. One might ask why bother with the winding number if this is all it does. The reason is that the notion of counting the number of times a curve winds around a point is rather vague. The winding number is precise. It is also the natural thing to consider in the general Cauchy integral formula presented below.

Consider a situation typified by the following picture in which Ω is the open set between the dotted curves and γ are closed rectifiable curves in Ω.

The following theorem is the general Cauchy integral formula.

**Definition 49.7.18** Let \{γ_{k}\}_{k=1}^{n} be continuous oriented curves having bounded variation. Then this is called a cycle if whenever, \( z \notin \bigcup_{k=1}^{n} γ_{k} \), \( \sum_{k=1}^{n} n(γ_{k}, z) \) is an integer.

By Theorem 49.7.15 if each γ_k is a closed curve, then \( \{γ_{k}\}_{k=1}^{n} \) is a cycle.

**Theorem 49.7.19** Let \( Ω \) be an open subset of the plane and let \( f : Ω → X \) be analytic. If \( γ_k : [a_k, b_k] → Ω, k = 1, \cdots, m \) are continuous curves having bounded variation such that for all \( z \notin \bigcup_{k=1}^{m} γ_k ([a_k, b_k]) \)

\[ \sum_{k=1}^{m} n(γ_k, z) \text{ equals an integer} \]

and for all \( z \notin Ω, \)

\[ \sum_{k=1}^{m} n(γ_k, z) = 0. \]

Then for all \( z ∈ Ω \setminus \bigcup_{k=1}^{m} γ_k ([a_k, b_k]), \)

\[ f(z) \sum_{k=1}^{m} n(γ_k, z) = \sum_{k=1}^{m} \frac{1}{2\pi i} \int_{γ_k} \frac{f(w)}{w - z} dw. \]
Proof: Let $\phi$ be defined on $\Omega \times \Omega$ by

$$
\phi(z, w) \equiv \begin{cases} 
\frac{f(w) - f(z)}{w - z} & \text{if } w \neq z, \\
\frac{f'(z)}{z} & \text{if } w = z.
\end{cases}
$$

Then $\phi$ is analytic as a function of both $z$ and $w$ and is continuous in $\Omega \times \Omega$. This is easily seen using Theorem 49.7.8. Consider the case of $w \to \phi(z, w)$.

$$
\lim_{w \to z} (w - z) \left( \phi(z, w) - \phi(z, z) \right) = \lim_{w \to z} \left( \frac{f(w) - f(z)}{w - z} - f'(z) \right) = 0.
$$

Thus $w \to \phi(z, w)$ has a removable singularity at $z$. The case of $z \to \phi(z, w)$ is similar.

Define

$$
h(z) = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \phi(z, w) \, dw.
$$

Is $h$ analytic on $\Omega$? To show this is the case, verify

$$
\int_{\partial T} h(z) \, dz = 0
$$

for every triangle, $T$, contained in $\Omega$ and apply Corollary 49.7.3. To do this, use Theorem 48.0.12 to obtain for each $k$, a sequence of functions, $\eta_{kn} \in C^1([a_k, b_k])$ such that

$$
\eta_{kn}(x) = \gamma_k(x) \text{ for } x \in \{a_k, b_k\}
$$

and

$$
\eta_{kn}([a_k, b_k]) \subset \Omega, \quad ||\eta_{kn} - \gamma_k|| < \frac{1}{n},
$$

$$
\left\| \int_{\eta_{kn}} \phi(z, w) \, dw - \int_{\gamma_k} \phi(z, w) \, dw \right\| < \frac{1}{n}, \quad (49.7.27)
$$

for all $z \in T$. Then applying Fubini’s theorem,

$$
\int_{\partial T} \int_{\eta_{kn}} \phi(z, w) \, dw \, dz = \int_{\eta_{kn}} \int_{\partial T} \phi(z, w) \, dz \, dw = 0
$$

because $\phi$ is given to be analytic. By

$$
\int_{\partial T} \int_{\gamma_k} \phi(z, w) \, dw \, dz = \lim_{n \to \infty} \int_{\partial T} \int_{\eta_{kn}} \phi(z, w) \, dw \, dz = 0
$$

and so $h$ is analytic on $\Omega$ as claimed.

Now let $H$ denote the set,

$$
H \equiv \left\{ z \in \mathbb{C} \setminus \bigcup_{k=1}^{m} \gamma_k([a_k, b_k]) : \sum_{k=1}^{m} n(\gamma_k, z) = 0 \right\}.
$$
49.7. THE GENERAL CAUCHY INTEGRAL FORMULA

$H$ is an open set because $z \to \sum_{k=1}^{m} n(\gamma_k, z)$ is integer valued by assumption and continuous. Define

$$g(z) = \begin{cases} h(z) & \text{if } z \in \Omega \\ \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \frac{f(w)}{w-z} \, dw & \text{if } z \in H. \end{cases}$$  \hspace{1cm} (49.7.28)

Why is $g(z)$ well defined? For $z \in \Omega \cap H$, $z \not\in \bigcup_{k=1}^{m} \gamma_k([a_k, b_k])$ and so

$$g(z) = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \phi(z, w) \, dw = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \frac{f(w) - f(z)}{w-z} \, dw$$

because $z \in H$. This shows $g(z)$ is well defined. Also, $g$ is analytic on $\Omega$ because it equals $h$ there. It is routine to verify that $g$ is analytic on $H$ also because of the second line of (49.7.28). By assumption, $\Omega^C \subseteq H$ because it is assumed that $\sum_{k=1}^{m} n(\gamma_k, z) = 0$ for $z \not\in \Omega$ and so $\Omega \cup H = \mathbb{C}$ showing that $g$ is an entire function.

Now note that $\sum_{k=1}^{m} n(\gamma_k, z) = 0$ for all $z$ contained in the unbounded component of $\mathbb{C} \setminus \bigcup_{k=1}^{m} \gamma_k([a_k, b_k])$ which component contains $B(0, r)^C$ for $r$ large enough. It follows that for $|z| > r$, it must be the case that $z \in H$ and so for such $z$, the bottom description of $g(z)$ found in (49.7.28) is valid. Therefore, it follows

$$\lim_{|z| \to \infty} |g(z)| = 0$$

and so $g$ is bounded and entire. By Liouville’s theorem, $g$ is a constant. Hence, from the above equation, the constant can only equal zero.

For $z \in \Omega \setminus \bigcup_{k=1}^{m} \gamma_k([a_k, b_k])$,

$$0 = h(z) = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \phi(z, w) \, dw = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \frac{f(w) - f(z)}{w-z} \, dw$$

$$= \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} \frac{f(w)}{w-z} \, dw - f(z) \sum_{k=1}^{m} n(\gamma_k, z).$$

This proves the theorem.

**Corollary 49.7.20** Let $\Omega$ be an open set and let $\gamma_k: [a_k, b_k] \to \Omega$, $k = 1, \ldots, m$, be closed, continuous and of bounded variation. Suppose also that

$$\sum_{k=1}^{m} n(\gamma_k, z) = 0$$
for all \( z \not\in \Omega \). Then if \( f : \Omega \to \mathbb{C} \) is analytic,
\[
\sum_{k=1}^{m} \int_{\gamma_k} f(w) \, dw = 0.
\]

**Proof:** This follows from Theorem 49.7.19 as follows. Let
\[
g(w) = f(w) \cdot (w - z)
\]
where \( z \in \Omega \setminus \bigcup_{k=1}^{m} \gamma_k ([a_k, b_k]) \). Then by this theorem,
\[
0 = 0 \sum_{k=1}^{m} n(\gamma_k, z) = g(z) \sum_{k=1}^{m} n(\gamma_k, z) = \sum_{k=1}^{m} \frac{1}{2\pi i} \int_{\gamma_k} \frac{g(w)}{w - z} \, dw = \frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} f(w) \, dw.
\]

Another simple corollary to the above theorem is Cauchy’s theorem for a simply connected region.

**Definition 49.7.21** An open set, \( \Omega \subseteq \mathbb{C} \) is a region if it is open and connected. A region, \( \Omega \) is simply connected if \( \mathbb{C} \setminus \Omega \) is connected where \( \mathbb{C} \) is the extended complex plane. In the future, the term simply connected open set will be an open set which is connected and \( \mathbb{C} \setminus \Omega \) is connected.

**Corollary 49.7.22** Let \( \gamma : [a, b] \to \Omega \) be a continuous closed curve of bounded variation where \( \Omega \) is a simply connected region in \( \mathbb{C} \) and let \( f : \Omega \to X \) be analytic. Then
\[
\int_{\gamma} f(w) \, dw = 0.
\]

**Proof:** Let \( D \) denote the unbounded component of \( \mathbb{C} \setminus \gamma^* \). Thus \( \infty \in \mathbb{C} \setminus \gamma^* \). Then the connected set, \( \mathbb{C} \setminus \Omega \) is contained in \( D \) since every point of \( \mathbb{C} \setminus \Omega \) must be in some component of \( \mathbb{C} \setminus \gamma^* \) and \( \infty \) is contained in both \( \mathbb{C} \setminus \Omega \) and \( D \). Thus \( D \) must be the component that contains \( \mathbb{C} \setminus \Omega \). It follows that \( n(\gamma, \cdot) \) must be constant on \( \mathbb{C} \setminus \Omega \), its value being its value on \( D \). However, for \( z \in D \),
\[
n(\gamma, z) = \frac{1}{2\pi i} \int_{\gamma} \frac{1}{w - z} \, dw
\]
and so \( \lim_{|z| \to \infty} n(\gamma, z) = 0 \) showing \( n(\gamma, z) = 0 \) on \( D \). Therefore this verifies the hypothesis of Theorem 49.7.19. Let \( z \in \Omega \cap D \) and define
\[
g(w) = f(w) \cdot (w - z).
\]
Thus \( g \) is analytic on \( \Omega \) and by Theorem 49.7.19,
\[
0 = n(z, \gamma) g(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{g(w)}{w - z} \, dw = \frac{1}{2\pi i} \int_{\gamma} f(w) \, dw.
\]

This proves the corollary.

The following is a very significant result which will be used later.
Corollary 49.7.23 Suppose \( \Omega \) is a simply connected open set and \( f : \Omega \rightarrow X \) is analytic. Then \( f \) has a primitive, \( F \), on \( \Omega \). Recall this means there exists \( F \) such that \( F'(z) = f(z) \) for all \( z \in \Omega \).

**Proof:** Pick a point, \( z_0 \in \Omega \) and let \( V \) denote those points, \( z \) of \( \Omega \) for which there exists a curve, \( \gamma : [a,b] \rightarrow \Omega \) such that \( \gamma \) is continuous, of bounded variation, \( \gamma(a) = z_0 \), and \( \gamma(b) = z \). Then it is easy to verify that \( V \) is both open and closed in \( \Omega \) and therefore, \( V = \Omega \) because \( \Omega \) is connected. Denote by \( \gamma_{z_0,z} \) such a curve from \( z_0 \) to \( z \) and define

\[
F(z) = \int_{\gamma_{z_0,z}} f(w) \, dw.
\]

Then \( F \) is well defined because if \( \gamma_j, j = 1, 2 \) are two such curves, it follows from Corollary 49.7.22 that

\[
\int_{\gamma_1} f(w) \, dw + \int_{-\gamma_2} f(w) \, dw = 0,
\]

implying that

\[
\int_{\gamma_1} f(w) \, dw = \int_{\gamma_2} f(w) \, dw.
\]

Now this function, \( F \) is a primitive because, thanks to Corollary 49.7.22

\[
(F(z + h) - F(z)) \frac{1}{h} = \frac{1}{h} \int_{\gamma_{z,z+h}} f(w) \, dw
\]

\[
= \frac{1}{h} \int_0^1 f(z + th) hdt
\]

and so, taking the limit as \( h \to 0 \), \( F'(z) = f(z) \).

49.7.5 An Example Of A Cycle

The next theorem deals with the existence of a cycle with nice properties. Basically, you go around the compact subset of an open set with suitable contours while staying in the open set. The method involves the following simple concept.

**Definition 49.7.24** A tiling of \( \mathbb{R}^2 = \mathbb{C} \) is the union of infinitely many equally spaced vertical and horizontal lines. You can think of the small squares which result as tiles. To tile the plane or \( \mathbb{R}^2 = \mathbb{C} \) means to consider such a union of horizontal and vertical lines. It is like graph paper. See the picture below for a representation of part of a tiling of \( \mathbb{C} \).

![Graph Paper](image-url)
Theorem 49.7.25 Let $K$ be a compact subset of an open set, $\Omega$. Then there exist continuous, closed, bounded variation oriented curves $\{\Gamma_j\}_{j=1}^m$ for which $\Gamma_j \cap K = \emptyset$ for each $j$, $\Gamma_j \subseteq \Omega$, and for all $p \in K$,
\[ \sum_{k=1}^m n(\Gamma_k, p) = 1. \]
while for all $z \notin \Omega$
\[ \sum_{k=1}^m n(\Gamma_k, z) = 0. \]

Proof: Let $\delta = \text{dist}(K, \Omega^C)$. Since $K$ is compact, $\delta > 0$. Now tile the plane with squares, each of which has diameter less than $\delta/2$.

Let $S$ denote the set of all the closed squares in this tiling which have nonempty intersection with $K$. Thus, all the squares of $S$ are contained in $\Omega$. First suppose $p$ is a point of $K$ which is in the interior of one of these squares in the tiling. Denote by $\partial S_k$ the boundary of $S_k$ one of the squares in $S$, oriented in the counter clockwise direction and $S_m$ denote the square of $S$ which contains the point, $p$ in its interior.

Let the edges of the square, $S_j$ be $\{\gamma_k\}_{k=1}^4$. Thus a short computation shows $n(\partial S_m, p) = 1$ but $n(\partial S_j, p) = 0$ for all $j \neq m$. The reason for this is that for $z$ in $S_j$, the values $\{z - p : z \in S_j\}$ lie in an open square, $Q$ which is located at a positive distance from 0. Then $\mathbb{C} \setminus Q$ is connected and $1/(z - p)$ is analytic on $Q$. It follows from Corollary 49.7.23 that this function has a primitive on $Q$ and so
\[ \int_{\partial S_j} \frac{1}{z - p} \, dz = 0. \]
Similarly, if \( z \notin \Omega \), \( n(\partial S_j, z) = 0 \). On the other hand, a direct computation will verify that \( n(p, \partial S_m) = 1 \). Thus \( 1 = \sum_{j,k} n(p, \gamma_k^j) = \sum_{S_j \in S} n(p, \partial S_j) \) and if \( z \notin \Omega \), \( 0 = \sum_{j,k} n(z, \gamma_k^j) = \sum_{S_j \in S} n(z, \partial S_j) \).

If \( \gamma_k^j \) coincides with \( \gamma_l^i \), then the contour integrals taken over this edge are taken in opposite directions and so the edge the two squares have in common can be deleted without changing \( \sum_{j,k} n(z, \gamma_k^j) \) for any \( z \) not on any of the lines in the tiling. For example, see the picture,

From the construction, if any of the \( \gamma_k^j \) contains a point of \( K \) then this point is on one of the four edges of \( S_j \) and at this point, there is at least one edge of some \( S_l \) which also contains this point. As just discussed, this shared edge can be deleted without changing \( \sum_{i,j} n(z, \gamma_k^i) \). Delete the edges of the \( S_k \) which intersect \( K \) but not the endpoints of these edges. That is, delete the open edges. When this is done, delete all isolated points. Let the resulting oriented curves be denoted by \( \{\gamma_k\}_{k=1}^m \).

Note that you might have \( \gamma_k^j = \gamma_l^i \). The construction is illustrated in the following picture.

Then as explained above, \( \sum_{k=1}^m n(p, \gamma_k) = 1 \). It remains to prove the claim about the closed curves.

Each orientation on an edge corresponds to a direction of motion over that edge. Call such a motion over the edge a route. Initially, every vertex, (corner of a square in \( S \)) has the property there are the same number of routes to and from that vertex. When an open edge whose closure contains a point of \( K \) is deleted,
CHAPTER 49. FUNDAMENTALS OF COMPLEX ANALYSIS

every vertex either remains unchanged as to the number of routes to and from that vertex or it loses both a route away and a route to. Thus the property of having the same number of routes to and from each vertex is preserved by deleting these open edges. The isolated points which result lose all routes to and from. It follows that upon removing the isolated points you can begin at any of the remaining vertices and follow the routes leading out from this and successive vertices according to orientation and eventually return to that end. Otherwise, there would be a vertex which would have only one route leading to it which does not happen. Now if you have used all the routes out of this vertex, pick another vertex and do the same process. Otherwise, pick an unused route out of the vertex and follow it to return. Continue this way till all routes are used exactly once, resulting in closed oriented curves, $\Gamma_k$. Then

$$\sum_k n(\Gamma_k, p) = \sum_j n(\gamma_j, p) = 1.$$ 

In case $p \in K$ is on some line of the tiling, it is not on any of the $\Gamma_k$ because $\Gamma_k \cap K = \emptyset$ and so the continuity of $z \to n(\Gamma_k, z)$ yields the desired result in this case also. This proves the lemma.

49.8 Exercises

1. If $U$ is simply connected, $f$ is analytic on $U$ and $f$ has no zeros in $U$, show there exists an analytic function, $F$, defined on $U$ such that $e^F = f$.

2. Let $f$ be defined and analytic near the point $a \in \mathbb{C}$. Show that then $f(z) = \sum_{k=0}^{\infty} b_k (z-a)^k$ whenever $|z-a| < R$ where $R$ is the distance between $a$ and the nearest point where $f$ fails to have a derivative. The number $R$, is called the radius of convergence and the power series is said to be expanded about $a$.

3. Find the radius of convergence of the function $\frac{1}{1+z^2}$ expanded about $a = 2$. Note there is nothing wrong with the function, $\frac{1}{1+z}$, when considered as a function of a real variable, $x$ for any value of $x$. However, if you insist on using power series, you find there is a limitation on the values of $x$ for which the power series converges due to the presence in the complex plane of a point, $i$, where the function fails to have a derivative.

4. Suppose $f$ is analytic on all of $\mathbb{C}$ and satisfies $|f(z)| < A + B |z|^{1/2}$. Show $f$ is constant.

5. What if you defined an open set, $U$ to be simply connected if $\mathbb{C} \setminus U$ is connected. Would it amount to the same thing? **Hint:** Consider the outside of $B(0,1)$.

6. Let $\gamma(t) = e^{it} : t \in [0, 2\pi]$. Find $\int_{\gamma} \frac{1}{z^n} dz$ for $n = 1, 2, \cdots$. 

7. Show $i \int_0^{2\pi} (2\cos \theta)^{2n} \, d\theta = \int_0^\infty (z + \frac{1}{2})^{2n} \frac{1}{2} \, dz$ where $\gamma(t) = e^{it} : t \in [0, 2\pi]$. Then evaluate this integral using the binomial theorem and the previous problem.

8. Suppose that for some constants $a, b \neq 0$, $a, b \in \mathbb{R}$, $f(z + ib) = f(z)$ for all $z \in \mathbb{C}$ and $f(z + a) = f(z)$ for all $z \in \mathbb{C}$. If $f$ is analytic, show that $f$ must be constant. Can you generalize this? **Hint:** This uses Liouville’s theorem.

9. Suppose $f(z) = u(x, y) + iv(x, y)$ is analytic for $z \in U$, an open set. Let $g(z) = u^*(x, y) + iv^*(x, y)$ where

$$\begin{pmatrix} u^* \\ v^* \end{pmatrix} = Q \begin{pmatrix} u \\ v \end{pmatrix}$$

where $Q$ is a unitary matrix. That is $QQ^* = Q^*Q = I$. When will $g$ be analytic?

10. Suppose $f$ is analytic on an open set, $U$, except for $\gamma^* \subset U$ where $\gamma$ is a one to one continuous function having bounded variation, but it is known that $f$ is continuous on $\gamma^*$. Show that in fact $f$ is analytic on $\gamma^*$ also. **Hint:** Pick a point on $\gamma^*$, say $\gamma(t_0)$ and suppose for now that $t_0 \in (a, b)$. Pick $r > 0$ such that $B = B(\gamma(t_0), r) \subseteq U$. Then show there exists $t_1 < t_0$ and $t_2 > t_0$ such that $\gamma([t_1, t_2]) \subseteq \overline{B}$ and $\gamma(t_i) \notin B$. Thus $\gamma([t_1, t_2])$ is a path across $B$ going through the center of $B$ which divides $B$ into two open sets, $B_1$, and $B_2$ along with $\gamma^*$. Let the boundary of $B_k$ consist of $\gamma([t_1, t_2])$ and a circular arc, $C_k$. Now letting $z \in B_k$, the line integral of $\frac{f(w)}{w-z}$ over $\gamma^*$ in two different directions cancels. Therefore, if $z \in B_k$, you can argue that $f(z) = \frac{1}{2\pi} \int_C \frac{f(w)}{w-z} \, dw$. By continuity, this continues to hold for $z \in \gamma((t_1, t_2))$. Therefore, $f$ must be analytic on $\gamma((t_1, t_2))$ also. This shows that $f$ must be analytic on $\gamma((a, b))$. To get the endpoints, simply extend $\gamma$ to have the same properties but defined on $[a - \varepsilon, b + \varepsilon]$ and repeat the above argument or else do this at the beginning and note that you get $[a, b] \subseteq (a - \varepsilon, b + \varepsilon)$.

11. Let $U$ be an open set contained in the upper half plane and suppose that there are finitely many line segments on the $x$ axis which are contained in the boundary of $U$. Now suppose that $f$ is defined, real, and continuous on these line segments and is defined and analytic on $U$. Now let $\tilde{U}$ denote the reflection of $U$ across the $x$ axis. Show that it is possible to extend $f$ to a function, $g$ defined on all of

$W \equiv \tilde{U} \cup U \cup \{\text{the line segments mentioned earlier}\}$

such that $g$ is analytic in $W$. **Hint:** For $z \in \tilde{U}$, the reflection of $U$ across the $x$ axis, let $g(z) = \bar{f}(\bar{z})$. Show that $g$ is analytic on $\tilde{U} \cup U$ and continuous on the line segments. Then use Problem 10 or Morera’s theorem to argue that $g$ is analytic on the line segments also. The result of this problem is known as the Schwarz reflection principle.
12. Show that rotations and translations of analytic functions yield analytic functions and use this observation to generalize the Schwarz reflection principle to situations in which the line segments are part of a line which is not the $x$ axis. Thus, give a version which involves reflection about an arbitrary line.
Chapter 50

The Open Mapping Theorem

50.1 A Local Representation

The open mapping theorem is an even more surprising result than the theorem about the zeros of an analytic function. The following proof of this important theorem uses an interesting local representation of the analytic function.

**Theorem 50.1.1** (Open mapping theorem) Let $\Omega$ be a region in $\mathbb{C}$ and suppose $f : \Omega \to \mathbb{C}$ is analytic. Then $f(\Omega)$ is either a point or a region. In the case where $f(\Omega)$ is a region, it follows that for each $z_0 \in \Omega$, there exists an open set, $V$ containing $z_0$ and $m \in \mathbb{N}$ such that for all $z \in V$,

$$f(z) = f(z_0) + \phi(z)^m$$

(50.1.1)

where $\phi : V \to B(0, \delta)$ is one to one, analytic and onto, $\phi(z_0) = 0$, $\phi'(z) \neq 0$ on $V$ and $\phi^{-1}$ analytic on $B(0, \delta)$. If $f$ is one to one then $m = 1$ for each $z_0$ and $f^{-1} : f(\Omega) \to \Omega$ is analytic.

**Proof:** Suppose $f(\Omega)$ is not a point. Then if $z_0 \in \Omega$ it follows there exists $r > 0$ such that $f(z) \neq f(z_0)$ for all $z \in B(z_0, r) \setminus \{z_0\}$. Otherwise, $z_0$ would be a limit point of the set,

$$\{z \in \Omega : f(z) - f(z_0) = 0\}$$

which would imply from Theorem 49.5.3 that $f(z) = f(z_0)$ for all $z \in \Omega$. Therefore, making $r$ smaller if necessary and using the power series of $f$,

$$f(z) = f(z_0) + (z - z_0)^m g(z) \left(\frac{z}{(z - z_0) g(z)^{1/m}}\right)^m$$

for all $z \in B(z_0, r)$, where $g(z) \neq 0$ on $B(z_0, r)$. As implied in the above formula, one wonders if you can take the $m^{th}$ root of $g(z)$.

$\frac{g'}{g}$ is an analytic function on $B(z_0, r)$ and so by Corollary 49.7.2 it has a primitive on $B(z_0, r)$, $h$. Therefore by the product rule and the chain rule, $(ge^{-h})' = 0$ and
so there exists a constant, \( C = e^{a+ib} \) such that on \( B(z_0, r) \),

\[
ge^{-h} = e^{a+ib}.
\]

Therefore,

\[
g(z) = e^{h(z)+a+ib}
\]

and so, modifying \( h \) by adding in the constant, \( a + ib \), \( g(z) = e^{h(z)} \) where \( h'(z) = \frac{g'(z)}{g(z)} \) on \( B(z_0, r) \). Letting

\[
\phi(z) = (z - z_0) e^{\frac{h(z)}{m}}
\]

implies formula \ref{eq:40} is valid on \( B(z_0, r) \). Now

\[
\phi'(z_0) = e^{\frac{h(z_0)}{m}} \neq 0.
\]

Shrinking \( r \) if necessary you can assume \( \phi'(z) \neq 0 \) on \( B(z_0, r) \). Is there an open set, \( V \) contained in \( B(z_0, r) \) such that \( \phi \) maps \( V \) onto \( B(0, \delta) \) for some \( \delta > 0 \)? Let \( \phi(z) = u(x, y) + iv(x, y) \) where \( z = x + iy \). Consider the mapping

\[
\begin{pmatrix}
x \\
y
\end{pmatrix} \rightarrow \begin{pmatrix}
  u(x, y) \\
v(x, y)
\end{pmatrix}
\]

where \( u, v \) are \( C^1 \) because \( \phi \) is given to be analytic. The Jacobian of this map at \( (x, y) \in B(z_0, r) \) is

\[
\begin{vmatrix}
u_x(x, y) & u_y(x, y) \\
v_x(x, y) & v_y(x, y)
\end{vmatrix} = \begin{vmatrix}
u_x(x, y) & v_x(x, y) \\
v_x(x, y) & u_x(x, y)
\end{vmatrix} = u_x(x, y)^2 + v_x(x, y)^2 = |\phi'(z)|^2 \neq 0.
\]

This follows from a use of the Cauchy Riemann equations. Also

\[
\begin{pmatrix}
u(x_0, y_0) \\
v(x_0, y_0)
\end{pmatrix} = \begin{pmatrix} 0 \\
0 \end{pmatrix}
\]

Therefore, by the inverse function theorem there exists an open set, \( V \), containing \( z_0 \) and \( \delta > 0 \) such that \( (u, v)^T \) maps \( V \) one to one onto \( B(0, \delta) \). Thus \( \phi \) is one to one onto \( B(0, \delta) \) as claimed. Applying the same argument to other points, \( z \) of \( V \) and using the fact that \( \phi'(z) \neq 0 \) at these points, it follows \( \phi \) maps open sets to open sets. In other words, \( \phi^{-1} \) is continuous.

It also follows that \( \phi^m \) maps \( V \) onto \( B(0, \delta^m) \). Therefore, the formula \ref{eq:40} implies that \( f \) maps the open set, \( V \), containing \( z_0 \) to an open set. This shows \( f(\Omega) \) is an open set because \( z_0 \) was arbitrary. It is connected because \( f \) is continuous and \( \Omega \) is connected. Thus \( f(\Omega) \) is a region. It remains to verify that \( \phi^{-1} \) is analytic on \( B(0, \delta) \). Since \( \phi^{-1} \) is continuous,

\[
\lim_{\phi(z_1) \to \phi(z)} \frac{\phi^{-1}(\phi(z_1)) - \phi^{-1}(\phi(z))}{\phi(z_1) - \phi(z)} = \lim_{z_1 \to z} \frac{z_1 - z}{\phi(z_1) - \phi(z)} = \frac{1}{\phi'(z)}.
\]
50.2. BRANCHES OF THE LOGARITHM

Therefore, $\phi^{-1}$ is analytic as claimed.

It only remains to verify the assertion about the case where $f$ is one to one. If $m > 1$, then $e^{2\pi i} \neq 1$ and so for $z_1 \in V$,

$$e^{2\pi i} \phi(z_1) \neq \phi(z_1).$$

(50.1.2)

But $e^{2\pi i} \phi(z_1) \in B(0, \delta)$ and so there exists $z_2 \neq z_1$ (since $\phi$ is one to one) such that $\phi(z_2) = e^{2\pi i} \phi(z_1)$. But then

$$\phi(z_2)^m = \left(e^{2\pi i} \phi(z_1)\right)^m = \phi(z_1)^m$$

implying $f(z_2) = f(z_1)$ contradicting the assumption that $f$ is one to one. Thus $m = 1$ and $f'(z) = \phi'(z) \neq 0$ on $V$. Since $f$ maps open sets to open sets, it follows that $f^{-1}$ is continuous and so

$$(f^{-1})'(f(z)) = \lim_{f(z_1) \to f(z)} \frac{f^{-1}(f(z_1)) - f^{-1}(f(z))}{f(z_1) - f(z)} = \lim_{z_1 \to z} \frac{z_1 - z}{f(z_1) - f(z)} = \frac{1}{f'(z)}.$$

This proves the theorem.

One does not have to look very far to find that this sort of thing does not hold for functions mapping $\mathbb{R}$ to $\mathbb{R}$. Take for example, the function $f(x) = x^2$. Then $f(\mathbb{R})$ is neither a point nor a region. In fact $f(\mathbb{R})$ fails to be open.

**Corollary 50.1.2** Suppose in the situation of Theorem 50.1.1 $m > 1$ for the local representation of $f$ given in this theorem. Then there exists $\delta > 0$ such that if $w \in B(f(z_0), \delta) = f(V)$ for $V$ an open set containing $z_0$, then $f^{-1}(w)$ consists of $m$ distinct points in $V$. (If $f$ is $m$ to one on $V$)

**Proof:** Let $w \in B(f(z_0), \delta)$. Then $w = f(\tilde{z})$ where $\tilde{z} \in V$. Thus $f(\tilde{z}) = f(z_0) + \phi(\tilde{z})^m$. Consider the $m$ distinct numbers, $\{e^{2k\pi i} \phi(\tilde{z})\}_{k=1}^m$. Then each of these numbers is in $B(0, \delta)$ and so since $\phi$ maps $V$ one to one onto $B(0, \delta)$, there are $m$ distinct numbers in $V$, $\{z_k\}_{k=1}^m$ such that $\phi(z_k) = e^{2k\pi i} \phi(\tilde{z})$. Then

$$f(z_k) = f(z_0) + \phi(z_k)^m = f(z_0) + \left(e^{2k\pi i} \phi(\tilde{z})\right)^m$$

$$= f(z_0) + e^{2k\pi i} \phi(\tilde{z})^m = f(z_0) + \phi(\tilde{z})^m = f(\tilde{z}) = w$$

This proves the corollary.

**50.2 Branches Of The Logarithm**

The argument used in to prove the next theorem was used in the proof of the open mapping theorem. It is a very important result and deserves to be stated as a theorem.
CHAPTER 50. THE OPEN MAPPING THEOREM

Theorem 50.2.1 Let $\Omega$ be a simply connected region and suppose $f : \Omega \to \mathbb{C}$ is analytic and nonzero on $\Omega$. Then there exists an analytic function, $g$ such that $e^{g(z)} = f(z)$ for all $z \in \Omega$.

Proof: The function, $f'/f$ is analytic on $\Omega$ and so by Corollary 50.7.23 there is a primitive for $f'/f$, denoted as $g_1$. Then

$$(e^{-g_1}f)' = -\frac{f'}{f}e^{-g_1}f + e^{-g_1}f' = 0$$

and so since $\Omega$ is connected, it follows $e^{-g_1}f$ equals a constant, $e^{a+ib}$. Therefore, $f(z) = e^{g_1(z)+a+ib}$. Define $g(z) \equiv g_1(z) + a + ib$.

The function, $g$ in the above theorem is called a branch of the logarithm of $f$ and is written as $\log(f(z))$.

Definition 50.2.2 Let $\rho$ be a ray starting at $0$. Thus $\rho$ is a straight line of infinite length extending in one direction with its initial point at $0$.

A special case of the above theorem is the following.

Theorem 50.2.3 Let $\rho$ be a ray starting at $0$. Then there exists an analytic function, $L(z)$ defined on $\mathbb{C} \setminus \rho$ such that

$$e^{L(z)} = z.$$  

This function, $L$ is called a branch of the logarithm. This branch of the logarithm satisfies the usual formula for logarithms, $L(zw) = L(z) + L(w)$ provided $zw \notin \rho$.

Proof: $\mathbb{C} \setminus \rho$ is a simply connected region because its complement with respect to $\mathbb{C}$ is connected. Furthermore, the function, $f(z) = z$ is not equal to zero on $\mathbb{C} \setminus \rho$. Therefore, by Theorem 50.2.1 there exists an analytic function $L(z)$ such that $e^{L(z)} = f(z) = z$. Now consider the problem of finding a description of $L(z)$. Each $z \in \mathbb{C} \setminus \rho$ can be written in a unique way in the form

$$z = |z| e^{i \arg_\theta(z)}$$

where $\arg_\theta(z)$ is the angle in $(\theta, \theta + 2\pi)$ associated with $z$. (You could of course have considered this to be the angle in $(\theta - 2\pi, \theta)$ associated with $z$ or in infinitely many other open intervals of length $2\pi$. The description of the log is not unique.) Then letting $L(z) = a + ib$

$$z = |z| e^{i \arg_\theta(z)} = e^{L(z)} = e^a e^{ib}$$

and so you can let $L(z) = \ln |z| + i \arg_\theta(z)$.

Does $L(z)$ satisfy the usual properties of the logarithm? That is, for $z, w \in \mathbb{C} \setminus \rho$, is $L(zw) = L(z) + L(w)$? This follows from the usual rules of exponents. You know $e^{z+w} = e^z e^w$. (You can verify this directly or you can reduce to the case where $z, w$ are real. If $z$ is a fixed real number, then the equation holds for all real $w$. Therefore, it must also hold for all complex $w$ because the real line contains a limit point. Now
for this fixed \( w \), the equation holds for all \( z \) real. Therefore, by similar reasoning, it holds for all complex \( z \).

Now suppose \( z, w \in \mathbb{C} \setminus \rho \) and \( zw \notin \rho \). Then

\[
e^{L(zw)} = zw, \quad e^{L(z)+L(w)} = e^{L(z)}e^{L(w)} = zw
\]

and so \( L(zw) = L(z) + L(w) \) as claimed. This proves the theorem.

In the case where the ray is the negative real axis, it is called the principal branch of the logarithm. Thus \( \arg(z) \) is a number between \( -\pi \) and \( \pi \).

**Definition 50.2.4** Let \( \log \) denote the branch of the logarithm which corresponds to the ray for \( \theta = \pi \). That is, the ray is the negative real axis. Sometimes this is called the principal branch of the logarithm.

### 50.3 Maximum Modulus Theorem

Here is another very significant theorem known as the maximum modulus theorem which follows immediately from the open mapping theorem.

**Theorem 50.3.1** (maximum modulus theorem) Let \( \Omega \) be a bounded region and let \( f : \Omega \to \mathbb{C} \) be analytic and \( f : \overline{\Omega} \to \mathbb{C} \) continuous. Then if \( z \in \Omega \),

\[
|f(z)| \leq \max \{ |f(w)| : w \in \partial \Omega \} . \tag{50.3.3}
\]

If equality is achieved for any \( z \in \Omega \), then \( f \) is a constant.

**Proof:** Suppose \( f \) is not a constant. Then \( f(\Omega) \) is a region and so if \( z \in \Omega \), there exists \( r > 0 \) such that \( B(f(z), r) \subseteq f(\Omega) \). It follows there exists \( z_1 \in \Omega \) with \( |f(z_1)| > |f(z)| \). Hence \( \max \{ |f(w)| : w \in \overline{\Omega} \} \) is not achieved at any interior point of \( \Omega \). Therefore, the point at which the maximum is achieved must lie on the boundary of \( \Omega \) and so

\[
\max \{ |f(w)| : w \in \partial \Omega \} = \max \{ |f(w)| : w \in \overline{\Omega} \} > |f(z)|
\]

for all \( z \in \Omega \) or else \( f \) is a constant. This proves the theorem.

You can remove the assumption that \( \Omega \) is bounded and give a slightly different version.

**Theorem 50.3.2** Let \( f : \Omega \to \mathbb{C} \) be analytic on a region, \( \Omega \) and suppose \( \overline{B(a, r)} \subseteq \Omega \). Then

\[
|f(a)| \leq \max \{ |f(a + re^{i\theta})| : \theta \in [0, 2\pi] \} .
\]

Equality occurs for some \( r > 0 \) and \( a \in \Omega \) if and only if \( f \) is constant in \( \Omega \) hence equality occurs for all such \( a, r \).
Chapter 50. The Open Mapping Theorem

Proof: The claimed inequality holds by Theorem 49.5.1. Suppose equality in the above is achieved for some $B(a, r) \subseteq \Omega$. Then by Theorem 50.3.1 $f$ is equal to a constant, $w$ on $B(a, r)$. Therefore, the function, $f(z) - w$ has a limit point which has a limit point in $\Omega$ and so by Theorem 50.3.1 $f(z) = w$ for all $z \in \Omega$.

Conversely, if $f$ is constant, then the equality in the above inequality is achieved for all $B(a, r) \subseteq \Omega$.

Next is yet another version of the maximum modulus principle which is in Conway [11]. Let $\Omega$ be an open set.

Definition 50.3.3 Define $\partial_{\infty} \Omega$ to equal $\partial \Omega$ in the case where $\Omega$ is bounded and $\partial \Omega \cup \{\infty\}$ in the case where $\Omega$ is not bounded.

Definition 50.3.4 Let $f$ be a complex valued function defined on a set $S \subseteq \mathbb{C}$ and let $a$ be a limit point of $S$.

$$\limsup_{z \to a} |f(z)| = \lim_{r \to 0} \{\sup |f(w)| : w \in B'(a, r) \cap S\}.$$  

The limit exists because $\{\sup |f(w)| : w \in B'(a, r) \cap S\}$ is decreasing in $r$. In case $a = \infty$,

$$\limsup_{z \to \infty} |f(z)| = \lim_{r \to \infty} \{\sup |f(w)| : |w| > r, w \in S\}.$$  

Note that if $\limsup_{z \to a} |f(z)| \leq M$ and $\delta > 0$, then there exists $r > 0$ such that if $z \in B'(a, r) \cap S$, then $|f(z)| < M + \delta$. If $a = \infty$, there exists $r > 0$ such that if $|z| > r$ and $z \in S$, then $|f(z)| < M + \delta$.

Theorem 50.3.5 Let $\Omega$ be an open set in $\mathbb{C}$ and let $f : \Omega \to \mathbb{C}$ be analytic. Suppose also that for every $a \in \partial_{\infty} \Omega$,

$$\limsup_{z \to a} |f(z)| \leq M < \infty.$$  

Then in fact $|f(z)| \leq M$ for all $z \in \Omega$.

Proof: Let $\delta > 0$ and let $H = \{z \in \Omega : |f(z)| > M + \delta\}$. Suppose $H \neq \emptyset$. Then $H$ is an open subset of $\Omega$. I claim that $H$ is actually bounded. If $\Omega$ is bounded, there is nothing to show so assume $\Omega$ is unbounded. Then the condition involving the $\limsup$ implies there exists $r > 0$ such that if $|z| > r$ and $z \in \Omega$, then $|f(z)| \leq M + \delta/2$. It follows $H$ is contained in $B(0, r)$ and so it is bounded. Now consider the components of $\Omega$. One of these components contains points from $H$. Let this component be denoted as $V$ and let $H_V \equiv H \cap V$. Thus $H_V$ is a bounded open subset of $V$. Let $U$ be a component of $H_V$. First suppose $U \subseteq V$; in this case, it follows that on $\partial U, |f(z)| = M + \delta$ and so by Theorem 50.3.1 $|f(z)| \leq M + \delta$ for all $z \in U$ contradicting the definition of $H$. Next suppose $\partial U$ contains a point of $\partial V, a$. Then in this case, $a$ violates the condition on $\limsup$. Either way you get a contradiction. Hence $H = \emptyset$ as claimed. Since $\delta > 0$ is arbitrary, this shows $|f(z)| \leq M$.  

50.4 Extensions Of Maximum Modulus Theorem

50.4.1 Phragmén Lindelöf Theorem

This theorem is an extension of Theorem 50.3.5. It uses a growth condition near the extended boundary to conclude that $f$ is bounded. I will present the version found in Conway [31]. It seems to be more of a method than an actual theorem. There are several versions of it.

Theorem 50.4.1 Let $\Omega$ be a simply connected region in $\mathbb{C}$ and suppose $f$ is analytic on $\Omega$. Also suppose there exists a function, $\phi$ which is nonzero and uniformly bounded on $\Omega$. Let $M$ be a positive number. Now suppose $\partial_\infty \Omega = A \cup B$ such that for every $a \in A$, $\limsup_{z \to a} |f(z)| \leq M$ and for every $b \in B$, and $\eta > 0$, $\limsup_{z \to b} |f(z)| \phi(z)^\eta \leq M$. Then $|f(z)| \leq M$ for all $z \in \Omega$.

Proof: By Theorem 50.2.1 there exists $\log (\phi(z))$ analytic on $\Omega$. Now define $g(z) = \exp (\eta \log (\phi(z)))$ so that $g(z) = \phi(z)^\eta$. Now also $|g(z)| = |\exp (\eta \log (\phi(z)))| = |\exp (\eta \ln |\phi(z)||) = |\phi(z)|^\eta$.

Let $m \geq |\phi(z)|$ for all $z \in \Omega$. Define $F(z) = f(z) g(z) m^{-\eta}$. Thus $F$ is analytic and for $b \in B$,

$$\limsup_{z \to b} |F(z)| = \limsup_{z \to b} |f(z)||\phi(z)|^\eta m^{-\eta} \leq M m^{-\eta}$$

while for $a \in A$,

$$\limsup_{z \to a} |F(z)| \leq M.$$

Therefore, for $\alpha \in \partial_\infty \Omega$, $\limsup_{z \to a} |F(z)| \leq \max (M, M \eta^{-\eta})$ and so by Theorem 50.2.1 $|f(z)| \leq \left( \frac{m^n}{|\phi(z)|} \right) \max (M, M \eta^{-\eta})$. Now let $\eta \to 0$ to obtain $|f(z)| \leq M$.

In applications, it is often the case that $B = \{ \infty \}$.

Now here is an interesting case of this theorem. It involves a particular form for $\Omega$, in this case $\Omega = \{ z \in \mathbb{C} : |\arg (z)| < \frac{\pi}{2a} \}$ where $a \geq \frac{1}{2}$.

Then $\partial \Omega$ equals the two slanted lines. Also on $\Omega$ you can define a logarithm, $\log (z) = \ln |z| + i \arg (z)$ where $\arg (z)$ is the angle associated with $z$ between $-\pi$
and $\pi$. Therefore, if $c$ is a real number you can define $z^c$ for such $z$ in the usual way:

$$
z^c \equiv \exp(c \log(z)) = \exp(c \ln|z| + i \arg(z))
$$

$$
= |z|^c \exp(ic \arg(z)) = |z|^c (\cos(c \arg(z)) + i \sin(c \arg(z))).
$$

If $|c| < a$, then $|\arg(z)| < \frac{\pi}{2}$ and so $\cos(c \arg(z)) > 0$. Therefore, for such $c$,

$$
|\exp(-z^c)| = |\exp(-|z|^c \cos(c \arg(z)) + i \sin(c \arg(z)))|
$$

$$
= |\exp(-|z|^c \cos(c \arg(z)))|
$$

which is bounded since $\cos(c \arg(z)) > 0$.

**Corollary 50.4.2** Let $\Omega = \{z \in \mathbb{C} : |\arg(z)| < \frac{\pi}{20}\}$ where $a \geq \frac{1}{2}$ and suppose $f$ is analytic on $\Omega$ and satisfies $\limsup_{z \to a} |f(z)| \leq M$ on $\partial \Omega$ and suppose there are positive constants, $P, b$ where $b < a$ and

$$
|f(z)| \leq P \exp\left(|z|^b\right)
$$

for all $|z|$ large enough. Then $|f(z)| \leq M$ for all $z \in \Omega$.

**Proof:** Let $b < c < a$ and let $\phi(z) \equiv \exp(-z^c)$. Then as discussed above, $\phi(z) \neq 0$ on $\Omega$ and $|\phi(z)|$ is bounded on $\Omega$. Now

$$
|\phi(z)|^\eta = |\exp(-|z|^c \eta (\cos(c \arg(z))))|
$$

$$
= \limsup_{z \to \infty} |f(z)| |\phi(z)|^\eta \leq \limsup_{z \to \infty} \frac{P \exp\left(|z|^b\right)}{|\exp(|z|^c \eta (\cos(c \arg(z))))|} = 0 \leq M
$$

and so by Theorem 31.4, $|f(z)| \leq M$.

The following is another interesting case. This case is presented in Rudin [10].

**Corollary 50.4.3** Let $\Omega$ be the open set consisting of $\{z \in \mathbb{C} : a < \text{Re} \, z < b\}$ and suppose $f$ is analytic on $\Omega$, continuous on $\overline{\Omega}$, and bounded on $\Omega$. Suppose also that $f(z) \leq 1$ on the two lines $\text{Re} \, z = a$ and $\text{Re} \, z = b$. Then $|f(z)| \leq 1$ for all $z \in \Omega$.

**Proof:** This time let $\phi(z) = \frac{1}{|1+z-a|}$. Thus $|\phi(z)| \leq 1$ because $\text{Re} \,(z - a) > 0$ and $\phi(z) \neq 0$ for all $z \in \Omega$. Also, $\limsup_{z \to a^\infty} |\phi(z)|^\eta = 0$ for every $\eta > 0$. Therefore, if $a$ is a point of the sides of $\Omega$, $\limsup_{z \to a^\infty} |f(z)| \leq 1$ while $\limsup_{z \to a^\infty} |f(z)| |\phi(z)|^\eta = 0 \leq 1$ and so by Theorem 31.4, $|f(z)| \leq 1$ on $\Omega$.

This corollary yields an interesting conclusion.

**Corollary 50.4.4** Let $\Omega$ be the open set consisting of $\{z \in \mathbb{C} : a < \text{Re} \, z < b\}$ and suppose $f$ is analytic on $\Omega$, continuous on $\overline{\Omega}$, and bounded on $\Omega$. Define

$$
M(x) \equiv \sup \{|f(z)| : \text{Re} \, z = x\}
$$

Then for $x \in (a, b)$,

$$
M(x) \leq M(a)^{\frac{x-a}{b-a}} M(b)^{\frac{b-x}{b-a}}.
$$
50.4. EXTENSIONS OF MAXIMUM MODULUS THEOREM

**Proof:** Let \( \varepsilon > 0 \) and define

\[
g(z) \equiv (M(a) + \varepsilon)^{\frac{b-a}{b-a}} (M(b) + \varepsilon)^{\frac{a-b}{b-a}}
\]

where for \( M > 0 \) and \( z \in \mathbb{C}, \, M^z = \exp(z \ln(M)) \). Thus \( g \neq 0 \) and so \( f/g \) is analytic on \( \Omega \) and continuous on \( \overline{\Omega} \). Also on the left side,

\[
\left| \frac{f(a+iy)}{g(a+iy)} \right| = \left| \frac{f(a+iy)}{(M(a) + \varepsilon)^{\frac{b-a}{b-a}} (M(b) + \varepsilon)^{\frac{a-b}{b-a}}} \right| = \left| \frac{f(a+iy)}{(M(a) + \varepsilon)^{\frac{b-a}{b-a}}} \right| \leq 1
\]

while on the right side a similar computation shows \( \left| \frac{f}{g} \right| \leq 1 \) also. Therefore, by Corollary \( \text{HJ5.93} \) \( |f/g| \leq 1 \) on \( \Omega \). Therefore, letting \( x + iy = z \),

\[
|f(z)| \leq \left| (M(a) + \varepsilon)^{\frac{b-a}{b-a}} (M(b) + \varepsilon)^{\frac{a-b}{b-a}} \right| = \left| (M(a) + \varepsilon)^{\frac{b-a}{b-a}} (M(b) + \varepsilon)^{\frac{a-b}{b-a}} \right|
\]

and so

\[
M(x) \leq (M(a) + \varepsilon)^{\frac{b-a}{b-a}} (M(b) + \varepsilon)^{\frac{a-b}{b-a}}.
\]

Since \( \varepsilon > 0 \) is arbitrary, it yields the conclusion of the corollary.

Another way of saying this is that \( x \to \ln(M(x)) \) is a convex function.

This corollary has an interesting application known as the Hadamard three circles theorem.

### 50.4.2 Hadamard Three Circles Theorem

Let \( 0 < R_1 < R_2 \) and suppose \( f \) is analytic on \( \{ z \in \mathbb{C} : R_1 < |z| < R_2 \} \). Then letting \( R_1 < a < b < R_2 \), note that \( g(z) \equiv \exp(z) \) maps the strip \( \{ z \in \mathbb{C} : \ln a < \text{Re} z < b \} \) onto \( \{ z \in \mathbb{C} : a < |z| < b \} \) and that in fact, \( g \) maps the line \( \ln r + iy \) onto the circle \( re^{i\theta} \). Now let \( M(x) \) be defined as above and \( m \) be defined by

\[
m(r) \equiv \max_{\theta} |f(re^{i\theta})|.
\]

Then for \( a < r < b \), Corollary \( \text{HJ5.93} \) implies

\[
m(r) = \sup_{y} |f(e^{\ln r + iy})| = M(\ln r) \leq M(\ln a)^{\ln(b/r)/\ln(b/a)} M(\ln b)^{\ln(r/a)/\ln(b/a)}
\]

and so

\[
m(r)^{\ln(b/a)} \leq m(a)^{\ln(b/r)} m(b)^{\ln(r/a)}.
\]

Taking logarithms, this yields

\[
\ln \left( \frac{b}{a} \right) \ln_m(r) \leq \ln \left( \frac{b}{r} \right) \ln M(a) + \ln \left( \frac{r}{a} \right) \ln M(b)
\]

which says the same as \( r \to \ln M(r) \) is a convex function of \( \ln r \).

The next example, also in Rudin \( \text{HJ5.2} \) is very dramatic. An unbelievably weak assumption is made on the growth of the function and still you get a uniform bound in the conclusion.
CHAPTER 50. THE OPEN MAPPING THEOREM

Corollary 50.4.5 Let \( \Omega = \{ z \in \mathbb{C} : |\text{Im}(z)| < \frac{\pi}{2} \} \). Suppose \( f \) is analytic on \( \Omega \), continuous on \( \overline{\Omega} \), and there exist constants, \( \alpha < 1 \) and \( A < \infty \) such that

\[
|f(z)| \leq \exp(A \exp(\alpha |x|)) \quad \text{for } z = x + iy
\]

and

\[
|f \left( x \pm i \frac{\pi}{2} \right)| \leq 1
\]

for all \( x \in \mathbb{R} \). Then \( |f(z)| \leq 1 \) on \( \Omega \).

**Proof:** This time let \( \phi(z) = |\exp(A \exp(\beta z)) \exp(A \exp(-\beta z))|^{-1} \) where \( \alpha < \beta < 1 \). Then \( \phi(z) \neq 0 \) on \( \Omega \) and for \( \eta > 0 \)

\[
|\phi(z)|^\eta = \frac{1}{|\exp(\eta A \exp(\beta z)) \exp(\eta A \exp(-\beta z))|}
\]

Now

\[
\exp(\eta A \exp(\beta z)) \exp(\eta A \exp(-\beta z)) = \exp(\eta A (\exp(\beta z) + \exp(-\beta z))) = \exp[\eta A (\cos(\beta y) (e^{\beta x} + e^{-\beta x}) + i \sin(\beta y) (e^{\beta x} - e^{-\beta x}))]
\]

and so

\[
|\phi(z)|^\eta = \frac{1}{\exp[i \eta A (\cos(\beta y) (e^{\beta x} + e^{-\beta x}))]}
\]

Now \( \cos \beta y > 0 \) because \( \beta < 1 \) and \( |y| < \frac{\pi}{2} \). Therefore,

\[
\limsup_{z \to \infty} |f(z)| |\phi(z)|^\eta \leq 0 \leq 1
\]

and so by Theorem 50.4.3, \( |f(z)| \leq 1 \).

**50.4.3 Schwarz’s Lemma**

This interesting lemma comes from the maximum modulus theorem. It will be used later as part of the proof of the Riemann mapping theorem.

**Lemma 50.4.6** Suppose \( F : B(0,1) \to B(0,1) \), \( F \) is analytic, and \( F(0) = 0 \). Then for all \( z \in B(0,1) \),

\[
|F(z)| \leq |z|,
\]

and

\[
|F'(0)| \leq 1.
\]

If equality holds in (50.4.3) then there exists \( \lambda \in \mathbb{C} \) with \( |\lambda| = 1 \) and

\[
F(z) = \lambda z.
\]
Proof: First note that by assumption, $F(z)/z$ has a removable singularity at 0 if its value at 0 is defined to be $F'(0)$. By the maximum modulus theorem, if $|z| < r < 1$,

$$\left| \frac{F(z)}{z} \right| \leq \max_{t \in [0,2\pi]} \left| \frac{F(re^{it})}{r} \right| \leq \frac{1}{r}.$$ 

Then letting $r \to 1$,

$$\left| \frac{F(z)}{z} \right| \leq 1$$

this shows 50.4.3 and it also verifies 50.4.4 on taking the limit as $z \to 0$. If equality holds in 50.4.3, then $|F(z)/z|$ achieves a maximum at an interior point so $F(z)/z$ equals a constant, $\lambda$ by the maximum modulus theorem. Since $F(z) = \lambda z$, it follows $F'(0) = \lambda$ and so $|\lambda| = 1$.

Rudin [102] gives a memorable description of what this lemma says. It says that if an analytic function maps the unit ball to itself, keeping 0 fixed, then it must do one of two things, either be a rotation or move all points closer to 0. (This second part follows in case $|F'(0)| < 1$ because in this case, you must have $|F(z)| \neq |z|$ and so by 50.4.3, $|F(z)| < |z|$)

50.4.4 One To One Analytic Maps On The Unit Ball

The transformation in the next lemma is of fundamental importance.

Lemma 50.4.7 Let $\alpha \in B(0,1)$ and define

$$\phi_\alpha(z) \equiv \frac{z - \alpha}{1 - \overline{\alpha}z}.$$ 

Then $\phi_\alpha : B(0,1) \to B(0,1)$, $\phi_\alpha : \partial B(0,1) \to \partial B(0,1)$, and is one to one and onto. Also $\phi_{-\alpha} = \phi_\alpha^{-1}$. Also

$$\phi'_\alpha(0) = 1 - |\alpha|^2, \quad \phi'(\alpha) = \frac{1}{1 - |\alpha|^2}.$$ 

Proof: First of all, for $|z| < 1/|\alpha|$,

$$\phi_\alpha \circ \phi_{-\alpha}(z) \equiv \frac{\left( \frac{z + \alpha}{1 + \overline{\alpha}z} \right) - \alpha}{1 - \frac{\alpha}{1 + \overline{\alpha}z}} \equiv z$$

after a few computations. If I show that $\phi_\alpha$ maps $B(0,1)$ to $B(0,1)$ for all $|\alpha| < 1$, this will have shown that $\phi_\alpha$ is one to one and onto $B(0,1)$.

Consider $|\phi_\alpha(e^{i\theta})|$. This yields

$$\left| \frac{e^{i\theta} - \alpha}{1 - \overline{\alpha}e^{i\theta}} \right| = \frac{1 - |\alpha|e^{-i\theta}}{1 - |\alpha|e^{i\theta}} = 1$$
where the first equality is obtained by multiplying by $|e^{-i\theta}| = 1$. Therefore, $\phi_\alpha$ maps $\partial B(0, 1)$ one to one and onto $\partial B(0, 1)$. Now notice that $\phi_\alpha$ is analytic on $B(0, 1)$ because the only singularity, a pole is at $z = 1/\pi$. By the maximum modulus theorem, it follows

$$|\phi_\alpha (z)| < 1$$

whenever $|z| < 1$. The same is true of $\phi_{-\alpha}$.

It only remains to verify the assertions about the derivatives. Long division gives $\phi_\alpha (z) = (-\pi)^{-1} + \left( -\alpha + (\pi)^{-1} \right)$ and so

$$\phi'_\alpha (z) = (1 - \pi z)^{-2} \left( -\alpha + (\pi)^{-1} \right)$$

Hence the two formulas follow. This proves the lemma.

One reason these mappings are so important is the following theorem.

**Theorem 50.4.8** Suppose $f$ is an analytic function defined on $B(0, 1)$ and $f$ maps $B(0, 1)$ one to one and onto $B(0, 1)$. Then there exists $\theta$ such that

$$f (z) = e^{i\theta} \phi_\alpha (z)$$

for some $\alpha \in B(0, 1)$.

**Proof:** Let $f (\alpha) = 0$. Then $h (z) \equiv f \circ \phi_{-\alpha} (z)$ maps $B(0, 1)$ one to one and onto $B(0, 1)$ and has the property that $h (0) = 0$. Therefore, by the Schwarz lemma,

$$|h (z)| \leq |z|.$$ 

but it is also the case that $h^{-1} (0) = 0$ and $h^{-1}$ maps $B(0, 1)$ to $B(0, 1)$. Therefore, the same inequality holds for $h^{-1}$. Therefore,

$$|z| = |h^{-1} (h (z))| \leq |h (z)|$$

and so $|h (z)| = |z|$. By the Schwarz lemma again, $h (z) \equiv f (\phi_{-\alpha} (z)) = e^{i\theta} z$. Letting $z = \phi_\alpha$, you get $f (z) = e^{i\theta} \phi_\alpha (z)$.

**50.5 Exercises**

1. Consider the function, $g (z) = \frac{z+i}{z-1}$. Show this is analytic on the upper half plane, $P+$ and maps the upper half plane one to one and onto $B(0, 1)$. **Hint:** First show $g$ maps the real axis to $\partial B(0, 1)$. This is really easy because you end up looking at a complex number divided by its conjugate. Thus $|g (z)| = 1$ for $z$ on $\partial (P+)$. Now show that $\lim \sup_{z \to \infty} |g (z)| = 1$. Then apply a version of the maximum modulus theorem. You might note that $g (z) = 1 + \frac{2i}{z+1}$. This will show $|g (z)| \leq 1$. Next pick $w \in B(0, 1)$ and solve $g (z) = w$. You just have to show there exists a unique solution and its imaginary part is positive.
2. Does there exist an entire function $f$ which maps $\mathbb{C}$ onto the upper half plane?

3. Letting $g$ be the function of Problem 4 show that $(g^{-1})'(0) = 2$. Also note that $g^{-1}(0) = i$. Now suppose $f$ is an analytic function defined on the upper half plane which has the property that $|f(z)| \leq 1$ and $f(i) = \beta$ where $|\beta| < 1$. Find an upper bound to $|f'(i)|$. Also find all functions, $f$ which satisfy the condition, $f(i) = \beta, |f(z)| \leq 1$, and achieve this maximum value. **Hint:** You could consider the function, $h(z) = \phi_{\beta} \circ f \circ g^{-1}(z)$ and check the conditions for the Schwarz lemma for this function, $h$.

4. This and the next two problems follow a presentation of an interesting topic in Rudin [112]. Let $\phi_{\alpha}$ be given in Lemma 50.4.7. Suppose $f$ is an analytic function defined on $B(0, 1)$ which satisfies $|f(z)| \leq 1$. Suppose also there are $\alpha, \beta \in B(0, 1)$ and it is required $f(\alpha) = \beta$. If $f$ is such a function, show that $|f'(\alpha)| \leq \frac{1-|\beta|^2}{1-|\alpha|^2}$. **Hint:** To show this consider $g = \phi_{\beta} \circ f \circ \phi_{-\alpha}$. Show $g(0) = 0$ and $|g(z)| \leq 1$ on $B(0, 1)$. Now use Lemma 50.4.8.

5. In Problem 5 show there exists a function, $f$ analytic on $B(0, 1)$ such that $f(\alpha) = \beta, |f(z)| \leq 0$, and $|f'(\alpha)| = \frac{1-|\beta|^2}{1-|\alpha|^2}$. **Hint:** You do this by choosing $g$ in the above problem such that equality holds in Lemma 50.4.7. Thus you need $g(z) = \lambda z$ where $|\lambda| = 1$ and solve $g = \phi_{\beta} \circ f \circ \phi_{-\alpha}$ for $f$.

6. Suppose that $f : B(0, 1) \to B(0, 1)$ and that $f$ is analytic, one to one, and onto with $f(\alpha) = 0$. Show there exists $\lambda, |\lambda| = 1$ such that $f(z) = \lambda \phi_{\alpha}(z)$. This gives a different way to look at Theorem 50.4.3. **Hint:** Let $g = f^{-1}$. Then $g'(0) f'(\alpha) = 1$. However, $f(\alpha) = 0$ and $g(0) = \alpha$. From Problem 4 with $\beta = 0$, you can conclude an inequality for $|f'(\alpha)|$ and another one for $|g'(0)|$. Then use the fact that the product of these two equals 1 which comes from the chain rule to conclude that equality must take place. Now use Problem 2 to obtain the form of $f$.

7. In Corollary 50.4.3 show that it is essential that $\alpha < 1$. That is, show there exists an example where the conclusion is not satisfied with a slightly weaker growth condition. **Hint:** Consider $\exp(\exp(z))$.

8. Suppose $\{f_n\}$ is a sequence of functions which are analytic on $\Omega$, a bounded region such that each $f_n$ is also analytic on $\Omega$. Suppose that $\{f_n\}$ converges uniformly on $\partial \Omega$. Show that then $\{f_n\}$ converges uniformly on $\Omega$ and that the function to which the sequence converges is analytic on $\Omega$ and continuous on $\Omega$.

9. Suppose $\Omega$ is a bounded region and there exists a point $z_0 \in \Omega$ such that $|f(z_0)| = \min \{|f(z)| : z \in \Omega\}$. Can you conclude $f$ must equal a constant?

10. Suppose $f$ is continuous on $B(a, r)$ and analytic on $B(a, r)$ and that $f$ is not constant. Suppose also $|f(z)| = C \neq 0$ for all $|z - a| = r$. Show that there exists $\alpha \in B(a, r)$ such that $f(\alpha) = 0$. **Hint:** If not, consider $f/C$ and $C/f$. Both would be analytic on $B(a, r)$ and are equal to 1 on the boundary.
11. Suppose $f$ is analytic on $B(0, 1)$ but for every $a \in \partial B(0, 1)$, \( \lim_{z \to a} |f(z)| = \infty \). Show there exists a sequence, \( \{z_n\} \subseteq B(0, 1) \) such that \( \lim_{n \to \infty} |z_n| = 1 \) and $f(z_n) = 0$.

### 50.6 Counting Zeros

The above proof of the open mapping theorem relies on the very important inverse function theorem from real analysis. There are other approaches to this important theorem which do not rely on the big theorems from real analysis and are more oriented toward the use of the Cauchy integral formula and specialized techniques from complex analysis. One of these approaches is given next which involves the notion of “counting zeros”. The next theorem is the one about counting zeros. It will also be used later in the proof of the Riemann mapping theorem.

**Theorem 50.6.1** Let $\Omega$ be an open set in $\mathbb{C}$ and let $\gamma : [a, b] \to \Omega$ be closed, continuous, bounded variation, and $n(\gamma, z) = 0$ for all $z \notin \Omega$. Suppose also that $f$ is analytic on $\Omega$ having zeros $a_1, \ldots, a_m$ where the zeros are repeated according to multiplicity, and suppose that none of these zeros are on $\gamma$. Then

$$
\frac{1}{2\pi i} \int_{\gamma} \frac{f'(z)}{f(z)} \, dz = m \sum_{k=1}^{m} n(\gamma, a_k).
$$

**Proof:** Let $f(z) = \prod_{j=1}^{m} (z - a_j) g(z)$ where $g(z) \neq 0$ on $\Omega$. Hence

$$
\frac{f'(z)}{f(z)} = \sum_{j=1}^{m} \frac{1}{z - a_j} + \frac{g'(z)}{g(z)}
$$

and so

$$
\frac{1}{2\pi i} \int_{\gamma} \frac{f'(z)}{f(z)} \, dz = \sum_{j=1}^{m} n(\gamma, a_j) + \frac{1}{2\pi i} \int_{\gamma} \frac{g'(z)}{g(z)} \, dz.
$$

But the function, $z \to \frac{g'(z)}{g(z)}$ is analytic and so by Corollary 49.7.20, the last integral in the above expression equals $0$. Therefore, this proves the theorem.

The following picture is descriptive of the situation described in the next theorem.

![Diagram](image)

**Theorem 50.6.2** Let $\Omega$ be a region, let $\gamma : [a, b] \to \Omega$ be closed continuous, and bounded variation such that $n(\gamma, z) = 0$ for all $z \notin \Omega$. Also suppose $f : \Omega \to \mathbb{C}$ is
50.6. COUNTING ZEROS

analytic and that $\alpha \not\in f(\gamma^*)$. Then $f \circ \gamma : [a, b] \to \mathbb{C}$ is continuous, closed, and bounded variation. Also suppose $\{a_1, \ldots, a_m\} = f^{-1}(\alpha)$ where these points are counted according to their multiplicities as zeros of the function $f - \alpha$. Then

$$n(f \circ \gamma, \alpha) = \sum_{k=1}^{m} n(\gamma, a_k).$$

Proof: It is clear that $f \circ \gamma$ is continuous. It only remains to verify that it is of bounded variation. Suppose first that $\gamma^* \subseteq B \subseteq \overline{B} \subseteq \Omega$ where $B$ is a ball. Then

$$|f(\gamma(t)) - f(\gamma(s))| = \left| \int_{0}^{1} f'(\gamma(s) + \lambda(\gamma(t) - \gamma(s))) (\gamma(t) - \gamma(s)) d\lambda \right| \leq C|\gamma(t) - \gamma(s)|$$

where $C \geq \max \{|f'(z)| : z \in \overline{B}\}$. Hence, in this case,

$$V(f \circ \gamma, [a, b]) \leq CV(\gamma, [a, b]).$$

Now let $\varepsilon$ denote the distance between $\gamma^*$ and $\mathbb{C} \setminus \Omega$. Since $\gamma^*$ is compact, $\varepsilon > 0$. By uniform continuity there exists $\delta = \frac{b-a}{p}$ for $p$ a positive integer such that if $|s-t| < \delta$, then $|\gamma(s) - \gamma(t)| < \frac{\varepsilon}{2}$. Then

$$\gamma([t, t + \delta]) \subseteq B\left(\gamma(t), \frac{\varepsilon}{2}\right) \subseteq \Omega.$$ 

Let $C \geq \max \{ |f'(z)| : z \in \bigcup_{j=1}^{p-1} B\left(\gamma(t_j), \frac{\varepsilon}{2}\right) \}$ where $t_j = \frac{j}{p}(b-a) + a$. Then from what was just shown,

$$V(f \circ \gamma, [a, b]) \leq \sum_{j=0}^{p-1} V(f \circ \gamma, [t_j, t_{j+1}]) \leq C \sum_{j=0}^{p-1} V(\gamma, [t_j, t_{j+1}]) < \infty$$

showing that $f \circ \gamma$ is bounded variation as claimed. Now from Theorem 49.7.15 there exists $\eta \in C^1([a, b])$ such that

$$\eta(a) = \gamma(a) = \gamma(b) = \eta(b), \eta([a, b]) \subseteq \Omega,$$

and

$$n(\eta, a_k) = n(\gamma, a_k), n(f \circ \gamma, \alpha) = n(f \circ \eta, \alpha) \quad (50.6.7)$$

for $k = 1, \ldots, m$. Then

$$n(f \circ \gamma, \alpha) = n(f \circ \eta, \alpha)$$
By Theorem 50.6.1, this equals \( \sum_{k=1}^{m} n(\gamma, a_k) \) which proves the theorem.

The next theorem is incredible and is very interesting for its own sake. The following picture is descriptive of the situation of this theorem.

---

**Theorem 50.6.3** Let \( f : B(a, R) \to \mathbb{C} \) be analytic and let

\[
 f(z) - \alpha = (z - a)^m g(z), \quad \infty > m \geq 1
\]

where \( g(z) \neq 0 \) in \( B(a, R) \). \( f(z) - \alpha \) has a zero of order \( m \) at \( z = a \). Then there exist \( \varepsilon, \delta > 0 \) with the property that for each \( z \) satisfying \( 0 < |z - \alpha| < \delta \), there exist points,

\[
 \{a_1, \ldots, a_m\} \subseteq B(a, \varepsilon),
\]

such that

\[
 f^{-1}(z) \cap B(a, \varepsilon) = \{a_1, \ldots, a_m\}
\]

and each \( a_k \) is a zero of order 1 for the function \( f(\cdot) - z \).

**Proof:** By Theorem 50.6.1, \( f \) is not constant on \( B(a, R) \) because it has a zero of order \( m \). Therefore, using this theorem again, there exists \( \varepsilon > 0 \) such that \( B(a, 2\varepsilon) \subseteq B(a, R) \) and there are no solutions to the equation \( f(z) - \alpha = 0 \) for \( z \in B(a, 2\varepsilon) \) except \( a \). Also assume \( \varepsilon \) is small enough that for \( 0 < |z - a| \leq 2\varepsilon \), \( f'(z) \neq 0 \). This can be done since otherwise, \( a \) would be a limit point of a sequence of points, \( z_n \), having \( f'(z_n) = 0 \) which would imply, by Theorem 50.6.1, that \( f' = 0 \) on \( B(a, R) \), contradicting the assumption that \( f - \alpha \) has a zero of order \( m \) and is therefore not constant. Thus the situation is described by the following picture.
Now pick $\gamma(t) = a + \varepsilon e^{it}, t \in [0, 2\pi]$. Then $\alpha \notin f(\gamma^*)$ so there exists $\delta > 0$ with

$$B(\alpha, \delta) \cap f(\gamma^*) = \emptyset.$$  \hfill (50.6.8)

Therefore, $B(\alpha, \delta)$ is contained on one component of $\mathbb{C} \setminus f(\gamma([0, 2\pi]))$. Therefore, $n(f \circ \gamma, a) = n(f \circ \gamma, z)$ for all $z \in B(\alpha, \delta)$. Now consider $f$ restricted to $B(a, 2\varepsilon)$. For $z \in B(\alpha, \delta)$, $f^{-1}(z)$ must consist of a finite set of points because $f'(w) \neq 0$ for all $w$ in $B(a, 2\varepsilon) \setminus \{a\}$ implying that the zeros of $f(\cdot) - z$ in $B(a, 2\varepsilon)$ have no limit point. Since $B(a, 2\varepsilon)$ is compact, this means there are only finitely many. By Theorem 50.6.2,

$$n(f \circ \gamma, z) = \sum_{k=1}^{p} n(\gamma, a_k)$$  \hfill (50.6.9)

where $\{a_1, \cdots, a_p\} = f^{-1}(z)$. Each point, $a_k$ of $f^{-1}(z)$ is either inside the circle traced out by $\gamma$, yielding $n(\gamma, a_k) = 1$, or it is outside this circle yielding $n(\gamma, a_k) = 0$ because of 50.6.8. It follows the sum in 50.6.9 reduces to the number of points of $f^{-1}(z)$ which are contained in $B(a, \varepsilon)$. Thus, letting those points in $f^{-1}(z)$ which are contained in $B(a, \varepsilon)$ be denoted by $\{a_1, \cdots, a_r\}$

$$n(f \circ \gamma, z) = r.$$

Also, by Theorem 50.6.1, $m = n(f \circ \gamma, a)$ because $a$ is a zero of $f - \alpha$ of order $m$. Therefore, for $z \in B(\alpha, \delta)$

$$m = n(f \circ \gamma, a) = n(f \circ \gamma, z) = r$$

It is required to show $r = m$, the order of the zero of $f - \alpha$. Therefore, $r = m$. Each of these $a_k$ is a zero of order 1 of the function $f(\cdot) - z$ because $f'(a_k) \neq 0$. This proves the theorem.

