$$A = \{ z \in I : g_m(z) = \phi \left( \lambda_T^{-1} \circ f(z) \right) \}.$$

Thus $z_0 \in I$. If $z \in I$ and if $w$ is close enough to $z$, then $w \in I$ also and so both sides of $56.1.40$ with $w$ in place of $z$ are in $\lambda_T^{-1}(f(I))$. But by construction, $\lambda$ is one to one on this set and since $\lambda$ is invariant with respect to $\phi$,

$$\lambda(g_m(w)) = \lambda(\lambda_T^{-1} \circ f(w)) = \lambda(\phi \circ \lambda_T^{-1} \circ f(w))$$

and consequently, $w \in A$. This shows $A$ is open. But $A$ is also closed in $I$ because the functions are continuous. Therefore, $A = I$ and so $56.1.40$ is obtained.

Letting $f(z) \in f(B(\gamma(T)), r)$,

$$\lambda(\phi(\lambda_T^{-1}(f(z)))) = \lambda(\lambda_T^{-1}(f(z))) = f(z)$$

and so $\phi \circ \lambda_T^{-1}$ is a local inverse for $\lambda$ on $f(B(\gamma(T)), r)$. Let the new function be $\left( \frac{g_m + 1}{\phi \circ \lambda_T^{-1} \circ f, B(\gamma(T), r)} \right)$. This has shown the initial function element can be continued along every curve through $a$.

By the monodromy theorem, there exists $g$ analytic on $V$ such that $g$ has values in $P_+$ and $g = g_0$ on $B(a, r_0)$. By the construction, it also follows $\lambda \circ g = f$. This last claim is easy to see because $\lambda \circ g = f$ on $B(a, r_0)$, a set with a limit point so the equation holds for all $z \in V$. This proves the lemma.

### 56.2 The Picard Theorem Again

Having done all this work on the modular function which is important for its own sake, there is an easy proof of the Picard theorem. In fact, this is the way Picard did it in 1879. I will state it slightly differently since it is no trouble to do so. 

**Theorem 56.2.1** Let $f$ be meromorphic on $\mathbb{C}$ and suppose $f$ misses three distinct points, $a, b, c$. Then $f$ is a constant function.

**Proof:** Let $\phi(z) \equiv \frac{z-a}{z-b}$. Then $\phi(c) = \infty$, $\phi(a) = 0$, and $\phi(b) = 1$. Now consider the function, $h = \phi \circ f$. Then $h$ misses the three points $\infty, 0$, and $1$. Since $h$ is meromorphic and does not have $\infty$ in its values, it must actually be analytic. Thus $h$ is an entire function which misses the two values $0$ and $1$. If $h$ is not constant, then by Lemma 56.1.29 there exists a function, $g$ analytic on $\mathbb{C}$ which has values
in the upper half plane, $P_+$ such that $\lambda \circ g = h$. However, $g$ must be a constant because there exists $\psi$ an analytic map on the upper half plane which maps the upper half plane to $B(0, 1)$. You can use the Riemann mapping theorem or more simply, $\psi(z) = \frac{z-i}{z+i}$. Thus $\psi \circ g$ equals a constant by Liouville’s theorem. Hence $g$ is a constant and so $h$ must also be a constant because $\lambda(g(z)) = h(z)$. This proves $f$ is a constant also. This proves the theorem.

56.3 Exercises

1. Show the set of modular transformations is a group. Also show those modular transformations which are congruent mod 2 to the identity as described above is a subgroup.

2. Suppose $f$ is an elliptic function with period module $M$. If $\{w_1, w_2\}$ and $\{w_1', w_2'\}$ are two bases, show that the resulting period parallelograms resulting from the two bases have the same area.

3. Given a module of periods with basis $\{w_1, w_2\}$ and letting a typical element of this module be denoted by $w$ as described above, consider the product

$$\sigma(z) = z \prod_{w \neq 0} \left(1 - \frac{z}{w} \right) e^{(z/w) + \frac{1}{2}(z/w)^2}.$$ 

Show this product converges uniformly on compact sets, is an entire function, and satisfies

$$\sigma'(z) / \sigma(z) = \zeta(z)$$

where $\zeta(z)$ was defined above as a primitive of $\varphi(z)$ and is given by

$$\zeta(z) = \frac{1}{z} + \sum_{w \neq 0} \frac{1}{z - w} + \frac{z}{w^2} + \frac{1}{w}.$$ 

4. Show $\zeta(z + w_i) = \zeta(z) + \eta_i$ where $\eta_i$ is a constant.

5. Let $P_a$ be the parallelogram shown in the following picture.
Show that $\frac{1}{2\pi i} \int_{\partial P} \zeta(z) \, dz = 1$ where the contour is taken once around the parallelogram in the counter clockwise direction. Next evaluate this contour integral directly to obtain Legendre’s relation,

$$\eta_1 w_2 - \eta_2 w_1 = 2\pi i.$$  

6. For \( \sigma \) defined in Problem 5.4 explain the following steps. For \( j = 1, 2 \)

$$\frac{\sigma'(z + w_j)}{\sigma(z + w_j)} = \zeta(z + w_j) = \zeta(z) + \eta_j = \frac{\sigma'(z)}{\sigma(z)} + \eta_j$$

Therefore, there exists a constant, \( C_j \) such that

$$\sigma(z + w_j) = C_j \sigma(z) e^{\eta_j z}.$$  

Next show \( \sigma \) is an odd function, \( (\sigma(-z) = -\sigma(z)) \) and then let \( z = -w_j/2 \) to find \( C_j = -e^{\eta_j w_j/2} \) and so

$$\sigma(z + w_j) = -\sigma(z) e^{\eta_j (z + \frac{w_j}{2})}. \quad (56.3.41)$$  

7. Show any even elliptic function, \( f \) with periods \( w_1 \) and \( w_2 \) for which 0 is neither a pole nor a zero can be expressed in the form

$$f(0) \prod_{k=1}^{n} \frac{\wp(z) - \wp(a_k)}{\wp(z) - \wp(b_k)}$$

where \( C \) is some constant. Here \( \wp \) is the Weierstrass function which comes from the two periods, \( w_1 \) and \( w_2 \). **Hint:** You might consider the above function in terms of the poles and zeros on a period parallelogram and recall that an entire function which is elliptic is a constant.

8. Suppose \( f \) is any elliptic function with \( \{w_1, w_2\} \) a basis for the module of periods. Using Theorem 56.1.8 and 56.3.41 show that there exists constants \( a_1, \cdots, a_n \) and \( b_1, \cdots, b_n \) such that for some constant \( C \),

$$f(z) = C \prod_{k=1}^{n} \frac{\sigma(z - a_k)}{\sigma(z - b_k)}.$$  

**Hint:** You might try something like this: By Theorem 56.1.8, it follows that if \( \{\alpha_k\} \) are the zeros and \( \{b_k\} \) the poles in an appropriate period parallelogram, \( \sum \alpha_k - \sum b_k \) equals a period. Replace \( \alpha_k \) with \( a_k \) such that \( \sum a_k - \sum b_k = 0 \). Then use 56.3.41 to show that the given formula for \( f \) is bi periodic. Anyway, you try to arrange things such that the given formula has the same poles as \( f \). Remember an entire elliptic function equals a constant.

9. Show that the map \( \tau \to 1 - \frac{1}{z} \) maps \( l_2 \) onto the curve, \( C \) in the above picture on the mapping properties of \( \lambda \).

10. Modify the proof of Theorem 56.1.22 to show that \( \lambda(\Omega) \cap \{z \in \mathbb{C} : \text{Im}(z) < 0\} = \emptyset \).
Part VI

Topics In Probability
Chapter 57

Basic Probability

Caution: This material on probability and stochastic processes may be half baked in places. I have not yet rewritten it several times. This is not to say that nothing else is half baked. However, the probability is higher here.

57.1 Random Variables And Independence

Recall Lemma 12.2.3 on Page 365 which is stated here for convenience.

Lemma 57.1.1 Let $M$ be a metric space with the closed balls compact and suppose $\lambda$ is a measure defined on the Borel sets of $M$ which is finite on compact sets. Then there exists a unique Radon measure, $\lambda$, which equals $\lambda$ on the Borel sets. In particular $\lambda$ must be both inner and outer regular on all Borel sets.

Also important is the following fundamental result which is called the Borel Cantelli lemma.

Lemma 57.1.2 Let $(\Omega, F, \lambda)$ be a measure space and let $\{A_i\}$ be a sequence of measurable sets satisfying
\[
\sum_{i=1}^{\infty} \lambda(A_i) < \infty.
\]
Then letting $S$ denote the set of $\omega \in \Omega$ which are in infinitely many $A_i$, it follows $S$ is a measurable set and $\lambda(S) = 0$.

Proof: $S = \bigcap_{k=1}^{\infty} \bigcup_{m=k}^{\infty} A_m$. Therefore, $S$ is measurable and also
\[
\lambda(S) \leq \lambda(\bigcup_{m=k}^{\infty} A_m) \leq \sum_{m=k}^{\infty} \lambda(A_k)
\]
and this converges to 0 as $k \to \infty$ because of the convergence of the series.

Here is another nice observation.

1897
CHAPTER 57. BASIC PROBABILITY

Proposition 57.1.3 Suppose $E_i$ is a separable Banach space. Then if $B_i$ is a Borel set of $E_i$, it follows $\prod_{i=1}^n B_i$ is a Borel set in $\prod_{i=1}^n E_i$.

**Proof:** An easy way to do this is to consider the projection maps.

$$\pi_i x \equiv x_i$$

Then these projection maps are continuous. Hence for $U$ an open set,

$$\pi_i^{-1}(U) = \prod_{j=1}^n A_j, \ A_j = E_j \text{ if } j \neq i \text{ and } A_i = U.$$  

Thus $\pi_i^{-1}(\text{open})$ equals an open set. Let

$$S \equiv \{ V \subseteq \mathbb{R} : \pi_i^{-1}(V) \text{ is Borel} \}$$

Then $S$ contains all the open sets and is clearly a $\sigma$ algebra. Therefore, $S$ contains the Borel sets. Let $B_i$ be a Borel set in $E_i$. Then

$$\prod_{i=1}^n B_i = \cap_{i=1}^n \pi_i^{-1}(B_i),$$

a finite intersection of Borel sets. ■

**Definition 57.1.4** A probability space is a measure space, $(\Omega, F, P)$ where $P$ is a measure satisfying $P(\Omega) = 1$. A random vector (variable) is a measurable function, $X : \Omega \rightarrow Z$ where $Z$ is some topological space. It is often the case that $Z$ will equal $\mathbb{R}^p$. Assume $Z$ is a separable Banach space. Define the following $\sigma$ algebra.

$$\sigma(X) \equiv \{ X^{-1}(E) : E \text{ is Borel in } Z \}$$

Thus $\sigma(X) \subseteq F$. For $E$ a Borel set in $Z$ define

$$\lambda_X(E) \equiv P(X^{-1}(E)).$$

This is called the distribution of the random variable, $X$. If

$$\int_{\Omega} |X(\omega)| dP < \infty$$

then define

$$E(X) \equiv \int_{\Omega} X dP$$

where the integral is defined as the Bochner integral.

Recall the following fundamental result which was proved earlier but which I will give a short proof of now.
57.1. RANDOM VARIABLES AND INDEPENDENCE

Proposition 57.1.5 Let \((\Omega, S, \mu)\) be a measure space and let \(X : \Omega \to Z\) where \(Z\) is a separable Banach space. Then \(X\) is strongly measurable if and only if \(X^{-1}(U) \in S\) for all \(U\) open in \(Z\).

**Proof:** To begin with, let \(D(a, r)\) be the closure of the open ball \(B(a, r)\). By Lemma 57.1.3, there exists \(\{f_i\} \subseteq B'\), the unit ball in \(Z'\) such that

\[\|z\|_Z = \sup_i |f_i(z)|\]

Then

\[D(a, r) = \{z : \|a - z\| \leq r\} = \cap_i \{z : |f_i(z) - f_i(a)| \leq r\} = \cap_i f_i^{-1}(B(f_i(a), r))\]

It follows that

\[X^{-1}(D(a, r)) = \cap_i X^{-1}(f_i^{-1}(B(f_i(a), r))) = \cap_i (f_i \circ X)^{-1}(B(f_i(a), r))\]

If \(X\) is strongly measurable, then it is weakly measurable and so each \(f_i \circ X\) is a real (complex) valued measurable function. Hence the expression on the right in the above is measurable. Now if \(U\) is any open set in \(Z\), then it is the countable union of such closed disks \(U = \bigcup_i D_i\). Therefore, \(X^{-1}(U) = \cap_i X^{-1}(D_i) \in S\). It follows that strongly measurable implies inverse images of open sets are in \(S\).

Conversely, suppose \(X^{-1}(U) \in S\) for every open \(U\). Then for \(f \in Z'\), \(f \circ X\) is real valued and measurable. Therefore, \(X\) is weakly measurable. By the Pettis theorem, it follows that \(f \circ X\) is strongly measurable. ■

Proposition 57.1.6 If \(X : \Omega \to Z\) is measurable, then \(\sigma(X)\) equals the smallest \(\sigma\) algebra such that \(X\) is measurable with respect to it. Also if \(X_i\) are random variables having values in separable Banach spaces \(Z_i\), then \(\sigma(X) = \sigma(X_1, \cdots, X_n)\) where \(X\) is the vector mapping \(\Omega\) to \(\prod_{i=1}^n Z_i\) and \(\sigma(X_1, \cdots, X_n)\) is the smallest \(\sigma\) algebra such that each \(X_i\) is measurable with respect to it.

**Proof:** Let \(\mathcal{G}\) denote the smallest \(\sigma\) algebra such that \(X\) is measurable with respect to this \(\sigma\) algebra. By definition \(X^{-1}(\text{open}) \in \mathcal{G}\). Furthermore, the set of all \(E\) such that \(X^{-1}(E) \in \mathcal{G}\) is a \(\sigma\) algebra. Hence it includes all the Borel sets. Hence \(X^{-1}(\text{Borel}) \in \mathcal{G}\) and so \(\mathcal{G} \supseteq \sigma(X)\). However, \(\sigma(X)\) defined above is a \(\sigma\) algebra such that \(X\) is measurable with respect to \(\sigma(X)\). Therefore, \(\mathcal{G} = \sigma(X)\).

Letting \(B_i\) be a Borel set in \(Z_i\), \(\prod_{i=1}^n B_i\) is a Borel set by Proposition 57.1.5 and so

\[X^{-1}\left(\prod_{i=1}^n B_i\right) = \cap_{i=1}^n X_i^{-1}(B_i) \in \sigma(X_1, \cdots, X_n)\]

If \(\mathcal{G}\) denotes the Borel sets \(F \subseteq \prod_{i=1}^n Z_i\) such that \(X^{-1}(F) \in \sigma(X_1, \cdots, X_n)\), then \(\mathcal{G}\) is clearly a \(\sigma\) algebra which contains the open sets. Hence \(\mathcal{G} = \mathcal{B}\) the Borel sets of
This shows that $\sigma(\mathbf{X}) \subseteq \sigma(X_1, \cdots, X_n)$. Next we observe that $\sigma(\mathbf{X})$ is a $\sigma$-algebra with the property that each $X_i$ is measurable with respect to $\sigma(\mathbf{X})$. This follows from $X_i^{-1}(B_i) = X^{-1}\left(\prod_{j=1}^{n} A_j\right) \in \sigma(\mathbf{X})$, where each $A_j = Z_j$ except for $A_i = B_i$. Since $\sigma(X_1, \cdots, X_n)$ is defined as the smallest such $\sigma$-algebra, it follows that $\sigma(\mathbf{X}) \supseteq \sigma(X_1, \cdots, X_n)$.

For random variables having values in a separable Banach space or even more generally for a separable metric space, much can be said about regularity of $\lambda_{\mathbf{X}}$.

**Definition 57.1.7** A measure, $\mu$ defined on $\mathcal{B}(E)$ will be called inner regular if for all $F \in \mathcal{B}(E)$,

$$\mu(F) = \sup \{ \mu(K) : K \subseteq F \text{ and } K \text{ is closed} \}$$

A measure, $\mu$ defined on $\mathcal{B}(E)$ will be called outer regular if for all $F \in \mathcal{B}(E)$,

$$\mu(F) = \inf \{ \mu(V) : V \supseteq F \text{ and } V \text{ is open} \}$$

When a measure is both inner and outer regular, it is called regular.

For probability measures, the above definition of regularity tends to come free. Note it is a little weaker than the usual definition of regularity because $K$ is only assumed to be closed, not compact.

**Lemma 57.1.8** Let $\mu$ be a finite measure defined on $\mathcal{B}(E)$ where $E$ is a metric space. Then $\mu$ is regular.

**Proof:** First note every open set is the countable union of closed sets and every closed set is the countable intersection of open sets. Here is why. Let $V$ be an open set and let

$$K_k \equiv \{ x \in V : \text{dist}(x, V^C) \geq 1/k \}.$$ 

Then clearly the union of the $K_k$ equals $V$. Next, for $K$ closed let

$$V_k \equiv \{ x \in E : \text{dist}(x, K) < 1/k \}.$$ 

Clearly the intersection of the $V_k$ equals $K$. Therefore, letting $V$ denote an open set and $K$ a closed set,

$$\mu(V) = \sup \{ \mu(K) : K \subseteq V \text{ and } K \text{ is closed} \}$$

$$\mu(K) = \inf \{ \mu(V) : V \supseteq K \text{ and } V \text{ is open} \}.$$ 

Also since $V$ is open and $K$ is closed,

$$\mu(V) = \inf \{ \mu(U) : U \supseteq V \text{ and } V \text{ is open} \}$$

$$\mu(K) = \sup \{ \mu(L) : L \subseteq K \text{ and } L \text{ is closed} \}.$$ 

In words, $\mu$ is regular on open and closed sets. Let

$$\mathcal{F} \equiv \{ F \in \mathcal{B}(E) \text{ such that } \mu \text{ is regular on } F \}.$$
Then $\mathcal{F}$ contains the open sets and the closed sets.

Suppose $F \in \mathcal{F}$. Then there exists $V \supseteq F$ such that $\mu (V \setminus F) < \varepsilon$. It follows $V^C \subseteq F^C$ and
\[
\mu (F^C \setminus V^C) = \mu (V \setminus F) < \varepsilon.
\]

Thus $F^C$ is inner regular. Since $F \in \mathcal{F}$, there exists $K \subseteq F$ where $K$ is closed and $\mu (F \setminus K) < \varepsilon$. Then also $K^C \supseteq F^C$ and
\[
\mu (K^C \setminus F^C) = \mu (F \setminus K) < \varepsilon.
\]

Thus if $F \in \mathcal{F}$ so is $F^C$.

Suppose now that $\{F_i\} \subseteq \mathcal{F}$, the $F_i$ being disjoint. Is $\bigcup F_i \in \mathcal{F}$? There exists $K_i \subseteq F_i$ such that $\mu (K_i) + \varepsilon/2^i > \mu (F_i)$. Then
\[
\mu (\bigcup_{i=1}^{\infty} F_i) = \sum_{i=1}^{\infty} \mu (F_i) \leq \varepsilon + \sum_{i=1}^{\infty} \mu (K_i)
\]
\[
< 2\varepsilon + \sum_{i=1}^{N} \mu (K_i) = 2\varepsilon + \mu (\bigcup_{i=1}^{N} K_i)
\]

provided $N$ is large enough. Thus it follows $\bigcup_{i=1}^{\infty} F_i$ is inner regular. Why is it outer regular? Let $V_i \supseteq F_i$ such that $\mu (F_i) + \varepsilon/2^i > \mu (V_i)$ and
\[
\mu (\bigcup_{i=1}^{\infty} F_i) = \sum_{i=1}^{\infty} \mu (F_i) > -\varepsilon + \sum_{i=1}^{\infty} \mu (V_i) \geq -\varepsilon + \mu (\bigcup_{i=1}^{\infty} V_i)
\]

which shows $\bigcup_{i=1}^{\infty} F_i$ is outer regular. It follows $\mathcal{F}$ contains the $\pi$ system consisting of open sets and so by the Lemma on $\pi$ systems, Lemma \[10.12.3, \mathcal{F}$ contains $\sigma (\tau)$ where $\tau$ is the set of open sets. Hence $\mathcal{F}$ contains the Borel sets and is itself a subset of the Borel sets by definition. Therefore, $\mathcal{F} = \mathcal{B} (E)$. \(\blacksquare\)

One can say more if the metric space is complete and separable. In fact in this case the above definition of inner regularity can be shown to imply the usual one.

**Lemma 57.1.9** Let $\mu$ be a finite measure on a $\sigma$ algebra containing $\mathcal{B} (E)$, the Borel sets of $E$, a separable complete metric space. Then if $C$ is a closed set,
\[
\mu (C) = \sup \{ \mu (K) : K \subseteq C \text{ and } K \text{ is compact} \}
\]

**Proof:** Let $\{a_k\}$ be a countable dense subset of $C$. Thus $\bigcup_{k=1}^{\infty} B \left( a_k, \frac{1}{n} \right) \supseteq C$. Therefore, there exists $m_n$ such that
\[
\mu \left( C \setminus \bigcup_{k=1}^{m_n} B \left( a_k, \frac{1}{n} \right) \right) = \mu (C \setminus C_n) < \frac{\varepsilon}{2^n}.
\]

Now let $K = C \cap (\cap_{n=1}^{\infty} C_n)$. Then $K$ is a subset of $C_n$ for each $n$ and so for each $\varepsilon > 0$ there exists an $\varepsilon$ net for $K$ since $C_n$ has a $1/n$ net, namely $a_1, \ldots, a_{m_n}$. Since
is closed, it is complete and so it is also compact since it is complete and totally bounded. Now

\[ \mu(C \setminus K) = \mu(\cup_{n=1}^{\infty} (C \setminus C_n)) < \sum_{n=1}^{\infty} \frac{\varepsilon}{2^n} = \varepsilon. \]

Thus \( \mu(C) \) can be approximated by \( \mu(K) \) for \( K \) a compact subset of \( C \). This proves the lemma.

**Definition 57.1.10** A measurable function \( X : (\Omega, \mathcal{F}, \mu) \to Z \) a topological space is called a random variable when \( \mu(\Omega) = 1 \). For such a random variable, one can define a distribution measure \( \lambda_X \) on the Borel sets of \( Z \) as follows.

\[ \lambda_X(G) \equiv \mu(X^{-1}(G)) \]

This is a well-defined measure on the Borel sets of \( Z \) because it makes sense for every \( G \) open and \( \mathcal{G} \equiv \{ G \subseteq Z : X^{-1}(G) \in \mathcal{F} \} \) is a \( \sigma \) algebra which contains the open sets, hence the Borel sets. Such a measurable function is also called a random vector.

**Corollary 57.1.11** Let \( X \) be a random variable (random vector) with values in a complete metric space, \( Z \). Then \( \lambda_X \) is an inner and outer regular measure defined on \( \mathcal{B}(Z) \).

**Proposition 57.1.12** For \( X \) a random vector defined above, \( X \) having values in a complete separable metric space \( Z \), then \( \lambda_X \) is inner and outer regular and Borel.

\[ (\Omega, P) \xrightarrow{X} (Z, \lambda_X) \xrightarrow{h} E \]

If \( h \) is Borel measurable and \( h \in L^1(Z, \lambda_X; E) \) for \( E \) a Banach space, then

\[ \int_{\Omega} h(X(\omega)) dP = \int_{Z} h(x) d\lambda_X. \quad (57.1.1) \]

In the case where \( Z = E \), a separable Banach space, if \( X \) is measurable then \( X \in L^1(\Omega; E) \) if and only if the identity map on \( E \) is in \( L^1(E; \lambda_X) \) and

\[ \int_{\Omega} X(\omega) dP = \int_{E} x d\lambda_X(x) \]

\[ (57.1.2) \]

**Proof:** The regularity claims are established above. It remains to verify \( 57.1.1 \).

Since \( h \in L^1(Z, E) \), it follows there exists a sequence of simple functions \( \{ h_n \} \) such that

\[ h_n(x) \to h(x), \quad \int_{Z} ||h_m - h_n|| d\lambda_X \to 0 \quad \text{as} \quad m, n \to \infty. \]

The first convergence above implies

\[ h_n \circ X \to h \circ X \quad \text{pointwise on} \quad \Omega \]  \[ (57.1.3) \]
57.2. Kolmogorov Extension Theorem for Polish Spaces

Let $M_t$ be a complete separable metric space. This is called a Polish space. $I$ will denote a totally ordered index set, (Like $\mathbb{R}$) and the interest will be in building a measure on the product space, $\prod_{t \in I} M_t$. By the well ordering principle, you can always put an order on any index set so this order is no restriction, but we do not insist on a well order and in fact, index sets of great interest are $\mathbb{R}$ or $[0, \infty)$. Also for $X$ a topological space, $\mathcal{B}(X)$ will denote the Borel sets.

**Notation 57.2.1** The symbol $J$ will denote a finite subset of $I$, $J = (t_1, \ldots, t_n)$, the $t_i$ taken in order. $E_J$ will denote a set which has a set $E_t$ of $\mathcal{B}(M_t)$ in the $t^{th}$ position for $t \in J$ and for $t \notin J$, the set in the $t^{th}$ position will be $M_t$. $K_J$ will denote a set which has a compact set in the $t^{th}$ position for $t \in J$ and for $t \notin J$, the
set in the $t^{th}$ position will be $M_t$. Also denote by $\mathcal{R}_J$ the sets $E_J$ and $\mathcal{R}$ the union of the $\mathcal{R}_J$. Let $E_J$ denote finite disjoint unions of sets of $\mathcal{R}_J$ and let $\mathcal{E}$ denote finite disjoint unions of sets of $\mathcal{R}$. Thus if $F$ is a set of $\mathcal{E}$, there exists $J$ such that $F$ is a finite disjoint union of sets of $\mathcal{R}_J$. For $F \in \Omega$, denote by $\pi_J(F)$ the set $\prod_{t \in J} F_t$ where $F = \prod_{t \in I} F_t$.

**Lemma 57.2.2** The sets, $\mathcal{E}_J$ defined above form an algebra of sets of $\prod_{t \in J} M_t$.

**Proof:** First consider $\mathcal{R}_J$. If $A, B \in \mathcal{R}_J$, then $A \cap B \in \mathcal{R}_J$ also. Is $A \setminus B$ a finite disjoint union of sets of $\mathcal{R}_J$? It suffices to verify that $\pi_J(A \setminus B)$ is a finite disjoint union of $\pi_J(\mathcal{R}_J)$. Let $|J|$ denote the number of indices in $J$. If $|J| = 1$, then it is obvious that $\pi_J(A \setminus B)$ is a finite disjoint union of $\mathcal{E}_J$. In fact, letting $J = (t)$ and the $t^{th}$ entry of $A$ is $A$ and the $t^{th}$ entry of $B$ is $B$, then the $t^{th}$ entry of $A \setminus B$ is $A \setminus B$, a Borel set of $M_t$, a finite disjoint union of Borel sets of $M_t$.

Suppose then that for $A, B$ sets of $\mathcal{R}_J$, $\pi_J(A \setminus B)$ is a finite disjoint union of sets of $\pi_J(\mathcal{R}_J)$ for $|J| \leq n$, and consider $J = (t_1, \cdots, t_n, t_{n+1})$. Let the $t_i^{th}$ entry of $A$ and $B$ be respectively $A_i$ and $B_i$. It follows that $\pi_J(A \setminus B)$ has the following in the entries for $J$

$$(A_1 \times A_2 \times \cdots \times A_n \times A_{n+1}) \setminus (B_1 \times B_2 \times \cdots \times B_n \times B_{n+1})$$

Letting $A$ represent $A_1 \times A_2 \times \cdots \times A_n$ and $B$ represent $B_1 \times B_2 \times \cdots \times B_n$, this is of the form

$$A \times (A_{n+1} \setminus B_{n+1}) \cup (A \setminus B) \times (A_{n+1} \setminus B_{n+1})$$

By induction, $(A \setminus B)$ is the finite disjoint union of sets of $\mathcal{R}_{(t_1, \cdots, t_n)}$. Therefore, the above is the finite disjoint union of sets of $\mathcal{R}_J$. It follows that $\mathcal{E}_J$ is an algebra.

Now suppose $A, B \in \mathcal{R}$. Then for some finite set $J$, both are in $\mathcal{R}_J$. Then from what was just shown,

$$A \setminus B \in \mathcal{E}_J \subseteq \mathcal{E}, A \cap B \in \mathcal{R}.$$ 

By Lemma 57.2.2 on Page 1904 this shows $\mathcal{E}$ is an algebra. ■

With this preparation, here is the Kolmogorov extension theorem. In the statement and proof of the theorem, $F_t$, $G_t$, and $E_t$ will denote Borel sets. Any list of indices from $I$ will always be assumed to be taken in order. Thus, if $J \subseteq I$ and $J = (t_1, \cdots, t_n)$, it will always be assumed $t_1 < t_2 < \cdots < t_n$.

**Theorem 57.2.3** For each finite set

$$J = (t_1, \cdots, t_n) \subseteq I,$$

suppose there exists a Borel probability measure, $\nu_J = \nu_{t_1, \cdots, t_n}$ defined on the Borel sets of $\prod_{t \in J} M_t$ such that the following consistency condition holds. If

$$(t_1, \cdots, t_n) \subseteq (s_1, \cdots, s_p),$$

then it is obvious that $\pi_J(A \setminus B)$ is a finite disjoint union of sets of $\mathcal{R}_J$. In fact, letting $J = (t)$ and the $t^{th}$ entry of $A$ is $A$ and the $t^{th}$ entry of $B$ is $B$, then the $t^{th}$ entry of $A \setminus B$ is $A \setminus B$, a Borel set of $M_t$, a finite disjoint union of Borel sets of $M_t$.

...
then
\[ \nu_{t_1 \cdots t_n} (F_{t_1} \times \cdots \times F_{t_n}) = \nu_{s_1 \cdots s_p} (G_{s_1} \times \cdots \times G_{s_p}) \] (57.2.5)
where if \( s_i = t_j \), then \( G_{s_i} = F_{t_j} \) and if \( s_i \) is not equal to any of the indices, \( t_k \), then \( G_{s_i} = M_{s_i} \). Then for \( \mathcal{E} \) defined in Definition 57.2.1, there exists a probability measure, \( P \) and a \( \sigma \) algebra \( \mathcal{F} = \sigma (\mathcal{E}) \) such that

\[
\left( \prod_{t \in I} M_t, P, \mathcal{F} \right)
\]
is a probability space. Also there exist measurable functions, \( X_s : \prod_{t \in I} M_t \rightarrow M_s \) defined as

\[ X_s x \equiv x_s \]
for each \( s \in I \) such that for each \( (t_1 \cdots t_n) \subseteq I \),

\[

\nu_{t_1 \cdots t_n} (F_{t_1} \times \cdots \times F_{t_n}) = P \left( [X_{t_1} \in F_{t_1}] \cap \cdots \cap [X_{t_n} \in F_{t_n}] \right) \\
= P \left( \left( X_{t_1}, \ldots, X_{t_n} \right) \in \prod_{j=1}^{n} F_{t_j} \right) = P \left( \prod_{t \in I} F_t \right) \tag{57.2.6}
\]

where \( F_t = M_t \) for every \( t \notin \{t_1 \cdots t_n\} \) and \( F_{t_i} \) is a Borel set. Also if \( f \) is a nonnegative function of finitely many variables, \( x_{t_1}, \ldots, x_{t_n} \), measurable with respect to \( B \left( \prod_{j=1}^{n} M_{t_j} \right) \), then \( f \) is also measurable with respect to \( \mathcal{F} \) and

\[
\int_{M_{t_1} \times \cdots \times M_{t_n}} f (x_{t_1}, \ldots, x_{t_n}) \, d\nu_{t_1 \cdots t_n} \\
= \int_{\prod_{t \in I} M_t} f (x_{t_1}, \ldots, x_{t_n}) \, dP \tag{57.2.7}
\]

**Proof:** Let \( \mathcal{E} \) be the algebra of sets defined in Definition 57.2.1. I want to define a measure on \( \mathcal{E} \). For \( F \in \mathcal{E} \), there exists \( J \) such that \( F \) is the finite disjoint unions of sets of \( \mathcal{R}_J \). Define

\[ P_0 (F) \equiv \nu_J (\pi_J (F)) \]

Then \( P_0 \) is well defined because of the consistency condition on the measures \( \nu_J \). \( P_0 \) is clearly finitely additive because the \( \nu_J \) are measures and one can pick \( J \) as large as desired to include all \( t \) where there may be something other than \( M_t \). Also, from the definition,

\[ P_0 (\Omega) = P_0 \left( \prod_{t \in I} M_t \right) = \nu_{t_1} (M_{t_1}) = 1. \]

Next I will show \( P_0 \) is a finite measure on \( \mathcal{E} \). After this it is only a matter of using the Caratheodory extension theorem to get the existence of the desired probability measure \( P \).
**Claim:** Suppose $E^n$ is in $E$ and suppose $E^n \downarrow \emptyset$. Then $P_0(E^n) \downarrow 0$.

**Proof of the claim:** If not, there exists a sequence such that although $E^n \downarrow \emptyset$, $P_0(E^n) \downarrow \varepsilon > 0$. Let $E^n \in E_k$. Thus it is a finite disjoint union of sets of $E_k$. By regularity of the measures $\nu_J$, which follows from Lemmas [10.6.12] and [10.6.13], there exists a compact set $K J_n \subseteq E^n$ such that

$$\nu_J(n(K J_n)) + \frac{\varepsilon}{2n+2} > \nu_J(n(E^n))$$

Thus

$$P_0(K J_n) + \frac{\varepsilon}{2n+2} = \nu_J(n(K J_n)) + \frac{\varepsilon}{2n+2} > \nu_J(n(E^n)) = P_0(E^n)$$

The interesting thing about these $K J_n$ is: they have the finite intersection property. Here is why.

$$\varepsilon \leq P_0(\bigcap_{k=1}^n K J_k) + P_0(E^n \setminus \bigcap_{k=1}^n K J_k)$$

$$\leq P_0(\bigcap_{k=1}^n K J_k) + P_0(\bigcup_{k=1}^n E^k \setminus K J_k)$$

$$< P_0(\bigcap_{k=1}^n K J_k) + \sum_{k=1}^{\infty} \frac{\varepsilon}{2^{k+2}} < P_0(\bigcap_{k=1}^n K J_k) + \varepsilon/2,$$

and so $P_0(\bigcap_{k=1}^n K J_k) > \varepsilon/2$. In considering all the $E^n$, there are countably many entries in the product space which have something other than $M_i$ in them. Say these are $\{t_1, t_2, \ldots\}$. Let $p_{t_i}$ be a point which is in the intersection of the $t_i$ components of the sets $K J_n$. The compact sets in the $t_i$ position must have the finite intersection property also because if not, the sets $K J_n$ can’t have it. Thus there is such a point. As to the other positions, use the axiom of choice to pick something in each of these. Thus the intersection of these $K J_n$ contains a point which is contrary to $E^n \downarrow \emptyset$ because these sets are contained in the $E^n$.