This is a very fascinating result partly because it implies that for values of $f$ near a value, $\alpha$, at which $f(\cdot) - \alpha$ has a zero of order $m$ for $m > 1$, the inverse image of these values includes at least $m$ points, not just one. Thus the topological properties of the inverse image changes radically. This theorem also shows that $f(B(a, \varepsilon)) \supseteq B(\alpha, \delta)$.

**Theorem 50.6.4 (open mapping theorem)** Let $\Omega$ be a region and $f : \Omega \to \mathbb{C}$ be analytic. Then $f(\Omega)$ is either a point or a region. If $f$ is one to one, then $f^{-1} : f(\Omega) \to \Omega$ is analytic.
CHAPTER 50. THE OPEN MAPPING THEOREM

**Proof:** If $f$ is not constant, then for every $\alpha \in f(\Omega)$, it follows from Theorem 49.5.3 that $f(\cdot) - \alpha$ has a zero of order $m < \infty$ and so from Theorem 50.6.3 for each $a \in \Omega$ there exist $\varepsilon, \delta > 0$ such that $f(B(a, \varepsilon)) \supset B(\alpha, \delta)$ which clearly implies that $f$ maps open sets to open sets. Therefore, $f(\Omega)$ is open, connected because $f$ is continuous. If $f$ is one to one, Theorem 50.6.3 implies that for every $\alpha \in f(\Omega)$ the zero of $f(\cdot) - \alpha$ is of order 1. Otherwise, that theorem implies that for $z$ near $\alpha$, there are $m$ points which $f$ maps to $z$ contradicting the assumption that $f$ is one to one. Therefore, $f'(z) \neq 0$ and since $f^{-1}$ is continuous, due to $f$ being an open map, it follows

$$\left(f^{-1}\right)'(f(z)) = \lim_{f(z_1)\to f(z)} \frac{f^{-1}(f(z_1)) - f^{-1}(f(z))}{f(z_1) - f(z)} = \lim_{z_1\to z} \frac{z_1 - z}{f(z_1) - f(z)} = \frac{1}{f'(z)}.$$ 

This proves the theorem.

50.7 **An Application To Linear Algebra**

Gerschgorin’s theorem gives a convenient way to estimate eigenvalues of a matrix from easy to obtain information. For $A$ an $n \times n$ matrix, denote by $\sigma(A)$ the collection of all eigenvalues of $A$.

**Theorem 50.7.1** Let $A$ be an $n \times n$ matrix. Consider the $n$ Gerschgorin discs defined as

$$D_i \equiv \left\{ \lambda \in \mathbb{C} : |\lambda - a_{ii}| \leq \sum_{j \neq i} |a_{ij}| \right\}.$$ 

Then every eigenvalue is contained in some Gerschgorin disc.

This theorem says to add up the absolute values of the entries of the $i^{th}$ row which are off the main diagonal and form the disc centered at $a_{ii}$ having this radius. The union of these discs contains $\sigma(A)$.

**Proof:** Suppose $Ax = \lambda x$ where $x \neq 0$. Then for $A = (a_{ij})$

$$\sum_{j \neq i} a_{ij}x_j = (\lambda - a_{ii})x_i.$$ 

Therefore, if we pick $k$ such that $|x_k| \geq |x_j|$ for all $x_j$, it follows that $|x_k| \neq 0$ since $|x| \neq 0$ and

$$|x_k| \sum_{j \neq k} |a_{kj}| \geq \sum_{j \neq k} |a_{kj}| |x_j| \geq |\lambda - a_{kk}| |x_k|.$$ 

Now dividing by $|x_k|$ we see that $\lambda$ is contained in the $k^{th}$ Gerschgorin disc.
More can be said using the theory about counting zeros. To begin with the distance between two \( n \times n \) matrices, \( A = (a_{ij}) \) and \( B = (b_{ij}) \) as follows.

\[
\| A - B \|_2^2 = \sum_{ij} |a_{ij} - b_{ij}|^2.
\]

Thus two matrices are close if and only if their corresponding entries are close.

Let \( A \) be an \( n \times n \) matrix. Recall the eigenvalues of \( A \) are given by the zeros of the polynomial, \( p_A(z) = \det(zI - A) \) where \( I \) is the \( n \times n \) identity. Then small changes in \( A \) will produce small changes in \( p_A(z) \) and \( p'_A(z) \).

Let \( k \) denote a very small closed circle which winds around \( z_k \), one of the eigenvalues of \( A \), in the counterclockwise direction so that \( n(z_k, z) = 1 \). This circle is to enclose only \( z_k \) and is to have no other eigenvalue on it. Then apply Theorem 50.6.1. According to this theorem

\[
\frac{1}{2\pi i} \int_{\gamma} \frac{p'_A(z)}{p_A(z)} \, dz
\]

is always an integer equal to the multiplicity of \( z_k \) as a root of \( p_A(t) \). Therefore, small changes in \( A \) result in no change to the above contour integral because it must be an integer and small changes in \( A \) result in small changes in the integral. Therefore whenever every entry of the matrix \( B \) is close enough to the corresponding entry of the matrix \( A \), the two matrices have the same number of zeros inside \( k \) under the usual convention that zeros are to be counted according to multiplicity. By making the radius of the small circle equal to \( \varepsilon \) where \( \varepsilon \) is less than the minimum distance between any two distinct eigenvalues of \( A \), this shows that if \( B \) is close enough to \( A \), every eigenvalue of \( B \) is closer than \( \varepsilon \) to some eigenvalue of \( A \). The next theorem is about continuous dependence of eigenvalues.

**Theorem 50.7.2** If \( \lambda \) is an eigenvalue of \( A \), then if \( \| B - A \| \) is small enough, some eigenvalue of \( B \) will be within \( \varepsilon \) of \( \lambda \).

Consider the situation that \( A(t) \) is an \( n \times n \) matrix and that \( t \to A(t) \) is continuous for \( t \in [0, 1] \).

**Lemma 50.7.3** Let \( \lambda(t) \in \sigma(A(t)) \) for \( t < 1 \) and let \( \Sigma_t = \cup_{s \geq t} \sigma(A(s)) \). Also let \( K_t \) be the connected component of \( \lambda(t) \) in \( \Sigma_t \). Then there exists \( \eta > 0 \) such that \( K_t \cap \sigma(A(s)) \neq \emptyset \) for all \( s \in [t, t + \eta] \).

**Proof:** Denote by \( D(\lambda(t), \delta) \) the disc centered at \( \lambda(t) \) having radius \( \delta > 0 \), with other occurrences of this notation being defined similarly. Thus

\[
D(\lambda(t), \delta) \equiv \{ z \in \mathbb{C} : |\lambda(t) - z| \leq \delta \}.
\]

Suppose \( \delta > 0 \) is small enough that \( \lambda(t) \) is the only element of \( \sigma(A(t)) \) contained in \( D(\lambda(t), \delta) \) and that \( p_{A(t)} \) has no zeroes on the boundary of this disc. Then by continuity, and the above discussion and theorem, there exists \( \eta > 0, t + \eta < 1 \), such that for \( s \in [t, t + \eta] \), \( p_{A(s)} \) also has no zeroes on the boundary of this disc and that
A(s) has the same number of eigenvalues, counted according to multiplicity, in the disc as A(t). Thus \( \sigma(A(s)) \cap D(\lambda(t), \delta) \neq \emptyset \) for all \( s \in [t, t + \eta] \). Now let

\[
H = \bigcup_{s \in [t,t+\eta]} \sigma(A(s)) \cap D(\lambda(t), \delta).
\]

I will show \( H \) is connected. Suppose not. Then \( H = P \cup Q \) where \( P, Q \) are separated and \( \lambda(t) \in P \). Let

\[
s_0 \equiv \inf \left\{ s : \lambda(s) \in Q \text{ for some } \lambda(s) \in \sigma(A(s)) \right\}.
\]

There exists \( \lambda(s_0) \in \sigma(A(s_0)) \cap D(\lambda(t), \delta) \). If \( \lambda(s_0) \notin Q \), then from the above discussion there are

\[
\lambda(s) \in \sigma(A(s)) \cap Q
\]

for \( s > s_0 \) arbitrarily close to \( \lambda(s_0) \). Therefore, \( \lambda(s_0) \in Q \) which shows that \( s_0 > t \) because \( \lambda(t) \) is the only element of \( \sigma(A(t)) \) in \( D(\lambda(t), \delta) \) and \( \lambda(t) \in P \). Now let \( s_n \uparrow s_0 \). Then \( \lambda(s_n) \in P \) for any

\[
\lambda(s_n) \in \sigma(A(s_n)) \cap D(\lambda(t), \delta)
\]

and from the above discussion, for some choice of \( s_n \to s_0 \), \( \lambda(s_n) \to \lambda(s_0) \) which contradicts \( P \) and \( Q \) separated and nonempty. Since \( P \) is nonempty, this shows \( Q = \emptyset \). Therefore, \( H \) is connected as claimed. But \( K_t \supseteq H \) and so \( K_t \cap \sigma(A(s)) \neq \emptyset \) for all \( s \in [t, t + \eta] \). This proves the lemma.

The following is the necessary theorem.

**Theorem 50.7.4** Suppose \( A(t) \) is an \( n \times n \) matrix and that \( t \to A(t) \) is continuous for \( t \in [0,1] \). Let \( \lambda(0) \in \sigma(A(0)) \) and define \( \Sigma = \cup_{t \in [0,1]} \sigma(A(t)) \). Let \( K_{\lambda(0)} = K_0 \) denote the connected component of \( \lambda(0) \) in \( \Sigma \). Then \( K_0 \cap \sigma(A(t)) \neq \emptyset \) for all \( t \in [0,1] \).

**Proof:** Let \( S \equiv \{ t \in [0,1] : K_0 \cap \sigma(A(s)) \neq \emptyset \text{ for all } s \in [0,t] \} \). Then \( 0 \in S \). Let \( t_0 = \sup(S) \). Say \( \sigma(A(t_0)) = \lambda_1(t_0), \ldots, \lambda_r(t_0) \). I claim at least one of these is a limit point of \( K_0 \) and consequently must be in \( K_0 \) which will show that \( S \) has a last point. Why is this claim true? Let \( s_n \uparrow t_0 \) so \( s_n \in S \). Now let the discs, \( D(\lambda_i(t_0), \delta), i = 1, \ldots, r \) be disjoint with \( p_{\lambda_i(t_0)} \) having no zeroes on \( \gamma_i \) the boundary of \( D(\lambda_i(t_0), \delta) \). Then for \( n \) large enough it follows from Theorem 50.4.4 and the discussion following it that \( \sigma(A(s_n)) \) is contained in \( \cup_{i=1}^r D(\lambda_i(t_0), \delta) \). Therefore, \( K_0 \cap (\sigma(A(t_0)) + D(0, \delta)) \neq \emptyset \) for all \( \delta \) small enough. This requires at least one of the \( \lambda_i(t_0) \) to be in \( K_0 \). Therefore, \( t_0 \in S \) and \( S \) has a last point.

Now by Lemma 50.4.2, if \( t_0 < 1 \), then \( K_0 \cup K_t \) would be a strictly larger connected set containing \( \lambda(0) \). (The reason this would be strictly larger is that \( K_0 \cap \sigma(A(s)) = \emptyset \) for some \( s \in (t, t + \eta) \) while \( K_t \cap \sigma(A(s)) \neq \emptyset \) for all \( s \in [t, t + \eta] \).) Therefore, \( t_0 = 1 \) and this proves the theorem.

The following is an interesting corollary of the Gerschgorin theorem.
Corollary 50.7.5 Suppose one of the Gerschgorin discs, $D_i$, is disjoint from the union of the others. Then $D_i$ contains an eigenvalue of $A$. Also, if there are $n$ disjoint Gerschgorin discs, then each one contains an eigenvalue of $A$.

Proof: Denote by $A(t)$ the matrix $(a'_{ij})$ where if $i \neq j$, $a'_{ij} = ta_{ij}$ and $a'_{ii} = a_{ii}$. Thus to get $A(t)$ we multiply all non diagonal terms by $t$. Let $t \in [0, 1]$. Then $A(0) = \text{diag}(a_{11}, \ldots, a_{nn})$ and $A(1) = A$. Furthermore, the map, $t \rightarrow A(t)$ is continuous. Denote by $D_j^j$ the Gerschgorin disc obtained from the $j$th row for the matrix, $A(t)$. Then it is clear that $D_j^j \subseteq D_j$ the $j$th Gerschgorin disc for $A$. Then $a_{ii}$ is the eigenvalue for $A(0)$ which is contained in the disc, consisting of the single point $a_{ii}$ which is contained in $D_i$. Letting $K$ be the connected component in $\Sigma$ for $\Sigma$ defined in Theorem 50.7.2 which is determined by $a_{ii}$, it follows by Gerschgorin’s theorem that $K \cap \sigma(A(t)) \subseteq \cup_{j=1}^n D_j^j \subseteq \cup_{j=1}^n D_j = D_i \cup (\cup_{j \neq i} D_j)$ and also, since $K$ is connected, there are no points of $K$ in both $D_i$ and $(\cup_{j \neq i} D_j)$. Since at least one point of $K$ is in $D_i$, $(a_{ii})$ it follows by Gerschgorin’s theorem 50.7.2 this shows there are points of $K \cap \sigma(A)$ in $D_i$. The last assertion follows immediately.

Actually, this can be improved slightly. It involves the following lemma.

Lemma 50.7.6 In the situation of Theorem 50.7.2 suppose $\lambda(0) = K_0 \cap \sigma(A(0))$ and that $\lambda(0)$ is a simple root of the characteristic equation of $A(0)$. Then for all $t \in [0, 1]$,
\[ \sigma(A(t)) \cap K_0 = \lambda(t) \]
where $\lambda(t)$ is a simple root of the characteristic equation of $A(t)$.

Proof: Let $S \equiv$
\[ \{t \in [0, 1] : K_0 \cap \sigma(A(s)) = \lambda(s), \text{ a simple eigenvalue for all } s \in [0, t]\} \]

Then $0 \in S$ so it is nonempty. Let $t_0 = \text{sup}(S)$ and suppose $\lambda_1 \neq \lambda_2$ are two elements of $\sigma(A(t_0)) \cap K_0$. Then choosing $\eta > 0$ small enough, and letting $D_i$ be disjoint discs containing $\lambda_i$ respectively, similar arguments to those of Lemma 50.7.2 imply
\[ H_i \equiv \cup_{s \in [t_0 - \eta, t_0]} \sigma(A(s)) \cap D_i \]
is a connected and nonempty set for $i = 1, 2$ which would require that $H_i \subseteq K_0$. But then there would be two different eigenvalues of $A(s)$ contained in $K_0$, contrary to the definition of $t_0$. Therefore, there is at most one eigenvalue, $\lambda(t_0) \in K_0 \cap \sigma(A(t_0))$. The possibility that it could be a repeated root of the characteristic equation must be ruled out. Suppose then that $\lambda(t_0)$ is a repeated root of the characteristic equation. As before, choose a small disc, $D$ centered at $\lambda(t_0)$ and $\eta$ small enough that
\[ H \equiv \cup_{s \in [t_0 - \eta, t_0]} \sigma(A(s)) \cap D \]
is a nonempty connected set containing either multiple eigenvalues of $A(s)$ or else a single repeated root to the characteristic equation of $A(s)$. But since $H$ is connected and contains $\lambda(t_0)$ it must be contained in $K_0$ which contradicts the condition for
CHAPTER 50. THE OPEN MAPPING THEOREM

s ∈ S for all these s ∈ [t₀ − η, t₀]. Therefore, t₀ ∈ S as hoped. If t₀ < 1, there exists a small disc centered at λ(t₀) and η > 0 such that for all s ∈ [t₀, t₀ + η], A(s) has only simple eigenvalues in D and the only eigenvalues of A(s) which could be in K₀ are in D. (This last assertion follows from noting that λ(t₀) is the only eigenvalue of A(t₀) in K₀ and so the others are at a positive distance from K₀. For s close enough to t₀, the eigenvalues of A(s) are either close to these eigenvalues of A(t₀) at a positive distance from K₀ or they are close to the eigenvalue, λ(t₀) in which case it can be assumed they are in D.) But this shows that t₀ is not really an upper bound to S. Therefore, t₀ = 1 and the lemma is proved.

With this lemma, the conclusion of the above corollary can be improved.

**Corollary 50.7.7** Suppose one of the Gerschgorin discs, Dᵢ is disjoint from the union of the others. Then Dᵢ contains exactly one eigenvalue of A and this eigenvalue is a simple root to the characteristic polynomial of A.

**Proof:** In the proof of Corollary 50.7.5, first note that aᵢᵢ is a simple root of A(0) since otherwise the iᵗʰ Gerschgorin disc would not be disjoint from the others. Also, K, the connected component determined by aᵢᵢ must be contained in Dᵢ because it is connected and by Gerschgorin’s theorem above, K ∩ σ (A(t)) must be contained in the union of the Gerschgorin discs. Since all the other eigenvalues of A(0), the aⱼⱼ, are outside Dᵢ, it follows that K ∩ σ (A(0)) = aᵢᵢ. Therefore, by Lemma 50.7.6, K ∩ σ (A(1)) = K ∩ σ (A) consists of a single simple eigenvalue. This proves the corollary.

**Example 50.7.8** Consider the matrix,

\[
\begin{pmatrix}
5 & 1 & 0 \\
1 & 1 & 1 \\
0 & 1 & 0
\end{pmatrix}
\]

The Gerschgorin discs are D (5, 1), D (1, 2), and D (0, 1). Then D (5, 1) is disjoint from the other discs. Therefore, there should be an eigenvalue in D (5, 1). The actual eigenvalues are not easy to find. They are the roots of the characteristic equation, \(t^3 - 6t^2 + 3t + 5 = 0\). The numerical values of these are \(-6.6966, 1.4231,\) and 5.24655, verifying the predictions of Gerschgorin’s theorem.

### 50.8 Exercises

1. Use Theorem 50.6.1 to give an alternate proof of the fundamental theorem of algebra. **Hint:** Take a contour of the form \(γ_r = re^{it}\) where \(t ∈ [0, 2π]\). Consider \(\int_{γ_r} \frac{p'(z)}{p(z)} dz\) and consider the limit as \(r → ∞\).

2. Let \(M\) be an \(n × n\) matrix. Recall that the eigenvalues of \(M\) are given by the zeros of the polynomial, \(p_M(z) = \det (M - zI)\) where \(I\) is the \(n × n\) identity. Formulate a theorem which describes how the eigenvalues depend on small
EXERCISES 1707

changes in $M$. **Hint:** You could define a norm on the space of $n \times n$ matrices as $||M|| = \sqrt{tr(MM^*)}$ where $M^*$ is the conjugate transpose of $M$. Thus

$$||M|| = \left( \sum_{j,k} |M_{jk}|^2 \right)^{1/2}.$$ 

Argue that small changes will produce small changes in $p_M(z)$. Then apply Theorem 50.6.1 using $\gamma_k$ a very small circle surrounding $z_k$, the $k^{th}$ eigenvalue.

3. Suppose that two analytic functions defined on a region are equal on some set, $S$ which contains a limit point. (Recall $p$ is a limit point of $S$ if every open set which contains $p$, also contains infinitely many points of $S$.) Show the two functions coincide. We defined $e^z \equiv e^x (\cos y + i \sin y)$ earlier and we showed that $e^z$, defined this way was analytic on $\mathbb{C}$. Is there any other way to define $e^z$ on all of $\mathbb{C}$ such that the function coincides with $e^x$ on the real axis?

4. You know various identities for real valued functions. For example $\cosh^2 x - \sinh^2 x = 1$. If you define $\cosh z \equiv \frac{e^z + e^{-z}}{2}$ and $\sinh z \equiv \frac{e^z - e^{-z}}{2}$, does it follow that 

$$\cosh^2 z - \sinh^2 z = 1$$

for all $z \in \mathbb{C}$? What about 

$$\sin (z + w) = \sin z \cos w + \cos z \sin w?$$

Can you verify these sorts of identities just from your knowledge about what happens for real arguments?

5. Was it necessary that $U$ be a region in Theorem 49.5.3? Would the same conclusion hold if $U$ were only assumed to be an open set? Why? What about the open mapping theorem? Would it hold if $U$ were not a region?

6. Let $f : U \to \mathbb{C}$ be analytic and one to one. Show that $f'(z) \neq 0$ for all $z \in U$. Does this hold for a function of a real variable?

7. We say a real valued function, $u$ is subharmonic if $u_{xx} + u_{yy} \geq 0$. Show that if $u$ is subharmonic on a bounded region, (open connected set) $U$, and continuous on $\overline{U}$ and $u \leq m$ on $\partial U$, then $u \leq m$ on $U$. **Hint:** If not, $u$ achieves its maximum at $(x_0, y_0) \in U$. Let $u(x_0, y_0) > m + \delta$ where $\delta > 0$. Now consider $u_\varepsilon(x, y) = \varepsilon x^2 + u(x, y)$ where $\varepsilon$ is small enough that $0 < \varepsilon x^2 < \delta$ for all $(x, y) \in U$. Show that $u_\varepsilon$ also achieves its maximum at some point of $U$ and that therefore, $u_{xx} + u_{yy} \leq 0$ at that point implying that $u_{xx} + u_{yy} \leq -\varepsilon$, a contradiction.

8. If $u$ is harmonic on some region, $U$, show that $u$ coincides locally with the real part of an analytic function and that therefore, $u$ has infinitely many
derivatives on $U$. \textbf{Hint:} Consider the case where $0 \in U$. You can always reduce to this case by a suitable translation. Now let $B(0, r) \subseteq U$ and use the Schwarz formula to obtain an analytic function whose real part coincides with $u$ on $\partial B(0, r)$. Then use Problem 8.

9. Show the solution to the Dirichlet problem of Problem 8 on Page 1661 is unique. You need to formulate this precisely and then prove uniqueness.
Chapter 51

Residues

Definition 51.0.1 The residue of $f$ at an isolated singularity $\alpha$ which is a pole, written $\text{res} (f, \alpha)$ is the coefficient of $(z - \alpha)^{-1}$ where

$$f(z) = g(z) + \sum_{k=1}^{m} \frac{b_k}{(z - \alpha)^k}.$$ 

Thus $\text{res} (f, \alpha) = b_1$ in the above.

At this point, recall Corollary 49.7.20 which is stated here for convenience.

Corollary 51.0.2 Let $\Omega$ be an open set and let $\gamma_k : [a_k, b_k] \to \Omega$, $\alpha = 1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that

$$\sum_{k=1}^{m} n(\gamma_k, z) = 0$$

for all $z \notin \Omega$. Then if $f : \Omega \to \mathbb{C}$ is analytic,

$$\sum_{k=1}^{m} \int_{\gamma_k} f(w) \, dw = 0.$$ 

The following theorem is called the residue theorem. Note the resemblance to Corollary 49.7.20.

Theorem 51.0.3 Let $\Omega$ be an open set and let $\gamma_k : [a_k, b_k] \to \Omega$, $k = 1, \cdots, m$, be closed, continuous and of bounded variation. Suppose also that

$$\sum_{k=1}^{m} n(\gamma_k, z) = 0$$

1709
for all \( z \notin \Omega \). Then if \( f : \Omega \to \mathbb{C} \) is meromorphic such that no \( \gamma_k \) contains any poles of \( f \),

\[
\frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} f(w) \, dw = \sum_{\alpha \in A} \text{res}(f, \alpha) \sum_{k=1}^{m} n(\gamma_k, \alpha) \tag{51.0.1}
\]

where here \( A \) denotes the set of poles of \( f \) in \( \Omega \). The sum on the right is a finite sum.

**Proof:** First note that there are at most finitely many \( \alpha \) which are not in the unbounded component of \( \mathbb{C} \setminus \bigcup_{k=1}^{m} \gamma_k([a_k, b_k]) \). Thus there exists a finite set, \( \{\alpha_1, \ldots, \alpha_N\} \subseteq A \) such that these are the only possibilities for which \( \sum_{k=1}^{n} n(\gamma_k, \alpha) \) might not equal zero. Therefore, \( \text{(51.0.1)} \) reduces to

\[
\frac{1}{2\pi i} \sum_{k=1}^{m} \int_{\gamma_k} f(w) \, dw = \sum_{j=1}^{N} \text{res}(f, \alpha_j) \sum_{k=1}^{m} n(\gamma_k, \alpha_j)
\]

and it is this last equation which is established. Near \( \alpha_j \),

\[
f(z) = g_j(z) + \sum_{r=1}^{m_j} \frac{b_j^r}{(z - \alpha_j)^r} = g_j(z) + Q_j(z)
\]

where \( g_j \) is analytic at and near \( \alpha_j \). Now define

\[
G(z) = f(z) - \sum_{j=1}^{N} Q_j(z)
\]

It follows that \( G(z) \) has a removable singularity at each \( \alpha_j \). Therefore, by Corollary \( \text{[49.7.20]} \),

\[
0 = \sum_{k=1}^{m} \int_{\gamma_k} G(z) \, dz = \sum_{k=1}^{m} \int_{\gamma_k} f(z) \, dz - \sum_{j=1}^{N} \sum_{k=1}^{m} \int_{\gamma_k} Q_j(z) \, dz.
\]

Now

\[
\sum_{k=1}^{m} \int_{\gamma_k} Q_j(z) \, dz = \sum_{k=1}^{m} \int_{\gamma_k} \left( \frac{b_j^1}{(z - \alpha_j)} + \sum_{r=2}^{m_j} \frac{b_j^r}{(z - \alpha_j)^r} \right) \, dz = \sum_{k=1}^{m} \frac{b_j^1}{(z - \alpha_j)} \, dz = \sum_{k=1}^{m} n(\gamma_k, \alpha_j) \text{res}(f, \alpha_j)(2\pi i).
\]
Therefore,
\[
\sum_{k=1}^{m} \int_{\gamma_k} f(z) \, dz = \sum_{j=1}^{N} \sum_{k=1}^{m} \int_{\gamma_k} Q_j(z) \, dz \\
= \sum_{j=1}^{N} \sum_{k=1}^{m} n(\gamma_k, \alpha_j) \text{res}(f, \alpha_j) (2\pi i) \\
= 2\pi i \sum_{j=1}^{N} \text{res}(f, \alpha_j) \sum_{k=1}^{m} n(\gamma_k, \alpha_j) \\
= (2\pi i) \sum_{\alpha \in A} \text{res}(f, \alpha) \sum_{k=1}^{m} n(\gamma_k, \alpha)
\]
which proves the theorem.

The following is an important example. This example can also be done by real variable methods and there are some who think that real variable methods are always to be preferred to complex variable methods. However, I will use the above theorem to work this example.

**Example 51.0.4** Find \( \lim_{R \to \infty} \int_{-R}^{R} \frac{\sin(x)}{x} \, dx \)

Things are easier if you write it as
\[
\lim_{R \to \infty} \frac{1}{i} \left( \int_{-R}^{-R^{-1}} \frac{e^{ix}}{x} \, dx + \int_{R^{-1}}^{R} \frac{e^{ix}}{x} \, dx \right)
\]

This gives the same answer because \( \cos(x)/x \) is odd. Consider the following contour in which the orientation involves counterclockwise motion exactly once around.

Denote by \( \gamma_{R^{-1}} \) the little circle and \( \gamma_R \) the big one. Then on the inside of this contour there are no singularities of \( e^{iz}/z \) and it is contained in an open set with the property that the winding number with respect to this contour about any point not in the open set equals zero. By Theorem

\[
\frac{1}{i} \left( \int_{-R}^{-R^{-1}} \frac{e^{ix}}{x} \, dx + \int_{\gamma_{R^{-1}}} \frac{e^{iz}}{z} \, dz + \int_{R^{-1}}^{R} \frac{e^{ix}}{x} \, dx + \int_{\gamma_R} \frac{e^{iz}}{z} \, dz \right) = 0 \quad (51.0.2)
\]
Now
\[ \left| \int_{\gamma_R} \frac{e^{iz}}{z} \, dz \right| = \left| \int_0^\pi e^{R(i \cos \theta - \sin \theta)} \, i d\theta \right| \leq \int_0^\pi e^{-R \sin \theta} \, d\theta \]
and this last integral converges to 0 by the dominated convergence theorem. Now consider the other circle. By the dominated convergence theorem again,
\[ \int_{\gamma_{R-1}} \frac{e^{iz}}{z} \, dz = \int_0^\pi e^{R^{-1}(i \cos \theta - \sin \theta)} \, i d\theta \to -i \pi \]
as \( R \to \infty \). Then passing to the limit in 51.0.2,
\[
\lim_{R \to \infty} \int_{-R}^R \frac{\sin(x)}{x} \, dx = \lim_{R \to \infty} \frac{1}{i} \left( \int_{-R}^{-R-1} \frac{e^{ix}}{x} \, dx + \int_{R-1}^R \frac{e^{ix}}{x} \, dx \right)
\]
\[= \lim_{R \to \infty} \frac{1}{i} \left( -\int_{\gamma_{R-1}} \frac{e^{iz}}{z} \, dz - \int_{\gamma_R} \frac{e^{iz}}{z} \, dz \right) = -\frac{1}{i} (-i \pi) = \pi. \]

**Example 51.0.5** Find \( \lim_{R \to \infty} \int_{-R}^R e^{ixt} \frac{\sin x}{x} \, dx \). Note this is essentially finding the inverse Fourier transform of the function, \( \sin(x)/x \).

This equals
\[
\lim_{R \to \infty} \int_{-R}^R (\cos(xt) + i \sin(xt)) \frac{\sin(x)}{x} \, dx
\]
\[= \lim_{R \to \infty} \int_{-R}^R \cos(xt) \frac{\sin(x)}{x} \, dx
\]
\[= \lim_{R \to \infty} \int_{-R}^R \cos(xt) \frac{\sin(x)}{x} \, dx
\]
\[= \lim_{R \to \infty} \frac{1}{2} \int_{-R}^R \frac{\sin(x(t + 1)) + \sin(x(1 - t))}{x} \, dx
\]
Let \( t \neq 1, -1 \). Then changing variables yields
\[
\lim_{R \to \infty} \left( \frac{1}{2} \int_{-R(1+t)}^{R(1+t)} \frac{\sin(u)}{u} \, du + \frac{1}{2} \int_{-R(1-t)}^{R(1-t)} \frac{\sin(u)}{u} \, du \right).
\]
In case \(|t| < 1\) Example 51.0.2 implies this limit is \( \pi \). However, if \( t > 1 \) the limit equals 0 and this is also the case if \( t < -1 \). Summarizing,
\[
\lim_{R \to \infty} \int_{-R}^R e^{ixt} \frac{\sin x}{x} \, dx = \begin{cases} 
\pi & \text{if } |t| < 1 \ 
0 & \text{if } |t| > 1.
\end{cases}
\]
51.1 Rouche’s Theorem And The Argument Principle

51.1.1 Argument Principle

A simple closed curve is just one which is homeomorphic to the unit circle. The Jordan Curve theorem states that every simple closed curve in the plane divides the plane into exactly two connected components, one bounded and the other unbounded. This is a very hard theorem to prove. However, in most applications the conclusion is obvious. Nevertheless, to avoid using this big topological result and to attain some extra generality, I will state the following theorem in terms of the winding number to avoid using it. This theorem is called the argument principle.

First recall that

\( f(z) = g(z)(z - \alpha)^m \) where \( g \) is an analytic function which is not equal to zero at \( \alpha \).

This is equivalent to having

\( f(z) = \sum_{k=1}^{m} b_k (z - \alpha)^k \) for \( z \) near \( \alpha \) where \( b_m \neq 0 \).

Also recall that

\( f(z) = h(z) + \sum_{k=1}^{p} b_k (z - \alpha)^k \) where \( b_p \neq 0 \) and \( h \) is a function analytic near \( \alpha \).

Theorem 51.1.1 (argument principle) Let \( f \) be meromorphic in \( \Omega \). Also suppose \( \gamma^* \) is a closed bounded variation curve containing none of the poles or zeros of \( f \) with the property that for all \( z \notin \Omega, n(\gamma, z) = 0 \) and for all \( z \in \Omega, n(\gamma, z) \) either equals 0 or 1. Now let \( \{p_1, \cdots, p_m\} \) and \( \{z_1, \cdots, z_n\} \) be respectively the poles and zeros for which the winding number of \( \gamma \) about these points equals 1. Let \( z_k \) be a zero of order \( r_k \) and let \( p_k \) be a pole of order \( l_k \).

Then

\[
\int_{\gamma} \frac{f'(z)}{f(z)} \, dz = \sum_{k=1}^{n} r_k - \sum_{k=1}^{m} l_k
\]

Proof: This theorem follows from computing the residues of \( f'/f \). It has residues at poles and zeros. I will do this now. First suppose \( f \) has a pole of order \( p \) at \( \alpha \). Then \( f \) has the form given in (51.1.3). Therefore,

\[
\frac{f'(z)}{f(z)} = \frac{h'(z) - \sum_{k=1}^{p} kb_k (z - \alpha)^{k+1}}{h(z) + \sum_{k=1}^{p} b_k (z - \alpha)^k}
\]

This is of the form

\[
= \frac{b_p}{s(z) + b_p} \left( r(z) - \frac{p b_p}{(z - \alpha)} \right) = \frac{b_p}{s(z) + b_p} \left( r(z) - \frac{p}{b_p} (z - \alpha) \right)
\]

where \( b_m \neq 0 \) and \( h \) is a function analytic near \( \alpha \).
where \( s(\alpha) = r(\alpha) = 0 \). From this, it is clear \( \text{res}(f'/f, \alpha) = -p \), the order of the pole.

Next suppose \( f \) has a zero of order \( p \) at \( \alpha \). Then

\[
\frac{f'(z)}{f(z)} = \frac{\sum_{k=p}^{\infty} a_k (z - \alpha)^{k-1}}{\sum_{k=p}^{\infty} a_k (z - \alpha)^k} = \frac{\sum_{k=p}^{\infty} a_k (z - \alpha)^{k-1-p}}{\sum_{k=p}^{\infty} a_k (z - \alpha)^{k-p}}
\]

and from this it is clear \( \text{res}(f'/f) = p \), the order of the zero. The conclusion of this theorem now follows from Theorem 51.0.3.

One can also generalize the theorem to the case where there are many closed curves involved. This is proved in the same way as the above.

**Theorem 51.1.2** (argument principle) Let \( f \) be meromorphic in \( \Omega \) and let \( \gamma_k : [a_k, b_k] \to \Omega, k = 1, \cdots, m \), be closed, continuous and of bounded variation. Suppose also that

\[
\sum_{k=1}^{m} n(\gamma_k, z) = 0
\]

and for all \( z \notin \Omega \) and for \( z \in \Omega \), \( \sum_{k=1}^{m} n(\gamma_k, z) \) either equals 0 or 1. Now let \( \{p_1, \cdots, p_m\} \) and \( \{z_1, \cdots, z_n\} \) be respectively the poles and zeros for which the above sum of winding numbers equals 1. Let \( z_k \) be a zero of order \( r_k \) and let \( p_k \) be a pole of order \( l_k \). Then

\[
\frac{1}{2\pi i} \int_{\gamma} \frac{f'(z)}{f(z)} \, dz = \sum_{k=1}^{n} r_k - \sum_{k=1}^{m} l_k
\]

There is also a simple extension of this important principle which I found in [59].

**Theorem 51.1.3** (argument principle) Let \( f \) be meromorphic in \( \Omega \). Also suppose \( \gamma^* \) is a closed bounded variation curve with the property that for all \( z \notin \Omega, n(\gamma, z) = 0 \) and for all \( z \in \Omega, n(\gamma, z) \) either equals 0 or 1. Now let \( \{p_1, \cdots, p_m\} \) and \( \{z_1, \cdots, z_n\} \) be respectively the poles and zeros for which the winding number of \( \gamma \) about these points equals 1 listed according to multiplicity. Thus if there is a pole of order \( m \) there will be this value repeated \( m \) times in the list for the poles. Also let \( g(z) \) be an analytic function. Then

\[
\frac{1}{2\pi i} \int_{\gamma} g(z) \frac{f'(z)}{f(z)} \, dz = \sum_{k=1}^{n} g(z_k) - \sum_{k=1}^{m} g(p_k)
\]

**Proof:** This theorem follows from computing the residues of \( g(f'/f) \). It has residues at poles and zeros. I will do this now. First suppose \( f \) has a pole of order
m at \( \alpha \). Then \( f \) has the form given in 51.1.3. Therefore,

\[
g(z) \frac{f'(z)}{f(z)} = \frac{g(z)}{h(z)} \left( h'(z) - \sum_{k=1}^{m} \frac{k b_k}{(z-\alpha)^{k+1}} \right)
\]

\[
= \frac{g(z)}{h(z)} \sum_{k=1}^{m} \frac{k b_k}{(z-\alpha)^k}
\]

From this, it is clear \( \text{res} (g(f'/f), \alpha) = mg(\alpha) \), where \( m \) is the order of the pole.

Thus \( g \) would have been listed \( m \) times in the list of poles. Hence the residue at this point is equivalent to adding \( g(\alpha) m \) times.

Next suppose \( f \) has a zero of order \( m \) at \( \alpha \). Then

\[
g(z) \frac{f'(z)}{f(z)} = g(z) \sum_{k=m+1}^{\infty} \frac{a_k}{(z-\alpha)^k} = g(z) \sum_{k=m}^{\infty} \frac{a_k}{(z-\alpha)^k}
\]

and from this it is clear \( \text{res} (g(f'/f)) = g(\alpha) m \), where \( m \) is the order of the zero.

The conclusion of this theorem now follows from the residue theorem, Theorem 51.0.3.

The way people usually apply these theorems is to suppose \( \gamma^* \) is a simple closed bounded variation curve, often a circle. Thus it has an inside and an outside, the outside being the unbounded component of \( \mathbb{C} \setminus \gamma^* \). The orientation of the curve is such that you go around it once in the counterclockwise direction. Then letting \( r_k \) and \( l_k \) be as described, the conclusion of the theorem follows. In applications, this is likely the way it will be.

### 51.1.2 Rouche’s Theorem

With the argument principle, it is possible to prove Rouche’s theorem. In the argument principle, denote by \( Z_f \) the quantity \( \sum_{k=1}^{m} r_k \) and by \( P_f \) the quantity \( \sum_{k=1}^{n} l_k \). Thus \( Z_f \) is the number of zeros of \( f \) counted according to the order of the zero with a similar definition holding for \( P_f \). Thus the conclusion of the argument principle is:

\[
\frac{1}{2\pi i} \int_{\gamma} \frac{f'(z)}{f(z)} \, dz = Z_f - P_f
\]

Rouche’s theorem allows the comparison of \( Z_h - P_h \) for \( h = f, g \). It is a wonderful and amazing result.

**Theorem 51.1.4 (Rouche’s theorem)**Let \( f, g \) be meromorphic in an open set \( \Omega \). Also suppose \( \gamma^* \) is a closed bounded variation curve with the property that for all \( z \notin \Omega, n(\gamma, z) = 0 \), no zeros or poles are on \( \gamma^* \), and for all \( z \in \Omega, n(\gamma, z) \) either equals 0 or 1. Let \( Z_f \) and \( P_f \) denote respectively the numbers of zeros and poles of
which have the property that the winding number equals 1, counted according to order, with \( Z_g \) and \( P_g \) being defined similarly. Also suppose that for \( z \in \gamma^* \)

\[
|f(z) + g(z)| < |f(z)| + |g(z)|.
\]  

(51.1.4)

Then

\[
Z_f - P_f = Z_g - P_g.
\]

**Proof:** From the hypotheses,

\[
\left| 1 + \frac{f(z)}{g(z)} \right| < 1 + \left| \frac{f(z)}{g(z)} \right|
\]

which shows that for all \( z \in \gamma^* \),

\[
\frac{f(z)}{g(z)} \in \mathbb{C} \setminus [0, \infty).
\]

Letting \( l \) denote a branch of the logarithm defined on \( \mathbb{C} \setminus [0, \infty) \), it follows that \( l \left( \frac{f(z)}{g(z)} \right) \) is a primitive for the function,

\[
\frac{(f/g)'}{(f/g)} = \frac{f'}{f} - \frac{g'}{g}.
\]

Therefore, by the argument principle,

\[
0 = \frac{1}{2\pi i} \int_{\gamma} (f/g)' \, dz = \frac{1}{2\pi i} \int_{\gamma} \left( \frac{f'}{f} - \frac{g'}{g} \right) \, dz = Z_f - P_f - (Z_g - P_g).
\]

This proves the theorem.

Often another condition other than 51.1.4 is used.

**Corollary 51.1.5** In the situation of Theorem 51.1.4 change 51.1.4 to the condition,

\[
|f(z) - g(z)| < |f(z)|
\]

for \( z \in \gamma^* \). Then the conclusion is the same.

**Proof:** The new condition implies \( \left| 1 - \frac{g}{f}(z) \right| < \left| \frac{g(z)}{f(z)} \right| \) on \( \gamma^* \). Therefore, \( \frac{g(z)}{f(z)} \notin (\infty, 0] \) and so you can do the same argument with a branch of the logarithm.

### 51.1.3 A Different Formulation

In [104] I found this modification for Rouche’s theorem concerned with the counting of zeros of analytic functions. This is a very useful form of Rouche’s theorem because it makes no mention of a contour.
51.1. ROUČE’S THEOREM AND THE ARGUMENT PRINCIPLE

**Theorem 51.1.6** Let \( \Omega \) be a bounded open set and suppose \( f, g \) are continuous on \( \overline{\Omega} \) and analytic on \( \Omega \). Also suppose \( |f(z)| < |g(z)| \) on \( \partial \Omega \). Then \( f \) and \( f + g \) have the same number of zeros in \( \Omega \) provided each zero is counted according to multiplicity.

**Proof:** Let \( K = \{ z \in \overline{\Omega} : |f(z)| \geq |g(z)| \} \). Then letting \( \lambda \in [0, 1] \), if \( z \notin K \), then \( |f(z)| < |g(z)| \) and so
\[
0 < |g(z)| - |f(z)| \leq |g(z)| - \lambda |f(z)| \leq |g(z) + \lambda f(z)|
\]
which shows that all zeros of \( g + \lambda f \) are contained in \( K \) which must be a compact subset of \( \Omega \) due to the assumption that \( |f(z)| < |g(z)| \) on \( \partial \Omega \). By Theorem 10.7.29 on Page 1064, there exists a cycle, \( \{ \gamma_k \}_{k=1}^n \) such that \( \bigcup_{k=1}^n \gamma_k \subseteq \Omega \setminus K \). Then, letting \( n = \sum_{k=1}^n n(\gamma_k, z) = 1 \) for every \( z \in K \) and \( \sum_{k=1}^n n(\gamma_k, z) = 0 \) for all \( z \notin \Omega \). Then as above, it follows from the residue theorem or more directly, Theorem 10.7.29,
\[
\sum_{k=1}^n \frac{1}{2\pi i} \int_{\gamma_k} \frac{\lambda f'(z) + g'(z)}{\lambda f(z) + g(z)} \, dz = \sum_{j=1}^p m_j
\]
where \( m_j \) is the order of the \( j \)-th zero of \( \lambda f + g \) in \( K \), hence in \( \Omega \). However,
\[
\lambda \to \sum_{k=1}^n \frac{1}{2\pi i} \int_{\gamma_k} \frac{\lambda f'(z) + g'(z)}{\lambda f(z) + g(z)} \, dz
\]
is integer valued and continuous so it gives the same value when \( \lambda = 0 \) as when \( \lambda = 1 \). When \( \lambda = 0 \) this gives the number of zeros of \( g \) in \( \Omega \) and when \( \lambda = 1 \) it is the number of zeros of \( f + g \). This proves the theorem.

Here is another formulation of this theorem.

**Corollary 51.1.7** Let \( \Omega \) be a bounded open set and suppose \( f, g \) are continuous on \( \overline{\Omega} \) and analytic on \( \Omega \). Also suppose \( |f(z) - g(z)| < |g(z)| \) on \( \partial \Omega \). Then \( f \) and \( g \) have the same number of zeros in \( \Omega \) provided each zero is counted according to multiplicity.

**Proof:** You let \( f - g \) play the role of \( f \) in Theorem 10.7.29. Thus \( f - g + f = f \) and \( g \) have the same number of zeros. Alternatively, you can give a proof of this directly as follows.

Let \( K = \{ z \in \Omega : |f(z) - g(z)| \geq |g(z)| \} \). Then if \( g(z) + \lambda (f(z) - g(z)) = 0 \) it follows
\[
0 = |g(z) + \lambda (f(z) - g(z))| \geq |g(z)| - \lambda |f(z) - g(z)|
\]
and so \( z \in K \). Thus all zeros of \( g(z) + \lambda (f(z) - g(z)) \) are contained in \( K \). By Theorem 10.7.29 on Page 1064, there exists a cycle, \( \{ \gamma_k \}_{k=1}^n \) such that \( \bigcup_{k=1}^n \gamma_k \subseteq \Omega \setminus K \). Then, letting \( n = \sum_{k=1}^n n(\gamma_k, z) = 1 \) for every \( z \in K \) and \( \sum_{k=1}^n n(\gamma_k, z) = 0 \) for all \( z \notin \Omega \). Then by Theorem 10.7.29,
\[
\sum_{k=1}^n \frac{1}{2\pi i} \int_{\gamma_k} \frac{\lambda (f'(z) - g'(z)) + g'(z)}{\lambda (f(z) - g(z)) + g(z)} \, dz = \sum_{j=1}^p m_j
\]
where \( m_j \) is the order of the \( j^{th} \) zero of \( \lambda(f - g) + g \) in \( K \), hence in \( \Omega \). The left side is continuous as a function of \( \lambda \) and so the number of zeros of \( g \) corresponding to \( \lambda = 0 \) equals the number of zeros of \( f \) corresponding to \( \lambda = 1 \). This proves the corollary.

### 51.2 Singularities And The Laurent Series

#### 51.2.1 What Is An Annulus?

In general, when you consider singularities, isolated or not, the fundamental tool is the Laurent series. This series is important for many other reasons also. In particular, it is fundamental to the spectral theory of various operators in functional analysis and is one way to obtain relationships between algebraic and analytical conditions essential in various convergence theorems. A Laurent series lives on an annulus. In all this \( f \) has values in \( X \) where \( X \) is a complex Banach space. If you like, let \( X = \mathbb{C} \).

**Definition 51.2.1** Define \( \text{ann} (a, R_1, R_2) \equiv \{ z : R_1 < |z - a| < R_2 \} \).

Thus \( \text{ann} (a, 0, R) \) would denote the punctured ball, \( B(a, R) \setminus \{0\} \) and when \( R_1 > 0 \), the annulus looks like the following.

![Annulus Diagram]

The annulus is the stuff between the two circles.

Here is an important lemma which is concerned with the situation described in the following picture.

![Diagram](images/lemma-diagram.png)

**Lemma 51.2.2** Let \( \gamma_r (t) \equiv a + re^{it} \) for \( t \in [0, 2\pi] \) and let \( |z - a| < r \). Then \( n (\gamma_r, z) = 1 \). If \( |z - a| > r \), then \( n (\gamma_r, z) = 0 \).

**Proof:** For the first claim, consider for \( t \in [0, 1] \),

\[
f(t) = n (\gamma_r, a + t (z - a)).
\]
Then from properties of the winding number derived earlier, \( f(t) \in \mathbb{Z}, f \) is continuous, and \( f(0) = 1 \). Therefore, \( f(t) = 1 \) for all \( t \in [0, 1] \). This proves the first claim because \( f(1) = n(\gamma_r, z) \).

For the second claim,

\[
\begin{align*}
n(\gamma_r, z) &= \frac{1}{2\pi i} \int_{\gamma_r} \frac{1}{w - z} \, dw \\
&= \frac{1}{2\pi i} \int_{\gamma_r} \frac{1}{w - a - (z - a)} \, dw \\
&= \frac{1}{2\pi} \int_{\gamma_r} \frac{1}{1 - \left(\frac{w - a}{z - a}\right)} \, dw \\
&= \frac{-1}{2\pi} \int_{\gamma_r} \sum_{k=0}^{\infty} \left(\frac{w - a}{z - a}\right)^k \, dw.
\end{align*}
\]

The series converges uniformly for \( w \in \gamma_r \), because

\[
\left|\frac{w - a}{z - a}\right| = \frac{r}{r + c}
\]

for some \( c > 0 \) due to the assumption that \( |z - a| > r \). Therefore, the sum and the integral can be interchanged to give

\[
n(\gamma_r, z) = \frac{-1}{2\pi} \int_{\gamma_r} \sum_{k=0}^{\infty} \left(\frac{w - a}{z - a}\right)^k \, dw = 0
\]

because \( w \to \left(\frac{w - a}{z - a}\right)^k \) has an antiderivative. This proves the lemma.

Now consider the following picture which pertains to the next lemma.

**Lemma 51.2.3** Let \( g \) be analytic on ann \((a, R_1, R_2)\). Then if \( \gamma_r(t) \equiv a + re^{it} \) for \( t \in [0, 2\pi] \) and \( r \in (R_1, R_2) \), then \( \int_{\gamma_r} g(z) \, dz \) is independent of \( r \).

**Proof:** Let \( R_1 < r_1 < r_2 < R_2 \) and denote by \( -\gamma_r(t) \) the curve, \( -\gamma_r(t) \equiv a + re^{i(2\pi - t)} \) for \( t \in [0, 2\pi] \). Then if \( z \in B(a, R_1) \), Lemma [12.14] implies both
n \left( \gamma_{r_2}, z \right) \text{ and } n \left( \gamma_{r_1}, z \right) = 1 \text{ and so}
\begin{align*}
n \left( -\gamma_{r_1}, z \right) + n \left( \gamma_{r_2}, z \right) &= -1 + 1 = 0.
\end{align*}

Also if \( z \notin B(a, R_2) \), then Lemma \[51.2.2\] implies \( n \left( \gamma_{r_j}, z \right) = 0 \) for \( j = 1, 2 \).
Therefore, whenever \( z \notin \text{ann} \left( a, R_1, R_2 \right) \), the sum of the winding numbers equals zero.
Therefore, by Theorem \[49.7.19\] applied to the function, \( f(w) = g(z) \left( w - z \right) \)
and \( z \in \text{ann} \left( a, R_1, R_2 \right) \),
\begin{align*}
f(z) \left( n \left( \gamma_{r_2}, z \right) + n \left( -\gamma_{r_1}, z \right) \right) &= 0 \left( n \left( \gamma_{r_2}, z \right) + n \left( -\gamma_{r_1}, z \right) \right) =
\frac{1}{2\pi i} \int_{r_2} g(w) \left( w - z \right) dw - \frac{1}{2\pi i} \int_{r_1} g(w) \left( w - z \right) dw
\end{align*}
which proves the desired result.

51.2.2 The Laurent Series

The Laurent series is like a power series except it allows for negative exponents.
First here is a definition of what is meant by the convergence of such a series.

**Definition 51.2.4** \( \sum_{n=-\infty}^{\infty} a_n \left( z - a \right)^n \) converges if both the series,
\begin{align*}
\sum_{n=0}^{\infty} a_n \left( z - a \right)^n \text{ and } \sum_{n=1}^{\infty} a_{-n} \left( z - a \right)^{-n}
\end{align*}
converge. When this is the case, the symbol, \( \sum_{n=-\infty}^{\infty} a_n \left( z - a \right)^n \) is defined as
\begin{align*}
\sum_{n=0}^{\infty} a_n \left( z - a \right)^n + \sum_{n=1}^{\infty} a_{-n} \left( z - a \right)^{-n}.
\end{align*}

**Lemma 51.2.5** Suppose
\begin{align*}
f(z) &= \sum_{n=-\infty}^{\infty} a_n \left( z - a \right)^n
\end{align*}
for all \( |z - a| \in (R_1, R_2) \). Then both \( \sum_{n=0}^{\infty} a_n \left( z - a \right)^n \) and \( \sum_{n=1}^{\infty} a_{-n} \left( z - a \right)^{-n} \)
converge absolutely and uniformly on \( \left\{ z : r_1 \leq |z - a| \leq r_2 \right\} \) for any \( r_1 < r_2 \) satisfying \( R_1 < r_1 < r_2 < R_2 \).

**Proof:** Let \( R_1 < |w - a| = r_1 - \delta < r_1 \). Then \( \sum_{n=1}^{\infty} a_{-n} \left( w - a \right)^{-n} \) converges and so
\begin{align*}
\lim_{n \rightarrow \infty} |a_{-n}| \left| w - a \right|^{-n} &= \lim_{n \rightarrow \infty} |a_{-n}| \left( r_1 - \delta \right)^{-n} = 0
\end{align*}
which implies that for all \( n \) sufficiently large, 
\[
|a_{-n}|(r_1 - \delta)^{-n} < 1.
\]

Therefore, 
\[
\sum_{n=1}^{\infty} |a_{-n}| |z - a|^{-n} = \sum_{n=1}^{\infty} |a_{-n}| (r_1 - \delta)^{-n} (r_1 - \delta)^n |z - a|^{-n}.
\]

Now for \( |z - a| \geq r_1 \), 
\[
|z - a|^{-n} \leq \frac{1}{r_1^n}
\]
and so for all sufficiently large \( n \)
\[
|a_{-n}| |z - a|^{-n} \leq \frac{(r_1 - \delta)^n}{r_1^n}.
\]

Therefore, by the Weierstrass \( M \) test, the series, \( \sum_{n=1}^{\infty} a_{-n} (z - a)^{-n} \) converges absolutely and uniformly on the set 
\[
\{ z \in \mathbb{C} : |z - a| \geq r_1 \}.
\]

Similar reasoning shows the series, \( \sum_{n=0}^{\infty} a_n (z - a)^n \) converges uniformly on the set 
\[
\{ z \in \mathbb{C} : |z - a| \leq r_2 \}.
\]

This proves the Lemma.

**Theorem 51.2.6** Let \( f \) be analytic on \( \text{ann} (a, R_1, R_2) \). Then there exist numbers, \( a_n \in \mathbb{C} \) such that for all \( z \in \text{ann} (a, R_1, R_2) \),
\[
f (z) = \sum_{n=-\infty}^{\infty} a_n (z - a)^n,
\]
where the series converges absolutely and uniformly on \( \overline{\text{ann} (a, r_1, r_2)} \) whenever \( R_1 < r_1 < r_2 < R_2 \). Also
\[
a_n = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{(w - a)^{n+1}} dw
\]
where \( \gamma (t) = a + re^{it}, t \in [0, 2\pi] \) for any \( r \in (R_1, R_2) \). Furthermore the series is unique in the sense that if \( \forall \gamma_2 \) holds for \( z \in \text{ann} (a, R_1, R_2) \), then \( a_n \) is given in \( \gamma_1 \).

**Proof:** Let \( R_1 < r_1 < r_2 < R_2 \) and define \( \gamma_1 (t) \equiv a + (r_1 - \varepsilon) e^{it} \) and \( \gamma_2 (t) \equiv a + (r_2 + \varepsilon) e^{it} \) for \( t \in [0, 2\pi] \) and \( \varepsilon \) chosen small enough that \( R_1 < r_1 - \varepsilon < r_2 + \varepsilon < R_2 \).
Then using Lemma 51.2.2, if \( z \notin \text{ann} (a, R_1, R_2) \) then

\[
n (-\gamma_1, z) + n (\gamma_2, z) = 0
\]

and if \( z \in \text{ann} (a, r_1, r_2) \),

\[
n (-\gamma_1, z) + n (\gamma_2, z) = 1.
\]

Therefore, by Theorem 49.7.19, for \( z \in \text{ann} (a, r_1, r_2) \)

\[
f (z) = \frac{1}{2\pi i} \left[ \int_{-\gamma_1} f (w) \frac{dw}{w-z} + \int_{\gamma_2} f (w) \frac{dw}{w-z} \right] = \frac{1}{2\pi i} \left[ \int_{\gamma_1} f (w) \frac{dw}{(z-a) \left( 1 - \frac{w-a}{z-a} \right)} + \int_{\gamma_2} f (w) \frac{dw}{(w-a) \left( 1 - \frac{z-a}{w-a} \right)} \right] = \frac{1}{2\pi i} \int_{\gamma_1} f (w) \sum_{n=0}^{\infty} \left( \frac{z-a}{w-a} \right)^n \frac{dw}{(z-a)^n} + \frac{1}{2\pi i} \int_{\gamma_2} f (w) \sum_{n=0}^{\infty} \left( \frac{w-a}{z-a} \right)^n \frac{dw}{(w-a)^n}.
\]

From the formula (51.2.7), it follows that for \( z \in \text{ann} (a, r_1, r_2) \), the terms in the first sum are bounded by an expression of the form \( C \left( \frac{r_2}{r_1+z} \right)^n \) while those in the second are bounded by one of the form \( C \left( \frac{r_1-z}{r_1} \right)^n \) and so by the Weierstrass M test, the convergence is uniform and so the integrals and the sums in the above formula may be interchanged and after renaming the variable of summation, this yields

\[
f (z) = \sum_{n=0}^{\infty} \left( \frac{1}{2\pi i} \int_{\gamma_2} f (w) \frac{dw}{(w-a)^{n+1}} \right) (z-a)^n + \sum_{n=0}^{\infty} \left( \frac{1}{2\pi i} \int_{\gamma_1} f (w) \frac{dw}{(z-a)^{n+1}} \right) (z-a)^n.
\]
\[
\sum_{n=-\infty}^{-1} \left( \frac{1}{2\pi i} \int_{\gamma_1} \frac{f(w)}{(w-a)^{n+1}} \right) (z-a)^n. \tag{51.2.8}
\]

Therefore, by Lemma 51.2.3, for any \( r \in (R_1, R_2) \),
\[
f(z) = \sum_{n=0}^{\infty} \left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f(w)}{(w-a)^{n+1}} \, dw \right) (z-a)^n + \]
\[
\sum_{n=-\infty}^{-1} \left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f(w)}{(w-a)^{n+1}} \right) (z-a)^n. \tag{51.2.9}
\]

and so
\[
f(z) = \sum_{n=-\infty}^{\infty} \left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f(w)}{(w-a)^{n+1}} \, dw \right) (z-a)^n.
\]

where \( r \in (R_1, R_2) \) is arbitrary. This proves the existence part of the theorem. It remains to characterize \( a_n \).

If \( f(z) = \sum_{n=-\infty}^{\infty} a_n (z-a)^n \) on \( \text{ann} (a, R_1, R_2) \) let
\[
f_n(z) = \sum_{k=-n}^{n} a_k (z-a)^k. \tag{51.2.10}
\]

This function is analytic in \( \text{ann} (a, R_1, R_2) \) and so from the above argument,
\[
f_n(z) = \sum_{k=-\infty}^{\infty} \left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f_n(w)}{(w-a)^{k+1}} \, dw \right) (z-a)^k. \tag{51.2.11}
\]

Also if \( k > n \) or if \( k < -n \),
\[
\left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f_n(w)}{(w-a)^{k+1}} \, dw \right) = 0.
\]

and so
\[
f_n(z) = \sum_{k=-\infty}^{n} \left( \frac{1}{2\pi i} \int_{\gamma_r} \frac{f_n(w)}{(w-a)^{k+1}} \, dw \right) (z-a)^k.
\]

which implies from \( \boxed{51.2.11} \) that for each \( k \in [-n, n] \),
\[
\frac{1}{2\pi i} \int_{\gamma_r} \frac{f_n(w)}{(w-a)^{k+1}} \, dw = a_k
\]

However, from the uniform convergence of the series,
\[
\sum_{n=0}^{\infty} a_n (w-a)^n
\]
and
\[ \sum_{n=1}^{\infty} a_n (w-a)^{-n} \]
ensured by Lemma 51.2.5 which allows the interchange of sums and integrals, if \( k \in [-n, n] \),
\[
\frac{1}{2\pi i} \int_{\gamma_r} \frac{f(w)}{(w-a)^{k+1}} dw = \frac{1}{2\pi i} \int_{\gamma_r} \frac{\sum_{m=0}^{\infty} a_m (w-a)^m + \sum_{m=1}^{\infty} a_{-m} (w-a)^{-m}}{(w-a)^{k+1}} dw \\
= \sum_{m=0}^{\infty} a_m \frac{1}{2\pi i} \int_{\gamma_r} (w-a)^{m-(k+1)} dw + \sum_{m=1}^{\infty} a_{-m} \int_{\gamma_r} (w-a)^{-m-(k+1)} dw \\
= \sum_{m=0}^{n} a_m \frac{1}{2\pi i} \int_{\gamma_r} (w-a)^{m-(k+1)} dw + \sum_{m=1}^{n} a_{-m} \int_{\gamma_r} (w-a)^{-m-(k+1)} dw \\
= \frac{1}{2\pi i} \int_{\gamma_r} f_n(w) (w-a)^{k+1} dw \\
\]
because if \( l > n \) or \( l < -n \),
\[
\int_{\gamma_r} a_l (w-a)^l (w-a)^{k+1} dw = 0 \\
\]
for all \( k \in [-n, n] \). Therefore,
\[
a_k = \frac{1}{2\pi i} \int_{\gamma_r} \frac{f(w)}{(w-a)^{k+1}} dw \\
\]
and so this establishes uniqueness. This proves the theorem.

### 51.2.3 Contour Integrals And Evaluation Of Integrals

Here are some examples of hard integrals which can be evaluated by using residues. This will be done by integrating over various closed curves having bounded variation.

**Example 51.2.7** The first example we consider is the following integral.
\[
\int_{-\infty}^{\infty} \frac{1}{1 + x^4} dx 
\]
One could imagine evaluating this integral by the method of partial fractions and it should work out by that method. However, we will consider the evaluation of this integral by the method of residues instead. To do so, consider the following picture.

Let \( \gamma_r(t) = re^{it}, t \in [0, \pi] \) and let \( \sigma_r(t) = t : t \in [-r, r] \). Thus \( \gamma_r \) parameterizes the top curve and \( \sigma_r \) parameterizes the straight line from \(-r\) to \(r\) along the \(x\) axis. Denoting by \( \Gamma_r \) the closed curve traced out by these two, we see from simple estimates that

\[
\lim_{r \to \infty} \int_{\gamma_r} \frac{1}{1 + z^4} dz = 0.
\]

This follows from the following estimate.

\[
\left| \int_{\gamma_r} \frac{1}{1 + z^4} dz \right| \leq \frac{1}{r^4 - 1} \pi r.
\]

Therefore,

\[
\int_{-\infty}^{\infty} \frac{1}{1 + x^4} dx = \lim_{r \to \infty} \int_{\Gamma_r} \frac{1}{1 + z^4} dz.
\]

We compute \( \int_{\Gamma_r} \frac{1}{1 + z^4} dz \) using the method of residues. The only residues of the integrand are located at points, \( z \) where \( 1 + z^4 = 0 \). These points are

\[
z = -\frac{1}{2} \sqrt{2} - \frac{1}{2} i\sqrt{2}, z = \frac{1}{2} \sqrt{2} - \frac{1}{2} i\sqrt{2},
\]

\[
z = \frac{1}{2} \sqrt{2} + \frac{1}{2} i\sqrt{2}, z = -\frac{1}{2} \sqrt{2} + \frac{1}{2} i\sqrt{2}
\]

and it is only the last two which are found in the inside of \( \Gamma_r \). Therefore, we need to calculate the residues at these points. Clearly this function has a pole of order one at each of these points and so we may calculate the residue at \( \alpha \) in this list by evaluating

\[
\lim_{z \to \alpha} (z - \alpha) \frac{1}{1 + z^4}
\]
Thus
\[
\text{Res}\left(f, \frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}\right) = \lim_{z \to \frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}} \left(z - \left(\frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}\right)\right) \frac{1}{1 + z^4} = -\frac{1}{8} \sqrt{2} - \frac{1}{8} i \sqrt{2}.
\]
Similarly we may find the other residue in the same way
\[
\text{Res}\left(f, -\frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}\right) = \lim_{z \to -\frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}} \left(z - \left(-\frac{1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2}\right)\right) \frac{1}{1 + z^4} = -\frac{1}{8} i \sqrt{2} + \frac{1}{8} \sqrt{2}.
\]
Therefore,
\[
\int_{\Gamma_r} \frac{1}{1 + z^4} dz = 2\pi i \left(-\frac{1}{8} i \sqrt{2} + \frac{1}{8} \sqrt{2} + \left(-\frac{1}{8} \sqrt{2} - \frac{1}{8} i \sqrt{2}\right)\right) = \frac{1}{2} \pi \sqrt{2}.
\]
Thus, taking the limit we obtain \(\frac{1}{2} \pi \sqrt{2} = \int_{-\infty}^{\infty} \frac{1}{1 + x^4} dx\).

Obviously many different variations of this are possible. The main idea being that the integral over the semicircle converges to zero as \(r \to \infty\).

Sometimes we don’t blow up the curves and take limits. Sometimes the problem of interest reduces directly to a complex integral over a closed curve. Here is an example of this.

**Example 51.2.8** The integral is
\[
\int_0^\pi \frac{\cos \theta}{2 + \cos \theta} d\theta
\]
This integrand is even and so it equals
\[
\frac{1}{2} \int_{-\pi}^\pi \frac{\cos \theta}{2 + \cos \theta} d\theta.
\]
For \(z\) on the unit circle, \(z = e^{i\theta}\), \(\pi = \frac{1}{2}\) and therefore, \(\cos \theta = \frac{1}{2}\left(z + \frac{1}{z}\right)\). Thus \(dz = i e^{i\theta} d\theta\) and so \(d\theta = \frac{dz}{i z}\). Note this is proceeding formally to get a complex integral which reduces to the one of interest. It follows that a complex integral which reduces to the one desired is
\[
\frac{1}{2i} \int_{\gamma} \frac{\frac{1}{2} \left(z + \frac{1}{z}\right)}{2 + \frac{1}{2} \left(z + \frac{1}{z}\right)} \frac{dz}{z} = \frac{1}{2i} \int_{\gamma} \frac{z^2 + 1}{z (4z + z^2 + 1)} dz
\]
where $\gamma$ is the unit circle. Now the integrand has poles of order 1 at those points where $z \left( 4z + z^2 + 1 \right) = 0$. These points are

$$0, -2 + \sqrt{3}, -2 - \sqrt{3}.$$  

Only the first two are inside the unit circle. It is also clear the function has simple poles at these points. Therefore,

$$\text{Res} \left( f, 0 \right) = \lim_{z \to 0} z \left( \frac{z^2 + 1}{z \left( 4z + z^2 + 1 \right)} \right) = 1.$$  

$$\text{Res} \left( f, -2 + \sqrt{3} \right) = \lim_{z \to -2 + \sqrt{3}} \left( z - (-2 + \sqrt{3}) \right) \frac{z^2 + 1}{z \left( 4z + z^2 + 1 \right)} = -\frac{2}{3}\sqrt{3}.$$  

It follows

$$\int_0^\pi \frac{\cos \theta}{2 + \cos \theta} \, d\theta = \frac{1}{2i} \int_{\gamma} \frac{z^2 + 1}{z \left( 4z + z^2 + 1 \right)} \, dz = \frac{1}{2i} \left( 1 - \frac{2}{3}\sqrt{3} \right) = \pi \left( 1 - \frac{2}{3}\sqrt{3} \right).$$  

Other rational functions of the trig functions will work out by this method also.

Sometimes you have to be clever about which version of an analytic function that reduces to a real function you should use. The following is such an example.

**Example 51.2.9** The integral here is

$$\int_0^\infty \frac{\ln x}{1 + x^4} \, dx.$$  

The same curve used in the integral involving $\frac{\sin x}{x}$ earlier will create problems with the log since the usual version of the log is not defined on the negative real axis. This does not need to be of concern however. Simply use another branch of the logarithm. Leave out the ray from 0 along the negative $y$ axis and use Theorem \ref{thm:50.2.3} to define $L(z)$ on this set. Thus $L(z) = \ln |z| + i \arg_1(z)$ where $\arg_1(z)$ will be the angle, $\theta$, between $-\frac{\pi}{2}$ and $\frac{3\pi}{2}$ such that $z = |z| e^{i\theta}$. Now the only singularities contained in this curve are

$$\frac{1}{2}\sqrt{2} + \frac{1}{2}i\sqrt{2}, \quad -\frac{1}{2}\sqrt{2} + \frac{1}{2}i\sqrt{2}$$  

and the integrand, $f$ has simple poles at these points. Thus using the same procedure as in the other examples,

$$\text{Res} \left( f, \frac{1}{2}\sqrt{2} + \frac{1}{2}i\sqrt{2} \right) = \ldots$$
and
\[ \text{Res} \left( f, \frac{-1}{2} \sqrt{2} + \frac{1}{2} i \sqrt{2} \right) = \frac{3}{32} \sqrt{2} \pi + \frac{3}{32} i \sqrt{2} \pi. \]

Consider the integral along the small semicircle of radius \( r \). This reduces to
\[ \int_0^\infty \ln |r| + i t \frac{dt}{1 + (r e^{it})^4} \]
which clearly converges to zero as \( r \to 0 \) because \( r \ln r \to 0 \). Therefore, taking the limit as \( r \to 0 \),
\[ \int_{\text{large semicircle}} \frac{L(z)}{1 + z^4} \frac{dz}{2i} = \lim_{R \to \infty} \int_{-R}^{-\infty} \frac{\ln(-t) + i \pi}{1 + t^4} \frac{dt}{1 + t^4} + \lim_{r \to 0^+} \int_r^R \frac{\ln t}{1 + t^4} \frac{dt}{1 + t^4} = 2 \pi i \left( \frac{3}{32} \sqrt{2} \pi + \frac{3}{32} i \sqrt{2} \pi + \frac{1}{32} \sqrt{2} \pi - \frac{1}{32} i \sqrt{2} \pi \right). \]

Observing that \( \int_{\text{large semicircle}} \frac{L(z)}{1 + z^4} \frac{dz}{2i} \to 0 \) as \( R \to \infty \),
\[ e(R) + 2 \lim_{r \to 0^+} \int_r^R \frac{\ln t}{1 + t^4} dt + i \pi \left[ \frac{1}{1 + t^4} \right]_0^\infty = \left( -\frac{1}{8} + \frac{1}{4} i \right) \pi^2 \sqrt{2} \]
where \( e(R) \to 0 \) as \( R \to \infty \). From an earlier example this becomes
\[ e(R) + 2 \lim_{r \to 0^+} \int_r^R \frac{\ln t}{1 + t^4} dt + i \pi \left( \frac{\sqrt{2}}{4} \pi \right) = \left( -\frac{1}{8} + \frac{1}{4} i \right) \pi^2 \sqrt{2}. \]

Now letting \( r \to 0^+ \) and \( R \to \infty \),
\[ 2 \int_0^\infty \frac{\ln t}{1 + t^4} dt = \left( -\frac{1}{8} + \frac{1}{4} i \right) \pi^2 \sqrt{2} - i \pi \left( \frac{\sqrt{2}}{4} \pi \right) = -\frac{1}{8} \sqrt{2} \pi^2, \]
and so
\[ \int_0^\infty \frac{\ln t}{1 + t^4} dt = -\frac{1}{16} \sqrt{2} \pi^2, \]
which is probably not the first thing you would think of. You might try to imagine how this could be obtained using elementary techniques.