With the claim, it follows $P_0$ is a measure on $E$. Here is why: If $E = \cup_{k=1}^\infty E^k$ where $E, E^k \in E$, then $(E \setminus \bigcup_{k=1}^n E^k) \downarrow \emptyset$ and so

$$P_0(\cup_{k=1}^n E^k) \rightarrow P_0(E).$$

Hence if the $E^k$ are disjoint, $P_0(\cup_{k=1}^n E^k) = \sum_{k=1}^n P_0(E^k) \rightarrow P_0(E)$. Thus for disjoint $E^k$ having $\cup_k E^k = E \in E$,

$$P_0(\cup_{k=1}^\infty E^k) = \sum_{k=1}^\infty P_0(E^k).$$

Now to conclude the proof, apply the Caratheodory extension theorem to obtain $P$ a probability measure which extends $P_0$ to a $\sigma$ algebra which contains $\sigma(E)$ the sigma algebra generated by $E$ with $P = P_0$ on $E$. Thus for $E_J \in E$, $P(E_J) = P_0(E_J) = \nu_J(P J E_J)$.
Next, let \( \prod_{I} M_{t}, F, P \) be the probability space and for \( x \in \prod_{I} M_{t} \) let \( X_{t}(x) = x_{t} \), the \( t^{th} \) entry of \( x \). It follows \( X_{t} \) is measurable (also continuous) because if \( U \) is open in \( M_{t} \), then \( X_{t}^{-1}(U) \) has \( U \) in the \( t^{th} \) slot and \( M_{s} \) everywhere else for \( s \neq t \). Thus inverse images of open sets are measurable. Also, letting \( J \) be a finite subset of \( I \) and for \( J = (t_{1}, \cdots, t_{n}) \), and \( F_{t_{1}}, \cdots, F_{t_{n}} \) Borel sets in \( M_{t_{1}}, \cdots, M_{t_{n}} \) respectively, it follows \( F_{J} \), where \( F_{J} \) has \( F_{t_{k}} \) in the \( t_{k}^{th} \) entry, is in \( \mathcal{E} \) and therefore,

\[
P\left(\left[ X_{t_{1}} \in F_{t_{1}} \right] \cap \left[ X_{t_{2}} \in F_{t_{2}} \right] \cap \cdots \cap \left[ X_{t_{n}} \in F_{t_{n}} \right]\right) = \] 
\[
P\left(\left[ \left( X_{t_{1}}, X_{t_{2}}, \cdots, X_{t_{n}} \right) \in F_{t_{1}} \times \cdots \times F_{t_{n}} \right]\right) = \] 
\[
P\left( F_{J} \right) = P_{0}(F_{J}) = \nu_{t_{1}, \cdots, t_{n}}(F_{t_{1}} \times \cdots \times F_{t_{n}}) \] 

Finally consider the claim about the integrals. Suppose \( f(x_{t_{1}}, \cdots, x_{t_{n}}) = \mathcal{X}_{F} \) where \( F \) is a Borel set of \( \prod_{I} M_{t} \) where \( J = (t_{1}, \cdots, t_{n}) \). To begin with suppose

\[
F = F_{t_{1}} \times \cdots \times F_{t_{n}} \] 

(57.2.8)

where each \( F_{t_{j}} \) is in \( \mathcal{B}(M_{t_{j}}) \). Then

\[
\int_{M_{t_{1}} \times \cdots \times M_{t_{n}}} \mathcal{X}_{F}(x_{t_{1}}, \cdots, x_{t_{n}}) \, d\nu_{t_{1}, \cdots, t_{n}} = \nu_{t_{1}, \cdots, t_{n}}(F_{t_{1}} \times \cdots \times F_{t_{n}}) \] 

\[
= P\left( \prod_{I} F_{i} \right) = \int_{\Omega} \mathcal{X}_{F}(x) \, dP \] 

\[
= \int_{\Omega} \mathcal{X}_{F}(x_{t_{1}}, \cdots, x_{t_{n}}) \, dP \] 

(57.2.9)

where \( F_{i} = M_{t_{i}} \) if \( t_{i} \notin J \). Let \( K \) denote sets, \( F \) of the sort in (57.2.8). It is clearly a \( \pi \) system. Now let \( \mathcal{G} \) denote those sets \( F \) in \( \mathcal{B}(\prod_{I} M_{t}) \) such that (57.2.9) holds. Thus \( \mathcal{G} \supset K \). It is clear that \( \mathcal{G} \) is closed with respect to countable disjoint unions and complements. Hence \( \mathcal{G} \supset \sigma(K) \) but \( \sigma(K) = \mathcal{B}(\prod_{I} M_{t}) \) because every open set in \( \prod_{I} M_{t} \) is the countable union of rectangles like in (57.2.8) in which each \( F_{t_{i}} \) is open. Therefore, (57.2.9) holds for every \( F \in \mathcal{B}(\prod_{I} M_{t}) \).

Passing to simple functions and then using the monotone convergence theorem yields the final claim of the theorem. 

\[ \blacksquare \]

57.3 Independence

The concept of independence is probably the main idea which separates probability from analysis and causes some of us to struggle to understand what is going on.

**Definition 57.3.1** Let \( (\Omega, \mathcal{F}, P) \) be a probability space. The sets in \( \mathcal{F} \) are called events. A set of events, \( \{A_{i}\}_{i \in I} \) is called independent if whenever \( \{A_{i_{k}}\}_{k=1}^{m} \) is a finite subset

\[
P\left( \bigcap_{k=1}^{m} A_{i_{k}} \right) = \prod_{k=1}^{m} P(A_{i_{k}}) .\]
Each of these events defines a rather simple \( \sigma \) algebra, \( (A_i, A_i^C, \emptyset, \Omega) \) denoted by \( F_i \). Now the following lemma is interesting because it motivates a more general notion of independent \( \sigma \) algebras.

**Lemma 57.3.2** Suppose \( B_i \in F_i \) for \( i \in I \). Then for any \( m \in \mathbb{N} 

\[
P(\cap_{k=1}^m B_{i_k}) = \prod_{k=1}^m P(B_{i_k}).
\]

**Proof:** The proof is by induction on the number \( l \) of the \( B_{i_k} \) which are not equal to \( A_{i_k} \). First suppose \( l = 0 \). Then the above assertion is true by assumption. Suppose it is so for some \( l \) and there are \( l + 1 \) sets not equal to \( A_{i_k} \). If any equals \( \emptyset \) there is nothing to show. Both sides equal 0. If any equals \( \Omega \), there is also nothing to show. You can ignore that set in both sides and then you have by induction the two sides are equal because you have no more than \( l \) sets different than \( A_{i_k} \). The only remaining case is where some \( B_{i_k} = A_{i_k}^C \). Say \( B_{i_{m+1}} = A_{i_{m+1}}^C \) for simplicity.

\[
P(\cap_{k=1}^{m+1} B_{i_k}) = P(A_{i_{m+1}}^C \cap \cap_{k=1}^m B_{i_k})
\]

\[
= P(\cap_{k=1}^m B_{i_k}) - P(A_{i_{m+1}} \cap \cap_{k=1}^m B_{i_k})
\]

Then by induction,

\[
= \prod_{k=1}^m P(B_{i_k}) - \prod_{k=1}^m P(A_{i_{m+1}}) \prod_{k=1}^m P(B_{i_k}) = \prod_{k=1}^m P(B_{i_k})(1 - P(A_{i_{m+1}}))
\]

\[
= P(A_{i_{m+1}}^C) \prod_{k=1}^m P(B_{i_k}) = \prod_{k=1}^{m+1} P(B_{i_k})
\]

thus proving it for \( l + 1 \). \( \blacksquare \)

This motivates a more general notion of independence in terms of \( \sigma \) algebras.

**Definition 57.3.3** If \( \{F_i\}_{i \in I} \) is any set of \( \sigma \) algebras contained in \( F \), they are said to be independent if whenever \( A_{i_k} \in F_{i_k} \) for \( k = 1, 2, \ldots, m \), then

\[
P(\cap_{k=1}^m A_{i_k}) = \prod_{k=1}^m P(A_{i_k}).
\]

A set of random variables \( \{X_i\}_{i \in I} \) is independent if the \( \sigma \) algebras \( \{\sigma(X_i)\}_{i \in I} \) are independent \( \sigma \) algebras. Here \( \sigma(X) \) denotes the smallest \( \sigma \) algebra such that \( X \) is measurable. Thus \( \sigma(X) = \{X^{-1}(U) : U \text{ is a Borel set}\} \). More generally, \( \sigma(X_i : i \in I) \) is the smallest \( \sigma \) algebra such that each \( X_i \) is measurable.

Note that by Lemma 57.3.2 you can consider independent events in terms of independent \( \sigma \) algebras. That is, a set of independent events can always be considered as events taken from a set of independent \( \sigma \) algebras. This is a more general notion because here the \( \sigma \) algebras might have infinitely many sets in them.
Lemma 57.3.4 Suppose the set of random variables, \( \{X_i\}_{i \in I} \) is independent. Also suppose \( I_1 \subseteq I \) and \( j \notin I_1 \). Then the \( \sigma \) algebras \( \sigma (X_i : i \in I_1) \), \( \sigma (X_j) \) are independent \( \sigma \) algebras.

Proof: Let \( B \in \sigma (X_j) \). I want to show that for any \( A \in \sigma (X_i : i \in I_1) \), it follows that \( P (A \cap B) = P (A) P (B) \). Let \( \mathcal{K} \) consist of finite intersections of sets of the form \( X_k^{-1} (B_k) \) where \( B_k \) is a Borel set and \( k \in I_1 \). Thus \( \mathcal{K} \) is a \( \pi \) system and \( \sigma (\mathcal{K}) = \sigma (X_i : i \in I_1) \). Now if you have one of these sets of the form \( A = \cap_{k=1}^m X_k^{-1} (B_k) \) where without loss of generality, it can be assumed the \( k \) are distinct since \( X_k^{-1} (B_k) \cap X_k^{-1} (B_k') = X_k^{-1} (B_k \cap B_k') \), then

\[
P (A \cap B) = P \left( \cap_{k=1}^m X_k^{-1} (B_k) \cap B \right) = P (B) \prod_{k=1}^m P (X_k^{-1} (B_k))
\]

Thus \( \mathcal{K} \) is contained in

\[
\mathcal{G} = \{ A \in \sigma (X_i : i \in I_1) : P (A \cap B) = P (A) P (B) \}.
\]

Now \( \mathcal{G} \) is closed with respect to complements and countable disjoint unions. Here is why: If each \( A_i \in \mathcal{G} \) and the \( A_i \) are disjoint,

\[
P \left( (\cup_{i=1}^\infty A_i) \cap B \right) = P \left( \cup_{i=1}^\infty (A_i \cap B) \right)
= \sum_{i} P (A_i \cap B) = \sum_{i} P (A_i) P (B)
= P (B) \sum_{i} P (A_i) = P (B) P \left( \cup_{i=1}^\infty A_i \right)
\]

If \( A \in \mathcal{G} \),

\[
P \left( A^C \cap B \right) + P (A \cap B) = P (B)
\]

and so

\[
P \left( A^C \cap B \right) = P (B) - P (A \cap B)
= P (B) - P (A) P (B)
= P (B) (1 - P (A)) = P (B) P (A^C).
\]

Therefore, from the lemma on \( \pi \) systems, Lemma 57.3.4 on Page 1909, it follows

\[
\mathcal{G} \supseteq \sigma (\mathcal{K}) = \sigma (X_i : i \in I_1).
\]

Lemma 57.3.5 If \( \{X_k\}_{k=1}^r \) are independent random variables having values in \( Z \) a separable metric space, and if \( g_k \) is a Borel measurable function, then \( \{g_k (X_k)\}_{k=1}^r \) is also independent. Furthermore, if the random variables have values in \( \mathbb{R} \), and they are all bounded, then

\[
E \left( \prod_{i=1}^r X_i \right) = \prod_{i=1}^r E (X_i).
\]
More generally, the above formula holds if it is only known that each \( X_i \in L^1(\Omega; \mathbb{R}) \) and
\[
\prod_{i=1}^r X_i \in L^1(\Omega; \mathbb{R}).
\]

**Proof:** First consider the claim about \( \{g_k(X_k)\}_{k=1}^r \). Letting \( O \) be an open set in \( Z \),
\[
(g_k \circ X_k)^{-1}(O) = X_k^{-1}(g_k^{-1}(O)) = X_k^{-1}(\text{Borel set}) \in \sigma(X_k).
\]
It follows \( (g_k \circ X_k)^{-1}(E) \) is in \( \sigma(X_k) \) whenever \( E \) is Borel because the sets whose inverse images are measurable includes the Borel sets. Thus \( \sigma(g_k \circ X_k) \subseteq \sigma(X_k) \) and this proves the first part of the lemma.

Let \( X_1 = \sum_{i=1}^m c_i X_{E_i} \), \( X_2 = \sum_{j=1}^m d_j X_{F_j} \), where \( P(E_i F_j) = P(E_i) P(F_j) \). Then
\[
\int X_1 X_2 dP = \sum_{i,j} d_j c_i P(E_i) P(F_j) = \left( \int X_1 dP \right) \left( \int X_2 dP \right)
\]
In general for \( X_1, X_2 \) independent, there exist sequences of bounded simple functions \( \{s_n\}, \{t_n\} \) measurable with respect to \( \sigma(X_1) \) and \( \sigma(X_2) \) respectively such that \( s_n \to X_1 \) pointwise and \( t_n \to X_2 \) pointwise. Then from the above and the dominated convergence theorem,
\[
\int X_1 X_2 dP = \lim_{n \to \infty} \int s_n t_n dP = \lim_{n \to \infty} \left( \int s_n dP \right) \left( \int t_n dP \right) = \left( \int X_1 dP \right) \left( \int X_2 dP \right)
\]
Next suppose there are \( m \) of these independent bounded random variables. Then \( \prod_{i=2}^m X_i \in \sigma(X_2, \cdots, X_m) \) and by Lemma 57.3.4, the two random variables \( X_1 \) and \( \prod_{i=2}^m X_i \) are independent. Hence from the above and induction,
\[
\int \prod_{i=1}^m X_i dP = \int X_1 \prod_{i=2}^m X_i dP = \int X_1 dP \int \prod_{i=2}^m X_i dP = \prod_{i=1}^m \int X_i dP
\]
Now consider the last claim. Replace each \( X_i \) with \( X_i^n \) where this is just a truncation of the form
\[
X_i^n = \begin{cases} 
X_i & \text{if } |X_i| \leq n \\
\text{n} & \text{if } X_i > n \\
\text{0} & \text{if } X_i < -n
\end{cases}
\]
Then by the first part
\[
E\left( \prod_{i=1}^r X_i^n \right) = \prod_{i=1}^r E(X_i^n)
\]
Now \( |\prod_{i=1}^r X_i^n| \leq |\prod_{i=1}^r X_i| \in L^1 \) and so by the dominated convergence theorem, you can pass to the limit in both sides to get the desired result. \( \blacksquare \)
Maybe this would be a good place to put a really interesting result known as the Doob Dynkin lemma. This amazing result is illustrated with the following diagram in which \( X = (X_1, \ldots, X_m) \).

\[
\begin{array}{ccc}
(\Omega, \sigma (X)) & \xrightarrow{X} & F \\
\downarrow & \swarrow & \downarrow \nearrow \\
(\prod_{i=1}^m E_i, \mathcal{B} (\prod_{i=1}^m E_i)) & & \end{array}
\]

You start with \( X \) and can write it as the composition \( g \circ X \) provided \( X \) is \( \sigma (X) \) measurable.

**Lemma 57.3.6** Let \((\Omega, \mathcal{F})\) be a measure space and let \( X_i : \Omega \to E_i \) where \( E_i \) is a separable Banach space. Suppose also that \( X : \Omega \to F \) where \( F \) is a separable Banach space. Then \( X \) is \( \sigma (X_1, \ldots, X_m) \) measurable if and only if there exists a Borel measurable function \( g : \prod_{i=1}^m E_i \to F \) such that \( X = g (X_1, \ldots, X_m) \).

**Proof:** First suppose \( X (\omega) = f X_W (\omega) \) where \( f \in F \) and \( W \in \sigma (X_1, \ldots, X_m) \).

Then by Proposition 57.3.5, \( W \) is of the form \((X_1, \ldots, X_m)^{-1} (B) \equiv X^{-1} (B)\) where \( B \) is Borel in \( \prod_{i=1}^m E_i \). Therefore,

\[
X (\omega) = f X_{X^{-1} (B)} (\omega) = f X_B (X (\omega)).
\]

Now suppose \( X \) is measurable with respect to \( \sigma (X_1, \ldots, X_m) \). Then there exist simple functions

\[
X_n (\omega) = \sum_{k=1}^{m_n} f_k X_{B_k} (X (\omega)) = g_n (X (\omega))
\]

where the \( B_k \) are Borel sets in \( \prod_{i=1}^m E_i \), such that \( X_n (\omega) \to X (\omega) \), each \( g_n \) being Borel. Thus \( g_n \) converges on \( X (\Omega) \). Furthermore, the set on which \( g_n \) does converge is a Borel set equal to

\[
\bigcap_{n=1}^{\infty} \bigcup_{m=1}^{\infty} \bigcap_{p, q \geq m} \left\| g_p - g_q \right\| < \frac{1}{n}
\]

which contains \( X (\Omega) \). Therefore, modifying \( g_n \) by multiplying it by the indicator function of this Borel set containing \( X (\Omega) \), we can conclude that \( g_n \) converges to a Borel function \( g \) and, passing to a limit in the above,

\[
X (\omega) = g (X (\omega))
\]

Conversely, suppose \( X (\omega) = g (X (\omega)) \). Why is \( X \sigma (X) \) measurable?

\[
X^{-1} (\text{open}) = X^{-1} (g^{-1} (\text{open})) = X^{-1} (\text{Borel}) \in \sigma (X) \]

\[\blacksquare\]
57.4 Independence For Banach Space Valued Random Variables

Recall that for $X$ a random variable, $\sigma(X)$ is the smallest $\sigma$ algebra containing all the sets of the form $X^{-1}(F)$ where $F$ is Borel. Since such sets, $X^{-1}(F)$ for $F$ Borel form a $\sigma$ algebra it follows $\sigma(X) = \{X^{-1}(F) : F \text{ is Borel} \}$.

Next consider the case where you have a set of $\sigma$ algebras. The following lemma is helpful when you try to verify such a set of $\sigma$ algebras is independent. It says you only need to check things on systems contained in the $\sigma$ algebras. This is really nice because it is much easier to consider the smaller $\pi$ systems than the whole $\sigma$ algebra.

**Lemma 57.4.1** Suppose $\{F_i\}_{i \in I}$ is a set of $\sigma$ algebras contained in $F$ where $F$ is a $\sigma$ algebra of sets of $\Omega$. Suppose that $\mathcal{K}_i \subseteq F_i$ is a $\pi$ system and $F_i = \sigma(\mathcal{K}_i)$. Suppose also that whenever $J$ is a finite subset of $I$ and $A_j \in \mathcal{K}_j$ for $j \in J$, it follows

$$P(\cap_{j \in J} A_j) = \prod_{j \in J} P(A_j).$$

Then $\{F_i\}_{i \in I}$ is independent.

**Proof:** I need to verify that under the given conditions, if $\{j_1, j_2, \ldots, j_n\} \subseteq I$ and $A_{j_k} \subseteq F_{j_k}$, then

$$P(\cap_{k=1}^n A_{j_k}) = \prod_{k=1}^n P(A_{j_k}).$$

By hypothesis, this is true if each $A_{j_k} \in \mathcal{K}_{j_k}$. Suppose it is true whenever there are at most $r - 1 \geq 0$ of the $A_{j_k}$ which are not in $\mathcal{K}_{j_k}$. Consider

$$\cap_{k=1}^n A_{j_k}$$

where there are $r$ sets which are not in the corresponding $\mathcal{K}_{j_k}$. Without loss of generality, say there are at most $r - 1$ sets in the first $n - 1$ which are not in the corresponding $\mathcal{K}_{j_k}$.

Pick $(A_{j_1}, \ldots, A_{j_{n-1}})$ let

$$\mathcal{G}_{(A_{j_1}, \ldots, A_{j_{n-1}})} = \left\{ B \in F_{j_n} : P(\cap_{k=1}^{n-1} A_{j_k} \cap B) = \prod_{k=1}^{n-1} P(A_{j_k}) P(B) \right\}$$

I am going to show $\mathcal{G}_{(A_{j_1}, \ldots, A_{j_{n-1}})}$ is closed with respect to complements and countable disjoint unions and then apply the Lemma on $\pi$ systems. By the induction
hypothesis, \( \mathcal{K}_n \subseteq \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) \). If \( B \in \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) \),

\[
\prod_{k=1}^{n-1} P(A_{j_k}) = P(\bigcap_{k=1}^{n-1} A_{j_k})
\]

\[
= P((\bigcap_{k=1}^{n-1} A_{j_k} \cap B^C) \cup (\bigcap_{k=1}^{n-1} A_{j_k} \cap B))
\]

\[
= P(\bigcap_{k=1}^{n-1} A_{j_k} \cap B^C) + P(\bigcap_{k=1}^{n-1} A_{j_k} \cap B)
\]

\[
= P(\bigcap_{k=1}^{n-1} A_{j_k} \cap B^C) + \prod_{k=1}^{n-1} P(A_{j_k}) P(B)
\]

and so

\[
P(\bigcap_{k=1}^{n-1} A_{j_k} \cap B^C) = \prod_{k=1}^{n-1} P(A_{j_k}) (1 - P(B))
\]

\[
= \prod_{k=1}^{n-1} P(A_{j_k}) P(B^C)
\]

showing if \( B \in \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) \), then so is \( B^C \). It is clear that \( \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) \) is closed with respect to disjoint unions also. Here is why. If \( \{B_j\}_{j=1}^{\infty} \) are disjoint sets in \( \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) \),

\[
P(\bigcup_{i=1}^{\infty} B_i \cap \bigcap_{k=1}^{n-1} A_{j_k}) = \sum_{i=1}^{\infty} P(B_i \cap \bigcap_{k=1}^{n-1} A_{j_k})
\]

\[
= \sum_{i=1}^{\infty} P(B_i) \prod_{k=1}^{n-1} P(A_{j_k})
\]

\[
= \prod_{k=1}^{n-1} P(A_{j_k}) \sum_{i=1}^{\infty} P(B_i)
\]

\[
= \prod_{k=1}^{n-1} P(A_{j_k}) P(\bigcup_{i=1}^{\infty} B_i)
\]

Therefore, by the \( \pi \) system lemma, Lemma \( \mathcal{G}(A_{j_1} \cdots A_{j_{n-1}}) = \mathcal{F}_n \). This proves the induction step in going from \( r - 1 \) to \( r \).

What is a useful \( \pi \) system for \( \mathcal{B}(E) \), the Borel sets of \( E \) where \( E \) is a Banach space?

Recall the fundamental lemma used to prove the Pettis theorem. It was proved on Page \( \text{Page} \).

**Lemma 57.4.2** Let \( E \) be a separable real Banach space. Sets of the form

\[
\{ x \in E : x_i^*(x) \leq \alpha_i, i = 1, 2, \cdots, m \}
\]
CHAPTER 57. BASIC PROBABILITY

where \( x^* \in D' \), a dense subspace of the unit ball of \( E' \) and \( \alpha_i \in [-\infty, \infty) \) are a \( \pi \) system, and denoting this \( \pi \) system by \( K \), it follows \( \sigma(K) = \mathcal{B}(E) \). The sets of \( K \) are examples of cylindrical sets. The \( D' \) is that set for the proof of the Pettis theorem.

Proof: The sets described are obviously a \( \pi \) system. I want to show \( \sigma(K) \) contains the closed balls because then \( \sigma(K) \) contains the open balls and hence the open sets and the result will follow. Let \( D' \) be described in Lemma 29.1.4. As pointed out earlier it can be any dense subset of \( B' \). Then

\[
\{ x \in E : ||x - a|| \leq r \}
\]

which equals a countable intersection of sets of the given \( \pi \) system. Therefore, every closed ball is contained in \( \sigma(K) \). It follows easily that every open ball is also contained in \( \sigma(K) \) because

\[
B(a,r) = \bigcup_{n=1}^{\infty} B(a,r - \frac{1}{n}).
\]

Since the Banach space is separable, it is completely separable and so every open set is the countable union of balls. This shows the open sets are in \( \sigma(K) \) and so \( \sigma(K) \supseteq \mathcal{B}(E) \). However, all the sets in the \( \pi \) system are closed hence Borel because they are inverse images of closed sets. Therefore, \( \sigma(K) \subseteq \mathcal{B}(E) \) and so \( \sigma(K) = \mathcal{B}(E) \).

As mentioned above, we can replace \( D' \) in the above with \( M \), any dense subset of \( E' \).

Observation 57.4.3 Denote by \( C_{\alpha,n} \) the set \( \{ \beta \in \mathbb{R}^n : \beta_1 \leq \alpha_1 \} \). Also denote by \( g_n \) an element of \( M^n \) with the understanding that \( g_n : E \to \mathbb{R}^n \) according to the rule

\[
g_n(x) \equiv (g_1(x) , \ldots , g_n(x)).
\]

Then the sets in the above lemma can be written as \( g_n^{-1}(C_{\alpha,n}) \). In other words, sets of the form \( g_n^{-1}(C_{\alpha,n}) \) form a \( \pi \) system for \( \mathcal{B}(E) \).

Next suppose you have some random variables having values in a separable Banach space, \( E \), \( \{ X_i \}_{i \in I} \). How can you tell if they are independent? To show they are independent, you need to verify that

\[
P\left( \bigcap_{k=1}^{n} X_{ik}^{-1}(F_{ik}) \right) = \prod_{k=1}^{n} P\left( X_{ik}^{-1}(F_{ik}) \right)
\]
whenever the $F_i$ are Borel sets in $E$. It is desirable to find a way to do this easily.

**Lemma 57.4.4** Let $\mathcal{K}$ be a $\pi$ system of sets of $E$, a separable real Banach space and let $(\Omega, F, P)$ be a probability space and $X : \Omega \rightarrow E$ be a random variable. Then

$$X^{-1}\left(\sigma(\mathcal{K})\right) = \sigma\left(X^{-1}(\mathcal{K})\right)$$

**Proof:** First note that $X^{-1}\left(\sigma(\mathcal{K})\right)$ is a $\sigma$ algebra which contains $X^{-1}(\mathcal{K})$ and so it contains $\sigma\left(X^{-1}(\mathcal{K})\right)$. Thus

$$X^{-1}\left(\sigma(\mathcal{K})\right) \supseteq \sigma\left(X^{-1}(\mathcal{K})\right)$$

Now let

$$\mathcal{G} = \{ A \in \sigma(\mathcal{K}) : X^{-1}(A) \in \sigma\left(X^{-1}(\mathcal{K})\right) \}$$

Then $\mathcal{G} \supseteq \mathcal{K}$. If $A \in \mathcal{G}$, then

$$X^{-1}(A) \in \sigma\left(X^{-1}(\mathcal{K})\right)$$

and so

$$X^{-1}(A)^\mathcal{C} = X^{-1}(A^\mathcal{C}) \in \sigma\left(X^{-1}(\mathcal{K})\right)$$

because $\sigma\left(X^{-1}(\mathcal{K})\right)$ is a $\sigma$ algebra. Hence $A^\mathcal{C} \in \mathcal{G}$. Finally suppose $\{A_i\}$ is a sequence of disjoint sets of $\mathcal{G}$. Then

$$X^{-1}\left(\bigcup_{i=1}^{\infty} A_i\right) = \bigcup_{i=1}^{\infty} X^{-1}(A_i) \in \sigma\left(X^{-1}(\mathcal{K})\right)$$

again because $\sigma\left(X^{-1}(\mathcal{K})\right)$ is a $\sigma$ algebra. It follows from Lemma 10.12.3 on Page 311 that $\mathcal{G} \supseteq \sigma(\mathcal{K})$ and this shows that whenever

$$A \in \sigma(\mathcal{K}), X^{-1}(A) \in \sigma\left(X^{-1}(\mathcal{K})\right).$$

Thus $X^{-1}(\sigma(\mathcal{K})) \supseteq \sigma\left(X^{-1}(\mathcal{K})\right)$. ■

With this lemma, here is the desired result about independent random variables. Essentially, you can reduce to the case of random vectors having values in $\mathbb{R}^n$.

### 57.5 Reduction To Finite Dimensions

Let $E$ be a Banach space and let $g \in (E')^n$. Then for $x \in E$, $g \circ x$ is the vector in $F^n$ which equals $(g_1(x), g_2(x), \ldots, g_n(x))$.

**Theorem 57.5.1** Let $X_i$ be a random variable having values in $E$ a real separable Banach space. The random variables $\{X_i\}_{i \in I}$ are independent if whenever

$$\{i_1, \cdots, i_n\} \subseteq I,$$

$m_{i_1}, \cdots, m_{i_n}$ are positive integers, and $g_{m_{i_1}}, \cdots, g_{m_{i_n}}$ are respectively in

$$(M)^{m_{i_1}}, \cdots, (M)^{m_{i_n}}$$

for $M$ a dense subspace of $E'$, $\{g_{m_{i_j}} \circ X_{i_j}\}_{j=1}^{n}$ are independent random vectors having values in $\mathbb{R}^{m_{i_1}}, \cdots, \mathbb{R}^{m_{i_n}}$ respectively.
Proof: It is necessary to show that the events $X_{ij}^{-1}(B_i)$ are independent events whenever $B_i$ are Borel sets. By Lemma 57.4.1 and the above Lemma 57.4.2, it suffices to verify that the events

$$X_{ij}^{-1}\left(g_{m_{ij}}^{-1}(C_{\bar{\alpha},m_{ij}})\right) = \left(g_{m_{ij}} \circ X_i\right)^{-1}(C_{\bar{\alpha},m_{ij}})$$

are independent where $C_{\bar{\alpha},m_{ij}}$ are the cones described in Lemma 57.4.2. Thus

$$\bar{\alpha} = (\alpha_{k_1}, \cdots, \alpha_{k_m})$$

$$C_{\bar{\alpha},m_{ij}} = \prod_{i=1}^m [-\infty, \alpha_{k_i}]$$

But this condition is implied when the finite dimensional valued random vectors $g_{m_{ij}} \circ X_i$ are independent.

The above assertion also goes the other way as you may want to show.

57.6 0, 1 Laws

I am following [105] for the proof of many of the following theorems. Recall the set of $\omega$ which are in infinitely many of the sets $\{A_n\}$ is

$$\bigcap_{n=1}^\infty \cup_{m=n}^\infty A_m.$$  

This is because $\omega$ is in the above set if and only if for every $n$ there exists $m \geq n$ such that it is in $A_m$.

Theorem 57.6.1 Suppose $A_n \in \mathcal{F}_n$ where the $\sigma$ algebras $\{\mathcal{F}_n\}_{n=1}^\infty$ are independent. Suppose also that

$$\sum_{k=1}^\infty P(A_k) = \infty.$$  

Then

$$P(\bigcap_{n=1}^\infty \cup_{m=n}^\infty A_m) = 1.$$  

Proof: It suffices to verify that

$$P\left(\bigcup_{n=1}^\infty \cap_{m=n}^\infty A_m^C\right) = 0$$

which can be accomplished by showing

$$P\left(\cap_{m=n}^\infty A_m^C\right) = 0.$$
for each $n$. The sets $\{A_k^C\}$ satisfy $A_k^C \in F_k$. Therefore, noting that $e^{-x} \geq 1 - x$,

$$P \left( \bigcap_{m=n}^{\infty} A_m^C \right) = \lim_{N \to \infty} P \left( \bigcap_{m=n}^{N} A_m^C \right) = \lim_{N \to \infty} \prod_{m=n}^{N} P (A_m^C)$$

$$= \lim_{N \to \infty} \prod_{m=n}^{N} (1 - P(A_m)) \leq \lim_{N \to \infty} \prod_{m=n}^{N} e^{-P(A_m)}$$

$$= \lim_{N \to \infty} \exp \left( - \sum_{m=n}^{N} P(A_m) \right) = 0. \quad \blacksquare$$

The Kolmogorov zero one law follows next. It has to do with something called a tail event.

**Definition 57.6.2** Let $\{F_n\}$ be a sequence of $\sigma$ algebras. Then $T_n \equiv \sigma(\cup_{k=n}^{\infty} F_k)$ where this means the smallest $\sigma$ algebra which contains each $F_k$ for $k \geq n$. Then a tail event is a set which is in the $\sigma$ algebra, $T \equiv \cap_{n=1}^{\infty} T_n$.

As usual, $(\Omega, F, P)$ is the underlying probability space such that all $\sigma$ algebras are contained in $F$.