The next example illustrates the use of what is referred to as a branch cut. It includes many examples.
Example 51.2.10  Mellin transformations are of the form

\[ \int_0^{\infty} f(x) x^\alpha \frac{dx}{x}. \]

Sometimes it is possible to evaluate such a transform in terms of the constant, \( \alpha \).

Assume \( f \) is an analytic function except at isolated singularities, none of which are on \((0, \infty)\). Also assume that \( f \) has the growth conditions,

\[ |f(z)| \leq \frac{C}{|z|^b}, \quad b > \alpha \]

for all large \( |z| \) and assume that

\[ |f(z)| \leq \frac{C'}{|z|^{b_1}}, \quad b_1 < \alpha \]

for all \( |z| \) sufficiently small. It turns out there exists an explicit formula for this Mellin transformation under these conditions. Consider the following contour.

In this contour the small semicircle in the center has radius \( \varepsilon \) which will converge to 0. Denote by \( \gamma_R \) the large circular path which starts at the upper edge of the slot and continues to the lower edge. Denote by \( \gamma_\varepsilon \) the small semicircular contour and denote by \( \gamma_{\varepsilon R^+} \) the straight part of the contour from 0 to \( R \) which provides the top edge of the slot. Finally denote by \( \gamma_{\varepsilon R^-} \) the straight part of the contour from \( R \) to 0 which provides the bottom edge of the slot. The interesting aspect of this problem is the definition of \( f(z) z^{\alpha-1} \). Let

\[ z^{\alpha-1} = e^{(\ln|z|+i\arg(z))(\alpha-1)} = e^{(\alpha-1)\log(z)} \]
where \( \arg(z) \) is the angle of \( z \) in \((0, 2\pi)\). Thus you use a branch of the logarithm which is defined on \( \mathbb{C} \setminus (0, \infty) \). Then it is routine to verify from the assumed estimates that

\[
\lim_{R \to \infty} \int_{\gamma_R} f(z) z^{a-1} \, dz = 0
\]

and

\[
\lim_{\varepsilon \to 0^+} \int_{\gamma_{\varepsilon}} f(z) z^{a-1} \, dz = 0.
\]

Also, it is routine to verify

\[
\lim_{\varepsilon \to 0^+} \int_{\gamma_{\varepsilon} R^+} f(z) z^{a-1} \, dz = \int_0^R f(x) x^{a-1} \, dx
\]

and

\[
\lim_{\varepsilon \to 0^+} \int_{\gamma_{\varepsilon} R^-} f(z) z^{a-1} \, dz = -e^{i2\pi(a-1)} \int_0^R f(x) x^{a-1} \, dx.
\]

Therefore, letting \( \Sigma_R \) denote the sum of the residues of \( f(z) z^{a-1} \) which are contained in the disk of radius \( R \) except for the possible residue at 0,

\[
e(R) + \left(1 - e^{i2\pi(a-1)}\right) \int_0^R f(x) x^{a-1} \, dx = 2\pi i \Sigma_R
\]

where \( e(R) \to 0 \) as \( R \to \infty \). Now letting \( R \to \infty \),

\[
\lim_{R \to \infty} \int_0^R f(x) x^{a-1} \, dx = \frac{2\pi i}{1 - e^{i2\pi(a-1)}} \Sigma = \frac{\pi e^{-\pi i a}}{\sin(\pi a)} \Sigma
\]

where \( \Sigma \) denotes the sum of all the residues of \( f(z) z^{a-1} \) except for the residue at 0.

The next example is similar to the one on the Mellin transform. In fact it is a Mellin transform but is worked out independently of the above to emphasize a slightly more informal technique related to the contour.

**Example 51.2.11** \( \int_0^\infty \frac{x^{p-1}}{1 + x} \, dx, \ p \in (0, 1) \).

Since the exponent of \( x \) in the numerator is larger than \(-1\). The integral does converge. However, the techniques of real analysis don’t tell us what it converges to. The contour to be used is as follows: From \((\varepsilon, 0)\) to \((r, 0)\) along the \( x \) axis and then from \((r, 0)\) to \((r, 0)\) counter clockwise along the circle of radius \( r \), then from \((r, 0)\) to \((\varepsilon, 0)\) along the \( x \) axis and from \((\varepsilon, 0)\) to \((\varepsilon, 0)\) clockwise along the circle of radius \( \varepsilon \). You should draw a picture of this contour. The interesting thing about this is that \( z^{p-1} \) cannot be defined all the way around 0. Therefore, use a branch of \( z^{p-1} \) corresponding to the branch of the logarithm obtained by deleting the positive \( x \) axis. Thus

\[
z^{p-1} = e^{i(\ln|z| + iA(z))(p-1)}
\]
where \( z = |z| e^{iA(z)} \) and \( A(z) \in (0, 2\pi) \). Along the integral which goes in the positive direction on the \( x \) axis, let \( A(z) = 0 \) while on the one which goes in the negative direction, take \( A(z) = 2\pi \). This is the appropriate choice obtained by replacing the line from \((\varepsilon, 0)\) to \((r, 0)\) with two lines having a small gap joined by a circle of radius \( \varepsilon \) and then taking a limit as the gap closes. You should verify that the two integrals taken along the circles of radius \( \varepsilon \) and \( r \) converge to 0 as \( \varepsilon \to 0 \) and as \( r \to \infty \). Therefore, taking the limit,

\[
\int_0^\infty \frac{x^{p-1}}{1+x} \, dx + \int_0^\infty \frac{x^{p-1}}{1+x} \left( e^{2\pi i(p-1)} \right) \, dx = 2\pi i \text{Res} (f, -1) .
\]

Calculating the residue of the integrand at \(-1\), and simplifying the above expression,

\[
\left(1 - e^{2\pi i(p-1)}\right) \int_0^\infty \frac{x^{p-1}}{1+x} \, dx = 2\pi i e^{(p-1)i\pi} .
\]

Upon simplification

\[
\int_0^\infty \frac{x^{p-1}}{1+x} \, dx = \frac{\pi}{\sin p\pi} .
\]

**Example 51.2.12** The Fresnel integrals are

\[
\int_0^\infty \cos (x^2) \, dx, \quad \int_0^\infty \sin (x^2) \, dx.
\]

To evaluate these integrals consider \( f(z) = e^{iz^2} \) on the curve which goes from the origin to the point \( r \) on the \( x \) axis and from this point to the point \( r \left( \frac{1+i}{\sqrt{2}} \right) \) along a circle of radius \( r \), and from there back to the origin as illustrated in the following picture.

Thus the curve to integrate over is shaped like a slice of pie. Denote by \( \gamma_r \) the
curved part. Since $f$ is analytic,

$$0 = \int_{\gamma_r} e^{iz^2} \, dz + \int_0^r e^{ix^2} \, dx - \int_0^r e^{i(\frac{t^2}{2})} \left( \frac{1 + i}{\sqrt{2}} \right) dt$$

$$= \int_{\gamma_r} e^{iz^2} \, dz + \int_0^r e^{ix^2} \, dx - \int_0^r e^{-t^2} \left( \frac{1 + i}{\sqrt{2}} \right) dt$$

$$= \int_{\gamma_r} e^{iz^2} \, dz + \int_0^r e^{ix^2} \, dx - \frac{\sqrt{\pi}}{2} \left( \frac{1 + i}{\sqrt{2}} \right) + e(r)$$

where $e(r) \to 0$ as $r \to \infty$. Here we used the fact that $\int_0^\infty e^{-t^2} \, dt = \frac{\sqrt{\pi}}{2}$. Now consider the first of these integrals.

$$\left| \int_{\gamma_r} e^{iz^2} \, dz \right| = \left| \int_0^{\frac{\pi}{4}} e^{i(r \cos^2 t)} \, rie^{it} \, dt \right|$$

$$\leq r \int_0^{\frac{\pi}{4}} e^{-r \sin 2t} \, dt$$

$$= \frac{r}{2} \int_0^1 e^{-ru} \, du$$

$$\leq \frac{r}{2} \int_0^{r^{-3/2}} \frac{1}{\sqrt{1-u^2}} \, du + \frac{r}{2} \left( \int_0^1 \frac{1}{\sqrt{1-u^2}} \right) e^{-(r^{1/2})}$$

which converges to zero as $r \to \infty$. Therefore, taking the limit as $r \to \infty$,

$$\frac{\sqrt{\pi}}{2} \left( \frac{1 + i}{\sqrt{2}} \right) = \int_0^\infty e^{ix^2} \, dx$$

and so

$$\int_0^\infty \sin x^2 \, dx = \frac{\sqrt{\pi}}{2\sqrt{2}} = \int_0^\infty \cos x^2 \, dx.$$ 

The following example is one of the most interesting. By an auspicious choice of the contour it is possible to obtain a very interesting formula for $\cot \pi z$ known as the Mittag-Leffler expansion of $\cot \pi z$.

**Example 51.2.13** Let $\gamma_N$ be the contour which goes from $-N - \frac{1}{2} - Ni$ horizontally to $N + \frac{1}{2} - Ni$ and from there, vertically to $N + \frac{1}{2} + Ni$ and then horizontally to $-N - \frac{1}{2} + Ni$. Thus the contour is a large rectangle and the direction of integration is in the counter clockwise direction. Consider the following integral.

$$I_N = \int_{\gamma_N} \frac{\pi \cos \pi z}{\sin \pi z} \, dz$$

where $\alpha \in \mathbb{R}$ is not an integer. This will be used to verify the formula of Mittag-Leffler,

$$\frac{1}{\alpha^2} + \sum_{n=1}^\infty \frac{2}{\alpha^2 - n^2} = \frac{\pi \cot \pi \alpha}{\alpha}. \quad (51.2.12)$$
You should verify that \( \cot \pi z \) is bounded on this contour and that therefore, \( I_N \to 0 \) as \( N \to \infty \). Now you compute the residues of the integrand at \( \pm \alpha \) and at \( n \) where \( |n| < N + \frac{1}{2} \) for \( n \) an integer. These are the only singularities of the integrand in this contour and therefore, you can evaluate \( I_N \) by using these. It is left as an exercise to calculate these residues and find that the residue at \( \pm \alpha \) is

\[
\frac{-\pi \cos \pi \alpha}{2\alpha \sin \pi \alpha}
\]

while the residue at \( n \) is

\[
\frac{1}{\alpha^2 - n^2}.
\]

Therefore,

\[
0 = \lim_{N \to \infty} I_N = \lim_{N \to \infty} 2\pi i \left[ \sum_{n=-N}^{N} \frac{1}{\alpha^2 - n^2} - \frac{\pi \cot \pi \alpha}{\alpha} \right]
\]

which establishes the following formula of Mittag Leffler.

\[
\lim_{N \to \infty} \sum_{n=-N}^{N} \frac{1}{\alpha^2 - n^2} = \frac{\pi \cot \pi \alpha}{\alpha}.
\]

Writing this in a slightly nicer form, yields 51.2.12.

### 51.3 Exercises

1. Example 51.2.7 found the integral of a rational function of a certain sort. The technique used in this example typically works for rational functions of the form \( \frac{f(x)}{g(x)} \) where \( \deg(g(x)) \geq \deg(f(x)) + 2 \) provided the rational function has no poles on the real axis. State and prove a theorem based on these observations.

2. Fill in the missing details of Example 51.2.13 about \( I_N \to 0 \). Note how important it was that the contour was chosen just right for this to happen. Also verify the claims about the residues.

3. Suppose \( f \) has a pole of order \( m \) at \( z = a \). Define \( g(z) \) by

\[
g(z) = (z - a)^m f(z).
\]

Show

\[
\text{Res}(f, a) = \frac{1}{(m-1)!} g^{(m-1)}(a).
\]

**Hint:** Use the Laurent series.
4. Give a proof of Theorem 51.1. \textbf{Hint:} Let $p$ be a pole. Show that near $p$, a pole of order $m$,

$$
\frac{f'(z)}{f(z)} = \frac{-m + \sum_{k=1}^{\infty} b_k (z-p)^k}{(z-p) + \sum_{k=2}^{\infty} c_k (z-p)^k}
$$

Show that $\text{Res}(f, p) = -m$. Carry out a similar procedure for the zeros.

5. Use Rouche’s theorem to prove the fundamental theorem of algebra which says that if $p(z) = z^n + a_{n-1}z^{n-1} + \cdots + a_1 z + a_0$, then $p$ has $n$ zeros in $\mathbb{C}$. \textbf{Hint:} Let $q(z) = -z^n$ and let $\gamma$ be a large circle, $\gamma(t) = re^{it}$ for $r$ sufficiently large.

6. Consider the two polynomials $z^5 + 3z^2 - 1$ and $z^5 + 3z^2$. Show that on $|z| = 1$, the conditions for Rouche’s theorem hold. Now use Rouche’s theorem to verify that $z^5 + 3z^2 - 1$ must have two zeros in $|z| < 1$.

7. Consider the polynomial, $z^{11} + 7z^5 + 3z^2 - 17$. Use Rouche’s theorem to find a bound on the zeros of this polynomial. In other words, find $r$ such that if $z$ is a zero of the polynomial, $|z| < r$. Try to make $r$ fairly small if possible.

8. Verify that $\int_0^{\infty} e^{-t^2} dt = \frac{\sqrt{\pi}}{2}$. \textbf{Hint:} Use polar coordinates.

9. Use the contour described in Example 51.2.7 to compute the exact values of the following improper integrals.

(a) $\int_{-\infty}^{\infty} \frac{x^2}{(x^2 + 4x + 13)^2} dx$

(b) $\int_0^{\infty} \frac{x^2}{(x^2 + a^2)^2} dx$

(c) $\int_{-\infty}^{\infty} \frac{dx}{(x^2 + a^2)(x^2 + b^2)}$, $a, b > 0$

10. Evaluate the following improper integrals.

(a) $\int_0^{\infty} \frac{\cos ax}{(x^2 + a^2)^2} dx$

(b) $\int_0^{\infty} \frac{x \sin x}{(x^2 + a^2)^2} dx$

11. Find the Cauchy principle value of the integral

$$
\int_{-\infty}^{\infty} \frac{\sin x}{(x^2 + 1)(x - 1)} dx
$$

defined as

$$
\lim_{\varepsilon \to 0^+} \left( \int_{-\infty}^{1-\varepsilon} \frac{\sin x}{(x^2 + 1)(x - 1)} dx + \int_{1+\varepsilon}^{\infty} \frac{\sin x}{(x^2 + 1)(x - 1)} dx \right).
$$

12. Find a formula for the integral $\int_{-\infty}^{\infty} \frac{dx}{(1+x^2)^{n+1}}$ where $n$ is a nonnegative integer.
13. Find \( \int_{-\infty}^{\infty} \frac{\sin^2 x}{x^2} \, dx \).

14. If \( m < n \) for \( m \) and \( n \) integers, show

\[
\int_0^{\infty} \frac{x^{2m}}{1 + x^{2n}} \, dx = \frac{\pi}{2n} \sin \left( \frac{2m+1}{2n} \pi \right).
\]

15. Find \( \int_{-\infty}^{\infty} \frac{1}{(1+x^4)^2} \, dx \).

16. Find \( \int_0^{\infty} \frac{\ln(x)}{1+x^2} \, dx = 0 \).

17. Suppose \( f \) has an isolated singularity at \( \alpha \). Show the singularity is essential if and only if the principal part of the Laurent series of \( f \) has infinitely many terms. That is, show \( f(z) = \sum_{k=0}^{\infty} a_k (z - \alpha)^k + \sum_{k=1}^{\infty} b_k \frac{1}{(z-\alpha)^k} \) where infinitely many of the \( b_k \) are nonzero.

18. Suppose \( \Omega \) is a bounded open set and \( f_n \) is analytic on \( \Omega \) and continuous on \( \overline{\Omega} \). Suppose also that \( f_n \to f \) uniformly on \( \overline{\Omega} \) and that \( f \neq 0 \) on \( \partial \Omega \). Show that for all \( n \) large enough, \( f_n \) and \( f \) have the same number of zeros on \( \Omega \) provided the zeros are counted according to multiplicity.
Chapter 52

Some Important Functional Analysis Applications

52.1 The Spectral Radius Of A Bounded Linear Transformation

As a very important application of the theory of Laurent series, I will give a short description of the spectral radius. This is a fundamental result which must be understood in order to prove convergence of various important numerical methods such as the Gauss Seidel or Jacobi methods.

Definition 52.1.1 Let $X$ be a complex Banach space and let $A \in \mathcal{L}(X, X)$. Then

$$r(A) = \left\{ \lambda \in \mathbb{C} : (\lambda I - A)^{-1} \in \mathcal{L}(X, X) \right\}$$

This is called the resolvent set. The spectrum of $A$, denoted by $\sigma(A)$ is defined as all the complex numbers which are not in the resolvent set. Thus

$$\sigma(A) = \mathbb{C} \setminus r(A)$$

Lemma 52.1.2 $\lambda \in r(A)$ if and only if $\lambda I - A$ is one to one and onto $X$. Also if $|\lambda| > ||A||$, then $\lambda \in \sigma(A)$. If the Neumann series,

$$\frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^{k}$$

converges, then

$$\frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^{k} = (\lambda I - A)^{-1}.$$
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

**Proof:** Note that to be in \( r(A) \), \( \lambda I - A \) must be one to one and map \( X \) onto \( X \) since otherwise, \((\lambda I - A)^{-1} \notin \mathcal{L}(X, X)\).

By the open mapping theorem, if these two algebraic conditions hold, then \((\lambda I - A)^{-1}\) is continuous and so this proves the first part of the lemma. Now suppose \(|\lambda| > ||A||\). Consider the Neumann series

\[
\frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^k.
\]

By the root test, Theorem 49.1.3 on Page 1646 this series converges to an element of \( \mathcal{L}(X, X) \) denoted here by \( B \). Now suppose the series converges. Letting \( B_n \equiv \frac{1}{\lambda} \sum_{k=0}^{n} \left( \frac{A}{\lambda} \right)^k \),

\[
(\lambda I - A) B_n = B_n (\lambda I - A) = \sum_{k=0}^{n} \left( \frac{A}{\lambda} \right)^k - \sum_{k=0}^{n-1} \left( \frac{A}{\lambda} \right)^{k+1}
\]

as \( n \to \infty \) because the convergence of the series requires the \( n^{th} \) term to converge to 0. Therefore,

\[
(\lambda I - A) B = B (\lambda I - A) = I
\]

which shows \( \lambda I - A \) is both one to one and onto and the Neumann series converges to \((\lambda I - A)^{-1}\). This proves the lemma.

This lemma also shows that \( \sigma(A) \) is bounded. In fact, \( \sigma(A) \) is closed.

**Lemma 52.1.3** \( r(A) \) is open. In fact, if \( \lambda \in r(A) \) and \(|\mu - \lambda| < \left| (\lambda I - A)^{-1} \right| ^{-1} \), then \( \mu \in r(A) \).

**Proof:** First note

\[
(\mu I - A) = \left( I - (\lambda - \mu) (\lambda I - A)^{-1} \right) (\lambda I - A) \quad (52.1.1)
\]

\[
= (\lambda I - A) \left( I - (\lambda - \mu) (\lambda I - A)^{-1} \right) \quad (52.1.2)
\]

Also from the assumption about \(|\lambda - \mu|\),

\[
\left| (\lambda - \mu) (\lambda I - A)^{-1} \right| \leq |\lambda - \mu| \left| (\lambda I - A)^{-1} \right| < 1
\]

and so by the root test,

\[
\sum_{k=0}^{\infty} \left( (\lambda - \mu) (\lambda I - A)^{-1} \right)^k
\]
52.1. THE SPECTRAL RADIUS OF A BOUNDED LINEAR TRANSFORMATION

converges to an element of \( \mathcal{L}(X, X) \). As in Lemma

\[
\sum_{k=0}^{\infty} \left( (\lambda - \mu) (\lambda I - A)^{-1} \right)^k = \left( I - (\lambda - \mu) (\lambda I - A)^{-1} \right)^{-1}.
\]

Therefore, from Lemma

\[
(\mu I - A)^{-1} = (\lambda I - A)^{-1} \left( I - (\lambda - \mu) (\lambda I - A)^{-1} \right)^{-1}.
\]

This proves the lemma.

Corollary 52.1.4 \( \sigma(A) \) is a compact set.

Proof: Lemma shows \( \sigma(A) \) is bounded and Lemma shows it is closed.

Definition 52.1.5 The spectral radius, denoted by \( \rho(A) \) is defined by

\[
\rho(A) \equiv \max \{ |\lambda| : \lambda \in \sigma(A) \}.
\]

Since \( \sigma(A) \) is compact, this maximum exists. Note from Lemma, \( \rho(A) \leq \|A\| \).

There is a simple formula for the spectral radius.

Lemma 52.1.6 If \( |\lambda| > \rho(A) \), then the Neumann series,

\[
\frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^k
\]

converges.

Proof: This follows directly from Theorem on Page and the observation above that \( \frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^k = (\lambda I - A)^{-1} \) for all \( |\lambda| > \|A\| \). Thus the analytic function, \( \lambda \to (\lambda I - A)^{-1} \) has a Laurent expansion on \( |\lambda| > \rho(A) \) by Theorem and it must coincide with \( \frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^k \) on \( |\lambda| > \|A\| \) so the Laurent expansion of \( \lambda \to (\lambda I - A)^{-1} \) must equal \( \frac{1}{\lambda} \sum_{k=0}^{\infty} \left( \frac{A}{\lambda} \right)^k \) on \( |\lambda| > \rho(A) \). This proves the lemma.

The theorem on the spectral radius follows. It is due to Gelfand.

Theorem 52.1.7 \( \rho(A) = \lim_{n \to \infty} \|A^n\|^{1/n} \).

Proof: If

\[
|\lambda| < \lim \sup_{n \to \infty} \|A^n\|^{1/n}
\]
then by the root test, the Neumann series does not converge and so by Lemma 52.1.6
\[ \rho(A) \geq \lim sup_{n \to \infty} ||A^n||^{1/n} . \]

Now let \( p \) be a positive integer. Then \( \lambda \in \sigma(A) \) implies \( \lambda^p \in \sigma(A^p) \) because
\[
\lambda^p I - A^p = (\lambda I - A) \left( \lambda^{p-1} + \lambda^{p-2}A + \cdots + A^{p-1} \right)
= \left( \lambda^{p-1} + \lambda^{p-2}A + \cdots + A^{p-1} \right) (\lambda I - A).
\]
It follows from Lemma 52.1.2 applied to \( A^p \) that for \( \lambda \in \sigma(A), |\lambda^p| \leq ||A^p|| \) and so
\[ \rho(A) \leq ||A^p||^{1/p} \]
and since \( p \) is arbitrary,
\[
\lim inf_{p \to \infty} ||A^p||^{1/p} \geq \rho(A) \geq \lim sup_{n \to \infty} ||A^n||^{1/n} .
\]
This proves the theorem.

52.2 Analytic Semigroups

52.2.1 Sectorial Operators And Analytic Semigroups

With the theory of functions of a complex variable, it is time to consider the notion of analytic semigroups. These are better than continuous semigroups. I am mostly following the presentation in Henry [57]. In what follows \( H \) will be a Banach space unless specified to be a Hilbert space.

**Definition 52.2.1** Let \( \phi < \pi/2 \) and for \( a \in \mathbb{R} \), let \( S_{a\phi} \) denote the sector in the complex plane
\[ \{ z \in \mathbb{C} \setminus \{a\} : |\arg(z - a)| \leq \pi - \phi \} \]
This sector is as shown below.

\[
\begin{align*}
\phi & \quad S_{a\phi} \\
& \quad a
\end{align*}
\]
A closed, densely defined linear operator, $A$ is called sectorial if for some sector as described above, it follows that for all $\lambda \in S_a\phi$,

$$(\lambda I - A)^{-1} \in \mathcal{L}(H, H)$$

and for some $M$ it satisfies

$$\left\| (\lambda I - A)^{-1} \right\| \leq \frac{M}{|\lambda - a|}$$

To begin with it is interesting to have a perturbation theorem for sectorial operators. First note that for $\lambda \in S_a\phi$,

$$A(\lambda I - A)^{-1} = -I + \lambda (\lambda I - A)^{-1}$$

**Proposition 52.2.2** Suppose $A$ is a sectorial operator as defined above so it is a densely defined closed operator on $D(A) \subseteq H$ which satisfies

$$\left\| A(\lambda I - A)^{-1} \right\| \leq C$$

(52.2.3)

whenever $|\lambda|$, $\lambda \in S_a\phi$, is sufficiently large and suppose $B$ is a densely defined closed operator such that $D(B) \supseteq D(A)$ and for all $x \in D(A)$,

$$\|Bx\| \leq \varepsilon \|Ax\| + K \|x\|$$

(52.2.4)

where $\varepsilon C < 1$. Then $A + B$ is also sectorial.

**Proof:** I need to consider $(\lambda I - (A + B))^{-1}$. This equals

$$\left( (\lambda I - A)^{-1} - (\lambda I - A)^{-1} (\lambda I - B) \right)^{-1}.$$  (52.2.5)

The issue is whether this makes any sense for all $\lambda \in S_b\phi$ for some $b \in \mathbb{R}$. Let $b > a$ be very large so that if $\lambda \in S_b\phi$, then (52.2.3) holds. Then from (52.2.5) it follows that for $\|x\| \leq 1$,

$$\left\| B(\lambda I - A)^{-1} x \right\| \leq \varepsilon \left\| A(\lambda I - A)^{-1} x \right\| + K \left\| (\lambda I - A)^{-1} x \right\|$$

and so if $b$ is made still larger, it follows this is less than $r < 1$ for all $\|x\| \leq 1$. Therefore, for such $b$,

$$\left( (I - B(\lambda I - A)^{-1}) \right)^{-1}$$

exists and so for such $b$, the expression in (52.2.5) makes sense and equals

$$(\lambda I - A)^{-1} \left( (I - B(\lambda I - A)^{-1}) \right)^{-1}$$
and furthermore,

\[
\left\| (\lambda I - A)^{-1} \left( I - B (\lambda I - A)^{-1} \right)^{-1} \right\| \leq \frac{M}{|\lambda - a|} \frac{1}{1 - r} \leq \frac{M'}{|\lambda - b|}
\]

by adjusting the constants because

\[
\frac{M}{|\lambda - a|} \frac{|\lambda - b|}{1 - r}
\]

is bounded for \( \lambda \in S_{b, \phi} \). This proves the proposition.

It is an interesting proposition because when you have compact embeddings, such inequalities tend to hold.

**Definition 52.2.3** Let \( \varepsilon > 0 \) and for a sectorial operator as defined above, let the contour \( \gamma_{\varepsilon, \phi} \) be as shown next where the orientation is also as shown by the arrow.

The little circle has radius \( \varepsilon \) in the above contour.

**Definition 52.2.4** For \( t \in S^0_{0(\phi + \pi/2)} \) the open sector shown in the following picture,
52.2. ANALYTIC SEMIGROUPS

Define

\begin{equation}
S(t) = \frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} (\lambda I - A)^{-1} d\lambda \tag{52.2.6}
\end{equation}

where \(\varepsilon\) is chosen such that \(t\) is a positive distance from the set of points included in \(\gamma_{\varepsilon, \phi}\). The situation is described by the following picture which shows \(S_{0}(\phi + \pi/2)\) and \(S_{0}\phi\). Note how the dotted line is at right angles to the solid line.

Also define \(S(0) = I\). It isn’t necessary that \(\varepsilon\) be small, just that \(\gamma_{\varepsilon, \phi}\) not contain \(t\). This is because the integrand in (52.2.6) is analytic.

Then it is necessary to show the above definition is well defined.

**Lemma 52.2.5** The above definition is well defined for \(t \in S_{0}(\phi + \pi/2)\). Also there is a constant, \(M_r\) such that

\[ ||S(t)|| \leq M_r \]

for every \(t \in S_{0}(\phi + \pi/2)\) such that \(|\arg t| \leq r < (\frac{\pi}{2} - \phi)\).
Proof: In the definition of $S(t)$ one can take $\epsilon = 1/|t|$. Then on the little circle which is part of $\gamma_{\epsilon, \phi}$ the contour integral equals

$$\frac{1}{2\pi} \int_{\phi - \pi}^{\pi - \phi} e^{\epsilon((\phi + \arg(t)))} \left( \frac{1}{|t|} e^{i\theta} - A \right)^{-1} \frac{1}{|t|} e^{i\theta} d\theta$$

and by assumption the norm of the integrand is no larger than

$$\frac{M}{1/|t| |t|}$$

and so the norm of this integral is dominated by

$$\frac{M}{2\pi} \int_{\phi - \pi}^{\pi - \phi} d\theta = \frac{M}{2\pi} (2\pi - 2\phi) \leq M$$

which is independent of $t$.

Now consider the part of the contour used to define $S(t)$ which is the top line segment. This equals

$$\frac{1}{2\pi i} \int_{1/|t|}^{\infty} e^{y\epsilon t} (ywI - A)^{-1} wdy$$

where $w$ is a fixed complex number of unit length which gives a direction for motion along this segment, $\arg(w) = \pi - \phi$. Then the norm of this is dominated by

$$\frac{1}{2\pi} \int_{1/|t|}^{\infty} |e^{y\epsilon t}| \frac{M}{y} dy = \frac{1}{2\pi} \int_{1/|t|}^{\infty} \exp(y |t| \cos(\arg(w) + \arg(t))) \frac{M}{y} dy$$

By assumption $|\arg(t)| \leq r < \left( \frac{\pi}{2} - \phi \right)$ and so

$$\arg(w) + \arg(t) \geq (\pi - \phi) - (-r) = \frac{\pi}{2} + \left( \left( \frac{\pi}{2} - \phi \right) - r \right) = \frac{\pi}{2} + \delta(r), \delta(r) > 0.$$ 

It follows the integral dominated by

$$\frac{1}{2\pi} \int_{1/|t|}^{\infty} \exp(-c(r) |t| y) \frac{M}{y} dy = \frac{1}{2\pi} \int_{1}^{\infty} \exp(-c(r) x) \frac{M |t|}{x |t|} \frac{1}{|t|} dx = \frac{1}{2\pi} \int_{1}^{\infty} \exp(-c(r) x) \frac{M}{x} dx$$

where $c(r) < 0$ independent of $|\arg(t)| \leq r$. A similar estimate holds for the integral on the bottom segment. Thus for $|\arg(t)| \leq r$, $||S(t)||$ is bounded. This proves the Lemma.
Also note that if the contour is shifted to the right slightly, the integral over the shifted contour, \( \gamma'_{\varepsilon, \phi} \), coincides with the integral over \( \gamma_{\varepsilon, \phi} \) thanks to the Cauchy integral formula and an approximation argument involving truncating the infinite contours and joining them at either end. Also note that in particular, \( ||S(t)|| \) is bounded for all positive real \( t \). The following is the main result.

**Theorem 52.2.6** Let \( A \) be a sectorial operator as defined in Definition 52.2.1 for the sector \( S_{0, \phi} \).

1. Then \( S(t) \) given above in 52.2.6 is analytic for \( t \in S_{0(\phi+\pi/2)}^0 \).
2. For any \( x \in H \) and \( t > 0 \), then for \( n \) a positive integer,

\[
S^{(n)}(t) x = A^n S(t) x
\]

3. \( S \) is a semigroup on the open sector, \( S_{0(\phi+\pi/2)}^0 \). That is, for all \( t, s \in S_{0(\phi+\pi/2)}^0 \),

\[
S(t+s) = S(t) S(s)
\]

4. \( t \to S(t) x \) is continuous at \( t = 0 \) for all \( x \in H \).

5. For some constants \( M, N \) such that if \( t \) is positive and real,

\[
||S(t)|| \leq M
\]

\[
||AS(t)|| \leq \frac{N}{t}
\]

**Proof:** Consider the first claim. This follows right away from the formula.

\[
S(t) = \frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} (\lambda I - A)^{-1} d\lambda
\]

The estimates for uniform convergence do not change for small changes in \( t \) and so the formula can be differentiated with respect to the complex variable \( t \) using the dominated convergence theorem to obtain

\[
S'(t) = \frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} \lambda e^{\lambda t} (\lambda I - A)^{-1} d\lambda
\]

\[
= \frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} \left( I + A (\lambda I - A)^{-1} \right) d\lambda
\]

\[
= \frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} A (\lambda I - A)^{-1} d\lambda
\]
because of the Cauchy integral theorem and an approximation result. Now approximating the infinite contour with a finite one and then the integral with Riemann sums, one can use the fact \( A \) is closed to take \( A \) out of the integral and write

\[
S'(t) = A \left( \frac{1}{2\pi i} \int_{\gamma_{\epsilon,\phi}} e^{\lambda t} (\lambda I - A)^{-1} d\lambda \right) = AS(t)
\]

To get the higher derivatives, note \( S(t) \) has infinitely many derivatives due to \( t \) being a complex variable. Therefore,

\[
S''(t) = \lim_{h \to 0} \frac{S'(t + h) - S'(t)}{h} = \lim_{h \to 0} A \frac{S(t + h) - S(t)}{h}
\]

and

\[
\frac{S(t + h) - S(t)}{h} \to AS(t)
\]

and so since \( A \) is closed, \( AS(t) \in D(A) \) and

\[
A^2 S(t)
\]

Continuing this way yields the claims 1.) and 2.). Note this also implies \( S(t) \in D(A) \) for each \( t \in S_0^{0(\phi + \pi/2)} \).

Next consider the semigroup property. Let \( s,t \in S_0^{0(0 + \pi/2)} \) and let \( \epsilon \) be sufficiently small that \( \gamma_{\epsilon,\phi} \) is at a positive distance from both \( s \) and \( t \). As described above let \( \gamma'_{\epsilon,\phi} \) denote the contour shifted slightly to the right, still at a positive distance from \( t \). Then

\[
S(t) S(s) = \left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\epsilon,\phi}} \int_{\gamma'_{\epsilon,\phi}} e^{\lambda t} (\lambda I - A)^{-1} e^{\mu s} (\mu I - A)^{-1} d\mu d\lambda
\]

At this point note that

\[
(\lambda I - A)^{-1} (\mu I - A)^{-1} = (\mu - \lambda)^{-1} \left( (\lambda I - A)^{-1} - (\mu I - A)^{-1} \right).
\]

Then substituting this in the integrals above, it equals

\[
\left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\epsilon,\phi}} \int_{\gamma'_{\epsilon,\phi}} e^{\mu s} e^{\lambda t} \left( (\mu - \lambda)^{-1} \left( (\lambda I - A)^{-1} - (\mu I - A)^{-1} \right) \right) d\mu d\lambda
\]

\[
= - \left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\epsilon,\phi}} e^{\lambda t} \int_{\gamma_{\epsilon,\phi}} e^{\mu s} (\mu - \lambda)^{-1} (\mu I - A)^{-1} d\mu d\lambda
\]

\[
+ \left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\epsilon,\phi}} \int_{\gamma'_{\epsilon,\phi}} e^{\mu s} (\mu - \lambda)^{-1} (\lambda I - A)^{-1} d\mu d\lambda
\]
The order of integration can be interchanged because of the absolute convergence and Fubini’s theorem. Then this reduces to

\[
= - \left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\varepsilon, \phi}} (\mu I - A)^{-1} e^{\mu s} \int_{\gamma_{\varepsilon, \phi}} e^{\lambda t} (\mu - \lambda)^{-1} d\lambda d\mu \\
+ \left( \frac{1}{2\pi i} \right)^2 \int_{\gamma_{\varepsilon, \phi}} (\lambda I - A)^{-1} e^{\lambda t} \int_{\gamma_{\varepsilon, \phi}} e^{\mu s} (\mu - \lambda)^{-1} d\mu d\lambda
\]

Now the following diagram might help in drawing some interesting conclusions.

The first iterated integral equals 0. This can be seen from the above picture. The inner integral taken over \( \gamma_{\varepsilon, \phi} \) is essentially equal to the integral over the closed contour in the above picture provided the radius of the part of the circle in the above closed contour is large enough. This closed contour integral equals 0 by the Cauchy integral theorem. The second iterated integral equals

\[
\frac{1}{2\pi i} \int_{\gamma_{\varepsilon, \phi}} (\lambda I - A)^{-1} e^{\lambda t} e^{\lambda s} d\lambda
\]

This can be seen from considering a similar closed contour, using the Cauchy integral formula. This verifies the semigroup identity.

Next consider 4.), the continuity at \( t = 0 \). This requires showing

\[
\lim_{t \to 0^+} S(t)x = x
\]

where the limit is taken through positive real values of \( t \). It suffices to let \( x \in D(A) \) because by Lemma \( \| S(t) \| \) is bounded for these values of \( t \). Also in doing the computation, let \( \gamma_{\varepsilon, \phi} \) equal \( \gamma_{1, \varepsilon, \phi} \) and it will be assumed \( t < 1 \). Then one must estimate

\[
\| S(t)x - x \| =
\]
\\begin{equation}
\left\| \frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\lambda t} (\lambda I - A)^{-1} x d\lambda - Ix \right\| \tag{52.2.7}
\end{equation}

By the Cauchy integral formula and approximating the integral with a contour integral over a finite closed contour,

$$
\frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\lambda t} \lambda d\lambda = 1
$$

and so equals

$$
\left\| \frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\lambda t} \left( (\lambda I - A)^{-1} - I \right) x d\lambda \right\|
$$

Changing the variable letting $\lambda t = \mu$, the above equals

$$
\left\| \frac{1}{2\pi i} \int_{\gamma_{1,0}} e^{\mu t} (\mu/t) I - A)^{-1} Ax \frac{1}{t} d\mu \right\|
$$

which is dominated by

$$
\frac{1}{2\pi} \int_{\gamma_{1,0}} e^{\mu |\cos \phi| t^2 M} \frac{1}{|\mu|^2} ||Ax|| \frac{1}{t} d|\mu| = tC ||Ax||.
$$

Therefore, $\lim_{t \to 0^+} ||S(t)x - x|| = 0$ whenever $x \in D(A)$. Since $S(t)$ is bounded for positive $t$, if $y \in H$ is arbitrary, choose $x \in D(A)$ close enough to $y$ such that

$$
||S(t)y - y|| \leq ||S(t)(y-x)|| + ||S(t)x - x|| + ||x - y|| \\
\leq \varepsilon/2 + ||S(t)x - x||
$$

and now if $t$ is close enough to 0 it follows the right side is less than $\varepsilon$. This proves 4).

Finally consider 5). The first part follows from Lemma 52.2.3. It remains to show the second part. Let $x \in H$. First suppose $t \neq 1$,

$$
||AS(t)x|| = \left\| \frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\lambda t} A(\lambda I - A)^{-1} x d\lambda \right\|
$$

$$
= \left\| \frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\lambda t} (-I + \lambda (\lambda I - A)^{-1}) x d\lambda \right\|
$$

$$
= \left\| \frac{1}{2\pi i} \int_{\gamma_{t-1,0}} e^{\mu \lambda} (\lambda I - A)^{-1} x d\lambda \right\|
$$

$$
= \left\| \frac{1}{2\pi i} \int_{\gamma_{1,0}} e^{\mu \lambda} \left( \frac{\mu}{t} I - A \right)^{-1} x \frac{1}{t} d\mu \right\|
$$
and this is dominated by
\[ \frac{1}{2\pi} \int_{\gamma_{1,\phi}} e^{\mu|\cos \psi} Md |\mu| \frac{1}{t} = \frac{N}{t}. \]

This proves the theorem.

What if \( A \) is sectorial in the more general sense with \( S_{a\phi} \) taking the place of \( S_{0\phi} \) and the resolvent estimate being
\[ (I - A)_{a\phi}^{1} \leq M \]

Then \( S_{a\phi} = a + S_{0\phi} \) and so for \( \lambda \in S_{0\phi}, (\lambda + a) \in S_{a\phi} \) and so
\[ (\lambda I - (A - aI))^{-1} = ((\lambda + a) I - A)^{-1} \in \mathcal{L}(H, H) \]

and
\[ \left\| (\lambda I - (A - aI))^{-1} \right\| \leq \left\| ((\lambda + a) - A)^{-1} \right\| \]

\[ \leq \frac{M}{|\lambda + a| - a} = \frac{M}{\lambda} \]

Therefore, letting \( A_{a} \equiv A - aI \), it follows the result of Theorem \[ \text{52.2.6} \] holds for this operator. There exists a semigroup, \( S_{a}(t) \) satisfying

1. \( S_{a}(t) \) is analytic for \( t \in S_{0(\phi+\pi/2)}^{0} \).
2. For any \( x \in H \) and \( t > 0 \), then for \( n \) a positive integer,
   \[ S_{a}^{(n)}(t) x = A_{a}^{n} S_{a}(t) x \]
3. \( S_{a} \) is a semigroup on the open sector, \( S_{0(\phi+\pi/2)}^{0} \). That is, for all \( t, s \in S_{0(\phi+\pi/2)}^{0} \),
   \[ S_{a}(t + s) = S_{a}(t) S_{a}(s) \]
4. \( t \to S_{a}(t) x \) is continuous at \( t = 0 \) for all \( x \in H \).
5. For some constants \( M, N \) such that if \( t \) is positive and real,\n   \[ ||S_{a}(t)|| \leq M \]
   \[ ||A_{a} S_{a}(t)|| \leq \frac{N}{t} \]

Define
\[ S(t) \equiv e^{at} S_{a}(t). \]

This satisfies the semigroup identity, is continuous at 0, and satisfies the inequality
\[ ||S(t)|| \leq Me^{at} \]
for all \( t \) real and nonnegative. What is its derivative?

\[
S'(t) = ae^{at}S(t) + (A - aI)e^{at}S(t) = Ae^{at} = AS(t)
\]

and by continuing this way using \( A \) is closed as before, it follows

\[
S^{(n)}(t) = A^n S(t).
\]

Also for \( t > 0 \),

\[
||AS(t)|| = ||e^{at}AS(t)||
\]

\[
= ||e^{at}(A - aI)S(t) + e^{at}aS(t)||
\]

\[
= ||e^{at}A_s(t) + e^{at}aS(t)||
\]

\[
\leq e^{a\eta} N + ae^{at}M = e^{at}\left(\frac{N}{t} + aM\right).
\]

It is clear \( S(t)x \) is continuous at \( 0 \) since this is true of \( S_a(t) \).

This proves the following corollary which is a useful generalization of the above major theorem.

**Corollary 52.2.7** Let \( A \) be sectorial satisfying

\[
(\lambda I - A)^{-1} \in \mathcal{L}(H, H) \quad \text{for } \lambda \in S_{a\phi}\n\]

for \( \phi < \pi/2 \) and

\[
\left|\left|\left(\lambda I - A\right)^{-1}\right|\right| \leq \frac{M}{|\lambda - a|}
\]

for all \( \lambda \in S_{a\lambda} \). Then there exists a semigroup, \( S(t) \) defined on \( S_{0(\phi + \pi/2)}^{(0)} \) which satisfies

1. \( S(t) \) is analytic for \( t \in S_{0(\phi + \pi/2)}^{(0)} \).

2. For any \( x \in H \) and \( t > 0 \), then for \( n \) a positive integer,

\[
S^{(n)}(t)x = A^n S(t)x
\]

3. \( S(t) \) is a semigroup on the open sector, \( S_{0(\phi + \pi/2)}^{(0)} \). That is, for all \( t, s \in S_{0(\phi + \pi/2)}^{(0)} \),

\[
S(t+s) = S(t)S(s)
\]

4. \( t \to S(t)x \) is continuous at \( t = 0 \) for all \( x \in H \).

5. For some constants \( M, N \) such that if \( t \) is positive and real,

\[
||S(t)|| \leq Me^{at}
\]

\[
||AS(t)|| \leq e^{at}\left(\frac{N}{t} + aM\right)
\]
52.2.2 The Numerical Range

In Hilbert space, there is a useful easy to check criterion which implies an operator is sectorial.

**Definition 52.2.8** Let \( A \) be a closed densely defined operator \( A : D(A) \to H \) for \( H \) a Hilbert space. The numerical range is the following set.

\[
\{(Au, u) : u \in D(A)\}
\]

Also recall the resolvent set, \( r(A) \) consists of those \( \lambda \in \mathbb{C} \) such that \( (\lambda I - A)^{-1} \in \mathcal{L}(H,H) \). Thus, to be in this set \( \lambda I - A \) is one to one and onto with continuous inverse.

**Proposition 52.2.9** Suppose the numerical range of \( A \), a closed densely defined operator \( A : D(A) \to H \) for \( H \) a Hilbert space is contained in the set

\[
\{z \in \mathbb{C} : |\arg(z)| \geq \pi - \phi\}
\]

where \( 0 < \phi < \pi/2 \) and suppose \( A^{-1} \in \mathcal{L}(H,H),(0 \in r(A)) \). Then \( A \) is sectorial with the sector \( S_{0,\phi'} \) where \( \pi/2 > \phi' > \phi \).

**Proof:** Here is a picture of the situation along with details used to motivate the proof.

In the picture the angle which is a little larger than \( \phi \) is \( \phi' \). Let \( \lambda \) be as shown with \( |\arg \lambda| \leq \pi - \phi' \). Then from the picture and trigonometry, if \( u \in D(A) \),

\[
|\lambda| \sin(\phi' - \phi) < \left| \lambda - \left( A \frac{u}{|u|}, \frac{u}{|u|} \right) \right|
\]

and so

\[
|u| |\lambda| \sin(\phi' - \phi) < \left| \lambda u - A u, \frac{u}{|u|} \right| \leq ||(\lambda I - A) u||
\]
Hence for all \( \lambda \) such that \( |\text{arg}\lambda| \leq \pi - \phi' \) and \( u \in D(A) \),

\[
|u| < \left( \frac{1}{\sin (\phi' - \phi)} \right) \left( \frac{1}{|\lambda|} \right) |(\lambda I - A)u|
\]

\[
= \frac{M}{|\lambda|} |(\lambda I - A)u|
\]

Thus \((\lambda I - A)\) is one to one on \(S_{0, \phi'}\) and if \( \lambda \in r(A) \), then

\[
\left\| (\lambda I - A)^{-1} \right\| < \frac{M}{|\lambda|}.
\]

By assumption \( 0 \in r(A) \). Now if \( |\mu| \) is small,

\[
(\mu I - A)^{-1}
\]

must exist because it equals

\[
((\mu A^{-1} - I)A)^{-1}
\]

and for \( |\mu| < \|A^{-1}\| \); \((\mu A^{-1} - I)^{-1} \in \mathcal{L}(H, H)\) since the infinite series

\[
\sum_{k=0}^{\infty} (-1)^k (\mu A^{-1})^k
\]

converges and must equal to \((\mu A^{-1} - I)^{-1}\). Therefore, there exists \( \mu \in S_{0, \phi'} \) such that \( \mu \neq 0 \) and \( \mu \in r(A) \). Also if \( \mu \neq 0 \) and \( \mu \in S_{0, \phi'} \), then if \( |\lambda - \mu| < \frac{|\mu|}{M} \), \((\lambda I - A)^{-1}\) must exist because

\[
(\lambda I - A)^{-1} = \left[ (\lambda - \mu)(\mu I - A)^{-1} - I \right] (\mu I - A)^{-1}
\]

where \( (\lambda - \mu)(\mu I - A)^{-1} - I \) exists because

\[
\left\| (\lambda - \mu)(\mu I - A)^{-1} \right\| = |\lambda - \mu| \left\| (\mu I - A)^{-1} \right\|
\]

\[
< \frac{|\mu|}{M} \frac{M}{|\mu|} = 1.
\]

It follows that if \( S \equiv \{ \lambda \in S_{0, \phi'} : \lambda \in r(A) \} \), then \( S \) is open in \( S_{0, \phi'} \). However, \( S \) is also closed because if \( \lambda = \lim_{n \to \infty} \lambda_n \) where \( \lambda_n \in S \), then if \( \lambda = 0 \), it is given \( \lambda \in S \). If \( \lambda \neq 0 \), then for large enough \( n \),

\[
|\lambda - \lambda_n| < \frac{\lambda_n}{M}
\]

and so \( \lambda \in S \). Since \( S_{0, \phi'} \) is connected, it follows \( S = S_{0, \phi'} \). This proves the proposition.
Corollary 52.2.10 If for some \( a \in \mathbb{R} \), the numerical values of \(-aI + A\) are in the set \( \{ \lambda : |\lambda| \geq \pi - \phi \} \) where \( 0 < \phi < \pi/2 \), and \( a \in r(A) \) then \( A \) is sectorial.

**Proof:** By assumption, \( 0 \leq r(aI + A) \) and also from Proposition 52.2.9, for \( \psi \geq 0 \), \( \phi > \phi' > 0 \):

\[
\left\| (aI + A)^{-1} \right\| \leq \frac{M}{|\mu|}
\]

Therefore, for \( \mu \in S_{0,\phi'} \), \( \mu + a \in r(A) \). Therefore, if \( \lambda \in S_{a,\phi'}, \lambda - a \in S_{0,\phi'} \):

\[
\left\| (A - \lambda I)^{-1} \right\| = \left\| (A - aI - (\lambda - a)I)^{-1} \right\| \leq \frac{M}{|\lambda - a|}
\]

This proves the corollary.

### 52.2.3 An Interesting Example

In this section related to this example, for \( V \) a Banach space, \( V' \) will denote the space of continuous conjugate linear functions defined on \( V \). Usually the symbol has meant the space of continuous linear functions but here they will be conjugate linear. That is \( f \in V' \) means

\[
f(ax + by) = \bar{a}f(x) + \bar{b}f(y)
\]

and \( f \) is continuous.

Let \( \Omega \) be a bounded open set in \( \mathbb{R}^n \) and define

\[
V_0 = \{ u \in C^\infty(\overline{\Omega}) : u = 0 \text{ on } \Gamma \}
\]

where \( \Gamma \) is some measurable subset of the boundary of \( \Omega \) and \( C^\infty(\overline{\Omega}) \) denotes the restrictions of functions in \( C^\infty(\mathbb{R}^n) \) to \( \Omega \). By Corollary 43.5.14 \( V_0 \) is dense in \( L^2(\Omega) \).

Now define the following for \( u, v \in V_0 \):

\[
A_0 u(v) \equiv -a \int_\Omega u\overline{v}dx - \int_\Omega a(x) \nabla u \cdot \nabla \overline{v}dx
\]

where \( a > 0 \) and \( a(x) \geq 0 \) is a \( C^1(\overline{\Omega}) \) function. Also define the following inner product on \( V_0 \):

\[
(u, v)_1 \equiv \int_\Omega (au\overline{v} + a(x) \nabla u \cdot \nabla \overline{v}) dx
\]

Let \( \|\cdot\|_1 \) denote the corresponding norm.

Of course \( V_0 \) is not a Banach space because it fails to be complete. \( u \in V \) will mean that \( u \in L^2(\Omega) \) and there exists a sequence \( \{u_n\} \subseteq V_0 \) such that

\[
\lim_{m,n \to \infty} \|u_n - u_m\|_1 = 0
\]
and

\[ \lim_{n \to \infty} |u_n - u|_{L^2(\Omega)} = 0. \]

For \( u \in V \), define \( \nabla u \) to be that element of \( L^2(\Omega; \mathbb{C}^n, a(x) \, dm_n) \), the space of vector valued \( L^2 \) functions taken with respect to the measure \( a(x) \, dm_n \) which satisfies

\[ |\nabla u - \nabla u_n|_{L^2(\Omega; \mathbb{C}^n, a(x) \, dm_n)} \to 0. \]

Denote this space by \( W \) for simplicity of notation.

**Observation 52.2.11** \( V \) is a Hilbert space with inner product given by

\[ (u, v)_1 \equiv \int_{\Omega} (au \nu + a(x) \nabla u \cdot \nabla v) \, dx \]

Everything is obvious except completeness. Suppose then that \( \{u_n\} \) is a Cauchy sequence in \( V \). Then there exists a unique \( u \in L^2(\Omega) \) such that \( |u_n - u|_{L^2(\Omega)} \to 0 \). Now let

\[ |w_n - u_n|_{L^2(\Omega)} + |\nabla w_n - \nabla u_n|_{W} < 1/2^n \]

It follows \( \{\nabla w_n\} \) is also a Cauchy sequence in \( W \) while \( \{w_n\} \) is a Cauchy sequence in \( L^2(\Omega) \) converging to \( u \). Thus the thing to which \( \nabla w_n \) converges in \( W \) is the definition of \( \nabla u \) and \( u \in V \). Thus

\[ ||u_n - u||_1 \leq ||u_n - w_n||_1 + ||w_n - u||_1 \]

and the last term converges to 0. Hence \( V \) is complete as claimed.

Then it is clear \( V \) is a Hilbert space. The next observation is a simple one involving the Riesz map.

**Definition 52.2.12** Let \( V \) be a Hilbert space and let \( V' \) be the space of continuous conjugate linear functions defined on \( V \). Then define \( R : V \to V' \) by

\[ Rx(y) \equiv (x, y). \]

This is called the Riesz map.

**Lemma 52.2.13** The Riesz map is one to one and onto and linear.

**Proof:** It is obvious it is one to one and linear. The only challenge is to show it is onto. Let \( z^* \in V' \). If \( z^*(V) = \{0\} \), then letting \( z = 0 \), it follows \( Rz = z^* \). If \( z^*(V) \neq 0 \), then

\[ \ker(z^*) \equiv \{x \in V : z^*(x) = 0\} \]

is a closed subspace. It is closed because \( z^* \) is continuous and it is just \( z^{*-1}(0) \). Since \( \ker(z^*) \) is not everything in \( V \) there exists

\[ w \in \ker(z^*)^\perp \equiv \{x : (x, y) = 0 \text{ for all } y \in \ker(z^*)}\]
and $w \neq 0$. Then
\[
    z^* \left( z^* (x) w - z^* (w) x \right) = z^* (x) z^* (w) - z^* (w) z^* (x) = 0
\]
and so $z^* (x) w - z^* (w) x \in \ker (z^*)$. Therefore, for any $x \in V$,
\[
    0 = \left( w, z^* (x) w - z^* (w) x \right) = z^* (x) (w, w) - z^* (w) (w, x)
\]
and so
\[
    z^* (x) = \left( \frac{z^* (w)}{||w||^2}, x \right)
\]
so let $z = w/||w||^2$. Then $Rz = z^*$ and so $R$ is onto. This proves the lemma.

Now for the $V$ described above,

\[
    Ru (v) = \int_{\Omega} \left( au v + a (x) \nabla u \cdot \nabla v \right) dx
\]

Also, as noted above $V$ is dense in $H \equiv L^2 (\Omega)$ and so if $H$ is identified with $H'$, it follows
\[
    V \subset H = H' \subset V'.
\]
Let $A : D (A) \to H$ be given by
\[
    D (A) \equiv \{ u \in V : Ru \in H \}
\]
and
\[
    A \equiv -R
\]
on $D (A)$. Then the numerical range for $A$ is contained in $(-\infty, -a]$ and so $A$ is sectorial by Proposition 52.2.9 provided $A$ is closed and densely defined.

Why is $D (A)$ dense? It is because it contains $C_\infty^c (\Omega)$ which is dense in $L^2 (\Omega)$. This follows from integration by parts which shows that for $u, v \in C_\infty^c (\Omega)$,
\[
    - \int_{\Omega} au \overline{v} dx - \int_{\Omega} a (x) \nabla u \cdot \nabla \overline{v} dx
\]
\[
    = - \int_{\Omega} au \overline{v} dx + \int_{\Omega} \nabla \cdot (a (x) \nabla u) \overline{v} dx
\]
and since $C_\infty^c (\Omega)$ is dense in $H$,
\[
    Au = -au + \nabla \cdot (a (x) \nabla u) \in L^2 (\Omega) = H.
\]

Why is $A$ closed? If $u_n \in D (A)$ and $u_n \to u$ in $H$ while $Au_n \to \xi$ in $H$, then it follows from the definition that $Ru_n \to -\xi$ and $\{ u_n \}$ converges to $u$ in $V$ so for any $v \in V$,
\[
    Ru (v) = \lim_{n \to \infty} Ru_n (v) = \lim_{n \to \infty} (Ru_n, v)_H = (-\xi, v)_H
\]
which shows $Ru = -\xi \in H$ and so $u \in D(A)$ and $Au = \xi$. Thus $A$ is closed. This completes the example.

Obviously you could follow identical reasoning to include many other examples of more complexity. What does it mean for $u \in D(A)$? It means that in a weak sense

$$-au + \nabla \cdot (a(x) \nabla u) \in H.$$ 

Since $A$ is sectorial for $S_{-a,\phi}$ for any $0 < \phi < \pi/2$, this has shown the existence of a weak solution to the partial differential equation along with appropriate boundary conditions,

$$-au + \nabla \cdot (a(x) \nabla u) = f, \quad u \in V.$$ 

What are these appropriate boundary conditions? $u = 0$ on $\Gamma$ is one. The other would be a variational boundary condition which comes from integration by parts. Letting $v \in V$, formally do the following using the divergence theorem.

$$(f,v)_H = \int_{\Omega} (-au + \nabla \cdot (a(x) \nabla u)) vdx$$

$$= \int_{\Omega} -auvdx + \int_{\partial\Omega} (a(x) \nabla u v) \cdot nds - \int_{\Omega} a(x) \nabla u (x) \cdot \nabla v (x) dx$$

$$= (f,v)_H + \int_{\partial\Omega \setminus \Gamma} (a(x) \nabla u) \cdot nvd$$

and so the other boundary condition is

$$a(x) \frac{\partial u}{\partial n} = 0 \text{ on } \partial\Omega \setminus \Gamma.$$ 

To what extent this weak solution is really a classical solution depends on more technical considerations.

### 52.2.4 Fractional Powers Of Sectorial Operators

It will always be assumed in this section that $A$ is sectorial for the sector $S_{-a,\phi}$ where $a > 0$. To begin with, here is a useful lemma which will be used in the presentation of these fractional powers.

**Lemma 52.2.14** The following holds for $\alpha \in (0,1)$ and $\sigma < t$.

$$\int_t^\sigma (t-s)^{\alpha-1} (s-\sigma)^{-\alpha} ds = \frac{\pi}{\sin(\pi \alpha)}.$$ 

In particular,

$$\int_0^1 (1-s)^{\alpha-1} s^{-\alpha} ds = \frac{\pi}{\sin(\pi \alpha)}.$$ 

Also for $\alpha, \beta > 0$

$$\Gamma(\alpha) \Gamma(\beta) = \left( \int_0^1 x^{\alpha-1} (1-x)^{\beta-1} dx \right) \Gamma(\alpha + \beta).$$
**Proof:** First change variables to get rid of the $\sigma$. Let $y = (t - \sigma)^{-1} (s - \sigma)$. Then the integral becomes

\[
\int_0^1 (t - [(t - \sigma) y + \sigma])^{\alpha-1} (t - \sigma)^{-\alpha} y^{\alpha} (t - \sigma) \, dy
= \int_0^1 ((t - \sigma) (1 - y))^{\alpha-1} (t - \sigma)^{-\alpha} y^{\alpha} (t - \sigma) \, dy
= \int_0^1 (1 - y)^{\alpha-1} y^{-\alpha} \, dy
\]

Next let $y = x^2$. The integral is

\[
2 \int_0^1 (1 - x^2)^{\alpha-1} x^{1-2\alpha} \, dx
\]

Next let $x = \sin \theta$

\[
2 \int_0^{\frac{\pi}{2}} (\cos (\theta))^{2\alpha-1} \sin^{(1-2\alpha)} (\theta) \, d\theta = 2 \int_0^{\frac{\pi}{2}} \left( \frac{\cos (\theta)}{\sin (\theta)} \right)^{2\alpha-1} \, d\theta
\]

Now change the variable again. Let $u = \cot (\theta)$. Then this yields

\[
2 \int_0^{\infty} \frac{u^{2\alpha-1}}{1 + u^2} \, du
\]

This is fairly easy to evaluate using contour integrals. Consider the following contour called $\Gamma_R$ for large $R$. As $R \to \infty$, the integral over the little circle converges to 0 and so does the integral over the big circle. There is one singularity at $i$.

Thus

\[
\lim_{R \to \infty} \int_{\Gamma_R} \frac{e^{(\ln |z| + i \arg(z))(1-2\alpha)}}{1 + z^2} \, dz =
\]

\[
= (1 + \cos (1 - 2\alpha) \pi) \int_0^{\infty} \frac{u^{2\alpha-1}}{1 + u^2} \, du
+ i \sin ((1 - 2\alpha) \pi) \int_0^{\infty} \frac{u^{2\alpha-1}}{1 + u^2} \, du
\]
= \pi \left( \cos \left( \frac{\pi}{2} (1 - 2\alpha) \right) + i \sin \left( \frac{\pi}{2} (1 - 2\alpha) \right) \right)

Then equating the imaginary parts yields

\sin ((1 - 2\alpha) \pi) \int_0^\infty \frac{u^{2\alpha - 1}}{1 + u^2} \, du = \pi \sin \left( \frac{\pi}{2} (1 - 2\alpha) \right)

and so using the trig identities for the sum of two angles,

\int_0^\infty \frac{u^{2\alpha - 1}}{1 + u^2} \, du = \frac{\pi \left( \sin \left( \frac{\pi}{2} (1 - 2\alpha) \right) \right)}{2 \sin \left( \frac{\pi}{2} (1 - 2\alpha) \right) \cos \left( \frac{\pi}{2} (1 - 2\alpha) \right)}

= \frac{2 \cos \left( \frac{\pi}{2} (1 - 2\alpha) \right)}{2 \sin (\pi \alpha)}

It remains to verify the last identity.

\Gamma (\alpha) \Gamma (\beta) = \int_0^\infty \int_0^\infty t^{\alpha - 1} e^{-t} s^{\beta - 1} e^{-s} \, ds \, dt

= \int_0^\infty \int_t^\infty t^{\alpha - 1} e^{-u} (u - t)^{\beta - 1} \, du \, dt

= \int_0^\infty e^{-u} \int_0^u t^{\alpha - 1} (u - t)^{\beta - 1} \, dt \, du

= \int_0^1 x^{\alpha - 1} (1 - x)^{\beta - 1} \, dx \int_0^\infty e^{-u} u^{\alpha + \beta - 1} \, du

= \left( \int_0^1 x^{\alpha - 1} (1 - x)^{\beta - 1} \, dx \right) \Gamma (\alpha + \beta)

This proves the lemma.

If it is not stated otherwise, in all that follows \( \alpha > 0 \).

**Definition 52.2.15** Let \( A \) be a sectorial operator corresponding to the sector \( S_{-\alpha \phi} \) where \( -\alpha < 0 \). Then define for \( \alpha > 0 \),

\((-A)^{-\alpha} = \frac{1}{\Gamma (\alpha)} \int_0^\infty t^{\alpha - 1} S (t) \, dt \)

where \( S (t) \) is the analytic semigroup generated by \( A \) as in Corollary 52.2.7. Note that from the estimate, \( || S (t) || \leq Me^{-\alpha t} \) of this corollary, the integral is well defined and is in \( \mathcal{L} (H, H) \).

**Theorem 52.2.16** For \((-A)^{-\alpha} \) as defined in Definition 52.2.15

\((-A)^{-\alpha} (-A)^{-\beta} = (-A)^{-(\alpha + \beta)} \) \hspace{1cm} (52.2.8)

Also

\((-A)^{-1} (-A) = I, \ (-A) (-A)^{-1} = I \) \hspace{1cm} (52.2.9)
and \((-A)^{-\alpha}\) is one to one if \(\alpha \geq 0\), defining \(A^0 \equiv I\).

If \(\alpha < \beta\), then

\[
(-A)^{-\beta} (H) \subseteq (-A)^{-\alpha} (H).
\] (52.2.10)

If \(\alpha \in (0,1)\), then

\[
(-A)^{-\alpha} = \frac{\sin(\pi\alpha)}{\pi} \int_0^\infty \lambda^{-\alpha} (\lambda I - A)^{-1} d\lambda
\] (52.2.11)

**Proof:** Consider 52.2.8. \((-A)^{\alpha} (-A)^{-\beta} = \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_0^\infty \int_0^\infty t^{\alpha-1} s^{\beta-1} S(t+s) \, ds \, dt\)

Changing variables and using Fubini’s theorem which is justified because of the absolute convergence of the iterated integrals, which follows from Corollary 52.2.7, this becomes

\[
\frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_0^\infty \int_0^\infty t^{\alpha-1} (u-t)^{\beta-1} S(u) \, dudt
\]

\[
= \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_0^u \int_0^t (u-t)^{\beta-1} S(u) \, dtdu
\]

\[
= \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \int_0^u S(u) \int_0^1 (ux)^{\alpha-1} (u-ux)^{\beta-1} \, dx \, du
\]

\[
= \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \left( \int_0^1 x^{\alpha-1} (1-x)^{\beta-1} \, dx \right) \int_0^\infty S(u) u^{\alpha+\beta-1} \, du
\]

\[
= \frac{1}{\Gamma(\alpha) \Gamma(\beta)} \left( \int_0^1 x^{\alpha-1} (1-x)^{\beta-1} \, dx \right) \Gamma(\alpha+\beta) (-A)^{-(\alpha+\beta)}
\]

\[
= (-A)^{-(\alpha+\beta)}
\]

This proves the first part of the theorem.

Consider 52.2.9. Since \(A\) is a closed operator, and approximating the integral with an appropriate sequence of Riemann sums, \((-A)^{-1}\) can be taken inside the integral and so

\[
(-A)^{-1} \int_0^\infty t^{1-1} S(t) \, dt = \int_0^\infty (-A) S(t) \, dt
\]

\[
= \int_0^\infty -\frac{d}{dt} (S(t)) \, dt = S(0) = I.
\]

Next let \(x \in D(-A)\). Then

\[
\frac{1}{\Gamma(1)} \int_0^\infty t^{1-1} S(t) \, dt (-A)x = -\int_0^\infty S(t) Ax \, dt
\]

\[
= -\int_0^\infty AS(t) \, xdt = \int_0^\infty -\frac{d}{dt} (S(t)) \, dt = Ix
\]
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

This shows that the integral in which \( \alpha = 1 \) deserves to be called \( A^{-1} \) so the definition is not bad notation. Also, by assumption, \( A^{-1} \) is one to one. Thus

\[
(-A)^{-1} (-A)^{-1} x = 0
\]

implies

\[
(-A)^{-1} x = 0
\]

hence \( x = 0 \) so that \( (-A)^{-2} \) is also one to one. Similarly, \( (-A)^{-m} \) is one to one for all positive integers \( m \).

From what was just shown, if \( (-A)^{-\alpha} x = 0 \) for \( \alpha \in (0, 1) \), then

\[
(-A)^{-1} x = (-A)^{-(1-\alpha)} (-A)^{-\alpha} x = 0
\]

and so \( x = 0 \). This shows \( (-A)^{-\alpha} \) is one to one for all \( \alpha \in [0, 1] \) if it is defined as \( (-A)^0 = I \).

What about \( \alpha > 1 \)? For such \( \alpha \), it is of the form \( m + \beta \) where \( \beta \in [0, 1) \) and \( m \) is a positive integer. Therefore, if

\[
(-A)^{-(m+\beta)} x = 0
\]

then

\[
(-A)^{-\beta} \left( (-A)^{-m} \right) x = 0
\]

and so from what was just shown,

\[
\left( (-A)^{-m} \right) x = 0
\]

and now this implies \( x = 0 \) so that \( (-A)^{-\alpha} \) is one to one for all \( \alpha \geq 0 \).

Consider \( \frac{d}{dx} \). It was shown above that

\[
(-A)^{-\alpha} (-A)^{-\beta} = (-A)^{-(\alpha+\beta)}
\]

Let \( x = (-A)^{-(\alpha+\beta)} y \). Then

\[
x = (-A)^{-\alpha} (-A)^{-\beta} y \subseteq (-A)^{-\alpha} (-A)^{-\beta} (H) \subseteq (-A)^{-\alpha} (H).
\]

This proves \( \frac{d}{dx} \). If \( \alpha < \beta \), \( (-A)^{-\beta} (H) \subseteq (-A)^{-\alpha} (H) \).

Now consider the problem of writing \( (-A)^{-\alpha} \) for \( \alpha \in (0, 1) \) in terms of \( A \), not mentioning \( S(t) \). By Proposition \( \frac{d}{dx} \),

\[
(\lambda I - A)^{-1} x = \int_0^\infty e^{-\lambda t} S(t) x dt
\]

Then

\[
\int_0^\infty \lambda^{-\alpha} (\lambda I - A)^{-1} d\lambda = \int_0^\infty \lambda^{-\alpha} \int_0^\infty e^{-\lambda t} S(t) dt d\lambda = \int_0^\infty S(t) \int_0^\infty \lambda^{-\alpha} e^{-\lambda t} dt d\lambda = \int_0^\infty S(t) \int_0^\infty \lambda^{\beta-1} e^{-\lambda t} dt d\lambda
\]
52.2. ANALYTIC SEMIGROUPS

where $\beta \equiv 1 - \alpha$. Then using Lemma 52.2.14, this equals

$$\int_0^\infty S(t) \int_0^\infty \mu^{\beta-1} t^{1-\beta} e^{-\mu t} dt S(t) \int_0^\infty \mu^{\beta-1} e^{-\mu} \mu = \int_0^\infty t^{\beta-1} S(t) \int_0^\infty \mu^{\beta-1} e^{-\mu} \mu$$

$$= \Gamma (1 - \alpha) \int_0^\infty t^{\alpha-1} S(t) dt = \Gamma (\alpha) \Gamma (1 - \alpha) (-A)^{-\alpha}$$

$$= \left( \int_0^1 x^{\alpha-1} (1-x)^{-\alpha} dx \right) (-A)^{-\alpha} = \frac{\pi}{\sin (\pi \alpha)} (-A)^{-\alpha}$$

and so this gives the formula

$$(-A)^{-\alpha} = \frac{\sin (\pi \alpha)}{\pi} \int_0^\infty \lambda^{-\alpha} (\lambda I - A)^{-1} d\lambda.$$

This proves 52.2.14.