**Lemma 57.6.3** Suppose $\{F_n\}_{n=1}^{\infty}$ are independent $\sigma$ algebras and suppose $A$ is a tail event and $A_k \in F_k$, $i = 1, \cdots, m$ are given sets. Then

$$P (A_{k_1} \cap \cdots \cap A_{k_m} \cap A) = P (A_{k_1} \cap \cdots \cap A_{k_m}) P(A)$$

**Proof:** Let $\mathcal{K}$ be the $\pi$ system consisting of finite intersections of the form

$$B_{m_1} \cap B_{m_2} \cap \cdots \cap B_{m_j}$$

where $m_i \in F_{k_i}$ for $k_i > \max \{k_1, \cdots, k_m\} \equiv N$. Thus $\sigma(\mathcal{K}) = \sigma(\cup_{i=N+1}^{\infty} F_i)$. Now let

$$\mathcal{G} \equiv \{B \in \sigma(\mathcal{K}) : P(A_{k_1} \cap \cdots \cap A_{k_m} \cap B) = P(A_{k_1} \cap \cdots \cap A_{k_m}) P(B)\}$$

Then $\mathcal{K} \subseteq \mathcal{G}$. It is also true that $\mathcal{G}$ is closed with respect to complements and countable disjoint unions. By the lemma on $\pi$ systems, $\mathcal{G} = \sigma(\mathcal{K}) = \sigma(\cup_{i=N+1}^{\infty} F_i)$.

Since $A$ is in $\sigma(\cup_{i=N+1}^{\infty} F_i)$ due to the assumption that it is a tail event, it follows that

$$P (A_{k_1} \cap \cdots \cap A_{k_m} \cap A) = P (A_{k_1} \cap \cdots \cap A_{k_m}) P(A) \quad \blacksquare$$

**Theorem 57.6.4** Suppose the $\sigma$ algebras, $\{F_n\}_{n=1}^{\infty}$ are independent and suppose $A$ is a tail event. Then $P(A)$ either equals 0 or 1.

**Proof:** Let $A \in T$. I want to show that $P(A) = P(A)^2$. Let $\mathcal{K}$ denote sets of the form $A_{k_1} \cap \cdots \cap A_{k_m}$ for some $m$, $A_{k_j} \in F_{k_j}$ where each $k_j > n$. Thus $\mathcal{K}$ is a $\pi$ system and

$$\sigma(\mathcal{K}) = \sigma(\cup_{k=n+1}^{\infty} F_k) \equiv T_{n+1}$$
CHAPTER 57. BASIC PROBABILITY

Let
\[ G = \{ B \in \mathcal{T}_{n+1} : P(A \cap B) = P(A)P(B) \} \]

Thus \( \mathcal{K} \subseteq G \) because

\[ P(A_{k_1} \cap \cdots \cap A_{k_m} \cap A) = P(A_{k_1} \cap \cdots \cap A_{k_m})P(A) \]

by Lemma 57.6.3. However, \( G \) is closed with respect to countable disjoint unions and complements. Here is why. If \( B \in G \),

\[ P(A \cap B^C) + P(A \cap B) = P(A) \]

and so \( B \in G \). If \( \{ B_i \}_{i=1}^\infty \) are disjoint sets in \( G \),

\[ P(A \cap \bigcup_{k=1}^\infty B_k) = \sum_{k=1}^\infty P(A \cap B_k) = P(A) \sum_{k=1}^\infty P(B_k) = P(A)P(\bigcup_{k=1}^\infty B_k) \]

and so \( \bigcup_{k=1}^\infty B_k \in G \). Therefore by the Lemma on \( \pi \) systems Lemma 10.12.3 on Page 311, it follows \( G = \sigma(\mathcal{K}) = \sigma(\bigcup_{k=n+1}^\infty F_k) \).

Thus for any \( B \in \sigma(\bigcup_{k=n+1}^\infty F_k) = \mathcal{T}_{n+1}, P(A \cap B) = P(A)P(B) \). However, \( A \) is in all of these \( \mathcal{T}_{n+1} \) and so \( P(A \cap A) = P(A)^2 \) so \( P(A) \) equals either 0 or 1.

What sorts of things are tail events of independent \( \sigma \) algebras?

**Theorem 57.6.5** Let \( \{X_k\} \) be a sequence of independent random variables having values in \( Z \) a Banach space. Then

\[ A = \{ \omega : \{X_k(\omega)\} \text{ converges} \} \]

is a tail event of the independent \( \sigma \) algebras \( \{\sigma(X_k)\} \). So is

\[ B = \{ \omega : \{ \sum_{k=1}^\infty X_k(\omega) \} \text{ converges} \} \]

**Proof:** Since \( Z \) is complete, \( A \) is the same as the set where \( \{X_k(\omega)\} \) is a Cauchy sequence. This set is

\[ \cap_{n=1}^\infty \cap_{p=1}^\infty \cup_{m=p}^\infty \cap_{l,k \geq m} \{ \omega : \|X_k(\omega) - X_l(\omega)\| < 1/n \} \]

Note that

\[ \cup_{m=p}^\infty \cap_{l,k \geq m} \{ \omega : \|X_k(\omega) - X_l(\omega)\| < 1/n \} \in \sigma(\cup_{j=p}^\infty \sigma(X_j)) \]
for every $p$ is the set where ultimately any pair of $X_k, X_l$ are closer together than $1/n$, 
\[
\cap_{p=1}^{\infty} \cup_{m=p}^{\infty} \cap_{l,k \geq m} \{ \omega : ||X_k(\omega) - X_l(\omega)|| < 1/n \}
\]
is a tail event. The set where $\{X_k(\omega)\}$ is a Cauchy sequence is the intersection of all these and is therefore, also a tail event.

Now consider $B$. This set is the same as the set where the partial sums are Cauchy sequences. Let $S_n \equiv \sum_{k=1}^{n} X_k$. The set where the sum converges is then
\[
\cap_{n=1}^{\infty} \cap_{p=2}^{\infty} \cup_{m=p}^{\infty} \cap_{l,k \geq m} \{ \omega : ||S_k(\omega) - S_l(\omega)|| < 1/n \}
\]
Say $k < l$ and consider for $m \geq p$
\[
\{ \omega : ||S_k(\omega) - S_l(\omega)|| < 1/n, \ k \geq m \}
\]
This is the same as
\[
\left\{ \omega : \left| \sum_{j=k-1}^{l} X_j(\omega) \right| < 1/n, \ k \geq m \right\} \in \sigma \left( \cup_{j=p-1}^{\infty} \sigma (X_j) \right)
\]
Thus
\[
\cup_{m=p}^{\infty} \cap_{l,k \geq m} \{ \omega : ||S_k(\omega) - S_l(\omega)|| < 1/n \} \in \sigma \left( \cup_{j=p-1}^{\infty} \sigma (X_j) \right)
\]
and so the intersection for all $p$ of these is a tail event. Then the intersection over all $n$ of these tail events is a tail event. \[\blacksquare\]

From this it can be concluded that if you have a sequence of independent random variables, $\{X_k\}$ the set where it converges is either of probability 1 or probability 0. A similar conclusion holds for the set where the infinite sum of these random variables converges. This is stated in the next corollary. This incredible assertion is the next corollary.

**Corollary 57.6.6** Let $\{X_k\}$ be a sequence of random variables having values in a Banach space. Then
\[
\lim_{n \to \infty} X_n(\omega)
\]
either exists for a.e. $\omega$ or the convergence fails to take place for a.e. $\omega$. Also if
\[
A \equiv \left\{ \omega : \sum_{k=1}^{\infty} X_k(\omega) \text{ converges} \right\},
\]
then $P(A) = 0$ or 1.

### 57.7 Kolmogorov’s Inequality, Strong Law Of Large Numbers

Kolmogorov’s inequality is a very interesting inequality which depends on independence of a set of random vectors. The random vectors have values in $\mathbb{R}^n$ or more generally some real separable Hilbert space.
Lemma 57.7.1 If \( Y, X \) are independent random variables having values in a real separable Hilbert space, \( H \) with \( \mathbb{E} \left( |X|^2 \right), \mathbb{E} \left( |Y|^2 \right) < \infty \), then

\[
\int_{\Omega} (X, Y) \, dP = \left( \int_{\Omega} X \, dP, \int_{\Omega} Y \, dP \right).
\]

Proof: Let \( \{e_k\} \) be a complete orthonormal basis. Thus

\[
\int_{\Omega} (X, Y) \, dP = \int_{\Omega} \sum_{k=1}^{\infty} (X, e_k) (Y, e_k) \, dP
\]

Now

\[
\int_{\Omega} \sum_{k=1}^{\infty} |(X, e_k) (Y, e_k)| \, dP \leq \int_{\Omega} \left( \sum_k |(X, e_k)|^2 \right)^{1/2} \left( \sum_k |(Y, e_k)|^2 \right)^{1/2} \, dP
\]

\[
= \int_{\Omega} |X| |Y| \, dP \leq \left( \int_{\Omega} |X|^2 \, dP \right)^{1/2} \left( \int_{\Omega} |Y|^2 \, dP \right)^{1/2} < \infty
\]

and so by Fubini’s theorem,

\[
\int_{\Omega} (X, Y) \, dP = \int_{\Omega} \sum_{k=1}^{\infty} (X, e_k) (Y, e_k) \, dP = \sum_{k=1}^{\infty} \int_{\Omega} (X, e_k) (Y, e_k) \, dP
\]

\[
= \sum_{k=1}^{\infty} \int_{\Omega} (X, e_k) \, dP \int_{\Omega} (Y, e_k) \, dP = \sum_{k=1}^{\infty} \left( \int_{\Omega} X \, dP, e_k \right) \left( \int_{\Omega} Y \, dP, e_k \right) \, dP
\]

\[
= \left( \int_{\Omega} X \, dP, \int_{\Omega} Y \, dP \right).
\]

Now here is Kolmogorov’s inequality.

Theorem 57.7.2 Suppose \( \{X_k\}_{k=1}^{n} \) are independent with \( \mathbb{E} (|X_k|) < \infty \), \( \mathbb{E} (X_k) = 0 \). Then for any \( \varepsilon > 0 \),

\[
P \left( \max_{1 \leq k \leq n} \left| \sum_{j=1}^{k} X_j \right| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{j=1}^{n} \mathbb{E} \left( |X_k|^2 \right).
\]

Proof: Let

\[
A = \left[ \max_{1 \leq k \leq n} \left| \sum_{j=1}^{k} X_j \right| \geq \varepsilon \right]
\]

Now let \( A_1 \equiv [|X_1| \geq \varepsilon] \) and if \( A_1, \cdots, A_m \) have been chosen,

\[
A_{m+1} = \left[ \sum_{j=1}^{m+1} X_j \geq \varepsilon \right] \cap \bigcap_{r=1}^{m} \left[ \sum_{j=1}^{r} X_j < \varepsilon \right]
\]
Thus the $A_k$ partition $A$ and $\omega \in A_k$ means

$$\left| \sum_{j=1}^{k} X_j \right| \geq \varepsilon$$

but this did not happen for $\left| \sum_{j=1}^{r} X_j \right|$ for any $r < k$. Note also that $A_k \in \sigma(X_1, \cdots, X_k)$. Then from algebra,

$$\left( \sum_{j=1}^{k} X_j \right)^2 = \left( \sum_{i=1}^{k} X_i + \sum_{j=k+1}^{n} X_j \right)^2 + \sum_{j=k+1}^{n} X_j$$

Written more succinctly,

$$\left( \sum_{j=1}^{k} X_j \right)^2 = \sum_{j=1}^{k} X_j^2 + \sum_{j > k} (X_i, X_j)$$

Now multiply both sides by $X_{A_k}$ and integrate. Suppose $i \leq k$ for one of the terms in the second sum. Then by Lemma 57.3.4 and $A_k \in \sigma(X_1, \cdots, X_k)$, the two random vectors $X_{A_k}X_i, X_j$ are independent,

$$\int \mathcal{X}_{A_k} (X_i, X_j) dP = \left( \int \mathcal{X}_{A_k} X_i dP, \int \mathcal{X}_{A_k} X_j dP \right) = 0$$

the last equality holding because by assumption $E(X_j) = 0$. Therefore, it can be assumed both $i, j$ are larger than $k$ and

$$\int \mathcal{X}_{A_k} \left| \sum_{j=1}^{k} X_j \right|^2 dP = \int \mathcal{X}_{A_k} \left| \sum_{j=1}^{k} X_j \right|^2 dP + \sum_{j > k} \int \mathcal{X}_{A_k} (X_i, X_j) dP ^{(57.7.10)}$$

The last term on the right is interesting. Suppose $i > j$. The integral inside the sum is of the form

$$\int (X_i, \mathcal{X}_{A_k} X_j) dP ^{(57.7.11)}$$

The second factor in the inner product is in

$$\sigma(X_1, \cdots, X_k, X_j)$$
and $X_i$ is not included in the list of random vectors. Thus by Lemma 57.3.4, the two random vectors $X_i, X_{A_k} X_j$ are independent and so reduces to

$$\left( \int_{\Omega} X_i dP, \int_{\Omega} X_{A_k} X_j dP \right) = \left( 0, \int_{\Omega} X_{A_k} X_j dP \right) = 0.$$  

A similar result holds if $j > i$. Thus the mixed terms in the last term of 57.7.10 are all equal to 0. Hence reduces to

$$\int_{\Omega} X_{A_k} \left| \sum_{j=1}^{n} X_j \right|^2 dP = \int_{\Omega} X_{A_k} \left| \sum_{j=1}^{k} X_j \right|^2 dP$$

$$+ \sum_{i>k} \int_{\Omega} X_{A_k} |X_i|^2 dP$$

and so

$$\int_{\Omega} X_{A_k} \left| \sum_{j=1}^{n} X_j \right|^2 dP \geq \int_{\Omega} X_{A_k} \left| \sum_{j=1}^{k} X_j \right|^2 dP \geq \epsilon^2 P(A_k).$$

Now, summing these yields

$$\epsilon^2 P(A) \leq \int_{\Omega} X_{A_k} \left| \sum_{j=1}^{n} X_j \right|^2 dP \leq \int_{\Omega} \left| \sum_{j=1}^{n} X_j \right|^2 dP$$

$$= \sum_{i,j} \int_{\Omega} (X_i, X_j) dP$$

By independence of the random vectors the mixed terms of the above sum equal zero and so it reduces to

$$\sum_{i=1}^{n} \int_{\Omega} |X_i|^2 dP \quad \blacksquare$$

This theorem implies the following amazing result.

**Theorem 57.7.3** Let $\{X_k\}_{k=1}^{\infty}$ be independent random vectors having values in a separable real Hilbert space and suppose $E(|X_k|) < \infty$ for each $k$ and $E(X_k) = 0$. Suppose also that

$$\sum_{j=1}^{\infty} E(|X_j|^2) < \infty.$$  

Then

$$\sum_{j=1}^{\infty} X_j$$

converges a.e.
57.7. KOLMOGOROV’S INEQUALITY, STRONG LAW OF LARGE NUMBERS

**Proof:** Let \( \varepsilon > 0 \) be given. By Kolmogorov’s inequality, Theorem 57.7.2, it follows that for \( p \leq m < n \)

\[
P \left( \max_{m \leq k \leq n} \left| \sum_{j=m}^{k} X_j \right| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{j=p}^{n} E \left( |X_j|^2 \right) \leq \frac{1}{\varepsilon^2} \sum_{j=p}^{\infty} E \left( |X_j|^2 \right).
\]

Therefore, letting \( n \to \infty \) it follows that for all \( m, n \) such that \( p \leq m \leq n \)

\[
P \left( \max_{p \leq m \leq n} \left| \sum_{j=m}^{n} X_j \right| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{j=p}^{\infty} E \left( |X_j|^2 \right).
\]

It follows from the assumption

\[
\sum_{j=1}^{\infty} E \left( |X_j|^2 \right) < \infty
\]

there exists a sequence, \( \{p_n\} \) such that if \( m \geq p_n \)

\[
P \left( \max_{k \geq m \geq p_n} \left| \sum_{j=m}^{k} X_j \right| \geq 2^{-n} \right) \leq 2^{-n}.
\]

By the Borel Cantelli lemma, Lemma 57.1.2, there is a set of measure 0, \( N \) such that for \( \omega \notin N \), \( \omega \) is in only finitely many of the sets,

\[
\max_{k \geq m \geq p_n} \left| \sum_{j=m}^{k} X_j \right| \geq 2^{-n}
\]

and so for \( \omega \notin N \), it follows that for large enough \( n \),

\[
\max_{k \geq m \geq p_n} \left| \sum_{j=m}^{k} X_j (\omega) \right| < 2^{-n}
\]

However, this says the partial sums \( \left\{ \sum_{j=1}^{k} X_j (\omega) \right\}_{k=1}^{\infty} \) are a Cauchy sequence. Therefore, they converge. ■

With this amazing result, there is a simple proof of the strong law of large numbers. In the following lemma, \( s_k \) and \( a_j \) could have values in any normed linear space.
Lemma 57.7.4 Suppose \( s_k \to s \). Then

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} s_k = s.
\]

Also if

\[
\sum_{j=1}^{\infty} \frac{a_j}{j}
\]

converges, then

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} a_j = 0.
\]

**Proof:** Consider the first part. Since \( s_k \to s \), it follows there is some constant, \( C \) such that \( |s_k| < C \) for all \( k \) and \( |s| < C \) also. Choose \( K \) so large that if \( k \geq K \), then for \( n > K \),

\[
|s - s_k| < \varepsilon/2,
\]

\[
\left| s - \frac{1}{n} \sum_{k=1}^{n} s_k \right| \leq \frac{1}{n} \sum_{k=1}^{n} |s_k - s|
\]

\[
= \frac{1}{n} \sum_{k=1}^{K} |s_k - s| + \frac{1}{n} \sum_{k=K}^{n} |s_k - s|
\]

\[
\leq \frac{2CK}{n} + \varepsilon \cdot \frac{n-K}{2} < \frac{2CK}{n} + \varepsilon/2
\]

Therefore, whenever \( n \) is large enough,

\[
\left| s - \frac{1}{n} \sum_{k=1}^{n} s_k \right| < \varepsilon.
\]

Now consider the second claim. Let

\[
s_k = \sum_{j=1}^{k} \frac{a_j}{j}
\]

and \( s = \lim_{k \to \infty} s_k \) Then by the first part,

\[
s = \lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} s_k = \lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} \sum_{j=1}^{k} \frac{a_j}{j}
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} a_j \sum_{k=j}^{n} 1 = \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \frac{a_j}{j} (n-j)
\]

\[
= \lim_{n \to \infty} \left( \frac{n}{j=1} \sum_{j=1}^{n} \frac{a_j}{j} - \frac{1}{n} \sum_{j=1}^{n} a_j \right) = s - \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} a_j \]

Now here is the strong law of large numbers.
Theorem 57.7.5 Suppose \( \{X_k\} \) are independent random variables and \( E(|X_k|) < \infty \) for each \( k \) and \( E(X_k) = m_k \). Suppose also

\[
\sum_{j=1}^{\infty} \frac{1}{j^2} E\left(|X_j - m_j|^2\right) < \infty. \tag{57.7.12}
\]

Then

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} (X_j - m_j) = 0
\]

Proof: Consider the sum

\[
\sum_{j=1}^{\infty} \frac{X_j - m_j}{j}.
\]

This sum converges a.e. because of \(57.7.12\) and Theorem 57.7.3 applied to the random vectors \( \{X_j - m_j\} \). Therefore, from Lemma 57.7.4 it follows that for a.e. \( \omega \),

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} (X_j(\omega) - m_j) = 0 \quad \blacksquare
\]

The next corollary is often called the strong law of large numbers. It follows immediately from the above theorem.

Corollary 57.7.6 Suppose \( \{X_j\}_{j=1}^{\infty} \) are independent having mean \( m \) and variance equal to

\[
\sigma^2 \equiv \int_{\Omega} |X_j - m|^2 \, dP < \infty.
\]

Then for a.e. \( \omega \in \Omega \)

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} X_j(\omega) = m
\]

57.8 The Characteristic Function

One of the most important tools in probability is the characteristic function. To begin with, assume the random variables have values in \( \mathbb{R}^p \).

**Definition 57.8.1** Let \( X \) be a random variable as above. The characteristic function is

\[
\phi_X(t) \equiv E(e^{it \cdot X}) \equiv \int_{\Omega} e^{it \cdot X(\omega)} \, dP = \int_{\mathbb{R}^p} e^{it \cdot x} \, d\lambda_X
\]

the last equation holding by Proposition 57.7.12.

Recall the following fundamental lemma and definition, Lemma 67.13 on Page 1089.
Definition 57.8.2 For $T \in \mathcal{G}^*$, define $FT, F^{-1}T \in \mathcal{G}^*$ by

$$FT(\phi) \equiv T(F\phi), \quad F^{-1}T(\phi) \equiv T(F^{-1}\phi)$$

Lemma 57.8.3 $F$ and $F^{-1}$ are both one to one, onto, and are inverses of each other.

The main result on characteristic functions is the following.

Theorem 57.8.4 Let $X$ and $Y$ be random vectors with values in $\mathbb{R}^p$ and suppose $E(e^{it\cdot X}) = E(e^{it\cdot Y})$ for all $t \in \mathbb{R}^p$. Then $X = Y$.

Proof: For $T \in \mathcal{G}$, let $X(T) = \int_{\mathbb{R}^p} e^{it\cdot x} d\mu_X$ and $Y(T) = \int_{\mathbb{R}^p} e^{it\cdot y} d\mu_Y$. Thus both $\mu_X$ and $\mu_Y$ are in $\mathcal{G}$. Then letting $T \in \mathcal{G}$ and using Fubini’s theorem,

$$\int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{it\cdot y} \psi(t) d\mu_Y(t) dt = \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{it\cdot y} d\mu_Y \psi(t) dt$$

$$= \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} E(e^{it\cdot Y}) \psi(t) dt$$

$$= \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} E(e^{it\cdot X}) \psi(t) dt$$

$$= \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{it\cdot x} d\mu_X \psi(t) dt$$

$$= \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{it\cdot x} \psi(t) d\mu_X$$

Thus $\lambda_Y(F^{-1}\psi) = \lambda_X(F^{-1}\psi)$. Since $\psi \in \mathcal{G}$ is arbitrary and $F^{-1}$ is onto, this implies $\lambda_X = \lambda_Y$ in $\mathcal{G}^*$. But $\mathcal{G}$ is dense in $C_0(\mathbb{R}^p)$ from the Stone Weierstrass theorem and so $\lambda_X = \lambda_Y$ as measures. Recall from real analysis the dual space of $C_0(\mathbb{R}^p)$ is the space of complex measures.

Alternatively, the above shows that since $F^{-1}$ is onto, for all $\psi \in \mathcal{G}$,

$$\int_{\mathbb{R}^p} \psi d\mu_Y = \int_{\mathbb{R}^p} \psi d\mu_X$$

and then, by a use of the Stone Weierstrass theorem, the above will hold for all $\psi \in C_0(\mathbb{R}^p)$ and now, by the Riesz representation theorem for positive linear functionals, the two measures are equal.

You can also give a version of this theorem in which reference is made only to the probability distribution measures.

Definition 57.8.5 For $\mu$ a probability measure on the Borel sets of $\mathbb{R}^n$, 

$$\phi_\mu(t) \equiv \int_{\mathbb{R}^n} e^{it\cdot x} d\mu.$$

Theorem 57.8.6 Let $\mu$ and $\nu$ be probability measures on the Borel sets of $\mathbb{R}^p$ and suppose $\phi_\mu(t) = \phi_\nu(t)$. Then $\mu = \nu$.

Proof: The proof is identical to the above. Just replace $\lambda_X$ with $\mu$ and $\lambda_Y$ with $\nu$. 

57.9 Conditional Probability

Here I will consider the concept of conditional probability depending on the theory of differentiation of general Radon measures. This leads to a different way of thinking about independence.

If \( X, Y \) are two random vectors defined on a probability space having values in \( \mathbb{R}^p_1 \) and \( \mathbb{R}^p_2 \) respectively, and if \( E \) is a Borel set in the appropriate space, then \((X, Y)\) is a random vector with values in \( \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \) and \( \lambda((X, Y)) (E \times \mathbb{R}^{p_2}) = \lambda_X (E) \), \( \lambda((X, Y)) (\mathbb{R}^{p_1} \times E) = \lambda_Y (E) \). Thus, by Theorem 57.3, there exist probability measures, denoted here by \( \lambda_{X|Y} \) and \( \lambda_{Y|X} \), such that whenever \( E \) is a Borel set in \( \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \),

\[
\int_{\mathbb{R}^{p_1} \times \mathbb{R}^{p_2}} X_E d\lambda_{X,Y} = \int_{\mathbb{R}^{p_1}} \int_{\mathbb{R}^{p_2}} X_E d\lambda_{Y|X} d\lambda_X,
\]

and

\[
\int_{\mathbb{R}^{p_1} \times \mathbb{R}^{p_2}} X_E d\lambda_{X,Y} = \int_{\mathbb{R}^{p_2}} \int_{\mathbb{R}^{p_1}} X_E d\lambda_{X|Y} d\lambda_Y.
\]

**Definition 57.9.1** Let \( X \) and \( Y \) be two random vectors defined on a probability space. The conditional probability measure of \( Y \) given \( X \) is the measure \( \lambda_{Y|X} \) in the above. Similarly the conditional probability measure of \( X \) given \( Y \) is the measure \( \lambda_{X|Y} \).

More generally, one can use the theory of slicing measures to consider any finite list of random vectors, \( \{X_i\} \), defined on a probability space with \( X_i \in \mathbb{R}^{p_i} \), and write the following for \( E \) a Borel set in \( \prod_{i=1}^n \mathbb{R}^{p_i} \).

\[
\int_{\mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_n}} X_E d\lambda_{(x_1, \ldots, x_n)} = \int_{\mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_{n-1}}} \int_{\mathbb{R}^{p_n}} X_E d\lambda_{X_1, \ldots, X_{n-1}}(x_1, \ldots, x_{n-1}) d\lambda(x_1, \ldots, x_{n-1})
\]

\[
= \int_{\mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_{n-2}}} \int_{\mathbb{R}^{p_{n-1}}} \int_{\mathbb{R}^{p_n}} X_E d\lambda_{X_1, \ldots, X_{n-1}}(x_1, \ldots, x_{n-1}) d\lambda_{X_{n-1}}(x_{n-1}) d\lambda(x_1, \ldots, x_{n-2})
\]

\[
\vdots
\]

\[
\int_{\mathbb{R}^{p_1}} \cdots \int_{\mathbb{R}^{p_n}} X_E d\lambda_{X_1, \ldots, X_{n-1}}(x_1, \ldots, x_{n-1}) d\lambda_{X_{n-1}}(x_{n-1}) \cdots d\lambda_{X_2}(x_2) d\lambda_{X_1}. \tag{57.9.13}
\]

Obviously, this could have been done in any order in the iterated integrals by simply modifying the “given” variables, those occurring after the symbol \( | \), to be those which have been integrated in an outer level of the iterated integral. For simplicity, write

\[
\lambda_{X_n|(x_1, \ldots, x_{n-1})} = \lambda_{X_n|x_1, \ldots, x_{n-1}}
\]

**Definition 57.9.2** Let \( \{X_1, \ldots, X_n\} \) be random vectors defined on a probability space having values in \( \mathbb{R}^{p_1}, \ldots, \mathbb{R}^{p_n} \) respectively. The random vectors are independent if for every \( E \) a Borel set in \( \mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_n} \),

\[
\int_{\mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_n}} X_E d\lambda_{(x_1, \ldots, x_n)}
\]
and the iterated integration may be taken in any order. If \( A \) is any set of random vectors defined on a probability space, \( A \) is independent if any finite set of random vectors from \( A \) is independent.

Thus, the random vectors are independent exactly when the dependence on the givens in (57.9.13) can be dropped.

Does this amount to the same thing as discussed earlier? Suppose you have three random variables \( X, Y, Z \). Let \( A = X^{-1}(E), B = Y^{-1}(F), C = Z^{-1}(G) \) where \( E, F, G \) are Borel sets. Thus these inverse images are typical sets in \( \sigma(X), \sigma(Y), \sigma(Z) \) respectively. First suppose that the random variables are independent in the earlier sense. Then

\[
P(A \cap B \cap C) = P(A) P(B) P(C)
\]

Also

\[
P(A \cap B \cap C) = \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \lambda_E(x) \lambda_F(y) \lambda_G(z) \, dx \, dy \, dz
\]

Thus

\[
\int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \lambda_E(x) \lambda_F(y) \lambda_G(z) \, dx \, dy \, dz = \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \lambda_E(x) \lambda_F(y) \lambda_G(z) \, dx \, dy \, dz
\]

Now letting \( G = \mathbb{R}^p \), it follows that

\[
\int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \lambda_E(x) \lambda_F(y) \, dx \, dy = \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} \lambda_E(x) \lambda_F(y) \, dx \, dy
\]

By uniqueness of the slicing measures or an application of the Besikovitch differentiation theorem, it follows that for \( \lambda_X \) a.e. \( x \),

\[
\lambda_Y = \lambda_{Y|x}
\]
Thus, using this in the above, 
\begin{align*}
\int_{\mathbb{R}^1} \int_{\mathbb{R}^2} \int_{\mathbb{R}^3} \mathcal{X}_E(x) \mathcal{X}_F(y) \mathcal{X}_G(z) \, d\lambda_Z \, d\lambda_Y \, d\lambda_X \\
= \int_{\mathbb{R}^1} \int_{\mathbb{R}^2} \int_{\mathbb{R}^3} \mathcal{X}_E(x) \mathcal{X}_F(y) \mathcal{X}_G(z) \, d\lambda_{Z|XY} \, d\lambda_Y \, d\lambda_X
\end{align*}
and also it reduces to
\begin{align*}
\int_{\mathbb{R}^1 \times \mathbb{R}^2} \int_{\mathbb{R}^3} \mathcal{X}_E(x) \mathcal{X}_F(y) \mathcal{X}_G(z) \, d\lambda_Z \, d\lambda_{(X,Y)} \\
= \int_{\mathbb{R}^1 \times \mathbb{R}^2} \int_{\mathbb{R}^3} \mathcal{X}_E(x) \mathcal{X}_F(y) \mathcal{X}_G(z) \, d\lambda_{Z|XY} \, d\lambda_{(X,Y)}
\end{align*}
Now by uniqueness of the slicing measures again, for \( \lambda_{(X,Y)} \) a.e. \((x,y)\), it follows that
\[ \lambda_Z = \lambda_{Z|XY} \]
Similar conclusions hold for \( \lambda_X, \lambda_Y \). In each case, off a set of measure zero the distribution measures equal the slicing measures.
Conversely, if the distribution measures equal the slicing measures off sets of measure zero as described above, then it is obvious that the random variables are independent. The same reasoning applies for any number of random variables.
Thus this gives a different and more analytical way to think of independence of finitely many random variables. Clearly, the argument given above will apply to any finite set of random variables.

**Proposition 57.9.3** Equations (57.9.14) and (57.9.13) hold with \( \mathcal{X}_E \) replaced by any nonnegative Borel measurable function and for any bounded continuous function or for any function in \( L^1 \).

**Proof:** The two equations hold for simple functions in place of \( \mathcal{X}_E \) and so an application of the monotone convergence theorem applied to an increasing sequence of simple functions converging pointwise to a given nonnegative Borel measurable function yields the conclusion of the proposition in the case of the nonnegative Borel function. For a bounded continuous function or one in \( L^1 \), one can apply the result just established to the positive and negative parts of the real and imaginary parts of the function.

**Lemma 57.9.4** Let \( X_1, \ldots, X_n \) be random vectors with values in \( \mathbb{R}^{p_1}, \ldots, \mathbb{R}^{p_n} \) respectively and let \( g : \mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_n} \to \mathbb{R}^k \) be Borel measurable. Then \( g(X_1, \ldots, X_n) \) is a random vector with values in \( \mathbb{R}^k \) and if \( h : \mathbb{R}^k \to [0, \infty) \), then
\begin{align*}
\int_{\mathbb{R}^k} h(y) \, d\lambda_{g(X_1, \ldots, X_n)}(y) = \\
\int_{\mathbb{R}^{p_1} \times \cdots \times \mathbb{R}^{p_n}} h(g(X_1, \ldots, X_n)) \, d\lambda_{(X_1, \ldots, X_n)}.
\end{align*}
(57.9.15)
If \( X_i \) is a random vector with values in \( \mathbb{R}^p \), \( i = 1, 2, \ldots \) and if \( g_i : \mathbb{R}^p \to \mathbb{R}^k \), where \( g_i \) is Borel measurable, then the random vectors \( g_i(X_i) \) are also independent whenever the \( X_i \) are independent.

**Proof:** First let \( E \) be a Borel set in \( \mathbb{R}^k \). From the definition,

\[
\lambda_{g(x_1,\ldots,x_n)}(E) = P(g(X_1,\ldots,X_n) \in E) = P((X_1,\ldots,X_n) \in g^{-1}(E)) = \lambda_{(X_1,\ldots,X_n)}(g^{-1}(E))
\]

\[
\int_{\mathbb{R}^k} \mathcal{L}_E d\lambda_{g(x_1,\ldots,x_n)} = \int_{\mathbb{R}^1 \times \cdots \times \mathbb{R}^n} \mathcal{L}_{g^{-1}(E)} d\lambda_{(x_1,\ldots,x_n)} = \int_{\mathbb{R}^1 \times \cdots \times \mathbb{R}^n} \mathcal{L}_E(g(x_1,\ldots,x_n)) d\lambda_{(x_1,\ldots,x_n)}
\]

This proves 57.9.15 in the case when \( h \) is \( \lambda_E \). To prove it in the general case, approximate the nonnegative Borel measurable function with simple functions for which the formula is true, and use the monotone convergence theorem.

It remains to prove the last assertion that functions of independent random vectors are also independent random vectors. Let \( E \) be a Borel set in \( \mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_n} \). Then for

\[
\pi_i(x_1,\ldots,x_n) \equiv x_i,
\]

\[
\int_{\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_n}} \mathcal{L}_E d\lambda_{(g_1(\pi_1,\ldots,\pi_n),\ldots,g_n(\pi_1,\ldots,\pi_n))} = \int_{\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_n}} \mathcal{L}_E \circ (g_1 \circ \pi_1,\ldots,g_n \circ \pi_n) d\lambda_{(x_1,\ldots,x_n)}
\]

\[
= \int_{\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_n}} \mathcal{L}_E \circ (g_1 \circ \pi_1,\ldots,g_n \circ \pi_n) d\lambda_{x_1} \cdots d\lambda_{x_n} = \int_{\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_n}} \mathcal{L}_E d\lambda_{g_1(x_n)} \cdots d\lambda_{g_1(x_1)}
\]

and this proves the last assertion.

**Proposition 57.9.5** Let \( \nu_1,\ldots,\nu_n \) be Radon probability measures defined on \( \mathbb{R}^p \). Then there exists a probability space and independent random vectors \( \{X_1,\ldots,X_n\} \) defined on this probability space such that \( \lambda_{X_i} = \nu_i \).

**Proof:** Let \( (\Omega,\mathcal{S},P) \equiv ((\mathbb{R}^p)^n,\mathcal{S}_1 \times \cdots \times \mathcal{S}_n,\nu_1 \times \cdots \times \nu_n) \) where this is just the product \( \sigma \) algebra and product measure which satisfies the following for measurable rectangles.

\[
(\nu_1 \times \cdots \times \nu_n) \left( \prod_{i=1}^n E_i \right) = \prod_{i=1}^n \nu_i(E_i).
\]
Now let $X_i(x_1, \ldots, x_i, \ldots, x_n) = x_i$. Then from the definition, if $E$ is a Borel set in $\mathbb{R}^p$,

$$\lambda_{X_i}(E) = P\{X_i \in E\} = (\nu_1 \times \cdots \times \nu_n)(\mathbb{R}^p \times \cdots \times E \times \cdots \times \mathbb{R}^p) = \nu_i(E).$$

Let $M$ consist of all Borel sets of $(\mathbb{R}^p)^n$ such that

$$\int_{\mathbb{R}^p} \cdots \int_{\mathbb{R}^p} X_E(x_1, \ldots, x_n) d\lambda x_1 \cdots d\lambda x_n = \int_{(\mathbb{R}^p)^n} X_E d\lambda(x_1, \ldots, x_n).$$

From what was just shown and the definition of $(\nu_1 \times \cdots \times \nu_n)$ that $M$ contains all sets of the form $\prod_{i=1}^n E_i$ where each $E_i \in$ Borel sets of $\mathbb{R}^p$. Therefore, $M$ contains the algebra of all finite disjoint unions of such sets. It is also clear that $M$ is a monotone class and so by the theorem on monotone classes, $M$ equals the Borel sets. You could also note that $M$ is closed with respect to complements and countable disjoint unions and apply Lemma 10.12.3. Therefore, the given random vectors are independent and this proves the proposition.

The following Lemma was proved earlier in a different way.

**Lemma 57.9.6** If $\{X_i\}_{i=1}^n$ are independent random variables having values in $\mathbb{R}$,

$$E\left(\prod_{i=1}^n X_i\right) = \prod_{i=1}^n E(X_i).$$

**Proof:** By Lemma 57.9.4 and denoting by $P$ the product, $\prod_{i=1}^n X_i$,

$$E\left(\prod_{i=1}^n X_i\right) = \int_{\mathbb{R}} zd\lambda_P(z) = \int_{\mathbb{R}^n} \prod_{i=1}^n x_id\lambda_{(X_1, \ldots, X_n)}$$

$$= \int_{\mathbb{R}} \cdots \int_{\mathbb{R}} \prod_{i=1}^n x_id\lambda_{X_1} \cdots d\lambda_{X_n} = \prod_{i=1}^n E(X_i).$$

**57.10 Conditional Expectation**

**Definition 57.10.1** Let $X$ and $Y$ be random vectors having values in $\mathbb{F}^{p_1}$ and $\mathbb{F}^{p_2}$ respectively. Then if

$$\int |x| d\lambda_{X|Y}(x) < \infty,$$

we define

$$E(X|Y) = \int x d\lambda_{X|Y}(x).$$

**Proposition 57.10.2** Suppose $\int_{\mathbb{F}^{p_1} \times \mathbb{F}^{p_2}} |x| d\lambda(x, y)(x) < \infty$. Then $E(X|Y)$ exists for $\lambda_Y$ a.e. $y$ and

$$\int_{\mathbb{F}^{p_2}} E(X|y) d\lambda_Y = \int_{\mathbb{F}^{p_1}} x d\lambda_X(x) = E(X).$$
**Proof:** \( \infty > \int_{\mathbb{F}_2} \int_{\mathbb{F}_1} |x| \, d\lambda_x(y) = \int_{\mathbb{F}_2} \int_{\mathbb{F}_1} |x| \, d\lambda_{X|Y}(x) \, d\lambda_Y(y) \) and so
\[
\int_{\mathbb{F}_1} |x| \, d\lambda_{X|Y}(x) < \infty
\]
, \( \lambda_Y \) a.e. Now
\[
\int_{\mathbb{F}_2} E(X|y) \, d\lambda_Y
\]

Next we define what is meant by an upcrossing.

**Definition 57.10.3** Let \( \{X_n\} \) be any sequence, finite or infinite, of random variables with values in \( \mathbb{R} \) which are defined on some probability space, \( (\Omega, \mathcal{S}, P) \). We say \( \{X_n\} \) is a Martingale if
\[
E(X_n|x_{n-1}, \ldots, x_1) = x_{n-1}
\]
and we say \( \{X_n\} \) is a submartingale if
\[
E(X_n|x_{n-1}, \ldots, x_1) \geq x_{n-1}.
\]

Next we define what is meant by an upcrossing.

**Definition 57.10.4** Let \( \{x_i\}_{i=1}^I \) be any sequence of real numbers, \( I \leq \infty \). Define an increasing sequence of integers \( \{m_k\} \) as follows. \( m_1 \) is the first integer \( \geq 1 \) such that \( x_{m_1} \leq a \), \( m_2 \) is the first integer larger than \( m_1 \) such that \( x_{m_2} \geq b \), \( m_3 \) is the first integer larger than \( m_2 \) such that \( x_{m_3} \leq a \), etc. Then each sequence, \( \{x_{m_{2k-1}}, \ldots, x_{m_{2k}}\} \), is called an upcrossing of \( [a, b] \).

**Proposition 57.10.5** Let \( \{X_i\}_{i=1}^n \) be a finite sequence of real random variables defined on \( \Omega \) where \( (\Omega, \mathcal{S}, P) \) is a probability space. Let \( U_{[a,b]}(\omega) \) denote the number of upcrossings of \( X_i(\omega) \) of the interval \( [a, b] \). Then \( U_{[a,b]} \) is a random variable.

**Proof:** Let \( X_0(\omega) = a+1 \), let \( Y_0(\omega) = 0 \), and let \( Y_k(\omega) \) remain 0 for \( k = 0, \ldots, l \) until \( X_l(\omega) \leq a \). When this happens (if ever), \( Y_{l+1}(\omega) = 1 \). Then let \( Y_i(\omega) \) remain 1 for \( i = l + 1, \ldots, r \) until \( X_r(\omega) \geq b \) when \( Y_{r+1}(\omega) = 0 \). Let \( Y_k(\omega) \) remain 0 for \( k \geq r + 1 \) until \( X_k(\omega) \leq a \) when \( Y_k(\omega) = 1 \) and continue in this way. Thus the upcrossings of \( X_i(\omega) \) are identified as unbroken strings of ones with a zero at each end, with the possible exception of the last string of ones which may be missing the zero at the upper end and may or may not be an upcrossing.

Note also that \( Y_0 \) is measurable because it is identically equal to 0 and that if \( Y_k \) is measurable, then \( Y_{k+1} \) is measurable because the only change in going from
57.10. CONDITIONAL EXPECTATION

$k$ to $k+1$ is a change from 0 to 1 or from 1 to 0 on a measurable set determined by $X_k$. Now let

$$Z_k(\omega) = \begin{cases} 1 & \text{if } Y_k(\omega) = 1 \text{ and } Y_{k+1}(\omega) = 0, \\ 0 & \text{otherwise,} \end{cases}$$

if $k < n$ and

$$Z_n(\omega) = \begin{cases} 1 & \text{if } Y_n(\omega) = 1 \text{ and } X_n(\omega) \geq b, \\ 0 & \text{otherwise.} \end{cases}$$

Thus $Z_k(\omega) = 1$ exactly when an upcrossing has been completed and each $Z_i$ is a random variable.

$$U_{[a,b]}(\omega) = \sum_{k=1}^{n} Z_k(\omega)$$

so $U_{[a,b]}$ is a random variable as claimed.

The following corollary collects some key observations found in the above construction.

**Corollary 57.10.6** $U_{[a,b]}(\omega)$ is the number of unbroken strings of ones in the sequence, $\{Y_k(\omega)\}$ there being at most one unbroken string of ones which produces no upcrossing. Also

$$Y_i(\omega) = \psi_i \left( \{X_j(\omega)\}_{j=1}^{i-1} \right), \quad (57.10.16)$$

where $\psi_i$ is some function of the past values of $X_j(\omega)$.

**Lemma 57.10.7** (upcrossing lemma) Let $\{X_i\}_{i=1}^{n}$ be a submartingale and suppose $E(|X_n|) < \infty$.

Then

$$E(U_{[a,b]}) \leq \frac{E(|X_n|) + |a|}{b - a}.$$  

**Proof:** Let $\phi(x) \equiv a + (x - a)^+$. Thus $\phi$ is a convex and increasing function.

$$\phi(X_{k+r}) - \phi(X_k) = \sum_{i=k+1}^{k+r} \phi(X_i) - \phi(X_{i-1})$$

$$= \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1})) Y_i + \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1})) (1 - Y_i).$$

The upcrossings of $\phi(X_i)$ are exactly the same as the upcrossings of $X_i$ and from Formula 57.10.16

$$E\left( \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1})) (1 - Y_i) \right)$$
CHAPTER 57. BASIC PROBABILITY

\[ \sum_{i=k+1}^{k+r} \int_{\mathbb{R}} (\phi(x_i) - \phi(x_{i-1})) \left( 1 - \psi_i \left( \{x_j \}_{j=1}^{i-1} \right) \right) d\lambda(x_1, \ldots, x_i) \]

\[ = \sum_{i=k+1}^{k+r} \int_{\mathbb{R}} (\phi(x_i) - \phi(x_{i-1})) \left( 1 - \psi_i \left( \{x_j \}_{j=1}^{i-1} \right) \right) d\lambda(x_1, \ldots, x_i) \]

By Jensen’s inequality, Problem 10 of Chapter 13.

\[ \int_{\mathbb{R}} (\phi(x_i) - \phi(x_{i-1})) d\lambda(x_1, \ldots, x_i) = 0 \]

because of the assumption that our sequence of random variables is a submartingale and the observation that \( \phi \) is both convex and increasing.

Now let the unbroken strings of ones for \( \{Y_i(\omega)\} \) be

\[ \{k_1, \ldots, k_1 + r_1\}, \{k_2, \ldots, k_2 + r_2\}, \ldots, \{k_m, \ldots, k_m + r_m\} \quad (57.10.17) \]

where \( m = V(\omega) \equiv \text{the number of unbroken strings of ones in the sequence } \{Y_i(\omega)\} \).

By Corollary 57.10.6 \( V(\omega) \geq U_{[a,b]}(\omega) \).

\[ \phi(X_n(\omega)) - \phi(X_1(\omega)) = \sum_{k=1}^{n} (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) Y_k(\omega) \]

\[ + \sum_{k=1}^{n} (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) (1 - Y_k(\omega)). \]

Summing the first sum over the unbroken strings of ones (the terms in which \( Y_i(\omega) = 0 \) contribute nothing), implies

\[ \phi(X_n(\omega)) - \phi(X_1(\omega)) \]
57.10. CONDITIONAL EXPECTATION

\[ \geq U_{[a,b]} (\omega) (b - a) + 0+ \]
\[ \sum_{k=1}^{n} (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) (1 - Y_k(\omega)) \] (57.10.18)

where the zero on the right side results from a string of ones which does not produce an upcrossing. It is here that we use \( \phi(x) \geq a \). Such a string begins with \( \phi(X_k(\omega)) = a \) and results in an expression of the form \( \phi(X_{k+m}(\omega)) - \phi(X_k(\omega)) \geq 0 \) since \( \phi(X_{k+m}(\omega)) \geq a \). If we had not replaced \( X_k \) with \( \phi(X_k) \), it would have been possible for \( \phi(X_{k+m}(\omega)) \) to be less than \( a \) and the zero in the above could have been a negative number.

Therefore from Formula \( 57.10.18 \),

\[ (b - a) E(U_{[a,b]}) \leq E(\phi(X_n) - \phi(X_1)) \leq E(\phi(X_n) - a) \]
\[ = E \left( (X_n - a)^+ \right) \leq |a| + E(|X_n|) \]

and this proves the lemma.

**Theorem 57.10.8** (submartingale convergence theorem) Let \( \{X_i\}_{i=1}^{\infty} \) be a submartingale with \( K \equiv \sup \{E(|X_n|) : n \geq 1\} < \infty \). Then there exists a random variable, \( X_\infty \), such that \( E(|X_\infty|) \leq K \) and \( \lim_{n \to \infty} X_n(\omega) = X_\infty(\omega) \) a.e.

**Proof:** Let \( a, b \in \mathbb{Q} \) and let \( a < b \). Let \( U_{[a,b]}(\omega) \) be the number of upcrossings of \( \{X_i(\omega)\}_{i=1}^{n} \). Then let

\[ U_{[a,b]}(\omega) \equiv \lim_{n \to \infty} U_{[a,b]}^n(\omega) = \text{number of upcrossings of } \{X_i(\omega)\}. \]

By the upcrossing lemma,

\[ E(U_{[a,b]}^n) \leq \frac{E(|X_n|) + |a|}{b - a} \leq \frac{K + |a|}{b - a} \]

and so by the monotone convergence theorem,

\[ E(U_{[a,b]}) \leq \frac{K + |a|}{b - a} < \infty \]

which shows \( U_{[a,b]}(\omega) \) is finite a.e., for all \( \omega \notin S_{[a,b]} \) where \( P(S_{[a,b]}) = 0 \). Define

\[ S \equiv \cup \{S_{[a,b]} : a, b \in \mathbb{Q}, a < b\}. \]

Then \( P(S) = 0 \) and if \( \omega \notin S \), \( \{X_k\}_{k=1}^{\infty} \) has only finitely many upcrossings of every interval having rational endpoints. Thus, for \( \omega \notin S \), \( \limsup_{k \to \infty} X_k(\omega) = \liminf_{k \to \infty} X_k(\omega) = \lim_{k \to \infty} X_k(\omega) = X_\infty(\omega) \). Letting \( X_\infty(\omega) = 0 \) for \( \omega \in S \), Fatou’s lemma implies

\[ \int_{\Omega} |X_\infty| dP = \int_{\Omega} \liminf_{n \to \infty} |X_n| dP \leq \liminf_{n \to \infty} \int_{\Omega} |X_n| dP \leq K \]

and so this proves the theorem.
57.11 Characteristic Functions And Independence

There is a way to tell if random vectors are independent by using their characteristic functions.

**Proposition 57.11.1** If $X_j$ is a random vector having values in $\mathbb{R}^{p_j}$, then the random vectors are independent if and only if

$$E(e^{itP}) = \prod_{j=1}^{n} E(e^{it_j X_j})$$

where $P \equiv \sum_{j=1}^{n} t_j \cdot X_j$ for $t_j \in \mathbb{R}^{p_j}$.

The proof of this proposition will depend on the following lemma.

**Lemma 57.11.2** Let $Y$ be a random vector with values in $\mathbb{R}^p$ and let $f$ be bounded and measurable with respect to the Radon measure $\lambda_Y$, and satisfy

$$\int f(y) e^{it \cdot y} d\lambda_Y = 0$$

for all $t \in \mathbb{R}^p$. Then $f(y) = 0$ for $\lambda_Y$ a.e. $y$.

**Proof:** You could write the following for $\phi \in G$

$$\int \phi(t) \int f(y) e^{it \cdot y} d\lambda_Y dt = 0 = \int f(y) \left( \int \phi(t) e^{it \cdot y} dt \right) d\lambda_Y$$

and now recall that the inverse Fourier transform maps $G$ onto $G$. Hence

$$\int f(y) \psi(y) d\lambda_Y = 0$$

for all $\psi \in G$. Thus this is also so for every $\psi \in C_0^\infty(\mathbb{R}^p)$ by an obvious application of the Stone Weierstrass theorem. Let $\{\phi_k\}$ be a sequence of functions in $C_0^\infty(\mathbb{R}^p)$ which converges to

$$\text{sgn}(f) \equiv \begin{cases} 
\frac{\tilde{f}}{|f|} & \text{if } f \neq 0 \\
0 & \text{if } f = 0
\end{cases}$$

pointwise and in $L^1(\mathbb{R}^p, \lambda_Y)$, each $|\phi_k| \leq 2$. Then for any $\psi \in C_0^\infty(\mathbb{R}^p)$,

$$0 = \int f(y) \phi_n(y) \psi(y) d\lambda_Y \to \int |f(y)| \psi(y) d\lambda_Y$$

Also, the above holds for any $\psi \in C_c(\mathbb{R}^p)$ as can be seen by taking such a $\psi$ and convolving with a mollifier. By the Riesz representation theorem, $f(y) = 0 \lambda_Y$ a.e. (The measure $\mu(E) = \int_E |f(y)| d\lambda_Y$ equals 0.)

**Proof of the proposition:** If the $X_j$ are independent, the formula follows from Lemma 57.9.6 and Lemma 57.9.5.
Now suppose the formula holds. Thus

\[ \prod_{j=1}^{n} E(e^{it_{j}X_{j}}) = \]

\[ = \int_{\mathbb{R}^{n}} \cdots \int_{\mathbb{R}^{n}} e^{it_{1}x_{1}} e^{it_{2}x_{2}} \cdots e^{it_{n}x_{n}} d\lambda_{X_{1}}d\lambda_{X_{2}} \cdots d\lambda_{X_{n}} = E(e^{tP}) \]

Then from the above Lemma 57.11.19, the following equals 0 for \( \lambda_{X_{n}} \) a.e. \( \lambda_{X_{n-1}} \) of measure zero. Continuing this way, it follows that for \( \lambda_{X_{n}} \) a.e. \( \lambda_{X_{n-1}} \) of measure zero.

Let \( t_{i} = 0 \) for \( i = 1, 2, \ldots, n-2 \). Then this implies

\[ = \int_{\mathbb{R}^{n-1}} \cdots \int_{\mathbb{R}^{n-1}} e^{it_{n-1}x_{n-1}} d\lambda_{X_{n-1}}|x_{n} = \int_{\mathbb{R}^{n-1}} e^{it_{n-1}x_{n-1}} d\lambda_{X_{n-1}}|x_{n} \]

By the fact that the characteristic function determines the distribution measure, Theorem 57.8.3, it follows that for these \( x_{n} \) off a set of \( \lambda_{X_{n}} \) measure zero, \( \lambda_{X_{n-1}} = \lambda_{X_{n-1}|x_{n}} \). Returning to 57.11.19, one can replace \( \lambda_{X_{n-1}|x_{n}} \) with \( \lambda_{X_{n-1}} \) to obtain

\[ = \int_{\mathbb{R}^{n}} \cdots \int_{\mathbb{R}^{n}} e^{it_{1}x_{1}} e^{it_{2}x_{2}} \cdots e^{it_{n}x_{n}} d\lambda_{X_{1}|x_{2}}d\lambda_{X_{2}|x_{3}} \cdots d\lambda_{X_{n-1}|x_{n}} \]

Next let \( t_{n} = 0 \) and applying the above Lemma 57.11.19 again, this implies that for \( \lambda_{X_{n-1}} \) a.e. \( x_{n-1} \), the following equals 0.

\[ = \int_{\mathbb{R}^{n}} \cdots \int_{\mathbb{R}^{n}} e^{it_{1}x_{1}} e^{it_{2}x_{2}} \cdots e^{it_{n}x_{n}} d\lambda_{X_{1}|x_{2} \cdots x_{n}}d\lambda_{X_{2}|x_{3} \cdots x_{n}} \cdots d\lambda_{X_{n-1}|x_{n}} \]

Let \( t_{i} = 0 \) for \( i = 1, 2, \ldots, n-3 \). Then you obtain

\[ e^{it_{n-2}x_{n-2}} d\lambda_{X_{n-2}} = \int_{\mathbb{R}^{n-2}} e^{it_{n-2}x_{n-2}} d\lambda_{X_{n-2}|x_{n}x_{n-1}} \]

and so \( \lambda_{X_{n-2}} = \lambda_{X_{n-2}|x_{n}x_{n-1}} \) for \( x_{n-1} \) off a set of \( \lambda_{X_{n-1}} \) measure zero. Continuing this way, it follows that

\[ \lambda_{X_{n-k}} = \lambda_{X_{n-k}|x_{n}x_{n-1} \cdots x_{n-k+1}} \]
for $x_{n-k+1}$ off of a set of $\lambda x_{n-k+1}$ measure zero. Thus if $E$ is Borel in $\mathbb{R}^{p_1}$, 

$$
\int_{\mathbb{R}^{p_1}} x_{2} d\lambda x_{2} | x_1 \cdots x_n = \int_{\mathbb{R}^{p_1}} x_{3} d\lambda x_{3} | x_1 \cdots x_n \cdots d\lambda x_{n} | x_1 \cdots x_n
$$

One could achieve this iterated integral in any order by similar arguments to the above. By Definition 57.9.2 and the discussion which follows, this implies that the random variables $X_i$ are independent.

Here is another proof of the Doob Dynkin lemma based on differentiation theory.

**Lemma 57.11.3** Suppose $X, Y_1, Y_2, \cdots, Y_k$ are random vectors $X$ having values in $\mathbb{R}^n$ and $Y_j$ having values in $\mathbb{R}^{p_j}$ and $X, Y_j \in L^1(\Omega)$. Suppose $X$ is $\sigma(Y_1, \cdots, Y_k)$ measurable. Thus

$$
\{ X^{-1}(E) : E \text{ Borel} \} \subseteq \left\{ (Y_1, \cdots, Y_k)^{-1}(F) : F \text{ Borel in } \prod_{j=1}^k \mathbb{R}^{p_j} \right\}
$$

Then there exists a Borel function, $g : \prod_{j=1}^k \mathbb{R}^{p_j} \to \mathbb{R}^n$ such that

$$
X = g(Y_1, Y_2, \cdots, Y_k).
$$

**Proof:** For the sake of brevity, denote by $Y$ the vector $(Y_1, \cdots, Y_k)$ and by $y$ the vector $(y_1, \cdots, y_k)$ and let $\prod_{j=1}^k \mathbb{R}^{p_j} = \mathbb{R}^p$. For $E$ a Borel set of $\mathbb{R}^n$,

$$
\int_{Y^{-1}(E)} XdP = \int_{\mathbb{R}^n \times \mathbb{R}^k} X_{\mathbb{R}^n \times E}(x, y) x d\lambda(x, y) = \int_{E} \int_{\mathbb{R}^n} x d\lambda x | y d\lambda y.
$$

Consider the function

$$
y \to \int_{\mathbb{R}^n} x d\lambda x | y.
$$
Since $d\lambda_Y$ is a Radon measure having inner and outer regularity, it follows the above function is equal to a Borel function for $\lambda_Y$ a.e. $y$. This function will be denoted by $g$. Then from 57.11.20

$$
\int_{Y^{-1}(E)} X \, dP = \int_E g(y) \, d\lambda_Y = \int_{\mathbb{R}^p} \lambda_{E}(y) \, g(y) \, d\lambda_Y
$$

$$
= \int_{\Omega} \lambda_{E}(Y(\omega)) \, g(Y(\omega)) \, dP
$$

$$
= \int_{Y^{-1}(E)} g(Y(\omega)) \, dP
$$

and since $Y^{-1}(E)$ is an arbitrary element of $\sigma(Y)$, this shows that since $X$ is $\sigma(Y)$ measurable,

$$
X = g(Y) \quad P \text{ a.e.}
$$

What about the case where $X$ is not necessarily measurable in $\sigma(Y_1, \cdots, Y_k)$?

**Lemma 57.11.4** There exists a unique function $Z(\omega)$ which satisfies

$$
\int_F X(\omega) \, dP = \int_F Z(\omega) \, dP
$$

for all $F \in \sigma(Y_1, \cdots, Y_k)$ such that $Z$ is $\sigma(Y_1, \cdots, Y_k)$ measurable. It is denoted by

$$
E(X|\sigma(Y_1, \cdots, Y_k))
$$

**Proof:** It is like the above. Letting $E$ be a Borel set in $\mathbb{R}^p$,

$$
\int_{Y^{-1}(E)} X \, dP = \int_{\mathbb{R}^n \times \mathbb{R}^p} \lambda_{\mathbb{R}^n \times E}(x,y) \, x \, d\lambda_{(X,Y)}
$$

$$
= \int_E \int_{\mathbb{R}^n} x \, d\lambda_{X|Y} \, d\lambda_Y.
$$

Now let $g(y) \equiv E(X|y_1, \cdots, y_k)$ be a Borel representative of

$$
\int_{\mathbb{R}^n} x \, d\lambda_{X|Y}
$$

It follows $\omega \to g(Y(\omega)) = E(X|Y_1(\omega), \cdots, Y_k(\omega))$ is $\sigma(Y_1, \cdots, Y_k)$ measurable because by definition $\omega \to Y(\omega)$ is $\sigma(Y_1, \cdots, Y_k)$ measurable and a Borel measurable function composed with a measurable one is still measurable. It follows that for all $E$ Borel in $\mathbb{R}^p$,

$$
\int_{Y^{-1}(E)} X \, dP = \int_E E(X|y_1, \cdots, y_k) \, d\lambda_Y
$$

$$
= \int_{Y^{-1}(E)} E(X|Y_1(\omega), \cdots, Y_k(\omega)) \, dP
$$
and so \(Z(\omega) = E(X|Y_1(\omega), \cdots, Y_k(\omega))\) works because a generic set of \(\sigma(Y_1, \cdots, Y_k)\) is \(Y^{-1}(E)\) for \(E\) a Borel set in \(R^p\). If both \(Z, Z_1\) work, then for all \(F \in \sigma(Y_1, \cdots, Y_k)\),

\[
\int_F (Z - Z_1) \, dP = 0
\]

Since \(F\) is arbitrary, some routine computations show \(Z = Z_1\) a.e. \(\blacksquare\)

**Observation 57.11.5** Note that a.e.

\[E(X|Y_1(\omega), \cdots, Y_k(\omega)) = E(X|\sigma(Y_1, \cdots, Y_k))\]

where the one on the left is the expected value of \(X\) given values of \(Y_j(\omega)\). This one corresponds to the sort of thing we say in words. The one on the right is an abstract concept which is usually obtained using the Radon Nikodym theorem and its description is given in the lemma. This lemma shows that its meaning is really to take the expected value of \(X\) given values for the \(Y_k\).

### 57.12 Characteristic Functions For Measures

Recall the characteristic function for a random variable having values in \(R^n\). I will give a review of this to begin with. Then the concept will be generalized to random variables (vectors) which have values in a real separable Banach space.

**Definition 57.12.1** Let \(X\) be a random variable. The characteristic function is

\[
\phi_X(t) \equiv E(e^{it \cdot X}) \equiv \int_{\Omega} e^{it \cdot X(\omega)} \, dP = \int_{R^p} e^{it \cdot x} \, d\lambda_X
\]

the last equation holding by Proposition 57.1.12 on Page 1940.

Recall the following fundamental lemma and definition, Lemma 29.3.4 on Page 1087.

**Definition 57.12.2** For \(T \in G^*\), define \(FT, F^{-1}T \in G^*\) by

\[
FT(\phi) \equiv T(F\phi), \quad F^{-1}T(\phi) \equiv T(F^{-1}\phi)
\]

**Lemma 57.12.3** \(F\) and \(F^{-1}\) are both one to one, onto, and are inverses of each other.

The main result on characteristic functions is the following in Theorem 57.8.4 on Page 1926 which is stated here for convenience.

**Theorem 57.12.4** Let \(X\) and \(Y\) be random vectors with values in \(R^p\) and suppose \(E(e^{it \cdot X}) = E(e^{it \cdot Y})\) for all \(t \in R^p\). Then \(\lambda_X = \lambda_Y\).

I want to do something similar for random variables which have values in a separable real Banach space, \(E\) instead of \(R^p\).
Corollary 57.12.5 Let $\mathcal{K}$ be a $\pi$ system of subsets of $\Omega$ and suppose two probability measures, $\mu$ and $\nu$ defined on $\sigma(\mathcal{K})$ are equal on $\mathcal{K}$. Then $\mu = \nu$.

Proof: This follows from the Lemma on Page 1941. Let
\[ \mathcal{G} \equiv \{ E \in \sigma(\mathcal{K}) : \mu(E) = \nu(E) \} \]
Then $\mathcal{K} \subseteq \mathcal{G}$, since $\mu$ and $\nu$ are both probability measures, it follows that if $E \in \mathcal{G}$, then so is $E^C$. Since these are measures, if $\{ A_i \}$ is a sequence of disjoint sets from $\mathcal{G}$ then
\[ \mu(\bigcup_{i=1}^{\infty} A_i) = \sum_i \mu(A_i) = \sum_i \nu(A_i) = \nu(\bigcup_{i=1}^{\infty} A_i) \]
and so from Lemma $\mathcal{G} = \sigma(\mathcal{K})$. 

Next recall the following fundamental lemma used to prove Pettis' theorem. It is proved on Page 1941 but is stated here for convenience.

Lemma 57.12.6 If $E$ is a separable Banach space with $B'$ the closed unit ball in $E'$, then there exists a sequence $\{ f_n \}_{n=1}^{\infty} \equiv D' \subseteq B'$ with the property that for every $x \in E$,
\[ \|x\| = \sup_{f \in D'} |f(x)| \]

Definition 57.12.7 Let $E$ be a separable real Banach space. A cylindrical set is one which is of the form
\[ \{ x \in E : x_i^*(x) \in \Gamma_i, i = 1, 2, \cdots, m \} \]
where here $x_i^* \in E'$ and $\Gamma_i$ is a Borel set in $\mathbb{R}$.

It is obvious that $\emptyset$ is a cylindrical set and that the intersection of two cylindrical sets is another cylindrical set. Thus the cylindrical sets form a $\pi$ system. What is the smallest $\sigma$ algebra containing the cylindrical sets? It is the Borel sets of $E$. This is a special case of Lemma 57.4.2. Recall why this was. Letting $\{ f_n \}_{n=1}^{\infty} = D'$ be the sequence of Lemma 57.4.2 it follows that
\[ \{ x \in E : \|x - a\| \leq \delta \} = \bigcap_{m=1}^{\infty} \left\{ x \in E : f_n(x) \in B(f_n(a), \delta) \right\} \]

which yields a countable intersection of cylindrical sets. It follows the smallest $\sigma$ algebra containing the cylindrical sets contains the closed balls and hence the open balls and consequently the open sets and so it contains the Borel sets. However, each cylindrical set is a Borel set and so in fact this $\sigma$ algebra equals $\mathcal{B}(E)$.

From Corollary 57.12.5 it follows that two probability measures which are equal on the cylindrical sets are equal on the Borel sets $\mathcal{B}(E)$.
**Definition 57.12.8** Let $\mu$ be a probability measure on $\mathcal{B}(E)$ where $E$ is a real separable Banach space. Then for $x^* \in E'$,

$$\phi_{\mu}(x^*) \equiv \int_E e^{ix^*(x)}d\mu(x).$$

$\phi_{\mu}$ is called the characteristic function for the measure $\mu$.

Note this is a little different than earlier when the symbol $\phi_{\chi(t)}$ was used and $X$ was a random variable. Here the focus is more on the measure than a random variable, $X$ such that $L(X) = \mu$. It might appear this is a more general concept but in fact this is not the case. You could just consider the separable Banach space or Polish space with the Borel algebra as your probability space and then consider the identity map as a random variable having the given measure as a distribution measure. Of course a major result is the one which says that the characteristic function determines the measures.

**Theorem 57.12.9** Let $\mu$ and $\nu$ be two probability measures on $\mathcal{B}(E)$ where $E$ is a separable real Banach space. Suppose

$$\phi_{\mu}(x^*) = \phi_{\nu}(x^*)$$

for all $x^* \in E'$. Then $\mu = \nu$.

**Proof:** It suffices to verify that $\mu(A) = \nu(A)$ for all $A \in \mathcal{K}$ where $\mathcal{K}$ is the set of cylindrical sets. Fix $g_n \in (E')^n$. Thus the two measures are equal if for all such $g_n$, $n \in \mathbb{N}$,

$$\mu\left(g_n^{-1}(B)\right) = \nu\left(g_n^{-1}(B)\right)$$

for $B$ a Borel set in $\mathbb{R}^n$. Of course, for such a choice of $g_n \in (E')^n$, there are measures defined on the Borel sets of $\mathbb{R}^n \mu_n$ and $\nu_n$, which are given by

$$\mu_n(B) \equiv \mu\left(g_n^{-1}(B)\right), \quad \nu_n(B) \equiv \nu\left(g_n^{-1}(B)\right)$$

and so it suffices to verify that these two measures are equal. So what are their characteristic functions? Note that $g_n$ is a random variable taking $E$ to $\mathbb{R}^n$ and $\mu_n$, $\nu_n$ are just the probability distribution measures of this random variable. Therefore,

$$\phi_{\mu_n}(t) \equiv \int_{\mathbb{R}^n} e^{it \cdot x}d\mu_n = \int_{\mathbb{R}^n} e^{it \cdot g_n(x)}d\mu$$

Similarly,

$$\phi_{\nu_n}(t) \equiv \int_{\mathbb{R}^n} e^{it \cdot x}d\nu_n = \int_{\mathbb{R}^n} e^{it \cdot g_n(x)}d\nu$$

Now $t \cdot g_n \in E'$ and so by assumption, the two ends of the above are equal. Hence $\phi_{\mu_n}(t) = \phi_{\nu_n}(t)$ and so by Theorem 57.8.6, $\mu_n = \nu_n$ which, as shown above, implies $\mu = \nu$. ■
Characteristic Functions And Independence In Banach Space

I will consider the relation between the characteristic function and independence of random variables having values in a Banach space. Recall an earlier proposition which relates independence of random vectors with characteristic functions. It is proved starting on Page 1936.

Proposition 57.13.1 Let \( \{X_k\}_{k=1}^n \) be random vectors such that \( X_k \) has values in \( \mathbb{R}^{p_k} \). Then the random vectors are independent if and only if

\[
E \left( e^{iP} \right) = \prod_{j=1}^n E \left( e^{it_j X_j} \right)
\]

where \( P \equiv \sum_{j=1}^n t_j \cdot X_j \) for \( t_j \in \mathbb{R}^{p_j} \).