**Definition 52.2.17** For $\alpha \geq 0$, define $(-A)^{\alpha}$ on $D((-A)^{\alpha}) \equiv (\lambda I - A)^{-1} (H)$ by

$$(-A)^{\alpha} \equiv \left((-A)^{-\alpha}\right)^{-1}$$

Note that if $\alpha, \beta > 0$, then if $x \in D \left((-A)^{\alpha+\beta}\right)$,

$$(-A)^{\alpha+\beta} x = \left((-A)^{-(\alpha+\beta)}\right)^{-1} x =$$

$$\left((-A)^{-\alpha} (-A)^{-\beta}\right)^{-1} x = (-A)^{\beta} (-A)^{\alpha} x.$$ (52.2.12)

Next let $\beta > \alpha > 0$ and let $x \in D \left((-A)^{\beta}\right)$. Then from what was just shown,

$$(-A)^{\alpha} (-A)^{\beta-\alpha} x = (-A)^{\beta} x$$

and so

$$(-A)^{\beta-\alpha} x = (-A)^{-\alpha} (-A)^{\beta} x$$

If $x \in D \left((-A)^{\beta}\right)$, does it follow that $(-A)^{-\alpha} x \in D \left((-A)^{\beta}\right)$? Note $x = (-A)^{-\beta} y$ and so

$$(-A)^{-\alpha} x = (-A)^{-\alpha} (-A)^{-\beta} y = (-A)^{-(\alpha+\beta)} y \in D \left((-A)^{\alpha+\beta}\right).$$

Therefore, from 52.2.17

$$(-A)^{\beta-\alpha} x = (-A)^{\beta-\alpha} (-A)^{\alpha} (-A)^{-\alpha} x = (-A)^{\beta} (-A)^{-\alpha} x.$$
Theorem 52.2.18 The definition of \((-A)^\alpha\) is well defined and \((-A)^\alpha\) is densely defined and closed. Also for any \(\alpha > 0\),

\[
\|(-A)^\alpha S(t)\| \leq \frac{C_\alpha}{\delta} \frac{1}{t^\alpha} e^{-\delta t} \quad (52.2.13)
\]

where \(-\delta > -\alpha\). Furthermore, \(C_\alpha\) is bounded as \(\alpha \to 0^+\) and is bounded on compact intervals of \((0, \infty)\). Also for \(\alpha \in (0, 1)\) and \(x \in D((-A)^\alpha)\),

\[
\|(S(t) - I)x\| \leq \frac{C_1 - \alpha}{\alpha \delta} \|(-A)^\alpha x\| \quad (52.2.14)
\]

There exists a constant \(C\) independent of \(\alpha \in [0, 1]\) such that for \(x \in D(A)\) and \(\varepsilon > 0\),

\[
\|(-A)^\alpha x\| \leq \varepsilon \|(-A) x\| + C e^{-\alpha/(1-\alpha)} \|x\| \quad (52.2.15)
\]

There exists a constant \(C'\) independent of \(\alpha \in [0, 1]\) such that for \(x \in D(A)\),

\[
\|(-A)^\alpha x\| \leq C' \|(-A) x\|^{\alpha} \|x\|^{1-\alpha} \quad (52.2.16)
\]

The formula \((52.2.16)\) is called an interpolation inequality.

**Proof:** It is obvious \((-A)^\alpha\) is densely defined because its domain is at least as large as \(D(A)\) which was assumed to be dense. It is a closed operator because if \(x_n \in D((-A)^\alpha)\) and \(x_n \to x, (-A)^\alpha x_n \to y\),

then

\((-A)^{-\alpha} x_n \to (-A)^{-\alpha} x,\ x_n = (-A)^{-\alpha} (-A)^\alpha x_n \to (-A)^{-\alpha} y\)

and so

\((-A)^{-\alpha} y = x\)

showing \(x \in D((-A)^\alpha)\) and \(y = (-A)^{-\alpha} x\). Thus \((-A)^\alpha\) is closed and densely defined.

Let \(-\delta > -\alpha\) where the sector for \(A\) was \(S_{-\alpha, \phi}, \alpha > 0\). Then recall from Corollary \(52.2.7\) there is a constant, \(N\) such that

\[
\|(-A) S(t)\| \leq \frac{N}{t} e^{-\delta t}
\]

What about \(\|(-A)^\alpha S(t)\|\)? First note that for \(\alpha \in [0, 1)\) this at least makes sense because \(S(t)\) maps into \(D(A)\). For any \(\alpha > 0\),

\[S(t) (-A)^{-\alpha} \|(-A)^\alpha S(t)\|

follows from the definition of \((-A)^{-\alpha}\). Therefore,

\[
(-A)^\alpha S(t) (-A)^{-\alpha} = S(t). \quad (52.2.17)
\]
Note this implies that on \( D((-A)^\alpha) \),
\[
(-A)^\alpha S(t) = S(t)(-A)^\alpha.
\]
Also
\[
(-A)^{-1} S(t) = S(t)(-A)^{-1} = S(t)(-A)^{-\alpha}(-A)^{-(1-\alpha)}
\]
and so
\[
S(t) = (-A) S(t) (-A)^{-\alpha}(-A)^{-(1-\alpha)}
\]
From (52.2.17) it follows
\[
(-A)^\alpha S(t) = (-A)(-A)^\alpha S(t)(-A)^{-\alpha}(-A)^{-(1-\alpha)}
\]
\[
= (-A) S(t) (-A)^{-(1-\alpha)}
\]
(52.2.18)
Then with this formula,
\[
\|(-A)^\alpha S(t)\| = \|(-A) S(t) (-A)^{-(1-\alpha)}\|
\]
\[
= \left\| \frac{1}{\Gamma(1-\alpha)} \int_0^\infty s^{1-\alpha} (-A) S(t+s) ds \right\|
\]
\[
\leq \frac{N}{(1-\alpha)} \int_0^\infty \frac{s^{1-\alpha}}{(t+s)^\alpha} e^{-\delta(s+t)} ds
\]
\[
= \frac{N}{\Gamma(1-\alpha)} \int_t^\infty \left(1 - \frac{u-t}{u}\right)^{1-\alpha} \frac{1}{u^\alpha} e^{-\delta u} ds
\]
\[
\leq \frac{N}{\Gamma(1-\alpha)} \frac{1}{t^\alpha} \int_t^\infty e^{-\delta u} ds = \frac{N}{\Gamma(1-\alpha)} \frac{1}{\delta t^\alpha} e^{-\delta t}
\]
\[
= C_\alpha \frac{1}{\delta} \frac{1}{t^\alpha} e^{-\delta t}.
\]
this establishes the formula when \( \alpha \in [0, 1] \). Next suppose \( \alpha = m \), a positive integer.
\[
\|A^m S(t)\| = \left\| A^m S \left( \frac{t}{m} \right)^m \right\|
\]
\[
= \left\| \left( A S \left( \frac{t}{m} \right) \right)^m \right\| \leq \frac{N}{m^m m^m}.
\]
This is why the above inequality holds.
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

If $\alpha, \beta > 0$,

$$
\|A^{\alpha+\beta}S(t)\| = \left\| A^{\alpha+\beta} S \left( \frac{t}{2} \right) S \left( \frac{t}{2} \right) \right\|
= \left\| A^\alpha S \left( \frac{t}{2} \right) A^\beta S \left( \frac{t}{2} \right) \right\|
\leq \frac{C_\alpha C_\beta}{t^{\alpha+\beta}} e^{-\delta t} = \frac{C}{t^{\alpha+\beta}} e^{-\delta t}
$$

Suppose now that $\alpha > 0$. Then

$$
\alpha = m + \beta
$$

where $\beta \in [0, 1)$. Then from what was just shown,

$$
\|A^{m+\beta}S(t)\| \leq \frac{C}{t^{m+\beta}} e^{-\delta t}.
$$

Next consider 52.2.14. First note that whenever $\alpha > 0$,

$$
(-A)^{-\alpha} S(s) = S(s) (-A)^{-\alpha}
$$

and so on $D((-A)^\alpha)$,

$$
S(s) = (-A)^\alpha S(s) (-A)^{-\alpha}, S(s) (-A)^\alpha = (-A)^\alpha S(s)
$$

Now for $x \in D((-A)^\alpha)$,

$$
\|(S(t) - I)x\| = \left\| - \int_0^t (-A) S(s) x ds \right\|
= \left\| - \int_0^t (-A)^{1-\alpha} (-A)^\alpha S(s) x ds \right\|
= \left\| - \int_0^t (-A)^{1-\alpha} S(s) (-A)^\alpha x ds \right\|
\leq \int_0^t \left\| (-A)^{1-\alpha} S(s) \right\| ds \|(-A)^\alpha x\|
\leq \int_0^t \frac{C_{1-\alpha}}{\delta} \frac{1}{s^{1-\alpha}} e^{-\delta s} ds \|(-A)^\alpha x\|
\leq \frac{C_{1-\alpha}}{\delta} \frac{1}{\alpha} \|(-A)^\alpha x\|
$$

and this shows 52.2.14.

Next consider 52.2.15. Let $x \in H$ and $\beta \in (0, 1)$. Then

$$
\left\|(-A)^{-\beta} x\right\| = \frac{1}{\Gamma(\beta)} \left\| \int_0^\infty t^{\beta-1} S(t) x dt \right\|
$$
52.2. ANALYTIC SEMIGROUPS

\[\begin{align*}
&= \frac{1}{\Gamma(\beta)} \left( \int_0^\eta t^{\beta-1} S(t) \, x \, dt + \int_\eta^\infty t^{\beta-1} S(t) \, x \, dt \right) \\
&\leq \frac{1}{\Gamma(\beta)} \int_0^\eta t^{\beta-1} ||S(t)\, x|| \, dt + \frac{1}{\Gamma(\beta)} \left( \int_\eta^\infty t^{\beta-1} S(t) \, x \, dt \right) \\
&\leq \frac{C}{\Gamma(\beta)} \frac{\eta^\beta}{\beta} ||x|| + \frac{1}{\Gamma(\beta)} \left( \int_\eta^\infty t^{\beta-1} S(t) \, x \, dt \right) \\
&\leq \frac{C}{\Gamma(\beta)} \frac{\eta^\beta}{\beta} ||x|| + \frac{1}{\Gamma(\beta)} \left( \int_\eta^\infty t^{\beta-1} S(t) \, x \, dt \right) \\
&= \frac{1}{\Gamma(\beta)} \left( \frac{C\eta^\beta}{\beta} ||x|| + \eta^\beta \frac{1}{\beta} \left( (1-\beta) \int_\eta^\infty t^{\beta-2} \, dt \right) \right) .
\end{align*}\]

Now let \( \delta = C\eta^\beta \) so \( \eta = C^{-1/\beta} \delta^{1/\beta} \) and \( \eta^{\beta-1} = C^{-1/\beta} \delta^{(\beta-1)/\beta} \). Thus for all \( x \in H \),

\[||(-A)^{\beta} x|| \leq \frac{1}{\Gamma(\beta)} \left( \frac{\delta}{\beta} ||x|| + 2C \frac{1}{\Gamma(\beta)} \frac{\delta^{(\beta-1)/\beta}}{\beta} ||A^{-1} x|| \right) .\]

Let \( \varepsilon = \frac{\delta}{\beta \Gamma(\beta)} = \frac{\delta}{\Gamma(1+\beta)} \). Then the above is of the form

\[||(-A)^{\beta} x|| \leq \varepsilon ||x|| + 2C \frac{1}{\Gamma(\beta)} (\frac{\delta}{\beta} ||A^{-1} x||) \]

because \( \Gamma \) is decreasing on \((0,1)\). I need to verify that for \( \beta \in (0,1) \),

\[\Gamma(1+\beta)^{(\beta-1)/\beta}\]

is bounded. It is continuous on \((0,1]\) and so if I can show \( \lim_{\beta \to 0^+} \Gamma(1+\beta)^{(\beta-1)/\beta} \) exists, then it will follow the function is bounded. It suffices to show

\[\lim_{\beta \to 0^+} \frac{\beta - 1}{\beta} \ln \Gamma(1+\beta) = -\lim_{\beta \to 0^+} \frac{\ln(1+\beta)}{\beta}\]

exists. Consider this. By L’Hospital’s rule and dominated convergence theorem, this is

\[\lim_{\beta \to 0^+} \frac{\int_0^\infty \ln(t) \, t^{\beta-1} \, e^{-t} \, dt}{\Gamma(1+\beta)} = \lim_{\beta \to 0^+} \frac{\int_0^\infty \ln(t) \, t^{\beta-1} \, e^{-t} \, dt}{\int_0^\infty \ln(t) \, e^{-t} \, dt} .\]
Thus the function is bounded independent of $\beta \in (0, 1)$. This shows there is a constant $C$ which is independent of $\beta \in (0, 1)$ such that for any $x \in H$,

$$\left\| (-A)^{-\beta} x \right\| \leq \varepsilon \|x\| + C\varepsilon^{(\beta-1)/\beta} \left\| A^{-1} x \right\|. \quad (52.2.19)$$

Now let $y \in D(A) = D((-A))$ and let $x = (-A) y$. Then the above becomes

$$\left\| (-A)^{-\beta} (-A) y \right\| \leq \varepsilon \|(-A) y\| + C\varepsilon^{(\beta-1)/\beta} \|y\|$$

I claim that

$$(-A)^{-\beta} (-A) y = (-A)^{1-\beta} y.$$

The reason for this is as follows.

$$(-A)^{\beta} (-A)^{1-\beta} y = (-A) y$$

and so the desired result follows from multiplying on the left by $(-A)^{-\beta}$. Hence

$$\left\| (-A)^{1-\beta} y \right\| \leq \varepsilon \|(-A) y\| + C\varepsilon^{(\beta-1)/\beta} \|y\|$$

Now let $1 - \beta = \alpha$ and obtain

$$\|(-A)^{\alpha} y\| \leq \varepsilon \|(-A) y\| + C\varepsilon^{-\alpha/(1-\alpha)} \|y\|$$

This proves $52.2.15$.

Finally choose $\varepsilon$ to minimize the right side of the above expression. Thus let

$$\varepsilon = \left( \frac{\alpha \|y\| C}{\|(-A) y\| (1 - \alpha)} \right)^{1-\alpha}$$

Then the above expression becomes

$$\|(-A)^{\alpha} y\| \leq \|(-A) y\| \left( \frac{\alpha \|y\| C}{\|(-A) y\| (1 - \alpha)} \right)^{1-\alpha}$$

$$+ C \left( \frac{\alpha \|y\| C}{\|(-A) y\| (1 - \alpha)} \right)^{1-\alpha} \frac{1}{\|y\|}$$

$$= \|(-A) y\|^\alpha \|y\|^{1-\alpha} \left( \frac{\alpha C}{(1 - \alpha)} \right)^{1-\alpha}$$

$$+ \|(-A) y\|^\alpha \|y\|^{1-\alpha} \left( \frac{\alpha C}{(1 - \alpha)} \right)^{-\alpha}$$

$$= \left( \frac{\alpha C}{(1 - \alpha)} \right)^{1-\alpha} + \left( \frac{\alpha C}{(1 - \alpha)} \right)^{-\alpha} \|(-A) y\|^\alpha \|y\|^{1-\alpha}$$

$$\leq C' \|(-A) y\|^\alpha \|y\|^{1-\alpha}$$
where $C'$ does not depend on $\alpha \in (0, 1)$. To see such a constant exists, note
\[
\lim_{\alpha \to 1} \left( \frac{\alpha C}{1 - \alpha} \right)^{1 - \alpha} = 1
\]
and
\[
\lim_{\alpha \to 1} \left( \frac{\alpha C}{1 - \alpha} \right)^{-\alpha} = 0
\]
while
\[
\lim_{\alpha \to 0} \left( \frac{\alpha C}{1 - \alpha} \right)^{1 - \alpha} = 0, \quad \lim_{\alpha \to 0} \left( \frac{\alpha C}{1 - \alpha} \right)^{-\alpha} = 1
\]
Of course $C'$ depends on $C$ but as shown above, this did not depend on $\alpha \in (0, 1)$.

This proves 52.2.16.

The following corollary follows from the proof of the above theorem.

**Corollary 52.2.19** Let $\alpha \in (0, 1)$. Then for all $\varepsilon > 0$, there exists a constant $C(\varepsilon, \alpha)$ such that
\[
\left\| (-A)^{-\alpha} x \right\| \leq \varepsilon \| x \| + C(\varepsilon, \alpha) \left\| (-A)^{-1} x \right\|
\]
Also if $A^{-1}$ is compact, then so is $(-A)^{-\alpha}$ for all $\alpha \in (0, 1)$.

**Proof:** The first part is done in the above theorem. Let $S$ be a bounded set and let $\eta > 0$. Then let $\varepsilon > 0$ be small enough that for all $x \in S, \varepsilon \| x \| < \eta/4$. Let \( \{ (-A)^{-1} x_n \} \) be a $\eta/(2 + 2C(\varepsilon, \alpha))$ net for \((-A)^{-1}(S)\). Then if \((-A)^{-\alpha} x \in (-A)^{-\alpha} S\), there exists $x_n$ such that
\[
\left\| (-A)^{-1} x_n - (-A)^{-1} x \right\| \leq \frac{\eta}{2 + 2C(\varepsilon, \alpha)}.
\]
Then
\[
\left\| (-A)^{-\alpha} x_n - (-A)^{-\alpha} x \right\| \leq \varepsilon \| x_n - x \| + C(\varepsilon, \alpha) \left\| (-A)^{-1} x_n - (-A)^{-1} x \right\|
\]
\[
< \frac{\eta}{2} + \frac{\eta}{2} = \eta
\]
showing $(-A)^{-\alpha}(S)$ has a $\eta$ net. Thus $(-A)^{-\alpha}$ is compact. This proves the corollary.

The next proposition gives a general interpolation inequality.

**Proposition 52.2.20** Let $0 < \alpha < \beta$ and let
\[
\gamma = \theta \beta + (1 - \theta) \alpha, \ \theta \in (0, 1).
\]
Then there exists a constant, $C$ such that for all $x \in D((-A)^{\gamma})$,
\[
\|(-A)^\gamma x\| \leq C \left\| (-A)^\beta x \right\|^\theta \|(-A)^\alpha x\|^{1-\theta}.
\]
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

Proof: This is an exercise in using 52.2.13. Letting \( x \in D((-A)^\theta) \),

\[
(-A)^\gamma x = (-A)^\theta (-A)^{-\theta} (-A)^\gamma x
\]

Therefore, letting \( C \) denote a generic constant, it follows since \((-A)^\theta\) is closed,

\[
\Gamma(\theta) \|(-A)^\gamma x\| = \left\| \int_0^\infty t^{\theta-1} (-A)^\theta S(t) (-A)^\gamma x \, dt \right\|
\]

\[
\leq \int_0^\eta t^{\theta-1} \left\| (-A)^\theta (-A)^{\gamma-\beta} S(t) (-A)^\beta x \right\| \, dt + \int_\eta^\infty t^{\theta-1} \left\| (-A)^\theta (-A)^{\gamma-\alpha} S(t) (-A)^\alpha x \right\| \, dt
\]

\[
\leq C \int_0^\eta t^{\theta-1} t^{-\beta} t^{\beta-\gamma} dt \|(-A)^\beta x\| + C \int_\eta^\infty t^{\theta-1} t^{-\theta} t^{\alpha-\gamma} dt \|(-A)^\alpha x\|
\]

\[
= C \left( \frac{\eta^{\beta-\gamma}}{\beta - \gamma} \|(-A)^\beta x\| + \frac{\eta^{\gamma-\alpha}}{\gamma - \alpha} \|(-A)^\alpha x\| \right)
\]

and now writing in what \( \gamma \) is in terms of \( \theta \) yields

\[
\Gamma(\theta) \|(-A)^\gamma x\| \leq C \left( \frac{1}{\beta - \alpha} \right) \left( \frac{(\eta^{\beta-\alpha})^{1-\theta}}{(1-\theta)} \|(-A)^\beta x\| + \frac{(\eta^{\beta-\alpha})^{-\theta}}{\theta} \|(-A)^\alpha x\| \right)
\]

Letting \( \lambda = \eta^{\beta-\alpha} \), it follows

\[
\Gamma(\theta) \|(-A)^\gamma x\| \leq C \left( \frac{1}{\beta - \alpha} \right) \left( \frac{\lambda^{1-\theta}}{(1-\theta)} \|(-A)^\beta x\| + \frac{\lambda^{-\theta}}{\theta} \|(-A)^\alpha x\| \right)
\]

then let

\[
\lambda = \frac{\|(-A)^\alpha x\|}{\|(-A)^\beta x\|}
\]

which is obtained from minimizing the expression on the right in the above. then placing this in the inequality yields

\[
\Gamma(\theta) \|(-A)^\gamma x\|
\]

\[
\leq C \left( \frac{1}{\beta - \alpha} \right) \left( \frac{\left( \frac{\|(-A)^\alpha x\|}{\|(-A)^\beta x\|} \right)^{1-\theta}}{(1-\theta)} \|(-A)^\beta x\| + \frac{\left( \frac{\|(-A)^\alpha x\|}{\|(-A)^\beta x\|} \right)^{-\theta}}{\theta} \|(-A)^\alpha x\| \right)
\]
\[ C \left( \frac{1}{\beta - \alpha} \right) \left( \frac{1}{1-\theta} + \frac{1}{\theta} \right) \|(-A)^\alpha x\|^{1-\theta} \|(-A)^\beta x\|^\theta \]

and this proves the proposition.

Note that the constant is not bounded as \( \theta \to 1 \).

Here is another interesting result about compactness.

**Proposition 52.2.21** Let \( A \) be sectorial for \( S_{-a, \phi} \) where \( -a < 0 \). Then the following are equivalent.

1. \((-A)^{-\alpha}\) is compact for all \( \alpha > 0 \).
2. \( S(t) \) is compact for each \( t > 0 \).

**Proof:** First suppose \((-A)^{-\alpha}\) is compact for all \( \alpha > 0 \). Then

\[
\Gamma(\alpha)(-A)^{-\alpha} = \int_0^t s^{\alpha-1} S(s) \, ds + \int_t^\infty s^{\alpha-1} S(s) \, ds
\]

\[
= t^{\alpha} S(t) - \int_0^t s^{\alpha} AS(s) \, ds + s^{\alpha-1} S(s) A^{-1} \bigg|_t^\infty
\]

\[-(\alpha - 1) \int_t^\infty s^{\alpha-2} S(s) A^{-1} \, ds
\]

Now

\[
\left\| \frac{s^{\alpha}}{\alpha} AS(s) \right\| \leq C \frac{s^{\alpha-1}}{\alpha}
\]

and so the second integral satisfies

\[
\left\| \int_0^t \frac{s^{\alpha}}{\alpha} AS(s) \, ds \right\| \leq C \frac{t^\alpha}{\alpha^2}
\]

\[
\Gamma(\alpha)(-A)^{-\alpha} = O(\frac{t^\alpha}{\alpha^2}) + \frac{t^\alpha}{\alpha} S(t)
\]

\[-t^{\alpha-1} A^{-1} S(t) - (\alpha - 1) \int_t^\infty s^{\alpha-2} S(s) \, ds A^{-1}
\]

It follows that for \( t > 0 \), and \( \varepsilon > 0 \) given,

\[
S(t) = \left( \frac{t^\alpha}{\alpha} - t^{\alpha-1} \right)^{-1} \left( \Gamma(\alpha)(-A)^{-\alpha}
\right.
\]

\[+ (\alpha - 1) \int_t^\infty s^{\alpha-2} S(s) \, ds A^{-1} + O\left( \frac{\varepsilon^\alpha}{\alpha^2} \right) \]

\[= \left( \frac{t^\alpha}{\alpha} - t^{\alpha-1} \right)^{-1} \left( \Gamma(\alpha)(-A)^{-\alpha}
\right.
\]

\[+ (\alpha - 1) \int_t^\infty s^{\alpha-2} S(s) \, ds A^{-1} + O\left( \frac{1}{\alpha} \right) \]

\[= N_\alpha + O\left( \frac{1}{\alpha} \right).
\]
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

where $N$ is a compact operator. Now let $B$ be a bounded set in $H$, $\|x\| \leq M$ for all $x \in B$ and let $\eta > 0$ be given. Then choose $\alpha$ large enough that $\left\| O \left( \frac{1}{\alpha} \right) \right\| < \frac{\eta}{4+4M}$. Then there exists a $\eta/2$ net, $\{N_\alpha x_n\}_{n=1}^N$ for $N_\alpha(B)$. Then consider $\{S(t)x_n\}_{n=1}^N$. For $x \in B$, there exists $x_n$ such that $\|N_\alpha x_n - N_\alpha x\| < \eta/2$. Then

$$\|S(t)x - S(t)x_n\| \leq \|S(t)x - N_\alpha x\| + \|N_\alpha x - N_\alpha x_n\| + \|N_\alpha x_n - S(t)x_n\|$$

$$\leq \frac{\eta}{4+4M}M + \frac{\eta}{2} + \frac{\eta}{4+4M}M < \eta$$

Thus $S(t)(B)$ has an $\eta$ net for every $\eta > 0$ and so $S(t)$ is compact.

Next suppose $S(t)$ is compact for all $t > 0$. Then

$$(-A)^{-\alpha} = \frac{1}{\Gamma(\alpha)} \int_0^\infty t^{\alpha-1}S(t)dt$$

and the integral is a limit in norm of Riemann sums of the form

$$\sum_{k=1}^m t_k^{\alpha-1}S(t_k)\Delta t_k$$

and each of these operators is compact. Since $(-A)^{-\alpha}$ is the limit in norm of compact operators, it must also be compact. This proves the proposition.

Here are some observations which are listed in the book by Henry [57]. Like the above proposition, these are exercises in this book.

**Observation 52.2.22** For each $x \in H$, $t \to tAS(t)x$ is continuous and $\lim_{t \to 0^+} tAS(t)x = 0$.

The reason for this is that if $x \in D(A)$, then

$$tAS(t)x = |tS(t)Ax| \to 0$$

as $t \to 0$. Now suppose $y \in H$ is arbitrary. Then letting $x \in D(A)$,

$$|tAS(t)y| \leq |tAS(t)(y-x)| + |tAS(t)x|$$

$$\leq \varepsilon + |tAS(t)x|$$

provided $x$ is close enough to $y$. The last term converges to 0 and so

$$\lim_{t \to 0^+} \sup_{t \to 0^+} |tAS(t)y| \leq \varepsilon$$

where $\varepsilon > 0$ is arbitrary. Thus

$$\lim_{t \to 0^+} |tAS(t)y| = 0.$$
Why is \( t \to tAS(t)x \) continuous on \([0, T]\)? This is true if \( x \in D(A) \) because \( t \to tS(t)Ax \) is continuous. If \( y \in H \) is arbitrary, let \( x_n \) converge to \( y \) in \( H \) where \( x_n \in D(A) \). Then
\[
|tAS(t)y - tAS(t)x_n| \leq C|y - x_n|
\]
and so the convergence is uniform. Thus \( t \to tAS(t)y \) is continuous because it is the uniform limit of a sequence of continuous functions.

**Observation 52.2.23** If \( x \in H \) and \( A \) is sectorial for \( S_{-\alpha, \phi} \), \(-\alpha < 0\), then for any \( \alpha \in [0, 1] \),
\[
\lim_{t \to 0^+} t^\alpha \|(-A)^\alpha S(t)x\| = 0.
\]

This follows as above because you can verify this is true for \( x \in D(A) \) and then use the fact shown above that
\[
t^\alpha \|(-A)^\alpha S(t)\| \leq C
\]
to extend it to \( x \) arbitrary.

### 52.2.5 A Scale Of Banach Spaces

Next I will present an important and interesting theorem which can be used to prove equivalence of certain norms.

**Theorem 52.2.24** Let \( A, B \) be sectorial for \( S_{-\alpha, \phi} \) where \(-\alpha < 0\) and suppose \( D(A) = D(B) \). Also suppose
\[
(A - B)(-A)^{-\alpha}, (A - B)(-B)^{-\alpha}
\]
are both bounded on \( D(A) \) for some \( \alpha \in (0, 1) \). Then for all \( \beta \in [0, 1] \),
\[
(-A)^\beta (-B)^{-\beta}, (-B)^\beta (-A)^{-\beta}
\]
are both bounded on \( D(A) = D(B) \). Also \( D((-A)^\beta) = D((-B)^\beta) \).

**Proof:** First of all it is a good idea to verify \((A - B)(-A)^{-\alpha}, (A - B)(-B)^{-\alpha}\) make sense on \( D(A) \). If \( x \in D(A) \), then why is \((A)^{-\alpha}x \in D(A)\)? Here is why. Since \( x \in D(A) \),
\[
x = (-A)^{-1}y
\]
for some \( y \in H \). Then
\[
(A)^{-\alpha}x = (A)^{-\alpha}(-A)^{-1}y = (A)^{-1}(-A)^{-\alpha}y \in D(A).
\]
The case of \((A - B)(-B)^{-\alpha}\) is similar.
CHAPTER 52. SOME IMPORTANT FUNCTIONAL ANALYSIS APPLICATIONS

Next for $\beta \in (0, 1)$ and $\lambda > 0$, use (52.2.16) to write

$$
\left\| (A) (\lambda I - A)^{-1} x \right\| \\
\leq \ C \left\| (A) (\lambda I - A)^{-1} x \right\| \beta \left\| ((\lambda I - A)^{-1} x \right\|^{1-\beta}
$$

$$
\leq \ C \left\| (A) (\lambda I - A)^{-1} \right\|^{\beta} \left\| ((\lambda I - A)^{-1} x \right\|^{1-\beta} \left\| x \right\|
$$

$$
\leq \ C \left(1 + \frac{\lambda}{(\lambda + \delta)}\right)^{\beta} \frac{M}{(\lambda + \delta)^{1-\beta}} \left\| x \right\| \equiv \ \frac{C}{(\lambda + \delta)^{1-\beta}} \left\| x \right\| \quad (52.2.20)
$$

where $-\alpha < -\delta < 0$ where $C$ denotes a generic constant. Similarly, for all $\beta \in (0, 1)$,

$$
\left\| (B) (\lambda I - B)^{-1} x \right\| \leq \ \frac{C}{(\lambda + \delta)^{1-\beta}} \left\| x \right\| \quad (52.2.21)
$$

Now from Theorem (52.2.16) and letting $\beta \in (0, 1)$,

$$
(\lambda I - B)^{-1} - (A)^{-1} = \frac{\sin (\pi \beta)}{\pi} \int_{0}^{\infty} \lambda^{-\beta} \left( (\lambda I - B)^{-1} - (A)^{-1} \right) d\lambda
$$

$$
= \frac{\sin (\pi \beta)}{\pi} \int_{0}^{\infty} \lambda^{-\beta} (A - B) (\lambda I - A)^{-1} d\lambda. \quad (52.2.22)
$$

Therefore, letting $x \in D(A)$ and letting $C$ denote a generic constant which can be changed from line to line and using (52.2.16) and (52.2.21),

$$
\left\| x - (B)^{\beta} (A)^{-\beta} x \right\|
\leq \ C \int_{0}^{\infty} \frac{1}{(\lambda + \delta)^{1-\beta}} \left\| (B)^{\beta} (A - B) (\lambda I - A)^{-1} x \right\| d\lambda
$$

The reason $(-B)^{\beta}$ goes inside the integral is that it is a closed operator. Then the above

$$
\leq \ C \int_{0}^{\infty} \frac{1}{(\lambda + \delta)^{1-\beta}} \left\| (A - B)(-A)^{-\alpha} (\lambda I - A)^{-1} x \right\| d\lambda
$$

$$
\leq \ C \int_{0}^{\infty} \frac{1}{(\lambda + \delta)^{1-\beta}} \left\| (-A)^{\alpha} (\lambda I - A)^{-1} x \right\| d\lambda
$$

$$
\leq \ C \int_{0}^{\infty} \frac{1}{(\lambda + \delta)^{1-\beta}} \frac{1}{(\lambda + \delta)^{1-\alpha}} d\lambda \left\| x \right\| = \ C \left\| x \right\|.
$$

It follows $(-B)^{\beta} (-A)^{-\beta}$ is bounded on $D(A)$. 

Next reverse $A$ and $B$ in $\mathcal{D}(A)$ This yields
\[
(-A)^{-\beta} - (-B)^{-\beta} = \frac{\sin(\pi\beta)}{\pi} \int_0^\infty \lambda^{-\beta} (\lambda I - A)^{-1} (B - A) (\lambda I - B)^{-1} d\lambda.
\]
Letting $x \in \mathcal{D}(A)$,
\[
\left\|x - (-A)^{-\beta} (-B)^{-\beta} x\right\| \leq C \int_0^\infty \lambda^{-\beta} \left\|(-A)^{\beta} (\lambda I - A)^{-1} (B - A) (\lambda I - B)^{-1} x\right\| d\lambda
\]
\[
\leq C \int_0^\infty \frac{1}{\lambda^\beta (\lambda + \delta)^{1-\beta}} \left\|(B - A) (-B)^{-\alpha} (\lambda I - B)^{-1} x\right\| d\lambda
\]
\[
\leq C \int_0^\infty \frac{1}{\lambda^\beta (\lambda + \delta)^{1-\beta}} \left\|x\right\| = C \left\|x\right\| \tag{52.2.24}
\]
This shows $(-A)^{-\beta} (-B)^{-\beta}$ is bounded on $\mathcal{D}(A) = \mathcal{D}(B)$. Note the assertion these are bounded refers to the norm on $H$.

It remains to verify $\mathcal{D}((-A)^{\beta}) = \mathcal{D}((-B)^{\beta})$. Since $\mathcal{D}(A)$ is dense in $H$ there exists a unique $L(A,B) \in \mathcal{L}(H,H)$ such that $L(A,B) = (-A)^{-\beta} (-B)^{-\beta}$ on $\mathcal{D}(A)$. Let $L(B,A)$ be defined similarly as a continuous linear map which equals $(-B)^{-\beta} (-A)^{-\beta}$ on $\mathcal{D}(A)$. Then
\[
(-A)^{-\beta} L(A,B) = (-B)^{-\beta}
\]
\[
(-B)^{-\beta} L(B,A) = (-A)^{-\beta}
\]
The first of these equations shows $\mathcal{D}((-B)^{\beta}) \subseteq \mathcal{D}((-A)^{\beta})$ and the second turns the inclusion around. Thus they are equal as claimed.

Next consider the case where $\beta = 1$. In this case
\[
(A - B) B^{-\alpha}
\]
is bounded on $\mathcal{D}(A)$ and so
\[
(A - B) B^{-\alpha} B^{-1+\alpha}
\]
is also bounded on $\mathcal{D}(A)$. But this equals
\[
(A - B) B^{-1}.
\]
Thus $AB^{-1}$ is bounded on $\mathcal{D}(A)$. Similarly you can show
\[
(B - A) A^{-1}
\]
is bounded which implies $BA^{-1}$ is bounded on $\mathcal{D}(A)$. This proves the theorem.
Definition 52.2.25 Let $A$ be sectorial for the sector $S_{a,\phi}$. Let $b > a$ so that $A - bI$ is sectorial for $S_{b,\phi}$ where $\delta = b - a$. Then for each $\alpha \in [0, 1]$, define a norm on $D ((bI - A)^\alpha) \equiv H_\alpha$ by

$$||x||_\alpha \equiv ||(bI - A)^\alpha x||$$

The $\{H_\alpha\}_{\alpha \in [0,1]}$ is called a scale of Banach spaces.

Proposition 52.2.26 The $H_\alpha$ above are Banach spaces and they decrease in $\alpha$. Furthermore, if $b_i > a$ for $i = 1, 2$ then the two norms associated with the $b_i$ are equivalent.

Proof: That the $H_\alpha$ are decreasing was shown above in Theorem 52.2.16. They are Banach spaces because $(bI - A)^\alpha$ is a closed mapping which is also one to one.

It only remains to verify the claim about the equivalence of the norms. Let $b_2 > b_1 > a$. Then if $\alpha \in (0, 1)$,

$$(b_1 I - A) - (b_2 I - A)) (b_2 I - A)^{-\alpha}$$

$$= (b_1 - b_2)(b_2 I - A)^{-\alpha} \in \mathcal{L}(H, H)$$

and so by Theorem 52.2.24, for each $\beta \in [0, 1]$,

$$D \left( (b_1 I - A)^\beta \right) = D \left( (b_2 I - A)^\beta \right)$$

so the spaces, $H_\beta$ are the same for either choice of $b > a$. Also from this theorem,

$$(b_1 I - A)^\beta (b_2 I - A)^{-\beta}, (b_2 I - A)^\beta (b_1 I - A)^{-\beta}$$

are both bounded on $D(A)$. Therefore, for $x \in H_\beta$

$$\left| \left| (b_1 I - A)^\beta x \right| \right| = \left| \left| (b_1 I - A)^\beta (b_2 I - A)^{-\beta} (b_2 I - A)^\beta x \right| \right|$$

$$\leq C \left| \left| (b_2 I - A)^\beta x \right| \right|$$

Similarly using the boundedness of $(b_2 I - A)^\beta (b_1 I - A)^{-\beta}$, it follows

$$\left| \left| (b_2 I - A)^\beta x \right| \right| \leq C' \left| \left| (b_1 I - A)^\beta x \right| \right|$$

Thus showing the two norms are equivalent. This proves the proposition.
Chapter 53

Complex Mappings

53.1 Conformal Maps

If \( \gamma(t) = x(t) + iy(t) \) is a \( C^1 \) curve having values in \( U \), an open set of \( \mathbb{C} \), and if \( f: U \to \mathbb{C} \) is analytic, consider \( f \circ \gamma \), another \( C^1 \) curve having values in \( \mathbb{C} \). Also, \( \gamma'(t) \) and \( (f \circ \gamma)'(t) \) are complex numbers so these can be considered as vectors in \( \mathbb{R}^2 \) as follows. The complex number, \( x + iy \) corresponds to the vector, \((x; y)\). Suppose that \( \gamma \) and \( \eta \) are two such \( C^1 \) curves having values in \( U \) and that \( \gamma(t_0) = \eta(s_0) = z \) and suppose that \( f: U \to \mathbb{C} \) is analytic. What can be said about the angle between \((f \circ \gamma)'(t_0)\) and \((f \circ \eta)'(s_0)\)? It turns out this angle is the same as the angle between \( \gamma'(t_0) \) and \( \eta'(s_0) \) assuming that \( f'(z) \neq 0 \). To see this, note \( (x, y) \cdot (a, b) = \frac{1}{2}(z\overline{w} + \overline{z}w) \) where \( z = x + iy \) and \( w = a + ib \). Therefore, letting \( \theta \) be the cosine between the two vectors, \((f \circ \gamma)'(t_0)\) and \((f \circ \eta)'(s_0)\), it follows from calculus that

\[
\cos \theta = \frac{(f \circ \gamma)'(t_0) \cdot (f \circ \eta)'(s_0)}{|(f \circ \eta)'(s_0)| \cdot |(f \circ \gamma)'(t_0)|}
\]

\[
= \frac{1}{2} \frac{f'(\gamma(t_0)) \gamma'(t_0) f'(\eta(s_0)) \eta'(s_0) + f'(\gamma(t_0)) \gamma'(t_0) f'(\eta(s_0)) \eta'(s_0)}{|f'(\gamma(t_0))| \cdot |f'(\eta(s_0))|}
\]

\[
= \frac{1}{2} \frac{f'(z) \overline{f'(z)} \gamma'(t_0) \eta'(s_0) + \overline{f'(z)} f'(z) \gamma'(t_0) \eta'(s_0)}{|f'(z)| \cdot |f'(z)|}
\]

\[
= \frac{1}{2} \left( \frac{\gamma'(t_0) \overline{\eta'(s_0)} + \eta'(s_0) \overline{\gamma'(t_0)}}{|\gamma'(t_0)| \cdot |\eta'(s_0)|} \right)
\]

which equals the angle between the vectors, \( \gamma'(t_0) \) and \( \eta'(t_0) \). Thus analytic mappings preserve angles at points where the derivative is nonzero. Such mappings are called isogonal.

Actually, they also preserve orientations. If \( z = x + iy \) and \( w = a + ib \) are two complex numbers, then \((x, y, 0)\) and \((a, b, 0)\) are two vectors in \( \mathbb{R}^3 \). Recall that the
CHAPTER 53. COMPLEX MAPPINGS

cross product, \((x, y, 0) \times (a, b, 0)\), yields a vector normal to the two given vectors such that the triple, \((x, y, 0), (a, b, 0)\), and \((x, y, 0) \times (a, b, 0)\) satisfies the right hand rule and has magnitude equal to the product of the sine of the included angle times the product of the two norms of the vectors. In this case, the cross product will produce a vector which is a multiple of \(k\), the unit vector in the direction of the \(z\) axis. In fact, you can verify by computing both sides that, letting \(z = x + iy\) and \(w = a + ib\),

\[
(x, y, 0) \times (a, b, 0) = \text{Re}(z \overline{w}) k.
\]

Therefore, in the above situation,

\[
(f \circ \gamma)'(t_0) \times (f \circ \eta)'(s_0) = \text{Re}\left(f'(\gamma(t_0)) \gamma'(t_0) i \overline{f'\eta'(\eta(s_0)) \eta'(s_0)}\right) k
\]

\[
= |f'(z)|^2 \text{Re}\left(\gamma'(t_0) i \overline{\eta'(s_0)}\right) k
\]

which shows that the orientation of \(\gamma'(t_0), \eta'(s_0)\) is the same as the orientation of \((f \circ \gamma)'(t_0), (f \circ \eta)'(s_0)\). Mappings which preserve both orientation and angles are called conformal mappings and this has shown that analytic functions are conformal mappings if the derivative does not vanish.

53.2 Fractional Linear Transformations

53.2.1 Circles And Lines

These mappings map lines and circles to either lines or circles.

Definition 53.2.1 A fractional linear transformation is a function of the form

\[
f(z) = \frac{az + b}{cz + d} \tag{53.2.1}
\]

where \(ad - bc \neq 0\).

Note that if \(c = 0\), this reduces to a linear transformation \((a/d) z + (b/d)\). Special cases of these are defined as follows.

- dilations: \(z \to \delta z, \delta \neq 0\),
- inversions: \(z \to \frac{1}{\overline{z}}\),
- translations: \(z \to z + \rho\).

The next lemma is the key to understanding fractional linear transformations.

Lemma 53.2.2 The fractional linear transformation, \((53.2.1)\), can be written as a finite composition of dilations, inversions, and translations.
53.2. FRACTIONAL LINEAR TRANSFORMATIONS

Proof: Let

\[ S_1(z) = z + \frac{d}{c}, \quad S_2(z) = \frac{1}{z}, \quad S_3(z) = \frac{(bc - ad)}{c^2} z \]

and

\[ S_4(z) = z + \frac{a}{c} \]

in the case where \( c \neq 0 \). Then \( f(z) \) given in Exercise 53.2.1 is of the form

\[ f(z) = S_4 \circ S_3 \circ S_2 \circ S_1. \]

Here is why.

\[ S_2(S_1(z)) = S_2 \left(z + \frac{d}{c}\right) = \frac{1}{z + \frac{d}{c}} = \frac{c}{zc + d}. \]

Now consider

\[ S_3 \left( \frac{c}{zc + d} \right) = \frac{(bc - ad)}{c^2} \left( \frac{c}{zc + d} \right) = \frac{bc - ad}{c(zc + d)}. \]

Finally, consider

\[ S_4 \left( \frac{bc - ad}{c(zc + d)} \right) = \frac{bc - ad}{c(zc + d)} + \frac{a}{c} = \frac{b + az}{zc + d}. \]

In case that \( c = 0 \), \( f(z) = \frac{a}{z} + \frac{b}{z} \) which is a translation composed with a dilation. Because of the assumption that \( ad - bc \neq 0 \), it follows that since \( c = 0 \), both \( a \) and \( d \neq 0 \). This proves the lemma.

This lemma implies the following corollary.

Corollary 53.2.3 Fractional linear transformations map circles and lines to circles or lines.

Proof: It is obvious that dilations and translations map circles to circles and lines to lines. What of inversions? If inversions have this property, the above lemma implies a general fractional linear transformation has this property as well.

Note that all circles and lines may be put in the form

\[ \alpha \left( x^2 + y^2 \right) - 2ax - 2by = r^2 - (a^2 + b^2) \]

where \( \alpha = 1 \) gives a circle centered at \((a, b)\) with radius \( r \) and \( \alpha = 0 \) gives a line. In terms of complex variables you may therefore consider all possible circles and lines in the form

\[ \alpha z \bar{z} + \beta z + \bar{\beta} \bar{z} + \gamma = 0, \tag{53.2.2} \]

To see this let \( \beta = \beta_1 + i\beta_2 \) where \( \beta_1 \equiv -a \) and \( \beta_2 \equiv b \). Note that even if \( \alpha \) is not 0 or 1 the expression still corresponds to either a circle or a line because you can
divide by \( \alpha \) if \( \alpha \neq 0 \). Now I verify that replacing \( z \) with \( \frac{1}{\bar{z}} \) results in an expression of the form in \( \ref{53.2.2} \). Thus, let \( w = \frac{1}{\bar{z}} \) where \( z \) satisfies \( \ref{53.2.2} \). Then
\[
(\alpha \bar{w} + \beta w + \gamma w \bar{w}) = \frac{1}{z\bar{z}} \left( \alpha z \bar{z} + \beta z + \bar{z} \right) = 0
\]
and so \( w \) also satisfies a relation like \( \ref{53.2.2} \). One simply switches \( \alpha \) with \( \gamma \) and \( \beta \) with \( \bar{\beta} \). Note the situation is slightly different than with dilations and translations.

The next example is quite important.

**Example 53.2.4** Consider the fractional linear transformation, \( w = \frac{z - i}{z + 1} \).

First consider what this mapping does to the points of the form \( z = x + i0 \). Substituting into the expression for \( w \),
\[
w = \frac{x - i}{x + i} = \frac{x^2 - 1 - 2xi}{x^2 + 1},
\]
a point on the unit circle. Thus this transformation maps the real axis to the unit circle.

The upper half plane is composed of points of the form \( x + iy \) where \( y > 0 \). Substituting in to the transformation,
\[
w = \frac{x + i(y - 1)}{x + i(y + 1)},
\]
which is seen to be a point on the interior of the unit disk because \( |y - 1| < |y + 1| \) which implies \( |x + i(y + 1)| > |x + i(y - 1)| \). Therefore, this transformation maps the upper half plane to the interior of the unit disk.

One might wonder whether the mapping is one to one and onto. The mapping is clearly one to one because it has an inverse, \( z = -i \frac{w - 1}{w + 1} \) for all \( w \) in the interior of the unit disk. Also, a short computation verifies that \( z \) so defined is in the upper half plane. Therefore, this transformation maps \( \{ z \in \mathbb{C} \text{ such that } \Im z > 0 \} \) one to one and onto the unit disk \( \{ z \in \mathbb{C} \text{ such that } |z| < 1 \} \).

A fancy way to do part of this is to use Theorem 50.3.1: \( \lim \sup_{z \to a} \left| \frac{z - i}{z + 1} \right| \leq 1 \) whenever \( a \) is the real axis or \( \infty \). Therefore, \( \left| \frac{z - i}{z + 1} \right| \leq 1 \). This is a little shorter.

### 53.2.2 Three Points To Three Points

There is a simple procedure for determining fractional linear transformations which map a given set of three points to another set of three points. The problem is as follows: There are three distinct points in the extended complex plane, \( z_1, z_2, \) and \( z_3 \) and it is desired to find a fractional linear transformation such that \( z_i \to w_i \) for \( i = 1, 2, 3 \) where here \( w_1, w_2, \) and \( w_3 \) are three distinct points in the extended
complex plane. Then the procedure says that to find the desired fractional linear transformation solve the following equation for \( w \).

\[
\frac{w - w_1}{w - w_3} \cdot \frac{w_2 - w_3}{w_2 - w_1} = \frac{z - z_1}{z - z_3} \cdot \frac{z_2 - z_3}{z_2 - z_1}
\]

The result will be a fractional linear transformation with the desired properties. If any of the points equals \( \infty \), then the quotient containing this point should be adjusted.

Why should this procedure work? Here is a heuristic argument to indicate why you would expect this to happen rather than a rigorous proof. The reader may want to tighten the argument to give a proof. First suppose \( z = z_1 \). Then the right side equals zero and so the left side also must equal zero. However, this requires \( w = w_1 \). Next suppose \( z = z_2 \). Then the right side equals 1. To get a 1 on the left, you need \( w = w_2 \). Finally suppose \( z = z_3 \). Then the right side involves division by 0. To get the same bad behavior, on the left, you need \( w = w_3 \).

**Example 53.2.5** Let \( \text{Im} \xi > 0 \) and consider the fractional linear transformation which takes \( \xi \) to 0, \( \overline{\xi} \) to \( \infty \) and 0 to \( \xi/\overline{\xi} \).

The equation for \( w \) is

\[
\frac{w - 0}{w - (\xi/\overline{\xi})} = \frac{z - \xi}{z - 0} \cdot \frac{\overline{\xi} - 0}{\overline{\xi} - \xi}
\]

After some computations,

\[
w = \frac{z - \xi}{z - \overline{\xi}}.
\]

Note that this has the property that \( \frac{z - \xi}{z - \overline{\xi}} \) is always a point on the unit circle because it is a complex number divided by its conjugate. Therefore, this fractional linear transformation maps the real line to the unit circle. It also takes the point, \( \xi \) to 0 and so it must map the upper half plane to the unit disk. You can verify the mapping is onto as well.

**Example 53.2.6** Let \( z_1 = 0, z_2 = 1, \) and \( z_3 = 2 \) and let \( w_1 = 0, w_2 = i, \) and \( w_3 = 2i \).

Then the equation to solve is

\[
\frac{w}{w - 2i} \cdot \frac{-i}{i} = \frac{z}{z - 2} \cdot \frac{-1}{1}
\]

Solving this yields \( w = iz \) which clearly works.
53.3 Riemann Mapping Theorem

From the open mapping theorem analytic functions map regions to other regions or else to single points. The Riemann mapping theorem states that for every simply connected region, $\Omega$ which is not equal to all of $\mathbb{C}$ there exists an analytic function, $f$ such that $f(\Omega) = B(0, 1)$ and in addition to this, $f$ is one to one. The proof involves several ideas which have been developed up to now. The proof is based on the following important theorem, a case of Montel’s theorem. Before, beginning, note that the Riemann mapping theorem is a classic example of a major existence theorem. In mathematics there are two sorts of questions, those related to whether something exists and those involving methods for finding it. The real questions are often related to questions of existence. There is a long and involved history for proofs of this theorem. The first proofs were based on the Dirichlet principle and turned out to be incorrect, thanks to Weierstrass who pointed out the errors. For more on the history of this theorem, see Hille [59].

The following theorem is really wonderful. It is about the existence of a subsequence having certain salubrious properties. It is this wonderful result which will give the existence of the mapping desired. The other parts of the argument are technical details to set things up and use this theorem.

53.3.1 Montel’s Theorem

**Theorem 53.3.1** Let $\Omega$ be an open set in $\mathbb{C}$ and let $\mathcal{F}$ denote a set of analytic functions mapping $\Omega$ to $B(0, M) \subseteq \mathbb{C}$. Then there exists a sequence of functions from $\mathcal{F}$, $\{f_n\}_{n=1}^\infty$, and an analytic function, $f$ such that $f_n^{(k)}$ converges uniformly to $f^{(k)}$ on every compact subset of $\Omega$.

**Proof:** First note there exists a sequence of compact sets, $K_n$ such that $K_n \subseteq \text{int} K_{n+1} \subseteq \Omega$ for all $n$ where here int $K$ denotes the interior of the set $K$, the union of all open sets contained in $K$ and $\cup_{n=1}^\infty K_n = \Omega$. In fact, you can verify that $B(0, n) \cap \{z \in \Omega : \text{dist}(z, \Omega^c) \leq \frac{1}{n}\}$ works for $K_n$. Then there exist positive numbers, $\delta_n$ such that if $z \in K_n$, then $B(z, \delta_n) \subseteq \text{int} K_{n+1}$. Now denote by $F_n$ the set of restrictions of functions of $\mathcal{F}$ to $K_n$. Then let $z \in K_n$ and let $\gamma(t) \equiv z + \delta_n e^{it}, t \in [0, 2\pi]$. It follows that for $z_1 \in B(z, \delta_n)$, and $f \in \mathcal{F}$,

$$|f(z) - f(z_1)| = \left| \frac{1}{2\pi i} \int_\gamma f(w) \left( \frac{1}{w - z} - \frac{1}{w - z_1} \right) dw \right| \leq \frac{1}{2\pi} \left| \int_\gamma f(w) \left( \frac{z - z_1}{(w - z)(w - z_1)} \right) dw \right|$$

Letting $|z_1 - z| < \frac{\delta_n}{2}$,

$$|f(z) - f(z_1)| \leq \frac{M}{2\pi} \frac{\delta_n |z - z_1|}{\delta_n^2 / 2} \leq 2M \frac{|z - z_1|}{\delta_n}.$$
It follows that $F_n$ is equicontinuous and uniformly bounded so by the Arzela Ascoli theorem there exists a sequence, \( \{ f_{nk} \}_{k=1}^{\infty} \subseteq F \) which converges uniformly on $K_n$. Let \( \{ f_{1k} \}_{k=1}^{\infty} \) converge uniformly on $K_1$. Then use the Arzela Ascoli theorem applied to this sequence to get a subsequence, denoted by \( \{ f_{nk} \}_{k=1}^{\infty} \) which converges uniformly on $K_n$ and so it converges uniformly on $K_m$ for all $m$. Denoting $f_{nm}$ by $f_n$ for short, this is the sequence of functions promised by the theorem. It is clear $\{ f_n \}_{n=1}^{\infty}$ converges uniformly on every compact subset of $\Omega$ because every such set is contained in $K_m$ for all $m$ large enough. Let $f(z)$ be the point to which $f_n(z)$ converges. Then $f$ is a continuous function defined on $\Omega$.

Alternatively, you could let $T \subseteq \Omega$ be a triangle. Then

$$
\int_{\partial T} f(z) \, dz = \lim_{n \to \infty} \int_{\partial T} f_n(z) \, dz = 0.
$$

Therefore, by Morera’s theorem, $f$ is analytic.

As for the uniform convergence of the derivatives of $f$, recall Theorem 53.3.2 about the existence of a cycle. Let $K$ be a compact subset of $\text{int}(K_n)$ and let \( \{ \gamma_k \}_{k=1}^{m} \) be closed oriented curves contained in $\text{int}(K_n) \setminus K$ such that $\sum_{k=1}^{m} n(\gamma_k, z) = 1$ for every $z \in K$. Also let $\eta$ denote the distance between $\cup_j \gamma_j$ and $K$. Then for $z \in K$,

$$
\left| f^{(k)}(z) - f_n^{(k)}(z) \right| = \left| \frac{k!}{2\pi i} \sum_{j=1}^{m} \int_{\gamma_j} \frac{f(w) - f_n(w)}{(w - z)^{k+1}} \, dw \right| \\
\leq \frac{k!}{2\pi} \| f - f_n \|_{K_n} \sum_{j=1}^{m} (\text{length of } \gamma_j) \frac{1}{\eta^{k+1}}.
$$

where here $\| f - f_n \|_{K_n} \equiv \sup \{|f_k(z) - f(z)| : z \in K_n\}$. Thus you get uniform convergence of the derivatives.

Since the family, $F$ satisfies the conclusion of Theorem 53.3.2 it is known as a normal family of functions. More generally,

**Definition 53.3.2** Let $F$ denote a collection of functions which are analytic on $\Omega$, a region. Then $F$ is normal if every sequence contained in $F$ has a subsequence which converges uniformly on compact subsets of $\Omega$.

The following result is about a certain class of fractional linear transformations. Recall Lemma 53.3.3 which is listed here for convenience.

**Lemma 53.3.3** For $\alpha \in B(0,1)$, let

$$
\phi_{\alpha}(z) \equiv \frac{z - \alpha}{1 - \overline{\alpha}z}.
$$
Then \( \phi \) maps \( B(0, 1) \) one to one and onto \( B(0, 1) \), \( \phi^{-1} = \phi \), and

\[
\phi'(\alpha) = \frac{1}{1 - |\alpha|^2}.
\]

The next lemma, known as Schwarz’s lemma is interesting for its own sake but will also be an important part of the proof of the Riemann mapping theorem. It was stated and proved earlier but for convenience it is given again here.

**Lemma 53.3.4** Suppose \( F : B(0, 1) \to B(0, 1) \), \( F \) is analytic, and \( F(0) = 0 \). Then for all \( z \in B(0, 1) \),

\[
|F(z)| \leq |z|, \quad (53.3.3)
\]

and

\[
|F'(0)| \leq 1. \quad (53.3.4)
\]

If equality holds in (53.3.4) then there exists \( \lambda \in \mathbb{C} \) with \( |\lambda| = 1 \) and

\[
F(z) = \lambda z. \quad (53.3.5)
\]

**Proof:** First note that by assumption, \( F(z)/z \) has a removable singularity at 0 if its value at 0 is defined to be \( F'(0) \). By the maximum modulus theorem, if \( |z| < r < 1 \),

\[
\left| \frac{F(z)}{z} \right| \leq \max_{t \in [0, 2\pi]} \left| \frac{F(re^{it})}{r} \right| \leq \frac{1}{r}.
\]

Then letting \( r \to 1 \),

\[
\left| \frac{F(z)}{z} \right| \leq 1
\]

this shows (53.3.3) and it also verifies (53.3.4) on taking the limit as \( z \to 0 \). If equality holds in (53.3.4), then \( |F(z)/z| \) achieves a maximum at an interior point so \( F(z)/z \) equals a constant, \( \lambda \) by the maximum modulus theorem. Since \( F(z) = \lambda z \), it follows \( F'(0) = \lambda \) and so \( |\lambda| = 1 \). This proves the lemma.

**Definition 53.3.5** A region, \( \Omega \) has the square root property if whenever \( f, \frac{1}{f} : \Omega \to \mathbb{C} \) are both analytic, it follows there exists \( \phi : \Omega \to \mathbb{C} \) such that \( \phi \) is analytic and \( f(z) = \phi^2(z) \).

The next theorem will turn out to be equivalent to the Riemann mapping theorem.

\(^1\)This implies \( f \) has no zero on \( \Omega \).
53.3. RIEMANN MAPPING THEOREM

53.3.2 Regions With Square Root Property

Theorem 53.3.6 Let $\Omega \neq \mathbb{C}$ for $\Omega$ a region and suppose $\Omega$ has the square root property. Then for $z_0 \in \Omega$ there exists $h : \Omega \to B(0,1)$ such that $h$ is one to one, onto, analytic, and $h'(z_0) = 0$.

**Proof:** Define $\mathcal{F}$ to be the set of functions, $f$ such that $f : \Omega \to B(0,1)$ is one to one and analytic. The first task is to show $\mathcal{F}$ is nonempty. Then, using Montel’s theorem it will be shown there is a function in $\mathcal{F}$, $h$, such that $|h'(z_0)| \geq \left|\psi'(z_0)\right|$ for all $\psi \in \mathcal{F}$. When this has been done it will be shown that $h$ is actually onto.

This will prove the theorem.

**Claim 1:** $\mathcal{F}$ is nonempty.

**Proof of Claim 1:** Since $\Omega \neq \mathbb{C}$ it follows there exists $\xi \notin \Omega$. Then it follows $z - \xi$ and $\frac{1}{z-\xi}$ are both analytic on $\Omega$. Since $\Omega$ has the square root property, there exists an analytic function, $\phi : \Omega \to \mathbb{C}$ such that $\phi^2(z) = z - \xi$ for all $z \in \Omega$. $\phi(z) = \sqrt{z - \xi}$. Since $z - \xi$ is not constant, neither is $\phi$ and it follows from the open mapping theorem that $\phi(\Omega)$ is a region. Note also that $\phi$ is one to one because if $\phi(z_1) = \phi(z_2)$, then you can square both sides and conclude $z_1 - \xi = z_2 - \xi$ implying $z_1 = z_2$.

Now pick $a \in \phi(\Omega)$. Thus $\sqrt{z_a - \xi} = a$. I claim there exists a positive lower bound to $|\sqrt{z - \xi} + a|$ for $z \in \Omega$. If not, there exists a sequence, $\{z_n\} \subseteq \Omega$ such that

$$\sqrt{z_n - \xi} + a = \sqrt{z_n - \xi} + \sqrt{z_a - \xi} \equiv \varepsilon_n \to 0.$$  

Then

$$\sqrt{z_n - \xi} = \left(\varepsilon_n - \sqrt{z_a - \xi}\right)$$  

and squaring both sides,

$$z_n - \xi = \varepsilon_n^2 - z_a - \xi - 2\varepsilon_n\sqrt{z_a - \xi}.$$  

Consequently, $(z_n - z_a) = \varepsilon_n^2 - 2\varepsilon_n\sqrt{z_a - \xi}$ which converges to 0. Taking the limit in (53.3.6) it follows $2\sqrt{z_a - \xi} = 0$ and so $\xi = z_a$, a contradiction to $\xi \notin \Omega$. Choose $r > 0$ such that for all $z \in \Omega$, $|\sqrt{z - \xi} + a| > r > 0$. Then consider

$$\psi(z) \equiv \frac{r}{\sqrt{z - \xi} + a}.$$  

This is one to one, analytic, and maps $\Omega$ into $B(0,1)$ ($|\sqrt{z - \xi} + a| > r$). Thus $\mathcal{F}$ is not empty and this proves the claim.

**Claim 2:** Let $z_0 \in \Omega$. There exists a finite positive real number, $\eta$, defined by

$$\eta \equiv \sup \{ |\psi'(z_0)| : \psi \in \mathcal{F} \}$$  

and an analytic function, $h \in \mathcal{F}$ such that $|h'(z_0)| = \eta$. Furthermore, $h(z_0) = 0$.

**Proof of Claim 2:** First you show $\eta < \infty$. Let $\gamma(t) = z_0 + re^{it}$ for $t \in [0,2\pi]$ and $r$ is small enough that $B(z_0,r) \subseteq \Omega$. Then for $\psi \in \mathcal{F}$, the Cauchy integral
CHAPTER 53. COMPLEX MAPPINGS

The formula for the derivative implies

\[ \psi'(z_0) = \frac{1}{2\pi i} \int_{\gamma} \frac{\psi(w)}{(w-z_0)^2} dw \]

and so \(|\psi'(z_0)| \leq (1/2\pi)2\pi r (1/r^2) = 1/r^2\). Therefore, \(\eta < \infty\) as desired. For \(\psi\) defined above in 53.3.7

\[ \psi'(z_0) = \frac{-r\phi'(z_0)}{(\phi(z_0) + a)^2} = -r \left(1/2\right) \left(\sqrt{z_0 - \xi}\right)^{-1} \neq 0. \]

Therefore, \(\eta > 0\). It remains to verify the existence of the function, \(h\).

By Theorem \(53.3.1\), there exists a sequence, \(\{\psi_n\}\), of functions in \(\mathcal{F}\) and an analytic function, \(h\), such that

\[ |\psi'_n(z_0)| \to \eta \quad (53.3.9) \]

and

\[ \psi_n \to h, \psi'_n \to h', \quad (53.3.10) \]

uniformly on all compact subsets of \(\Omega\). It follows

\[ |h'(z_0)| = \lim_{n \to \infty} |\psi'_n(z_0)| = \eta \quad (53.3.11) \]

and for all \(z \in \Omega\),

\[ |h(z)| = \lim_{n \to \infty} |\psi_n(z)| \leq 1. \quad (53.3.12) \]

By \(53.3.11\), \(h\) is not a constant. Therefore, in fact, \(|h(z)| < 1\) for all \(z \in \Omega\) in \(53.3.12\) by the open mapping theorem.

Next it must be shown that \(h\) is one to one in order to conclude \(h \in \mathcal{F}\). Pick \(z_1 \in \Omega\) and suppose \(z_2\) is another point of \(\Omega\). Since the zeros of \(h - h(z_1)\) have no limit point, there exists a circular contour bounding a circle which contains \(z_2\) but not \(z_1\) such that \(\gamma^*\) contains no zeros of \(h - h(z_1)\).

Using the theorem on counting zeros, Theorem 50.6.1, and the fact that \(\psi_n\) is one to one,

\[ 0 = \lim_{n \to \infty} \frac{1}{2\pi i} \int_{\gamma} \frac{\psi'_n(w)}{\psi_n(w) - \psi_n(z_1)} dw \]

\[ = \frac{1}{2\pi i} \int_{\gamma} \frac{h'(w)}{h(w) - h(z_1)} dw, \]
which shows that \( h - h(z_1) \) has no zeros in \( B(z_2, r) \). In particular \( z_2 \) is not a zero of \( h - h(z_1) \). This shows that \( h \) is one to one since \( z_2 \neq z_1 \) was arbitrary. Therefore, \( h \in \mathcal{F} \). It only remains to verify that \( h(z_0) = 0 \).

If \( h(z_0) \neq 0 \), consider \( \phi_{h(z_0)} \circ h \) where \( \phi_\alpha \) is the fractional linear transformation defined in Lemma 53.3.3. By this lemma it follows \( \phi_{h(z_0)} \circ h \in \mathcal{F} \). Now using the chain rule,

\[
\left| \left( \phi_{h(z_0)} \circ h \right)'(z_0) \right| = \left| \phi_{h(z_0)}'(h(z_0)) \left| h'(z_0) \right| \right| = \left| \frac{1}{1 - |h(z_0)|^2} \left| h'(z_0) \right| \right| = \left| \frac{1}{1 - |h(z_0)|^2} \right| \eta > \eta
\]

Contradicting the definition of \( \eta \). This proves Claim 2.

**Claim 3:** The function, \( h \) just obtained maps \( \Omega \) onto \( B(0, 1) \).

**Proof of Claim 3:** To show \( h \) is onto, use the fractional linear transformation of Lemma 53.3.3. Suppose \( h \) is not onto. Then there exists \( \alpha \in B(0, 1) \setminus h(\Omega) \). Then \( 0 \neq \phi_\alpha \circ h(z) \) for all \( z \in \Omega \) because

\[
\phi_\alpha \circ h(z) = \frac{h(z) - \alpha}{1 - \overline{\alpha}h(z)}
\]

and it is assumed \( \alpha \notin h(\Omega) \). Therefore, since \( \Omega \) has the square root property, you can consider an analytic function \( z \to \sqrt{\phi_\alpha \circ h(z)} \). This function is one to one because both \( \phi_\alpha \) and \( h \) are. Also, the values of this function are in \( B(0, 1) \) by Lemma 53.3.3 so it is in \( \mathcal{F} \).

Now let

\[\psi \equiv \phi \sqrt{\phi_\alpha \circ h(z_0)} \circ \sqrt{\phi_\alpha \circ h}. \tag{53.3.13}\]

Thus

\[\psi(z_0) = \phi \sqrt{\phi_\alpha \circ h(z_0)} \circ \sqrt{\phi_\alpha \circ h(z_0)} = 0\]

and \( \psi \) is a one to one mapping of \( \Omega \) into \( B(0, 1) \) so \( \psi \) is also in \( \mathcal{F} \). Therefore,

\[\left| \psi'(z_0) \right| \leq \eta, \left| \left( \sqrt{\phi_\alpha \circ h}'(z_0) \right) \right| \leq \eta. \tag{53.3.14}\]

Define \( s(w) \equiv w^2 \). Then using Lemma 53.3.3 in particular, the description of \( \phi^{-1}_{\alpha} = \phi_{-\alpha} \), you can solve 53.3.14 for \( h \) to obtain

\[
h(z) = \phi_{-\alpha} \circ s \circ \phi \sqrt{\phi_\alpha \circ h(z_0)} \circ \psi = \phi_{-\alpha} \circ s \circ \phi \sqrt{\phi_\alpha \circ h(z_0)} \circ \psi(z) = (F \circ \psi)(z) \tag{53.3.15}\]
Now
\[ F(0) = \phi_{-\alpha} \circ s \circ \phi_{-\sqrt{\phi_\alpha \circ h(z_0)}}(0) = \phi^{-1}_\alpha(\phi_\alpha \circ h(z_0)) = h(z_0) = 0 \]

and \( F \) maps \( B(0,1) \) into \( B(0,1) \). Also, \( F \) is not one to one because it maps \( B(0,1) \) to \( B(0,1) \) and has \( s \) in its definition. Thus there exists \( z_1 \in B(0,1) \) such that \( \phi_{-\sqrt{\phi_\alpha \circ h(z_0)}}(z_1) = -\frac{1}{2} \) and another point \( z_2 \in B(0,1) \) such that \( \phi_{-\sqrt{\phi_\alpha \circ h(z_0)}}(z_2) = \frac{1}{2} \). However, thanks to \( s \), \( F(z_1) = F(z_2) \).

Since \( F(0) = h(z_0) = 0 \), you can apply the Schwarz lemma to \( F \). Since \( F \) is not one to one, it can’t be true that \( F(z) = \lambda z \) for \( |\lambda| = 1 \) and so by the Schwarz lemma it must be the case that \( |F'(0)| < 1 \). But this implies from 53.3.15 and 53.3.14 that
\[ \eta = |h'(z_0)| = |F'(\psi(z_0))| |\psi'(z_0)| \]
\[ = |F'(0)| |\psi'(z_0)| < |\psi'(z_0)| \leq \eta, \]
a contradiction. This proves the theorem.

The following lemma yields the usual form of the Riemann mapping theorem.

**Lemma 53.3.7** Let \( \Omega \) be a simply connected region with \( \Omega \neq \mathbb{C} \). Then \( \Omega \) has the square root property.