It turns out there is a generalization of the above proposition to the case where the random variables have values in a real separable Banach space. Before proving this recall an earlier theorem which had to do with reducing to the case where the random variables had values in \( \mathbb{R}^n \), Theorem 57.5.1. It is restated here for convenience.

Theorem 57.13.2 The random variables \( \{X_i\}_{i \in I} \) are independent if whenever

\[ \{i_1, \ldots, i_n\} \subseteq I, \]

\( m_{i_1}, \ldots, m_{i_n} \) are positive integers, and \( g_{m_{i_1}}, \ldots, g_{m_{i_n}} \) are in

\( (E')^{m_{i_1}}, \ldots, (E')^{m_{i_n}} \)

respectively, \( \left\{ g_{m_{i_j}} \circ X_{i_j} \right\}_{j=1}^n \) are independent random vectors having values in

\( \mathbb{R}^{m_{i_1}}, \ldots, \mathbb{R}^{m_{i_n}} \)

respectively.

Now here is the theorem about independence and the characteristic functions.

Theorem 57.13.3 Let \( \{X_k\}_{k=1}^n \) be random variables such that \( X_k \) has values in \( E_k \), a real separable Banach space. Then the random variables are independent if and only if

\[
E \left( e^{iP} \right) = \prod_{j=1}^n E \left( e^{it_j^* (X_j)} \right)
\]

where \( P \equiv \sum_{j=1}^n t_j^* (X_j) \) for \( t_j^* \in E_j^* \).
CHAPTER 57. BASIC PROBABILITY

Proof: If the random variables are independent, then so are the random variables, $t^*_j (X_j)$ and so the equation follows.

The interesting case is when the equation holds.

It suffices to consider only the case where each $E_k = E$. This is because you can consider each $X_j$ to have values in $\prod_{k=1}^n E_k$ by letting $X_j$ take its values in the $j^{th}$ component of the product and 0 in the other components. Can you draw the conclusion the random variables are independent? By Theorem 57.5.1, it suffices to show the random variables $\{g_{mk} \circ X_k\}_{k=1}^n$ are independent where $g_{mk} = (x_1^*, \cdots, x_{mk}^*) \in (E')^m$. This happens if whenever $t_{mk} \in \mathbb{R}^{mk}$ and

$$P = \sum_{k=1}^n t_{mk} \cdot (g_{mk} \circ X_k),$$

it follows

$$E(e^{iP}) = \prod_{k=1}^n E \left( e^{it_{mk} \cdot (g_{mk} \circ X_k)} \right). \quad (57.13.21)$$

However, the expression on the right in (57.13.21) equals

$$\prod_{k=1}^n E \left( e^{i(t_{mk} \cdot g_{mk}) \circ X_k} \right)$$

and $t_{mk} \cdot g_{mk} \equiv \sum_{j=1}^{mk} t_j x_j^* \in E'$. Also the expression on the left equals $E \left( e^{\sum_{k=1}^n t_{mk} \cdot (g_{mk} \circ X_k)} \right)$

Therefore, by assumption, (57.13.21) holds.

There is an obvious corollary which is useful.

**Corollary 57.13.4** Let $\{X_k\}_{k=1}^n$ be random variables such that $X_k$ has values in $E_k$, a real separable Banach space. Then the random variables are independent if and only if

$$E(e^{iP}) = \prod_{j=1}^n E \left( e^{it^*_j (X_j)} \right)$$

where $P \equiv \sum_{j=1}^n t^*_j (X_j)$ for $t^*_j \in M_j$ where $M_j$ is a dense subset of $E_j'$.

Proof: The easy direction follows from Theorem 57.13.3. Suppose then the above equation holds for all $t^*_j \in M_j$. Then let $t^*_j \in E'$ and let $\{t^*_{nj}\}$ be a sequence in $M_j$ such that

$$\lim_{n \to \infty} t^*_{nj} = t^*_j \text{ in } E'$$

Then define

$$P = \sum_{j=1}^n t^*_j X_j, \quad P_n = \sum_{j=1}^n t^*_{nj} X_j.$$
It follows
\[
E \left( e^{iP} \right) = \lim_{n \to \infty} E \left( e^{iP_n} \right) = \lim_{n \to \infty} \prod_{j=1}^{n} E \left( e^{i\mathcal{N}_j(X_j)} \right) = \prod_{j=1}^{n} E \left( e^{i\mathcal{N}_j(X_j)} \right)
\]

\section{57.14 Convolution And Sums}

Lemma 57.14.3 on Page 1945 makes possible a definition of convolution of two probability measures defined on $\mathcal{B}(E)$ where $E$ is a separable Banach space as well as some other interesting theorems which held earlier in the context of locally compact spaces. I will first show a little theorem about density of continuous functions in $L^p(E)$ and then define the convolution of two finite measures. First here is a simple technical lemma.

\textbf{Lemma 57.14.1} Suppose $K$ is a compact subset of $U$ an open set in $E$ a metric space. Then there exists $\delta > 0$ such that
\[
\text{dist} (x, K) + \text{dist} (x, U^C) \geq \delta \text{ for all } x \in E.
\]

\textbf{Proof:} For each $x \in K$, there exists a ball, $B(x, \delta_x)$ such that $B(x, 3\delta_x) \subseteq U$. Finitely many of these balls cover $K$ because $K$ is compact, say $\{B(x_i, \delta_{x_i})\}_{i=1}^{m}$. Let
\[
0 < \delta < \min (\delta_{x_i} : i = 1, 2, \cdots, m).
\]

Now pick any $x \in K$. Then $x \in B(x_i, \delta_{x_i})$ for some $x_i$ and so $B(x, \delta) \subseteq B(x_i, 2\delta_{x_i}) \subseteq U$. Therefore, for any $x \in K$, dist $(x, U^C) \geq \delta$. If $x \in B(x_i, 2\delta_{x_i})$ for some $x_i$, it follows dist $(x, U^C) \geq \delta$ because when $x \in B(x, \delta)$ then $B(x, \delta) \subseteq B(x_i, 3\delta_{x_i}) \subseteq U$. If $x \notin B(x_i, 2\delta_{x_i})$ for any of the $x_i$, then $x \notin B(y, \delta)$ for any $y \in K$ because all these sets are contained in some $B(x_i, 2\delta_{x_i})$. Consequently dist $(x, K) \geq \delta$. This proves the lemma.

From this lemma, there is an easy corollary.

\textbf{Corollary 57.14.2} Suppose $K$ is a compact subset of $U$, an open set in $E$ a metric space. Then there exists a uniformly continuous function $f$ defined on all of $E$, having values in $[0, 1]$ such that $f(x) = 0$ if $x \notin U$ and $f(x) = 1$ if $x \in K$.

\textbf{Proof:} Consider
\[
f(x) \equiv \frac{\text{dist}(x, U^C)}{\text{dist}(x, U^C) + \text{dist}(x, K)}.
\]

Then some algebra yields
\[
|f(x) - f(x')| \leq
\]
1946  

CHAPTER 57. BASIC PROBABILITY

\[ \frac{1}{\delta} \left( |\text{dist} (x, U^C) - \text{dist} (x', U^C)| + |\text{dist} (x, K) - \text{dist} (x', K)| \right) \]

where \( \delta \) is the constant of Lemma 57.14.1. Now it is a general fact that

\[ |\text{dist} (x, S) - \text{dist} (x', S)| \leq d(x, x'). \]

Therefore,

\[ |f(x) - f(x')| \leq \frac{2}{\delta} d(x, x') \]

and this proves the corollary.

Now suppose \( \mu \) is a finite measure defined on the Borel sets of a separable Banach space, \( E \). It was shown above that \( \mu \) is inner and outer regular. Lemma 57.1.9 on Page 1901 shows that \( \mu \) is inner regular in the usual sense with respect to compact sets. This makes possible the following theorem.

**Theorem 57.14.3** Let \( \mu \) be a finite measure on \( \mathcal{B}(E) \) where \( E \) is a separable Banach space and let \( f \in L^p(E; \mu) \). Then for any \( \epsilon > 0 \), there exists a uniformly continuous, bounded \( g \) defined on \( E \) such that

\[ \|f - g\|_{L^p(E)} < \epsilon. \]

**Proof:** As usual in such situations, it suffices to consider only \( f \geq 0 \). Then by Theorem 9.3.9 on Page 227 and an application of the monotone convergence theorem, there exists a simple measurable function,

\[ s(x) \equiv \sum_{k=1}^{m} c_k \chi_{A_k}(x) \]

such that \( \|f - s\|_{L^p(E)} < \epsilon/2 \). Now by regularity of \( \mu \) there exist compact sets, \( K_k \) and open sets, \( V_k \) such that \( 2 \sum_{k=1}^{m} |c_k| \mu(V_k \setminus K_k)^{1/p} < \epsilon/2 \) and by Corollary 57.14.2 there exist uniformly continuous functions \( g_k \) having values in \([0,1]\) such that \( g_k = 1 \) on \( K_k \) and \( 0 \) on \( V_k^C \). Then consider

\[ g(x) = \sum_{k=1}^{m} c_k g_k(x). \]
This function is bounded and uniformly continuous. Furthermore,

\[ \|s - g\|_{L^p(E)} \leq \left( \int_E \left| \sum_{k=1}^{m} c_k \mathcal{X}_{A_k}(x) - \sum_{k=1}^{m} c_k \mathcal{X}_{B_k}(x) \right|^p d\mu \right)^{1/p} \]

\[ \leq \left( \int_E \left| \sum_{k=1}^{m} c_k \mathcal{X}_{A_k}(x) - \mathcal{X}_{B_k}(x) \right|^p d\mu \right)^{1/p} \]

\[ \leq \sum_{k=1}^{m} |c_k| \left( \int_E |\mathcal{X}_{A_k}(x) - \mathcal{X}_{B_k}(x)|^p d\mu \right)^{1/p} \]

\[ \leq \sum_{k=1}^{m} |c_k| \left( \int_{V_k \setminus K_k} 2^p d\mu \right)^{1/p} \]

\[ = 2 \sum_{k=1}^{m} |c_k| \mu(V_k \setminus K_k)^{1/p} < \varepsilon/2. \]

Therefore,

\[ \|f - g\|_{L^p} \leq \|f - s\|_{L^p} + \|s - g\|_{L^p} < \varepsilon/2 + \varepsilon/2. \]

This proves the theorem.

**Lemma 57.14.4** Let \( A \in \mathcal{B}(E) \) where \( \mu \) is a finite measure on \( \mathcal{B}(E) \) for \( E \) a separable Banach space. Also let \( x_i \in E \) for \( i = 1, 2, \cdots, m \). Then for \( x \in E^m \),

\[ x \to \mu \left( A + \sum_{i=1}^{m} x_i \right), \quad x \to \mu \left( A - \sum_{i=1}^{m} x_i \right) \]

are Borel measurable functions. Furthermore, the above functions are

\[ \mathcal{B}(E) \times \cdots \times \mathcal{B}(E) \]

measurable where the above denotes the product measurable sets as described in Theorem 10.12.6 on Page 315.

**Proof:** First consider the case where \( A = U \), an open set. Let

\[ y \in \left\{ x \in E^m : \mu \left( U + \sum_{i=1}^{m} x_i \right) > \alpha \right\} \quad (57.14.22) \]

Then from Lemma 57.13.4 on Page 315 there exists a compact set, \( K \subseteq U + \sum_{i=1}^{m} y_i \) such that \( \mu(K) > \alpha \). Then if \( y' \) is close enough to \( y \), it follows \( K \subseteq U + \sum_{i=1}^{m} y' \) also. Therefore, for all \( y' \) close enough to \( y \),

\[ \mu \left( U + \sum_{i=1}^{m} y' \right) \geq \mu(K) > \alpha. \]
In other words the set described in \(57.14.22\) is an open set and so \(y \to \mu (U + \sum_{i=1}^{m} y_i)\) is Borel measurable whenever \(U\) is an open set in \(E\).

Define a \(\pi\) system, \(\mathcal{K}\) to consist of all open sets in \(E\). Then define \(\mathcal{G}\) as

\[
\left\{ A \in \sigma (\mathcal{K}) = \mathcal{B} (E) : y \to \mu \left( A + \sum_{i=1}^{m} y_i \right) \text{ is Borel measurable} \right\}
\]

I just showed \(\mathcal{G} \supseteq \mathcal{K}\). Now suppose \(A \in \mathcal{G}\). Then

\[
\mu \left( A^c + \sum_{i=1}^{m} y_i \right) = \mu (E) - \mu \left( A + \sum_{i=1}^{m} y_i \right)
\]

and so \(A^c \in \mathcal{G}\) whenever \(A \in \mathcal{G}\). Next suppose \(\{A_i\}\) is a sequence of disjoint sets of \(\mathcal{G}\). Then

\[
\mu \left( \bigcup_{i=1}^{\infty} A_i + \sum_{j=1}^{m} y_j \right) = \mu \left( \bigcup_{i=1}^{\infty} \left( A_i + \sum_{j=1}^{m} y_j \right) \right) = \sum_{i=1}^{\infty} \mu \left( A_i + \sum_{j=1}^{m} y_j \right)
\]

and so \(\bigcup_{i=1}^{\infty} A_i \in \mathcal{G}\) because the above is the sum of Borel measurable functions. By the lemma on \(\pi\) systems, Lemma \(10.12.3\) on Page 311, it follows \(\mathcal{G} = \sigma (\mathcal{K}) = \mathcal{B} (E)\).

Similarly, \(x \to \mu \left( A - \sum_{j=1}^{m} x_j \right)\) is also Borel measurable whenever \(A \in \mathcal{B} (E)\).

Finally note that

\[
\mathcal{B} (E) \times \cdots \times \mathcal{B} (E)
\]

contains the open sets of \(E^m\) because the separability of \(E\) implies the existence of a countable basis for the topology of \(E^m\) consisting of sets of the form \(\prod_{i=1}^{m} U_i\) where the \(U_i\) come from a countable basis for \(E\). Since every open set is the countable union of sets like the above, each being a measurable box, the open sets are contained in

\[
\mathcal{B} (E) \times \cdots \times \mathcal{B} (E)
\]

which implies \(\mathcal{B} (E^m) \subseteq \mathcal{B} (E) \times \cdots \times \mathcal{B} (E)\) also. This proves the lemma.

With this lemma, it is possible to define the convolution of two finite measures.

**Definition 57.14.5** Let \(\mu\) and \(\nu\) be two finite measures on \(\mathcal{B} (E)\), for \(E\) a separable Banach space. Then define a new measure, \(\mu \ast \nu\) on \(\mathcal{B} (E)\) as follows

\[
\mu \ast \nu (A) \equiv \int_{E} \nu (A - x) \, d\mu (x).
\]

This is well defined because of Lemma \(57.14.4\) which says that \(x \to \nu (A - x)\) is Borel measurable.
Here is an interesting theorem about convolutions. However, first here is a little lemma. The following picture is descriptive of the set described in the following lemma.

Lemma 57.14.6 For $A$ a Borel set in $E$, a separable Banach space, define

$$S_A = \{(x, y) \in E \times E : x + y \in A\}$$

Then $S_A \in \mathcal{B}(E) \times \mathcal{B}(E)$, the $\sigma$ algebra of product measurable sets, the smallest $\sigma$ algebra which contains all the sets of the form $A \times B$ where $A$ and $B$ are Borel.

Proof: Let $K$ denote the open sets in $E$. Then $K$ is a $\pi$ system. Let

$$\mathcal{G} = \{A \in \sigma(K) = \mathcal{B}(E) : S_A \in \mathcal{B}(E) \times \mathcal{B}(E)\}.$$ 

Then $K \subseteq \mathcal{G}$ because if $U \in K$ then $S_U$ is an open set in $E \times E$ and all open sets are in $\mathcal{B}(E) \times \mathcal{B}(E)$ because a countable basis for the topology of $E \times E$ are sets of the form $B \times C$ where $B$ and $C$ come from a countable basis for $E$. Therefore, $K \subseteq \mathcal{G}$. Now let $A \in \mathcal{G}$. For $(x, y) \in E \times E$, either $x + y \in A$ or $x + y \notin A$. Hence $E \times E = S_A \cup S_{A^c}$ which shows that if $A \in \mathcal{G}$ then so is $A^c$. Finally if $\{A_i\}$ is a sequence of disjoint sets of $\mathcal{G}$

$$S_{\bigcup_{i=1}^{\infty} A_i} = \bigcup_{i=1}^{\infty} S_{A_i},$$

and this shows that $\mathcal{G}$ is also closed with respect to countable unions of disjoint sets. Therefore, by the lemma on $\pi$ systems, Lemma 10.12.3 on Page 311 it follows $\mathcal{G} = \sigma(K) = \mathcal{B}(E)$. This proves the lemma.

Theorem 57.14.7 Let $\mu$, $\nu$, and $\lambda$ be finite measures on $\mathcal{B}(E)$ for $E$ a separable Banach space. Then

$$\mu * \nu = \nu * \mu \quad (57.14.23)$$

$$(\mu * \nu) * \lambda = \mu * (\nu * \lambda) \quad (57.14.24)$$

If $\mu$ is the distribution for an $E$ valued random variable, $X$ and if $\nu$ is the distribution for an $E$ valued random variable, $Y$, and $X$ and $Y$ are independent, then $\mu * \nu$ is the distribution for the random variable, $X + Y$. Also the characteristic function of a convolution equals the product of the characteristic functions.
**Proof:** First consider (57.14.23). Letting $A \in \mathcal{B}(E)$, the following computation holds from Fubini's theorem and Lemma (57.14.6):

$$
\mu * \nu (A) \equiv \int_E \nu (A - x) \, d\mu (x) = \int_E \int_E X_{S\lambda} (x, y) \, d\nu (y) \, d\mu (x)
$$

$$
= \int_E \int_E X_{S\lambda} (x, y) \, d\mu (x) \, d\nu (y) = \nu * \mu (A).
$$

Next consider (57.14.24). Using (57.14.23) whenever convenient,

$$(\mu * \nu) * \lambda (A) \equiv \int_E (\mu * \nu) (A - x) \, d\lambda (x)
$$

$$
= \int_E \nu (A - x - y) \, d\mu (y) \, d\lambda (x)
$$

while

$$
\mu * (\nu * \lambda) (A) \equiv \int_E (\nu * \lambda) (A - y) \, d\mu (y)
$$

$$
= \int_E \nu (A - y - x) \, d\lambda (x) \, d\mu (y)
$$

$$
= \int_E \nu (A - y - x) \, d\mu (y) \, d\lambda (x).
$$

The necessary product measurability comes from Lemma (57.14.4). Recall

$$(\mu * \nu) (A) \equiv \int_E \nu (A - x) \, d\mu (x).$$

Therefore, if $s$ is a simple function, $s (x) = \sum_{k=1}^n c_k X_{A_k} (x)$,

$$
\int_E s \, d(\mu * \nu) = \sum_{k=1}^n c_k \int_E \nu (A_k - x) \, d\mu (x)
$$

$$
= \int_E \left( \sum_{k=1}^n c_k \nu (A_k - x) \right) \, d\mu (x)
$$

$$
= \int_E \left( \sum_{k=1}^n c_k X_{A_k} (y) \, d\nu (y) \right) \, d\mu (x)
$$

$$
= \int_E \int_E s (x + y) \, d\nu (y) \, d\mu (x)
$$

Approximating with simple functions it follows that whenever $f$ is bounded and measurable or nonnegative and measurable,

$$
\int_E f \, d(\mu * \nu) = \int_E \int_E f (x + y) \, d\nu (y) \, d\mu (x) \quad (57.14.25)
$$
57.15. THE CONVERGENCE OF SUMS OF SYMMETRIC RANDOM VARIABLES

Therefore, letting $Z = X + Y$, and $\lambda$ the distribution of $Z$, it follows from independence of $X$ and $Y$ that for $t^* \in E'$,

$$\phi_{\lambda} (t^*) \equiv E \left( e^{it^* (Z)} \right) = E \left( e^{it^* (X + Y)} \right) = E \left( e^{it^* (X)} \right) E \left( e^{it^* (Y)} \right)$$

But also, it follows from

$$\phi_{\lambda} (t^*) = \phi_{(\mu * \nu)} (t^*) \quad \text{for} \quad t^* \in E'$$

Since $\phi_{\lambda} (t^*) = \phi_{(\mu * \nu)} (t^*)$, it follows $\lambda = \mu * \nu$.

Note the last part of this argument shows the characteristic function of a convolution equals the product of the characteristic functions. This proves the theorem.

57.15 The Convergence Of Sums Of Symmetric Random Variables

It turns out that when random variables have symmetric distributions, some remarkable things can be said about infinite sums of these random variables. Conditions are given here that enable one to conclude the convergence of the sequence of partial sums from the convergence of some subsequence of partial sums.

The following lemma is like an earlier result but is proved here for convenience.

**Definition 57.15.1** Let $X$ be a random variable. $L(X) = \mu$ means $\lambda_X = \mu$. This is called the law of $X$. It is the same as saying the distribution measure of $X$ is $\mu$.

**Lemma 57.15.2** Let $(\Omega, \mathcal{F}, P)$ be a probability space and let $X : \Omega \to E$ be a random variable, where $E$ is a real separable Banach space. Also let $L(X) = \mu$, a probability measure defined on $\mathcal{B}(E)$, the Borel sets of $E$. Suppose $h : E \to \mathbb{R}$ is in $L^1 (E; \mu)$ or is nonnegative and Borel measurable. Then

$$\int_{\Omega} (h \circ X) dP = \int_E h (x) d\mu.$$  

**Proof:** First suppose $A$ is a Borel set in $E$. Then

$$\int_E X_A (x) d\mu \equiv \mu (A) \equiv P ([X \in A])$$

$$\int_{\Omega} (X_A \circ X) dP = \int E X^{-1} (A) (\omega) dP \equiv P (X^{-1} (A)) \equiv P ([X \in A])$$
Thus for nonnegative simple Borel measurable functions $s$, it follows
\[ \int \Omega (s \circ X) dP = \int_E s(x) d\mu \]
Now approximating with an increasing sequence of nonnegative simple functions and using the monotone convergence theorem, the desired formula holds for nonnegative Borel measurable functions $h$.

If $h$ is Borel measurable and in $L^1 (E; \mu)$, then you can consider the formula for the positive and negative parts and get the result in this case also. This proves the lemma.

Here is a simple definition and lemma about random variables whose distribution is symmetric.

**Definition 57.15.3** Let $X$ be a random variable defined on a probability space, $(\Omega, F, P)$ having values in a Banach space, $E$. Then it has a symmetric distribution if whenever $A$ is a Borel set,
\[ P ([X \in A]) = P ([X \in -A]) \]
In terms of the distribution,
\[ \lambda_X = \lambda_{-X}. \]

It is good to observe that if $X, Y$ are independent random variables defined on a probability space, $(\Omega, F, P)$ such that each has symmetric distribution, then $X + Y$ also has symmetric distribution. Here is why. Let $A$ be a Borel set in $E$. Then by Theorem 57.14.7 on Page 1949,
\[ \lambda_{X+Y} (A) = \int_E \lambda_X (A - z) d\lambda_Y (z) = \int_E \lambda_{-X} (A - z) d\lambda_{-Y} (z) = \lambda_{-(X+Y)} (A) = \lambda_{X+Y} (-A) \]
By induction, it follows that if you have $n$ independent random variables each having symmetric distribution, then their sum has symmetric distribution.

Here is a simple lemma about random variables having symmetric distributions. It will depend on Lemma 57.15.2 on Page 1951.

**Lemma 57.15.4** Let $X \equiv (X_1, \cdots, X_n)$ and $Y$ be random variables defined on a probability space, $(\Omega, F, P)$ such that $X_i, i = 1, 2, \cdots, n$ and $Y$ have values in $E$ a separable Banach space. Thus $X$ has values in $E^n$. Suppose also that $\{X_1, \cdots, X_n, Y\}$ are independent and that $Y$ has symmetric distribution. Then if $A \in \mathcal{B}(E^n)$, it follows
\[
P \left( \left| X \in A \right| \cap \left\{ \left\| \sum_{i=1}^n X_i + Y \right\| < r \right\} \right) = P \left( \left| X \in A \right| \cap \left\{ \left\| \sum_{i=1}^n X_i - Y \right\| < r \right\} \right) \]
You can also change the inequalities in the obvious way, < to ≤, > or ≥.

**Proof:** Denote by \(\lambda_X\) and \(\lambda_Y\) the distribution measures for \(X\) and \(Y\) respectively. Since the random variables are independent, the distribution for the random variable, \((X, Y)\) mapping into \(E^{n+1}\) is \(\lambda_X \times \lambda_Y\) where this denotes product measure. Since the Banach space is separable, the Borel sets are contained in the product measurable sets. Then by symmetry of the distribution of \(Y\)

\[
P \left( X \in A \cap \left[ \left\| \sum_{i=1}^{n} X_i + Y \right\| < r \right] \right)
\]

\[
= \int_{E^n \times E} \chi_A(x) \chi_{B(0,r)} \left( \sum_{i=1}^{n} x_i + y \right) d(\lambda_X \times \lambda_Y)(x,y)
\]

\[
= \int_E \int_{E^n} \chi_A(x) \chi_{B(0,r)} \left( \sum_{i=1}^{n} x_i + y \right) d\lambda_X d\lambda_Y
\]

\[
= \int_E \int_{E^n} \chi_A(x) \chi_{B(0,r)} \left( \sum_{i=1}^{n} x_i + y \right) d\lambda_X d\lambda_{-Y}
\]

\[
= \int_{E^n \times E} \chi_A(x) \chi_{B(0,r)} \left( \sum_{i=1}^{n} x_i + y \right) d(\lambda_X \times \lambda_{-Y})(x,y)
\]

\[
= P \left( X \in A \cap \left[ \left\| \sum_{i=1}^{n} X_i + (-Y) \right\| < r \right] \right)
\]

This proves the lemma. Other cases are similar.

Now here is a really interesting lemma.

**Lemma 57.15.5** Let \(E\) be a real separable Banach space. Assume \(\xi_1, \cdots, \xi_N\) are independent random variables having values in \(E\), a separable Banach space which have symmetric distributions. Also let \(S_k = \sum_{i=1}^{k} \xi_i\). Then for any \(r > 0\),

\[
P \left( \left[ \sup_{k \leq N} \|S_k\| > r \right] \right) \leq 2P \left( \|S_N\| > r \right).
\]

**Proof:** First of all,

\[
P \left( \left[ \sup_{k \leq N} \|S_k\| > r \right] \right)
\]

\[
= P \left( \left[ \sup_{k \leq N} \|S_k\| > r \text{ and } \|S_N\| > r \right] \right)
\]
\[ P \left( \sup_{k \leq N-1} \|S_k\| > r \text{ and } \|S_N\| \leq r \right) \]
\[ \leq P (\|S_N\| > r) + P \left( \sup_{k \leq N-1} \|S_k\| > r \text{ and } \|S_N\| \leq r \right) \quad (57.15.26) \]

I need to estimate the second of these terms. Let
\[ A_1 \equiv [\|S_1\| > r], \ldots, A_k \equiv [\|S_k\| > r, \|S_j\| \leq r \text{ for } j < k] . \]

Thus \( A_k \) consists of those \( \omega \) where \( \|S_k(\omega)\| > r \) for the first time at \( k \). Thus
\[ \left( \sup_{k \leq N-1} \|S_k\| > r \text{ and } \|S_N\| \leq r \right) = \bigcup_{j=1}^{N-1} A_j \cap [\|S_N\| \leq r] \]
and the sets in the above union are disjoint. Consider \( A_j \cap [\|S_N\| \leq r] \). For \( \omega \) in this set,
\[ \|S_j(\omega)\| > r, \|S_i(\omega)\| \leq r \text{ if } i < j. \]

Since \( \|S_N(\omega)\| \leq r \) in this set, it follows
\[ \|S_N(\omega)\| = \left\| S_j(\omega) + \sum_{i=j+1}^{N} \xi_i(\omega) \right\| \leq r \]

Thus
\[ P \left( A_j \cap [\|S_N\| \leq r] \right) \]
\[ = P \left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \right) \cap \left[ \left\| S_j + \sum_{i=j+1}^{N} \xi_i \right\| \leq r \right] \quad (57.15.27) \]
\[ = P \left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \right) \cap \left[ \left\| S_j - \sum_{i=j+1}^{N} \xi_i \right\| \leq r \right] \quad (57.15.28) \]

Now \( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \) is of the form
\[ \left( \xi_1, \ldots, \xi_j \right) \in A \]
for some Borel set, \( A \). Then letting \( Y = \sum_{i=j+1}^{N} \xi_i \) in Lemma 57.15.25 and \( X_i = \xi_i \),
\[ P \left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \right) \cap \left[ \left\| S_j - \sum_{i=j+1}^{N} \xi_i \right\| \leq r \right] \]
\[ = P \left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \right) \cap \left[ \left\| S_j - (S_N - S_j) \right\| \leq r \right] \]
\[ = P \left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap \|S_j\| > r \right) \cap \left[ \left\| 2S_j - S_N \right\| \leq r \right] \]

Now since \( \|S_j(\omega)\| > r \),
\[ \left\| 2S_j - S_N \right\| \leq r \]
\[ \leq 2\|S_j\| - \|S_N\| \leq r \]
\[ \leq 2r - \|S_N\| < r \]
\[ = \|S_N\| > r \]
57.15. THE CONVERGENCE OF SUMS OF SYMMETRIC RANDOM VARIABLES

and so, referring to 57.15.27, this has shown

\[ P(A_j \cap \|S_N\| \leq r) \]
\[ = P\left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap [\|S_j\| > r] \cap [\|2S_j - S_N\| \leq r] \right) \]
\[ \leq P\left( \bigcap_{i=1}^{j-1} [\|S_i\| \leq r] \cap [\|S_j\| > r] \cap [\|S_N\| > r] \right) \]
\[ = P(A_j \cap \|S_N\| > r). \]

It follows that

\[ P\left( \left( \sup_{k \leq N-1} \|S_k\| > r \text{ and } \|S_N\| \leq r \right) \right) = \sum_{i=1}^{N-1} P(A_j \cap \|S_N\| \leq r) \]
\[ \leq \sum_{i=1}^{N-1} P(A_j \cap \|S_N\| > r) \leq P(\|S_N\| > r) \]

and using 57.15.26, this proves the lemma.

This interesting lemma will now be used to prove the following which concludes a sequence of partial sums converges given a subsequence of the sequence of partial sums converges.

**Lemma 57.15.6** Let \( \{\zeta_k\} \) be a sequence of independent random variables having values in a separable real Banach space, \( E \) whose distributions are symmetric. Letting \( S_k \equiv \sum_{i=1}^{k} \zeta_i \), suppose \( \{S_{n_k}\} \) converges a.e. Also suppose that for every \( m > n_k \),

\[ P\left( \|S_m - S_{n_k}\|_E > 2^{-k} \right) < 2^{-k}. \]  
(57.15.29)

Then in fact,

\[ S_k(\omega) \to S(\omega) \text{ a.e.} \omega \]  
(57.15.30)

and off a set of measure zero, the convergence of \( S_k \) to \( S \) is uniform.

**Proof:** Let \( n_k \leq l \leq m \). Then by Lemma 57.15.6,

\[ P\left( \left( \sup_{n_k \leq l \leq m} \|S_l - S_{n_k}\| > 2^{-k} \right) \right) \leq 2P\left( \|S_m - S_{n_k}\| > 2^{-k} \right) \]

In using this lemma, you could renumber the \( \zeta_i \) so that the sum

\[ \sum_{j=n_k+1}^{l} \zeta_j \]

corresponds to

\[ \sum_{j=1}^{l-n_k} \zeta_j \]
CHAPTER 57. BASIC PROBABILITY

where \( \xi_j = \xi_{j+nk} \).

Then using (57.15.29),

\[
P\left( \sup_{\eta_k \leq \eta_m} ||S_l - S_{nk}|| > 2^{-k} \right) \leq 2 P\left( ||S_m - S_{nk}|| > 2^{-k} \right) < 2^{-(k-1)}
\]

If \( S_l (\omega) \) fails to converge then \( \omega \) must be in infinitely many of the sets,

\[
\left[ \sup_{\eta_k < \eta} ||S_l - S_{nk}|| > 2^{-k} \right]
\]

each of which has measure no more than \( 2^{-(k-1)} \). Thus \( \omega \) must be in a set of measure zero. This proves the lemma.

57.16 The Multivariate Normal Distribution

Definition 57.16.1 A random vector, \( \mathbf{X} \), with values in \( \mathbb{R}^p \) has a multivariate normal distribution written as \( \mathbf{X} \sim N_p (\mathbf{m}, \Sigma) \) if for all Borel \( E \subseteq \mathbb{R}^p \),

\[
\lambda_\mathbf{X} (E) = \int_{\mathbb{R}^p} \mathcal{N}_E (x) \frac{1}{(2\pi)^{p/2} \det (\Sigma)^{1/2}} e^{-\frac{1}{2}(x-\mathbf{m})^T \Sigma^{-1} (x-\mathbf{m})} dx
\]

for \( \mu \) a given vector and \( \Sigma \) a given positive definite symmetric matrix.

Theorem 57.16.2 For \( \mathbf{X} \sim N_p (\mathbf{m}, \Sigma) \), \( \mathbf{m} = E (\mathbf{X}) \) and

\[
\Sigma = E ( (\mathbf{X} - \mathbf{m})(\mathbf{X} - \mathbf{m})^T )
\]

Proof: Let \( R \) be an orthogonal transformation such that

\[
R\Sigma R^* = D = \text{diag} (\sigma_1^2, \ldots, \sigma_p^2).
\]

Changing the variable by \( x - \mathbf{m} = R^* y \),

\[
E (\mathbf{X}) = \int_{\mathbb{R}^p} xe^{-\frac{1}{2}(x-\mathbf{m})^T \Sigma^{-1} (x-\mathbf{m})} dx \left( \frac{1}{(2\pi)^{p/2} \det (\Sigma)^{1/2}} \right) = \int_{\mathbb{R}^p} (R^* y + \mathbf{m}) e^{-\frac{1}{2}y^T D^{-1} y} dy \left( \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \right) = \mathbf{m} \int_{\mathbb{R}^p} e^{-\frac{1}{2}y^T D^{-1} y} dy \left( \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \right) = \mathbf{m}
\]

by Fubini’s theorem and the easy to establish formula

\[
\frac{1}{\sqrt{2\pi\sigma}} \int_{\mathbb{R}} e^{-\frac{x^2}{2\sigma^2}} dx = 1.
\]
Next let $M \equiv E \left( (X - \mathbf{m})(X - \mathbf{m})^T \right)$. Thus, changing the variable as above by $x - \mathbf{m} = R^*y$

$$M = \int_{\mathbb{R}^p} (x - \mathbf{m})(x - \mathbf{m})^T e^{-\frac{1}{2}(x-\mathbf{m})^T \Sigma^{-1}(x-\mathbf{m})} dx \left( \frac{1}{(2\pi)^{p/2} \det(\Sigma)^{1/2}} \right)$$

$$= R^* \int_{\mathbb{R}^p} y i y^* e^{-\frac{1}{2}y^* D^{-1} y} dy \left( \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \right) R$$

Therefore,

$$(RMR^*)_{ij} = \int_{\mathbb{R}^p} y_i y_j e^{-\frac{1}{2}y^* D^{-1} y} dy \left( \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \right) = 0,$$

so; $RMR^*$ is a diagonal matrix.

$$(RMR^*)_{ii} = \int_{\mathbb{R}^p} y_i^2 e^{-\frac{1}{2}y^* D^{-1} y} dy \left( \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \right).$$

Using Fubini’s theorem and the easy to establish equations,

$$\frac{1}{\sqrt{2\pi\sigma}} \int_R e^{-\frac{y^2}{2\sigma^2}} dy = 1, \quad \frac{1}{\sqrt{2\pi\sigma}} \int_R y^2 e^{-\frac{y^2}{2\sigma^2}} dy = \sigma^2,$$

it follows $(RMR^*)_{ii} = \sigma_i^2$. Hence $RMR^* = D$ and so $M = R^* D R = \Sigma$. \hfill \blacksquare

**Theorem 57.16.3** Suppose $X_1 \sim N_p(\mathbf{m}_1, \Sigma_1)$, $X_2 \sim N_p(\mathbf{m}_2, \Sigma_2)$ and the two random vectors are independent. Then

$$X_1 + X_2 \sim N_p(\mathbf{m}_1 + \mathbf{m}_2, \Sigma_1 + \Sigma_2). \quad (57.16.31)$$

Also, if $X \sim N_p(\mathbf{m}, \Sigma)$ then $-X \sim N_p(-\mathbf{m}, \Sigma)$. Furthermore, if $X \sim N_p(\mathbf{m}, \Sigma)$ then

$$E \left( e^{it \cdot X} \right) = e^{it \cdot \mathbf{m}} e^{-\frac{1}{2}t^* \Sigma t}. \quad (57.16.32)$$

Also if $a$ is a constant and $X \sim N_p(\mathbf{m}, \Sigma)$ then $aX \sim N_p(a \mathbf{m}, a^2 \Sigma)$. 

**Proof:** Consider $E \left( e^{it \cdot X} \right)$ for $X \sim N_p(\mathbf{m}, \Sigma)$.

$$E \left( e^{it \cdot X} \right) = \frac{1}{(2\pi)^{p/2} (\det \Sigma)^{1/2}} \int_{\mathbb{R}^p} e^{it \cdot x} e^{-\frac{1}{2}(x-\mathbf{m})^T \Sigma^{-1}(x-\mathbf{m})} dx.$$ 

Let $R$ be an orthogonal transformation such that

$$R \Sigma R^* = D = \text{diag}(\sigma_1^2, \cdots, \sigma_p^2).$$

Then let $R(x - \mathbf{m}) = y$. Then

$$E \left( e^{it \cdot X} \right) = \frac{1}{(2\pi)^{p/2} \prod_{i=1}^p \sigma_i} \int_{\mathbb{R}^p} e^{it \cdot (R^* y + \mathbf{m})} e^{-\frac{1}{2}y^* D^{-1} y} dy.$$
Therefore
\[ E(e^{itX}) = \frac{1}{(2\pi)^{p/2}} \prod_{i=1}^{p} \sigma_i \int_{\mathbb{R}^p} e^{is(y+rtm)} e^{-\frac{1}{2}y^\top D^{-1}y} dy \]
where \( s = Rt \). This equals
\[ e^{itm} \prod_{i=1}^{p} \left( \int_{\mathbb{R}} e^{is_i y_i} e^{-\frac{1}{2}y_i^2} dy_i \right) \frac{1}{\sqrt{2\pi \sigma_i}} \]
\[ = e^{itm} \prod_{i=1}^{p} \left( \int_{\mathbb{R}} e^{is_i y_i} e^{-\frac{1}{2}y_i^2} du_i \right) \frac{1}{\sqrt{2\pi}} \]
\[ = e^{itm} \prod_{i=1}^{p} e^{-\frac{1}{2}s_i^2 \sigma_i^2} \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-\frac{1}{2}(u-is_i)^2} du \]
\[ = e^{itm} e^{-\frac{1}{2} \sum_{i=1}^{p} s_i^2 \sigma_i^2} = e^{itm} e^{-\frac{1}{2}t^\top \Sigma t} \]
This proves (57.16.32).

Since \( X_1 \) and \( X_2 \) are independent, \( e^{itX_1} \) and \( e^{itX_2} \) are also independent. Hence
\[ E(e^{it(X_1+X_2)}) = E(e^{itX_1}) E(e^{itX_2}). \]
Thus,
\[ E(e^{itX_1+X_2}) = E(e^{itX_1}) E(e^{itX_2}) \]
\[ = e^{itm_1} e^{-\frac{1}{2}t^\top \Sigma t} e^{itm_2} e^{-\frac{1}{2}t^\top \Sigma t} \]
\[ = e^{it(m_1+m_2)} e^{-\frac{1}{2}t^\top (\Sigma_1+\Sigma_2) t} \]
which is the characteristic function of a random vector distributed as
\[ N_p(m_1 + m_2, \Sigma_1 + \Sigma_2). \]
Now it follows that \( X_1 + X_2 \sim N_p(m_1 + m_2, \Sigma_1 + \Sigma_2) \) by Theorem 57.8.4. This proves (57.16.33).

The assertion about \(-X\) is also easy to see because
\[ E(e^{it(-X)}) = E(e^{(-t)X}) \]
\[ = \frac{1}{(2\pi)^{p/2} (\det \Sigma)^{1/2}} \int_{\mathbb{R}^p} e^{i(-t)\cdot x} e^{-\frac{1}{2}(x-m)^\top \Sigma^{-1}(x-m)} dx \]
\[ = \frac{1}{(2\pi)^{p/2} (\det \Sigma)^{1/2}} \int_{\mathbb{R}^p} e^{it\cdot x} e^{-\frac{1}{2}(x+m)^\top \Sigma^{-1}(x+m)} dx \]
which is the characteristic function of a random variable which is \( N(-m, \Sigma) \). Theorem 57.8.3 again implies \(-X \sim N(-m, \Sigma)\). Finally consider the last claim. You
apply what is known about $X$ with $t$ replaced with $at$ and then massage things. This gives the characteristic function for $aX$ is given by

$$E(\exp(it\cdot aX)) = \exp(it\cdot am) \exp\left(-\frac{1}{2} t^* \Sigma a^2 t\right)$$

which is the characteristic function of a normal random vector having mean $am$ and covariance $a^2 \Sigma$. This proves the theorem.

Following [94], a random vector has a generalized normal distribution if its characteristic function is given as

$$e^{it\cdot m} e^{-\frac{1}{2} t^* \Sigma t} \quad (57.16.33)$$

where $\Sigma$ is symmetric and has nonnegative eigenvalues. For a random real valued variable, $m$ is scalar and so is $\Sigma$ so the characteristic function of such a generalized normally distributed random variable is

$$e^{it\mu} e^{-\frac{1}{2} t^2 \sigma^2} \quad (57.16.34)$$

These generalized normal distributions do not require $\Sigma$ to be invertible, only that the eigenvalues be nonnegative. In one dimension this would correspond the characteristic function of a Dirac measure having point mass 1 at $\mu$. In higher dimensions, it could be a mixture of such things with more familiar things. I won’t try very hard to distinguish between generalized normal distributions and normal distributions in which the covariance matrix has all positive eigenvalues.

Here are some other interesting results about normal distributions found in [94]. The next theorem has to do with the question whether a random vector is normally distributed in the above generalized sense.

**Theorem 57.16.4** Let $X = (X_1, \cdots, X_p)$ where each $X_i$ is a real valued random variable. Then $X$ is normally distributed in the above generalized sense if and only if every linear combination, $\sum_{j=1}^{p} a_j X_i$ is normally distributed. In this case the mean of $X$ is

$$m = (E(X_1), \cdots, E(X_p))$$

and the covariance matrix for $X$ is

$$\Sigma_{jk} = E((X_j - m_j)(X_k - m_k)^*) .$$

**Proof:** Suppose first $X$ is normally distributed. Then its characteristic function is of the form

$$\phi_X(t) = E(e^{it\cdot X}) = e^{it\cdot m} e^{-\frac{1}{2} t^* \Sigma t} .$$

Then letting $a = (a_1, \cdots, a_p)$

$$E\left(e^{it\cdot \sum_{j=1}^{p} a_j X_i}\right) = E\left(e^{ita\cdot X}\right) = e^{it\cdot a\cdot m} e^{-\frac{1}{2} a^* \Sigma a t^2}$$

which is the characteristic function of a normally distributed random variable with mean $a \cdot m$ and variance $\sigma^2 = a^* \Sigma a$. This proves half of the theorem. If $X$ is normally distributed, then every linear combination is normally distributed.
Next suppose \( \sum_{j=1}^{p} a_j X_j = a \cdot X \) is normally distributed with mean \( \mu \) and variance \( \sigma^2 \) so that its characteristic function is given in Corollary \ref{cor:ch57.16.34}. I will now relate \( \mu \) and \( \sigma^2 \) to various quantities involving the \( X_j \). Letting \( m_j = E(X_j), m = (m_1, \cdots, m_p) \^* \),

\[
\mu = \sum_{j=1}^{p} a_j E(X_j) = \sum_{j=1}^{p} a_j m_j, \quad \sigma^2 = E \left( \sum_{j=1}^{p} a_j X_j - \sum_{j=1}^{p} a_j m_j \right)^2
\]

\[
= E \left( \sum_{j=1}^{p} a_j (X_j - m_j) \right)^2 = \sum_{j,k} a_j a_k E((X_j - m_j)(X_k - m_k))
\]

It follows the mean of the normally distributed random variable, \( a \cdot X \) is

\[
\mu = \sum_{j} a_j m_j = a \cdot m
\]

and its variance is

\[
\sigma^2 = a^* E((X - m)(X - m)^*) a
\]

Therefore,

\[
E \left( e^{ita \cdot X} \right) = e^{ita} e^{-\frac{1}{2} t^2 \sigma^2} = e^{ita \cdot m} e^{-\frac{1}{2} t^2 a^* E((X-m)(X-m)^*) a}.
\]

Then letting \( s = ta \) this shows

\[
E \left( e^{is \cdot X} \right) = e^{is \cdot m} e^{-\frac{1}{2} s^* E((X-m)(X-m)^*) s} = e^{is \cdot m} e^{-\frac{1}{2} s^* \Sigma s}
\]

which is the characteristic function of a normally distributed random variable with \( m \) given above and \( \Sigma \) given by

\[
\Sigma_{jk} = E((X_j - m_j)(X_k - m_k))
\]

By assumption, \( a \) is completely arbitrary and so it follows that \( s \) is also. Hence, \( X \) is normally distributed as claimed.

**Corollary 57.16.5** Let \( X = (X_1, \cdots, X_p) \), \( Y = (Y_1, \cdots, Y_p) \) where each \( X_i, Y_i \) is a real valued random variable. Suppose also that for every \( a \in \mathbb{R}^p, a \cdot X \) and \( a \cdot Y \) are both normally distributed with the same mean and variance. Then \( X \) and \( Y \) are both multivariate normal random vectors with the same mean and variance.

**Proof:** In the Proof of Theorem \ref{thm:ch57.16.4} the proof implies that the characteristic functions of \( a \cdot X \) and \( a \cdot Y \) are both of the form

\[
e^{itm} e^{-\frac{1}{2} \sigma^2 t^2}.
\]
Then as in the proof of that theorem, it must be the case that

\[ m = \sum_{j=1}^{p} a_j m_j \]

where \( E(X_i) = m_i = E(Y_i) \) and

\[
\sigma^2 = a^* E((X - m)(X - m)^*) a \\
= a^* E((Y - m)(Y - m)^*) a
\]

and this last equation must hold for every \( a \). Therefore,

\[
E((X - m)(X - m)^*) = E((Y - m)(Y - m)^*) \equiv \Sigma
\]

and so the characteristic function of both \( X \) and \( Y \) is \( e^{i\mathbf{s} \cdot \mathbf{m}} e^{-\frac{1}{2} \mathbf{s}^* \Sigma \mathbf{s}} \) as in the proof of Theorem 57.16.4.

**Theorem 57.16.6** Suppose \( X = (X_1, \cdots, X_p) \) is normally distributed with mean \( \mathbf{m} \) and covariance \( \Sigma \). Then if \( X_1 \) is uncorrelated with any of the \( X_i \), meaning

\[
E((X_1 - m_1)(X_j - m_j)) = 0 \quad \text{for} \quad j > 1,
\]

then \( X_1 \) and \( (X_2, \cdots, X_p) \) are both normally distributed and the two random vectors are independent. Here \( m_j \equiv E(X_j) \). More generally, if the covariance matrix is a diagonal matrix, the random variables, \( \{X_1, \cdots, X_p\} \) are independent.

**Proof:** From Theorem 57.16.4,

\[
\Sigma = E((X - m)(X - m)^*) .
\]

Then by assumption,

\[
\Sigma = \begin{pmatrix} \sigma_1^2 & 0 \\ 0 & \Sigma_{p-1} \end{pmatrix} . \tag{57.16.35}
\]

I need to verify that if \( E \in \sigma(X_1) \) and \( F \in \sigma(X_2, \cdots, X_p) \), then

\[
P(E \cap F) = P(E) P(F).
\]

Let \( E = X_1^{-1}(A) \) and \( F = (X_2, \cdots, X_p)^{-1}(B) \) where \( A \) and \( B \) are Borel sets in \( \mathbb{R} \) and \( \mathbb{R}^{p-1} \) respectively. Thus I need to verify that

\[
P((X_1, X_2, \cdots, X_p) \in (A, B)) = \\
\mu(x_1, (x_2, \cdots, x_p))(A \times B) = \mu_{X_1}(A) \mu_{(x_2, \cdots, x_p)}(B) . \tag{57.16.36}
\]

Using Fubini’s theorem, and definitions,

\[
\mu((x_1, (x_2, \cdots, x_p))(A \times B) =
\]
\[ \int_{\mathbb{R}^p} \lambda_{A \times B} (x) \frac{1}{(2\pi)^{p/2} \det (\Sigma)^{1/2}} e^{-\frac{1}{2} (x - m)^{\top} \Sigma^{-1} (x - m)} \, dx \]

\[ = \int_{\mathbb{R}^p} \lambda_A (x_1) \int_{\mathbb{R}^{p-1}} \lambda_B (X_2, \ldots, X_p) \cdot \frac{1}{(2\pi)^{(p-1)/2} \sqrt{2\pi} (\sigma_1^2)^{1/2} \det (\Sigma_{p-1})^{1/2}} e^{-\frac{1}{2} (x_1 - m_1)^2} \cdot e^{-\frac{1}{2} (x' - m')^{\top} \Sigma_{p-1}^{-1} (x' - m')} \, dx' \, dx_1 \]

where \( x' = (x_2, \ldots, x_p) \) and \( m' = (m_2, \ldots, m_p) \). Now this equals

\[ \int_{\mathbb{R}} \lambda_A (x_1) \frac{1}{\sqrt{2\pi} \sigma_1^2} e^{-\frac{1}{2} (x_1 - m_1)^2} \int_{B} \frac{1}{(2\pi)^{(p-1)/2} \sqrt{2\pi} (\sigma_1^2)^{1/2} \det (\Sigma_{p-1})^{1/2}} e^{-\frac{1}{2} ( x_1 - m_1)^2} \, dx_1 \]

\[ = \frac{1}{\sqrt{2\pi} \sigma_1^2} \int_{B} \frac{1}{(2\pi)^{(p-1)/2} \sqrt{2\pi} (\sigma_1^2)^{1/2} \det (\Sigma_{p-1})^{1/2}} e^{-\frac{1}{2} (x_1 - m_1)^2} \, dx_1 \]

which shows \( X_1 \) is normally distributed as claimed. Similarly, letting \( A = \mathbb{R} \),

\[ \mu_{(X_2, \ldots, X_p)} (B) = \mu_{(X_1, X_2, \ldots, X_p)} (A \times \mathbb{R}^{p-1}) \]

\[ = \int_{\mathbb{R}} \lambda_A (x_1) \frac{1}{\sqrt{2\pi} \sigma_1^2} e^{-\frac{1}{2} (x_1 - m_1)^2} \, dx_1 \]

and \( (X_2, \ldots, X_p) \) is also normally distributed with mean \( m' \) and covariance \( \Sigma_{p-1} \). Now from \[ 57.16.36 \] follows. In case the covariance matrix is diagonal, the above reasoning extends in an obvious way to prove the random variables, \( \{X_1, \ldots, X_p\} \) are independent.

However, another way to prove this is to use Proposition \[ 57.11.1 \] on Page \[ 1936 \] and consider the characteristic function. Let \( E (X_j) = m_j \) and

\[ P = \sum_{j=1}^{p} t_j X_j. \]

Then since \( \mathbf{X} \) is normally distributed and the covariance is a diagonal,

\[ D = \begin{pmatrix} \sigma_1^2 & 0 \\ \vdots & \ddots \\ 0 & \sigma_p^2 \end{pmatrix} \]
57.17. USE OF CHARACTERISTIC FUNCTIONS TO FIND MOMENTS

Let $X$ be a random variable with characteristic function

$$
\phi_X (t) = E (\exp (itX))
$$

Then this can be used to find moments of the random variable assuming they exist. The $k^{th}$ moment is defined as

$$
E (X^k).
$$

This can be done by using the dominated convergence theorem to differentiate the characteristic function with respect to $t$ and then plugging in $t = 0$. For example,

$$
\phi_X' (t) = E (iX \exp (itX))
$$

and now plugging in $t = 0$ you get $iE (X)$. Doing another differentiation you obtain

$$
\phi_X'' (t) = E (-X^2 \exp (itX))
$$
and plugging in $t = 0$ you get $-E\left(X^2\right)$ and so forth.

An important case is where $X$ is normally distributed with mean 0 and variance $\sigma^2$. In this case, as shown above, the characteristic function is

$$e^{-\frac{1}{2}t^2\sigma^2}$$

Also all moments exist when $X$ is normally distributed. So what are these moments?

\[D_t\left(e^{-\frac{1}{2}t^2\sigma^2}\right) = -t\sigma^2 e^{-\frac{1}{2}t^2\sigma^2}\]

and plugging in $t = 0$ you find the mean equals 0 as expected.

\[D_t\left(-\sigma^2 e^{-\frac{1}{2}t^2\sigma^2} + t^2\sigma^4 e^{-\frac{1}{2}t^2\sigma^2}\right) = 3\sigma^4 t e^{-\frac{1}{2}t^2\sigma^2} - t^3 \sigma^6 e^{-\frac{1}{2}t^2\sigma^2}\]

Then $E\left(X^3\right) = 0$.

\[D_t\left(3\sigma^4 t e^{-\frac{1}{2}t^2\sigma^2} - t^3 \sigma^6 e^{-\frac{1}{2}t^2\sigma^2}\right) = 3\sigma^4 e^{-\frac{1}{2}t^2\sigma^2} - 6\sigma^6 t^2 e^{-\frac{1}{2}t^2\sigma^2} + t^4 \sigma^8 e^{-\frac{1}{2}t^2\sigma^2}\]

and so $E\left(X^4\right) = 3\sigma^4$. By now you can see the pattern. If you continue this way, you find the odd moments are all 0 and

\[E\left(X^{2m}\right) = C_m \left(\sigma^2\right)^m.\]  \hfill (57.17.40)

This is an important observation.

### 57.18 The Central Limit Theorem

The central limit theorem is one of the most marvelous theorems in mathematics. It can be proved through the use of characteristic functions. Recall for $x \in \mathbb{R}^p$,

\[||x||_\infty \equiv \max \{|x_j|, j = 1, \cdots, p\}.

Also recall the definition of the distribution function for a random vector, $X$.

\[F_X(x) \equiv P(X_j \leq x_j, j = 1, \cdots, p).

**Definition 57.18.1** Let $\{X_n\}$ be random vectors with values in $\mathbb{R}^p$. Then $\{\lambda_{X_n}\}_{n=1}^\infty$ is called “tight” if for all $\varepsilon > 0$ there exists a compact set, $K_\varepsilon$ such that

\[\lambda_{X_n}(\{x : x \notin K_\varepsilon\}) < \varepsilon\]
for all $\lambda_{X_n}$. Similarly, if $\{\mu_n\}$ is a sequence of probability measures defined on the Borel sets of $\mathbb{R}^p$, then this sequence is “tight” if for each $\varepsilon > 0$ there exists a compact set, $K_\varepsilon$ such that

$$
\mu_n ([x \notin K_\varepsilon]) < \varepsilon
$$

for all $\mu_n$.

**Lemma 57.18.2** If $\{X_n\}$ is a sequence of random vectors with values in $\mathbb{R}^p$ such that

$$
\lim_{n \to \infty} \phi_{X_n} (t) = \psi(t)
$$

for all $t$, where $\psi(0) = 1$ and $\psi$ is continuous at 0, then $\{\lambda_{X_n}\}_{n=1}^\infty$ is tight.

**Proof:** Let $e_j$ be the $j^{th}$ standard unit basis vector.

$$
\frac{1}{u} \int_{-u}^u \left| 1 - \phi_{X_n} (te_j) \right| dt = \left| \frac{1}{u} \int_{-u}^u \left( 1 - \int_{\mathbb{R}^p} e^{itx} d\lambda_{X_n} \right) dt \right|
$$

$$
= \left| \frac{1}{u} \int_{-u}^u \left( \int_{\mathbb{R}^p} (1 - e^{itx_j}) d\lambda_{X_n} \right) dt \right|
$$

$$
= \left| \int_{\mathbb{R}^p} \frac{1}{u} \int_{-u}^u (1 - e^{itx_j}) dt d\lambda_{X_n} (x) \right|
$$

$$
\geq 2 \int_{\|x_j\| \geq \frac{2}{u}} \left( 1 - \frac{1}{|ux_j|} \right) d\lambda_{X_n} (x)
$$

$$
\geq 2 \int_{\|x_j\| \geq \frac{2}{u}} \left( 1 - \frac{1}{|u(2/u)|} \right) d\lambda_{X_n} (x)
$$

$$
= \int_{\|x_j\| \geq \frac{2}{u}} d\lambda_{X_n} (x)
$$

$$
= \lambda_{X_n} \left( \left\{ x : |x_j| \geq \frac{2}{u} \right\} \right).
$$

If $\varepsilon > 0$ is given, there exists $r > 0$ such that if $u \leq r$,

$$
\frac{1}{u} \int_{-u}^u (1 - \psi(te_j)) dt < \varepsilon/p
$$
for all \( j = 1, \ldots, p \) and so, by the dominated convergence theorem, the same is true with \( \phi_{\mathbf{X}_n} \) in place of \( \psi \) provided \( n \) is large enough, say \( n \geq N(u) \). Thus, if \( u \leq r \), and \( n \geq N(u) \),

\[
\lambda_{\mathbf{X}_n} \left( \left\{ \mathbf{x} : |x_j| \geq \frac{2}{u} \right\} \right) < \varepsilon / p
\]

for all \( j \in \{1, \ldots, p\} \). It follows that for \( u \leq r \) and \( n \geq N(u) \),

\[
\lambda_{\mathbf{X}_n} \left( \left\{ \mathbf{x} : ||\mathbf{x}||_{\infty} \geq \frac{2}{u} \right\} \right) < \varepsilon.
\]

because

\[
\left\{ \mathbf{x} : ||\mathbf{x}||_{\infty} \geq \frac{2}{u} \right\} \subseteq \bigcup_{j=1}^{p} \left\{ \mathbf{x} : |x_j| \geq \frac{2}{u} \right\}
\]

This proves the lemma because there are only finitely many measures, \( \lambda_{\mathbf{X}_n} \) for \( n < N(u) \) and the compact set can be enlarged finitely many times to obtain a single compact set, \( K_{\varepsilon} \) such that for all \( n, \lambda_{\mathbf{X}_n} ([\mathbf{x} \notin K_{\varepsilon}]) < \varepsilon \). This proves the lemma.

**Lemma 57.18.3** If \( \phi_{\mathbf{X}_n}(t) \to \phi_{\mathbf{X}}(t) \) for all \( t \), then whenever \( \psi \in \mathcal{S} \),

\[
\lambda_{\mathbf{X}_n}(\psi) = \int_{\mathbb{R}^p} \psi(y) d\lambda_{\mathbf{X}_n}(y) \to \int_{\mathbb{R}^p} \psi(y) d\lambda_{\mathbf{X}}(y) = \lambda_{\mathbf{X}}(\psi)
\]

as \( n \to \infty \).

**Proof:** Recall that if \( \mathbf{X} \) is any random vector, its characteristic function is given by

\[
\phi_{\mathbf{X}}(y) = \int_{\mathbb{R}^p} e^{iy \cdot \mathbf{x}} d\lambda_{\mathbf{X}}(x).
\]

Also remember the inverse Fourier transform. Letting \( \psi \in \mathcal{S} \), the Schwartz class,

\[
F^{-1}(\lambda_{\mathbf{X}})(\psi) = \lambda_{\mathbf{X}}(F^{-1} \psi) = \int_{\mathbb{R}^p} F^{-1} \psi d\lambda_{\mathbf{X}}
\]

\[
= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{iy \cdot \mathbf{x}} \psi(y) d\lambda_{\mathbf{X}}(y)
\]

\[
= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \psi(x) \int_{\mathbb{R}^p} e^{iy \cdot \mathbf{x}} d\lambda_{\mathbf{X}}(y) dx
\]

\[
= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \psi(x) \phi_{\mathbf{X}}(x) dx
\]

and so, considered as elements of \( \mathcal{S}^* \),

\[
F^{-1}(\lambda_{\mathbf{X}}) = \phi_{\mathbf{X}}(\cdot) (2\pi)^{-(p/2)} \in L^\infty.
\]
By the dominated convergence theorem

$$(2\pi)^{p/2} F^{-1} (\lambda_{X_n}) (\psi) \equiv \int_{\mathbb{R}^p} \phi_{X_n} (t) \psi (t) \, dt$$

$$\to \int_{\mathbb{R}^p} \phi_X (t) \psi (t) \, dt$$

$$= (2\pi)^{p/2} F^{-1} (\lambda_X) (\psi)$$

whenever $\psi \in \mathcal{S}$. Thus

$$\lambda_{X_n} (\psi) = \int_{\mathbb{R}^p} \psi \, d\lambda_{X_n} = \int_{\mathbb{R}^p} \psi \, d\lambda_X$$

This proves the lemma.

**Lemma 57.18.4** If $\phi_{X_n} (t) \to \phi_X (t)$, then if $\psi$ is any bounded uniformly continuous function,

$$\lim_{n \to \infty} \int_{\mathbb{R}^p} \psi \, d\lambda_{X_n} = \int_{\mathbb{R}^p} \psi \, d\lambda_X.$$

**Proof:** Let $\varepsilon > 0$ be given, let $\psi$ be a bounded function in $C^\infty (\mathbb{R}^p)$. Now let $\eta \in C^\infty_c (Q_r)$ where $Q_r \equiv [-r, r]^p$ satisfy the additional requirement that $\eta = 1$ on $Q_{r/2}$ and $\eta (x) \in [0, 1]$ for all $x$. By Lemma 57.18.2 the set, $\{\lambda_{X_n}\}_{n=1}^\infty$, is tight and so if $\varepsilon > 0$ is given, there exists $r$ sufficiently large such that for all $n$,

$$\int_{[x \notin Q_{r/2}]} |1 - \eta| \, |\psi| \, d\lambda_{X_n} < \frac{\varepsilon}{3},$$

and

$$\int_{[x \notin Q_{r/2}]} |1 - \eta| \, |\psi| \, d\lambda_X < \frac{\varepsilon}{3}.$$ 

Thus,

$$\left| \int_{\mathbb{R}^p} \psi \, d\lambda_{X_n} - \int_{\mathbb{R}^p} \psi \, d\lambda_X \right| \leq \left| \int_{\mathbb{R}^p} \psi \, d\lambda_{X_n} - \int_{\mathbb{R}^p} \psi \eta \, d\lambda_{X_n} \right| +$$

$$\left| \int_{\mathbb{R}^p} \psi \eta \, d\lambda_{X_n} - \int_{\mathbb{R}^p} \psi \eta \, d\lambda_X \right| + \left| \int_{\mathbb{R}^p} \psi \eta \, d\lambda_X - \int_{\mathbb{R}^p} \psi \, d\lambda_X \right|$$

$$\leq \frac{2\varepsilon}{3} + \left| \int_{\mathbb{R}^p} \psi \eta \, d\lambda_{X_n} - \int_{\mathbb{R}^p} \psi \eta \, d\lambda_X \right| < \varepsilon$$

whenever $n$ is large enough by Lemma 57.18.2 because $\psi \eta \in \mathcal{S}$. This establishes the conclusion of the lemma in the case where $\psi$ is also infinitely differentiable. To consider the general case, let $\psi$ only be uniformly continuous and let $\psi_k = \psi * \phi_k$ where $\phi_k$ is a mollifier whose support is in $(-1/k, 1/k)^p$. Then $\psi_k$ converges uniformly to $\psi$ and so the desired conclusion follows for $\psi$ after a routine estimate. This proves the lemma.
Definition 57.18.5 Let $\mu$ be a Radon measure on $\mathbb{R}^p$. A Borel set, $A$, is a $\mu$ continuity set if $\mu(\partial A) = 0$ where $\partial A \equiv \overline{A} \setminus \text{int}(A)$ and int denotes the interior.

The main result is the following continuity theorem. More can be said about the equivalence of various criteria [18].

Theorem 57.18.6 If $\phi_{X_n}(t) \to \phi_X(t)$ then $\lambda_{X_n}(A) \to \lambda_X(A)$ whenever $A$ is a $\lambda_X$ continuity set.

Proof: First suppose $K$ is a closed set and let
$$\psi_k(x) \equiv (1 - k \text{ dist}(x,K))^+.\$$
Thus, since $K$ is closed $\lim_{k \to \infty} \psi_k(x) = \lambda'_K(x)$. Choose $k$ large enough that
$$\int_{\mathbb{R}^p} \psi_k d\lambda_X \leq \lambda_X(K) + \varepsilon.$$ Then by Lemma 57.18.4, applied to the bounded uniformly continuous function $\psi_k$,
$$\limsup_{n \to \infty} \lambda_{X_n}(K) \leq \limsup_{n \to \infty} \int \psi_k d\lambda_{X_n} = \int \psi_k d\lambda_X \leq \lambda_X(K) + \varepsilon.$$ Since $\varepsilon$ is arbitrary, this shows
$$\limsup_{n \to \infty} \lambda_{X_n}(K) \leq \lambda_X(K)$$ for all $K$ closed.

Next suppose $V$ is open and let
$$\psi_k(x) = 1 - \left(1 - k \text{ dist}(x,V^C)\right)^+.$$ Thus $\psi_k(x) \in [0,1], \psi_k = 1$ if $\text{ dist}(x,V^C) \geq 1/k$, and $\psi_k = 0$ on $V^C$. Since $V$ is open, it follows
$$\lim_{k \to \infty} \psi_k(x) = \lambda'_V(x).$$ Choose $k$ large enough that
$$\int \psi_k d\lambda_X \geq \lambda_X(V) - \varepsilon.$$ Then by Lemma 57.18.4,
$$\liminf_{n \to \infty} \lambda_{X_n}(V) \geq \liminf_{n \to \infty} \int \psi_k(x) d\lambda_{X_n} =$$
$$= \int \psi_k(x) d\lambda_X \geq \lambda_X(V) - \varepsilon.$$
and since $\varepsilon$ is arbitrary,

$$\lim_{n \to \infty} \inf_{V} \lambda_{X_n}(V) \geq \lambda_{X}(V).$$

Now let $\lambda_{X}(\partial A) = 0$ for $A$ a Borel set.

$$\lambda_{X}(\text{int}(A)) \leq \lim_{n \to \infty} \inf_{V} \lambda_{X_n}(\text{int}(A)) \leq \lim_{n \to \infty} \inf_{V} \lambda_{X_n}(A) \leq \lim_{n \to \infty} \sup_{V} \lambda_{X_n}(A) \leq \lambda_{X}(\bar{A}).$$

But $\lambda_{X}(\text{int}(A)) = \lambda_{X}(A)$ by assumption and so $\lim_{n \to \infty} \lambda_{X_n}(A) = \lambda_{X}(A)$ as claimed. This proves the theorem.

As an application of this theorem the following is a version of the central limit theorem in the situation in which the limit distribution is multivariate normal. It concerns a sequence of random vectors, $\{X_k\}_{k=1}^{\infty}$, which are identically distributed, have finite mean $m$, and satisfy

$$E\left|X_k\right|^2 < \infty. \quad (57.18.41)$$

**Theorem 57.18.7** Let $\{X_k\}_{k=1}^{\infty}$ be random vectors satisfying (57.18.41), which are independent and identically distributed with mean $m$ and positive definite covariance $\Sigma = E((X-m)(X-m)^\ast)$. Let

$$Z_n = \sum_{j=1}^{n} \frac{X_j - m}{\sqrt{n}}. \quad (57.18.42)$$

Then for $Z \sim N_p(0, \Sigma)$,

$$\lim_{n \to \infty} F_{Z_n}(x) = F_Z(x) \quad (57.18.43)$$

for all $x$.