**Proof:** Let \( f \) and \( \frac{1}{f} \) both be analytic on \( \Omega \). Then \( \frac{F}{f} \) is analytic on \( \Omega \) so by Corollary 53.3.2, there exists \( \tilde{F} \), analytic on \( \Omega \) such that \( F = \frac{\tilde{F}}{f} \) on \( \Omega \). Then \( \left( f e^{-\tilde{F}} \right)' = 0 \) and so \( f(z) = Ce^{\tilde{F}} = e^{a+ib} e^{\tilde{F}} \). Now let \( F = \tilde{F} + a + ib \). Then \( F \) is still a primitive of \( f'/f \) and \( f(z) = e^{F(z)} \). Now let \( \phi(z) = e^{\frac{1}{2}F(z)} \). Then \( \phi \) is the desired square root and so \( \Omega \) has the square root property.

**Corollary 53.3.8** (Riemann mapping theorem) Let \( \Omega \) be a simply connected region with \( \Omega \neq \mathbb{C} \) and let \( z_0 \in \Omega \). Then there exists a function, \( f : \Omega \to B(0,1) \) such that \( f \) is one to one, analytic, and onto with \( f(z_0) = 0 \). Furthermore, \( f^{-1} \) is also analytic.

**Proof:** From Theorem 53.3.7 and Lemma 53.3.7 there exists a function, \( f : \Omega \to B(0,1) \) which is one to one, onto, and analytic such that \( f(z_0) = 0 \). The assertion that \( f^{-1} \) is analytic follows from the open mapping theorem.

### 53.4 Analytic Continuation

#### 53.4.1 Regular And Singular Points

Given a function which is analytic on some set, can you extend it to an analytic function defined on a larger set? Sometimes you can do this. It was done in the proof of the Cauchy integral formula. There are also reflection theorems like those
discussed in the exercises starting with Problem 16 on Page 1683 Here I will give a systematic way of extending an analytic function to a larger set. I will emphasize simply connected regions. The subject of analytic continuation is much larger than the introduction given here. A good source for much more on this is found in Alfors [2]. The approach given here is suggested by Rudin [102] and avoids many of the standard technicalities.

**Definition 53.4.1** Let \( f \) be analytic on \( B(a,r) \) and let \( \beta \in \partial B(a,r) \). Then \( \beta \) is called a regular point of \( f \) if there exists some \( \delta > 0 \) and a function, \( g \) analytic on \( B(\beta, \delta) \) such that \( g = f \) on \( B(\beta, \delta) \cap B(a,r) \). Those points of \( \partial B(a,r) \) which are not regular are called singular.

\[ g(z) = \begin{cases} f(z) & \text{if } z \in B(a,r) \\ g_{z_k}(z) & \text{if } z \in B(z_k, \delta_{z_k}) \end{cases} \]

**Theorem 53.4.2** Suppose \( f \) is analytic on \( B(a,r) \) and the power series

\[ f(z) = \sum_{k=0}^{\infty} a_k (z-a)^k \]

has radius of convergence \( r \). Then there exists a singular point on \( \partial B(a,r) \).

**Proof:** If not, then for every \( z \in \partial B(a,r) \) there exists \( \delta_z > 0 \) and \( g_z \) analytic on \( B(z, \delta_z) \) such that \( g_z = f \) on \( B(z, \delta_z) \cap B(a,r) \). Since \( \partial B(a,r) \) is compact, there exist \( z_1, \ldots, z_n \), points in \( \partial B(a,r) \) such that \( \{B(z_k, \delta_{z_k})\}_{k=1}^{n} \) covers \( \partial B(a,r) \). Now define

\[ g(z) = \begin{cases} f(z) & \text{if } z \in B(a,r) \\ g_{z_k}(z) & \text{if } z \in B(z_k, \delta_{z_k}) \end{cases} \]

Is this well defined? If \( z \in B(z_i, \delta_{z_i}) \cap B(z_j, \delta_{z_j}) \), is \( g_{z_i}(z) = g_{z_j}(z) \)? Consider the following picture representing this situation.
You see that if \( z \in B(z_i, \delta_{z_i}) \cap B(z_j, \delta_{z_j}) \) then \( I \equiv B(z_i, \delta_{z_i}) \cap B(z_j, \delta_{z_j}) \cap B(a, r) \) is a nonempty open set. Both \( g_{z_i} \) and \( g_{z_j} \) equal \( f \) on \( I \). Therefore, they must be equal on \( B(z_i, \delta_{z_i}) \cap B(z_j, \delta_{z_j}) \) because \( I \) has a limit point. Therefore, \( g \) is well defined and analytic on an open set containing \( \overline{B(a, r)} \). Since \( g \) agrees with \( f \) on \( B(a, r) \), the power series for \( g \) is the same as the power series for \( f \) and converges on a ball which is larger than \( B(a, r) \) contrary to the assumption that the radius of convergence of the above power series equals \( r \). This proves the theorem.

### 53.4.2 Continuation Along A Curve

Next I will describe what is meant by continuation along a curve. The following definition is standard and is found in Rudin [8].

**Definition 53.4.3** A function element is an ordered pair, \((f, D)\) where \( D \) is an open ball and \( f \) is analytic on \( D \). \((f_0, D_0)\) and \((f_1, D_1)\) are direct continuations of each other if \( D_1 \cap D_0 \neq \emptyset \) and \( f_0 = f_1 \) on \( D_1 \cap D_0 \). In this case I will write \((f_0, D_0) \sim (f_1, D_1)\). A chain is a finite sequence, of disks, \( \{D_0, \ldots, D_n\} \) such that \( D_{i-1} \cap D_i \neq \emptyset \). A chain is a given function element and there exist function elements, \((f_i, D_i)\) such that \( \{D_0, \ldots, D_n\} \) is a chain and \((f_{j-1}, D_{j-1}) \sim (f_j, D_j)\) then \((f_n, D_n)\) is called the analytic continuation of \((f_0, D_0)\) along the chain \( \{D_0, \ldots, D_n\} \). Now suppose \( \gamma \) is an oriented curve with parameter interval \([a, b]\) and there exists a chain, \( \{D_0, \ldots, D_n\} \) such that \( \gamma^* \subseteq \bigcup_{k=1}^{n} D_k \), \( \gamma(a) \) is the center of \( D_0 \), \( \gamma(b) \) is the center of \( D_n \), and there is an increasing list of numbers in \([a, b]\), \( a = s_0 < s_1 \cdots < s_n = b \) such that \( \gamma([s_i, s_{i+1}]) \subseteq D_i \) and \((f_n, D_n)\) is an analytic continuation of \((f_0, D_0)\) along the chain. Then \((f_n, D_n)\) is called an analytic continuation of \((f_0, D_0)\) along the curve \( \gamma \). (\( \gamma \) will always be a continuous curve. Nothing more is needed.)

In the above situation it does not follow that if \( D_n \cap D_0 \neq \emptyset \), that \( f_n = f_0 \)! However, there are some cases where this will happen. This is the monodromy theorem which follows. This is as far as I will go on the subject of analytic continuation. For more on this subject including a development of the concept of Riemann surfaces, see Alfors [2].

**Lemma 53.4.4** Suppose \((f, B(0, r))\) for \( r < 1 \) is a function element and \((f, B(0, r))\) can be analytically continued along every curve in \( B(0, 1) \) that starts at 0. Then there exists an analytic function, \( g \) defined on \( B(0, 1) \) such that \( g = f \) on \( B(0, r) \).

**Proof:** Let

\[
R = \sup\{r_1 \geq r \mid \text{there exists } g_{r_1} \text{ analytic on } B(0, r_1) \text{ which agrees with } f \text{ on } B(0, r)\}.
\]

Define \( g_R(z) \equiv g_{r_1}(z) \) where \( |z| < r_1 \). This is well defined because if you use \( r_1 \) and \( r_2 \), both \( g_{r_1} \) and \( g_{r_2} \) agree with \( f \) on \( B(0, r) \), a set with a limit point and so the two functions agree at every point in both \( B(0, r_1) \) and \( B(0, r_2) \). Thus \( g_R \) is analytic on \( B(0, R) \). If \( R < 1 \), then by the assumption there are no singular points
on \( B(0,R) \) and so Theorem \ref{thm:analytic-continuation} implies the radius of convergence of the power series for \( g_R \) is larger than \( R \) contradicting the choice of \( R \). Therefore, \( R = 1 \) and this proves the lemma. Let \( g = g_R \).

The following theorem is the main result in this subject, the monodromy theorem.

**Theorem 53.4.5** Let \( \Omega \) be a simply connected proper subset of \( \mathbb{C} \) and suppose \((f, B(a,r))\) is a function element with \( B(a,r) \subseteq \Omega \). Suppose also that this function element can be analytically continued along every curve through \( a \). Then there exists \( G \) analytic on \( \Omega \) such that \( G \) agrees with \( f \) on \( B(a,r) \).

**Proof:** By the Riemann mapping theorem, there exists \( h : \Omega \to B(0,1) \) which is analytic, one to one and onto such that \( f(a) = 0 \). Since \( h \) is an open map, there exists \( \delta > 0 \) such that

\[
B(0,\delta) \subseteq h(B(a,r)).
\]

It follows \( f \circ h^{-1} \) can be analytically continued along every curve through 0. By Lemma \ref{lem:analytic-continuation} there exists \( g \) analytic on \( B(0,1) \) which agrees with \( f \circ h^{-1} \) on \( B(0,\delta) \). Define \( G(z) = g(h(z)) \). For \( z = h^{-1}(w) \), it follows \( G(h^{-1}(w)) = g(w) \).

If \( w \in B(0,\delta) \), then \( G(h^{-1}(w)) = f \circ h^{-1}(w) \) and so \( G = f \) on \( h^{-1}(B(0,\delta)) \), an open set contained in \( B(a,r) \). Therefore, \( G = f \) on \( B(a,r) \) because \( h^{-1}(B(0,\delta)) \) has a limit point. This proves the theorem.

Actually, you sometimes want to consider the case where \( \Omega = \mathbb{C} \). This requires a small modification to obtain from the above theorem.

**Corollary 53.4.6** Suppose \((f, B(a,r))\) is a function element with \( B(a,r) \subseteq \mathbb{C} \). Suppose also that this function element can be analytically continued along every curve through \( a \). Then there exists \( G \) analytic on \( \mathbb{C} \) such that \( G \) agrees with \( f \) on \( B(a,r) \).

**Proof:** Let \( \Omega_1 \equiv \{ z \in \mathbb{C} : a + it : t > a \} \) and \( \Omega_2 \equiv \{ z \in \mathbb{C} : a - it : t > a \} \). Here is a picture of \( \Omega_1 \).

\[
\Omega_1
\]

A picture of \( \Omega_2 \) is similar except the line extends down from the boundary of \( B(a,r) \).

Thus \( B(a,r) \subseteq \Omega_1 \) and \( \Omega_1 \) is simply connected and proper. By Theorem \ref{thm:analytic-continuation} there exist analytic functions, \( G_i \) analytic on \( \Omega_i \) such that \( G_i = f \) on \( B(a,r) \). Thus \( G_1 = G_2 \) on \( B(a,r) \), a set with a limit point. Therefore, \( G_1 = G_2 \) on \( \Omega_1 \cap \Omega_2 \). Now let \( G(z) = G_i(z) \) where \( z \in \Omega_i \). This is well defined and analytic on \( \mathbb{C} \). This proves the corollary.
53.5 The Picard Theorems

The Picard theorem says that if \( f \) is an entire function and there are two complex numbers not contained in \( f(\mathbb{C}) \), then \( f \) is constant. This is certainly one of the most amazing things which could be imagined. However, this is only the little Picard theorem. The big Picard theorem is even more incredible. This one asserts that to be non constant the entire function must take every value of \( \mathbb{C} \) but two infinitely many times! I will begin with the little Picard theorem. The method of proof I will use is the one found in Saks and Zygmund [104], Conway [31], and Hille [59]. This is not the way Picard did it in 1879. That approach is very different and is presented at the end of the material on elliptic functions. This approach is much more recent dating it appears from around 1924.

**Lemma 53.5.1** Let \( f \) be analytic on a region containing \( B(0,r) \) and suppose

\[
\left| f'(0) \right| = b > 0, \quad f(0) = 0,
\]

and \( |f(z)| \leq M \) for all \( z \in B(0,r) \). Then \( f(B(0,r)) \supseteq B\left(0, \frac{r^2b^2}{6M}\right) \).

**Proof:** By assumption,

\[
f(z) = \sum_{k=0}^{\infty} a_k z^k, \quad |z| \leq r. \tag{53.5.16}
\]

Then by the Cauchy integral formula for the derivative,

\[
a_k = \frac{1}{2\pi i} \int_{\partial B(0,r)} \frac{f(w)}{w^{k+1}} \, dw
\]

where the integral is in the counter clockwise direction. Therefore,

\[
|a_k| \leq \frac{1}{2\pi} \int_{0}^{2\pi} \left| \frac{f(re^{i\theta})}{r^k} \right| \, d\theta \leq \frac{M}{r^k}.
\]

In particular, \( br \leq M \). Therefore, from \( |f(z)| \geq b|z| - \sum_{k=2}^{\infty} \frac{M}{r^k} |z|^k = b|z| - \frac{M \left( \frac{|z|}{r} \right)^2}{1 - \left( \frac{|z|}{r} \right)} \)

\[
= b|z| - \frac{M |z|^2}{r^2 - r|z|}
\]

Suppose \( |z| = \frac{r^2b}{4M} < r \). Then this is no larger than

\[
\frac{1}{4} \frac{b^2}{M (4M - br)} \geq \frac{1}{4} \frac{b^2}{M (4M - M)} = \frac{r^2b^2}{6M}.
\]
53.5. THE PICARD THEOREMS

Let \( |w| < \frac{r^2 b}{4M} \). Then for \( |z| = \frac{r^2 b}{4M} \) and the above,

\[
|w| = |(f(z) - w) - f(z)| < \frac{r^2 b}{4M} \leq |f(z)|
\]

and so by Rouche’s theorem, \( z \rightarrow f(z) - w \) and \( z \rightarrow f(z) \) have the same number of zeros in \( B\left(0, \frac{r^2 b}{4M}\right) \). But \( f \) has at least one zero in this ball and so this shows there exists at least one \( z \in B\left(0, \frac{r^2 b}{4M}\right) \) such that \( f(z) - w = 0 \). This proves the lemma.

53.5.1 Two Competing Lemmas

Lemma 53.5.1 is a really nice lemma but there is something even better, Bloch’s lemma. This lemma does not depend on the bound of \( f \). Like the above two lemmas it is interesting for its own sake and in addition is the key to a fairly short proof of Picard’s theorem. It features the number \( \frac{1}{24} \). The best constant is not currently known.

Lemma 53.5.2 Let \( f \) be analytic on an open set containing \( B(0, R) \) and suppose \( |f'(0)| > 0 \). Then there exists \( a \in B(0, R) \) such that

\[
f(B(0, R)) \supseteq B\left(f(a), \frac{|f'(0)| R}{24}\right).
\]

**Proof:** Let \( K(\rho) \equiv \max\{|f'(z)| : |z| = \rho\} \). For simplicity, let \( C_\rho \equiv \{z : |z| = \rho\} \).

**Claim:** \( K \) is continuous from the left.

**Proof of claim:** Let \( z_\rho \in C_\rho \) such that \( |f'(z_\rho)| = K(\rho) \). Then by the maximum modulus theorem, if \( \lambda \in (0, 1) \),

\[
|f'(\lambda z_\rho)| \leq K(\lambda \rho) \leq K(\rho) = |f'(z_\rho)|.
\]

Letting \( \lambda \rightarrow 1 \) yields the claim.

Let \( \rho_0 \) be the largest such that \((R - \rho_0) K(\rho_0) = R |f'(0)| \). (Note \((R - 0) K(0) = R |f'(0)| \).) Thus \( \rho_0 < R \) because \((R - R) K(R) = 0 \). Let \( |a| = \rho_0 \) such that \( |f'(a)| = K(\rho_0) \). Thus

\[
|f'(a)| (R - \rho_0) = |f'(0)| R
\]  

(53.5.17)

Now let \( r = \frac{R - \rho_0}{2} \). From 53.5.17,

\[
|f'(a)| r = \frac{1}{2} |f'(0)| R, \ B(a, r) \subseteq B(0, \rho_0 + r) \subseteq B(0, R).
\]

(53.5.18)
Therefore, if \( z \in B(a, r) \), it follows from the maximum modulus theorem and the definition of \( \rho_0 \) that
\[
|f'(z)| \leq K(\rho_0 + r) < \frac{R|f'(0)|}{R - \rho_0 - r} = \frac{2R|f'(0)|}{2r} \leq \frac{R|f'(0)|}{r} \quad (53.5.19)
\]

Let \( g(z) = f(a + z) - f(a) \) where \( z \in B(0, r) \). Then \( |g'(0)| = |f'(a)| > 0 \) and for \( z \in B(0, r) \),
\[
|g(z)| \leq \left| \int_{\gamma(a, z)} g'(w) \, dw \right| \leq |z - a| \frac{R|f'(0)|}{r} = R|f'(0)|.
\]

By Lemma 53.5.1 and 53.5.18,
\[
g(B(0, r)) \supseteq B\left(0, \frac{r^2 |f'(a)|^2}{6R|f'(0)|}\right) = B\left(0, \frac{r^2 \left( \frac{1}{r^2} |f'(0)| R^2 \right)^2}{6R|f'(0)|}\right) = B\left(0, \frac{|f'(0)| R^2}{24}\right).
\]

Now \( g(B(0, r)) = f(B(a, r)) - f(a) \) and so this implies
\[
f(B(0, R)) \supseteq f(B(a, r)) \supseteq B\left(f(a), \frac{|f'(0)| R}{24}\right).
\]

This proves the lemma.

Here is a slightly more general version which allows the center of the open set to be arbitrary.

**Lemma 53.5.3** Let \( f \) be analytic on an open set containing \( \overline{B(z_0, R)} \) and suppose \( |f'(z_0)| > 0 \). Then there exists \( a \in B(z_0, R) \) such that
\[
f(B(z_0, R)) \supseteq B\left(f(a), \frac{|f'(z_0)| R}{24}\right).
\]
53.5. THE PICARD THEOREMS

Let \( g(z) \equiv f(z_0 + z) - f(z_0) \) for \( z \in B(0, R) \). Then \( g'(0) = f'(z_0) \) and so by Lemma 53.5.2 there exists \( a_1 \in B(0, R) \) such that

\[
g(B(0, R)) \supseteq B\left(g(a_1), \frac{|f'(z_0)| R}{24}\right).
\]

Now \( g(B(0, R)) = f(B(z_0, R)) - f(z_0) \) and \( g(a_1) = f(a) - f(z_0) \) for some \( a \in B(z_0, R) \) and so

\[
f(B(z_0, R)) - f(z_0) \supseteq B\left(g(a_1), \frac{|f'(z_0)| R}{24}\right)
\]

\[
\quad = B\left(f(a) - f(z_0), \frac{|f'(z_0)| R}{24}\right)
\]

which implies

\[
f(B(z_0, R)) \supseteq B\left(f(a), \frac{|f'(z_0)| R}{24}\right)
\]

as claimed. This proves the lemma.

No attempt was made to find the best number to multiply by \( R |f'(z_0)| \). A discussion of this is given in Conway [31]. See also [3]. Much larger numbers than 1/24 are available and there is a conjecture due to Alfors about the best value. The conjecture is that 1/24 can be replaced with

\[
\frac{\Gamma\left(\frac{1}{2}\right) \Gamma\left(\frac{11}{12}\right)}{(1 + \sqrt{3})^{1/2} \Gamma\left(\frac{1}{4}\right)} \approx 0.47186
\]

You can see there is quite a gap between the constant for which this lemma is proved above and what is thought to be the best constant.

Bloch’s lemma above gives the existence of a ball of a certain size inside the image of a ball. By contrast the next lemma leads to conditions under which the values of a function do not contain a ball of certain radius. It concerns analytic functions which do not achieve the values 0 and 1.

**Lemma 53.5.4** Let \( F \) denote the set of functions, \( f \) defined on \( \Omega \), a simply connected region which do not achieve the values 0 and 1. Then for each such function, it is possible to define a function analytic on \( \Omega \), \( H(z) \) by the formula

\[
H(z) \equiv \log \left[ \frac{\log(f(z))}{2\pi i} - \frac{\log(f(z))}{2\pi i} - 1 \right].
\]

There exists a constant \( C \) independent of \( f \in F \) such that \( H(\Omega) \) does not contain any ball of radius \( C \).

**Proof:** Let \( f \in F \). Then since \( f \) does not take the value 0, there exists \( g_1 \) a primitive of \( f'/f \). Thus

\[
\frac{d}{dz} (e^{-g_1} f) = 0
\]
so there exists $a, b$ such that $f(z) e^{-g_1(z)} = e^{a + bi}$. Letting $g(z) = g_1(z) + a + ib$, it follows $e^{g(z)} = f(z)$. Let $\log f(z) = g_1(z) + a + ib$; then for $n \in \mathbb{Z}$, the integers,

$$\frac{\log f(z)}{2\pi i}, \frac{\log f(z)}{2\pi i} - 1 \neq n$$

because if equality held, then $f(z) = 1$ which does not happen. It follows $\frac{\log f(z)}{2\pi i}$ and $\frac{\log f(z)}{2\pi i} - 1$ are never equal to zero. Therefore, using the same reasoning, you can define a logarithm of these two quantities and therefore, a square root. Hence there exists a function analytic on $\Omega$,

$$\sqrt{\frac{\log f(z)}{2\pi i}} - \sqrt{\frac{\log f(z)}{2\pi i} - 1}.$$  \hspace{1cm} (53.5.20)

For $n$ a positive integer, this function cannot equal $\sqrt{n} \pm \sqrt{n - 1}$ because if it did, then

$$\left(\sqrt{\frac{\log f(z)}{2\pi i}} - \sqrt{\frac{\log f(z)}{2\pi i} - 1}\right) = \sqrt{n} \pm \sqrt{n - 1}$$ \hspace{1cm} (53.5.21)

and you could take reciprocals of both sides to obtain

$$\left(\sqrt{\frac{\log f(z)}{2\pi i}} + \sqrt{\frac{\log f(z)}{2\pi i} - 1}\right) = \sqrt{n} \mp \sqrt{n - 1}.$$ \hspace{1cm} (53.5.22)

Then adding (53.5.21) and (53.5.22)

$$2\sqrt{\frac{\log f(z)}{2\pi i}} = 2\sqrt{n}$$

which contradicts the above observation that $\frac{\log f(z)}{2\pi i}$ is not equal to an integer.

Also, the function of (53.5.20) is never equal to zero. Therefore, you can define the logarithm of this function also. It follows

$$H(z) = \log\left(\sqrt{\frac{\log f(z)}{2\pi i}} - \sqrt{\frac{\log f(z)}{2\pi i} - 1}\right) \neq \ln\left(\sqrt{n} \pm \sqrt{n - 1}\right) + 2m\pi i$$

where $m$ is an arbitrary integer and $n$ is a positive integer. Now

$$\lim_{n \to \infty} \ln\left(\sqrt{n} + \sqrt{n - 1}\right) = \infty$$

and $\lim_{n \to \infty} \ln\left(\sqrt{n} - \sqrt{n - 1}\right) = -\infty$ and so $\mathbb{C}$ is covered by rectangles having vertices at points $\ln\left(\sqrt{n} \pm \sqrt{n - 1}\right) + 2m\pi i$ as described above. Each of these rectangles has height equal to $2\pi$ and a short computation shows their widths are bounded. Therefore, there exists $C$ independent of $f \in F$ such that $C$ is larger than the diameter of all these rectangles. Hence $H(\Omega)$ cannot contain any ball of radius larger than $C$. 

53.5.2 The Little Picard Theorem

Now here is the little Picard theorem. It is easy to prove from the above.

**Theorem 53.5.5** If \( h \) is an entire function which omits two values then \( h \) is a constant.

**Proof:** Suppose the two values omitted are \( a \) and \( b \) and that \( h \) is not constant. Let \( f(z) = (h(z) - a) / (b - a) \). Then \( f \) omits the two values 0 and 1. Let \( H \) be defined in Lemma 53.5.4. Then \( H(z) \) is clearly not of the form \( az + b \) because then it would have values equal to the vertices \( \ln(\sqrt{n} + \sqrt{n - 1}) + 2m\pi i \) or else be constant neither of which happen if \( h \) is not constant. Therefore, by Liouville’s theorem, \( H' \) must be unbounded. Pick \( r \) such that \( \|H'(z)\| > 24C \) where \( C \) is such that \( H(C) \) contains no balls of radius larger than \( C \): This proves Picard’s theorem.

The following is another formulation of this theorem.

**Corollary 53.5.6** If \( f \) is a meromorphic function defined on \( \mathbb{C} \) which omits three distinct values, \( a, b, c \), then \( f \) is a constant.

**Proof:** Let \( \phi(z) = \frac{z-a}{z-c} \). Then \( \phi(c) = \infty, \phi(a) = 0, \) and \( \phi(b) = 1 \). Now consider the function, \( h = \phi \circ f \). Then \( h \) misses the three points \( \infty, 0, \) and 1. Since \( h \) is meromorphic and does not have \( \infty \) in its values, it must actually be analytic. Thus \( h \) is an entire function which misses the two values 0 and 1. Therefore, \( h \) is constant by Theorem 53.5.5.

53.5.3 Schottky’s Theorem

**Lemma 53.5.7** Let \( f \) be analytic on an open set containing \( \overline{B(0, R)} \) and suppose that \( f \) does not take on either of the two values 0 or 1. Also suppose \( |f(0)| \leq \beta \). Then letting \( \theta \in (0, 1) \), it follows

\[
|f(z)| \leq M(\beta, \theta)
\]

for all \( z \in B(0, \theta R) \), where \( M(\beta, \theta) \) is a function of only the two variables \( \beta, \theta \). (In particular, there is no dependence on \( R \).)

**Proof:** Consider the function, \( H(z) \) used in Lemma 53.5.4 given by

\[
H(z) = \log \left( \sqrt{\frac{\log(f(z))}{2\pi i}} - \sqrt{\frac{\log(f(z))}{2\pi i}} - 1 \right).
\]

You notice there are two explicit uses of logarithms. Consider first the logarithm inside the radicals. Choose this logarithm such that

\[
\log(f(0)) = \ln |f(0)| + i \arg(f(0)), \quad \arg(f(0)) \in (-\pi, \pi].
\]
You can do this because
\[ e^{\log(f(0))} = f(0) = e^{\ln|f(0)| + i\alpha} = e^{\ln|f(0)| + i\alpha} \]
and by replacing \( \alpha \) with \( \alpha + 2m\pi \) for a suitable integer, \( m \) it follows the above equation still holds. Therefore, you can assume \( \log(H(0)) \) equals
\[ \ln \left( \sqrt{\frac{\log(f(0))}{2\pi i}} - \sqrt{\frac{\log(f(0))}{2\pi i}} - 1 \right) + i \arg \left( \sqrt{\frac{\log(f(0))}{2\pi i}} - \sqrt{\frac{\log(f(0))}{2\pi i}} - 1 \right) \]
(53.5.25)
where the imaginary part is no larger than \( \pi \) in absolute value.

Now if \( \xi \in B(0, R) \) is a point where \( H'(\xi) \neq 0 \), then by Lemma 53.5.2
\[ H(B(\xi, R - |\xi|)) \supseteq B\left( H(a), \frac{|H'(\xi)(R - |\xi|)|}{24} \right) \]
where \( a \) is some point in \( B(\xi, R - |\xi|) \). But by Lemma 53.5.4 \( H(B(\xi, R - |\xi|)) \) contains no balls of radius \( C \) where \( C \) depended only on the maximum diameters of those rectangles having vertices \( \ln (\sqrt{n} \pm \sqrt{n - 1}) + 2m\pi i \) for \( n \) a positive integer and \( m \) an integer. Therefore,
\[ \frac{|H'(\xi)(R - |\xi|)|}{24} < C \]
and consequently
\[ |H'(\xi)| < \frac{24C}{R - |\xi|} \]
Even if \( H'(\xi) = 0 \), this inequality still holds. Therefore, if \( z \in B(0, R) \) and \( \gamma(0, z) \) is the straight segment from 0 to \( z \),
\[ |H(z) - H(0)| = \left| \int_{\gamma(0,z)} H'(w) \, dw \right| = \left| \int_0^1 H'(tz) \, z \, dt \right| \leq \int_0^1 |H'(tz)\, z| \, dt \leq \int_0^1 \frac{2AC}{R - t|z|} \, |z| \, dt \]
\[ = 24C \ln \left( \frac{R}{R - |z|} \right) \]
Therefore, for \( z \in \partial B(0, \theta R) \),
\[ |H(z)| \leq |H(0)| + 24C \ln \left( \frac{1}{1 - \theta} \right) \]
(53.5.26)
By the maximum modulus theorem, the above inequality holds for all \( |z| < \theta R \) also.
Next I will use \( H(z) = \log \left( \sqrt{\frac{\log(f(z))}{2\pi i}} - \sqrt{\frac{\log(f(z))}{2\pi i} - 1} \right) \)
and so

\[
2H(z) = \log \left( \sqrt{\frac{\log(f(z))}{2\pi i}} - \sqrt{\frac{\log(f(z))}{2\pi i} - 1} \right)^2
\]

\[
-2H(z) = \log \left( \sqrt{\frac{\log(f(z))}{2\pi i}} - \sqrt{\frac{\log(f(z))}{2\pi i} - 1} \right)^2
\]

Therefore,

\[
\left( \sqrt{\frac{\log(f(z))}{2\pi i}} + \sqrt{\frac{\log(f(z))}{2\pi i} - 1} \right)^2
\]

\[
+ \left( \sqrt{\frac{\log(f(z))}{2\pi i}} - \sqrt{\frac{\log(f(z))}{2\pi i} - 1} \right)^2
\]

\[
= \exp(2H(z)) + \exp(-2H(z))
\]

and

\[
\left( \frac{\log(f(z))}{\pi i} - 1 \right) = \frac{1}{2} \left( \exp(2H(z)) + \exp(-2H(z)) \right).
\]

Thus

\[
\log(f(z)) = \pi i + \frac{\pi i}{2} \left( \exp(2H(z)) + \exp(-2H(z)) \right)
\]

which shows

\[
|f(z)| = \left| \exp \left( \frac{\pi i}{2} (\exp(2H(z)) + \exp(-2H(z))) \right) \right|
\]

\[
\leq \exp \left( \frac{\pi}{2} \left( |\exp(2H(z))| + |\exp(-2H(z))| \right) \right)
\]

\[
\leq \exp \left( \frac{\pi}{2} \left( |\exp(2H(z))| + |\exp(-2H(z))| \right) \right)
\]

\[
\leq \exp \left( \frac{\pi}{2} \left( 2|H(z)| + \exp(|-2H(z)|) \right) \right)
\]

\[
= \exp(\pi \exp 2|H(z)|).
\]
Now from \[53.5.26\] this is dominated by

\[
\exp \left( \pi \exp 2 \left| H (0) \right| + 24 \ln \left( \frac{1}{1 - \theta} \right) \right)
\]

\[
= \exp \left( \pi \exp (2 \left| H (0) \right|) \exp \left( 48 \ln \left( \frac{1}{1 - \theta} \right) \right) \right) \tag{53.5.27}
\]

Consider \(\exp (2 \left| H (0) \right|)\). I want to obtain an inequality for this which involves \(\beta\). This is where I will use the convention about the logarithms discussed above.

From \[53.5.26\]

\[
2 \left| H (0) \right| = 2 \left| \log \left( \sqrt{\frac{\log (f(0))}{2 \pi i}} - \sqrt{\frac{\log (f(0))}{2 \pi i} - 1} \right) \right|
\]

\[
\leq 2 \left( \left( \ln \left( \sqrt{\frac{\log (f(0))}{2 \pi i}} - \sqrt{\frac{\log (f(0))}{2 \pi i} - 1} \right) \right)^2 + \pi^2 \right)^{1/2}
\]

\[
\leq 2 \left( \left( \ln \left( \sqrt{\frac{\log (f(0))}{2 \pi i}} + \sqrt{\frac{\log (f(0))}{2 \pi i} - 1} \right) \right)^2 + \pi^2 \right)^{1/2}
\]

\[
\leq 2 \left( \left( \log \left( \left| \frac{\log (f(0))}{2 \pi i} \right| + \left| \frac{\log (f(0))}{2 \pi i} - 1 \right| \right) \left| + 2 \pi \right. \right)^2 + 2 \pi
\]

\[
= \ln \left( \left| \frac{\log (f(0))}{2 \pi i} \right| + \left| \frac{\log (f(0))}{2 \pi i} - 2 \right| \right) + 2 \pi \tag{53.5.28}
\]

Consider \(\left| \frac{\log (f(0))}{\pi} \right|\)

\[
\frac{\log (f(0))}{\pi} = - \ln \left| f(0) \right| + \frac{\arg (f(0))}{\pi}
\]

and so

\[
\left| \frac{\log (f(0))}{\pi} \right| = \left( \left| \frac{\ln \left| f(0) \right|}{\pi} \right| ^2 + \left( \frac{\arg (f(0))}{\pi} \right) ^2 \right)^{1/2}
\]

\[
\leq \left( \left( \frac{\ln \beta}{\pi} \right) ^2 + \left( \frac{\pi}{\pi} \right) ^2 \right)^{1/2}
\]

\[
= \left( \left| \frac{\ln \beta}{\pi} \right| ^2 + 1 \right)^{1/2}.
\]
Similarly,

\[ \left| \frac{\log (f(0))}{\pi i} - 2 \right| \leq \left( \frac{\ln \beta}{2} + (2 + 1)^2 \right)^{1/2} = \left( \frac{\ln \beta}{2} + 9 \right)^{1/2} \]

It follows from \(53.5.28\) that

\[ 2 |H(0)| \leq \ln \left( 2 \left( \frac{\ln \beta}{2} + 9 \right)^{1/2} \right) + 2\pi. \]

Hence from \(53.5.27\)

\[ |f(z)| \leq \exp \left( \pi \exp \left( \ln \left( 2 \left( \frac{\ln \beta}{2} + 9 \right)^{1/2} \right) + 2\pi \right) \exp \left( 48C \ln \left( \frac{1}{1 - \theta} \right) \right) \right) \]

and so, letting \(M(\beta, \theta)\) be given by the above expression on the right, the lemma is proved.

The following theorem will be referred to as Schottky’s theorem. It looks just like the above lemma except it is only assumed that \(f\) is analytic on \(B(0, R)\) rather than on an open set containing \(\overline{B(0, R)}\). Also, the case of an arbitrary center is included along with arbitrary points which are not attained as values of the function.

**Theorem 53.5.8** Let \(f\) be analytic on \(B(z_0, R)\) and suppose that \(f\) does not take on either of the two distinct values \(a\) or \(b\). Also suppose \(|f(z_0)| \leq \beta\). Then letting \(\theta \in (0, 1)\), it follows

\[ |f(z)| \leq M(a, b, \beta, \theta) \]

for all \(z \in B(z_0, \theta R)\), where \(M(a, b, \beta, \theta)\) is a function of only the variables \(\beta, \theta, a, b\). (In particular, there is no dependence on \(R\).)

**Proof:** First you can reduce to the case where the two values are 0 and 1 by considering

\[ h(z) \equiv \frac{f(z) - a}{b - a}. \]

If there exists an estimate of the desired sort for \(h\), then there exists such an estimate for \(f\). Of course here the function, \(M\) would depend on \(a\) and \(b\). Therefore, there is no loss of generality in assuming the points which are missed are 0 and 1.

Apply Lemma \(53.5.27\) to \(B(0, R_1)\) for the function, \(g(z) \equiv f(z_0 + z)\) and \(R_1 < R\). Then if \(\beta \geq |f(z_0)| = |g(0)|\), it follows \(|g(z)| = |f(z_0 + z)| \leq M(\beta, \theta)\) for every \(z \in B(0, \theta R_1)\). Now let \(\theta \in (0, 1)\) and choose \(R_1 < R\) large enough that \(\theta R = \theta_1 R_1\) where \(\theta_1 \in (0, 1)\). Then if \(|z - z_0| < \theta R\), it follows

\[ |f(z)| \leq M(\beta, \theta_1). \]

Now let \(R_1 \to R\) so \(\theta_1 \to \theta\).
53.5.4 A Brief Review

First recall the definition of the metric on \( \hat{\mathbb{C}} \). For convenience it is listed here again. Consider the unit sphere, \( S^2 \) given by \((z - 1)^2 + y^2 + x^2 = 1\). Define a map from the complex plane to the surface of this sphere as follows. Extend a line from the point, \( p \) in the complex plane to the point \((0, 0, 2)\) on the top of this sphere and let \( \theta(p) \) denote the point of this sphere which the line intersects. Define \( \theta\) as sometimes called stereographic projection. The mapping \( \theta^{-1} \) is clearly continuous because it takes converging sequences, to converging sequences. Furthermore, it is clear that \( \theta^{-1} \) is also continuous. In terms of the extended complex plane, \( \hat{\mathbb{C}} \), a sequence, \( z_n \) converges to \( z \) if and only if \( z_n \) converges to \((0, 0, 2)\) and a sequence, \( z_n \) converges to \( z \in \mathbb{C} \) if and only if \( \theta(z_n) \to \theta(z) \).

In fact this makes it easy to define a metric on \( \hat{\mathbb{C}} \).

**Definition 53.5.9** Let \( z, w \in \hat{\mathbb{C}} \). Then let \( d(x, y) \equiv |\theta(x) - \theta(y)| \) where this last distance is the usual distance measured in \( \mathbb{R}^3 \).

**Theorem 53.5.10** \( (\hat{\mathbb{C}}, d) \) is a compact, hence complete metric space.

**Proof:** Suppose \( \{z_n\} \) is a sequence in \( \hat{\mathbb{C}} \). This means \( \{\theta(z_n)\} \) is a sequence in \( S^2 \) which is compact. Therefore, there exists a subsequence, \( \{\theta z_{n_k}\} \) and a point, \( z \in S^2 \) such that \( \theta z_{n_k} \to \theta z \) in \( S^2 \) which implies immediately that \( d(z_{n_k}, z) \to 0 \). A compact metric space must be complete.

Also recall the interesting fact that meromorphic functions are continuous with values in \( \hat{\mathbb{C}} \) which is reviewed here for convenience. It came from the theory of classification of isolated singularities.

**Theorem 53.5.11** Let \( \Omega \) be an open subset of \( \mathbb{C} \) and let \( f : \Omega \to \hat{\mathbb{C}} \) be meromorphic. Then \( f \) is continuous with respect to the metric, \( d \) on \( \hat{\mathbb{C}} \).

**Proof:** Let \( z_n \to z \) where \( z \in \Omega \). Then if \( z \) is a pole, it follows from Theorem \( 49.7.11 \) that

\[
d(f(z_n), \infty) \equiv d(f(z_n), f(z)) \to 0.
\]

If \( z \) is not a pole, then \( f(z_n) \to f(z) \) in \( \mathbb{C} \) which implies

\[
|\theta(f(z_n)) - \theta(f(z))| = d(f(z_n), f(z)) \to 0.
\]

Recall that \( \theta \) is continuous on \( \mathbb{C} \).

The fundamental result behind all the theory about to be presented is the Ascoli Arzela theorem also listed here for convenience.
Definition 53.5.12 Let \((X, d)\) be a complete metric space. Then it is said to be locally compact if \(B(x, r)\) is compact for each \(r > 0\).

Thus if you have a locally compact metric space, then if \(\{a_n\}\) is a bounded sequence, it must have a convergent subsequence.

Let \(K\) be a compact subset of \(\mathbb{R}^n\) and consider the continuous functions which have values in a locally compact metric space, \((X, d)\) where \(d\) denotes the metric on \(X\). Denote this space as \(C(K, X)\).

Definition 53.5.13 For \(f, g \in C(K, X)\), where \(K\) is a compact subset of \(\mathbb{R}^n\) and \(X\) is a locally compact complete metric space define

\[
\rho_K(f, g) = \sup \{d(f(x), g(x)) : x \in K\}.
\]

The Ascoli Arzela theorem, Theorem 6.4.4 is a major result which tells which subsets of \(C(K, X)\) are sequentially compact.

Definition 53.5.14 Let \(A \subseteq C(K, X)\) for \(K\) a compact subset of \(\mathbb{R}^n\). Then \(A\) is said to be uniformly equicontinuous if for every \(\varepsilon > 0\) there exists a \(\delta > 0\) such that whenever \(x, y \in K\) with \(|x - y| < \delta\) and \(f \in A\),

\[
d(f(x), f(y)) < \varepsilon.
\]

The set, \(A\) is said to be uniformly bounded if for some \(M < \infty\), and \(a \in X\),

\[
f(x) \in B(a, M)
\]

for all \(f \in A\) and \(x \in K\).

The Ascoli Arzela theorem follows.

Theorem 53.5.15 Suppose \(K\) is a nonempty compact subset of \(\mathbb{R}^n\) and \(A \subseteq C(K, X)\), is uniformly bounded and uniformly equicontinuous where \(X\) is a locally compact complete metric space. Then if \(\{f_k\} \subseteq A\), there exists a function, \(f \in C(K, X)\) and a subsequence, \(f_{k_l}\) such that

\[
\lim_{l \to \infty} \rho_K(f_{k_l}, f) = 0.
\]

In the cases of interest here, \(X = \hat{\mathbb{C}}\) with the metric defined above.

53.5.5 Montel’s Theorem

The following lemma is another version of Montel’s theorem. It is this which will make possible a proof of the big Picard theorem.
Lemma 53.5.16 Let \( \Omega \) be a region and let \( \mathcal{F} \) be a set of functions analytic on \( \Omega \) none of which achieve the two distinct values, \( a \) and \( b \). If \( \{f_n\} \subseteq \mathcal{F} \) then one of the following hold: Either there exists a function, \( f \) analytic on \( \Omega \) and a subsequence, \( \{f_{n_k}\} \) such that for any compact subset, \( K \) of \( \Omega \),

\[
\lim_{k \to \infty} \|f_{n_k} - f\|_{K,\infty} = 0.
\]  
(53.5.29)

or there exists a subsequence \( \{f_{n_k}\} \) such that for all compact subsets \( K \),

\[
\lim_{k \to \infty} \rho_K (f_{n_k}, \infty) = 0.
\]  
(53.5.30)

Proof: Let \( B(z_0, 2R) \subseteq \Omega \). There are two cases to consider. The first case is that there exists a subsequence, \( n_k \) such that \( \{f_{n_k}(z_0)\} \) is bounded. The second case is that \( \lim_{n \to \infty} |f_{n_k}(z_0)| = \infty \).

Consider the first case. By Theorem 53.5.15 \( \{f_{n_k}(z)\} \) is uniformly bounded on \( B(z_0, R) \) because by this theorem, and letting \( \theta = 1/2 \) applied to \( B(z_0, 2R) \), it follows \( |f_{n_k}(z)| \leq M(a, b, \frac{1}{2}, \beta) \) where \( \beta \) is an upper bound to the numbers, \( |f_{n_k}(z_0)| \).

The Cauchy integral formula implies the existence of a uniform bound on the \( \{f'_{n_k}\} \) which implies the functions are equicontinuous and uniformly bounded. Therefore, by the Ascoli Arzela theorem there exists a further subsequence which converges uniformly on \( B(z_0, R) \) to a function, \( f \) analytic on \( B(z_0, R) \). Thus denoting this subsequence by \( \{f_{n_k}\} \) to save on notation,

\[
\lim_{k \to \infty} \|f_{n_k} - f\|_{B(z_0, R),\infty} = 0.
\]  
(53.5.31)

Consider the second case. In this case, it follows \( \{1/f_n(z_0)\} \) is bounded on \( B(z_0, R) \) and so by the same argument just given \( \{1/f_n(z)\} \) is uniformly bounded on \( B(z_0, R) \). Therefore, a subsequence converges uniformly on \( B(z_0, R) \). But \( \{1/f_n(z)\} \) converges to 0 and so this requires that \( \{1/f_n(z)\} \) must converge uniformly to 0. Therefore,

\[
\lim_{k \to \infty} \rho_{B(z_0, R)} (f_{n_k}, \infty) = 0.
\]  
(53.5.32)

Now let \( \{D_k\} \) denote a countable set of closed balls, \( D_k = B(z_k, R_k) \) such that \( B(z_k, 2R_k) \subseteq \Omega \) and \( \bigcup_{k=1}^{\infty} \text{int}(D_k) = \Omega \). Using a Cantor diagonal process, there exists a subsequence, \( \{f_{n_k}\} \) of \( \{f_n\} \) such that for each \( D_j \), one of the above two alternatives holds. That is, either

\[
\lim_{k \to \infty} \|f_{n_k} - g_j\|_{D_j,\infty} = 0
\]  
(53.5.33)

or,

\[
\lim_{k \to \infty} \rho_{D_j} (f_{n_k}, \infty) = 0.
\]  
(53.5.34)

Let \( A = \{ \cup \text{int}(D_j) : \text{Lemma 53.5.15 holds} \} \), \( B = \{ \cup \text{int}(D_j) : \text{Lemma 53.5.16 holds} \} \). Note that the balls whose union is \( A \) cannot intersect any of the balls whose union is \( B \). Therefore, one of \( A \) or \( B \) must be empty since otherwise, \( \Omega \) would not be connected.
If \( K \) is any compact subset of \( \Omega \), it follows \( K \) must be a subset of some finite collection of the \( D_j \). Therefore, one of the alternatives in the lemma must hold. That the limit function, \( f \) must be analytic follows easily in the same way as the proof in Theorem 53.3.1 on Page 1750. You could also use Morera’s theorem. This proves the lemma.

53.5.6 The Great Big Picard Theorem

The next theorem is the main result which the above lemmas lead to. It is the Big Picard theorem, also called the Great Picard theorem. Recall \( B' (a, r) \) is the deleted ball consisting of all the points of the ball except the center.

**Theorem 53.5.17** Suppose \( f \) has an isolated essential singularity at 0. Then for every \( R > 0 \), and \( \beta \in \mathbb{C} \), \( f^{-1} (\beta) \cap B' (0, R) \) is an infinite set except for one possible exceptional \( \beta \).

**Proof:** Suppose this is not true. Then there exists \( R_1 > 0 \) and two points, \( \alpha \) and \( \beta \) such that \( f^{-1} (\beta) \cap B' (0, R_1) \) and \( f^{-1} (\alpha) \cap B' (0, R_1) \) are both finite sets. Then shrinking \( R_1 \) and calling the result \( R \), there exists \( B (0, R) \) such that

\[
f^{-1} (\beta) \cap B' (0, R) = \emptyset, \quad f^{-1} (\alpha) \cap B' (0, R) = \emptyset.
\]

Now let \( A_0 \) denote the annulus \( \{ z \in \mathbb{C} : \frac{R}{2} < |z| < \frac{3R}{2} \} \) and let \( A_n \) denote the annulus \( \{ z \in \mathbb{C} : \frac{R}{2^n} < |z| < \frac{3R}{2^n} \} \). The reason for the 3 is to insure that \( A_n \cap A_{n+1} \neq \emptyset \). This follows from the observation that \( 3R/2^{2+n} > R/2^{2+n} \). Now define a set of functions on \( A_0 \) as follows:

\[
f_n (z) = f \left( \frac{z}{2^n} \right).
\]

By the choice of \( R \), this set of functions missed the two points \( \alpha \) and \( \beta \). Therefore, by Lemma 53.5.10 there exists a subsequence such that one of the two options presented there holds.

First suppose \( \lim_{k \to \infty} ||f_{n_k} - f||_{K, \infty} = 0 \) for all \( K \) a compact subset of \( A_0 \) and \( f \) is analytic on \( A_0 \). In particular, this happens for \( \gamma_0 \) the circular contour having radius \( R/2 \). Thus \( f_{n_k} \) must be bounded on this contour. But this says the same thing as \( f (z/2^n) \) is bounded for \( |z| = R/2 \), this holding for each \( k = 1, 2, \ldots \). Thus there exists a constant, \( M \) such that on each of a shrinking sequence of concentric circles whose radii converge to 0, \( |f (z)| \leq M \). By the maximum modulus theorem, \( |f (z)| \leq M \) at every point between successive circles in this sequence. Therefore, \( |f (z)| \leq M \) in \( B' (0, R) \) contradicting the Weierstrass Casorati theorem.

The other option which might hold from Lemma 53.5.10 is that \( \lim_{k \to \infty} \rho_K (f_{n_k}, \infty) = 0 \) for all \( K \) compact subset of \( A_0 \). Since \( f \) has an essential singularity at 0 the zeros of \( f \) in \( B (0, R) \) are isolated. Therefore, for all \( k \) large enough, \( f_{n_k} \) has no zeros for \( |z| < 3R/2^2 \). This is because the values of \( f_{n_k} \) are the values of \( f \) on \( A_{n_k} \), a small annulus which avoids all the zeros of \( f \) whenever \( k \) is large enough. Only consider \( k \) large. Then use the above argument on the analytic functions \( 1/f_{n_k} \). By the assumption that \( \lim_{k \to \infty} \rho_K (f_{n_k}, \infty) = 0 \), it follows \( \lim_{k \to \infty} ||1/f_{n_k} - 0||_{K, \infty} = 0 \) and
so as above, there exists a shrinking sequence of concentric circles whose radii converge to 0 and a constant, $M$ such that for $z$ on any of these circles, $|1/f(z)| \leq M$. This implies that on some deleted ball, $B'(0, r)$ where $r \leq R$, $|f(z)| \geq 1/M$ which again violates the Weierstrass Casorati theorem. This proves the theorem.

As a simple corollary, here is what this remarkable theorem says about entire functions.

**Corollary 53.5.18** Suppose $f$ is entire and nonconstant and not a polynomial. Then $f$ assumes every complex value infinitely many times with the possible exception of one.

**Proof:** Since $f$ is entire, $f(z) = \sum_{n=0}^{\infty} a_n z^n$. Define for $z \neq 0$,

$$g(z) = f\left(\frac{1}{z}\right) = \sum_{n=0}^{\infty} a_n \left(\frac{1}{z}\right)^n.$$ 

Thus 0 is an isolated essential singular point of $g$. By the big Picard theorem, Theorem 53.5.17, it follows $g$ takes every complex number but possibly one an infinite number of times. This proves the corollary.

Note the difference between this and the little Picard theorem which says that an entire function which is not constant must achieve every value but two.

### 53.6 Exercises

1. Prove that in Theorem 53.3.1 it suffices to assume $F$ is uniformly bounded on each compact subset of $\Omega$.

2. Find conditions on $a, b, c, d$ such that the fractional linear transformation, $\frac{az+b}{cz+d}$ maps the upper half plane onto the upper half plane.

3. Let $D$ be a simply connected region which is a proper subset of $\mathbb{C}$. Does there exist an entire function, $f$ which maps $\mathbb{C}$ onto $D$? Why or why not?

4. Verify the conclusion of Theorem 53.5.17 involving the higher order derivatives.

5. What if $\Omega = \mathbb{C}$? Does there exist an analytic function, $f$ mapping $\Omega$ one to one and onto $B(0, 1)$? Explain why or why not. Was $\Omega \neq \mathbb{C}$ used in the proof of the Riemann mapping theorem?

6. Verify that $|\phi_\alpha(z)| = 1$ if $|z| = 1$. Apply the maximum modulus theorem to conclude that $|\phi_\alpha(z)| \leq 1$ for all $|z| < 1$.

7. Suppose that $|f(z)| \leq 1$ for $|z| = 1$ and $f(\alpha) = 0$ for $|\alpha| < 1$. Show that $|f(z)| \leq |\phi_\alpha(z)|$ for all $z \in B(0, 1)$. **Hint:** Consider $\frac{f(z)}{z-\alpha}$ which has a removable singularity at $\alpha$. Show the modulus of this function is bounded by 1 on $|z| = 1$. Then apply the maximum modulus theorem.
53.6. EXERCISES

8. Let $U$ and $V$ be open subsets of $\mathbb{C}$ and suppose $u : U \to \mathbb{R}$ is harmonic while $h$ is an analytic map which takes $V$ one to one onto $U$. Show that $u \circ h$ is harmonic on $V$.

9. Show that for a harmonic function, $u$ defined on $B(0,R)$, there exists an analytic function, $h = u + iv$ where

$$v(x,y) = \int_0^y u_x(x,t) \, dt - \int_0^x u_y(t,0) \, dt.$$

10. Suppose $\Omega$ is a simply connected region and $u$ is a real valued function defined on $\Omega$ such that $u$ is harmonic. Show there exists an analytic function, $f$ such that $u = \text{Re } f$. Show this is not true if $\Omega$ is not a simply connected region. \textbf{Hint:} You might use the Riemann mapping theorem and Problems 8 and 9. For the second part it might be good to try something like $u(x,y) = \ln(x^2 + y^2)$ on the annulus $1 < |z| < 2$.

11. Show that $w = \frac{1+z}{1-z}$ maps \{$z \in \mathbb{C} : \text{Im } z > 0 \text{ and } |z| < 1$\} to the first quadrant, \{$z = x + iy : x, y > 0$\}.

12. Let $f(z) = \frac{az+b}{cz+d}$ and let $g(z) = \frac{a_1z+b_1}{c_1z+d_1}$. Show that $f \circ g(z)$ equals the quotient of two expressions, the numerator being the top entry in the vector

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} a_1 \\ c_1 \end{pmatrix} \begin{pmatrix} z \\ 1 \end{pmatrix},$$

and the denominator being the bottom entry. Show that if you define

$$\phi\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) = \frac{az+b}{cz+d},$$

then $\phi(AB) = \phi(A) \circ \phi(B)$. Find an easy way to find the inverse of $f(z) = \frac{az+b}{cz+d}$ and give a condition on the $a, b, c, d$ which insures this function has an inverse.

13. The modular group\footnote{This is the terminology used in Rudin’s book Real and Complex Analysis.} is the set of fractional linear transformations, $\frac{az+b}{cz+d}$ such that $a, b, c, d$ are integers and $ad - bc = 1$. Using Problem 12 or brute force show this modular group is really a group with the group operation being composition. Also show the inverse of $\frac{az+b}{cz+d}$ is $\frac{dz-b}{-cz+a}$.

14. Let $\Omega$ be a region and suppose $f$ is analytic on $\Omega$ and that the functions $f_n$ are also analytic on $\Omega$ and converge to $f$ uniformly on compact subsets of $\Omega$. Suppose $f$ is one to one. Can it be concluded that for an arbitrary compact set, $K \subseteq \Omega$ that $f_n$ is one to one for all $n$ large enough?
15. The Vitali theorem says that if \( \Omega \) is a region and \( \{f_n\} \) is a uniformly bounded sequence of functions which converges pointwise on a set, \( S \subseteq \Omega \) which has a limit point in \( \Omega \), then in fact, \( \{f_n\} \) must converge uniformly on compact subsets of \( \Omega \) to an analytic function. Prove this theorem. **Hint:** If the sequence fails to converge, show you can get two different subsequences converging uniformly on compact sets to different functions. Then argue these two functions coincide on \( S \).

16. Does there exist a function analytic on \( B(0,1) \) which maps \( B(0,1) \) onto \( B'(0,1) \), the open unit ball in which 0 has been deleted?
Chapter 54

Approximation By Rational Functions

54.1 Runge’s Theorem

Consider the function, $\frac{1}{z} = f(z)$ for $z$ defined on $\Omega \equiv B(0, 1) \setminus \{0\} = B'(0, 1)$. Clearly, $f$ is analytic on $\Omega$. Suppose you could approximate $f$ uniformly by polynomials on $\text{ann}(0, \frac{1}{2}; \frac{3}{4})$, a compact subset of $\Omega$. Then, there would exist a suitable polynomial $p(z)$, such that $\left| \frac{1}{2\pi i} \int_\gamma f(z) - p(z) \, dz \right| < \frac{1}{10}$ where here $\gamma$ is a circle of radius $\frac{2}{3}$. However, this is impossible because $\frac{1}{2\pi i} \int_\gamma f(z) \, dz = 1$ while $\frac{1}{2\pi i} \int_\gamma p(z) \, dz = 0$. This shows you can’t expect to be able to uniformly approximate analytic functions on compact sets using polynomials. This is just horrible! In real variables, you can approximate any continuous function on a compact set with a polynomial. However, that is just the way it is. It turns out that the ability to approximate an analytic function on $\Omega$ with polynomials is dependent on $\Omega$ being simply connected.

All these theorems work for $f$ having values in a complex Banach space. However, I will present them in the context of functions which have values in $\mathbb{C}$. The changes necessary to obtain the extra generality are very minor.

Definition 54.1.1 Approximation will be taken with respect to the following norm.

$$||f - g||_{K, \infty} \equiv \sup \{ ||f(z) - g(z)|| : z \in K \}$$

54.1.1 Approximation With Rational Functions

It turns out you can approximate analytic functions by rational functions, quotients of polynomials. The resulting theorem is one of the most profound theorems in complex analysis. The basic idea is simple. The Riemann sums for the Cauchy integral formula are rational functions. The idea used to implement this observation is that if you have a compact subset, $K$ of an open set, $\Omega$ there exists a cycle
composed of closed oriented curves \( \{ \gamma_j \}_{j=1}^n \) which are contained in \( \Omega \setminus K \) such that for every \( z \in K \), \( \sum_{k=1}^n n(\gamma_k, z) = 1 \). One more ingredient is needed and this is a theorem which lets you keep the approximation but move the poles.

To begin with, consider the part about the cycle of closed oriented curves. Recall Theorem 49.7.25 which is stated for convenience.

**Theorem 54.1.2** Let \( K \) be a compact subset of an open set, \( \Omega \). Then there exist continuous, closed, bounded variation oriented curves \( \{ \gamma_j \}_{j=1}^m \) for which \( \gamma_j \cap K = \emptyset \) for each \( j \), \( \gamma_j \subseteq \Omega \), and for all \( p \in K \),

\[
\sum_{k=1}^m n(p, \gamma_k) = 1.
\]

and

\[
\sum_{k=1}^m n(z, \gamma_k) = 0
\]

for all \( z \notin \Omega \).

This theorem implies the following.

**Theorem 54.1.3** Let \( K \subseteq \Omega \) where \( K \) is compact and \( \Omega \) is open. Then there exist oriented closed curves, \( \gamma_k \) such that \( \gamma_k \cap K = \emptyset \) but \( \gamma_k \subseteq \Omega \), such that for all \( z \in K \),

\[
f(z) = \frac{1}{2\pi i} \sum_{k=1}^p \int_{\gamma_k} \frac{f(w)}{w-z}dw.
\]

(54.1.1)

**Proof:** This follows from Theorem 49.7.25 and the Cauchy integral formula. As shown in the proof, you can assume the \( \gamma_k \) are linear mappings but this is not important.

Next I will show how the Cauchy integral formula leads to approximation by rational functions, quotients of polynomials.

**Lemma 54.1.4** Let \( K \) be a compact subset of an open set, \( \Omega \) and let \( f \) be analytic on \( \Omega \). Then there exists a rational function, \( Q \) whose poles are not in \( K \) such that

\[
||Q - f||_{K, \infty} < \varepsilon.
\]

**Proof:** By Theorem 54.1.3 there are oriented curves, \( \gamma_k \) described there such that for all \( z \in K \),

\[
f(z) = \frac{1}{2\pi i} \sum_{k=1}^p \int_{\gamma_k} \frac{f(w)}{w-z}dw.
\]

(54.1.2)

Defining \( g(w, z) \equiv \frac{f(w)}{w-z} \) for \( (w, z) \in \bigcup_{k=1}^p \gamma_k^* \times K \), it follows since the distance between \( K \) and \( \bigcup_k \gamma_k^* \) is positive that \( g \) is uniformly continuous and so there exists a \( \delta > 0 \) such that if \( ||\mathcal{P}|| < \delta \), then for all \( z \in K \),

\[
\left| f(z) - \frac{1}{2\pi i} \sum_{k=1}^p \sum_{j=1}^n \frac{f(\gamma_k(\tau_j))(\gamma_k(t_j) - \gamma_k(t_{j-1}))}{\gamma_k(\tau_j) - z} \right| < \frac{\varepsilon}{2}.
\]
The complicated expression is obtained by replacing each integral in Runge’s theorem with a Riemann sum. Simplifying the appearance of this, it follows there exists a rational function of the form

\[ R(z) = \sum_{k=1}^{M} \frac{A_k}{w_k - z} \]

where the \( w_k \) are elements of components of \( \mathbb{C} \setminus K \) and \( A_k \) are complex numbers or in the case where \( f \) has values in \( X \), these would be elements of \( X \) such that

\[ ||R - f||_{K,\infty} < \frac{\varepsilon}{2}. \]

This proves the lemma.

### 54.1.2 Moving The Poles And Keeping The Approximation

Lemma 54.1.4 is a nice lemma but needs refining. In this lemma, the Riemann sum handed you the poles. It is much better if you can pick the poles. The following theorem from advanced calculus, called Merten’s theorem, will be used.

### 54.1.3 Merten’s Theorem.

**Theorem 54.1.5** Suppose \( \sum_{i=r}^{\infty} a_i \) and \( \sum_{j=r}^{\infty} b_j \) both converge absolutely. Then

\[
\left( \sum_{i=r}^{\infty} a_i \right) \left( \sum_{j=r}^{\infty} b_j \right) = \sum_{n=r}^{\infty} c_n
\]

where

\[ c_n = \sum_{k=r}^{n} a_k b_{n-k+r}. \]

**Proof:** Let \( p_{nk} = 1 \) if \( r \leq k \leq n \) and \( p_{nk} = 0 \) if \( k > n \). Then

\[ c_n = \sum_{k=r}^{\infty} p_{nk} a_k b_{n-k+r}. \]

---

1Actually, it is only necessary to assume one of the series converges and the other converges absolutely. This is known as Merten’s theorem and may be read in the 1974 book by Apostol listed in the bibliography.
Also,
\begin{align*}
\sum_{k=r}^{\infty} \sum_{n=r}^{\infty} p_{nk} |a_k| b_{n-k+r} & = \sum_{k=r}^{\infty} |a_k| \sum_{n=r}^{\infty} p_{nk} |b_{n-k+r}| \\
& = \sum_{k=r}^{\infty} |a_k| \sum_{n=k}^{\infty} |b_{n-k+r}| \\
& = \sum_{k=r}^{\infty} |a_k| \sum_{n=k}^{\infty} |b_{n-(k-r)}| \\
& = \sum_{k=r}^{\infty} |a_k| \sum_{m=r}^{\infty} |b_m| < \infty.
\end{align*}
Therefore,
\begin{align*}
\sum_{n=r}^{\infty} c_n &= \sum_{n=r}^{\infty} \sum_{k=r}^{\infty} a_k b_{n-k+r} = \sum_{n=r}^{\infty} \sum_{k=r}^{\infty} p_{nk} a_k b_{n-k+r} \\
& = \sum_{k=r}^{\infty} a_k \sum_{n=k}^{\infty} p_{nk} b_{n-k+r} = \sum_{k=r}^{\infty} a_k \sum_{n=k}^{\infty} b_{n-k+r} \\
& = \sum_{k=r}^{\infty} a_k \sum_{m=r}^{\infty} b_m
\end{align*}
and this proves the theorem.

It follows that \( \sum_{n=r}^{\infty} c_n \) converges absolutely. Also, you can see by induction that you can multiply any number of absolutely convergent series together and obtain a series which is absolutely convergent. Next, here are some similar results related to Merten’s theorem.

**Lemma 54.1.6** Let \( \sum_{n=0}^{\infty} a_n (z) \) and \( \sum_{n=0}^{\infty} b_n (z) \) be two convergent series for \( z \in K \) which satisfy the conditions of the Weierstrass M test. Thus there exist positive constants, \( A_n \) and \( B_n \) such that \( |a_n (z)| \leq A_n, |b_n (z)| \leq B_n \) for all \( z \in K \) and \( \sum_{n=0}^{\infty} A_n < \infty, \sum_{n=0}^{\infty} B_n < \infty \). Then defining the Cauchy product,
\[
c_n (z) \equiv \sum_{k=0}^{n} a_{n-k} (z) b_k (z),
\]
it follows \( \sum_{n=0}^{\infty} c_n (z) \) also converges absolutely and uniformly on \( K \) because \( c_n (z) \) satisfies the conditions of the Weierstrass M test. Therefore,
\[
\sum_{n=0}^{\infty} c_n (z) = \left( \sum_{k=0}^{\infty} a_k (z) \right) \left( \sum_{n=0}^{\infty} b_n (z) \right). \tag{54.1.3}
\]

**Proof:**
\[
|c_n (z)| \leq \sum_{k=0}^{n} |a_{n-k} (z)| |b_k (z)| \leq \sum_{k=0}^{n} A_{n-k} B_k.
\]
Also,
\[
\sum_{n=0}^{\infty} \sum_{k=0}^{n} A_{n-k} B_k = \sum_{k=0}^{\infty} \sum_{n=k}^{\infty} A_{n-k} B_k
\]
\[
= \sum_{k=0}^{\infty} B_k \sum_{n=0}^{\infty} A_n < \infty.
\]

The claim of \(54.1.3\) follows from Merten’s theorem. This proves the lemma.

**Corollary 54.1.7** Let \( P \) be a polynomial and let \( \sum_{n=0}^{\infty} a_n(z) \) converge uniformly and absolutely on \( K \) such that the \( a_n \) satisfy the conditions of the Weierstrass \( M \) test. Then there exists a series for \( P(\sum_{n=0}^{\infty} a_n(z)) \), \( \sum_{n=0}^{\infty} c_n(z) \), which also converges absolutely and uniformly for \( z \in K \) because \( c_n(z) \) also satisfies the conditions of the Weierstrass \( M \) test.

The following picture is descriptive of the following lemma. This lemma says that if you have a rational function with one pole off a compact set, then you can approximate on the compact set with another rational function which has a different pole.

![Diagram](image)

**Lemma 54.1.8** Let \( R \) be a rational function which has a pole only at \( a \in V \), a component of \( \mathbb{C} \setminus K \) where \( K \) is a compact set. Suppose \( b \in V \). Then for \( \varepsilon > 0 \) given, there exists a rational function, \( Q \), having a pole only at \( b \) such that
\[
\| R - Q \|_{K, \infty} < \varepsilon. \tag{54.1.4}
\]

If it happens that \( V \) is unbounded, then there exists a polynomial, \( P \) such that
\[
\| R - P \|_{K, \infty} < \varepsilon. \tag{54.1.5}
\]

**Proof:** Say that \( b \in V \) satisfies \( \mathcal{P} \) if for all \( \varepsilon > 0 \) there exists a rational function, \( Q_b \), having a pole only at \( b \) such that
\[
\| R - Q_b \|_{K, \infty} < \varepsilon
\]

Now define a set,
\[
S = \{ b \in V : b \text{ satisfies } \mathcal{P} \}
\]
Observe that \( S \neq \emptyset \) because \( a \in S \).

I claim \( S \) is open. Suppose \( b_1 \in S \). Then there exists a \( \delta > 0 \) such that

\[
\frac{|b_1 - b|}{|z - b|} < \frac{1}{2}
\]

for all \( z \in K \) whenever \( b \in B(b_1, \delta) \). In fact, it suffices to take \( |b - b_1| < \frac{\text{dist}(b_1, K)}{4} \) because then

\[
\frac{|b_1 - b|}{|z - b|} < \frac{\text{dist}(b_1, K)}{4} \leq \frac{|z - b_1| - |b_1 - b|}{|z - b_1|}
\]

for all \( z \in K \) whenever \( b \in B(b_1, \delta) \). In fact, it suffices to take

\[
|b - b_1| < \frac{\text{dist}(b_1, K)}{4}
\]

because then

\[
|b_1 - b| < \frac{\text{dist}(b_1, K)}{4} \leq \frac{|z - b_1| - |b_1 - b|}{|z - b_1|}
\]

Since \( b_1 \) satisfies \( \mathcal{P} \), there exists a rational function \( Q_{b_1} \) with the desired properties. It is shown next that you can approximate \( Q_{b_1} \) with \( Q_b \) thus yielding an approximation to \( R \) by the use of the triangle inequality,

\[
||R - Q_{b_1}||_{K, \infty} + ||Q_{b_1} - Q_b||_{K, \infty} \geq ||R - Q_b||_{K, \infty}.
\]

Since \( Q_{b_1} \) has poles only at \( b_1 \), it follows it is a sum of functions of the form \( \sum_{k=0}^{\infty} \frac{(b_1 - b)^k}{(z - b_1)^n} \). Therefore, it suffices to consider the terms of \( Q_{b_1} \) or that \( Q_{b_1} \) is of the special form

\[
Q_{b_1}(z) = \frac{1}{(z - b_1)^n}.
\]

However,

\[
\frac{1}{(z - b_1)^n} = \frac{1}{(z - b)^n} \left( \frac{1 - \frac{b_1 - b}{z - b}}{z - b_1} \right)^n
\]

Now from the choice of \( b_1 \), the series

\[
\sum_{k=0}^{\infty} \frac{(b_1 - b)^k}{(z - b)} = \frac{1}{(1 - \frac{b_1 - b}{z - b})^n}
\]

converges absolutely independent of the choice of \( z \in K \) because

\[
\left| \frac{(b_1 - b)^k}{(z - b)} \right| < \frac{1}{2^k}
\]

By Corollary \ref{corollary}, the same is true of the series for \( \frac{1}{(1 - \frac{b_1 - b}{z - b})^n} \). Thus a suitable partial sum can be made uniformly on \( K \) as close as desired to \( \frac{1}{(1 - \frac{b_1 - b}{z - b})^n} \). This shows that \( b \) satisfies \( \mathcal{P} \) whenever \( b \) is close enough to \( b_1 \) verifying that \( S \) is open.

Next it is shown \( S \) is closed in \( V \). Let \( b_n \in S \) and suppose \( b_n \to b \in V \). Then since \( b_n \in S \), there exists a rational function, \( Q_{b_n} \) such that

\[
||Q_{b_n} - R||_{K, \infty} < \frac{\varepsilon}{2}.
\]
Then for all $n$ large enough,

\[ \frac{1}{2} \text{dist} (b, K) \geq |b_n - b| \]

and so for all $n$ large enough,

\[ \frac{|b - b_n|}{|z - b_n|} < \frac{1}{2} \]

for all $z \in K$. Pick such a $b_n$. As before, it suffices to assume $Q_{b_n}$ is of the form $\frac{1}{(z - b_n)^n}$. Then

\[ Q_{b_n} (z) = \frac{1}{(z - b_n)^n} = \frac{1}{(z - b)^n \left( 1 - \frac{b_n - b}{z - b} \right)^n} \]

and because of the estimate, there exists $M$ such that for all $z \in K$

\[ \left| \frac{1}{(1 - \frac{b_n - b}{z - b})^n} - \sum_{k=0}^{M} a_k \left( \frac{b_n - b}{z - b} \right)^k \right| < \frac{\varepsilon \left( \text{dist} (b, K) \right)^n}{2}. \tag{54.1.7} \]

Therefore, for all $z \in K$

\[ \left| Q_{b_n} (z) - \frac{1}{(z - b)^n} \sum_{k=0}^{M} a_k \left( \frac{b_n - b}{z - b} \right)^k \right| \]

\[ \leq \frac{\varepsilon \left( \text{dist} (b, K) \right)^n}{2} \frac{1}{\text{dist} (b, K)^n} = \frac{\varepsilon}{2} \]

and so, letting $Q_b (z) = \frac{1}{(z - b)^n} \sum_{k=0}^{M} a_k \left( \frac{b_n - b}{z - b} \right)^k$,

\[ \| R - Q_b \|_{K, \infty} \leq \| R - Q_{b_n} \|_{K, \infty} + \| Q_{b_n} - Q_b \|_{K, \infty} \]

\[ < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon \]

showing that $b \in S$. Since $S$ is both open and closed in $V$ it follows that, since $S \neq \emptyset$, $S = V$. Otherwise $V$ would fail to be connected.