**Proof:** The characteristic function of $Z_n$ is given by

$$\phi_{Z_n}(t) = E\left(e^{it \cdot \sum_{j=1}^{n} \frac{X_j - m}{\sqrt{n}}}\right) = \prod_{j=1}^{n} E\left(e^{it \cdot \left(\frac{X_j - m}{\sqrt{n}}\right)}\right).$$

By Taylor's theorem applied to real and imaginary parts of $e^{ix}$, it follows

$$e^{ix} = 1 + ix - f(x) \frac{x^2}{2}$$

where $|f(x)| < 2$ and

$$\lim_{x \to 0} f(x) = 1.$$
Thus
\[ e^{it \frac{(X - m)}{\sqrt{n}}} = 1 + it \cdot \frac{X - m}{\sqrt{n}} - \frac{(t \cdot (X - m))^2}{2n} \]
\[ + \left( 1 - f \left( t \cdot \left( \frac{X - m}{\sqrt{n}} \right) \right) \right) \frac{(t \cdot (X - m))^2}{2n}. \]

Thus
\[ \phi_{Z_n}(t) = \prod_{j=1}^{n} \left[ 1 - \frac{1}{2n} \left( t \cdot \frac{(X - m)}{\sqrt{n}} \right) \right]^{1/2} + e_n \]
\[ = \prod_{j=1}^{n} \left[ 1 - \frac{1}{2n} t^* \Sigma t + \frac{1}{2n} \right] \left( 1 - f \left( t \cdot \left( \frac{X - m}{\sqrt{n}} \right) \right) \right) \frac{(t \cdot (X - m))^2}{2n} \right]. \]

(Note \((t \cdot (X - m))^2 = t^* (X - m) (X - m)^* t.\) Now here is a simple inequality for complex numbers whose moduli are no larger than one. I will give a proof of this at the end. It follows easily by induction.

\[ |z_1 \cdots z_n - w_1 \cdots w_n| \leq \sum_{k=1}^{n} |z_k - w_k|. \]

Also for each \( t, \) and all \( n \) large enough,
\[ \left| \frac{1}{2n} E \left( 1 - f \left( t \cdot \left( \frac{X - m}{\sqrt{n}} \right) \right) \right) \frac{(t \cdot (X - m))^2}{2n} \right| < 1. \]

Applying (57.18.45) to (57.18.44),
\[ \phi_{Z_n}(t) = \prod_{j=1}^{n} \left( 1 - \frac{1}{2n} t^* \Sigma t + \frac{1}{2n} \right) + e_n \]
\[ = \left( 1 - \frac{1}{2n} t^* \Sigma t \right)^n + e_n \]

where
\[ |e_n| \leq \sum_{j=1}^{n} \left| \frac{1}{2n} E \left( 1 - f \left( t \cdot \left( \frac{X - m}{\sqrt{n}} \right) \right) \right) \frac{(t \cdot (X - m))^2}{2n} \right| \]
\[ = \frac{1}{2} \left| E \left( 1 - f \left( t \cdot \left( \frac{X - m}{\sqrt{n}} \right) \right) \right) \frac{(t \cdot (X - m))^2}{2n} \right| \]
which converges to 0 as \( n \to \infty \) by the Dominated Convergence theorem. Therefore,
\[
\lim_{n \to \infty} \phi_{Z_n}(t) = 0 \quad \text{as} \quad n \to \infty
\]
and so
\[
\lim_{n \to \infty} \phi_{Z_n}(t) = e^{-\frac{1}{2}t^*t} = \phi_Z(t)
\]
where \( Z \sim N_p(0, \Sigma) \). Therefore, \( F_{Z_n}(x) \to F_Z(x) \) for all \( x \) because \( R_x = \prod_{k=1}^{p} (-\infty, x_k] \) is a set of \( \lambda_Z \) continuity due to the assumption that \( \lambda_Z \ll m \) which is implied by \( Z \sim N_p(0, \Sigma) \). This proves the theorem.

Here is the proof of the little inequality used above. The inequality is obviously true if \( n = 1 \). Assume it is true for \( n \). Then since all the numbers have absolute value no larger than one,
\[
\prod_{i=1}^{n+1} z_i - \prod_{i=1}^{n+1} w_i \leq \prod_{i=1}^{n+1} z_i - \prod_{i=1}^{n} w_i + z_{n+1} \prod_{i=1}^{n} w_i - \prod_{i=1}^{n+1} w_i
\]
\[
\leq \sum_{k=1}^{n+1} |z_k - w_k|
\]
by induction.

Suppose \( X \) is a random vector with covariance \( \Sigma \) and mean \( m \), and suppose also that \( \Sigma^{-1} \) exists. Consider \( \Sigma^{-1/2} (X - m) \equiv Y \). Then \( E(Y) = 0 \) and
\[
E(YY^*) = E \left( \Sigma^{-1/2} (X - m) (X^* - m) \Sigma^{-1/2} \right)
\]
\[
= \Sigma^{-1/2} E((X - m)(X^* - m)) \Sigma^{-1/2} = I.
\]
Thus \( Y \) has zero mean and covariance \( I \). This implies the following corollary to Theorem 57.18.7.

**Corollary 57.18.8** Let independent identically distributed random variables,
\[
\{X_j\}_{j=1}^{\infty}
\]
have mean \( m \) and positive definite covariance \( \Sigma \) where \( \Sigma^{-1} \) exists. Then if
\[
Z_n \equiv \sum_{j=1}^{n} \Sigma^{-1/2} \frac{X_j - m}{\sqrt{n}},
\]
it follows that for \( Z \sim N_p(0, I) \),
\[
F_{Z_n}(x) \to F_Z(x)
\]
for all \( x \).
57.19 Characteristic Functions Of Probability Measures

Recall one can define the characteristic function of a probability measure. In a sense it is more natural.

**Definition 57.19.1** Let \( \mu \) be a probability measure defined on the Borel sets of \( \mathbb{R}^p \). Then

\[
\phi_{\mu}(t) = \int_{\mathbb{R}^p} e^{it\cdot x} d\mu.
\]

Also \( \{\mu_n\}_{n=1}^{\infty} \) is called “tight” if for all \( \varepsilon > 0 \) there exists a compact set, \( K_\varepsilon \) such that

\[
\mu_n ([x \notin K_\varepsilon]) < \varepsilon
\]

for all \( \mu_n \).

Then there is a version of Lemma 57.18.2 whose proof is identical to the proof of that lemma.

**Lemma 57.19.2** If \( \{\mu_n\} \) is a sequence of Borel probability measures defined on the Borel sets of \( \mathbb{R}^p \) such that

\[
\lim_{n \to \infty} \phi_{\mu_n}(t) = \psi(t)
\]

for all \( t \), where \( \psi(0) = 1 \) and \( \psi \) is continuous at \( 0 \), then \( \{\mu_n\}_{n=1}^{\infty} \) is tight.

**Proof:** Let \( e_j \) be the \( j \)th standard unit basis vector. Letting \( t = te_j \) in the definition,

\[
\left| \frac{1}{u} \int_{-u}^{u} \left( 1 - \phi_{\mu_n}(te_j) \right) dt \right| \quad (57.19.46)
\]

\[
= \left| \frac{1}{u} \int_{-u}^{u} \left( 1 - \int_{\mathbb{R}^p} e^{itx_j} d\mu_n(x) \right) dt \right|
\]

\[
= \left| \frac{1}{u} \int_{-u}^{u} \left( \int_{\mathbb{R}^p} \left( 1 - e^{itx_j} \right) d\mu_n(x) \right) dt \right|
\]

\[
= \left| \int_{\mathbb{R}^p} \frac{1}{u} \int_{-u}^{u} \left( 1 - e^{itx_j} \right) dt d\mu_n(x) \right|
\]

\[
= \left| \int_{\mathbb{R}^p} \left( 1 - \frac{\sin(ux_j)}{ux_j} \right) d\mu_n(x) \right|
\]

\[
\geq 2 \int_{|x_j| \geq \frac{2}{u}} \left( 1 - \frac{1}{|ux_j|} \right) d\mu_n(x)
\]

\[
\geq 2 \int_{|x_j| \geq \frac{2}{u}} \left( 1 - \frac{1}{|u| (2/u)} \right) d\mu_n(x)
\]
57.19. **CHARACTERISTIC FUNCTIONS OF PROBABILITY MEASURES**

\[
= \int_{[|x_j| \geq \frac{2}{u}]} 1 \, d\mu_n(x) \\
= \mu_n \left( \left\{ x : |x_j| \geq \frac{2}{u} \right\} \right).
\]

If \( \varepsilon > 0 \) is given, there exists \( r > 0 \) such that if \( u \leq r \),

\[
\frac{1}{u} \int_{-u}^{u} (1 - \psi(te)) \, dt < \varepsilon/p
\]

for all \( j = 1, \ldots, p \) and so, by the dominated convergence theorem, the same is true with \( \phi_{\mu_n} \) in place of \( \psi \) provided \( n \) is large enough, say \( n \geq N(u) \). Thus, from Lemma 57.19.46, if \( u \leq r \) and \( n \geq N(u) \),

\[
\mu_n \left( \left\{ x : |x_j| \geq \frac{2}{u} \right\} \right) < \varepsilon/p
\]

for all \( j \in \{1, \ldots, p\} \). It follows that for \( u \leq r \) and \( n \geq N(u) \),

\[
\mu_n \left( \left\{ x : \|x\|_\infty \geq \frac{2}{u} \right\} \right) < \varepsilon.
\]

because

\[
\left\{ x : \|x\|_\infty \geq \frac{2}{u} \right\} \subseteq \bigcup_{j=1}^{p} \left \{ x : |x_j| \geq \frac{2}{u} \right \}
\]

This proves the lemma because there are only finitely many measures, \( \mu_n \) for \( n < N(u) \) and the compact set can be enlarged finitely many times to obtain a single compact set, \( K_\varepsilon \) such that for all \( n, \mu_n \left( \{x \notin K_\varepsilon \} \right) < \varepsilon. \]

As before, there are simple modifications of Lemmas 57.18.3 and 57.18.4. The first of these is as follows.

**Lemma 57.19.3** If \( \phi_{\mu_n}(t) \to \phi_{\mu}(t) \) for all \( t \), then whenever \( \psi \in \mathcal{S} \), the Schwartz class,

\[
\mu_n(\psi) = \int_{\mathbb{R}^p} \psi(y) \, d\mu_n(y) \to \int_{\mathbb{R}^p} \psi(y) \, d\mu(y) = \mu(\psi)
\]

as \( n \to \infty \).

**Proof:** By definition,

\[
\phi_{\mu}(y) = \int_{\mathbb{R}^p} e^{iy \cdot x} \, d\mu(x).
\]
Also remember the inverse Fourier transform. Letting $\psi \in \mathcal{S}$, the Schwartz class,

$$F^{-1}(\mu)(\psi) = \mu(F^{-1}\psi) = \int_{\mathbb{R}^p} F^{-1}\psi \, d\mu$$

$$= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \int_{\mathbb{R}^p} e^{iy \cdot x} \psi(x) \, dx \, d\mu(y)$$

$$= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \psi(x) \int_{\mathbb{R}^p} e^{iy \cdot x} d\mu(y) \, dx$$

$$= \frac{1}{(2\pi)^{p/2}} \int_{\mathbb{R}^p} \psi(x) \phi_\mu(x) \, dx$$

and so, considered as elements of $\mathcal{S}^*$,

$$F^{-1}(\mu) = \phi_\mu(\cdot)(2\pi)^{-(p/2)} \in L^\infty.$$

By the dominated convergence theorem

$$(2\pi)^{p/2} F^{-1}(\mu_n)(\psi) = \int_{\mathbb{R}^p} \phi_{\mu_n}(t) \psi(t) \, dt$$

$$\quad \rightarrow \int_{\mathbb{R}^p} \phi_\mu(t) \psi(t) \, dt$$

$$= (2\pi)^{p/2} F^{-1}(\mu)(\psi)$$

whenever $\psi \in \mathcal{S}$. Thus

$$\mu_n(\psi) = F F^{-1} \mu_n(\psi) \equiv F^{-1} \mu_n(F\psi) \rightarrow F^{-1} \mu(F\psi)$$

$$= F^{-1} F \mu(\psi) = \mu(\psi). \blacksquare$$

The version of Lemma 57.19.4 is the following.

**Lemma 57.19.4** If $\phi_{\mu_n}(t) \rightarrow \phi_\mu(t)$ where $\{\mu_n\}$ and $\mu$ are probability measures defined on the Borel sets of $\mathbb{R}^p$, then if $\psi$ is any bounded uniformly continuous function,

$$\lim_{n \rightarrow \infty} \int_{\mathbb{R}^p} \psi \, d\mu_n = \int_{\mathbb{R}^p} \psi \, d\mu.$$

**Proof:** Let $\varepsilon > 0$ be given, let $\psi$ be a bounded function in $C^\infty(\mathbb{R}^p)$. Now let $\eta \in C^\infty(\mathbb{Q})$ where $\mathbb{Q} = [-r, r]^p$ satisfy the additional requirement that $\eta = 1$ on $Q_{r/2}$ and $\eta(x) \in [0, 1]$ for all $x$. By Lemma 57.19.2, the set, $\{\mu_n\}_{n=1}^\infty$, is tight and so if $\varepsilon > 0$ is given, there exists $r$ sufficiently large such that for all $n$,

$$\int_{[x \notin Q_{r/2}]} |1 - \eta| |\psi| \, d\mu_n < \frac{\varepsilon}{3},$$

and

$$\int_{[x \notin Q_{r/2}]} |1 - \eta| |\psi| \, d\mu < \frac{\varepsilon}{3}.$$
Thus,
\[
\int_{\mathbb{R}^p} \psi d\mu_n - \int_{\mathbb{R}^p} \psi d\mu \leq \int_{\mathbb{R}^p} \psi d\mu_n - \int_{\mathbb{R}^p} \psi d\mu_n + \int_{\mathbb{R}^p} \psi d\mu - \int_{\mathbb{R}^p} \psi d\mu
\]
\[
\leq 2\varepsilon + \int_{\mathbb{R}^p} \psi d\mu_n - \int_{\mathbb{R}^p} \psi d\mu < \varepsilon
\]
whenever \( n \) is large enough by Lemma 57.19.3 because \( \psi \eta \in \mathcal{S} \). This establishes the conclusion of the lemma in the case where \( \psi \) is also infinitely differentiable. To consider the general case, let \( \psi \) only be uniformly continuous and let \( \phi_k = \psi \ast \phi_k \) where \( \phi_k \) is a mollifier whose support is in \( (-1/k, 1/k)^p \). Then \( \psi_k \) converges uniformly to \( \psi \) and so the desired conclusion follows for \( \psi \) after a routine estimate.

The next theorem is really important. It gives the existence of a measure based on an assumption that a set of measures is tight. The next theorem is Prokhorov’s theorem about a tight set of measures. Recall that \( \Lambda \) is tight means that for every \( \varepsilon > 0 \) there exists \( K \) compact such that \( \mu (K^c) < \varepsilon \) for all \( \mu \in \Lambda \).

**Theorem 57.19.5** Let \( \Lambda = \{\mu_n\}_{n=1}^{\infty} \) be a sequence of probability measures defined on the Borel sets of \( \mathbb{R}^p \). If \( \Lambda \) is tight then there exists a probability measure, \( \lambda \) and a subsequence of \( \{\mu_n\}_{n=1}^{\infty} \), still denoted by \( \{\mu_n\}_{n=1}^{\infty} \) such that whenever \( \phi \) is a continuous bounded complex valued function defined on \( E \),

\[
\lim_{n \to \infty} \int K_n \phi d\mu_n = \int \phi d\lambda.
\]

**Proof:** By tightness, there exists an increasing sequence of compact sets, \( \{K_n\} \) such that

\[
\mu (K_n) > 1 - \frac{1}{n}
\]

for all \( \mu \in \Lambda \). Now letting \( \mu \in \Lambda \) and \( \phi \in C (K_n) \) such that \( ||\phi||_\infty \leq 1 \), it follows

\[
\left| \int_{K_n} \phi d\mu \right| \leq \mu (K_n) \leq 1
\]

and so the restrictions of the measures of \( \Lambda \) to \( K_n \) are contained in the unit ball of \( C (K_n)' \). Recall from the Riesz representation theorem, the dual space of \( C (K_n) \) is a space of complex Borel measures. Theorem 15.5.5 on Page 445 implies the unit ball of \( C (K_n)' \) is weak * sequentially compact. This follows from the observation that \( C (K_n) \) is separable which follows easily from the Weierstrass approximation theorem. Thus the unit ball in \( C (K_n)' \) is actually metrizable by Theorem 15.5.5 on Page 445. Therefore, there exists a subsequence of \( \Lambda \), \( \{\mu_{1k}\} \) such that their restrictions to \( K_1 \) converge weak * to a measure, \( \lambda_1 \in C (K_1)' \). That is, for every \( \phi \in C (K_1) \),

\[
\lim_{k \to \infty} \int_{K_1} \phi d\mu_{1k} = \int_{K_1} \phi d\lambda_1
\]
By the same reasoning, there exists a further subsequence \( \{\mu_{2k}\} \) such that the restrictions of these measures to \( K_2 \) converge weak * to a measure \( \lambda_2 \in C(K_2)' \) etc. Continuing this way,

\[
\begin{align*}
\mu_{11}, \mu_{12}, \mu_{13}, & \cdots \rightarrow \text{Weak * in } C(K_1)'
\mu_{21}, \mu_{22}, \mu_{23}, & \cdots \rightarrow \text{Weak * in } C(K_2)'
\mu_{31}, \mu_{32}, \mu_{33}, & \cdots \rightarrow \text{Weak * in } C(K_3)'
& \vdots
\end{align*}
\]

Here the \( j^{th} \) sequence is a subsequence of the \( (j - 1)^{th} \). Let \( \lambda_n \) denote the measure in \( C(K_n)' \) to which the sequence \( \{\mu_{nk}\} \) converges weak *.

Claim: For \( p > n \), the restriction of \( \lambda_p \) to the Borel sets of \( K_n \) equals \( \lambda_n \).

Proof of claim: Let \( H \) be a compact subset of \( K_n \). Then there are sets, \( V_l \) open in \( K_n \) which are decreasing and whose intersection equals \( H \). This follows because this is a metric space. Then let \( H < \phi_l < V_l \). It follows

\[
\lambda_n (V_l) \geq \int_{K_n} \phi_l d\lambda_n = \lim_{k \to \infty} \int_{K_n} \phi_l d\mu_k = \lim_{k \to \infty} \int_{K_p} \phi_l d\mu_k = \int_{K_p} \phi_l d\lambda_p \geq \lambda_p (H).
\]

Now considering the ends of this inequality, let \( l \to \infty \) and pass to the limit to conclude

\[
\lambda_n (H) \geq \lambda_p (H).
\]

Similarly,

\[
\lambda_n (H) \leq \int_{K_n} \phi_l d\lambda_n = \lim_{k \to \infty} \int_{K_n} \phi_l d\mu_k = \lim_{k \to \infty} \int_{K_p} \phi_l d\mu_k = \int_{K_p} \phi_l d\lambda_p \leq \lambda_p (V_l).
\]

Then passing to the limit as \( l \to \infty \), it follows

\[
\lambda_n (H) \leq \lambda_p (H).
\]

Thus the restriction of \( \lambda_p, \lambda_p|_{K_n} \) to the compact sets of \( K_n \) equals \( \lambda_n \). Then by inner regularity it follows the two measures, \( \lambda_p|_{K_n} \), and \( \lambda_n \) are equal on all Borel sets of \( K_n \). Recall that for finite measures on the Borel sets of separable metric spaces, regularity is obtained for free.

It is fairly routine to exploit regularity of the measures to verify that \( \lambda_m (F) \geq 0 \) for all \( F \) a Borel subset of \( K_{m} \). (Whenever \( \phi \geq 0, \int_{K_{m}} \phi d\lambda_{m} \geq 0 \) because \( \int_{K_{m}} \phi d\mu_{k} \geq 0 \). Now you can approximate \( X_{F} \) with a suitable nonnegative \( \phi \) using regularity of the measure.) Also, letting \( \phi = 1 \),

\[
1 \geq \lambda_{m} (K_{m}) \geq 1 - \frac{1}{m}, \quad (57.19.47)
\]
Define for $F$ a Borel set, 

$$\lambda(F) \equiv \lim_{n \to \infty} \lambda_n(F \cap K_n).$$

The limit exists because the sequence on the right is increasing due to the above observation that $\lambda_n = \lambda_m$ on the Borel subsets of $K_m$ whenever $n > m$. Thus for $n > m$

$$\lambda_n(F \cap K_n) \geq \lambda_n(F \cap K_m) = \lambda_m(F \cap K_m).$$

Now let $\{F_k\}$ be a sequence of disjoint Borel sets. Then

$$\lambda(\bigcup_{k=1}^{\infty} F_k) = \lim_{n \to \infty} \lambda_n(\bigcup_{k=1}^{\infty} F_k \cap K_n) = \lim_{n \to \infty} \lambda_n(\bigcap_{k=1}^{\infty} (F_k \cap K_n))$$

$$= \lim_{n \to \infty} \sum_{k=1}^{\infty} \lambda_n(F_k \cap K_n) = \sum_{k=1}^{\infty} \lambda(F_k)$$

the last equation holding by the monotone convergence theorem.

It remains to verify

$$\lim_{k \to \infty} \int \phi d\mu_k = \int \phi d\lambda$$

for every $\phi$ bounded and continuous. This is where tightness is used again. Suppose $\|\phi\|_{\infty} < M$. Then as noted above,

$$\lambda_n(K_n) = \lambda(K_n)$$

because for $p > n, \lambda_p(K_n) = \lambda_n(K_n)$ and so letting $p \to \infty$, the above is obtained. Also, from 57.19.47,

$$\lambda(K_n^C) = \lim_{p \to \infty} \lambda_p(K_n^C \cap K_p)$$

$$\leq \limsup_{p \to \infty} (\lambda_p(K_p) - \lambda_p(K_n))$$

$$\leq \limsup_{p \to \infty} (\lambda_p(K_p) - \lambda_n(K_n))$$

$$\leq \limsup_{p \to \infty} \left(1 - \left(1 - \frac{1}{n}\right)\right) = \frac{1}{n}$$

Consequently,

$$\left| \int \phi d\mu_k - \int \phi d\lambda \right| \leq \left| \int_{K_n^C} \phi d\mu_k + \int_{K_n} \phi d\mu_k - \left( \int_{K_n} \phi d\lambda + \int_{K_n^C} \phi d\lambda \right) \right|$$

$$\leq \left| \int_{K_n} \phi d\mu_k - \int_{K_n} \phi d\lambda \right| + \left| \int_{K_n^C} \phi d\mu_k - \int_{K_n^C} \phi d\lambda \right|$$

$$\leq \left| \int_{K_n} \phi d\mu_k - \int_{K_n} \phi d\lambda \right| + \left| \int_{K_n^C} \phi d\mu_k - \int_{K_n^C} \phi d\lambda \right|$$

$$\leq \left( \int_{K_n} \phi d\mu_k - \int_{K_n} \phi d\lambda \right) + \frac{M}{n} + \frac{M}{n}$$
First let \( n \) be so large that \( 2M/n < \varepsilon/2 \) and then pick \( k \) large enough that the above expression is less than \( \varepsilon \). ■

**Definition 57.19.6** Let \( \mu, \{\mu_n\} \) be probability measures defined on the Borel sets of \( \mathbb{R}^p \) and let the sequence of probability measures, \( \{\mu_n\} \) satisfy

\[
\lim_{n \to \infty} \int \phi \, d\mu_n = \int \phi \, d\mu.
\]

for every \( \phi \) a bounded continuous function. Then \( \mu_n \) is said to converge weakly to \( \mu \).

With the above, it is possible to prove the following amazing theorem of Levy.

**Theorem 57.19.7** Suppose \( \{\mu_n\} \) is a sequence of probability measures defined on the Borel sets of \( \mathbb{R}^p \) and let \( \{\phi_{\mu_n}\} \) denote the corresponding sequence of characteristic functions. If there exists \( \psi \) which is continuous at \( 0 \), \( \psi(0) = 1 \), and for all \( t \),

\[
\phi_{\mu_n}(t) \to \psi(t),
\]

then there exists a probability measure, \( \lambda \) defined on the Borel sets of \( \mathbb{R}^p \) and

\[
\phi_{\lambda}(t) = \psi(t).
\]

That is, \( \psi \) is a characteristic function of a probability measure. Also, \( \{\mu_n\} \) converges weakly to \( \lambda \).

**Proof:** By Lemma 57.19.2 \( \{\mu_n\} \) is tight. Therefore, there exists a subsequence \( \{\mu_{n_k}\} \) converging weakly to a probability measure, \( \lambda \). In particular,

\[
\phi_{\lambda}(t) = \int e^{itx} \, d\lambda(x) = \lim_{n \to \infty} \int e^{itx} \, d\mu_{n_k}(x) = \lim_{n \to \infty} \phi_{\mu_{n_k}}(t) = \psi(t)
\]

The last claim follows from this and Lemma 57.19.4. ■

Note how it was only necessary to assume \( \psi(0) = 1 \) and \( \psi \) is continuous at \( 0 \) in order to conclude that \( \psi \) is a characteristic function. Thus you find that \( |\psi(t)| \leq 1 \) for free. This helps to see why Prokhorov’s and Levy’s theorems are so amazing.

### 57.20 Generalized Multivariate Normal

In this section is a further explanation of generalized multivariable normal random variables. Recall that these have characteristic function equal to \( e^{it^\prime m - \frac{1}{2}t^\prime \Sigma t} \) where \( \Sigma \geq 0, \Sigma = \Sigma^\prime \). The new detail is the case that \( \det(\Sigma) = 0 \).
Definition 57.20.1 A random vector, $\mathbf{X}$, with values in $\mathbb{R}^p$ has a multivariate normal distribution written as

$$\mathbf{X} \sim N_p(\mathbf{m}, \Sigma)$$

if for all Borel $E \subseteq \mathbb{R}^p$, the distribution measure is given by

$$\lambda_{\mathbf{X}}(E) = \int_{\mathbb{R}^p} \lambda_{E}(x) \frac{1}{(2\pi)^{p/2} \det(\Sigma)^{1/2}} e^{-\frac{1}{2}(\mathbf{x} - \mathbf{m})^{\ast}(\Sigma^{-1}(\mathbf{x} - \mathbf{m}))} \, dx$$

for $\mathbf{m}$ a given vector and $\Sigma$ a given positive definite symmetric matrix. Recall also that the characteristic function of this random variable is

$$E(e^{it^{\ast}\mathbf{X}}) = e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma t}$$

(57.20.48)

So what if $\det(\Sigma) = 0$? Is there a probability measure having characteristic equation

$$e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma t}$$

Let $\Sigma_n \to \Sigma$ in the Frobenius norm, $\det(\Sigma_n) > 0$. That is the $ij$th components converge. Let $\mathbf{X}_n$ be the random variable which is associated with $\mathbf{m}$ and $\Sigma_n$. Thus for $\phi \in C_0(\mathbb{R}^p)$,

$$|\lambda_{\mathbf{X}_n}(\phi)| \equiv \left| \int_{\mathbb{R}^p} \phi(x) \frac{1}{(2\pi)^{p/2} \det(\Sigma_n)^{1/2}} e^{-\frac{1}{2}(\mathbf{x} - \mathbf{m})^{\ast}(\Sigma_n^{-1}(\mathbf{x} - \mathbf{m}))} \, dx \right| \leq \|\phi\|_{C_0(\mathbb{R}^p)}$$

Thus these $\lambda_{\mathbf{X}_n}$ are bounded in the weak * topology of $C_0(\mathbb{R}^p)'$ which is the space of signed measures. By the separability of $C_0(\mathbb{R}^p)$ and the Banach Alaoglu theorem and the Riesz representation theorem for $C_0(\mathbb{R}^p)'$, there is a subsequence still denoted as $\lambda_{\mathbf{X}_n}$ which converges weak * to a finite measure $\mu$. Is $\mu$ a probability measure? Is the characteristic function of this measure $e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma t}$?

Note that $E(e^{it^{\ast}\mathbf{X}_n}) = e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma_n t} \to e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma t}$ and this last function of $t$ is continuous at $0$. Therefore, by Lemma 57.18.3, these measures $\lambda_{\mathbf{X}_n}$ are also tight. Let $\varepsilon > 0$ be given. Then there is a compact set $K_\varepsilon$ such that $\lambda_{\mathbf{X}_n}(\mathbf{x} \notin K_\varepsilon) < \varepsilon$. Now let $\phi = 1$ on $K_\varepsilon$ and $\phi \in C_c(\mathbb{R}^p)$, $\phi \geq 0, \phi(x) \in [0, 1]$. Then

$$(1 - \varepsilon) \leq \int_{\mathbb{R}^p} \phi d\lambda_{\mathbf{X}_n} \to \int_{\mathbb{R}^p} \phi d\mu \leq \mu(\mathbb{R}^p)$$

and so, since $\varepsilon$ is arbitrary, this shows that $\mu(\mathbb{R}^p) \geq 1$. However, $\mu(\mathbb{R}^p) \leq 1$ because

$$\mu(\mathbb{R}^p) \leq \int_{\mathbb{R}^p} \psi d\mu + \varepsilon \leq \int_{\mathbb{R}^p} \psi d\lambda_{\mathbf{X}_n} + 2\varepsilon \leq 1 + 2\varepsilon$$

for suitable $\psi \in C_c(\mathbb{R}^p)$ having values in $[0, 1]$ and $n$. Thus $\mu$ is indeed a probability measure.

Now what of its characteristic function?

$$e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma t} = \lim_{n \to \infty} e^{it^{\ast}\mathbf{m} - \frac{1}{2}t^{\ast}\Sigma_n t} = \lim_{n \to \infty} \int_{\mathbb{R}^p} e^{it^{\ast}\mathbf{x}} d\lambda_{\mathbf{X}_n}(x)$$

(57.20.49)
Is this equal to 
\[ \int_{\mathbb{R}^p} e^{it \cdot x} d\mu(x) \] 

Using tightness again,

\[ \left| \int_{\mathbb{R}^p} e^{it \cdot x} d\mu(x) - \int_{\mathbb{R}^p} e^{it \cdot x} d\lambda_{X_n}(x) \right| \leq \left| \int_{\mathbb{R}^p} e^{it \cdot x} d\mu(x) - \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\mu(x) \right| \]

\[ + \left| \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\mu(x) - \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\lambda_{X_n}(x) \right| \]

\[ + \left| \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\lambda_{X_n}(x) - \int_{\mathbb{R}^p} e^{it \cdot x} d\lambda_{X_n}(x) \right| \]

\[ \leq \varepsilon + \left| \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\mu(x) - \int_{\mathbb{R}^p} \psi e^{it \cdot x} d\lambda_{X_n}(x) \right| + \varepsilon \]

for a suitable choice of \( \psi \in C_c(\mathbb{R}^p) \) having values in \([0, 1]\). The middle term is less than \( \varepsilon \) if \( n \) large enough thanks to the weak * convergence of \( \lambda_{X_n} \) to \( \mu \). Hence the last limit in \( 57.20.49 \) equals \( \int_{\mathbb{R}^p} e^{it \cdot x} d\mu(x) \) as hoped. Letting \( X \) be a random variable having \( \mu \) as its distribution measure, (You could take \( \Omega = \mathbb{R}^p \) and the measurable sets the Borel sets,) what about \( E((X - m)(X - m)^\top) \)? Is it equal to \( \Sigma \)? What about the question whether \( X \in L^q(\Omega; \mathbb{R}^p) \) for all \( q > 1 \)? This is clearly true for the case where \( \Sigma^{-1} \) exists, but what of the case where \( \det(\Sigma) = 0 \)?

For simplicity, say \( m = 0 \).

\[ \int_{\Omega} |X|^q dP = \int_0^\infty P(|X|^q > \lambda) d\lambda = \int_0^\infty \mu(|X|^q > \lambda) d\lambda \]

\[ \leq \int_0^\infty \mu(|X|^q > \lambda) d\lambda \leq \int_0^\infty \int_{\mathbb{R}^p} (1 - \psi_\lambda) d\mu d\lambda \]

where \( \psi_\lambda = 1 \) on \( B \left( 0, \frac{1}{2} \lambda^{1/q} \right) \) is nonnegative, and is in \( C_c \left( B \left( 0, \lambda^{1/q} \right) \right) \). Now from the above, \( \mu(\mathbb{R}^p) = \lambda_{X_n}(\mathbb{R}^p) = 1 \) and so the inside integral satisfies

\[ \int_{\mathbb{R}^p} (1 - \psi_\lambda) d\mu = \lim_{n \to \infty} \int_{\mathbb{R}^p} (1 - \psi_\lambda) d\lambda_{X_n} \quad (57.20.50) \]

because

\[ \int_{\mathbb{R}^p} d\mu = \int_{\mathbb{R}^p} d\lambda_{X_n} = 1 \]

and as to the other terms, the weak * convergence gives

\[ \int_{\mathbb{R}^p} \psi_\lambda d\mu = \lim_{n \to \infty} \int_{\mathbb{R}^p} \psi_\lambda d\lambda_{X_n} \]

Each of these integrals in \( 57.20.50 \) is no larger than 1. Hence from Fatou’s lemma,

\[ \int_{\Omega} |X|^q dP \leq \int_0^\infty \int_{\mathbb{R}^p} (1 - \psi_\lambda) d\mu d\lambda \leq \lim_{n \to \infty} \inf \int_0^\infty \int_{\mathbb{R}^p} (1 - \psi_\lambda) d\lambda_{X_n} d\lambda \]
Is this on the right finite? It is dominated by

$$\lim_{n \to \infty} \int_0^\infty \lambda_{X_n} \left( |x|^q > \frac{1}{2^q} \lambda \right) d\lambda = \lim_{n \to \infty} 2^q \int_0^\infty \lambda_{X_n} \left( |x|^q > \delta \right) d\delta$$

So is a subsequence of \( E(|X_n|^q) \) bounded? It equals

$$\int_{\Omega} |x|^q \frac{1}{(2\pi)^{p/2} \det(\Sigma_n)^{1/2}} e^{-\frac{1}{2} (x-m)^T \Sigma_n^{-1} (x-m)} dx$$

and for \( q \) an even integer, this moment can be computed using the characteristic function.

$$e^{-\frac{1}{2} t^T \Sigma_n t} = \int_{\mathbb{R}^p} e^{it \cdot x} d\lambda_{X_n}$$

Also, it suffices to consider \( E(X_k^n) \). Differentiate both sides. Using the repeated index summation convention,

$$e^{-\frac{1}{2} t^T \Sigma_n t} (-\Sigma_{nk} t_j) = \int_{\mathbb{R}^p} ix_k e^{it \cdot x} d\mu$$

Now differentiate again.

$$e^{-\frac{1}{2} t^T \Sigma_n t} (-\Sigma_{nk} t_j) (-\Sigma_{nk} t_j) + (-\Sigma_{nkk}) = - \int_{\mathbb{R}^p} x_k^2 e^{it \cdot x} d\lambda_{X_n}$$

Next let \( t = 0 \) to conclude that \( E\left(X_k^n\right) = \Sigma_{nkk} \). Of course you can continue differentiating as long as desired and obtain \( E\left(X_k^n\right) \) is equal to some polynomial formula involving \( \Sigma_{nkk} \) and these are given to converge to \( \Sigma_{kk} \). Therefore, for any \( q > 1 \), \( \{E(|X_n|^q)\} \) is bounded and so from the above,

$$\int_{\Omega} |x|^q dP \leq \lim_{n \to \infty} 2^q E\left(|X_n|^q\right) < \infty$$

So yes, \( X \) is indeed in \( L^q(\Omega, \mathbb{R}^p) \) for every \( q \). What about the covariance?