It remains to consider the case where $V$ is unbounded. Pick $b \in V$ large enough that

\[ \left| \frac{z}{b} \right| < \frac{1}{2} \tag{54.1.8} \]

for all $z \in K$. From what was just shown, there exists a rational function, $Q_b$ having a pole only at $b$ such that $\| Q_b - R \|_{K, \infty} < \frac{\varepsilon}{2}$. It suffices to assume that $Q_b$ is of the
CHAPTER 54. APPROXIMATION BY RATIONAL FUNCTIONS

form

\[ Q_b(z) = \frac{p(z)}{(z - b)^n} = \frac{p(z)}{(z - b)^n} \left(1 \frac{1}{b^n (1 - \frac{z}{b})^n} \right) \]

\[ = p(z) (-1)^n \frac{1}{b^n} \left( \sum_{k=0}^{\infty} \left( \frac{z}{b} \right)^k \right)^n \]

Then by an application of Corollary 54.1.7 there exists a partial sum of the power series for \( Q_b \) which is uniformly close to \( Q_b \) on \( K \). Therefore, you can approximate \( Q_b \) and therefore also \( R \) uniformly on \( K \) by a polynomial consisting of a partial sum of the above infinite sum. This proves the theorem.

If \( f \) is a polynomial, then \( f \) has a pole at \( \infty \). This will be discussed more later.

54.1.4 Runge’s Theorem

Now what follows is the first form of Runge’s theorem.

**Theorem 54.1.9** Let \( K \) be a compact subset of an open set, \( \Omega \) and let \( \{b_j\} \) be a set which consists of one point from each component of \( \hat{\mathbb{C}} \setminus K \). Let \( f \) be analytic on \( \Omega \). Then for each \( \varepsilon > 0 \), there exists a rational function, \( Q \) whose poles are all contained in the set, \( \{b_j\} \) such that

\[ ||Q - f||_{K, \infty} < \varepsilon. \]

(54.1.9)

If \( \hat{\mathbb{C}} \setminus K \) has only one component, then \( Q \) may be taken to be a polynomial.

**Proof:** By Lemma 54.1.8 there exists a rational function of the form

\[ R(z) = \sum_{k=1}^{M} \frac{A_k}{w_k - z} \]

where the \( w_k \) are elements of components of \( \mathbb{C} \setminus K \) and \( A_k \) are complex numbers such that

\[ ||R - f||_{K, \infty} < \frac{\varepsilon}{2}. \]

Consider the rational function, \( R_k(z) = \frac{A_k}{w_k - z} \) where \( w_k \in V_j \), one of the components of \( \mathbb{C} \setminus K \), the given point of \( V_j \) being \( b_j \). By Lemma 54.1.8, there exists a function, \( Q_k \) which is either a rational function having its only pole at \( b_j \) or a polynomial, depending on whether \( V_j \) is bounded such that

\[ ||R_k - Q_k||_{K, \infty} < \frac{\varepsilon}{2M}. \]

Letting \( Q(z) = \sum_{k=1}^{M} Q_k(z) \),

\[ ||R - Q||_{K, \infty} < \frac{\varepsilon}{2}. \]
It follows
\[ ||f - Q||_{K, \infty} \leq ||f - R||_{K, \infty} + ||R - Q||_{K, \infty} < \varepsilon. \]

In the case of only one component of \( \mathbb{C} \setminus K \), this component is the unbounded component and so you can take \( Q \) to be a polynomial. This proves the theorem.

The next version of Runge’s theorem concerns the case where the given points are contained in \( \partial \mathbb{C} \setminus \Omega \) for \( \Omega \) an open set rather than a compact set. Note that here there could be uncountably many components of \( \partial \mathbb{C} \setminus \Omega \) because the components are no longer open sets. An easy example of this phenomenon in one dimension is where \( \Omega = [0, 1] \setminus P \) for \( P \) the Cantor set. Then you can show that \( \mathbb{R} \setminus \Omega \) has uncountably many components. Nevertheless, Runge’s theorem will follow from Theorem 54.1.9 with the aid of the following interesting lemma.

**Lemma 54.1.10** Let \( \Omega \) be an open set in \( \mathbb{C} \). Then there exists a sequence of compact sets, \( \{K_n\} \) such that
\[ \Omega = \bigcup_{n=1}^{\infty} K_n, \quad K_n \subseteq \text{int } K_{n+1}, \quad \text{for all } n \text{ sufficiently large, and every component of } \partial \mathbb{C} \setminus K_n \text{ contains a component of } \partial \mathbb{C} \setminus \Omega. \]

**Proof:** Let
\[ V_n = \{ z : |z| > n \} \cup \bigcup_{z \in \Omega} B \left( z, \frac{1}{n} \right). \]

Thus \( \{ z : |z| > n \} \) contains the point, \( \infty \). Now let
\[ K_n = \partial \mathbb{C} \setminus V_n = \mathbb{C} \setminus \Omega \subseteq \Omega. \]

You should verify that \( 54.1.10 \) and \( 54.1.11 \) hold. It remains to show that every component of \( \partial \mathbb{C} \setminus K_n \) contains a component of \( \partial \mathbb{C} \setminus \Omega \). Let \( D \) be a component of \( \partial \mathbb{C} \setminus K_n \).

If \( \infty \notin D \), then \( D \) contains no point of \( \{ z : |z| > n \} \) because this set is connected and \( D \) is a component. (If it did contain a point of this set, it would have to contain the whole set.) Therefore, \( D \subseteq \bigcup_{z \in \Omega} B \left( z, \frac{1}{n} \right) \) and so \( D \) contains some point of \( B \left( z, \frac{1}{n} \right) \) for some \( z \notin \Omega \). Therefore, since this ball is connected, it follows \( D \) must contain the whole ball and consequently \( D \) contains some point of \( \Omega^C \). (The point \( z \) at the center of the ball will do.) Since \( D \) contains \( z \notin \Omega \), it must contain the component, \( H_z \), determined by this point. The reason for this is that
\[ H_z \subseteq \partial \mathbb{C} \setminus \Omega \subseteq \partial \mathbb{C} \setminus K_n \]

and \( H_z \) is connected. Therefore, \( H_z \) can only have points in one component of \( \partial \mathbb{C} \setminus K_n \). Since it has a point in \( D \), it must therefore, be totally contained in \( D \). This verifies the desired condition in the case where \( \infty \notin D \).
Now suppose that $\infty \in D$, $\infty \notin \Omega$ because $\Omega$ is given to be a set in $\mathbb{C}$. Letting $H_\infty$ denote the component of $\mathbb{C} \setminus \Omega$ determined by $\infty$, it follows both $D$ and $H_\infty$ contain $\infty$. Therefore, the connected set, $H_\infty$ cannot have any points in another component of $\mathbb{C} \setminus K_n$ and it is a set which is contained in $\mathbb{C} \setminus K_n$ so it must be contained in $D$. This proves the lemma.

The following picture is a very simple example of the sort of thing considered by Runge’s theorem. The picture is of a region which has a couple of holes.

![Example of a region with a couple of holes](image_url)

However, there could be many more holes than two. In fact, there could be infinitely many. Nor does it follow that the components of the complement of $\Omega$ need to have any interior points. Therefore, the picture is certainly not representative.

**Theorem 54.1.11 (Runge)** Let $\Omega$ be an open set, and let $A$ be a set which has one point in each component of $\mathbb{C} \setminus \Omega$ and let $f$ be analytic on $\Omega$. Then there exists a sequence of rational functions, $\{R_n\}$ having poles only in $A$ such that $R_n$ converges uniformly to $f$ on compact subsets of $\Omega$.

**Proof:** Let $K_n$ be the compact sets of Lemma 54.1.10 where each component of $\mathbb{C} \setminus K_n$ contains a component of $\mathbb{C} \setminus \Omega$. It follows each component of $\mathbb{C} \setminus K_n$ contains a point of $A$. Therefore, by Theorem 54.1.9 there exists $R_n$ a rational function with poles only in $A$ such that

$$||R_n - f||_{K_n, \infty} < \frac{1}{n}.$$  

It follows, since a given compact set, $K$ is a subset of $K_n$ for all $n$ large enough, that $R_n \to f$ uniformly on $K$. This proves the theorem.

**Corollary 54.1.12** Let $\Omega$ be simply connected and $f$ analytic on $\Omega$. Then there exists a sequence of polynomials, $\{p_n\}$ such that $p_n \to f$ uniformly on compact sets of $\Omega$.

**Proof:** By definition of what is meant by simply connected, $\mathbb{C} \setminus \Omega$ is connected and so there are no bounded components of $\mathbb{C} \setminus \Omega$. Therefore, in the proof of Theorem 54.1.11 when you use Theorem 54.1.9, you can always have $R_n$ be a polynomial by Lemma 54.1.8.

### 54.2 The Mittag-Leffler Theorem

#### 54.2.1 A Proof From Runge’s Theorem

This theorem is fairly easy to prove once you have Theorem 54.1.11. Given a set of complex numbers, does there exist a meromorphic function having its poles equal
54.2. THE MITTAG-LEFFLER THEOREM

The Mittag-Leffler theorem provides a very satisfactory answer to this question. Actually, it says somewhat more. You can specify, not just the location of the pole but also the kind of singularity the meromorphic function is to have at that pole.

**Theorem 54.2.1** Let \( P \equiv \{z_k\}_{k=1}^{\infty} \) be a set of points in an open subset of \( \mathbb{C}, \Omega \). Suppose also that \( P \subseteq \Omega \subseteq \mathbb{C} \). For each \( z_k \), denote by \( S_k(z) \) a function of the form

\[
S_k(z) = \sum_{j=1}^{m_k} \frac{a^j_k}{(z-z_k)^j}.
\]

Then there exists a meromorphic function, \( Q \) defined on \( \Omega \) such that the poles of \( Q \) are the points, \( \{z_k\}_{k=1}^{\infty} \) and the singular part of the Laurent expansion of \( Q \) at \( z_k \) equals \( S_k(z) \). In other words, for \( z \) near \( z_k \), \( Q(z) = g_k(z) + S_k(z) \) for some function, \( g_k \) analytic near \( z_k \).

**Proof:** Let \( \{K_n\} \) denote the sequence of compact sets described in Lemma 54.1.10. Thus \( \bigcup_{n=1}^{\infty} K_n = \Omega, K_n \subseteq \text{int}(K_{n+1}) \subseteq K_{n+1} \cdots \), and the components of \( \mathcal{C} \setminus K_n \) contain the components of \( \mathcal{C} \setminus \Omega \). Renumbering if necessary, you can assume each \( K_n \neq \emptyset \). Also let \( K_0 = \emptyset \). Let \( P_m \equiv P \cap (K_m \setminus K_{m-1}) \) and consider the rational function, \( R_m \) defined by

\[
R_m(z) \equiv \sum_{z_k \in K_m \setminus K_{m-1}} S_k(z).
\]

Since each \( K_m \) is compact, it follows \( P_m \) is finite and so the above really is a rational function. Now for \( m > 1 \), this rational function is analytic on some open set containing \( K_{m-1} \). There exists a set of points, \( A \) one point in each component of \( \mathcal{C} \setminus \Omega \). Consider \( \mathcal{C} \setminus K_{m-1} \). Each of its components contains a component of \( \mathcal{C} \setminus \Omega \) and so for each of these components of \( \mathcal{C} \setminus K_{m-1} \), there exists a point of \( A \) which is contained in it. Denote the resulting set of points by \( A' \). By Theorem 54.1.3 there exists a rational function, \( Q_m \) whose poles are all contained in the set, \( A' \subseteq \Omega^C \) such that

\[
\|R_m - Q_m\|_{K_{m-1}, \infty} < \frac{1}{2^m}.
\]

The meromorphic function is

\[
Q(z) \equiv R_1(z) + \sum_{k=2}^{\infty} (R_k(z) - Q_k(z)).
\]

It remains to verify this function works. First consider \( K_1 \). Then on \( K_1 \), the above sum converges uniformly. Furthermore, the terms of the sum are analytic in some open set containing \( K_1 \). Therefore, the infinite sum is analytic on this open set and so for \( z \in K_1 \) the function, \( f \) is the sum of a rational function, \( R_1 \), having poles at
P₁ with the specified singular terms and an analytic function. Therefore, Q works on K₁. Now consider Kₘ for m > 1. Then

\[
Q(z) = R₁(z) + \sum_{k=2}^{m+1} (R_k(z) - Q_k(z)) + \sum_{k=m+2}^{\infty} (R_k(z) - Q_k(z)) .
\]

As before, the infinite sum converges uniformly on Kₘ₊₁ and hence on some open set, O containing Kₘ. Therefore, this infinite sum equals a function which is analytic on O. Also,

\[
R₁(z) + \sum_{k=2}^{m+1} (R_k(z) - Q_k(z))
\]

is a rational function having poles at ∪ₖ₌₁ⁿ Pₖ with the specified singularities because the poles of each Qₖ are not in Ω. It follows this function is meromorphic because it is analytic except for the points in P. It also has the property of retaining the specified singular behavior.

### 54.2.2 A Direct Proof Without Runge’s Theorem

There is a direct proof of this important theorem which is not dependent on Runge’s theorem in the case where Ω = C. I think it is arguably easier to understand and the Mittag-Leffler theorem is very important so I will give this proof here.

**Theorem 54.2.2** Let P ≡ {zₖ}ₖ₌₁ⁿ be a set of points in C which satisfies \( \lim_{n \to \infty} |z_n| = \infty \). For each zₖ, denote by Sₖ(z) a polynomial in \( 1/z - z_k \) which is of the form

\[
Sₖ(z) = \sum_{j=1}^{mₖ} aₖ^j (z - zₖ)².
\]

Then there exists a meromorphic function, Q defined on C such that the poles of Q are the points, \{zₖ\}ₖ₌₁ⁿ and the singular part of the Laurent expansion of Q at zₖ equals Sₖ(z). In other words, for z near zₖ,

\[Q(z) = gₖ(z) + Sₖ(z)\]

for some function, gₖ analytic in some open set containing zₖ.

**Proof:** First consider the case where none of the zₖ = 0. Letting

\[Kₖ ≡ \{z : |z| \leq |z_k|/2\},\]

does not exist a power series for \( 1/z - z_k \) which converges uniformly and absolutely on this set. Here is why:

\[
\frac{1}{z - z_k} = \left( \frac{-1}{1 - \frac{z}{z_k}} \right) \frac{1}{z_k} = \frac{-1}{z_k} \sum_{l=0}^{\infty} \left( \frac{z}{z_k} \right)^l.
\]
and the Weierstrass $M$ test can be applied because
\[
\left| z \right| < \frac{1}{2}
\]
on this set. Therefore, by Corollary 54.1.7, $S_k(z)$, being a polynomial in \( \frac{1}{z-z_k} \), has a power series which converges uniformly to $S_k(z)$ on $K_k$. Therefore, there exists a polynomial, $P_k(z)$ such that
\[
||P_k - S_k||_{B(0, |z_k|/2), \infty} < \frac{1}{2^k}.
\]
Let
\[
Q(z) = \sum_{k=1}^{\infty} (S_k(z) - P_k(z)).
\]
Consider $z \in K_m$ and let $N$ be large enough that if $k > N$, then $|z_k| > 2|z|$
\[
Q(z) = \sum_{k=1}^{N} (S_k(z) - P_k(z)) + \sum_{k=N+1}^{\infty} (S_k(z) - P_k(z)).
\]
On $K_m$, the second sum converges uniformly to a function analytic on int($K_m$) (interior of $K_m$) while the first is a rational function having poles at $z_1, \ldots, z_N$. Since any compact set is contained in $K_m$ for large enough $m$, this shows $Q(z)$ is meromorphic as claimed and has poles with the given singularities.

Now consider the case where the poles are at $\{z_k\}_{k=0}^\infty$ with $z_0 = 0$. Everything is similar in this case. Let
\[
Q(z) = S_0(z) + \sum_{k=1}^{\infty} (S_k(z) - P_k(z)).
\]
The series converges uniformly on every compact set because of the assumption that $\lim_{n \to \infty} |z_n| = \infty$ which implies that any compact set is contained in $K_k$ for $k$ large enough. Choose $N$ such that $z \in \text{int}(K_N)$ and $z_n \notin K_N$ for all $n \geq N + 1$. Then
\[
Q(z) = S_0(z) + \sum_{k=1}^{N} (S_k(z) - P_k(z)) + \sum_{k=N+1}^{\infty} (S_k(z) - P_k(z)).
\]
The last sum is analytic on int($K_N$) because each function in the sum is analytic due to the fact that none of its poles are in $K_N$. Also, $S_0(z) + \sum_{k=1}^{N} (S_k(z) - P_k(z))$ is a finite sum of rational functions so it is a rational function and $P_k$ is a polynomial so $z_m$ is a pole of this function with the correct singularity whenever $z_m \in \text{int}(K_N)$. 
54.2.3 Functions Meromorphic On $\hat{\mathbb{C}}$

Sometimes it is useful to think of isolated singular points at $\infty$.

**Definition 54.2.3** Suppose $f$ is analytic on $\{z \in \mathbb{C} : |z| > r\}$. Then $f$ is said to have a removable singularity at $\infty$ if the function, $g(z) \equiv f(\frac{1}{z})$ has a removable singularity at 0. $f$ is said to have a pole at $\infty$ if the function, $g(z) = f(\frac{1}{z})$ has a pole at 0. Then $f$ is said to be meromorphic on $\hat{\mathbb{C}}$ if all its singularities are isolated and either poles or removable.

So what is $f$ like for these cases? First suppose $f$ has a removable singularity at $\infty$. Then $zg(z)$ converges to 0 as $z \to 0$. It follows $g(z)$ must be analytic near 0 and so can be given as a power series. Thus $f(z)$ is of the form $f(z) = g\left(\frac{1}{z}\right) = \sum_{n=0}^{\infty} a_n \left(\frac{1}{z}\right)^n$. Next suppose $f$ has a pole at $\infty$. This means $g(z)$ has a pole at 0 so $g(z)$ is of the form $g(z) = \sum_{k=1}^{m} b_k z^k + h(z)$ where $h(z)$ is analytic near 0. Thus in the case of a pole at $\infty$, $f(z)$ is of the form $f(z) = g\left(\frac{1}{z}\right) = \sum_{k=1}^{m} b_k z^k + \sum_{n=0}^{\infty} a_n \left(\frac{1}{z}\right)^n$.

It turns out that the functions which are meromorphic on $\hat{\mathbb{C}}$ are all rational functions. To see this suppose $f$ is meromorphic on $\hat{\mathbb{C}}$ and note that there exists $r > 0$ such that $f(z)$ is analytic for $|z| > r$. This is required if $\infty$ is to be isolated. Therefore, there are only finitely many poles of $f$ for $|z| \leq r, \{a_1, \cdots, a_m\}$, because by assumption, these poles are isolated and this is a compact set. Let the singular part of $f$ at $a_k$ be denoted by $S_k(z)$. Then $f(z) - \sum_{k=1}^{m} S_k(z)$ is analytic on all of $\mathbb{C}$. Therefore, it is bounded on $|z| \leq r$. In one case, $f$ has a removable singularity at $\infty$. In this case, $f$ is bounded as $z \to \infty$ and $\sum S_k$ also converges to 0 as $z \to \infty$. Therefore, by Liouville's theorem, $f(z) - \sum_{k=1}^{m} S_k(z)$ equals a constant and so $f - \sum S_k$ is a constant. Thus $f$ is a rational function. In the other case that $f$ has a pole at $\infty$, $f(z) - \sum_{k=1}^{m} S_k(z) - \sum_{k=1}^{m} b_k z^k = \sum_{n=0}^{\infty} a_n \left(\frac{1}{z}\right)^n - \sum_{k=1}^{m} S_k(z)$. Now $f(z) - \sum_{k=1}^{m} S_k(z) - \sum_{k=1}^{m} b_k z^k$ is analytic on $\mathbb{C}$ and so is bounded on $|z| \leq r$. But now $\sum_{n=0}^{\infty} a_n \left(\frac{1}{z}\right)^n - \sum_{k=1}^{m} S_k(z)$ converges to 0 as $z \to \infty$ and so by Liouville's theorem, $f(z) - \sum_{k=1}^{m} S_k(z) - \sum_{k=1}^{m} b_k z^k$ must equal a constant and again, $f(z)$ equals a rational function.

54.2.4 Great And Glorious Theorem, Simply Connected Regions

Here is given a laundry list of properties which are equivalent to an open set being simply connected. Recall Definition 39.7.24 on Page 1875 which said that an open set, $\Omega$ is simply connected means $\mathbb{C} \setminus \Omega$ is connected. Recall also that this is not the same thing at all as saying $\mathbb{C} \setminus \Omega$ is connected. Consider the outside of a disk for example. I will continue to use this definition for simply connected because it is the most convenient one for complex analysis. However, there are many other equivalent conditions. First here is an interesting lemma which is interesting for its own sake. Recall $n(p, \gamma)$ means the winding number of $\gamma$ about $p$. Now recall Theorem 49.7.24 implies the following lemma in which $B^C$ is playing the role of $\Omega$ in Theorem 49.7.24.
Lemma 54.2.4 Let $K$ be a compact subset of $B^C$, the complement of a closed set. Then there exist continuous, closed, bounded variation oriented curves $\{\Gamma_j\}_{j=1}^m$ for which $\Gamma_j \cap K = \emptyset$ for each $j$, $\Gamma_j^* \subseteq \Omega$, and for all $p \in K$,

$$\sum_{k=1}^m n(\Gamma_k, p) = 1.$$ 

while for all $z \in B$

$$\sum_{k=1}^m n(\Gamma_k, z) = 0.$$

Definition 54.2.5 Let $\gamma$ be a closed curve in an open set, $\Omega$, $\gamma : [a, b] \rightarrow \Omega$. Then $\gamma$ is said to be homotopic to a point, $p$ in $\Omega$ if there exists a continuous function, $H : [0,1] \times [a, b] \rightarrow \Omega$ such that $H(0, t) = p$, $H(\alpha, a) = H(\alpha, b)$, and $H(1, t) = \gamma(t)$. This function, $H$ is called a homotopy.

Lemma 54.2.6 Suppose $\gamma$ is a closed continuous bounded variation curve in an open set, $\Omega$ which is homotopic to a point. Then if $a = 2 \Omega$, it follows $n(a, \gamma) = 0$.

Proof: Let $H$ be the homotopy described above. The problem with this is that it is not known that $H(\alpha, \cdot)$ is of bounded variation. There is no reason it should be. Therefore, it might not make sense to take the integral which defines the winding number. There are various ways around this. Extend $H$ as follows. $H(\alpha, t) = H(\alpha, a)$ for $t < a$, $H(\alpha, t) = H(\alpha, b)$ for $t > b$. Let $\varepsilon > 0$.

$$H_{\varepsilon}(\alpha, t) = \frac{1}{2\varepsilon} \int_{-2\varepsilon + t + \frac{2\varepsilon}{|t-a|}(t-a)}^{t + \frac{2\varepsilon}{|t-a|}(t-a)} H(\alpha, s) ds, \quad H_{\varepsilon}(0, t) = p.$$ 

Thus $H_{\varepsilon}(\alpha, \cdot)$ is a closed curve which has bounded variation and when $\alpha = 1$, this converges to $\gamma$ uniformly on $[a, b]$. Therefore, for $\varepsilon$ small enough, $n(a, H_{\varepsilon}(1, \cdot)) = n(a, \gamma)$ because they are both integers and as $\varepsilon \to 0$, $n(a, H_{\varepsilon}(1, \cdot)) \to n(a, \gamma)$. Also, $H_{\varepsilon}(\alpha, t) \to H(\alpha, t)$ uniformly on $[0,1] \times [a, b]$ because of uniform continuity of $H$. Therefore, for small enough $\varepsilon$, you can also assume $H_{\varepsilon}(\alpha, t) \in \Omega$ for all $\alpha, t$. Now $\alpha \to n(a, H_{\varepsilon}(\alpha, \cdot))$ is continuous. Hence it must be constant because the winding number is integer valued. But

$$\lim_{\alpha \to 0} \frac{1}{2\pi i} \int_{H_{\varepsilon}(\alpha, \cdot)} \frac{1}{z - a} dz = 0$$

because the length of $H_{\varepsilon}(\alpha, \cdot)$ converges to 0 and the integrand is bounded because $a \notin \Omega$. Therefore, the constant can only equal 0. This proves the lemma.

Now it is time for the great and glorious theorem on simply connected regions. The following equivalence of properties is taken from Rudin [102]. There is a slightly different list in Conway [31], and a shorter list in Ash [4].

Theorem 54.2.7 The following are equivalent for an open set, $\Omega$. 

---

**54.2. THE MITTAG-LEFFLER THEOREM**

---

1821
1. \( \Omega \) is homeomorphic to the unit disk, \( B(0,1) \).

2. Every closed curve contained in \( \Omega \) is homotopic to a point in \( \Omega \).

3. If \( z \notin \Omega \), and if \( \gamma \) is a closed bounded variation continuous curve in \( \Omega \), then 
   \( n(\gamma,z) = 0 \).

4. \( \Omega \) is simply connected, \( (\overline{\mathbb{C}} \setminus \Omega \) is connected and \( \Omega \) is connected. \)

5. Every function analytic on \( \Omega \) can be uniformly approximated by polynomials on compact subsets.

6. For every \( f \) analytic on \( \Omega \) and every closed continuous bounded variation curve, \( \gamma \),
   \[ \int_{\gamma} f(z) \, dz = 0. \]

7. Every function analytic on \( \Omega \) has a primitive on \( \Omega \).

8. If \( f,1/f \) are both analytic on \( \Omega \), then there exists an analytic, \( g \) on \( \Omega \) such that 
   \( f = \exp(g) \).

9. If \( f,1/f \) are both analytic on \( \Omega \), then there exists \( \phi \) analytic on \( \Omega \) such that 
   \( f = \phi^2 \).

**Proof:**

1. Assume \( \Omega \) and let \( \gamma \) be a closed curve in \( \Omega \). Let \( h \) be the homeomorphism, 
   \( h : B(0,1) \to \Omega \). Let \( H(\alpha,t) = h(\alpha(h^{-1}(t))) \). This works.

2. Suppose \( \Omega \) but \( \Omega \) fails to hold. Then if \( \overline{\mathbb{C}} \setminus \Omega \) is not connected, there exist 
   disjoint nonempty sets, \( A \) and \( B \) such that \( \overline{A} \cap B = A \cap \overline{B} = \emptyset \). It follows each 
   of these sets must be closed because neither can have a limit point in \( \Omega \) nor in 
   the other. Also, one and only one of them contains \( \infty \). Let this set be \( B \). Thus 
   \( A \) is a closed set which must also be bounded. Otherwise, there would exist a 
   sequence of points in \( A \), \( \{a_n\} \) such that \( \lim_{n \to \infty} a_n = \infty \) which would contradict 
   the requirement that no limit points of \( A \) can be in \( B \). Therefore, \( A \) is a compact 
   set contained in the open set, \( B^C = \{z \in \mathbb{C} : z \notin B\} \). Pick \( p \in A \). By Lemma 54.2.4, 
   there exist continuous bounded variation closed curves \( \{\Gamma_k\}_{k=1}^m \) which are contained 
   in \( B^C \), do not intersect \( A \) and such that 
   \[ 1 = \sum_{k=1}^m n(p,\Gamma_k) \]

   However, if these curves do not intersect \( A \) and they also do not intersect \( B \) then 
   they must be all contained in \( \Omega \). Since \( p \notin \Omega \), it follows by \( \emptyset \) that for each \( k \), 
   \( n(p,\Gamma_k) = 0 \), a contradiction.

3. This is Corollary 54.1.12 on Page 1816.
Every polynomial has a primitive and so the integral over any closed bounded variation curve of a polynomial equals 0. Let \( f \) be analytic on \( \Omega \). Then let \( \{ f_n \} \) be a sequence of polynomials converging uniformly to \( f \) on \( \gamma^* \). Then

\[
0 = \lim_{n \to \infty} \int_{\gamma} f_n(z) \, dz = \int_{\gamma} f(z) \, dz.
\]

Pick \( z_0 \in \Omega \). Letting \( \gamma \) be a bounded variation continuous curve joining \( z_0 \) to \( z \) in \( \Omega \), you define a primitive for \( f \) as follows.

\[
F(z) = \int_{\gamma(z_0,z)} f(w) \, dw.
\]

This is well defined by \( \quad \) and is easily seen to be a primitive. You just write the difference quotient and take a limit using \( \quad \).

\[
\lim_{w \to 0} \frac{F(z + w) - F(z)}{w} = \lim_{w \to 0} \frac{1}{w} \left( \int_{\gamma(z_0,z+w)} f(u) \, du - \int_{\gamma(z_0,z)} f(u) \, du \right) = \lim_{w \to 0} \frac{1}{w} \int_{\gamma(z,z+w)} f(u) \, du = \lim_{w \to 0} \frac{1}{w} \int_{0}^{1} f(z + tw) \, dt = f(z).
\]

Suppose then that \( f, 1/f \) are both analytic. Then \( f'/f \) is analytic and so it has a primitive by \( \quad \). Let this primitive be \( g_1 \). Then

\[
(e^{-g_1} f)' = e^{-g_1} (-g_1') f + e^{-g_1} f' = -e^{-g_1} \left( \frac{f'}{f} \right) f + e^{-g_1} f' = 0.
\]

Therefore, since \( \Omega \) is connected, it follows \( e^{-g_1} f \) must equal a constant. (Why?) Let the constant be \( e^{a+ib} \). Then \( f(z) = e^{g_1(z)} e^{a+ib} \). Therefore, you let \( g(z) = g_1(z) + a + ib \).

Suppose then that \( f, 1/f \) are both analytic on \( \Omega \). Then by \( \quad \) \( f(z) = e^{g(z)} \). Let \( \phi(z) \equiv e^{g(z)/2} \).

There are two cases. First suppose \( \Omega = \mathbb{C} \). This satisfies condition \( \quad \) because if \( f, 1/f \) are both analytic, then the same argument involved in \( \quad \) gives the existence of a square root. A homeomorphism is \( h(z) \equiv \frac{z}{\sqrt{1+|z|^2}} \). It obviously maps onto \( B(0,1) \) and is continuous. To see it is 1 - 1 consider the case of \( z_1 \) and \( z_2 \) having different arguments. Then \( h(z_1) \neq h(z_2) \). If \( z_2 = t z_1 \) for a positive \( t \neq 1 \), then it is also clear \( h(z_1) \neq h(z_2) \). To show \( h^{-1} \) is continuous, note that if you have an open set in \( \mathbb{C} \) and a point in this open set, you can get a small open set containing this point by allowing the modulus and the argument to lie in some open interval. Reasoning this way, you can verify \( \phi \) maps open sets to open sets. In the case where \( \Omega \neq \mathbb{C} \), there exists a one to one analytic map which maps \( \Omega \) onto \( B(0,1) \) by the Riemann mapping theorem. This proves the theorem.
54.3 Exercises

1. Let $a \in \mathbb{C}$. Show there exists a sequence of polynomials, $\{p_n\}$ such that $p_n(a) = 1$ but $p_n(z) \to 0$ for all $z \neq a$.

2. Let $l$ be a line in $\mathbb{C}$. Show there exists a sequence of polynomials $\{p_n\}$ such that $p_n(z) \to 1$ on one side of this line and $p_n(z) \to -1$ on the other side of the line. **Hint:** The complement of this line is simply connected.

3. Suppose $\Omega$ is a simply connected region, $f$ is analytic on $\Omega$, $f \neq 0$ on $\Omega$, and $n \in \mathbb{N}$. Show that there exists an analytic function, $g$ such that $g(z)^n = f(z)$ for all $z \in \Omega$. That is, you can take the $n^{th}$ root of $f(z)$. If $\Omega$ is a region which contains 0, is it possible to find $g(z)$ such that $g$ is analytic on $\Omega$ and $g(z)^2 = z$?

4. Suppose $\Omega$ is a region (connected open set) and $f$ is an analytic function defined on $\Omega$ such that $f(z) \neq 0$ for any $z \in \Omega$. Suppose also that for every positive integer, $n$ there exists an analytic function, $g_n$ defined on $\Omega$ such that $g_n^n(z) = f(z)$. Show that then it is possible to define an analytic function, $L$ on $f(\Omega)$ such that $e^{L(f(z))} = f(z)$ for all $z \in \Omega$.

5. You know that $\phi(z) \equiv \frac{z+1}{z+1}$ maps the upper half plane onto the unit ball. Its inverse, $\psi(z) = \frac{1+z}{1-z}$ maps the unit ball onto the upper half plane. Also for $z$ in the upper half plane, you can define a square root as follows. If $z = |z| e^{i\theta}$ where $\theta \in (0, \pi)$, let $z^{1/2} = |z|^{1/2} e^{i\theta/2}$ so the square root maps the upper half plane to the first quadrant. Now consider

$$z \to \exp \left( -i \log \left[ i \left( \frac{1 + z}{1 - z} \right)^{1/2} \right] \right). \quad (54.3.13)$$

Show this is an analytic function which maps the unit ball onto an annulus. Is it possible to find a one to one analytic map which does this?
Chapter 55

Infinite Products

The Mittag-Leffler theorem gives existence of a meromorphic function which has specified singular part at various poles. It would be interesting to do something similar to zeros of an analytic function. That is, given the order of the zero at various points, does there exist an analytic function which has these points as zeros with the specified orders? You know that if you have the zeros of the polynomial, you can factor it. Can you do something similar with analytic functions which are just limits of polynomials? These questions involve the concept of an infinite product.

Definition 55.0.1 \[ \prod_{n=1}^{\infty} (1 + u_n) \equiv \lim_{n \to \infty} \prod_{k=1}^{n} (1 + u_k) \quad \text{whenever this limit exists.} \] If \( u_n = u_n(z) \) for \( z \in H \), we say the infinite product converges uniformly on \( H \) if the partial products, \( \prod_{k=1}^{n} (1 + u_k(z)) \) converge uniformly on \( H \).

The main theorem is the following.

Theorem 55.0.2 Let \( H \subseteq C \) and suppose that \( \sum_{n=1}^{\infty} |u_n(z)| \) converges uniformly on \( H \) where \( u_n(z) \) bounded on \( H \). Then

\[ P(z) = \prod_{n=1}^{\infty} (1 + u_n(z)) \]

converges uniformly on \( H \). If \( (n_1, n_2, \cdots) \) is any permutation of \( (1, 2, \cdots) \), then for all \( z \in H \),

\[ P(z) = \prod_{k=1}^{\infty} (1 + u_{n_k}(z)) \]

and \( P \) has a zero at \( z_0 \) if and only if \( u_n(z_0) = -1 \) for some \( n \).
Proof: First a simple estimate:

\[
\prod_{k=m}^{n} (1 + |u_k(z)|) = \exp \left( \ln \left( \prod_{k=m}^{n} (1 + |u_k(z)|) \right) \right) = \exp \left( \sum_{k=m}^{n} \ln (1 + |u_k(z)|) \right) \\
\leq \exp \left( \sum_{k=m}^{\infty} |u_k(z)| \right) < e
\]

for all \( z \in H \) provided \( m \) is large enough. Since \( \sum_{k=1}^{\infty} |u_k(z)| \) converges uniformly on \( H \), \( |u_k(z)| < \frac{1}{2} \) for all \( z \in H \) provided \( k \) is large enough. Thus you can take \( \log (1 + u_k(z)) \):

Pick \( N_0 \) such that for \( n > m \geq N_0 \),

\[
|u_m(z)| < \frac{1}{2} \prod_{k=m}^{n} (1 + |u_k(z)|) < e.
\]

Now having picked \( N_0 \), the assumption the \( u_n \) are bounded on \( H \) implies there exists a constant, \( C \), independent of \( z \in H \) such that for all \( z \in H \),

\[
\prod_{k=1}^{N_0} (1 + |u_k(z)|) < C. \tag{55.0.2}
\]

Let \( N_0 < M < N \). Then

\[
\left| \prod_{k=1}^{N} (1 + u_k(z)) - \prod_{k=1}^{M} (1 + u_k(z)) \right| \\
\leq \prod_{k=1}^{N_0} (1 + |u_k(z)|) \left| \prod_{k=N_0+1}^{N} (1 + u_k(z)) - \prod_{k=N_0+1}^{M} (1 + u_k(z)) \right| \\
\leq C \left| \prod_{k=N_0+1}^{M} (1 + u_k(z)) \right| \left| \prod_{k=M+1}^{N} (1 + u_k(z)) - 1 \right| \\
\leq Ce \left| \prod_{k=M+1}^{N} (1 + |u_k(z)|) - 1 \right|.
\]

Since \( 1 \leq \prod_{k=M+1}^{N} (1 + |u_k(z)|) \leq e \), it follows the term on the far right is domi-
nated by
\[ Ce^2 \left| \ln \left( \prod_{k=M+1}^{N} (1 + |u_k(z)|) \right) - \ln 1 \right| \]
\[ \leq Ce^2 \sum_{k=M+1}^{N} \ln (1 + |u_k(z)|) \]
\[ \leq Ce^2 \sum_{k=M+1}^{N} |u_k(z)| < \varepsilon \]

uniformly in \( z \in H \) provided \( M \) is large enough. This follows from the simple observation that if \( 1 < x < e \), then \( x - 1 \leq \varepsilon (\ln x - \ln 1) \). Therefore, \( \{ \prod_{k=1}^{n} (1 + u_k(z)) \}_{n=1}^{\infty} \) is uniformly Cauchy on \( H \) and therefore, converges uniformly on \( H \). Let \( P(z) \) denote the function it converges to.

What about the permutations? Let \( \{n_1, n_2, \ldots \} \) be a permutation of the indices. Let \( \varepsilon > 0 \) be given and let \( N_0 \) be such that if \( n > N_0 \),
\[ \left| \prod_{k=1}^{n} (1 + u_k(z)) - P(z) \right| < \varepsilon \]
for all \( z \in H \). Let \( \{1, 2, \ldots, n\} \subset \{n_1, n_2, \ldots, n_{p(n)}\} \) where \( p(n) \) is an increasing sequence. Then from 55.0.1 and 55.0.2,
\[ \left| P(z) - \prod_{k=1}^{p(n)} (1 + u_{n_k}(z)) \right| \]
\[ \leq \left| P(z) - \prod_{k=1}^{n} (1 + u_k(z)) \right| + \prod_{k=1}^{n} (1 + u_k(z)) \left| 1 - \prod_{n_k > n} (1 + u_{n_k}(z)) \right| \]
\[ \leq \varepsilon + \prod_{k=1}^{n} (1 + u_k(z)) - \prod_{k=1}^{p(n)} (1 + u_{n_k}(z)) \]
\[ \leq \varepsilon + \prod_{k=1}^{n} (1 + |u_k(z)|) \left| 1 - \prod_{n_k > n} (1 + u_{n_k}(z)) \right| \]
\[ \leq \varepsilon + \prod_{k=1}^{N_0} (1 + |u_k(z)|) \left| \prod_{k=N_0+1}^{n} (1 + |u_k(z)|) \right| 1 - \prod_{n_k > n} (1 + u_{n_k}(z)) \]
\[ \leq \varepsilon + Ce^{M(p(n))} \prod_{n_k > n} (1 + |u_{n_k}(z)|) - 1 \]
\[ \leq \varepsilon + Ce^{M(p(n))} \prod_{k=n+1}^{M(p(n))} (1 + |u_{n_k}(z)|) - 1 \]

where \( M(p(n)) \) is the largest index in the permuted list, \( \{n_1, n_2, \ldots, n_{p(n)}\} \).
from 19.4.1, this last term is dominated by
\[ \varepsilon + Ce^2 \left| \ln \left( \prod_{k=n+1}^{M(n)} (1 + |u_{n_k}(z)|) \right) - \ln 1 \right| \]
\[ \leq \varepsilon + Ce^2 \sum_{k=n+1}^{\infty} \ln (1 + |u_{n_k}|) \leq \varepsilon + Ce^2 \sum_{k=n+1}^{\infty} |u_{n_k}| < 2\varepsilon \]
for all \( n \) large enough uniformly in \( z \in H \). Therefore, \( |P(z) - \prod_{k=1}^{p(n)} (1 + u_{n_k}(z))| < 2\varepsilon \) whenever \( n \) is large enough. This proves the part about the permutation.

It remains to verify the assertion about the points, \( z_0 \), where \( P(z_0) = 0 \): Obviously, if \( u_n(z_0) = -1 \), then \( P(z_0) = 0 \). Suppose then that \( P(z_0) = 0 \) and \( M > N_0 \). Then
\[ \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| = \left| \prod_{k=1}^{M} (1 + u_k(z_0)) - \prod_{k=1}^{\infty} (1 + u_k(z_0)) \right| \]
\[ \leq \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| \left| 1 - \prod_{k=M+1}^{\infty} (1 + u_k(z_0)) \right| \]
\[ \leq \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| \left| \prod_{k=M+1}^{\infty} (1 + |u_k(z_0)|) - 1 \right| \]
\[ \leq e \left( \sum_{k=M+1}^{\infty} \ln (1 + |u_k(z)|) \right) \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| \]
\[ \leq e \left( \sum_{k=M+1}^{\infty} |u_k(z)| \right) \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| \]
\[ \leq \frac{1}{2} \left| \prod_{k=1}^{M} (1 + u_k(z_0)) \right| \]
whenever \( M \) is large enough. Therefore, for such \( M \),
\[ \prod_{k=1}^{M} (1 + u_k(z_0)) = 0 \]
and so \( u_k(z_0) = -1 \) for some \( k \leq M \). This proves the theorem.
55.1 Analytic Function With Prescribed Zeros

Suppose you are given complex numbers, \( \{ z_n \} \) and you want to find an analytic function, \( f(z) \) such that these numbers are the zeros of \( f \). How can you do it? The problem is easy if there are only finitely many of these zeros, \( \{ z_1, z_2, \ldots, z_m \} \). You just write \( (z - z_1)(z - z_2) \cdots (z - z_m) \). Now if none of the \( z_k = 0 \) you could also write it as \( \prod_{k=1}^{m} \left( 1 - \frac{z}{z_k} \right) \) and this might have a better chance of success in the case of infinitely many prescribed zeros. However, you would need to verify something like \( \sum_{n=1}^\infty \left| \frac{z}{z_n} \right| < \infty \) which might not be so. The way around this is to adjust the product, making it \( \prod_{k=1}^{\infty} \left( 1 - \frac{z}{z_k} \right) e^{g_k(z)} \) where \( g_k(z) \) is some analytic function. Recall also that for \( |x| < 1 \), \( \ln \left( (1 - x)^{-1} \right) = \sum_{n=1}^\infty \frac{x^n}{n} \). If you had \( x/x_n \) small and real, then \( 1 = (1 - x/x_n) \exp \left( \ln \left( (1 - x/x_n)^{-1} \right) \right) \) and \( \prod_{k=1}^{\infty} \) 1 of course converges but loses all the information about zeros. However, this is why it is not too unreasonable to consider factors of the form

\[
\left( 1 - \frac{z}{z_k} \right) e^{\sum_{k=1}^{p_k} \left( \frac{z}{z_k} \right)^k}
\]

where \( p_k \) is suitably chosen.

First here are some estimates.

Lemma 55.1.1 For \( z \in \mathbb{C} \),

\[
|e^z - 1| \leq |z| e^{|z|},
\]

and if \( |z| \leq 1/2 \),

\[
\left| \sum_{k=m}^\infty \frac{z^k}{k!} \right| \leq \frac{1}{m} \frac{|z|^m}{1 - |z|} \leq \frac{2}{m} |z|^m \leq \frac{1}{m} \frac{1}{2^{m-1}}.
\]

Proof: Consider 55.1.3

\[
|e^z - 1| = \left| \sum_{k=1}^\infty \frac{z^k}{k!} \right| \leq \sum_{k=1}^\infty \frac{|z|^k}{k!} = e^{|z|} - 1 \leq |z| e^{|z|}
\]

the last inequality holding by the mean value theorem. Now consider 55.1.4

\[
\left| \sum_{k=m}^\infty \frac{z^k}{k!} \right| \leq \sum_{k=m}^\infty \frac{|z|^k}{k!} \leq \frac{1}{m} \sum_{k=m}^\infty |z|^k = \frac{1}{m} \frac{|z|^m}{1 - |z|} \leq \frac{2}{m} |z|^m \leq \frac{1}{m} \frac{1}{2^{m-1}}.
\]

This proves the lemma.

The functions, \( E_p \) in the next definition are called the elementary factors.
**Definition 55.1.2** Let \( E_0 (z) \equiv 1 - z \) and for \( p \geq 1 \),
\[
E_p (z) \equiv (1 - z) \exp \left( z + \frac{z^2}{2} + \cdots + \frac{z^p}{p} \right)
\]

In terms of this new symbol, here is another estimate. A sharper inequality is available in Rudin [102] but it is more difficult to obtain.

**Corollary 55.1.3** For \( E_p \) defined above and \( |z| \leq 1/2 \),
\[
|E_p (z) - 1| \leq 3 |z|^{p+1}.
\]

**Proof:** From elementary calculus, \( \ln (1 - x) = - \sum_{n=1}^{\infty} \frac{x^n}{n} \) for all \( |x| < 1 \). Therefore, for \( |z| < 1 \),
\[
\log (1 - z) = - \sum_{n=1}^{\infty} \frac{z^n}{n}, \quad \log \left( (1 - z)^{-1} \right) = \sum_{n=1}^{\infty} \frac{z^n}{n},
\]
because the function \( \log (1 - z) \) and the analytic function, \( - \sum_{n=1}^{\infty} \frac{z^n}{n} \), both are equal to \( \ln (1 - x) \) on the real line segment \((-1, 1)\), a set which has a limit point. Therefore, using Lemma 55.1.1,
\[
|E_p (z) - 1| = \left| (1 - z) \exp \left( z + \frac{z^2}{2} + \cdots + \frac{z^p}{p} \right) - 1 \right|
\]
\[
= \left| (1 - z) \exp \left( \log \left( (1 - z)^{-1} \right) - \sum_{n=p+1}^{\infty} \frac{z^n}{n} \right) - 1 \right|
\]
\[
= \exp \left( - \sum_{n=p+1}^{\infty} \frac{z^n}{n} \right) - 1
\]
\[
\leq - \sum_{n=p+1}^{\infty} \frac{z^n}{n} e^{\left| \sum_{n=p+1}^{\infty} \frac{z^n}{n} \right|}
\]
\[
\leq \frac{1}{p+1} \cdot 2 \cdot e^{1/(p+1)} |z|^{p+1} \leq 3 |z|^{p+1}
\]
This proves the corollary.

With this estimate, it is easy to prove the Weierstrass product formula.

**Theorem 55.1.4** Let \( \{z_n\} \) be a sequence of nonzero complex numbers which have no limit point in \( \mathbb{C} \) and let \( \{p_n\} \) be a sequence of nonnegative integers such that
\[
\sum_{n=1}^{\infty} \left( \frac{R}{|z_n|} \right)^{p_n+1} < \infty \quad (55.1.5)
\]
for all \( R \in \mathbb{R} \). Then

\[
P(z) \equiv \prod_{n=1}^{\infty} E_{p_n} \left( \frac{z}{z_n} \right)
\]

is analytic on \( \mathbb{C} \) and has a zero at each point, \( z_n \), and at no others. If \( w \) occurs \( m \) times in \( \{ z_n \} \), then \( P \) has a zero of order \( m \) at \( w \).

**Proof:** Since \( \{ z_n \} \) has no limit point, it follows \( \lim_{n \to \infty} |z_n| = \infty \). Therefore, if \( p_n = n - 1 \) the condition, \( 55.1.5 \) holds for this choice of \( p_n \). Now by Theorem 55.0.2, the infinite product in this theorem will converge uniformly on \( |z| \leq R \) if the same is true of the sum,

\[
\sum_{n=1}^{\infty} \left| E_{p_n} \left( \frac{z}{z_n} \right) - 1 \right|.
\]

But by Corollary 55.1.4, the \( n^{\text{th}} \) term of this sum satisfies

\[
\left| E_{p_n} \left( \frac{z}{z_n} \right) - 1 \right| \leq 3 \left| \frac{z}{z_n} \right|^{p_n + 1}.
\]

Since \( |z_n| \to \infty \), there exists \( N \) such that for \( n > N, |z_n| > 2R \). Therefore, for \( |z| < R \) and letting \( \theta < a = \min \{|z_n| : n \leq N\} \),

\[
\sum_{n=1}^{\infty} \left| E_{p_n} \left( \frac{z}{z_n} \right) - 1 \right| \leq 3 \sum_{n=1}^{N} \left| \frac{R}{a} \right|^{p_n + 1}
+ 3 \sum_{n=N}^{\infty} \left( \frac{R}{2R} \right)^{p_n + 1} < \infty.
\]

By the Weierstrass \( M \) test, the series in 55.1.6 converges uniformly for \( |z| < R \) and so the same is true of the infinite product. It follows from Lemma 49.3.13 on Page 1657 that \( P(z) \) is analytic on \( |z| < R \) because it is a uniform limit of analytic functions.

Also by Theorem 55.0.2, the zeros of the analytic \( P(z) \) are exactly the points, \( \{ z_n \} \), listed according to multiplicity. That is, if \( z_n \) is a zero of order \( m \), then if it is listed \( m \) times in the formula for \( P(z) \), then it is a zero of order \( m \) for \( P \). This proves the theorem.

The following corollary is an easy consequence and includes the case where there is a zero at 0.

**Corollary 55.1.5** Let \( \{ z_n \} \) be a sequence of nonzero complex numbers which have no limit point and let \( \{ p_n \} \) be a sequence of nonnegative integers such that

\[
\sum_{n=1}^{\infty} \left( \frac{r}{|z_n|} \right)^{1+p_n} < \infty
\]
for all \( r \in \mathbb{R} \). Then
\[
P(z) \equiv z^m \prod_{n=1}^{\infty} E_{p_n} \left( \frac{z}{z_n} \right)
\]
is analytic \( \Omega \) and has a zero at each point, \( z_n \) and at no others along with a zero of order \( m \) at 0. If \( w \) occurs \( m \) times in \( \{z_n\} \), then \( P \) has a zero of order \( m \) at \( w \).

The above theory can be generalized to include the case of an arbitrary open set. First, here is a lemma.

**Lemma 55.1.6** Let \( \Omega \) be an open set. Also let \( \{z_n\} \) be a sequence of points in \( \Omega \) which is bounded and which has no point repeated more than finitely many times such that \( \{z_n\} \) has no limit point in \( \Omega \). Then there exists a function \( \Omega \) is analytic on \( \Omega \) which is bounded below by a positive constant. Therefore, there

Proof: Since \( \partial \Omega \) is closed, there exists \( w_n \in \partial \Omega \) such that \( \text{dist} (z_n, \partial \Omega) = |z_n - w_n| \). Now if there is a subsequence, \( \{z_{n_k}\} \) such that \( |z_{n_k} - w_{n_k}| \geq \varepsilon \) for all \( k \), then \( \{z_{n_k}\} \) must possess a limit point because it is a bounded infinite set of points. However, this limit point can only be in \( \Omega \) because \( \{z_{n_k}\} \) is an open set by the open mapping theorem. This is a contradiction. Therefore, \( \lim_{n \to \infty} |z_n - w_n| = 0 \). This proves the lemma.

**Corollary 55.1.7** Let \( \{z_n\} \) be a sequence of complex numbers contained in \( \Omega \), an open subset of \( \mathbb{C} \) which has no limit point in \( \Omega \). Suppose each \( z_n \) is repeated no more than finitely many times. Then there exists a function \( f \) which is analytic on \( \Omega \) whose zeros are exactly \( \{z_n\} \). If \( w \in \{z_n\} \) and \( w \) is listed \( m \) times, then \( w \) is a zero of order \( m \) of \( f \).

Proof: There is nothing to prove if \( \{z_n\} \) is finite. You just let \( f(z) = \prod_{j=1}^{m} (z - z_j) \) where \( \{z_j\} = \{z_1, \cdots, z_m\} \).

Pick \( w \in \Omega \setminus \{z_n\}_{n=1}^{\infty} \) and let \( h(z) = \frac{1}{z - w} \). Since \( w \) is not a limit point of \( \{z_n\} \), there exists \( r > 0 \) such that \( B(w, r) \) contains no points of \( \{z_n\} \). Let \( \Omega_1 \equiv \Omega \setminus \{w\} \). Now \( h \) is not constant and so \( h(\Omega_1) \) is an open set by the open mapping theorem. In fact, \( h \) maps each component of \( \Omega \) to a region. \( |z_n - w| > r \) for all \( z_n \) and so \( |h(z_n)| < r^{-1} \). Thus the sequence, \( \{h(z_n)\} \) is a bounded sequence in the open set \( h(\Omega_1) \). It has no limit point in \( h(\Omega_1) \) because this is true of \( \{z_n\} \) and \( \Omega_1 \). By Lemma 55.1.6 there exist \( w_n \in \partial h(\Omega_1) \) such that \( \lim_{n \to \infty} |w_n - h(z_n)| = 0 \). Consider for \( z \in \Omega_1 \)
\[
f(z) \equiv \prod_{n=1}^{\infty} E_n \left( \frac{h(z_n) - w_n}{h(z) - w_n} \right).
\]
Letting \( K \) be a compact subset of \( \Omega_1 \), \( h(K) \) is a compact subset of \( h(\Omega_1) \) and so if \( z \in K \), then \( |h(z) - w_n| \) is bounded below by a positive constant. Therefore, there exists \( N \) large enough that for all \( z \in K \) and \( n \geq N \),
\[
\frac{|h(z_n) - w_n|}{|h(z) - w_n|} < \frac{1}{2}
\]
and so by Corollary 55.1.3, for all $z \in K$ and $n \geq N$,

$$
E_n \left( \frac{h(z_n) - w_n}{h(z) - w_n} - 1 \right) \leq 3 \left( \frac{1}{2} \right)^n.
$$

Therefore,

$$
\sum_{n=1}^{\infty} \left| E_n \left( \frac{h(z_n) - w_n}{h(z) - w_n} - 1 \right) \right|
$$

converges uniformly for $z \in K$. This implies $\prod_{n=1}^{\infty} E_n \left( \frac{h(z_n) - w_n}{h(z) - w_n} \right)$ also converges uniformly for $z \in K$ by Theorem 55.1.2. Since $K$ is arbitrary, this shows $f$ defined in 55.1.8 is analytic on $\Omega$.

Also if $z_n$ is listed $m$ times so it is a zero of multiplicity $m$ and $w_n$ is the point from $\partial (h(\Omega_1))$ closest to $h(z_n)$, then there are $m$ factors in 55.1.8 which are of the form

$$
E_n \left( \frac{h(z_n) - w_n}{h(z) - w_n} \right) = \left( 1 - \frac{h(z_n) - w_n}{h(z) - w_n} \right) e^{g_n(z)}
$$

$$
= \left( \frac{h(z) - h(z_n)}{h(z) - w_n} \right) e^{g_n(z)}
$$

$$
= \frac{z_n - z}{(z - w)(z_n - w)} \left( \frac{1}{h(z) - w_n} \right) e^{g_n(z)}
$$

$$
= (z - z_n) G_n(z)
$$

(55.1.10)

where $G_n$ is an analytic function which is not zero at and near $z_n$. Therefore, $f$ has a zero of order $m$ at $z_n$. This proves the theorem except for the point, $w$ which has been left out of $\Omega_1$. It is necessary to show $f$ is analytic at this point also and right now, $f$ is not even defined at $w$.

The $\{w_n\}$ are bounded because $\{h(z_n)\}$ is bounded and $\lim_{n \to \infty} |w_n - h(z_n)| = 0$ which implies $|w_n - h(z_n)| \leq C$ for some constant, $C$. Therefore, there exists $\delta > 0$ such that if $z \in B'(w, \delta)$, then for all $n$,

$$
\frac{|h(z_n) - w|}{|1 - w_n|} = \frac{|h(z_n) - w_n|}{|h(z) - w_n|} < \frac{1}{2}.
$$

Thus 55.1.4 holds for all $z \in B'(w, \delta)$ and $n$ so by Theorem 55.1.2, the infinite product in 55.1.8 converges uniformly on $B'(w, \delta)$. This implies $f$ is bounded in $B'(w, \delta)$ and so $w$ is a removable singularity and $f$ can be extended to $w$ such that the result is analytic. It only remains to verify $f(w) \neq 0$. After all, this would not do because it would be another zero other than those in the given list. By 55.1.10, a partial product is of the form

$$
\prod_{n=1}^{N} \left( \frac{h(z) - h(z_n)}{h(z) - w_n} \right) e^{g_n(z)}
$$

(55.1.11)
where

\[ g_n(z) = \left( \frac{h(z_n) - w_n}{h(z) - w_n} + \frac{1}{2} \left( \frac{h(z_n) - w_n}{h(z) - w_n} \right)^2 + \cdots + \frac{1}{n^2} \left( \frac{h(z_n) - w_n}{h(z) - w_n} \right)^n \right) \]

Each of the quotients in the definition of \( g_n(z) \) converges to 0 as \( z \to w \) and so the partial product of \( g_n(z) \) converges to 1 as \( z \to w \) because \( \left( \frac{h(z) - h(z_n)}{h(z) - w_n} \right) \to 1 \) as \( z \to w \).

If \( f(w) = 0 \), then if \( z \) is close enough to \( w \), it follows \( |f(z)| < \frac{1}{2} \). Also, by the uniform convergence on \( B'(w, \delta) \), it follows that for some \( N \), the partial product up to \( N \) must also be less than \( 1/2 \) in absolute value for all \( z \) close enough to \( w \) and as noted above, this does not occur because such partial products converge to 1 as \( z \to w \). Hence \( f(w) \neq 0 \). This proves the corollary.

Recall the definition of a meromorphic function on Page 1671. It was a function which is analytic everywhere except at a countable set of isolated points at which the function has a pole. It is clear that the quotient of two analytic functions yields a meromorphic function but is this the only way it can happen?

**Theorem 55.1.8** Suppose \( Q \) is a meromorphic function on an open set, \( \Omega \). Then there exist analytic functions on \( \Omega \), \( f(z) \) and \( g(z) \) such that \( Q(z) = f(z)/g(z) \) for all \( z \) not in the set of poles of \( Q \).

**Proof:** Let \( Q \) have a pole of order \( m \) at \( z \). Then by Corollary 55.1.7 there exists an analytic function, \( g \) which has a zero of order \( m \) at every \( z \in \Omega \). It follows \( gQ \) has a removable singularity at the poles of \( Q \). Therefore, there is an analytic function, \( f \) such that \( f(z) = g(z)Q(z) \). This proves the theorem.

**Corollary 55.1.9** Suppose \( \Omega \) is a region and \( Q \) is a meromorphic function defined on \( \Omega \) such that the set, \( \{ z \in \Omega : Q(z) = c \} \) has a limit point in \( \Omega \). Then \( Q(z) = c \) for all \( z \in \Omega \).

**Proof:** From Theorem 55.1.8 there are analytic functions, \( f, g \) such that \( Q = \frac{f}{g} \). Therefore, the zero set of the function, \( f(z) - cg(z) \) has a limit point in \( \Omega \) and so \( f(z) - cg(z) = 0 \) for all \( z \in \Omega \). This proves the corollary.

### 55.2 Factoring A Given Analytic Function

The next theorem is the Weierstrass factorization theorem which can be used to factor a given analytic function \( f \). If \( f \) has a zero of order \( m \) when \( z = 0 \), then you could factor out a \( z^m \) and from there consider the factorization of what remains when you have factored out the \( z^m \). Therefore, the following is the main thing of interest.
Theorem 55.2.1 Let \( f \) be analytic on \( \mathbb{C} \), \( f(0) \neq 0 \), and let the zeros of \( f \), be \( \{z_k\} \), listed according to order. (Thus if \( z \) is a zero of order \( m \), it will be listed \( m \) times in the list, \( \{z_k\} \).) Choosing nonnegative integers, \( p_n \) such that for all \( r > 0 \),

\[
\sum_{n=1}^{\infty} \left( \frac{r}{|z_n|} \right)^{p_n+1} < \infty,
\]

There exists an entire function, \( g \) such that

\[
f(z) = e^{g(z)} \prod_{n=1}^{\infty} E_{p_n} \left( \frac{z}{z_n} \right).
\] (55.2.12)

Note that \( e^{g(z)} \neq 0 \) for any \( z \) and this is the interesting thing about this function.

**Proof:** \( \{z_n\} \) cannot have a limit point because if there were a limit point of this sequence, it would follow from Theorem 49.5.3 that \( f(z) = 0 \) for all \( z \), contradicting the hypothesis that \( f(0) \neq 0 \). Hence \( \lim\limits_{n \to \infty} |z_n| = \infty \) and so

\[
\sum_{n=1}^{\infty} \left( \frac{r}{|z_n|} \right)^{1+n-1} = \sum_{n=1}^{\infty} \left( \frac{r}{|z_n|} \right)^n < \infty
\]

by the root test. Therefore, by Theorem 55.1.4

\[
P(z) = \prod_{n=1}^{\infty} E_{p_n} \left( \frac{z}{z_n} \right)
\]

a function analytic on \( \mathbb{C} \) by picking \( p_n = n - 1 \) or perhaps some other choice. (\( p_n = n - 1 \) works but there might be another choice that would work.) Then \( f/P \) has only removable singularities in \( \mathbb{C} \) and no zeros thanks to Theorem 55.1.4. Thus, letting \( h(z) = f(z)/P(z) \), Corollary 49.7.23 implies that \( h'/h \) has a primitive, \( \bar{g} \). Then

\[
\left( he^{-\bar{g}} \right)' = 0
\]

and so

\[
h(z) = e^{a+ib} e^{\bar{g}(z)}
\]

for some constants, \( a, b \). Therefore, letting \( g(z) = \bar{g}(z) + a + ib \), \( h(z) = e^{g(z)} \) and thus 55.1.12 holds. This proves the theorem.

**Corollary 55.2.2** Let \( f \) be analytic on \( \mathbb{C} \), \( f \) has a zero of order \( m \) at \( 0 \), and let the other zeros of \( f \) be \( \{z_k\} \), listed according to order. (Thus if \( z \) is a zero of order \( l \), it will be listed \( l \) times in the list, \( \{z_k\} \).) Also let

\[
\sum_{n=1}^{\infty} \left( \frac{r}{|z_n|} \right)^{1+p_n} < \infty
\] (55.2.13)

for any choice of \( r > 0 \). Then there exists an entire function, \( g \) such that

\[
f(z) = z^m e^{g(z)} \prod_{n=1}^{\infty} E_{p_n} \left( \frac{z}{z_n} \right).
\] (55.2.14)
**CHAPTER 55. INFINITE PRODUCTS**

**Proof:** Since \( f \) has a zero of order \( m \) at 0, it follows from Theorem 49.5.3 that \( \{z_k\} \) cannot have a limit point in \( \mathbb{C} \) and so you can apply Theorem 55.2.1 to the function, \( f(z)/z^m \) which has a removable singularity at 0. This proves the corollary.

### 55.2.1 Factoring Some Special Analytic Functions

Factoring a polynomial is in general a hard task. It is true it is easy to prove the factors exist but finding them is another matter. Corollary 55.2.2 gives the existence of factors of a certain form but it does not tell how to find them. This should not be surprising. You can’t expect things to get easier when you go from polynomials to analytic functions. Nevertheless, it is possible to factor some popular analytic functions. These factorizations are based on the following Mittag-Leffler expansions.

By an auspicious choice of the contour and the method of residues it is possible to obtain a very interesting formula for \( \cot z \):

**Example 55.2.3** Let \( \gamma_N \) be the contour which goes from \( -N - \frac{1}{2} - Ni \) horizontally to \( N + \frac{1}{2} - Ni \) and from there, vertically to \( N + \frac{1}{2} + Ni \) and then horizontally to \( -N - \frac{1}{2} + Ni \) and finally vertically to \( -N - \frac{1}{2} - Ni \). Thus the contour is a large rectangle and the direction of integration is in the counter clockwise direction.

Consider the integral

\[
I_N = \int_{\gamma_N} \frac{\pi \cos \pi z}{\sin \pi z (\alpha^2 - z^2)} dz
\]

where \( \alpha \in \mathbb{R} \) is not an integer. This will be used to verify the formula of Mittag-Leffler,

\[
\frac{1}{\alpha} + \sum_{n=1}^{\infty} \frac{2\alpha}{\alpha^2 - n^2} = \pi \cot \pi \alpha.
\]  

First you show that cot \( \pi z \) is bounded on this contour. This is easy using the formula for \( \cot(z) = e^{i\pi(z+\frac{1}{2})} \). Therefore, \( I_N \to 0 \) as \( N \to \infty \) because the integrand is of order \( 1/N^2 \) while the diameter of \( \gamma_N \) is of order \( N \). Next you compute the residues of the integrand at \( \pm \alpha \) and at \( n \) where \( |n| < N + \frac{1}{2} \) for \( n \) an integer. These are the only singularities of the integrand in this contour and therefore, using the residue theorem, you can evaluate \( I_N \) by using these. You can calculate these residues and find that the residue at \( \pm \alpha \) is

\[
\frac{-\pi \cos \pi \alpha}{2\alpha \sin \pi \alpha}
\]

while the residue at \( n \) is

\[
\frac{1}{\alpha^2 - n^2}.
\]

Therefore

\[
0 = \lim_{N \to \infty} I_N = \lim_{N \to \infty} 2\pi i \left[ \sum_{n=-N}^{N} \frac{1}{\alpha^2 - n^2} - \frac{\pi \cot \pi \alpha}{\alpha} \right]
\]
which establishes the following formula of Mittag Leffler.

\[
\lim_{N \to \infty} \sum_{n=-N}^{N} \frac{1}{\alpha^2 - n^2} = \frac{\pi \cot \pi \alpha}{\alpha}.
\]

Writing this in a slightly nicer form, you obtain 55.2.15.

This is a very interesting formula. This will be used to factor \( \sin(\pi z) \). The zeros of this function are at the integers. Therefore, considering 55.2.13 you can pick \( p_n = 1 \) in the Weierstrass factorization formula. Therefore, by Corollary 55.2.2 there exists an analytic function \( g(z) \) such that

\[
\sin(\pi z) = e^{g(z)} \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right) e^{z^2/z_n}
\]  

(55.2.16)

where the \( z_n \) are the nonzero integers. Remember you can permute the factors in these products. Therefore, this can be written more conveniently as

\[
\sin(\pi z) = ze^{g(z)} \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right)
\]

and it is necessary to find \( g(z) \). Differentiating both sides of 55.2.16

\[
\pi \cos(\pi z) = e^{g(z)} \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right) + zg'(z) e^{g(z)} \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right)
\]

\[
+ ze^{g(z)} \sum_{n=1}^{\infty} \left( \frac{2z}{n^2} \left( \prod_{k \neq n} \left( 1 - \left( \frac{z}{k} \right)^2 \right) \right)
\]

Now divide both sides by \( \sin(\pi z) \) to obtain

\[
\pi \cot(\pi z) = \frac{1}{z} + g'(z) - \sum_{n=1}^{\infty} \frac{2z/n^2}{(1 - z^2/n^2)}
\]

\[
= \frac{1}{z} + g'(z) + \sum_{n=1}^{\infty} \frac{2z}{z^2 - n^2}.
\]

By 55.2.14, this yields \( g'(z) = 0 \) for \( z \) not an integer and so \( g(z) = c \), a constant. So far this yields

\[
\sin(\pi z) = ze^{c} \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right)
\]

and it only remains to find \( c \). Divide both sides by \( \pi z \) and take a limit as \( z \to 0 \). Using the power series of \( \sin(\pi z) \), this yields

\[
1 = \frac{e^c}{\pi}
\]
and so \( c = \ln \pi \). Therefore,

\[ \sin (\pi z) = \pi \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right). \]  \hspace{1cm} (55.17)

**Example 55.2.4** Find an interesting formula for \( \tan (\pi z) \).

This is easy to obtain from the formula for \( \cot (\pi z) \).

\[ \cot \left( \pi \left( z + \frac{1}{2} \right) \right) = -\tan \pi z \]

for \( z \) real and therefore, this formula holds for \( z \) complex also. Therefore, for \( z + \frac{1}{2} \)
not an integer

\[ \pi \cot \left( \pi \left( z + \frac{1}{2} \right) \right) = \frac{2}{2z + 1} + \sum_{n=1}^{\infty} \frac{2z + 1}{(2z + 1)^2 - n^2} \]

### 55.3 The Existence Of An Analytic Function With Given Values

The Weierstrass product formula, Theorem 55.1.4, along with the Mittag-Leffler theorem, Theorem 54.2.1, can be used to obtain an analytic function which has given values on a countable set of points, having no limit point. This is clearly an amazing result and indicates how potent these theorems are. In fact, you can show that it isn’t just the values of the function which may be specified at the points in this countable set of points but the derivatives up to any finite order.

**Theorem 55.3.1** Let \( \{z_k\} \) be a set of points in \( \mathbb{C} \), which has no limit point. For each \( z_k \), consider

\[ \sum_{j=0}^{m_k} a_j^k (z - z_k)^j. \]  \hspace{1cm} (55.18)

Then there exists an analytic function defined on \( \mathbb{C} \) such that the Taylor series of \( f \) at \( z_k \) has the first \( m_k \) terms given by (55.18).

**Proof:** By the Weierstrass product theorem, Theorem 55.1.4, there exists an analytic function, \( f \) defined on all of \( \Omega \) such that \( f \) has a zero of order \( m_k + 1 \) at \( z_k \). Consider this \( z_k \) Thus for \( z \) near \( z_k \),

\[ f(z) = \sum_{j=m_k+1}^{\infty} c_j (z - z_k)^j \]

\[ ^1 \text{This says you can specify the first } m_k \text{ derivatives of the function at the point } z_k.\]
55.3. THE EXISTENCE OF AN ANALYTIC FUNCTION WITH GIVEN VALUES

where \( c_{m+1} \neq 0 \). You choose \( b_1, b_2, \ldots, b_{m+1} \) such that

\[
f(z) = \sum_{j=0}^{m} a_j^k (z - z_k)^j + \sum_{k=m+1}^{\infty} c_j^k (z - z_k)^j.
\]

Thus you need

\[
\sum_{l=1}^{m+1} \sum_{j=m+1}^{\infty} c_j b_l (z - z_k)^{j-l} = \sum_{r=0}^{m} a_r^k (z - z_k)^r + \text{Higher order terms}.
\]

It follows you need to solve the following system of equations for \( b_1, \ldots, b_{m+1} \).

\[
\begin{aligned}
c_{m+1} b_{m+1} &= a_0^k \\
c_{m+2} b_{m+1} + c_{m+1} b_m &= a_1^k \\
c_{m+3} b_{m+1} + c_{m+2} b_m + c_{m+1} b_{m-1} &= a_2^k \\
&\vdots \\
c_{m+m+1} b_{m+1} + c_{m+m} b_m + \cdots + c_{m+1} b_1 &= a_m^k
\end{aligned}
\]

Since \( c_{m+1} \neq 0 \), it follows there exists a unique solution to the above system.

You first solve for \( b_{m+1} \) in the top. Then, having found it, you go to the next and use \( c_{m+1} \neq 0 \) again to find \( b_m \) and continue in this manner. Let \( S_k(z) \) be determined in this manner for each \( z_k \). By the Mittag-Leffler theorem, there exists a Meromorphic function, \( g \) such that \( g \) has exactly the singularities, \( S_k(z) \).

Therefore, \( f(z)g(z) \) has removable singularities at each \( z_k \) and for \( z \) near \( z_k \), the first \( m_k \) terms of \( fg \) are as prescribed. This proves the theorem.

**Corollary 55.3.2** Let \( P = \{z_k\}_{k=1}^{\infty} \) be a set of points in \( \Omega \), an open set such that \( P \) has no limit points in \( \Omega \). For each \( z_k \), consider

\[
\sum_{j=0}^{m} a_j^k (z - z_k)^j.
\]

Then there exists an analytic function defined on \( \Omega \) such that the Taylor series of \( f \) at \( z_k \) has the first \( m_k \) terms given by (55.3.19).

**Proof:** The proof is identical to the above except you use the versions of the Mittag-Leffler theorem and Weierstrass product which pertain to open sets.

**Definition 55.3.3** Denote by \( H(\Omega) \) the analytic functions defined on \( \Omega \), an open subset of \( \mathbb{C} \). Then \( H(\Omega) \) is a commutative ring\(^2\) with the usual operations of addition and multiplication. A set, \( I \subseteq H(\Omega) \) is called a finitely generated ideal of the ring if \( I \) is of the form

\[
\left\{ \sum_{k=1}^{n} g_k f_k : f_k \in H(\Omega) \text{ for } k = 1, 2, \ldots, n \right\}
\]

\(^2\)It is not a field because you can’t divide two analytic functions and get another one.
where \( g_1, \ldots, g_n \) are given functions in \( H(\Omega) \). This ideal is also denoted as \([g_1, \ldots, g_n]\) and is called the ideal generated by the functions, \( \{g_1, \ldots, g_n\} \). Since there are finitely many of these functions it is called a finitely generated ideal. A principal ideal is one which is generated by a single function. An example of such a thing is \([1] = H(\Omega)\).

Then there is the following interesting theorem.

**Theorem 55.3.4** Every finitely generated ideal in \( H(\Omega) \) for \( \Omega \) a connected open set (region) is a principal ideal.

**Proof:** Let \( I = [g_1, \ldots, g_n] \) be a finitely generated ideal as described above. Then if any of the functions has no zeros, this ideal would consist of \( H(\Omega) \) because then \( g_i^{-1} \in H(\Omega) \) and so \( 1 \in I \). It follows all the functions have zeros. If any of the functions has a zero of infinite order, then the function equals zero on \( \Omega \) because \( \Omega \) is connected and can be deleted from the list. Similarly, if the zeros of any of these functions have a limit point in \( \Omega \), then the function equals zero and can be deleted from the list. Thus, without loss of generality, all zeros are of finite order and there are no limit points of the zeros in \( \Omega \). Let \( m(g_i, z) \) denote the order of the zero of \( g_i \) at \( z \). If \( g_i \) has no zero at \( z \), then \( m(g_i, z) = 0 \).

I claim that if no point of \( \Omega \) is a zero of all the \( g_i \), then the conclusion of the theorem is true and in fact \([g_1, \ldots, g_n] = [1] = H(\Omega)\). The claim is obvious if \( n = 1 \) because this assumption that no point is a zero of all the functions implies \( g \neq 0 \) and so \( g^{-1} \) is analytic. Hence \( 1 \in [g_1] \). Suppose it is true for \( n - 1 \) and consider \([g_1, \ldots, g_n]\) where no point of \( \Omega \) is a zero of all the \( g_i \). Even though this may be true of \( \{g_1, \ldots, g_{n-1}\} \) it may not be true of \( \{g_1, \ldots, g_{n-1}\} \). By Corollary 55.1.7 there exists \( \phi \), a function analytic on \( \Omega \) such that \( m(\phi, z) = \min\{m(g_i, z), i = 1, 2, \ldots, n - 1\} \). Thus the functions \( \{g_1/\phi, \ldots, g_{n-1}/\phi\} \) are all analytic. Could they all equal zero at some point, \( z \)? If so, pick \( i \) where \( m(\phi, z) = m(g_i, z) \). Thus \( g_i/\phi \) is not equal to zero at \( z \) after all and so these functions are analytic there is no point of \( \Omega \) which is a zero of all of them. By induction, \([g_1/\phi, \ldots, g_{n-1}/\phi] = H(\Omega)\). (Also there are no new zeros obtained in this way.)

Now this means there exist functions \( f_i \in H(\Omega) \) such that

\[
\sum_{i=1}^{n} f_i \left( \frac{g_i}{\phi} \right) = 1
\]

and so \( \phi = \sum_{i=1}^{n} f_i g_i \). Therefore, \( [\phi] \subseteq [g_1, \ldots, g_{n-1}] \). On the other hand, if \( \sum_{k=1}^{n-1} h_k g_k \in [g_1, \ldots, g_{n-1}] \) you could define \( h = \sum_{k=1}^{n-1} h_k g_k/\phi \), an analytic function with the property that \( h \phi = \sum_{k=1}^{n-1} h_k g_k \) which shows \( [\phi] = [g_1, \ldots, g_{n-1}] \). Therefore,

\[
[g_1, \ldots, g_{n}] = [\phi, g_n]
\]

Now \( \phi \) has no zeros in common with \( g_n \) because the zeros of \( \phi \) are contained in the set of zeros for \( g_1, \ldots, g_{n-1} \). Now consider a zero, \( \alpha \) of \( \phi \). It is not a zero of \( g_n \) and
so near \( \alpha \), these functions have the form

\[
\phi(z) = \sum_{k=m}^{\infty} a_k (z - \alpha)^k, \quad g_n(z) = \sum_{k=0}^{\infty} b_k (z - \alpha)^k, \quad b_0 \neq 0.
\]

I want to determine coefficients for an analytic function, \( h \) such that

\[
m(1 - hg_n, \alpha) \geq m(\phi, \alpha). \tag{55.3.20}
\]

Let

\[
h(z) = \sum_{k=0}^{\infty} c_k (z - \alpha)^k
\]

and the \( c_k \) must be determined. Using Merten’s theorem, the power series for \( 1 - hg_n \) is of the form

\[
1 - b_0 c_0 - \sum_{j=1}^{\infty} \left( \sum_{r=0}^{j} b_{j-r} c_r \right) (z - \alpha)^j.
\]

First determine \( c_0 \) such that \( 1 - c_0 b_0 = 0 \). This is no problem because \( b_0 \neq 0 \). Next you need to get the coefficients of \( (z - \alpha) \) to equal zero. This requires

\[
b_1 c_0 + b_0 c_1 = 0.
\]

Again, there is no problem because \( b_0 \neq 0 \). In fact, \( c_1 = (-b_1 c_0 / b_0) \). Next consider the second order terms if \( m \geq 2 \).

\[
b_2 c_0 + b_1 c_1 + b_0 c_2 = 0
\]

Again there is no problem in solving, this time for \( c_2 \) because \( b_0 \neq 0 \). Continuing this way, you see that in every step, the \( c_k \) which needs to be solved for is multiplied by \( b_0 \neq 0 \). Therefore, by Corollary 55.1.7 there exists an analytic function, \( h \) satisfying (55.3.20). Therefore, \( (1 - hg_n)/\phi \) has a removable singularity at every zero of \( \phi \) and so may be considered an analytic function. Therefore,

\[
1 = \frac{1 - hg_n}{\phi} \phi + hg_n \in [\phi, g_n] = [g_1 \cdots g_n]
\]

which shows \([g_1 \cdots g_n] = H(\Omega) = [1] \). It follows the claim is established.

Now suppose \( \{g_1, \cdots, g_n\} \) are just elements of \( H(\Omega) \). As explained above, it can be assumed they all have zeros of finite order and the zeros have no limit point in \( \Omega \) since if these occur, you can delete the function from the list. By Corollary 55.1.7, there exists \( \phi \in H(\Omega) \) such that \( m(\phi, z) \leq \min \{m(g_i, z) : i = 1, \cdots, n\} \).

Then \( g_k/\phi \) has a removable singularity at each zero of \( g_k \) and so can be regarded as an analytic function. Also, as before, there is no point which is a zero of each \( g_k/\phi \) and so by the first part of this argument, \([g_1/\phi \cdots g_n/\phi] = H(\Omega) \). As in the first part of the argument, this implies \([g_1 \cdots g_n] = [\phi] \) which proves the theorem. \([g_1 \cdots g_n]\) is a principal ideal as claimed.

The following corollary follows from the above theorem. You don’t need to assume \( \Omega \) is connected.
Corollary 55.3.5 Every finitely generated ideal in $H(\Omega)$ for $\Omega$ an open set is a principal ideal.

Proof: Let $[g_1, \cdots, g_n]$ be a finitely generated ideal in $H(\Omega)$. Let $\{U_k\}$ be the components of $\Omega$. Then applying the above to each component, there exists $h_k \in H(U_k)$ such that restricting each $g_i$ to $U_k$, $[g_1, \cdots, g_n] = [h_k]$. Then let $h(z) = h_k(z)$ for $z \in U_k$. This is an analytic function which works.

55.4 Jensen’s Formula

This interesting formula relates the zeros of an analytic function to an integral. The proof given here follows Alfors, [2]. First, here is a technical lemma.

Lemma 55.4.1

$$\int_{-\pi}^{\pi} \ln |1 - e^{i\theta}| \, d\theta = 0.$$ 

Proof: First note that the only problem with the integrand occurs when $\theta = 0$. However, this is an integrable singularity so the integral will end up making sense. Letting $z = e^{i\theta}$, you could get the above integral as a limit as $\varepsilon \to 0$ of the following contour integral where $\gamma_\varepsilon$ is the contour shown in the following picture with the radius of the big circle equal to 1 and the radius of the little circle equal to $\varepsilon$.

$$\int_{\gamma_\varepsilon} \ln |1 - z| \, \frac{dz}{iz}.$$ 

On the indicated contour, $1 - z$ lies in the half plane $\text{Re } z > 0$ and so $\log (1 - z) = \ln |1 - z| + i \arg (1 - z)$. The above integral equals

$$\int_{\gamma_\varepsilon} \log (1 - z) \, \frac{dz}{iz} - \int_{\gamma_\varepsilon} \frac{\arg (1 - z)}{z} \, dz.$$ 

The first of these integrals equals zero because the integrand has a removable singularity at 0. The second equals

$$i \int_{-\pi}^{\pi} \arg \left(1 - e^{i\theta} \right) \, d\theta + i \int_{\pi}^{\pi} \arg \left(1 - e^{i\theta} \right) \, d\theta$$

$$+ \varepsilon i \int_{-\pi}^{\pi} \theta \, d\theta + \varepsilon i \int_{\pi}^{\pi} \theta \, d\theta.$$
where $\eta, \lambda \to 0$ as $\varepsilon \to 0$. The last two terms converge to 0 as $\varepsilon \to 0$ while the first two add to zero. To see this, change the variable in the first integral and then recall that when you multiply complex numbers you add the arguments. Thus you end up integrating $\arg$ (real valued function) which equals zero.

In this material on Jensen’s equation, $\varepsilon$ will denote a small positive number. Its value is not important as long as it is positive. Therefore, it may change from place to place. Now suppose $f$ is analytic on $B(0, r + \varepsilon)$, and $f$ has no zeros on $\overline{B(0, r)}$. Then you can define a branch of the logarithm which makes sense for complex numbers near $f(z)$. Thus $z \to \log(f(z))$ is analytic on $B(0, r + \varepsilon)$. Therefore, its real part, $u(x, y) \equiv \ln |f(x + iy)|$ must be harmonic. Consider the following lemma.

**Lemma 55.4.2** Let $u$ be harmonic on $B(0, r + \varepsilon)$. Then

$$u(0) = \frac{1}{2\pi} \int_{-\pi}^{\pi} u(re^{i\theta}) \, d\theta.$$  

**Proof:** For a harmonic function, $u$ defined on $B(0, r + \varepsilon)$, there exists an analytic function, $h = u + iv$ where

$$v(x, y) = \int_{0}^{y} u_x(x, t) \, dt - \int_{0}^{x} u_y(t, 0) \, dt.$$  

By the Cauchy integral theorem,

$$h(0) = \frac{1}{2\pi i} \int_{\gamma_r} \frac{h(z)}{z} \, dz = \frac{1}{2\pi} \int_{-\pi}^{\pi} h(re^{i\theta}) \, d\theta.$$  

Therefore, considering the real part of $h$,

$$u(0) = \frac{1}{2\pi} \int_{-\pi}^{\pi} u(re^{i\theta}) \, d\theta.$$  

This proves the lemma.

Now this shows the following corollary.

**Corollary 55.4.3** Suppose $f$ is analytic on $B(0, r + \varepsilon)$ and has no zeros on $\overline{B(0, r)}$. Then

$$\ln |f(0)| = \frac{1}{2\pi} \int_{-\pi}^{\pi} \ln |f(re^{i\theta})|$$  

(55.4.21)

What if $f$ has some zeros on $|z| = r$ but none on $B(0, r)$? It turns out 55.4.21 is still valid. Suppose the zeros are at $\{re^{i\theta_k}\}_{k=1}^{m}$, listed according to multiplicity. Then let

$$g(z) = \frac{f(z)}{\prod_{k=1}^{m} (z - re^{i\theta_k})}.$$
It follows $g$ is analytic on $B(0, r + \varepsilon)$ but has no zeros in $\overline{B(0, r)}$. Then \[55.4.21\] holds for $g$ in place of $f$. Thus

$$\ln |f(0)| - \sum_{k=1}^{m} \ln |r|$$

$$= \frac{1}{2\pi} \int_{-\pi}^{\pi} \ln |f(re^{i\theta})| \, d\theta - \frac{1}{2\pi} \sum_{k=1}^{m} \ln |re^{i\omega} - re^{i\theta}| \, d\theta$$

$$= \frac{1}{2\pi} \int_{-\pi}^{\pi} \ln |f(re^{i\theta})| \, d\theta - \frac{1}{2\pi} \sum_{k=1}^{m} \ln |e^{i\omega} - e^{i\theta}| \, d\theta - \sum_{k=1}^{m} \ln |r|$$

Therefore, \[55.4.21\] will continue to hold exactly when \(\frac{1}{2\pi} \int_{-\pi}^{\pi} \sum_{k=1}^{m} \ln |e^{i\omega} - 1| \, d\theta = 0\). But this is the content of Lemma \[55.4.1\]. This proves the following lemma.

**Lemma 55.4.4** Suppose $f$ is analytic on $B(0, r + \varepsilon)$ and has no zeros on $B(0, r)$. Then

$$\ln |f(0)| = \frac{1}{2\pi} \int_{-\pi}^{\pi} \ln |f(re^{i\theta})|$$

(55.4.22)

With this preparation, it is now not too hard to prove Jensen’s formula. Suppose there are $n$ zeros of $f$ in $B(0, r)$, \(\{a_k\}_{k=1}^{n}\), listed according to multiplicity, none equal to zero. Let

$$F(z) = f(z) \prod_{i=1}^{n} \frac{r^2 - \overline{a_i}z}{r(z - a_i)}.$$ 

Then $F$ is analytic on $B(0, r + \varepsilon)$ and has no zeros in $B(0, r)$. The reason for this is that $f(z) / \prod_{i=1}^{n} r(z - a_i)$ has no zeros there and $r^2 - \overline{a_i}z$ cannot equal zero if $|z| < r$ because if this expression equals zero, then

$$|z| = \frac{r^2}{|a_i|} > r.$$ 

The other interesting thing about $F(z)$ is that when $z = re^{i\theta}$,

$$F(re^{i\theta}) = f(re^{i\theta}) \prod_{i=1}^{n} \frac{r^2 - \overline{a_i}re^{i\theta}}{r(re^{i\theta} - a_i)}$$

$$= f(re^{i\theta}) \prod_{i=1}^{n} \frac{r - \overline{a_i}e^{i\theta}}{(re^{i\theta} - a_i)} = f(re^{i\theta}) e^{i\theta} \prod_{i=1}^{n} \frac{re^{-i\theta} - \overline{a_i}}{re^{i\theta} - a_i}$$

so $|F(re^{i\theta})| = |f(re^{i\theta})|$. 

Theorem 55.4.5 Let \( f \) be analytic on \( B(0, r + \varepsilon) \) and suppose \( f(0) \neq 0 \). If the zeros of \( f \) in \( B(0, r) \) are \( \{a_k\}_{k=1}^{n} \), listed according to multiplicity, then

\[
\ln |f(0)| = -\sum_{i=1}^{n} \ln \left( \frac{r}{|a_i|} \right) + \frac{1}{2\pi} \int_{0}^{2\pi} \ln |f(re^{i\theta})| \, d\theta.
\]

Proof: From the above discussion and Lemma 55.4.4,

\[
\ln |F(0)| = \frac{1}{2\pi} \int_{-\pi}^{\pi} \ln |f(re^{i\theta})| \, d\theta
\]

But \( F(0) = f(0) \prod_{i=1}^{n} \frac{r}{a_i} \) and so \( \ln |F(0)| = \ln |f(0)| + \sum_{i=1}^{n} \ln \left| \frac{r}{a_i} \right| \). Therefore,

\[
\ln |f(0)| = -\sum_{i=1}^{n} \ln \left| \frac{r}{a_i} \right| + \frac{1}{2\pi} \int_{0}^{2\pi} \ln |f(re^{i\theta})| \, d\theta
\]

as claimed.

Written in terms of exponentials this is

\[
|f(0)| \prod_{k=1}^{n} \left| \frac{r}{a_k} \right| = \exp \left( \frac{1}{2\pi} \int_{0}^{2\pi} \ln |f(re^{i\theta})| \, d\theta \right).
\]

55.5 Blaschke Products

The Blaschke product is a way to produce a function which is bounded and analytic on \( B(0,1) \) which also has given zeros in \( B(0,1) \). The interesting thing here is that there may be infinitely many of these zeros. Thus, unlike the above case of Jensen’s inequality, the function is not analytic on \( B(0,1) \). Recall for purposes of comparison, Liouville’s theorem which says bounded entire functions are constant.

The Blaschke product gives examples of bounded functions on \( B(0,1) \) which are definitely not constant.

Theorem 55.5.1 Let \( \{\alpha_n\} \) be a sequence of nonzero points in \( B(0,1) \) with the property that

\[
\sum_{n=1}^{\infty} (1 - |\alpha_n|) < \infty.
\]

Then for \( k \geq 0 \), an integer

\[
B(z) = z^k \prod_{k=1}^{\infty} \frac{\alpha_n - z |\alpha_n|}{1 - \alpha_n z |\alpha_n|}
\]

is a bounded function which is analytic on \( B(0,1) \) which has zeros only at 0 if \( k > 0 \) and at the \( \alpha_n \).

\(^{3}\)Wilhelm Blaschke, 1915
**Proof:** From Theorem 55.2, the above product will converge uniformly on $B(0, r)$ for $r < 1$ to an analytic function if

$$
\sum_{k=1}^{\infty} \left| \frac{\alpha_n - z}{1 - \frac{\alpha_n z}{\alpha_n}} - 1 \right|
$$

converges uniformly on $B(0, r)$. But for $|z| < r$,

$$
\left| \frac{\alpha_n - z}{1 - \frac{\alpha_n z}{\alpha_n}} - 1 \right| = \left| \frac{\alpha_n - z}{1 - \frac{\alpha_n z}{\alpha_n}} - \frac{\alpha_n (1 - \frac{\alpha_n z}{\alpha_n})}{\alpha_n} \right| = \left| \frac{\alpha_n z - \alpha_n + |\alpha_n|^2 z}{(1 - \frac{\alpha_n z}{\alpha_n}) \alpha_n} \right| = \left| \frac{\alpha_n z - \alpha_n - |\alpha_n|^2 z}{(1 - \frac{\alpha_n z}{\alpha_n}) \alpha_n} \right| = |\alpha_n - 1| \left| \frac{\alpha_n + z |\alpha_n|}{(1 - \frac{\alpha_n z}{\alpha_n}) \alpha_n} \right| = |\alpha_n - 1| \left| \frac{1 + z (|\alpha_n|/\alpha_n)}{(1 - \frac{\alpha_n z}{\alpha_n})} \right| \leq |\alpha_n - 1| \left| \frac{1 + |z|}{1 - |z|} \right| \leq |\alpha_n - 1| \left| \frac{1 + r}{1 - r} \right|
$$

and so the assumption on the sum gives uniform convergence of the product on $B(0, r)$ to an analytic function. Since $r < 1$ is arbitrary, this shows $B(z)$ is analytic on $B(0, 1)$ and has the specified zeros because the only place the factors equal zero are at the $\alpha_n$ or 0.

Now consider the factors in the product. The claim is that they are all no larger in absolute value than 1. This is very easy to see from the maximum modulus theorem. Let $|\alpha| < 1$ and $\phi(z) = \frac{\alpha - z}{1 - \bar{\alpha} z}$. Then $\phi$ is analytic near $B(0, 1)$ because its only pole is $1/\bar{\alpha}$. Consider $z = e^{i\theta}$. Then

$$
|\phi(e^{i\theta})| = \left| \frac{\alpha - e^{i\theta}}{1 - \bar{\alpha} e^{i\theta}} \right| = \left| \frac{1 - \alpha e^{-i\theta}}{1 - \bar{\alpha} e^{i\theta}} \right| = 1.
$$

Thus the modulus of $\phi(z)$ equals 1 on $\partial B(0, 1)$. Therefore, by the maximum modulus theorem, $|\phi(z)| < 1$ if $|z| < 1$. This proves the claim that the terms in the product are no larger than 1 and shows the function determined by the Blaschke product is bounded. This proves the theorem.

Note in the conditions for this theorem the one for the sum, $\sum_{n=1}^{\infty} (1 - |\alpha_n|) < \infty$. The Blaschke product gives an analytic function, whose absolute value is bounded by 1 and which has the $\alpha_n$ as zeros. What if you had a bounded function, analytic on $B(0, 1)$ which had zeros at $\{\alpha_k\}$? Could you conclude the condition on
the sum? The answer is yes. In fact, you can get by with less than the assumption that \( f \) is bounded but this will not be presented here. See Rudin [102]. This theorem is an exciting use of Jensen’s equation.

**Theorem 55.5.2** Suppose \( f \) is an analytic function on \( B(0,1) \), \( f(0) \neq 0 \), and \( |f(z)| \leq M \) for all \( z \in B(0,1) \). Suppose also that the zeros of \( f \) are \( \{\alpha_k\}_{k=1}^{\infty} \), listed according to multiplicity. Then \( \sum_{k=1}^{\infty} (1 - |\alpha_k|) < \infty \).

**Proof:** If there are only finitely many zeros, there is nothing to prove so assume there are infinitely many. Also let the zeros be listed such that \( |\alpha_n| \geq |\alpha_{n+1}| \cdots \). Let \( n(r) \) denote the number of zeros in \( B(0,r) \). By Jensen’s formula,

\[
\ln |f(0)| + \sum_{i=1}^{n(r)} \ln r - \ln |\alpha_i| = \frac{1}{2\pi} \int_0^{2\pi} \ln |f(re^{i\theta})| \, d\theta \leq \ln (M).
\]

Therefore, by the mean value theorem,

\[
\sum_{i=1}^{n(r)} \frac{1}{r} (r - |\alpha_i|) \leq \sum_{i=1}^{n(r)} \ln r - \ln |\alpha_i| \leq \ln (M) - \ln |f(0)|
\]

As \( r \to 1^- \), \( n(r) \to \infty \), and so an application of Fatou’s lemma yields

\[
\sum_{i=1}^{\infty} (1 - |\alpha_i|) \leq \liminf_{r \to 1^-} \frac{1}{r} \sum_{i=1}^{n(r)} (r - |\alpha_i|) \leq \ln (M) - \ln |f(0)|.
\]

This proves the theorem.

You don’t need the assumption that \( f(0) \neq 0 \).

**Corollary 55.5.3** Suppose \( f \) is an analytic function on \( B(0,1) \) and \( |f(z)| \leq M \) for all \( z \in B(0,1) \). Suppose also that the nonzero zeros \( \{\alpha_k\}_{k=1}^{n} \) of \( f \) are \( \{\alpha_k\}_{k=1}^{\infty} \), listed according to multiplicity. Then \( \sum_{k=1}^{\infty} (1 - |\alpha_k|) < \infty \).

**Proof:** Suppose \( f \) has a zero of order \( m \) at 0. Then consider the analytic function, \( g(z) = f(z)/z^m \) which has the same zeros except for 0. The argument goes the same way except here you use \( g \) instead of \( f \) and only consider \( r > r_0 > 0 \).

\[\text{This is a fun thing to say: nonzero zeros.}\]
Thus from Jensen’s equation,

\[
\ln |g(0)| + \sum_{i=1}^{n(r)} \ln r - \ln |\alpha_i|
\]

\[
= \frac{1}{2\pi} \int_{0}^{2\pi} \ln |g(re^{i\theta})| \, d\theta
\]

\[
= \frac{1}{2\pi} \int_{0}^{2\pi} \ln |f(re^{i\theta})| \, d\theta - \frac{1}{2\pi} \int_{0}^{2\pi} m \ln (r)
\]

\[
\leq M + \frac{1}{2\pi} \int_{0}^{2\pi} m \ln (r^{-1})
\]

\[
\leq M + m \ln \left(\frac{1}{r_0}\right).
\]

Now the rest of the argument is the same.

An interesting restatement yields the following amazing result.

**Corollary 55.5.4** Suppose \( f \) is analytic and bounded on \( B(0, 1) \) having zeros \( \{\alpha_n\} \).

Then if \( \sum_{k=1}^{\infty} (1 - |\alpha_n|) = \infty \), it follows \( f \) is identically equal to zero.

55.5.1 The Müntz-Szasz Theorem Again

Corollary makes possible an easy proof of a remarkable theorem named above which yields a wonderful generalization of the Weierstrass approximation theorem. In what follows \( b > 0 \). The Weierstrass approximation theorem states that linear combinations of \( 1, t, t^2, t^3, \ldots \) (polynomials) are dense in \( C([0, b]) \). Let \( \lambda_1 < \lambda_2 < \lambda_3 < \cdots \) be an increasing list of positive real numbers. This theorem tells when linear combinations of \( 1, t^{\lambda_1}, t^{\lambda_2}, \cdots \) are dense in \( C([0, b]) \). The proof which follows is like the one given in Rudin [102]. There is a much longer one in Cheney [32] which discusses more aspects of the subject. See also Page 520 where the version given in Cheney is presented. This other approach is much more elementary and does not depend in any way on the theory of functions of a complex variable. There are those of us who automatically prefer real variable techniques. Nevertheless, this proof by Rudin is a very nice and insightful application of the preceding material. Cheney refers to the theorem as the second Müntz theorem. I guess Szasz must also have been involved.

**Theorem 55.5.5** Let \( \lambda_1 < \lambda_2 < \lambda_3 < \cdots \) be an increasing list of positive real numbers and let \( a > 0 \). If

\[
\sum_{n=1}^{\infty} \frac{1}{\lambda_n} = \infty, \tag{55.5.23}
\]

then linear combinations of \( 1, t^{\lambda_1}, t^{\lambda_2}, \cdots \) are dense in \( C([0, b]) \).
Proof: Let \( X \) denote the closure of linear combinations of \( \{1, t^{\lambda_1}, t^{\lambda_2}, \ldots\} \) in \( C([0,b]) \). If \( X \neq C([0,b]) \), then let \( f \in C([0,b]) \setminus X \), define \( \Lambda \in C([0,b])' \) as follows. First let \( \Lambda_0 : X + \mathbb{C}f \) be given by \( \Lambda_0 (g + \alpha f) = \alpha \|f\|_{\infty} \). Then
\[
\sup_{\|g + \alpha f\| \leq 1} |\Lambda_0 (g + \alpha f)| = \sup_{\|g + \alpha f\| \leq 1} |\alpha| \|f\|_{\infty}
= \sup_{\|g + \alpha f\| \leq \frac{1}{\eta}} |\alpha| \|f\|_{\infty}
= \sup_{\|f + \alpha f\| \leq \frac{1}{\eta}} |\alpha| \|f\|_{\infty}
\]
Now \( \text{dist} (f, X) > 0 \) because \( X \) is closed. Therefore, there exists a lower bound, \( \eta > 0 \) to \( \|g + f\| \) for \( g \in X \). Therefore, the above is no larger than
\[
\sup_{|\alpha| \leq \frac{1}{\eta}} |\alpha| \|f\|_{\infty} = \left( \frac{1}{\eta} \right) \|f\|_{\infty}
\]
which shows that \( \|\Lambda_0\| \leq \left( \frac{1}{\eta} \right) \|f\|_{\infty} \). By the Hahn Banach theorem \( \Lambda_0 \) can be extended to \( \Lambda \in C([0,b])' \) which has the property that \( \Lambda(X) = 0 \) but \( \Lambda(f) = \|f\| \neq 0 \). By the Weierstrass approximation theorem, Theorem 7.1.6 or one of its cases, there exists a polynomial, \( p \) such that \( \Lambda(p) \neq 0 \). Therefore, if it can be shown that whenever \( \Lambda(X) = 0 \), it is the case that \( \Lambda(p) = 0 \) for all polynomials, it must be the case that \( X \) is dense in \( C([0,b]) \).

By the Riesz representation theorem the elements of \( C([0,b])' \) are complex measures. Suppose then that for \( \mu \) a complex measure it follows that for all \( \lambda_k \),
\[
\int_{[0,b]} t^{\lambda_k} d\mu = 0.
\]
I want to show that then
\[
\int_{[0,b]} t^k d\mu = 0
\]
for all positive integers. It suffices to modify \( \mu \) is necessary to have \( \mu (\{0\}) = 0 \) since this will not change any of the above integrals. Let \( \mu_1 (E) = \mu (E \cap (0,b)) \) and use \( \mu_1 \). I will continue using the symbol, \( \mu \).

For \( \text{Re} (z) > 0 \), define
\[
F(z) = \int_{[0,b]} t^{-z} d\mu = \int_{(0,b)} t^{-z} d\mu
\]
The function \( t^z = \exp (z \ln (t)) \) is analytic. I claim that \( F(z) \) is also analytic for \( \text{Re} z > 0 \). Apply Morera’s theorem. Let \( T \) be a triangle in \( \text{Re} z > 0 \). Then
\[
\int_{\partial T} F(z) dz = \int_{\partial T} \int_{(0,b)} e^{(z \ln (t))} \xi d|\mu| \, dz
\]
Now \( \int_{\partial T} \) can be split into three integrals over intervals of \( \mathbb{R} \) and so this integral is essentially a Lebesgue integral taken with respect to Lebesgue measure. Furthermore, \( e^{(z \ln(t))} \) is a continuous function of the two variables and \( \xi \) is a function of only the one variable, \( t \). Thus the integrand is product measurable. The iterated integral is also absolutely integrable because \( |e^{(z \ln(t))}| \leq e^{x\ln t} \leq e^{x\ln b} \) where \( x + iy = z \) and \( x \) is given to be positive. Thus the integrand is actually bounded. Therefore, you can apply Fubini’s theorem and write

\[
\int_{\partial T} F(z) \, dz = \int_{\partial T} \int_{[0,b]} e^{(z \ln(t))} \xi d|\mu| \, dz
\]

By Morera’s theorem, \( F \) is analytic on \( \text{Re} \, z > 0 \) which is given to have zeros at the \( \lambda_k \).

Now let \( \phi(z) = \frac{1+z}{1-z} \). Then \( \phi \) maps \( B(0,1) \) one to one onto \( \text{Re} \, z > 0 \). Let \( 0 < r < 1 \).

\[
\phi(re^{i\theta}) = \frac{1 + re^{i\theta}}{1 - re^{i\theta}} = \frac{1 - r^2 + i2r \sin \theta}{1 + r^2 - 2r \cos \theta}
\]

and so \( \text{Re} \, \phi(re^{i\theta}) > 0 \). Now the inverse of \( \phi \) is \( \phi^{-1}(z) = \frac{z-1}{z+1} \). For \( \text{Re} \, z > 0 \),

\[
|\phi^{-1}(z)|^2 = \frac{z-1}{z+1} \cdot \frac{\overline{z} - 1}{\overline{z} + 1} = \frac{|z|^2 - 2 \text{Re} \, z + 1}{|z|^2 + 2 \text{Re} \, z + 1} < 1.
\]

Consider \( F \circ \phi \), an analytic function defined on \( B(0,1) \). This function is given to have zeros at \( z_n \) where \( \phi(z_n) = \frac{1+z_n}{1-z_n} = \lambda_n \). This reduces to \( z_n = \frac{-1+\lambda_n}{1+\lambda_n} \). Now

\[
1 - |z_n| \geq \frac{c}{1 + \lambda_n}
\]

for a positive constant, \( c \). It is given that \( \sum \frac{1}{\lambda_n} = \infty \), so it follows \( \sum (1 - |z_n|) = \infty \) also. Therefore, by Corollary 55.5.3, \( F \circ \phi = 0 \). It follows \( F = 0 \) also. In particular, \( F(k) \) for \( k \) a positive integer equals zero. This has shown that if \( \Lambda \in C((0,b)^t \) and \( \Lambda \) sends 1 and all the \( t^k \) to 0, then \( \Lambda \) sends 1 and all \( t^k \) for \( k \) a positive integer to zero. As explained above, \( X \) is dense in \( C((0,b)^t \).

The converse of this theorem is also true and is proved in Rudin [102].

55.6 Exercises

1. Suppose \( f \) is an entire function with \( f(0) = 1 \). Let

\[
M(r) = \max \{|f(z)| : |z| = r\}.
\]

Use Jensen’s equation to establish the following inequality.

\[
M(2r) \geq 2^{n(r)}
\]

where \( n(r) \) is the number of zeros of \( f \) in \( B(0,r) \).
2. The version of the Blaschke product presented above is that found in most complex variable texts. However, there is another one in [30]. Instead of \( \frac{\alpha_n - z}{1 - \overline{\alpha_n} z} \), you use \( \frac{\alpha_n - z}{\overline{\alpha_n} - z} \).

Prove a version of Theorem 55.5.1 using this modification.

3. The Weierstrass approximation theorem holds for polynomials of \( n \) variables on any compact subset of \( \mathbb{R}^n \). Give a multidimensional version of the Müntz-Szasz theorem which will generalize the Weierstrass approximation theorem for \( n \) dimensions. You might just pick a compact subset of \( \mathbb{R}^n \) in which all components are positive. You have to do something like this because otherwise, \( t^3 \) might not be defined.

4. Show \( \cos(\pi z) = \prod_{k=1}^{\infty} \left( 1 - \frac{4z^2}{(2k-1)^2} \right) \).

5. Recall \( \sin(\pi z) = z\pi \prod_{n=1}^{\infty} \left( 1 - \left( \frac{z}{n} \right)^2 \right) \). Use this to derive Wallis product, \( \frac{\pi}{2} = \prod_{k=1}^{\infty} \frac{(4k)^3}{(2k-1)(2k+1)} \).

6. The order of an entire function, \( f \) is defined as

\[
\inf \left\{ a \geq 0 : |f(z)| \leq e^{a|z|^n} \text{ for all large enough } |z| \right\}
\]

If no such \( a \) exists, the function is said to be of infinite order. Show the order of an entire function is also equal to \( \limsup_{r \to \infty} \frac{\ln(\ln(M(r)))}{\ln(r)} \) where \( M(r) \equiv \max \{|f(z)| : |z| = r\} \).

7. Suppose \( \Omega \) is a simply connected region and let \( f \) be meromorphic on \( \Omega \). Suppose also that the set, \( \{ z \in \Omega : f(z) = c \} \) has a limit point in \( \Omega \). Can you conclude \( f(z) = c \) for all \( z \in \Omega \)?

8. This and the next collection of problems are dealing with the gamma function. Show that

\[
\left| \left( 1 + \frac{z}{n} \right) e^{-\frac{z}{n}} - 1 \right| \leq \frac{C(z)}{n^2}
\]

and therefore,

\[
\sum_{n=1}^{\infty} \left| \left( 1 + \frac{z}{n} \right) e^{-\frac{z}{n}} - 1 \right| < \infty
\]

with the convergence uniform on compact sets.

9. \( \uparrow \) Show \( \prod_{n=1}^{\infty} \left( 1 + \frac{z}{n} \right) e^{-\frac{z}{n}} \) converges to an analytic function on \( \mathbb{C} \) which has zeros only at the negative integers and that therefore,

\[
\prod_{n=1}^{\infty} \left( 1 + \frac{z}{n} \right)^{-1} e^{\frac{z}{n}}
\]
10. Show there exists \( \gamma \) such that if
\[
\Gamma (z) = \frac{e^{-\gamma z}}{z} \prod_{n=1}^{\infty} \left( 1 + \frac{z}{n} \right)^{-1} e^{\frac{z}{n}},
\]
then \( \Gamma (1) = 1 \). Thus \( \Gamma \) is a meromorphic function having simple poles at the negative integers. **Hint:** \( \prod_{n=1}^{\infty} (1 + n)^{1/n} e^{-1/n} = c = e^\gamma \).

11. Now show that
\[
\gamma = \lim_{n \to \infty} \left[ \sum_{k=1}^{n} \frac{1}{k} - \ln n \right]
\]

12. Justify the following argument leading to Gauss’s formula
\[
\Gamma (z) = \lim_{n \to \infty} \left( \prod_{k=1}^{n} \left( \frac{k}{k+z} \right) e^{\frac{z}{k}} \right) \frac{e^{-\gamma z}}{z}
\]
\[
= \lim_{n \to \infty} \frac{n!}{(1+z)(2+z)\cdots(n+z)} e^{z(\sum_{k=1}^{n} \frac{1}{k})} \frac{e^{-\gamma z}}{z}
\]
\[
= \lim_{n \to \infty} \frac{n!}{(1+z)(2+z)\cdots(n+z)} e^{z[\sum_{k=1}^{n} \frac{1}{k} - \ln n]} \frac{e^{-\gamma z}}{z}
\]
\[
= \lim_{n \to \infty} \frac{n!}{(1+z)(2+z)\cdots(n+z)} e^{-\gamma z}
\]

13. Verify from the Gauss formula above that \( \Gamma (z+1) = \Gamma (z) z \) and that for \( n \) a nonnegative integer, \( \Gamma (n+1) = n! \).

14. The usual definition of the gamma function for positive \( x \) is
\[
\Gamma_1 (x) = \int_{0}^{\infty} e^{-t} t^{x-1} dt.
\]
Show \( \left( 1 - \frac{t}{n} \right)^n \leq e^{-t} \) for \( t \in [0, n] \). Then show
\[
\int_{0}^{n} \left( 1 - \frac{t}{n} \right)^n t^{x-1} dt = \frac{n! n^x}{x(x+1)\cdots(x+n)}.
\]
Use the first part to conclude that
\[
\Gamma_1 (x) = \lim_{n \to \infty} \frac{n! n^x}{x(x+1)\cdots(x+n)} = \Gamma (x).
\]
**Hint:** To show \( \left( 1 - \frac{u}{n} \right)^n \leq e^{-u} \) for \( u \in [0, 1] \), verify this is equivalent to showing \( 1-u \leq e^{-nu} \) for \( u \in [0, 1] \).
15. Show \( \Gamma (z) = \int_0^\infty e^{-tz} \frac{dt}{t} \) whenever \( \text{Re } z > 0 \). \textbf{Hint:} You have already shown that this is true for positive real numbers. Verify this formula for \( \text{Re } z > 0 \) yields an analytic function.

16. Show \( \left( \frac{1}{2} \right) = \sqrt{\pi} \). Then find \( \Gamma \left( \frac{5}{2} \right) \).

17. Show that \( \int_{-\infty}^{\infty} e^{-\frac{s^2}{2}} ds = \sqrt{2\pi} \). \textbf{Hint:} Denote this integral by \( I \) and observe that \( I^2 = \int_{\mathbb{R}^2} e^{-(x^2+y^2)/2} dxdy \). Then change variables to polar coordinates, \( x = r \cos(\theta), y = r \sin \theta \).

18. Now that you know what the gamma function is, consider in the formula for \( \Gamma (\alpha + 1) \) the following change of variables. \( t = \alpha + 1/s \). Then in terms of the new variable, \( s \), the formula for \( \Gamma (\alpha + 1) \) is

\[
e^{-\alpha} \alpha^{\alpha + \frac{1}{2}} \int_{-\sqrt{\alpha}}^{\infty} e^{-\sqrt{s}} \left( 1 + \frac{s}{\sqrt{\alpha}} \right)^\alpha ds
\]

\[
e^{-\alpha} \alpha^{\alpha + \frac{1}{2}} \int_{-\sqrt{\alpha}}^{\infty} e^{\alpha \left( \ln(1+\frac{1}{\sqrt{\alpha}}) - \frac{1}{s} \right)} ds
\]

Show the integrand converges to \( e^{-\frac{s^2}{2}} \). Show that then

\[
\lim_{\alpha \to \infty} \frac{\Gamma (\alpha + 1)}{e^{-\alpha} \alpha^{\alpha + (1/2)}} = \int_{-\infty}^{\infty} e^{-\frac{s^2}{2}} ds = \sqrt{2\pi}.
\]

\textbf{Hint:} You will need to obtain a dominating function for the integral so that you can use the dominated convergence theorem. You might try considering \( s \in (-\sqrt{\alpha}, \sqrt{\alpha}) \) first and consider something like \( e^{1-(s^2/4)} \) on this interval. Then look for another function for \( s > \sqrt{\alpha} \). This formula is known as Stirling’s formula.

19. This and the next several problems develop the zeta function and give a relation between the zeta and the gamma function. Define for \( 0 < r < 2\pi \)

\[
I_r (z) = \int_0^{2\pi} e^{(z-1)(\ln r + i\theta)} \frac{ire^\theta}{e^{re^\theta} - 1} d\theta + \int_r^\infty e^{(z-1)(\ln t + 2\pi i)} \frac{ire^\theta}{e^{re^\theta} - 1} dt (55.6.24)
\]

\[+ \int_{\infty}^r e^{(z-1)\ln t} \frac{ire^\theta}{e^{re^\theta} - 1} dt
\]

Show that \( I_r \) is an entire function. The reason \( 0 < r < 2\pi \) is that this prevents \( e^{re^\theta} - 1 \) from equaling zero. The above is just a precise description of the contour integral, \( \int_{\gamma} \frac{e^{z-1}}{e^{\gamma} - 1} dw \) where \( \gamma \) is the contour shown below.
in which on the integrals along the real line, the argument is different in going from \( r \) to \( \infty \) than it is in going from \( \infty \) to \( r \). Now I have not defined such contour integrals over contours which have infinite length and so have chosen to simply write out explicitly what is involved. You have to work with these integrals given above anyway but the contour integral just mentioned is the motivation for them. **Hint:** You may want to use convergence theorems from real analysis if it makes this more convenient but you might not have to.

20. \( \uparrow \) In the context of Problem 19 define for small \( \delta > 0 \)

\[
I_{r\delta}(z) = \int_{\gamma_{r\delta}} \frac{w^{z-1}}{e^w - 1} \, dw
\]

where \( \gamma_{r\delta} \) is shown below.

Show that \( \lim_{\delta \to 0} I_{r\delta}(z) = I_r(z) \). **Hint:** Use the dominated convergence theorem if it makes this go easier. This is not a hard problem if you use these theorems but you can probably do it without them with more work.

21. \( \uparrow \) In the context of Problem 20 show that for \( r_1 < r \), \( I_{r\delta}(z) - I_{r_1\delta}(z) \) is a contour integral,

\[
\int_{\gamma_{r_1,\delta}} \frac{w^{z-1}}{e^w - 1} \, dw
\]

where the oriented contour is shown below.
In this contour integral, \( w^{z-1} \) denotes \( e^{(z-1)\log(w)} \) where \( \log(w) = \ln|w| + i\arg(w) \) for \( \arg(w) \in (0,2\pi) \). Explain why this integral equals zero. From Problem 24 it follows that \( I_r = I_{r_1} \). Therefore, you can define an entire function, \( I(z) \equiv I_r(z) \) for all \( r \) positive but sufficiently small. Hint: Remember the Cauchy integral formula for analytic functions defined on simply connected regions. You could argue there is a simply connected region containing \( \gamma_{r,r_1,\delta} \).

22. \( \uparrow \) In case \( \text{Re} \, z > 1 \), you can get an interesting formula for \( I(z) \) by taking the limit as \( r \to 0 \). Recall that

\[
I_r(z) = \int_0^{2\pi} \frac{e^{(z-1)(\ln r + i\theta)} - 1}{e^{re^{i\theta}} - 1} ire^{i\theta} d\theta + \int_r^\infty \frac{e^{(z-1)(\ln t + 2\pi i)}}{e^t - 1} dt (55.6.25)
\]

and now it is desired to take a limit in the case where \( \text{Re} \, z > 1 \). Show the first integral above converges to 0 as \( r \to 0 \). Next argue the sum of the two last integrals converges to

\[
\left(e^{(z-1)2\pi i} - 1\right) \int_0^\infty \frac{e^{(z-1)\ln(t)}}{e^t - 1} dt.
\]

Thus

\[
I(z) = \left(e^{z\pi i} - 1\right) \int_0^\infty \frac{e^{(z-1)\ln(t)}}{e^t - 1} dt \quad (55.6.26)
\]

when \( \text{Re} \, z > 1 \).

23. \( \uparrow \) So what does all this have to do with the zeta function and the gamma function? The zeta function is defined for \( \text{Re} \, z > 1 \) by

\[
\sum_{n=1}^\infty \frac{1}{n^z} \equiv \zeta(z).
\]

By Problem 25 whenever \( \text{Re} \, z > 0 \),

\[
\Gamma(z) = \int_0^\infty e^{-t}t^{z-1} dt.
\]
Change the variable and conclude
\[
\Gamma(z) \frac{1}{n^z} = \int_0^\infty e^{-ns} s^{z-1} ds.
\]
Therefore, for \(\text{Re } z > 1\),
\[
\zeta(z) \Gamma(z) = \sum_{n=1}^{\infty} \int_0^\infty e^{-ns} s^{z-1} ds.
\]
Now show that you can interchange the order of the sum and the integral. This is possibly most easily done by using Fubini’s theorem. Show that \(\sum_{n=1}^{\infty} \int_0^\infty |e^{-ns}s^{z-1}| ds < \infty\) and then use Fubini’s theorem. I think you could do it other ways though. It is possible to do it without any reference to Lebesgue integration. Thus
\[
\zeta(z) \Gamma(z) = \int_0^\infty s^{z-1} \sum_{n=1}^{\infty} e^{-ns} ds
\]
\[
= \int_0^\infty \frac{s^{z-1}e^{-s}}{1-e^{-s}} ds = \int_0^\infty \frac{s^{z-1}ds}{e^s - 1}
\]
By 55.6.26,
\[
I(z) = (e^{z2\pi i} - 1) \int_0^\infty \frac{e^{(z-1)\ln(t)}}{e^t - 1} dt
\]
\[
= (e^{z2\pi i} - 1) \zeta(z) \Gamma(z)
\]
\[
= (e^{2\pi iz} - 1) \zeta(z) \Gamma(z)
\]
whenever \(\text{Re } z > 1\).

24. ↑ Now show there exists an entire function, \(h(z)\) such that
\[
\zeta(z) = \frac{1}{z-1} + h(z)
\]
for \(\text{Re } z > 1\). Conclude \(\zeta(z)\) extends to a meromorphic function defined on all of \(\mathbb{C}\) which has a simple pole at \(z = 1\), namely, the right side of the above formula. Hint: Use Problem 10 to observe that \(\Gamma(z)\) is never equal to zero but has simple poles at every nonnegative integer. Then for \(\text{Re } z > 1\),
\[
\zeta(z) \equiv \frac{I(z)}{(e^{2\pi iz} - 1) \Gamma(z)}.
\]
By 55.6.27 \(\zeta\) has no poles for \(\text{Re } z > 1\). The right side of the above equation is defined for all \(z\). There are no poles except possibly when \(z\) is a nonnegative integer. However, these points are not poles either because of Problem 10 which states that \(\Gamma\) has simple poles at these points thus cancelling the simple
zeros of \((e^{2\pi i z} - 1)\). The only remaining possibility for a pole for \(\zeta\) is at \(z = 1\). Show it has a simple pole at this point. You can use the formula for \(I(z)\)

\[
I(z) \equiv \int_0^{2\pi} \frac{e^{(z-1)(\ln r + i\theta)}}{e^{\theta i} - 1} ire^{i\theta} d\theta + \int_r^{\infty} \frac{e^{(z-1)(\ln t + 2\pi i)}}{e^t - 1} dt
\]

(55.6.27)

Thus \(I(1)\) is given by

\[
I(1) \equiv \int_0^{2\pi} \frac{1}{e^{\theta i} - 1} ire^{i\theta} d\theta + \int_r^{\infty} \frac{1}{e^t - 1} dt + \int_\infty^r \frac{1}{e^t - 1} dt
\]

\[= \int_{\gamma_r} \frac{dw}{e^{\omega} - 1}\] where \(\gamma_r\) is the circle of radius \(r\). This contour integral equals \(2\pi i\) by the residue theorem. Therefore,

\[\frac{I(z)}{(e^{2\pi i z} - 1) \Gamma(z)} = \frac{1}{z - 1} + h(z)\]

where \(h(z)\) is an entire function. People worry a lot about where the zeros of \(\zeta\) are located. In particular, the zeros for \(\text{Re} \, z \in (0, 1)\) are of special interest. The Riemann hypothesis says they are all on the line \(\text{Re} \, z = 1 = 2\). This is a good problem for you to do next.

25. There is an important relation between prime numbers and the zeta function due to Euler. Let \(\{p_n\}_{n=1}^\infty\) be the prime numbers. Then for \(\text{Re} \, z > 1\),

\[\prod_{n=1}^{\infty} \frac{1}{1 - p_n^{-z}} = \zeta(z)\,.
\]

To see this, consider a partial product.

\[\prod_{n=1}^{N} \frac{1}{1 - p_n^{-z}} = \prod_{n=1}^{N} \sum_{j=1}^{\infty} \left( \frac{1}{p_n^z} \right)^j \,.
\]

Let \(S_N\) denote all positive integers which use only \(p_1, \ldots, p_N\) in their prime factorization. Then the above equals \(\sum_{n \in S_N} \frac{1}{n^z}\). Letting \(N \to \infty\) and using the fact that \(\text{Re} \, z > 1\) so that the order in which you sum is not important (See Theorem [56.0.1] or recall advanced calculus.) you obtain the desired equation. Show \(\sum_{n=1}^{\infty} \frac{1}{p_n} = \infty\).
Chapter 56

Elliptic Functions

This chapter is to give a short introduction to elliptic functions. There is much more available. There are books written on elliptic functions. What I am presenting here follows Alfors [2] although the material is found in many books on complex analysis. Hille, [59] has a much more extensive treatment than what I will attempt here. There are also many references and historical notes available in the book by Hille. Another good source for more having much the same emphasis as what is presented here is in the book by Saks and Zygmund [104]. This is a very interesting subject because it has considerable overlap with algebra.

Before beginning, recall that an absolutely convergent series can be summed in any order and you always get the same answer. The easy way to see this is to think of the series as a Lebesgue integral with respect to counting measure and apply convergence theorems as needed. The following theorem provides the necessary results.

**Theorem 56.0.1** Suppose \( \sum_{n=1}^{\infty} |a_n| < \infty \) and let \( \theta, \phi : \mathbb{N} \to \mathbb{N} \) be one to one and onto mappings. Then \( \sum_{n=1}^{\infty} a_{\phi(n)} \) and \( \sum_{n=1}^{\infty} a_{\theta(n)} \) both converge and the two sums are equal.

**Proof:** By the monotone convergence theorem,

\[
\sum_{n=1}^{\infty} |a_n| = \lim_{n \to \infty} \sum_{k=1}^{n} |a_{\phi(k)}| = \lim_{n \to \infty} \sum_{k=1}^{n} |a_{\theta(k)}|
\]

but these last two equal \( \sum_{k=1}^{\infty} |a_{\phi(k)}| \) and \( \sum_{k=1}^{\infty} |a_{\theta(k)}| \) respectively. Therefore, \( \sum_{k=1}^{\infty} a_{\theta(k)} \) and \( \sum_{k=1}^{\infty} a_{\phi(k)} \) exist (\( n \to a_{\theta(n)} \) is in \( L^1 \) with respect to counting measure.) It remains to show the two are equal. There exists \( M \) such that if \( n > M \) then

\[
\sum_{k=n+1}^{\infty} |a_{\phi(k)}| < \varepsilon, \quad \sum_{k=n+1}^{\infty} |a_{\theta(k)}| < \varepsilon
\]
\[
\sum_{k=1}^{\infty} a_{\phi(k)} - \sum_{k=1}^{n} a_{\phi(k)} < \varepsilon, \quad \sum_{k=1}^{\infty} a_{\theta(k)} - \sum_{k=1}^{n} a_{\theta(k)} < \varepsilon
\]
CHAPTER 56. ELLIPTIC FUNCTIONS

Pick such an \( n \) denoted by \( n_1 \). Then pick \( n_2 > n_1 > M \) such that
\[
\{ \theta(1), \cdots, \theta(n_1) \} \subseteq \{ \phi(1), \cdots, \phi(n_2) \}.
\]
Then
\[
\sum_{k=1}^{n_2} a_{\phi(k)} = \sum_{k=1}^{n_1} a_{\theta(k)} + \sum_{\phi(k) \notin \{\theta(1), \cdots, \theta(n_1)\}} a_{\phi(k)}.
\]
Therefore,
\[
\left| \sum_{k=1}^{n_2} a_{\phi(k)} - \sum_{k=1}^{n_1} a_{\theta(k)} \right| = \left| \sum_{\phi(k) \notin \{\theta(1), \cdots, \theta(n_1)\}, k \leq n_2} a_{\phi(k)} \right|
\]
Now all of these \( \phi(k) \) in the last sum are contained in \( \{ \theta(n_1 + 1), \cdots \} \) and so the last sum above is dominated by
\[
\leq \sum_{k=n_1+1}^{\infty} |a_{\theta(k)}| < \varepsilon.
\]
Therefore,
\[
\left| \sum_{k=1}^{\infty} a_{\phi(k)} - \sum_{k=1}^{\infty} a_{\theta(k)} \right| \leq \left| \sum_{k=1}^{n_2} a_{\phi(k)} - \sum_{k=1}^{n_1} a_{\theta(k)} \right| + \sum_{k=1}^{n_2} a_{\phi(k)} - \sum_{k=1}^{n_1} a_{\theta(k)}
\]
and since \( \varepsilon \) is arbitrary, it follows \( \sum_{k=1}^{\infty} a_{\phi(k)} = \sum_{k=1}^{\infty} a_{\theta(k)} \) as claimed. This proves the theorem.

56.1 Periodic Functions

Definition 56.1.1 A function defined on \( \mathbb{C} \) is said to be periodic if there exists \( w \) such that \( f(z + w) = f(z) \) for all \( z \in \mathbb{C} \). Denote by \( M \) the set of all periods. Thus if \( w_1, w_2 \in M \) and \( a, b \in \mathbb{Z}, \) then \( aw_1 + bw_2 \in M \). For this reason \( M \) is called the module of periods. In all which follows it is assumed \( f \) is meromorphic.

Theorem 56.1.2 Let \( f \) be a meromorphic function and let \( M \) be the module of periods. Then if \( M \) has a limit point, then \( f \) equals a constant. If this does not happen then either there exists \( w_1 \in M \) such that \( Zw_1 = M \) or there exist \( w_1, w_2 \in M \) such that \( M = \{ aw_1 + bw_2 : a, b \in \mathbb{Z} \} \) and \( w_1/w_2 \) is not real. Also if \( \tau = w_2/w_1, \)
\[
|\tau| \geq 1, \quad -\frac{1}{2} \leq \Re \tau \leq \frac{1}{2}.
\]

1 A module is like a vector space except instead of a field of scalars, you have a ring of scalars.
Proof: Suppose \( f \) is meromorphic and \( M \) has a limit point, \( w_0 \). By Theorem 56.1.3 on Page 1662 there exist analytic functions, \( p,q \) such that \( f(z) = \frac{p(z)}{q(z)} \). Now pick \( z_0 \) such that \( z_0 \) is not a pole of \( f \). Then letting \( w_n \to w_0 \) where \( \{w_n\} \subseteq M \), \( f(z_0 + w_n) = f(z_0) \). Therefore, \( p(z_0 + w_n) = f(z_0) q(z_0 + w_n) \) and so the analytic function, \( p(z) - f(z_0) q(z) \) has a zero set which has a limit point. Therefore, this function is identically equal to zero because of Theorem 56.1.4 on Page 1662. Thus \( f \) equals a constant as claimed.

This has shown that if \( f \) is not constant, then \( M \) is discrete. Therefore, there exists \( w_1 \in M \) such that \(|w_1| = \min \{|w| : w \in M\} \). Suppose first that every element of \( M \) is a real multiple of \( w_1 \). Thus, if \( w \in M \), it follows there exists a real number, \( x \) such that \( w = xw_1 \). Then there exist positive integers, \( k,k+1 \) such that \( k \leq x < k+1 \). If \( x > k \), then \( xw_1 - kw_1 = (x-k)w_1 \) is a period having smaller absolute value than \(|w_1|\) which would be a contradiction. Hence, \( x = k \) and so \( M = \mathbb{Z}w_1 \).

Now suppose there exists \( w_2 \in M \) which is not a real multiple of \( w_1 \). You can let \( w_2 \) be the element of \( M \) having this property which has smallest absolute value. Now let \( w \in M \). Since \( w_1 \) and \( w_2 \) point in different directions, it follows \( w = xw_1 + yw_2 \) for some real numbers, \( x,y \). Let \(|m-x| \leq \frac{1}{2} \) and \(|n - y| \leq \frac{1}{2} \) where \( m,n \) are integers. Therefore,

\[
w = mw_1 + nw_2 + (x-m)w_1 + (y-n)w_2
\]

and so

\[
w - mw_1 - nw_2 = (x-m)w_1 + (y-n)w_2
\]  \hspace{1cm} (56.1.1)

Now since \( w_2/w_1 \notin \mathbb{R} \),

\[
|\{(x-m)w_1 + (y-n)w_2\}| < \{|(x-m)w_1| + |(y-n)w_2|\} = \frac{1}{2}|w_1| + \frac{1}{2}|w_2|.
\]

Therefore, from \( \text{ Sin. \& } \),

\[
|w - mw_1 - nw_2| = |(x-m)w_1 + (y-n)w_2| < \frac{1}{2}|w_1| + \frac{1}{2}|w_2| \leq |w_2|
\]

and so the period, \( w - mw_1 - nw_2 \) cannot be a non real multiple of \( w_1 \) because \( w_2 \) is the one which has smallest absolute value and this period has smaller absolute value than \( w_2 \). Therefore, the ratio \( w - mw_1 - nw_2/w_1 \) must be a real number, \( x \). Thus

\[
w - mw_1 - nw_2 = xw_1
\]

Since \( w_1 \) has minimal absolute value of all periods, it follows \(|x| \geq 1 \). Let \( k \leq x < k+1 \) for some integer, \( k \). If \( x > k \), then

\[
w - mw_1 - nw_2 - kw_1 = (x-k)w_1
\]

which would contradict the choice of \( w_1 \) as being the period having minimal absolute value because the expression on the left in the above is a period and it equals
something which has absolute value less than $|w_1|$. Therefore, $x = k$ and $w$ is an integer linear combination of $w_1$ and $w_2$. It only remains to verify the claim about $\tau$.

From the construction, $|w_1| \leq |w_2|$ and $|w_2| \leq |w_1 - w_2|, |w_2| \leq |w_1 + w_2|$. Therefore,

$$|\tau| \geq 1, |\tau| \leq |1 - \tau|, |\tau| \leq |1 + \tau|.$$ 

The last two of these inequalities imply $-1/2 \leq \text{Re} \tau \leq 1/2$.

This proves the theorem.

**Definition 56.1.3** For $f$ a meromorphic function which has the last of the above alternatives holding in which $M = \{aw_1 + bw_2 : a, b \in \mathbb{Z}\}$, the function, $f$ is called elliptic. This is also called doubly periodic.

**Theorem 56.1.4** Suppose $f$ is an elliptic function which has no poles. Then $f$ is constant.

**Proof:** Since $f$ has no poles it is analytic. Now consider the parallelograms determined by the vertices, $mw_1 + nw_2$ for $m, n \in \mathbb{Z}$. By periodicity of $f$ it must be bounded because its values are identical on each of these parallelograms. Therefore, it equals a constant by Liouville’s theorem.

**Definition 56.1.5** Define $P_a$ to be the parallelogram determined by the points

$$a + mw_1 + nw_2, a + (m+1)w_1 + nw_2, a + mw_1 + (n+1)w_2$$

Such $P_a$ will be referred to as a period parallelogram. The sum of the orders of the poles in a period parallelogram which contains no poles or zeros of $f$ on its boundary is called the order of the function. This is well defined because of the periodic property of $f$.

**Theorem 56.1.6** The sum of the residues of any elliptic function, $f$ equals zero on every $P_a$ if $a$ is chosen so that there are no poles on $\partial P_a$.

**Proof:** Choose $a$ such that there are no poles of $f$ on the boundary of $P_a$. By periodicity,

$$\int_{\partial P_a} f(z) \, dz = 0$$

because the integrals over opposite sides of the parallelogram cancel out because the values of $f$ are the same on these sides and the orientations are opposite. It follows from the residue theorem that the sum of the residues in $P_a$ equals 0.

**Theorem 56.1.7** Let $P_a$ be a period parallelogram for a nonconstant elliptic function, $f$ which has order equal to $m$. Then $f$ assumes every value in $f(P_a)$ exactly $m$ times.
56.1. PERIODIC FUNCTIONS

Proof: Let \( c \in f ( P_a ) \) and consider \( P_{a'} \) such that \( f^{-1} ( c ) \cap P_{a'} = f^{-1} ( c ) \cap P_a \) and \( P_{a'} \) contains the same poles and zeros of \( f - c \) as \( P_a \) but \( P_{a'} \) has no zeros of \( f ( z ) - c \) or poles of \( f \) on its boundary. Thus \( f' ( z ) / ( f ( z ) - c ) \) is also an elliptic function and so Theorem 56.1.8 applies. Consider

\[
\frac{1}{2\pi i} \int_{\partial P_{a'}} \frac{f' ( z )}{f ( z ) - c} \, dz.
\]

By the argument principle, this equals \( N_z - N_p \) where \( N_z \) equals the number of zeros of \( f ( z ) - c \) and \( N_p \) equals the number of the poles of \( f ( z ) \). From Theorem 56.1.8 this must equal zero because it is the sum of the residues of \( f' / ( f - c ) \) and so \( N_z = N_p \).

Now \( N_p \) equals the number of poles in \( P_a \) counted according to multiplicity.

There is an even better theorem than this one.

Theorem 56.1.8 Let \( f \) be a non constant elliptic function and suppose it has poles \( p_1, \ldots, p_m \) and zeros, \( z_1, \ldots, z_m \) in \( P_a \), listed according to multiplicity where \( \partial P_a \) contains no poles or zeros of \( f \). Then \( \sum_{k=1}^{m} z_k - \sum_{k=1}^{m} p_k \in M \), the module of periods.

Proof: You can assume \( \partial P_a \) contains no poles or zeros of \( f \) because if it did, then you could consider a slightly shifted period parallelogram, \( P_{a'} \) which contains no new zeros and poles but which has all the old ones but no poles or zeros on its boundary. By Theorem 56.1.8 on Page 1668

\[
\frac{1}{2\pi i} \int_{\partial P_a} \frac{f' ( z )}{f ( z )} \, dz = \sum_{k=1}^{m} z_k - \sum_{k=1}^{m} p_k. \tag{56.1.2}
\]

Denoting by \( \gamma ( z, w ) \) the straight oriented line segment from \( z \) to \( w \),

\[
\int_{\partial P_a} z \frac{f' ( z )}{f ( z )} \, dz = \int_{\gamma ( a, a+w_1 )} z \frac{f' ( z )}{f ( z )} \, dz + \int_{\gamma ( a+w_1, a+w_2, a+w_2+a+w_2 )} z \frac{f' ( z )}{f ( z )} \, dz \\
+ \int_{\gamma ( a+w_2, a+w_2+w_2+w_2 )} z \frac{f' ( z )}{f ( z )} \, dz + \int_{\gamma ( a+w_2, a+w_2+w_2+w_2 )} z \frac{f' ( z )}{f ( z )} \, dz \\
= \int_{\gamma ( a, a+w_1 )} ( z - ( z + w_2 ) ) \frac{f' ( z )}{f ( z )} \, dz \\
+ \int_{\gamma ( a, a+w_2 )} ( z - ( z + w_1 ) ) \frac{f' ( z )}{f ( z )} \, dz
\]

Now near these line segments \( f' / f \) is analytic and so there exists a primitive, \( g_{w_1} ( z ) \) on \( \gamma ( a, a+w_1 ) \) by Corollary 56.1.8 on Page 1668 which satisfies \( e^{g_{w_1} ( z )} = f ( z ) \).

Therefore,

\[
= -w_2 ( g_{w_1} ( a + w_1 ) - g_{w_1} ( a ) ) - w_1 ( g_{w_2} ( a + w_2 ) - g_{w_2} ( a ) ) .
\]
Now by periodicity of $f$ it follows $f(a + w_1) = f(a) = f(a + w_2)$. Hence

$$g_{w_1}(a + w_1) - g_{w_1}(a) = 2m\pi i$$

for some integer, $m$ because

$$e^{g_{w_1}(a+w_1)} - e^{g_{w_1}(a)} = f(a + w_1) - f(a) = 0.$$ 

Therefore, from 56.1.2, there exist integers, $k, l$ such that

$$\frac{1}{2\pi i} \int_{\partial P_a} z f'(z) f(z) dz = \frac{1}{2\pi i} \left[ -w_2 (g_{w_1}(a + w_1) - g_{w_1}(a)) - w_1 (g_{w_2}(a + w_2) - g_{w_2}(a)) \right]$$

$$= \frac{1}{2\pi i} \left[ -w_2 (2k\pi i) - w_1 (2l\pi i) \right]$$

$$= -w_2 k - w_1 l \in M.$$ 

From 56.1.2 it follows

$$\sum_{k=1}^{m} z_k - \sum_{k=1}^{m} p_k \in M.$$ 

This proves the theorem.

Hille says this relation is due to Liouville. There is also a simple corollary which follows from the above theorem applied to the elliptic function, $f(z) - c$.

**Corollary 56.1.9** Let $f$ be a non constant elliptic function and suppose the function, $f(z) - c$ has poles $p_1, \cdots, p_m$ and zeros, $z_1, \cdots, z_m$ on $P_a$, listed according to multiplicity where $\partial P_a$ contains no poles or zeros of $f(z) - c$. Then $\sum_{k=1}^{m} z_k - \sum_{k=1}^{m} p_k \in M$, the module of periods.

### 56.1.1 The Unimodular Transformations

**Definition 56.1.10** Suppose $f$ is a nonconstant elliptic function and the module of periods is of the form $\{aw_1 + bw_2\}$ where $a, b$ are integers and $w_1/w_2$ is not real. Then by analogy with linear algebra, $\{w_1, w_2\}$ is referred to as a basis. The unimodular transformations will refer to matrices of the form

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

where all entries are integers and

$$ad - bc = \pm 1.$$ 

These linear transformations are also called the modular group.

The following is an interesting lemma which ties matrices with the fractional linear transformations.
Lemma 56.1.11 Define

\[ \phi \left( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \equiv \frac{az+b}{cz+d}. \]

Then

\[ \phi(AB) = \phi(A) \circ \phi(B), \]

(56.1.3)

\[ \phi(A)(z) = z \text{ if and only if } A = cI \]

where \( I \) is the identity matrix and \( c \neq 0 \). Also if \( f(z) = \frac{az+b}{cz+d} \), then \( f^{-1}(z) \) exists if and only if \( ad - cb \neq 0 \). Furthermore it is easy to find \( f^{-1} \).

Proof: The equation in (56.1.3) is just a simple computation. Now suppose \( \phi(A)(z) = z \). Then letting \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \), this requires

\[ az + b = z(cz + d) \]

and so \( az + b = cz^2 + dz \). Since this is to hold for all \( z \) it follows \( c = 0 = b \) and \( a = d \). The other direction is obvious.

Consider the claim about the existence of an inverse. Let \( ad - cb \neq 0 \) for \( f(z) = \frac{az+b}{cz+d} \). Then

\[ f(z) = \phi \left( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \]

It follows \( \begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} \) exists and equals \( \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \). Therefore,

\[ z = \phi(I)(z) = \phi \left( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \left( \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \right)(z) \]

\[ = \phi \left( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \circ \phi \left( \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \right)(z) \]

\[ = f \circ f^{-1}(z) \]

which shows \( f^{-1} \) exists and it is easy to find.

Next suppose \( f^{-1} \) exists. I need to verify the condition \( ad - cb \neq 0 \). If \( f^{-1} \) exists, then from the process used to find it, you see that it must be a fractional linear transformation. Letting \( A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) so \( \phi(A) = f \), it follows there exists a matrix \( B \) such that

\[ \phi(BA)(z) = \phi(B) \circ \phi(A)(z) = z. \]

However, it was shown that this implies \( BA \) is a nonzero multiple of \( I \) which requires that \( A^{-1} \) must exist. Hence the condition must hold.
Theorem 56.1.12  If \( f \) is a nonconstant elliptic function with a basis \( \{ w_1, w_2 \} \) for the module of periods, then \( \{ w_1', w_2' \} \) is another basis, if and only if there exists a unimodular transformation, \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} = A \) such that
\[
\begin{pmatrix}
  w_1' \\
  w_2'
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} w_1 \\
  w_2
\end{pmatrix}.
\] (56.1.4)

Proof: Since \( \{ w_1, w_2 \} \) is a basis, there exist integers, \( a, b, c, d \) such that \( \begin{pmatrix} w_1 \\
  w_2
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} w_1' \\
  w_2'
\end{pmatrix} \) holds. It remains to show the transformation determined by the matrix is unimodular. Taking conjugates,
\[
\begin{pmatrix}
  \overline{w_1'} \\
  \overline{w_2'}
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \overline{w_1} \\
  \overline{w_2}
\end{pmatrix}.
\]
Therefore,
\[
\begin{pmatrix}
  w_1' \\
  w_2'
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \overline{w_1} \\
  \overline{w_2}
\end{pmatrix}.
\]
Now since \( \{ w_1', w_2' \} \) is also given to be a basis, there exits another matrix having all integer entries, \( \begin{pmatrix} e & f \\ g & h \end{pmatrix} \) such that
\[
\begin{pmatrix} \overline{w_1'} \\
  \overline{w_2'}
\end{pmatrix} = \begin{pmatrix} e & f \\ g & h \end{pmatrix} \begin{pmatrix} w_1' \\
  w_2'
\end{pmatrix}
\]
and
\[
\begin{pmatrix} w_1 \\
  w_2
\end{pmatrix} = \begin{pmatrix} e & f \\ g & h \end{pmatrix} \begin{pmatrix} w_1' \\
  w_2'
\end{pmatrix}.
\]
Therefore,
\[
\begin{pmatrix}
  w_1' \\
  w_2'
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} e & f \\ g & h \end{pmatrix} \begin{pmatrix} \overline{w_1'} \\
  \overline{w_2'}
\end{pmatrix}.
\]
However, since \( w_1'/w_2' \) is not real, it is routine to verify that
\[
\det \begin{pmatrix} \overline{w_1'} & \overline{w_2'} \\
  w_2' & w_1'
\end{pmatrix} \neq 0.
\]
Therefore,
\[
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} e & f \\ g & h \end{pmatrix}
\]
and so \( \det \begin{pmatrix} a & b \\ c & d \end{pmatrix} \det \begin{pmatrix} e & f \\ g & h \end{pmatrix} = 1 \). But the two matrices have all integer entries and so both determinants must equal either 1 or \(-1\).

Next suppose
\[
\begin{pmatrix}
  w_1' \\
  w_2'
\end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} w_1 \\
  w_2
\end{pmatrix}
\] (56.1.5)
where \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) is unimodular. I need to verify that \( \{w'_1, w'_2\} \) is a basis. If \( w \in M \), there exist integers, \( m, n \) such that

\[
 w = mw_1 + nw_2 = \begin{pmatrix} m & n \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \end{pmatrix}
\]

From \[ \ref{6.1.5} \]

\[
 \pm \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \begin{pmatrix} w'_1 \\ w'_2 \end{pmatrix} = \begin{pmatrix} w_1 \\ w_2 \end{pmatrix}
\]

and so

\[
 w = \pm \begin{pmatrix} m & n \end{pmatrix} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} \begin{pmatrix} w'_1 \\ w'_2 \end{pmatrix}
\]

which is an integer linear combination of \( \{w'_1, w'_2\} \). It only remains to verify that \( w'_1/w'_2 \) is not real.

**Claim:** Let \( w_1 \) and \( w_2 \) be nonzero complex numbers. Then \( w_2/w_1 \) is not real if and only if

\[
 w_1 \overline{w_2} - \overline{w_1}w_2 = \det \begin{pmatrix} w_1 & \overline{w_1} \\ w_2 & \overline{w_2} \end{pmatrix} \neq 0
\]

**Proof of the claim:** Let \( \lambda = w_2/w_1 \). Then

\[
 w_1 \overline{w_2} - \overline{w_1}w_2 = \lambda w_1 \overline{w_1} - \overline{w_1} \lambda w_1 = (\lambda - \lambda) |w_1|^2
\]

Thus the ratio is not real if and only if \( (\lambda - \lambda) \neq 0 \) if and only if \( w_1 \overline{w_2} - \overline{w_1}w_2 \neq 0 \).

Now to verify \( w'_2/w'_1 \) is not real,

\[
 \det \begin{pmatrix} w'_1 & \overline{w'_1} \\ w'_2 & \overline{w'_2} \end{pmatrix} = \det \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} w_1 & \overline{w_1} \\ w_2 & \overline{w_2} \end{pmatrix} = \pm \det \begin{pmatrix} w_1 & \overline{w_1} \\ w_2 & \overline{w_2} \end{pmatrix} \neq 0
\]

This proves the theorem.

### 56.1.2 The Search For An Elliptic Function

By Theorem \[ \ref{6.1.3} \] and \[ \ref{6.1.4} \] if you want to find a nonconstant elliptic function it must fail to be analytic and also have either no terms in its Laurent expansion which are of the form \( b_1 (z - a)^{-1} \) or else these terms must cancel out. It is simplest to look for a function which simply does not have them. Weierstrass looked for a function of the form

\[
 \varphi(z) = \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(z - w)^2} - \frac{1}{w^2} \right)
\]  \[ \text{(56.1.6)} \]
where \( w \) consists of all numbers of the form \( aw_1 + bw_2 \) for \( a, b \) integers. Sometimes people write this as \( \varphi(z, w_1, w_2) \) to emphasize its dependence on the periods, \( w_1 \) and \( w_2 \) but I won’t do so. It is understood there exist these periods, which are given. This is a reasonable thing to try. Suppose you formally differentiate the right side. Never mind whether this is justified for now. This yields

\[
\varphi'(z) = \frac{-2}{z^3} - \sum_{w \neq 0} \frac{-2}{(z-w)^3} = \sum_{w} \frac{-2}{(z-w)^3}
\]

which is clearly periodic having both periods \( w_1 \) and \( w_2 \). Therefore, \( \varphi(z + w_1) - \varphi(z) \) and \( \varphi(z + w_2) - \varphi(z) \) are both constants, \( c_1 \) and \( c_2 \) respectively. The reason for this is that since \( \varphi' \) is periodic with periods \( w_1 \) and \( w_2 \); it follows \( \varphi'(z + w_i) = 0 \) as long as \( z \) is not a period. From 56.1.6 you can see right away that

\[
\varphi(z) = \varphi(-z)
\]

Indeed

\[
\begin{align*}
\varphi(-z) &= \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(-z-w)^2} - \frac{1}{w^2} \right) \\
&= \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(-z+w)^2} - \frac{1}{w^2} \right) = \varphi(z).
\end{align*}
\]

and so

\[
\begin{align*}
c_1 &= \varphi \left( \frac{w_1}{2} + w_1 \right) - \varphi \left( -\frac{w_1}{2} \right) \\
&= \varphi \left( \frac{w_1}{2} \right) - \varphi \left( -\frac{w_1}{2} \right) = 0
\end{align*}
\]

which shows the constant for \( \varphi(z + w_1) - \varphi(z) \) must equal zero. Similarly the constant for \( \varphi(z + w_2) - \varphi(z) \) also equals zero. Thus \( \varphi \) is periodic having the two periods \( w_1, w_2 \).

Of course to justify this, you need to consider whether the series of \( \varphi(z, w_1, w_2) \) converges. Consider the terms of the series.

\[
\left| \frac{1}{(z-w)^2} - \frac{1}{w^2} \right| = |z| \left| \frac{2w-z}{(z-w)^2w^2} \right|
\]

If \( |w| > 2|z| \), this can be estimated more. For such \( w \),

\[
\begin{align*}
&\left| \frac{1}{(z-w)^2} - \frac{1}{w^2} \right| \\
&= |z| \left| \frac{2w-z}{(z-w)^2w^2} \right| \leq |z| \left( \frac{5/2}{|w|} \right) \left( \frac{|w|}{|w| - |z|} \right)^2 \\
&\leq |z| \left( \frac{5/2}{|w|^2} \right)^2 = |z| \frac{10}{|w|}.\n\end{align*}
\]
It follows the series in converges uniformly and absolutely on every compact set, $K$ provided $\sum_{w \neq 0} \frac{1}{|w|^3}$ converges. This question is considered next.

**Claim:** There exists a positive number, $k$ such that for all pairs of integers, $m, n$, not both equal to zero,

$$\frac{|mw_1 + nw_2|}{|m| + |n|} \geq k > 0.$$ 

**Proof of claim:** If not, there exists $m_k$ and $n_k$ such that

$$\lim_{k \to \infty} \frac{m_k}{|m_k| + |n_k|} w_1 + \frac{n_k}{|m_k| + |n_k|} w_2 = 0$$

However, $\left( \frac{m_k}{|m_k| + |n_k|}, \frac{n_k}{|m_k| + |n_k|} \right)$ is a bounded sequence in $\mathbb{R}^2$ and so, taking a subsequence, still denoted by $k$, you can have

$$\left( \frac{m_k}{|m_k| + |n_k|}, \frac{n_k}{|m_k| + |n_k|} \right) \to (x, y) \in \mathbb{R}^2$$

and so there are real numbers, $x, y$ such that $xw_1 + yw_2 = 0$ contrary to the assumption that $w_2/w_1$ is not equal to a real number. This proves the claim.

Now from the claim,

$$\sum_{w \neq 0} \frac{1}{|w|^3} = \sum_{(m, n) \neq (0, 0)} \frac{1}{|mw_1 + nw_2|^3} \leq \sum_{(m, n) \neq (0, 0)} \frac{1}{k^3 (|m| + |n|)^3} = \frac{1}{k^3} \sum_{j=1}^{\infty} \frac{4j}{j^3} < \infty.$$

Now consider the series in Letting $z \in B(0, R)$,

$$\wp(z) = \frac{1}{z^2} + \sum_{w \neq 0, |w| \leq R} \left( \frac{1}{(z - w)^2} - \frac{1}{w^2} \right) + \sum_{w \neq 0, |w| > R} \left( \frac{1}{(z - w)^2} - \frac{1}{w^2} \right)$$

and the last series converges uniformly on $B(0, R)$ to an analytic function. Thus $\wp$ is a meromorphic function and also the argument given above involving differentiation of the series termwise is valid. Thus $\wp$ is an elliptic function as claimed. This is called the Weierstrass $\wp$ function. This has proved the following theorem.

**Theorem 56.1.13** The function $\wp$ defined above is an example of an elliptic function. On any compact set, $\wp$ equals a rational function added to a series which is uniformly and absolutely convergent on the compact set.
56.1.3 The Differential Equation Satisfied By $\wp$

For $z$ not a pole,

$$\wp' (z) = \frac{-2}{z^3} - \sum_{w \neq 0} \frac{2}{(z - w)^3}$$

Also since there are no poles of order 1 you can obtain a primitive for $\wp$, $-\zeta$. To do so, recall

$$\wp(z) = \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(z - w)^2} - \frac{1}{w^2} \right)$$

where for $|z| < R$ this is the sum of a rational function with a uniformly convergent series. Therefore, you can take the integral along any path, $\gamma (0, z)$ from 0 to $z$ which misses the poles of $\wp$. By the uniform convergence of the above integral, you can interchange the sum with the integral and obtain

$$\zeta(z) = \frac{1}{z} + \sum_{w \neq 0} \frac{1}{z - w} + \frac{z}{w^2} + \frac{1}{w} \quad (56.1.7)$$

This function is odd. Here is why.

$$\zeta(-z) = \frac{1}{-z} + \sum_{w \neq 0} \frac{1}{-z - w} - \frac{z}{w^2} + \frac{1}{w}$$

while

$$-\zeta(z) = \frac{1}{-z} + \sum_{w \neq 0} \frac{-1}{z - w} - \frac{z}{w^2} - \frac{1}{w} = \frac{1}{-z} + \sum_{w \neq 0} \frac{-1}{z + w} - \frac{z}{w^2} + \frac{1}{w}.$$ 

Now consider $\wp$. It will be used to find the Laurent expansion about the origin for $\zeta$ which will then be differentiated to obtain the Laurent expansion for $\wp$ at the origin. Since $w \neq 0$ and the interest is for $z$ near 0 so $|z| < |w|$, 

$$\frac{1}{z - w} + \frac{z}{w^2} + \frac{1}{w} = \frac{z}{w^2} + \frac{1}{w} - \frac{1}{w} \frac{1 - \frac{z}{w}}{}$$

$$= \frac{z}{w^2} + \frac{1}{w} - \frac{1}{w} \sum_{k=0}^{\infty} (\frac{z}{w})^k$$

$$= \frac{1}{w} \sum_{k=2}^{\infty} \left( \frac{z}{w} \right)^k$$

\footnote{I don’t know why it is traditional to refer to this antiderivative as $-\zeta$ rather than $\zeta$ but I am following the convention. I think it is to minimize the number of minus signs in the next expression.}
56.1. PERIODIC FUNCTIONS

From

\[ \zeta(z) = \frac{1}{z} + \sum_{w \neq 0} \left( -\sum_{k=2}^{\infty} \frac{z^k}{w^{k+1}} \right) \]

\[ = \frac{1}{z} - \sum_{k=2}^{\infty} \sum_{w \neq 0} \frac{z^k}{w^{k+1}} = \frac{1}{z} - \sum_{k=2}^{\infty} \sum_{w \neq 0} \frac{z^{2k-1}}{w^{2k}} \]

because the sum over odd powers must be zero because for each \( w \neq 0 \), there exists \(-w \neq 0\) such that the two terms \( \frac{z^{2k}}{w^{2k+1}} \) and \( \frac{z^{2k}}{(-w)^{2k+1}} \) cancel each other. Hence

\[ \zeta(z) = \frac{1}{z} - \sum_{k=2}^{\infty} G_k z^{2k-1} \]

where \( G_k = \sum_{w \neq 0} \frac{1}{w^{2k}} \). Now with this,

\[ -\zeta'(z) = \varphi(z) = \frac{1}{z^2} + \sum_{k=2}^{\infty} G_k (2k-1) z^{2k-2} \]

\[ = \frac{1}{z^2} + 3G_2 z^2 + 5G_3 z^4 + \cdots \]

Therefore,

\[ \varphi'(z) = -\frac{2}{z^3} + 6G_2 z + 20G_3 z^3 + \cdots \]

\[ \varphi'(z)^2 = \frac{4}{z^6} - \frac{24G_2}{z^4} - 80G_3 + \cdots \]

\[ 4\varphi(z)^3 = 4 \left( \frac{1}{z^2} + 3G_2 z^2 + 5G_3 z^4 + \cdots \right)^3 \]

\[ = \frac{4}{z^6} + \frac{36}{z^4} G_2 + 60G_3 + \cdots \]

and finally

\[ 60G_2 \varphi(z) = \frac{60G_2}{z^2} + 0 + \cdots \]

where in the above, the positive powers of \( z \) are not listed explicitly. Therefore,

\[ \varphi'(z)^2 - 4\varphi(z)^3 + 60G_2 \varphi(z) + 140G_3 = \sum_{n=1}^{\infty} a_n z^n \]

In deriving the equation it was assumed \(|z| < |w|\) for all \( w = aw_1 + bw_2 \) where \( a, b \) are integers not both zero. The left side of the above equation is periodic with respect to \( w_1 \) and \( w_2 \) where \( w_2/w_1 \) is not a real number. The only possible poles of the left side are at \( 0, w_1, w_2, \) and \( w_1 + w_2 \), the vertices of the parallelogram determined by \( w_1 \) and \( w_2 \). This follows from the original formula for \( \varphi(z) \). However, the above
equation shows the left side has no pole at 0. Since the left side is periodic with periods \( w_1 \) and \( w_2 \), it follows it has no pole at the other vertices of this parallelogram either. Therefore, the left side is periodic and has no poles. Consequently, it equals a constant by Theorem 56.1.4. But the right side of the above equation shows this constant is 0 because this side equals zero when \( z = 0 \). Therefore, \( \varphi \) satisfies the differential equation,
\[
\varphi'(z)^2 - 4\varphi(z)^3 + 60G_2\varphi(z) + 140G_3 = 0.
\]
It is traditional to define \( 60G_2 \equiv g_2 \) and \( 140G_3 \equiv g_3 \). Then in terms of these new quantities the differential equation is
\[
\varphi'(z)^2 = 4\varphi(z)^3 - g_2\varphi(z) - g_3.
\]
Suppose \( e_1, e_2 \) and \( e_3 \) are zeros of the polynomial \( 4w^3 - g_2w - g_3 = 0 \). Then the above equation can be written in the form
\[
\varphi'(z)^2 = 4(\varphi(z) - e_1)(\varphi(z) - e_2)(\varphi(z) - e_3). \tag{56.1.8}
\]

### 56.1.4 A Modular Function

The next task is to find the \( e_i \) in (56.1.8). First recall that \( \varphi \) is an even function. That is \( \varphi(-z) = \varphi(z) \). This follows from (56.1.6) which is listed here for convenience.

\[
\varphi(z) \equiv \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(z-w)^2} - \frac{1}{w^2} \right). \tag{56.1.9}
\]

Thus
\[
\varphi(-z) = \frac{1}{z^2} + \sum_{w \neq 0} \left( \frac{1}{(-z-w)^2} - \frac{1}{w^2} \right) = \varphi(z).
\]

Therefore, \( \varphi(w_1 - z) = \varphi(z - w_1) = \varphi(z) \) and so \( -\varphi'(w_1 - z) = \varphi'(z) \). Letting \( z = w_1/2 \), it follows \( \varphi'(w_1/2) = 0 \). Similarly, \( \varphi'(w_2/2) = 0 \) and \( \varphi'((w_1 + w_2)/2) = 0 \). Therefore, from (56.1.8)
\[
0 = 4(\varphi(w_1/2) - e_1)(\varphi(w_1/2) - e_2)(\varphi(w_1/2) - e_3).
\]

It follows one of the \( e_i \) must equal \( \varphi(w_1/2) \). Similarly, one of the \( e_i \) must equal \( \varphi(w_2/2) \) and one must equal \( \varphi((w_1 + w_2)/2) \).

**Lemma 56.1.14** *The numbers, \( \varphi(w_1/2), \varphi(w_2/2), \text{ and } \varphi((w_1 + w_2)/2) \) are distinct.*
Proof: Choose $P_a$, a period parallelogram which contains the pole 0, and the points $w_1/2, w_2/2$, and $(w_1 + w_2)/2$ but no other pole of $\varphi(z)$. Also $\partial P_a^*$ does not contain any zeros of the elliptic function, $z \rightarrow \varphi(z) - \varphi(w_1/2)$. This can be done by shifting $P_0$ slightly because the poles are only at the points $aw_1 + bw_2$ for $a, b$ integers and the zeros of $\varphi(z) - \varphi(w_1/2)$ are discrete.

If $\varphi(w_2/2) = \varphi(w_1/2)$, then $\varphi(z) = \varphi(w_1/2)$ has two zeros, $w_2/2$ and $w_1/2$ and since the pole at $0$ is of order 2, this is the order of $\varphi(z) - \varphi(w_1/2)$ on $P_a$, hence by Theorem 56.1.7 on Page 1862 these are the only zeros of this function on $P_a$. It follows by Corollary 56.1.9 on Page 1864 which says the sum of the zeros minus the sum of the poles is in $M$, $w_2/2 + w_1/2 \in M$. Thus there exist integers, $a, b$ such that

$$\frac{w_1 + w_2}{2} = aw_1 + bw_2$$

which implies $(2a - 1)w_1 + (2b - 1)w_2 = 0$ contradicting $w_2/w_1$ not being real. Similar reasoning applies to the other pairs of points in $\{w_1/2, w_2/2, (w_1 + w_2)/2\}$. For example, consider $(w_1 + w_2)/2$ and choose $P_a$ such that its boundary contains no zeros of the elliptic function, $z \rightarrow \varphi(z) - \varphi((w_1 + w_2)/2)$ and $P_a$ contains no poles of $\varphi$ on its interior other than 0. Then if $\varphi(w_2/2) = \varphi((w_1 + w_2)/2)$, it follows from Theorem 56.1.7 on Page 1862 $w_2/2$ and $(w_1 + w_2)/2$ are the only two zeros of $\varphi(z) - \varphi((w_1 + w_2)/2)$ on $P_a$ and by Corollary 56.1.9 on Page 1864

$$\frac{w_1 + w_1 + w_2}{2} = aw_1 + bw_2 \in M$$

for some integers $a, b$ which leads to the same contradiction as before about $w_1/w_2$ not being real. The other cases are similar. This proves the lemma.

Lemma 56.1.14 proves the $e_i$ are distinct. Number the $e_i$ such that

$$e_1 = \varphi(w_1/2), e_2 = \varphi(w_2/2)$$

and

$$e_3 = \varphi((w_1 + w_2)/2).$$

To summarize, it has been shown that for complex numbers, $w_1$ and $w_2$ with $w_2/w_1$ not real, an elliptic function, $\varphi$ has been defined. Denote this function as...
$\varphi(z) = \varphi(z, w_1, w_2)$. This in turn determined numbers, $e_i$ as described above. Thus these numbers depend on $w_1$ and $w_2$ and as described above,

$$
e_1(w_1, w_2) = \varphi\left(\frac{w_1}{2}, w_1, w_2\right), \quad e_2(w_1, w_2) = \varphi\left(\frac{w_2}{2}, w_1, w_2\right)$$

$$e_3(w_1, w_2) = \varphi\left(\frac{w_1 + w_2}{2}, w_1, w_2\right).$$

Therefore, using the formula for $\varphi$, 56.1.9,

$$\varphi(z) = \frac{1}{z^2} + \sum_{w \neq 0} \frac{1}{(z - w)^2} - \frac{1}{w^2}$$

you see that if the two periods $w_1$ and $w_2$ are replaced with $tw_1$ and $tw_2$ respectively, then

$$e_i(tw_1, tw_2) = t^{-2}e_i(w_1, w_2).$$

Let $\tau$ denote the complex number which equals the ratio, $w_2/w_1$ which was assumed in all this to not be real. Then

$$e_i(w_1, w_2) = w_1^{-2}e_i(1, \tau)$$

Now define the function, $\lambda(\tau)$

$$\lambda(\tau) = \frac{e_3(1, \tau) - e_2(1, \tau)}{e_1(1, \tau) - e_2(1, \tau)} \left(\begin{array}{cc} e_3(w_1, w_2) & -e_2(w_1, w_2) \\ e_3(w_1, w_2) & -e_2(w_1, w_2) \end{array}\right).$$

(56.1.10)

This function is meromorphic for $\text{Im} \tau > 0$ or for $\text{Im} \tau < 0$. However, since the denominator is never equal to zero the function must actually be analytic on both the upper half plane and the lower half plane. It never is equal to 0 because $e_3 \neq e_2$ and it never equals 1 because $e_3 \neq e_1$. This is stated as an observation.

**Observation 56.1.15** The function, $\lambda(\tau)$ is analytic for $\tau$ in the upper half plane and never assumes the values 0 and 1.

This is a very interesting function. Consider what happens when

$$\left(\begin{array}{c} w' \\ w'' \end{array}\right) = \left(\begin{array}{cc} a & b \\ c & d \end{array}\right) \left(\begin{array}{c} w_1 \\ w_2 \end{array}\right)$$

and the matrix is unimodular. By Theorem 56.1.12 on Page 1866, $\{w'_1, w'_2\}$ is just another basis for the same module of periods. Therefore, $\varphi(z, w_1, w_2) = \varphi(z, w'_1, w'_2)$ because both are defined as sums over the same values of $w$, just in different order which does not matter because of the absolute convergence of the sums on compact subsets of $C$. Since $\varphi$ is unchanged, it follows $\varphi'(z)$ is also unchanged and so the numbers, $e_i$ are also the same. However, they might be permuted in which case the function $\lambda(\tau)$ defined above would change. What would it take for $\lambda(\tau)$ to not change? In other words, for which unimodular transformations will $\lambda$
be left unchanged? This happens if and only if no permuting takes place for the $e_i$. This occurs if $\varphi \left( \frac{w_i}{2} \right) = \varphi \left( \frac{w'_i}{2} \right)$ and $\varphi \left( \frac{w_2}{2} \right) = \varphi \left( \frac{w'_2}{2} \right)$. If
\[
\frac{w'_i}{2} - \frac{w_i}{2} \in M, \quad \frac{w'_2}{2} - \frac{w_2}{2} \in M
\]
then $\varphi \left( \frac{w_i}{2} \right) = \varphi \left( \frac{w'_i}{2} \right)$ and so $e_1$ will be unchanged and similarly for $e_2$ and $e_3$. This occurs exactly when
\[
\frac{1}{2} ((a - 1) w_1 + bw_2) \in M, \quad \frac{1}{2} (cw_1 + (d - 1) w_2) \in M.
\]
This happens if $a$ and $d$ are odd and if $b$ and $c$ are even. Of course the stylish way to say this is
\[
a \equiv 1 \mod 2, \quad d \equiv 1 \mod 2, \quad b \equiv 0 \mod 2, \quad c \equiv 0 \mod 2. \quad (56.1.11)
\]
This has shown that for unimodular transformations satisfying (56.1.11) $\lambda$ is unchanged. Letting $\tau$ be defined as above,
\[
\tau' = \frac{w'_2}{w'_1} = \frac{cw_1 + dw_2}{aw_1 + bw_2} = \frac{c + d\tau}{a + b\tau},
\]
Thus for unimodular transformations, \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) satisfying (56.1.11), or more succinctly,
\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \sim \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mod 2 \quad (56.1.12)
\]
it follows that
\[
\lambda \left( \frac{c + d\tau}{a + b\tau} \right) = \lambda (\tau) \quad (56.1.13)
\]
Furthermore, this is the only way this can happen.

**Lemma 56.1.16** $\lambda (\tau) = \lambda (\tau')$ if and only if
\[
\tau' = \frac{a\tau + b}{c\tau + d}
\]
where (56.1.11) holds.

**Proof:** It only remains to verify that if $\varphi \left( \frac{w'_1}{2} \right) = \varphi \left( \frac{w_1}{2} \right)$ then it is necessary that
\[
\frac{w'_1}{2} - \frac{w_1}{2} \in M
\]
with a similar requirement for $w_2$ and $w'_2$. If $\frac{w'_1}{2} - \frac{w_1}{2} \notin M$, then there exist integers, $m, n$ such that
\[
\frac{w'_1}{2} = mw_1 + nw_2
\]
is in the interior of $P_0$, the period parallelogram whose vertices are $0, w_1, w_1 + w_2,$ and $w_2$. Therefore, it is possible to choose small $a$ such that $P_a$ contains the pole, $0, \frac{w_1}{2},$ and $\frac{-w'_1}{2} + mw_1 + nw_2$ but no other poles of $\wp$ and in addition, $\partial P_a^*$ contains no zeros of $z \rightarrow \wp(z) - \wp(\frac{w_1}{2})$. Then the order of this elliptic function is 2. By assumption, and the fact that $\wp$ is even,

$$
\wp\left(\frac{-w'_1}{2} + mw_1 + nw_2\right) = \wp\left(\frac{-w'_1}{2}\right) = \wp\left(\frac{w_1}{2}\right) = \wp\left(\frac{w_1}{2}\right).
$$

It follows both $\frac{-w'_1}{2} + mw_1 + nw_2$ and $\frac{w_1}{2}$ are zeros of $\wp(z) - \wp(\frac{w_1}{2})$ and so by Theorem 56.1.7 on Page 1862 these are the only two zeros of this function in $P_a$. Therefore, from Corollary 56.1.9 on Page 1864

$$
\frac{w_1}{2} \frac{w_1}{2} = \frac{-w'_1}{2} + mw_1 + nw_2 \in M
$$

which shows $\frac{w_1}{2} - \frac{w'_1}{2} \in M$. This completes the proof of the lemma.

Note the condition in the lemma is equivalent to the condition 56.1.13 because you can relabel the coefficients. The message of either version is that the coefficient of $\tau$ in the numerator and denominator is odd while the constant in the numerator denominator is even.

Next, \( \left( \begin{array}{cc} 1 & 0 \\ 2 & 1 \end{array} \right) \sim \left( \begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array} \right) \mod 2 \) and therefore,

$$
\lambda \left( \begin{array}{c} 2 + \tau \\ 1 \end{array} \right) = \lambda (\tau + 2) = \lambda (\tau).
$$

Thus $\lambda$ is periodic of period 2.

Thus $\lambda$ leaves invariant a certain subgroup of the unimodular group. According to the next definition, $\lambda$ is an example of something called a modular function.

**Definition 56.1.17** When an analytic or meromorphic function is invariant under a group of linear transformations, it is called an automorphic function. A function which is automorphic with respect to a subgroup of the modular group is called a modular function or an elliptic modular function.

Now consider what happens for some other unimodular matrices which are not congruent to the identity mod 2. This will yield other functional equations for $\lambda$ in addition to the fact that $\lambda$ is periodic of period 2. As before, these functional equations come about because $\wp$ is unchanged when you change the basis for $M$, the module of periods. In particular, consider the unimodular matrices

$$
\left( \begin{array}{cc} 1 & 0 \\ 1 & 1 \end{array} \right), \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right).
$$

Consider the first of these. Thus

$$
\left( \begin{array}{c} w'_1 \\ w'_2 \end{array} \right) = \left( \begin{array}{c} w_1 \\ w_1 + w_2 \end{array} \right)
$$
Hence \( \tau' = w_2'/w_1' = (w_1 + w_2)/w_1 = 1 + \tau \). Then from the definition of \( \lambda \),

\[
\lambda(\tau') = \lambda(1 + \tau) = \frac{\varphi\left(\frac{w_1 + w_2}{2}\right) - \varphi\left(\frac{w_2}{2}\right)}{\varphi\left(\frac{w_1}{2}\right) - \varphi\left(\frac{w_2}{2}\right)} = \frac{\varphi\left(\frac{w_1 + w_2}{2}\right) - \varphi\left(\frac{w_1 + w_2}{2}\right)}{\varphi\left(\frac{w_1}{2}\right) - \varphi\left(\frac{w_1 + w_2}{2}\right)} = \frac{-\varphi\left(\frac{w_1 + w_2}{2}\right) - \varphi\left(\frac{w_1}{2}\right) + \varphi\left(\frac{w_2}{2}\right) - \varphi\left(\frac{w_1 + w_2}{2}\right)}{\varphi\left(\frac{w_1}{2}\right) - \varphi\left(\frac{w_1 + w_2}{2}\right)} = \frac{\lambda(\tau)}{\lambda(\tau) - 1}. \tag{56.1.16}
\]

Summarizing the important feature of the above,

\[
\lambda(1 + \tau) = \frac{\lambda(\tau)}{\lambda(\tau) - 1}. \tag{56.1.17}
\]

Next consider the other unimodular matrix in 56.1.16. In this case \( w_1' = w_2 \) and
$w'_2 = w_1$. Therefore, $\tau' = w'_2/w'_1 = w_1/w_2 = 1/\tau$. Then

$$
\lambda(\tau') = \lambda(1/\tau) = \frac{\wp\left(\frac{w'_1 + w'_2}{2}\right) - \wp\left(\frac{w'_2}{2}\right)}{\wp\left(\frac{w'_1}{2}\right) - \wp\left(\frac{w'_2}{2}\right)}
= \frac{\wp\left(w'_1 + w'_2\right) - \wp\left(w'_2\right)}{\wp\left(w'_1\right) - \wp\left(w'_2\right)}
= \frac{e_3 - e_1}{e_2 - e_1} = \frac{-e_3 - e_2 + e_2 - e_1}{e_1 - e_2}
= - (\lambda(\tau) - 1) = -\lambda(\tau) + 1.
$$

(56.1.18)

You could try other unimodular matrices and attempt to find other functional equations if you like but this much will suffice here.

### 56.1.5 A Formula For $\lambda$

Recall the formula of Mittag-Leffler for $\cot(\pi\alpha)$ given in 55.2.15. For convenience, here it is.

$$
\frac{1}{\alpha} + \sum_{n=1}^{\infty} \frac{2\alpha}{\alpha^2 - n^2} = \pi \cot \pi \alpha.
$$

As explained in the derivation of this formula it can also be written as

$$
\sum_{n=-\infty}^{\infty} \frac{\alpha}{\alpha^2 - n^2} = \pi \cot \pi \alpha.
$$

Differentiating both sides yields

$$
\pi^2 \csc^2(\pi \alpha) = \sum_{n=-\infty}^{\infty} \frac{\alpha^2 + n^2}{(\alpha^2 - n^2)^2}
= \sum_{n=-\infty}^{\infty} \frac{(\alpha + n)^2 - 2\alpha n}{(\alpha + n)^2 (\alpha - n)^2}
= \sum_{n=-\infty}^{\infty} \frac{(\alpha + n)^2}{(\alpha + n)^2 (\alpha - n)^2} - \sum_{n=-\infty}^{\infty} \frac{2\alpha n}{(\alpha^2 - n^2)^2}
= \sum_{n=-\infty}^{\infty} \frac{1}{(\alpha - n)^2}.
$$

(56.1.19)

Now this formula can be used to obtain a formula for $\lambda(\tau)$. As pointed out above, $\lambda$ depends only on the ratio $w_2/w_1$ and so it suffices to take $w_1 = 1$ and $w_2 = \tau$. Thus

$$
\lambda(\tau) = \frac{\wp\left(\frac{1+\tau}{2}\right) - \wp\left(\frac{\tau}{2}\right)}{\wp\left(\frac{1}{2}\right) - \wp\left(\frac{\tau}{2}\right)}.
$$

(56.1.20)
From the original formula for \( \varphi \),

\[
\varphi \left( \frac{1 + \tau}{2} \right) - \varphi \left( \frac{\tau}{2} \right) = \frac{1}{(\frac{1+\tau}{2})^2} - \frac{1}{(\frac{\tau}{2})^2} + \sum_{(k,m)\neq (0,0)} \frac{1}{(k - \frac{1}{2} + (m - \frac{1}{2}) \tau)^2} - \frac{1}{(k + (m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(k - \frac{1}{2} + (m - \frac{1}{2}) \tau)^2} - \frac{1}{(k + (m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(k - \frac{1}{2} + (m - \frac{1}{2}) \tau)^2} - \frac{1}{(k + (m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(\frac{1}{2} + (m + \frac{1}{2}) \tau - k)^2} - \frac{1}{((m + \frac{1}{2}) \tau - k)^2}. \quad (56.1.21)
\]

Similarly,

\[
\varphi \left( \frac{1}{2} \right) - \varphi \left( \frac{\tau}{2} \right) = \frac{1}{(\frac{1}{2})^2} - \frac{1}{(\frac{\tau}{2})^2} + \sum_{(k,m)\neq (0,0)} \frac{1}{(k - \frac{1}{2} + m\tau)^2} - \frac{1}{(k + (m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(k - \frac{1}{2} + m\tau)^2} - \frac{1}{(k + (m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(k - \frac{1}{2} - m\tau)^2} - \frac{1}{(k + (-m - \frac{1}{2}) \tau)^2}
\]

\[
= \sum_{(k,m)\in \mathbb{Z}^2} \frac{1}{(\frac{1}{2} + m\tau - k)^2} - \frac{1}{((m + \frac{1}{2}) \tau - k)^2}. \quad (56.1.22)
\]

Now use \( \text{Equation} \) to sum these over \( k \). This yields,

\[
\varphi \left( \frac{1 + \tau}{2} \right) - \varphi \left( \frac{\tau}{2} \right) = \sum_{m} \frac{\pi^2}{\sin^2(\pi (\frac{1}{2} + (m + \frac{1}{2}) \tau))} - \frac{\pi^2}{\sin^2(\pi (m + \frac{1}{2}) \tau)}
\]

\[
= \sum_{m} \frac{\pi^2}{\cos^2(\pi (m + \frac{1}{2}) \tau)} - \frac{\pi^2}{\sin^2(\pi (m + \frac{1}{2}) \tau)}
\]
and

$$
\varphi \left( \frac{1}{2} \right) - \varphi \left( \frac{\tau}{2} \right) = \sum_m \frac{\pi^2}{\sin^2 \left( \pi \left( \frac{1}{2} + m \tau \right) \right)} - \frac{\pi^2}{\sin^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)} \\
= \sum_m \frac{\pi^2}{\cos^2 \left( \pi m \tau \right)} - \frac{\pi^2}{\sin^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)}.
$$

The following interesting formula for \( \lambda \) results.

$$
\lambda (\tau) = \frac{\sum_m \frac{1}{\cos^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)} - \frac{1}{\sin^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)}}{\sum_m \frac{1}{\cos^2 \left( \pi m \tau \right)} - \frac{1}{\sin^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)}}.
$$

From this it is obvious \( \lambda (-\tau) = \lambda (\tau) \). Therefore, from 56.1.18,

$$
- \lambda (\tau) + 1 = \lambda \left( \frac{1}{\tau} \right) = \lambda \left( -\frac{1}{\tau} \right)
$$

(56.1.23)

(56.1.24)

(56.1.25)

(56.1.26)

(56.1.27)

56.1.6 Mapping Properties Of \( \lambda \)

The two functional equations, 56.1.24 and 56.1.17, along with some other properties presented above are of fundamental importance. For convenience, they are summarized here in the following lemma.

**Lemma 56.1.18** The following functional equations hold for \( \lambda \).

$$
\lambda (1 + \tau) = \frac{\lambda (\tau)}{\lambda (\tau) - 1}, 1 = \lambda (\tau) + \lambda \left( -\frac{1}{\tau} \right)
$$

$$
\lambda (\tau + 2) = \lambda (\tau),
$$

\( \lambda (z) = \lambda (w) \) if and only if there exists a unimodular matrix,

$$
\begin{pmatrix}
    a & b \\
    c & d
\end{pmatrix} \sim \begin{pmatrix}
    1 & 0 \\
    0 & 1
\end{pmatrix} \mod 2
$$

such that

$$
\begin{align*}
    w &= az + b \\
    cz + d
\end{align*}
$$

Consider the following picture.
In this picture, \( l_1 \) is the \( y \) axis and \( l_2 \) is the line, \( x = 1 \) while \( C \) is the top half of the circle centered at \( \left( \frac{1}{2}, 0 \right) \) which has radius \( 1/2 \). Note the above formula implies \( \lambda \) has real values on \( l_1 \) which are between 0 and 1. This is because \( \lim_{b \to 0^+} \lambda (ib) = 1 \).

\[
\lambda (ib) = \frac{\sum_{m} \cos^2(\pi (m + \frac{1}{2})b) - \sin^2(\pi (m + \frac{1}{2})b)}{\sum_{m} \cos^2(\pi mb) - \sin^2(\pi (m + \frac{1}{2})b)}
\]

\[
= \frac{\sum_{m} \frac{1}{\cosh^2(\pi (m + \frac{1}{2})b)} + \sinh^2(\pi (m + \frac{1}{2})b)}{1} \in (0, 1).
\]  

(56.1.28)

This follows from the observation that

\[
\cos (ix) = \cosh (x), \sin (ix) = i \sinh (x).
\]

Thus it is clear from (56.1.28) that \( \lim_{b \to 0^+} \lambda (ib) = 1 \).

Next I need to consider the behavior of \( \lambda (\tau) \) as \( \text{Im} (\tau) \to \infty \). From (56.1.28) listed here for convenience,

\[
\lambda (\tau) = \frac{\sum_{m} \cos^2(\pi (m + \frac{1}{2})\tau) - \sin^2(\pi (m + \frac{1}{2})\tau)}{\sum_{m} \cos^2(\pi m\tau) - \sin^2(\pi (m + \frac{1}{2})\tau)}.
\]  

(56.1.29)

it follows

\[
\lambda (\tau) = \frac{\frac{1}{\cosh^2(\pi \frac{1}{2})\tau) - \sinh^2(\pi \frac{1}{2})\tau)}{1 + B (\tau)} + A (\tau)
\]

\[
= \frac{2 \cosh^2(\pi \frac{1}{2})\tau) - \sin^2(\pi \frac{1}{2})\tau)}{1 + B (\tau)} + A (\tau)
\]  

(56.1.30)

Where \( A (\tau), B (\tau) \to 0 \) as \( \text{Im} (\tau) \to \infty \). I took out the \( m = 0 \) term involving \( 1/\cosh^2(\pi m\tau) \) in the denominator and the \( m = -1 \) and \( m = 0 \) terms in the numerator of (56.1.29). In fact, \( e^{-i\pi(a+ib)}A(a+ib), e^{-i\pi(a+ib)}B(a+ib) \) converge to zero uniformly in \( a \) as \( b \to \infty \).

Lemma 56.1.19 For \( A, B \) defined in (56.1.28), \( e^{-i\pi(a+ib)}C(a+ib) \to 0 \) uniformly in \( a \) for \( C = A, B \).

Proof: From (56.1.28)

\[
e^{-i\pi \tau} A (\tau) = \sum_{m \neq 0, \neq -1} e^{-i\pi \tau} \frac{\cos^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right) - \sinh^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)}{\cosh^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right) - \sinh^2 \left( \pi \left( m + \frac{1}{2} \right) \tau \right)}
\]

Now let \( \tau = a + ib \). Then letting \( \alpha_m = \pi \left( m + \frac{1}{2} \right) \),

\[
\cos (\alpha_m a + i\alpha_m b) = \cos (\alpha_m a) \cosh (\alpha_m b) - i \sinh (\alpha_m b) \sin (\alpha_m a)
\]

\[
\sin (\alpha_m a + i\alpha_m b) = \sin (\alpha_m a) \cosh (\alpha_m b) + i \cos (\alpha_m a) \sinh (\alpha_m b)
\]
Therefore,
\[
|\cos^2 (\alpha_m a + i\alpha_m b)| = \cos^2 (\alpha_m a) \cosh^2 (\alpha_m b) + \sinh^2 (\alpha_m b) \sin^2 (\alpha_m a) \\
\geq \sinh^2 (\alpha_m b).
\]

Similarly,
\[
|\sin^2 (\alpha_m a + i\alpha_m b)| = \sin^2 (\alpha_m a) \cosh^2 (\alpha_m b) + \cos^2 (\alpha_m a) \sinh^2 (\alpha_m b) \\
\geq \sinh^2 (\alpha_m b).
\]

It follows that for \( \tau = a + ib \) and \( b \) large
\[
|e^{-i\pi\tau} A(\tau)| \leq \sum_{m \neq 0 \atop m \neq -1} \frac{2e^{\pi b}}{\sinh^2 (\pi (m + \frac{1}{2}) b)} + \sum_{m = -\infty}^{\infty} \frac{2e^{\pi b}}{\sinh^2 (\pi (m + \frac{1}{2}) b)}
\]
\[
= 2 \sum_{m = 1}^{\infty} \frac{2e^{\pi b}}{\sinh^2 (\pi (m + \frac{1}{2}) b)} = 4 \sum_{m = 1}^{\infty} \frac{e^{\pi b}}{\sinh^2 (\pi (m + \frac{3}{2}) b)}
\]

Now a short computation shows
\[
\frac{e^{\pi b}}{\sinh^2 (\pi (m + \frac{1}{2}) b)} = \frac{\sinh^2 (\pi (m + \frac{1}{2}) b)}{\sinh^2 (\pi (m + \frac{3}{2}) b)} \leq \frac{1}{e^{3\pi b}}.
\]

Therefore, for \( \tau = a + ib \),
\[
|e^{-i\pi\tau} A(\tau)| \leq 4 \frac{e^{\pi b}}{\sinh (\frac{3\pi b}{2})} \sum_{m = 1}^{\infty} \left( \frac{1}{e^{3\pi b}} \right)^m \\
\leq 4 \frac{e^{\pi b}}{\sinh (\frac{3\pi b}{2})} \frac{1/e^{3\pi b}}{1 - (1/e^{3\pi b})}
\]
which converges to zero as \( b \to \infty \). Similar reasoning will establish the claim about \( B(\tau) \). This proves the lemma.

**Lemma 56.1.20** \( \lim_{b \to \infty} \lambda (a + ib) e^{-i\pi(a+ib)} = 16 \) uniformly in \( a \in \mathbb{R} \).

**Proof:** From \( 56.1.30 \) and Lemma \( 56.1.19 \), this lemma will be proved if it is shown
\[
\lim_{b \to \infty} \left( \frac{2}{\cos^2 (\pi (\frac{1}{2}) (a + ib))} - \frac{2}{\sin^2 (\pi (\frac{1}{2}) (a + ib))} \right) e^{-i\pi(a+ib)} = 16
\]
uniformly in \( a \in \mathbb{R} \). Let \( \tau = a + ib \) to simplify the notation. Then the above expression equals

\[
\left( \frac{8}{(e^{i\frac{\pi}{2}} + e^{-i\frac{\pi}{2}})^2} + \frac{8}{(e^{i\frac{\pi}{2}} - e^{-i\frac{\pi}{2}})^2} \right) e^{-i\tau} = \left( \frac{8ie^{i\tau}}{(e^{i\tau} + 1)^2} + \frac{8ie^{-i\tau}}{(e^{i\tau} - 1)^2} \right) e^{-i\tau} = \frac{8}{(e^{i\tau} + 1)^2} + \frac{8}{(e^{i\tau} - 1)^2} = 16 \frac{1 + e^{2i\tau}}{(1 - e^{2i\tau})^2}.
\]

Now

\[
\left| \frac{1 + e^{2i\tau}}{(1 - e^{2i\tau})^2} - 1 \right| = \left| \frac{1 + e^{2i\tau}}{(1 - e^{2i\tau})^2} - \frac{(1 - e^{2i\tau})^2}{(1 - e^{2i\tau})^2} \right| 
\leq \frac{|3e^{2i\tau} - e^{4i\tau}|}{(1 - e^{-2\pi b})^2} \leq \frac{3e^{-2\pi b} + e^{-4\pi b}}{(1 - e^{-2\pi b})^2}
\]

and this estimate proves the lemma.

**Corollary 56.1.21** \( \lim_{b \to \infty} \lambda(a + ib) = 0 \) uniformly in \( a \in \mathbb{R} \). Also \( \lambda(ib) \) for \( b > 0 \) is real and is between 0 and 1, \( \lambda \) is real on the line, \( l_2 \) and on the curve, \( C \) and \( \lim_{b \to 0^+} \lambda(1 + ib) = -\infty \).

**Proof:** From Lemma 56.1.20

\[
|\lambda(a + ib) e^{-\pi(a+ib)} - 16| < 1
\]

for all \( a \) provided \( b \) is large enough. Therefore, for such \( b \),

\[
|\lambda(a + ib)| \leq 17e^{-\pi b}.
\]

proves the assertion about \( \lambda(-ib) \) real.

By the first part, \( \lim_{b \to \infty} |\lambda(ib)| = 0 \). Now from 56.1.24

\[
\lim_{b \to 0^+} \lambda(ib) = \lim_{b \to 0^+} \left( 1 - \lambda \left( \frac{-1}{ib} \right) \right) = \lim_{b \to 0^+} \left( 1 - \lambda \left( \frac{i}{b} \right) \right) = 1. \quad (56.1.31)
\]

by Corollary 56.1.21.

Next consider the behavior of \( \lambda \) on line \( l_2 \) in the above picture. From 56.1.24 and 56.1.25,

\[
\lambda(1 + ib) = \frac{\lambda(ib)}{\lambda(ib) - 1} < 0
\]
and so as \( b \to 0^+ \) in the above, \( \lambda(1 + ib) \to -\infty \).

It is left as an exercise to show that the map \( \tau \to 1 - \frac{1}{\tau} \) maps \( l_2 \) onto the curve, \( C \). Therefore, by (56.1.22), for \( \tau \in l_2 \),

\[
\lambda \left( 1 - \frac{1}{\tau} \right) = \frac{\lambda \left( \frac{1}{-\tau} \right)}{\lambda \left( \frac{1}{\tau} \right)} - 1 = \frac{1 - \lambda(\tau)}{1 - \lambda(\tau)} - 1 = \frac{\lambda(\tau) - 1}{\lambda(\tau)} \in \mathbb{R}
\]

(56.1.32)

(56.1.33)

It follows \( \lambda \) is real on the boundary of \( \Omega \) in the above picture. This proves the corollary.

Now, following Alfors \([4]\), cut off \( \Omega \) by considering the horizontal line segment, \( z = a + ib_0 \) where \( b_0 \) is very large and positive and \( a \in [0, 1] \). Also cut \( \Omega \) off by the images of this horizontal line, under the transformations \( z = \frac{1}{\tau} \) and \( z = 1 - \frac{1}{\tau} \). These are arcs of circles because the two transformations are fractional linear transformations. It is left as an exercise for you to verify these arcs are situated as shown in the following picture. The important thing to notice is that for \( b_0 \) large the points of these circles are close to the origin and \((1, 0)\) respectively. The following picture is a summary of what has been obtained so far on the mapping by \( \lambda \).

In the picture, the descriptions are of \( \lambda \) acting on points of the indicated boundary of \( \Omega \). Consider the oriented contour which results from \( \lambda(z) \) as \( z \) moves first up \( l_2 \) as indicated, then along the line \( z = a + ib \) and then down \( l_1 \) and then along \( C_1 \) to \( C \) and along \( C \) till \( C_2 \) and then along \( C_2 \) to \( l_2 \). As indicated in the picture, this involves going from a large negative real number to a small negative real number and then over a smooth curve which stays small to a real positive number and from there to a real number near \( 1 \). \( \lambda(z) \) stays fairly near \( 1 \) on \( C_1 \) provided \( b_0 \) is large so that the circle, \( C_1 \) has very small radius. Then along \( C \), \( \lambda(z) \) is real until it hits \( C_2 \). What about the behavior of \( \lambda \) on \( C_2 \)? For \( z \in C_2 \), it follows from the definition of \( C_2 \) that \( z = 1 - \frac{1}{\tau} \) where \( \tau \) is on the line, \( a + ib_0 \). Therefore, by Lemma (56.1.20).
56.1. PERIODIC FUNCTIONS

\[ \lambda(z) = \lambda \left( 1 - \frac{1}{\tau} \right) = \frac{\lambda \left( \frac{1}{\tau} \right)}{\lambda \left( \frac{1}{1 + \tau} \right) - 1} = \frac{\lambda \left( \frac{1}{\tau} \right)}{\lambda \left( \frac{1}{1 + \tau} \right) - 1} \]

which is approximately equal to

\[ 1 - \frac{1}{16e^{i(\pi + ib_0)}} = 1 - \frac{e^{\pi b_0}e^{-i\pi}}{16}. \]

These points are essentially on a large half circle in the upper half plane which has radius approximately \( e^{b_0} \).

Now let \( w \in \mathbb{C} \) with \( \text{Im}(w) \neq 0 \). Then for \( b_0 \) large enough, the motion over the boundary of the truncated region indicated in the above picture results in \( \lambda \) tracing out a large simple closed curve oriented in the counter clockwise direction which includes \( w \) on its interior if \( \text{Im}(w) > 0 \) but which excludes \( w \) if \( \text{Im}(w) < 0 \).

**Theorem 56.1.22** Let \( \Omega \) be the domain described above. Then \( \lambda \) maps \( \Omega \) one to one and onto the upper half plane of \( \mathbb{C} \), \( \{ z \in \mathbb{C} \text{ such that } \text{Im}(z) > 0 \} \). Also, the line \( \lambda(l_1) = (0, 1), \lambda(l_2) = (-\infty, 0) \), and \( \lambda(C) = (1, \infty) \).

**Proof:** Let \( \text{Im}(w) > 0 \) and denote by \( \gamma \) the oriented contour described above and illustrated in the above picture. Then the winding number of \( \lambda \circ \gamma \) about \( w \) equals 1. Thus

\[ \frac{1}{2\pi i} \int_{\lambda \circ \gamma} \frac{1}{z - w} dz = 1. \]

But, splitting the contour integrals into \( l_2 \), the top line, \( l_1, C_1, C, \) and \( C_2 \) and changing variables on each of these, yields

\[ 1 = \frac{1}{2\pi i} \int_{\gamma} \frac{\lambda'(z)}{\lambda(z) - w} dz \]

and by the theorem on counting zeros, Theorem 50.6.1 on Page 1008, the function, \( z \rightarrow \lambda(z) - w \) has exactly one zero inside the truncated \( \Omega \). However, this shows this function has exactly one zero inside \( \Omega \) because \( b_0 \) was arbitrary as long as it is sufficiently large. Since \( w \) was an arbitrary element of the upper half plane, this verifies the first assertion of the theorem. The remaining claims follow from the above description of \( \lambda \), in particular the estimate for \( \lambda \) on \( C_2 \). This proves the theorem.

Note also that the argument in the above proof shows that if \( \text{Im}(w) < 0 \), then \( w \) is not in \( \lambda(\Omega) \). However, if you consider the reflection of \( \Omega \) about the y axis, then it will follow that \( \lambda \) maps this set one to one onto the lower half plane. The argument will make significant use of Theorem 51.6.3 on Page 1009 which is stated here for convenience.
Theorem 56.1.23 Let \( f : B(a, R) \to \mathbb{C} \) be analytic and let
\[
f(z) - \alpha = (z - a)^m g(z), \quad \infty > m \geq 1
\]
where \( g(z) \neq 0 \) in \( B(a, R) \). (\( f(z) - \alpha \) has a zero of order \( m \) at \( z = a \).) Then there exist \( \varepsilon, \delta > 0 \) with the property that for each \( z \) satisfying \( 0 < |z - \alpha| < \delta \), there exist points,
\[
\{a_1, \ldots, a_m\} \subseteq B(a, \varepsilon),
\]
such that
\[
f^{-1}(z) \cap B(a, \varepsilon) = \{a_1, \ldots, a_m\}
\]
and each \( a_k \) is a zero of order 1 for the function \( f(\cdot) - z \).

Corollary 56.1.24 Let \( \Omega \) be the region above. Consider the set of points, \( Q = \overline{\Omega \cup \Omega'} \setminus \{0, 1\} \) described by the following picture.

Then \( \lambda(Q) = \mathbb{C} \setminus \{0, 1\} \). Also \( \lambda'(z) \neq 0 \) for every \( z \) in \( \bigcup_{k=\infty}^{-\infty} (Q + 2k) \equiv H \).

**Proof:** By Theorem 56.1.22, this will be proved if it can be shown that \( \lambda'(\Omega') = \{z \in \mathbb{C} : \text{Im}(z) < 0\} \). Consider \( \lambda_1 \) defined on \( \Omega' \) by
\[
\lambda_1(x + iy) \equiv \overline{\lambda(-x + iy)}.
\]

**Claim:** \( \lambda_1 \) is analytic.

**Proof of the claim:** You just verify the Cauchy Riemann equations. Letting \( \lambda(x + iy) = u(x, y) + iv(x, y) \),
\[
\lambda_1(x + iy) = u(-x, y) - iv(-x, y) \equiv u_1(x, y) + iv(x, y).
\]

Then \( u_{1x}(x, y) = -u_x(-x, y) \) and \( v_{1y}(x, y) = -v_y(-x, y) = -u_x(-x, y) \) since \( \lambda \) is analytic. Thus \( u_{1x} = v_{1y} \). Next, \( u_{1y}(x, y) = u_y(-x, y) \) and \( v_{1x}(x, y) = -u_x(-x, y) = -v_y(-x, y) \) and so \( u_{1y} = -v_x \).

Now recall that on \( l_1, \lambda \) takes real values. Therefore, \( \lambda_1 = \lambda \) on \( l_1 \), a set with a limit point. It follows \( \lambda = \lambda_1 \) on \( \Omega' \cup \Omega \). By Theorem 56.1.22 \( \lambda \) maps \( \Omega \) one to one onto the upper half plane. Therefore, from the definition of \( \lambda_1 = \lambda \), it follows \( \lambda \) maps \( \Omega' \) one to one onto the lower half plane as claimed. This has shown that \( \lambda \)
is one to one on $\Omega \cup \Omega'$. This also verifies from Theorem 56.1.33 on Page 1174 that $\lambda' \neq 0$ on $\Omega \cup \Omega'$.

Now consider the lines $l_2$ and $C$. If $\lambda'(z) = 0$ for $z \in l_2$, a contradiction can be obtained. Pick such a point. If $\lambda'(z) = 0$, then $z$ is a zero of order $m \geq 2$ of the function, $\lambda - \lambda(z)$. Then by Theorem 56.1.33 there exist $\delta, \varepsilon > 0$ such that if $w \in B(\lambda(z), \delta)$, then $\lambda^{-1}(w) \cap B(z, \varepsilon)$ contains at least $m$ points.

In particular, for $z_1 \in \Omega \cap B(z, \varepsilon)$ sufficiently close to $z$, $\lambda(z_1) \in B(\lambda(z), \delta)$ and so the function $\lambda - \lambda(z_1)$ has at least two distinct zeros. These zeros must be in $B(z, \varepsilon) \cap \Omega$ because $\lambda(z_1)$ has positive imaginary part and the points on $l_2$ are mapped by $\lambda$ to a real number while the points of $B(z, \varepsilon) \setminus \Omega$ are mapped by $\lambda$ to the lower half plane thanks to the relation, $\lambda(z + 2) = \lambda(z)$. This contradicts $\lambda$ one to one on $\Omega$. Therefore, $\lambda' \neq 0$ on $l_2$. Consider $C$. Points on $C$ are of the form $1 - \frac{1}{\tau}$ where $\tau \in l_2$. Therefore, using \textit{56.1.33},

$$\lambda \left(1 - \frac{1}{\tau}\right) = \frac{\lambda(\tau) - 1}{\lambda(\tau)}.$$ 

Taking the derivative of both sides,

$$\lambda' \left(1 - \frac{1}{\tau}\right) \left(\frac{1}{\tau^2}\right) = \frac{\lambda'(\tau)}{\lambda(\tau)} \neq 0.$$ 

Since $\lambda$ is periodic of period 2 it follows $\lambda'(z) \neq 0$ for all $z \in \cup_{k=-\infty}^{\infty} (Q + 2k)$.

\textbf{Lemma 56.1.25} If $\operatorname{Im}(\tau) > 0$ then there exists a unimodular \begin{pmatrix} a & b \\ c & d \end{pmatrix} such that

$$\frac{c + d\tau}{a + b\tau}$$
is contained in the interior of \( Q \). In fact, \( \left| \frac{c + d\tau}{a + b\tau} \right| \geq 1 \) and

\[-1/2 \leq \text{Re} \left( \frac{c + d\tau}{a + b\tau} \right) \leq 1/2.\]

**Proof:** Letting a basis for the module of periods of \( \varphi \) be \( \{1, \tau\} \), it follows from Theorem 56.1.2 on Page 1860 that there exists a basis for the same module of periods, \( \{w'_1, w'_2\} \) with the property that for \( \tau' = w'_2/w'_1 \)

\[|\tau'| \geq 1, \quad -\frac{1}{2} \leq \text{Re} \tau' \leq \frac{1}{2}.\]

Since this is a basis for the same module of periods, there exists a unimodular matrix, \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \) such that

\[
\begin{pmatrix} w'_1 \\ w'_2 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 1 \\ \tau \end{pmatrix}.
\]

Hence,

\[
\tau' = \frac{w'_2}{w'_1} = \frac{c + d\tau}{a + b\tau}.
\]

Thus \( \tau' \) is in the interior of \( H \). In fact, it is on the interior of \( \Omega' \cup \Omega \equiv Q \).

\[\begin{array}{c}
\end{array}\]

**56.1.7 A Short Review And Summary**

With this lemma, it is easy to extend Corollary 56.1.24. First, a simple observation and review is a good idea. Recall that when you change the basis for the module of periods, the Weierstrass \( \varphi \) function does not change and so the set of \( \epsilon_i \) used in defining \( \lambda \) also do not change. Letting the new basis be \( \{w'_1, w'_2\} \), it was shown that

\[
\begin{pmatrix} w'_1 \\ w'_2 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \end{pmatrix}.
\]
56.1. PERIODIC FUNCTIONS

for some unimodular transformation, \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} \). Letting \( \tau = w_2/w_1 \) and \( \tau' = w'_2/w'_1 \)

\[
\tau' = \frac{c + d\tau}{a + b\tau} \equiv \phi(\tau)
\]

Now as discussed earlier

\[
\lambda(\tau') = \lambda(\phi(\tau)) = \frac{\phi\left(\frac{w_1' + w_2'}{\tau'}\right) - \phi\left(\frac{w_2'}{\tau'}\right)}{\phi\left(\frac{w_1'}{\tau'}\right) - \phi\left(\frac{w_2'}{\tau'}\right)}
\]

These numbers in the above fraction must be the same as \( \phi\left(\frac{1 + \tau'}{\tau}\right), \phi\left(\frac{1}{\tau}\right) \), but they might occur differently. This is because \( \phi \) does not change and these numbers are the zeros of a polynomial having coefficients involving only numbers and \( \phi(z) \). It could happen for example that \( \phi\left(\frac{1 + \tau'}{\tau}\right) = \phi\left(\frac{1}{\tau}\right) \) in which case this would change the value of \( \lambda \). In effect, you can keep track of all possibilities by simply permuting the \( e_i \) in the formula for \( \lambda(\tau) \) given by \( \frac{e_1 - e_2}{e_1 - e_2} \). Thus consider the following permutation table.

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

Corresponding to this list of 6 permutations, all possible formulas for \( \lambda(\phi(\tau)) \) can be obtained as follows. Letting \( \tau' = \phi(\tau) \) where \( \phi \) is a unimodular matrix corresponding to a change of basis,

\[
\lambda(\tau') = \frac{e_3 - e_2}{e_1 - e_2} = \lambda(\tau) \quad (56.1.34)
\]

\[
\lambda(\tau') = \frac{e_1 - e_3}{e_2 - e_3} = \frac{e_3 - e_2 + e_2 - e_1}{e_3 - e_2} = 1 - \frac{1}{\lambda(\tau)} = \frac{\lambda(\tau) - 1}{\lambda(\tau)} \quad (56.1.35)
\]

\[
\lambda(\tau') = \frac{e_2 - e_1}{e_3 - e_1} = -\left[\frac{e_3 - e_2 - (e_1 - e_2)}{e_1 - e_2}\right]^{-1} = -[\lambda(\tau) - 1]^{-1} = \frac{1}{1 - \lambda(\tau)} \quad (56.1.36)
\]

\[
\lambda(\tau') = \frac{e_3 - e_1}{e_2 - e_1} = -\left[\frac{e_3 - e_2 - (e_1 - e_2)}{e_1 - e_2}\right] = -[\lambda(\tau) - 1] = 1 - \lambda(\tau) \quad (56.1.37)
\]
\[
\lambda(\tau') = \frac{e_2 - e_1}{e_1 - e_3} = \frac{e_3 - e_2}{e_3 - e_2 - (e_1 - e_2)} = \frac{1}{1 - \frac{1}{\lambda(\tau)}} = \frac{\lambda(\tau)}{\lambda(\tau) - 1}
\] (56.1.38)

\[
\lambda(\tau') = \frac{e_1 - e_3}{e_3 - e_2} = \frac{1}{\lambda(\tau)}
\] (56.1.39)

**Corollary 56.1.26** \(\lambda'(\tau) \neq 0\) for all \(\tau\) in the upper half plane, denoted by \(P_+\).

**Proof:** Let \(\tau \in P_+\). By Lemma 56.1.27 there exists \(\phi\) a unimodular transformation and \(\tau'\) in the interior of \(Q\) such that \(\tau' = \phi(\tau)\). Now from the definition of \(\lambda\) in terms of the \(e_i\), there is at worst a permutation of the \(e_i\) and so it might be the case that \(\lambda(\phi(\tau)) \neq \lambda(\tau)\) but it is the case that \(\lambda(\phi(\tau)) = \xi(\lambda(\tau))\) where \(\xi'(z) \neq 0\). Here \(\xi\) is one of the functions determined by \[\text{(56.1.37)}\] and analytic continuation. A review of the monodromy theorem will be listed above in \[\text{(56.1.38)}\] All the possibilities are \(\xi(z) = z, \frac{z - 1}{z}, \frac{1}{1 - z}, \frac{1}{1 - z}, \frac{1}{z - 1}, \frac{1}{z}\) and these are the same as the possibilities for \(\xi^{-1}\). Therefore, \(\lambda'(\phi(\tau)) \phi'(\tau) = \xi'(\lambda(\tau)) \lambda'(\tau)\) and so \(\lambda'(\tau) \neq 0\) as claimed.

Now I will present a lemma which is of major significance. It depends on the remarkable mapping properties of the modular function and the monodromy theorem from analytic continuation. A review of the monodromy theorem will be listed here for convenience. First recall the definition of the concept of function elements and analytic continuation.

**Definition 56.1.27** A function element is an ordered pair, \((f, D)\) where \(D\) is an open ball and \(f\) is analytic on \(D\). \((f_0, D_0)\) and \((f_1, D_1)\) are direct continuations of each other if \(D_1 \cap D_0 \neq \emptyset\) and \(f_0 = f_1\) on \(D_1 \cap D_0\). In this case I will write \((f_0, D_0) \sim (f_1, D_1)\). A chain is a finite sequence, of disks, \(\{D_0, \ldots, D_n\}\) such that \(D_{i-1} \cap D_i \neq \emptyset\). If \((f_0, D_0)\) is a given function element and there exist function elements, \((f_1, D_1)\) such that \(\{D_0, \ldots, D_n\}\) is a chain and \((f_{j-1}, D_{j-1}) \sim (f_j, D_j)\) then \((f_n, D_n)\) is called the analytic continuation of \((f_0, D_0)\) along the chain \(\{D_0, \ldots, D_n\}\). Now suppose \(\gamma\) is an oriented curve with parameter interval \([a, b]\) and there exists a chain, \(\{D_0, \ldots, D_n\}\) such that \(\gamma^{-1} \subseteq \bigcup_{k=1}^n D_k\), \(\gamma(a)\) is the center of \(D_0\), \(\gamma(b)\) is the center of \(D_n\), and there is an increasing list of numbers in \([a, b]\), \(a = s_0 < s_1 < \cdots < s_n = b\) such that \(\gamma([s_i, s_{i+1}]) \subseteq D_i\) and \((f_n, D_n)\) is an analytic continuation of \((f_0, D_0)\) along the chain. Then \((f_n, D_n)\) is called an analytic continuation of \((f_0, D_0)\) along the curve \(\gamma\). \(\gamma\) will always be a continuous curve. Nothing more is needed.

Then the main theorem is the monodromy theorem listed next, Theorem 56.1.28 and its corollary on Page 1795.

**Theorem 56.1.28** Let \(\Omega\) be a simply connected subset of \(\mathbb{C}\) and suppose \((f, B(a, r))\) is a function element with \(B(a, r) \subseteq \Omega\). Suppose also that this function element can be analytically continued along every curve through \(a\). Then there exists \(G\) analytic on \(\Omega\) such that \(G\) agrees with \(f\) on \(B(a, r)\).
Here is the lemma.

**Lemma 56.1.29** Let \( \lambda \) be the modular function defined on \( P_+ \) the upper half plane. Let \( V \) be a simply connected region in \( \mathbb{C} \) and let \( f : V \to \mathbb{C} \setminus \{0,1\} \) be analytic and nonconstant. Then there exists an analytic function, \( g : V \to P_+ \) such that \( \lambda \circ g = f \).

**Proof:** Let \( a \in V \) and choose \( r_0 \) small enough that \( f(B(a,r_0)) \) contains neither 0 nor 1. You need only let \( B(a,r_0) \subseteq V \). Now there exists a unique point in \( Q,r_0 \) such that \( \lambda(r_0) = f(a) \). By Corollary 56.1.24 \( \lambda'(r_0) \neq 0 \) and so by the open mapping theorem, Theorem 56.1.26 on Page 981, there exists \( B(r_0,R_0) \subseteq P_+ \) such that \( \lambda \) is one to one on \( B(r_0,R_0) \) and has a continuous inverse. Then picking \( r_0 \) still smaller, it can be assumed \( f(B(a,r_0)) \subseteq \lambda(B(r_0,R_0)) \). Thus there exists a local inverse for \( \lambda, \lambda_0^{-1} \) defined on \( f(B(a,r_0)) \) having values in \( B(r_0,R_0) \cap \lambda^{-1}(f(B(a,r_0))) \). Then defining \( g_0 \equiv \lambda_0^{-1} \circ f, (g_0,B(a,r_0)) \) is a function element. I need to show this can be continued along every curve starting at \( a \) in such a way that each function in each function element has values in \( P_+ \).

Let \( \gamma : [a,b] \to V \) be a continuous curve starting at \( a, (\gamma(a) = a) \) and suppose that if \( t < T \) there exists a nonnegative integer \( m \) and a function element \((g_m,B(\gamma(t),r_m))\) which is an analytic continuation of \((g_0,B(a,r_0))\) along \( \gamma \) where \( g_m(\gamma(t)) \in P_+ \) and each function in every function element for \( j \leq m \) has values in \( P_+ \). Thus for some small \( T > 0 \) this has been achieved.

Then consider \( f(\gamma(T)) \equiv \mathbb{C} \setminus \{0,1\} \). As in the first part of the argument, there exists a unique \( \gamma(T) \equiv \mathbb{Q} \) such that \( \lambda(\gamma(T)) = f(\gamma(T)) \) and for \( r \) small enough there is an analytic local inverse, \( \lambda_T^{-1} \), between \( f(B(\gamma(T),r)) \) and \( \lambda^{-1}(f(B(\gamma(T),r))) \cap B(\tau_T,R_T) \subseteq P_+ \) for some \( R_T > 0 \). By the assumption that the analytic continuation can be carried out for \( t < T \), there exists \( \{t_0,\ldots,t_m = t\} \) and function elements \((g_j,B(\gamma(t_j),r_j)), j = 0,\ldots,m \) as just described with \( g_j(\gamma(t_j)) \in P_+ \) and \( \lambda \circ g_j = f \) on \( B(\gamma(t_j),r_j) \) such that for \( t \in [t_m,T], \gamma(t) \in B(\gamma(T),r) \). Let

\[
I = B(\gamma(t_m),r_m) \cap B(\gamma(T),r) .
\]

Then since \( \lambda_T^{-1} \) is a local inverse, it follows for all \( z \in I \)

\[
\lambda(g_m(z)) = f(z) = \lambda(\lambda_T^{-1} \circ f(z))
\]

Pick \( z_0 \in I \). Then by Lemma 56.1.28 on Page 981 there exists a unimodular mapping of the form

\[
\phi(z) = \frac{az+b}{cz+d}
\]

where

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \sim \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \mod 2
\]

such that

\[
g_m(z_0) = \phi(\lambda_T^{-1} \circ f(z_0)) .
\]

Since both \( g_m(z_0) \) and \( \phi(\lambda_T^{-1} \circ f(z_0)) \) are in the upper half plane, it follows \( ad - cb = 1 \) and \( \phi \) maps the upper half plane to the upper half plane. Note the pole of
$\phi$ is real and all the sets being considered are contained in the upper half plane so $\phi$ is analytic where it needs to be.

**Claim:** For all $z \in I$,

$$g_m(z) = \phi \circ \lambda_T^{-1} \circ f(z). \quad (56.1.40)$$

**Proof:** For $z = z_0$ the equation holds. Let