From the definition of the characteristic function,

$$e^{-\frac{1}{2} t^T \Sigma t} = \int_{\mathbb{R}^p} e^{it \cdot x} d\mu$$

and so taking the derivative with respect to \( t_k \) of both sides,

$$e^{-\frac{1}{2} t^T \Sigma t} (-\Sigma_{kj} t_j) = \int_{\mathbb{R}^p} ix_k e^{it \cdot x} d\mu$$

Now differentiate with respect to \( t_l \) on both sides.

$$e^{-\frac{1}{2} t^T \Sigma t} (-\Sigma_{kj} t_j) + e^{-\frac{1}{2} t^T \Sigma t} (-\Sigma_{kl}) = \int_{\mathbb{R}^p} ix_k (ix_l) e^{it \cdot x} d\mu = - \int_{\mathbb{R}^p} x_k x_l e^{it \cdot x} d\mu$$
Now let \( t = 0 \) to obtain
\[
\Sigma_{kl} = \int_{\mathbb{R}^p} x_k x_l e^{it \cdot x} d\mu = E(X_k X_l)
\]
If \( \mathbf{m} \neq 0 \), the same kind of argument holds with a little more details. This proves the following theorem.

**Theorem 57.20.2** Let \( \Sigma \) be nonnegative and self adjoint \( p \times p \) matrix. Then there exists a random variable \( \mathbf{X} \) whose distribution measure \( \lambda_\mathbf{X} \) has characteristic function
\[
e^{it \cdot \mathbf{m}} e^{-\frac{1}{2}t^* \Sigma t}
\]
Also
\[
E \left( (\mathbf{X} - \mathbf{m})(\mathbf{X} - \mathbf{m})^* \right) = \Sigma
\]
that is
\[
E \left( (X_i - m_i)(X_j - m_j) \right) = \Sigma_{ij}
\]
This is generalized normally distributed random variable.

There is an interesting corollary to this theorem.

**Corollary 57.20.3** Let \( H \) be a real Hilbert space. Then there exist random variables \( W(h) \) for \( h \in H \) such that each is normally distributed with mean 0 and for every \( h, g \), \( W(h), W(g) \) is normally distributed and
\[
E(W(h) W(g)) = (h, g)_H
\]
Furthermore, if \( \{e_i\} \) is an orthogonal set of vectors of \( H \), then \( \{W(e_i)\} \) are independent random variables. Also for any finite set \( \{f_1, f_2, \cdots, f_n\} \),
\[
(W(f_1), W(f_2), \cdots, W(f_n))
\]
is normally distributed.

**Proof:** Let \( \mu_{h_1, \cdots, h_m} \) be a multivariate normal distribution with covariance \( \Sigma_{ij} = (h_i, h_j) \) and mean 0. Thus the characteristic function of this measure is
\[
e^{-\frac{1}{2}t^* \Sigma t}
\]
Now suppose \( \mu_{k_1, \cdots, k_n} \) is another such measure where for simplicity,
\[
\{h_1 \cdots h_m, k_{m+1} \cdots k_n\} = \{k_1 \cdots k_n\}
\]
Let \( \nu \) be a measure on \( \mathcal{B}(\mathbb{R}^m) \) which is given by
\[
\nu(E) = \mu_{k_1, \cdots, k_n}(E \times \mathbb{R}^{n-m})
\]
Then does it follow that \( \nu = \mu_{h_1, \cdots, h_m} \)? If so, then the Kolmogorov consistency condition will hold for these measures \( \mu_{h_1, \cdots, h_m} \). To determine whether this is so,
take the characteristic function of \( \nu \). Let \( \Sigma_1 \) be the \( n \times n \) matrix which comes from the \( \{ k_1 \cdots k_n \} \) and let \( \Sigma_2 \) be the one which comes from the \( \{ h_1 \cdots h_m \} \).

\[
\int_{\mathbb{R}^n} e^{it \cdot x} d\nu (x) = \int_{\mathbb{R}^m} \int_{\mathbb{R}^m} e^{i(t \cdot 0) - (x \cdot y)} d\mu_{k_1 \cdots k_n} (x, y) = e^{-\frac{1}{2}(t^* 0)^* \Sigma_1 (t, 0)} = e^{-\frac{1}{2}t^* \Sigma_2 t}
\]

which is the characteristic function for \( \mu_{h_1 \cdots h_m} \). Therefore, these two measures are the same and the Kolmogorov consistency condition holds. It follows that there exists a measure \( \mu \) defined on the Borel sets of \( \prod_{h \in H} \mathbb{R} \) which extends all of these measures. This argument also shows that if a random vector \( X \) has characteristic function \( e^{-\frac{1}{2}t^* \Sigma t} \), then if \( X_k \) is one of its components, then the characteristic function of \( X_k \) is \( e^{-\frac{1}{2}t^* |h_k|^2} \) so this scalar valued random variable has mean zero and variance \( |h_k|^2 \). Then if \( \omega \in \prod_{h \in H} \mathbb{R} \)

\[
W (h) (\omega) \equiv \pi_h (\omega)
\]

where \( \pi_h \) denotes the projection onto position \( h \) in this product. Also define

\[
(W (f_1), W (f_2), \cdots, W (f_n)) \equiv \pi_{f_1 \cdots f_n} (\omega)
\]

Then this is a random variable whose covariance matrix is just \( \Sigma_{ij} = (f_i, f_j)_H \) and whose characteristic equation is \( e^{-\frac{1}{2}t^* \Sigma t} \) so this verifies that

\[
(W (f_1), W (f_2), \cdots, W (f_n))
\]

is normally distributed with covariance \( \Sigma \). If you have two of them, \( W (g), W (h) \), then \( E (W (h) W (g)) = (h, g)_H \). This follows from what was just shown that \( (W (f), W (g)) \) is normally distributed and so the covariance will be

\[
\begin{pmatrix}
|f|^2 & (f, g) \\
(f, g) & |g|^2
\end{pmatrix}
= 
\begin{pmatrix}
E (W (f)^2) & E (W (f) W (g)) \\
E (W (f) W (g)) & E (W (g)^2)
\end{pmatrix}
\]

Finally consider the claim about independence. Any finite subset of \( \{ W (e_i) \} \) is generalized normal with the covariance matrix being a diagonal. Therefore, writing in terms of the distribution measures, this diagonal matrix allows the iterated integrals to be split apart and it follows that

\[
E \left( \exp \left( \sum_{k=1}^{m} t_k W (e_k) \right) \right) = \prod_{k=1}^{m} \exp (it_k W (e_k))
\]

and so this follows from Proposition 57.11.1. Note that in this case, the covariance matrix will not have zero determinant.
57.21 Positive Definite Functions, Bochner’s Theorem

First here is a nice little lemma about matrices.

Lemma 57.21.1 Suppose $M$ is an $n \times n$ matrix. Suppose also that

$$\alpha^* M \alpha = 0$$

for all $\alpha \in \mathbb{C}^n$. Then $M = 0$.

Proof: Suppose $\lambda$ is an eigenvalue for $M$ and let $\alpha$ be an associated eigenvector.

$$0 = \alpha^* M \alpha = \alpha^* \lambda \alpha = \lambda \alpha^* \alpha = \lambda |\alpha|^2$$

and so all the eigenvalues of $M$ equal zero. By Schur’s theorem there is a unitary matrix $U$ such that

$$M = U \begin{pmatrix} 0 & *_{1} \\ \vdots & \ddots \\ 0 & 0 \end{pmatrix} U^* \quad (57.21.51)$$

where the matrix in the middle has zeros down the main diagonal and zeros below the main diagonal. Thus

$$M^* = U \begin{pmatrix} 0 & 0 \\ \vdots & \ddots \\ *_{2} & 0 \end{pmatrix} U^*$$

where $M^*$ has zeros down the main diagonal and zeros above the main diagonal. Also taking the adjoint of the given equation for $M$, it follows that for all $\alpha$,

$$\alpha^* M^* \alpha = 0$$

Therefore, $M + M^*$ is Hermitian and has the property that

$$\alpha^* (M + M^*) \alpha = 0.$$ 

Thus $M + M^* = 0$ because it is unitarily similar to a diagonal matrix and the above equation can only hold for all $\alpha$ if $M + M^*$ has all zero eigenvalues which implies the diagonal matrix has zeros down the main diagonal. Therefore, from the formulas for $M, M^*$,

$$0 = U \left( \begin{pmatrix} 0 & 0 \\ \vdots & \ddots \\ *_{2} & 0 \end{pmatrix} + \begin{pmatrix} 0 & *_{1} \\ \vdots & \ddots \\ 0 & 0 \end{pmatrix} \right) U^*$$

and so the sum of the two matrices in the middle must also equal 0. Hence the entries of the matrix in the middle in [57.21.51] are all equal to zero. Thus $M = 0$ as claimed.
Definition 57.21.2 A Borel measurable function, \( f : \mathbb{R}^n \to \mathbb{C} \) is called positive definite if whenever \( \{t_k\}_{k=1}^p \subseteq \mathbb{R}^n, \alpha \in \mathbb{C}^p \)
\[
\sum_{k,j} f(t_j - t_k) \alpha_j \overline{\alpha_k} \geq 0 \quad (57.21.52)
\]

The first thing to notice about a positive definite function is the following which implies these functions are automatically bounded.

Lemma 57.21.3 If \( f \) is positive definite then whenever \( \{t_k\}_{k=1}^p \) are \( p \) points in \( \mathbb{R}^n \), \( |f(t_j - t_k)| \leq f(0) \). In particular, for all \( t \), \( |f(t)| \leq f(0) \).

Proof: Let \( F \) be the \( p \times p \) matrix such that
\[
F_{kj} = f(t_j - t_k).
\]

Then (57.21.52) is of the form
\[
\alpha^* F \alpha = (F \alpha, \alpha) \geq 0 \quad (57.21.53)
\]
where this is the inner product in \( \mathbb{C}^p \). Letting \( [\alpha, \beta] \equiv (F \alpha, \beta) \equiv \beta^* F \alpha \), it is obvious that \( [\alpha, \beta] \) satisfies
\[
[\alpha, \alpha] \geq 0, [a \alpha + b \beta, \gamma] = a [\alpha, \gamma] + b [\beta, \gamma].
\]
I claim it also satisfies
\[
[\alpha, \beta] = [\beta, \alpha].
\]
To verify this last claim, note that since \( \alpha^* F \alpha \) is real,
\[
\alpha^* F^* \alpha = \alpha^* F \alpha \geq 0
\]
and so for all \( \alpha \in \mathbb{C}^p \),
\[
\alpha^* (F^* - F) \alpha = 0
\]
which from Lemma 57.21.1 implies \( F^* = F \). Hence \( F \) is self adjoint and it follows
\[
[\alpha, \beta] \equiv \beta^* F \alpha = \beta^* F^* \alpha = \alpha^T F^* T \beta = \alpha^* F \beta = [\beta, \alpha].
\]

Therefore, the Cauchy Schwarz inequality holds for \([\cdot, \cdot]\) and it follows
\[
||[\alpha, \beta]|| = |(F \alpha, \beta)| \leq (F \alpha, \alpha)^{1/2} (F \beta, \beta)^{1/2}.
\]

Letting \( \alpha = e_k \) and \( \beta = e_j \), it follows \( F_{ss} \geq 0 \) for all \( s \) and
\[
|F_{kj}| \leq F_{kk}^{1/2} F_{jj}^{1/2}
\]
which says nothing more than
\[
|f(t_j - t_k)| \leq f(0)^{1/2} f(0)^{1/2} = f(0).
\]

This proves the lemma.

With this information, here is another useful lemma involving positive definite functions. It is interesting because it looks like the formula which defines what it means for the function to be positive definite.
**Lemma 57.21.4** Let $f$ be a positive definite function as defined above and let $\mu$ be a finite Borel measure. Then

$$
\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - y) \, d\mu(x) \, d\mu(y) \geq 0. 
$$

(57.21.54)

If $\mu$ also has the property that it is symmetric, $\mu(F) = \mu(-F)$ for all $F$ Borel, then

$$
\int_{\mathbb{R}^n} f(x) \, d(\mu \ast \mu)(x) \geq 0.
$$

(57.21.55)

**Proof:** By definition if $\{t_j\}_{j=1}^p \subseteq \mathbb{R}^n$, and letting $\alpha = (1, \cdots, 1)^T \in \mathbb{R}^n$,

$$
\sum_{j,k} f(t_j - t_k) \geq 0.
$$

Therefore, integrating over each of the variables,

$$
0 \leq \sum_{j=1}^p \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(t_j - t_j) \, d\mu(t_j) \, d\mu(t_j) + \sum_{j \neq k} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(t_j - t_k) \, d\mu(t_j) \, d\mu(t_k)
$$

and so

$$
0 \leq f(0) \mu(\mathbb{R}^n)^2 + p(p-1) \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - y) \, d\mu(x) \, d\mu(y).
$$

Dividing both sides by $p(p-1)$ and letting $p \to \infty$, it follows

$$
0 \leq \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - y) \, d\mu(x) \, d\mu(y)
$$

which shows (57.21.54).

To verify (57.21.55), use

$$
\int_{\mathbb{R}^n} f \, d(\mu \ast \mu) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x + y) \, d\mu(x) \, d\mu(y)
$$

and since $\mu$ is symmetric, this equals

$$
\int_{\mathbb{R}^n} \int_{\mathbb{R}^n} f(x - y) \, d\mu(x) \, d\mu(y) \geq 0
$$

by the first part of the lemma. This proves the lemma.

**Lemma 57.21.5** Let $\mu_t$ be the measure defined on $\mathcal{B}(\mathbb{R}^n)$ by

$$
\mu_t(F) = \frac{1}{\sqrt{2\pi t}} \int_F e^{-\frac{1}{2} |x|^2} \, dx
$$

for $t > 0$. Then $\mu_t \ast \mu_t = \mu_{2t}$ and each $\mu_t$ is a probability measure.
Proof: By Theorem 57.14.7,

\[
\phi_{\mu_{t}, \mu_{t}}(s) = \phi_{\mu_{t}}(s) \phi_{\mu_{s}}(s) = \left(e^{-\frac{1}{2}t|s|^2}\right)^2 = e^{-\frac{1}{2}(2t)|s|^2} = \phi_{\mu_{2t}}(s).
\]

Each \(\mu_{t}\) is a probability measure because it is the distribution of a normally distributed random variable of mean \(0\) and covariance \(tI\).

Now let \(\mu\) be a probability measure on \(B(\mathbb{R}^n)\).

\[
\phi_{\mu}(t) \equiv \int e^{it \cdot y} d\mu(y)
\]

and so by the dominated convergence theorem, \(\phi_{\mu}\) is continuous and also \(\phi_{\mu}(0) = 1\). I claim \(\phi_{\mu}\) is also positive definite. Let \(\alpha \in \mathbb{C}^p\) and \(\{t_k\}_{k=1}^{p}\) a sequence of points of \(\mathbb{R}^n\). Then

\[
\sum_{k,j} \phi_{\mu}(t_k - t_j) \alpha_k \alpha_j = \sum_{k,j} \int e^{it_k \cdot y} \alpha_k e^{-it_j \cdot y} \bar{\alpha_j} d\mu(y) = \int \sum_{k,j} e^{it_k \cdot y} \alpha_k e^{it_j \cdot y} \bar{\alpha_j} d\mu(y).
\]

Now let \(\beta(y) \equiv (e^{it_1 \cdot y} \alpha_1, \cdots, e^{it_p \cdot y} \alpha_p)^T\). Then the above equals

\[
\int (1, \cdots, 1) \beta(y) \beta^* (y) \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} d\mu
\]

The integrand is of the form

\[
\beta^* \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} \beta^* \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} \geq 0
\]

because it is just a complex number times its conjugate.

Thus every characteristic function is continuous, equals 1 at 0, and is positive definite. Bochner’s theorem goes the other direction.

To begin with, suppose \(\mu\) is a finite measure on \(B(\mathbb{R}^n)\). Then for \(\mathcal{S}\) the Schwartz class, \(\mu\) can be considered to be in the space of linear transformations defined on \(\mathcal{S}, \mathcal{S}^*\) as follows.

\[
\mu(f) \equiv \int f d\mu.
\]

Recall \(F^{-1}(\mu)\) is defined as

\[
F^{-1}(\mu)(f) \equiv \mu(F^{-1}f) = \int_{\mathbb{R}^n} F^{-1}f d\mu
\]
CHAPTER 57. BASIC PROBABILITY

\[
\frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} e^{ix \cdot y} f(y) \, dy \, d\mu \\
= \int_{\mathbb{R}^n} \left( \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} e^{ix \cdot y} \, d\mu \right) f(y) \, dy
\]

and so \( F^{-1}(\mu) \) is the bounded continuous function

\[
y \mapsto \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} e^{ix \cdot y} \, d\mu.
\]

Now the following lemma has the main ideas for Bochner's theorem.

**Lemma 57.21.6** Suppose \( \psi(t) \) is positive definite, \( t \rightarrow \psi(t) \) is in \( L^1(\mathbb{R}^n, m_n) \) where \( m_n \) is Lebesgue measure, \( \psi(0) = 1 \), and \( \psi \) is continuous at 0. Then there exists a unique probability measure, \( \mu \) defined on the Borel sets of \( \mathbb{R}^n \) such that

\[
\phi^\mu(t) = \psi(t).
\]

**Proof:** If the conclusion is true, then

\[
\psi(t) = \int_{\mathbb{R}^n} e^{it \cdot x} \, d\mu(x) = (2\pi)^{n/2} F^{-1}(\mu)(t).
\]

Recall that \( \mu \in \mathcal{S}^* \), the algebraic dual of \( \mathcal{S} \). Therefore, in \( \mathcal{S}^* \),

\[
\frac{1}{(2\pi)^{n/2}} F(\psi) = \mu.
\]

That is, for all \( f \in \mathcal{S} \),

\[
\int_{\mathbb{R}^n} f(y) \, d\mu(y) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} F(\psi)(y) f(y) \, dy \\
= \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} f(y) \left( \int_{\mathbb{R}^n} e^{-iy \cdot x} \psi(x) \, dx \right) dy. (57.21.56)
\]

I will show

\[
f \rightarrow \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} f(y) \left( \int_{\mathbb{R}^n} e^{-iy \cdot x} \psi(x) \, dx \right) dy
\]

is a positive linear functional and then it will follow from [57.21.56] that \( \mu \) is unique. Thus it is needed to show the inside integral in [57.21.56] is nonnegative. First note that the integrand is a positive definite function of \( x \) for each fixed \( y \). This follows from

\[
\sum_{k,j} e^{-iy \cdot (x_k - x_j)} \psi(x_k - x_j) \alpha_k \overline{\alpha_j}
\]

\[
= \sum_{k,j} \psi(x_k - x_j) \left( e^{-iy \cdot (x_k) \alpha_k} \overline{e^{-iy \cdot (x_j) \alpha_j}} \right) \geq 0.
\]
Let $t > 0$ and

$$h_{2t} (x) \equiv \frac{1}{(4\pi t)^{n/2}} e^{-\frac{1}{2} |x|^2}.$$  

Then by dominated convergence theorem,

$$\int_{\mathbb{R}^n} e^{-iy \cdot x} \psi (x) \, dx = \lim_{t \to \infty} \int_{\mathbb{R}^n} e^{-iy \cdot x} \psi (x) \, h_{2t} (x) \, dx$$

Letting $d\eta_{2t} = h_{2t} (x) \, dx$, it follows from Lemma 57.21.5, $\eta_{2t} = \eta_t \ast \eta_t$ and since these are symmetric measures, it follows from Lemma 57.21.4, the above equals

$$\lim_{t \to \infty} \int_{\mathbb{R}^n} e^{-iy \cdot x} \psi (x) \, d(\eta_t \ast \eta_t) \geq 0$$

Thus the above functional is a positive linear functional and so there exists a unique Radon measure, $\mu$ satisfying

$$\int_{\mathbb{R}^n} f (y) \, d\mu (y) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} F(\psi) (y) \, f (y) \, dy$$

$$= \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} f (y) \left( \int_{\mathbb{R}^n} e^{-iy \cdot x} \psi (x) \, dx \right) \, dy$$

$$= \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \psi (x) \left( \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} f (y) \, e^{-iy \cdot x} \, dy \right) \, dx$$

for all $f \in C_c (\mathbb{R}^n)$. Thus from the dominated convergence theorem, the above holds for all $f \in \mathcal{S}$ also. Hence for all $f \in \mathcal{S}$ and considering $\mu$ as an element of $\mathcal{S}^*$,

$$F^{-1} \mu (F f) = \mu (f) = \int_{\mathbb{R}^n} f (y) \, d\mu (y)$$

$$= \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \psi (x) \, F (f) (x) \, dx$$

$$= \frac{1}{(2\pi)^{n/2}} F(\psi) (f) = \frac{1}{(2\pi)^{n/2}} \psi (F f).$$

It follows that in $\mathcal{S}^*$,

$$\psi = (2\pi)^{n/2} F^{-1} \mu$$

Thus

$$\psi (t) = \int_{\mathbb{R}^n} e^{it \cdot x} \, d\mu$$

in $L^1$. Since the right side is continuous and the left is given continuous at $t = 0$ and equal to 1 there, it follows

$$1 = \psi (0) = \int_{\mathbb{R}^n} e^{i0 \cdot x} \, d\mu = \mu (\mathbb{R}^n)$$

and so $\mu$ is a probability measure as claimed. This proves the lemma.

The following is Bochner’s theorem.
**Theorem 57.21.7** Let $\psi$ be positive definite, continuous at 0, and $\psi(0) = 1$. Then there exists a unique Radon probability measure $\mu$ such that $\psi = \phi_\mu$.

**Proof:** If $\psi \in L^1(\mathbb{R}^n, m_n)$, then the result follows from Lemma 57.21.6. By Lemma 57.21.3 $\psi$ is bounded. Consider

$$
\psi_t(x) \equiv \psi(x) \frac{1}{(2\pi t)^{n/2}} e^{-\frac{1}{2} |x|^2}.
$$

Then $\psi_t(0) = 1$, $x \to \psi_t(x)$ is continuous at 0, and $\psi_t \in L^1(\mathbb{R}^n, m_n)$. Therefore, by Lemma 57.21.4 there exists a unique Radon probability measure $\mu_t$ such that

$$
\psi_t(x) = \int_{\mathbb{R}^n} e^{i\mathbf{x} \cdot \mathbf{y}} d\mu_t(y) = \phi_{\mu_t}(x)
$$

Now letting $t \to \infty$,

$$
\lim_{t \to \infty} \psi_t(x) = \lim_{t \to \infty} \phi_{\mu_t}(x) = \psi(x).
$$

By Levy’s theorem, Theorem 57.19.7, it follows there exists $\mu$, a probability measure on $\mathcal{B}(\mathbb{R}^n)$ such that $\psi(x) = \phi_{\mu}(x)$. The measure is unique because the characteristic functions are uniquely determined by the measure. This proves the theorem.
Chapter 58

Conditional Expectation And Martingales

58.1 Conditional Expectation

From Observation 57.11.5 on Page 1940, it was shown that the conditional expectation of a random variable $X$ given some others really is just what the words suggest. Given $\omega \in \Omega$, it results in a value for the “other” random variables and then you essentially take the expectation of $X$ given this information which yields the value of the conditional expectation of $X$ given the other random variables. It was also shown in Lemma 57.11.4 that this gives the same result as finding a $\sigma(X_1, \cdots, X_n)$ measurable function $Z$ such that for all $F \in \sigma(X_1, \cdots, X_n)$,

$$\int_F X dP = \int_F Z dP$$

This was done for a particular type of $\sigma$ algebra but there is no need to be this specialized. The following is the general version of conditional expectation given a $\sigma$ algebra and this is what will be done from now on.

Definition 58.1.1 Let $(\Omega, \mathcal{M}, P)$ be a probability space and let $\mathcal{S} \subseteq \mathcal{F}$ be two $\sigma$ algebras contained in $\mathcal{M}$. Let $f$ be $\mathcal{F}$ measurable and in $L^1(\Omega)$. Then $E(f|\mathcal{S})$, called the conditional expectation of $f$ with respect to $\mathcal{S}$ is defined as follows:

$E(f|\mathcal{S})$ is $\mathcal{S}$ measurable

For all $E \in \mathcal{S}$,

$$\int_E E(f|\mathcal{S}) dP = \int_E f dP$$

1991
Lemma 58.1.2 The above is well defined. Also, if $S \subseteq F$ then
\[ E \left( X \mid S \right) = E \left( E \left( X \mid F \right) \mid S \right). \tag{58.1.1} \]

If $Z$ is bounded and measurable in $S$ then
\[ ZE \left( X \mid S \right) = E \left( ZX \mid S \right). \tag{58.1.2} \]

Proof: Let a finite measure on $S$, $\mu$ be given by
\[ \mu(E) \equiv \int_E f dP. \]
Then $\mu \ll P$ and so by the Radon Nikodym theorem, there exists a unique $S$ measurable function, $E(f|S)$ such that
\[ \int_E f dP = \mu(E) = \int_E E(f|S) dP \]
for all $E \in S$.

Let $F \in S$. Then
\[ \int_F E \left( E \left( X \mid F \right) \mid S \right) dP = \int_F E \left( X \mid F \right) dP = \int_F X dP = \int_F E \left( X \mid S \right) dP \]
and so, by uniqueness, $E \left( E \left( X \mid F \right) \mid S \right) = E \left( X \mid S \right)$. This shows (58.1.1).

To establish (58.1.2), note that if $Z = X_F$ where $F \in S$,
\[ \int_F X_F E \left( X \mid S \right) dP = \int_F X_F X dP = \int_F E \left( X_F X \mid S \right) dP \]
which shows (58.1.2) in the case where $Z$ is the indicator function of a set in $S$. It follows this also holds for simple functions. Let $\{s_n\}$ be a sequence of simple functions which converges uniformly to $Z$ and let $F \in S$. Then by what was just shown,
\[ \int_F s_n E \left( X \mid S \right) dP = \int_F s_n X dP = \int_F E \left( s_n X \mid S \right) dP \]
Now
\[ \left| \int_F E \left( s_n X \mid S \right) dP - \int_F E \left( ZX \mid S \right) dP \right| \leq \int_F |s_n X - ZX| dP = \int_F |s_n - Z| |X| dP \]
which converges to 0 by the dominated convergence theorem. Then passing to the limit using the dominated convergence theorem, yields
\[ \int_F ZE \left( X \mid S \right) dP = \int_F ZX dP \equiv \int_F E \left( ZX \mid S \right) dP. \]
58.1. CONDITIONAL EXPECTATION

Since this holds for every \( F \in \mathcal{S} \), this shows \( \text{III.2} \). The next major result is a generalization of Jensen’s inequality whose proof depends on the following lemma about convex functions.

**Lemma 58.1.3** Let \( \phi \) be a convex real valued function defined on an interval \( I \). Then for each \( x \in I \), there exists \( a_x \) such that for all \( t \in I \),

\[
\phi(t) \geq a_x(t-x) + \phi(x).
\]

Also \( \phi \) is continuous on \( I \).

**Proof:** Let \( x \in I \) and let \( t > x \). Then by convexity of \( \phi \),

\[
\frac{\phi(x + \lambda(t-x)) - \phi(x)}{\lambda(t-x)} \leq \frac{\phi(x)(1-\lambda) + \lambda\phi(t) - \phi(x)}{\lambda(t-x)}
\]

\[
= \frac{\phi(t) - \phi(x)}{t-x}.
\]

Therefore \( t \to \frac{\phi(t) - \phi(x)}{t-x} \) is increasing if \( t > x \). If \( t < x \)

\[
\frac{\phi(x + \lambda(t-x)) - \phi(x)}{\lambda(t-x)} \geq \frac{\phi(x)(1-\lambda) + \lambda\phi(t) - \phi(x)}{\lambda(t-x)}
\]

\[
= \frac{\phi(t) - \phi(x)}{t-x}
\]

and so \( t \to \frac{\phi(t) - \phi(x)}{t-x} \) is increasing for \( t \neq x \). Let

\[
a_x \equiv \inf \left\{ \frac{\phi(t) - \phi(x)}{t-x} : t > x \right\}.
\]

Then if \( t_1 < x \), and \( t > x \),

\[
\frac{\phi(t_1) - \phi(x)}{t_1-x} \leq a_x \leq \frac{\phi(t) - \phi(x)}{t-x}.
\]

Thus for all \( t \in I \),

\[
\phi(t) \geq a_x(t-x) + \phi(x).
\]

The continuity of \( \phi \) follows easily from this and the observation that convexity simply says that the graph of \( \phi \) lies below the line segment joining two points on its graph. Thus, we have the following picture which clearly implies continuity. \( \blacksquare \)
Lemma 58.1.4 Let $I$ be an open interval on $\mathbb{R}$ and let $\phi$ be a convex function defined on $I$. Then there exists a sequence $\{(a_n, b_n)\}$ such that

$$\phi(t) = \sup \{a_n t + b_n, n = 1, \ldots\}.$$ 

**Proof:** Let $a_x$ be as defined in the above lemma. Let

$$\psi(x) \equiv \sup \{a_r (x - r) + \phi(r) : r \in \mathbb{Q} \cap I\}.$$ 

Thus if $r_1 \in \mathbb{Q}$,

$$\psi(r_1) \equiv \sup \{a_r (r_1 - r) + \phi(r) : r \in \mathbb{Q} \cap I\} \geq \phi(r_1)$$

Then $\psi$ is convex on $I$ so $\psi$ is continuous. Therefore, $\psi(t) \geq \phi(t)$ for all $t \in I$. By

$$\psi(t) \geq \phi(t) \geq \sup \{a_r (t - r) + \phi(r), r \in \mathbb{Q} \cap I\} \equiv \psi(t).$$

Thus $\psi(t) = \phi(t)$. Let $\mathbb{Q} \cap I = \{r_n\}$, $a_n = a_{r_n}$ and $b_n = -a_{r_n}r_n + \phi(r_n)$. \[ \square \]

Lemma 58.1.5 If $X \leq Y$, then $E(X|\mathcal{S}) \leq E(Y|\mathcal{S})$ a.e. Also

$$X \rightarrow E(X|\mathcal{S})$$

is linear.

**Proof:** Let $A \in \mathcal{S}$.

$$\int_A E(X|\mathcal{S})dP \equiv \int_A XdP \leq \int_A YdP \equiv \int_A E(Y|\mathcal{S})dP.$$ 

Hence $E(X|\mathcal{S}) \leq E(Y|\mathcal{S})$ a.e. as claimed. It is obvious $X \rightarrow E(X|\mathcal{S})$ is linear.

Theorem 58.1.6 (Jensen’s inequality)Let $X(\omega) \in I$ and let $\phi : I \rightarrow \mathbb{R}$ be convex. Suppose

$$E(|X|), E(|\phi(X)|) < \infty.$$ 

Then

$$\phi(E(X|\mathcal{S})) \leq E(\phi(X)|\mathcal{S}).$$ 

**Proof:** Let $\phi(x) = \sup \{a_n x + b_n\}$. Letting $A \in \mathcal{S}$,

$$\frac{1}{P(A)} \int_A E(X|\mathcal{S})dP = \frac{1}{P(A)} \int_A XdP \in I \text{ a.e.}$$

whenever $P(A) \neq 0$. Hence $E(X|\mathcal{S})(\omega) \in I$ a.e. and so it makes sense to consider $\phi(E(X|\mathcal{S}))$. Now

$$a_n E(X|\mathcal{S}) + b_n = E(a_n X + b_n|\mathcal{S}) \leq E(\phi(X)|\mathcal{S}).$$

Thus

$$\sup \{a_n E(X|\mathcal{S}) + b_n\} = \phi(E(X|\mathcal{S})) \leq E(\phi(X)|\mathcal{S}) \text{ a.e.} \[ \square \]$$
58.2 Discrete Martingales

**Definition 58.2.1** Let $S_k$ be an increasing sequence of $\sigma$-algebras which are subsets of $S$ and $X_k$ be a sequence of real-valued random variables with $E(|X_k|) < \infty$ such that $X_k$ is $S_k$ measurable. Then this sequence is called a martingale if

$$E(X_{k+1}|S_k) = X_k,$$

a submartingale if

$$E(X_{k+1}|S_k) \geq X_k,$$

and a supermartingale if

$$E(X_{k+1}|S_k) \leq X_k.$$

Saying that $X_k$ is $S_k$ measurable is referred to by saying $\{X_k\}$ is adapted to $S_k$.

Note that if $\{X_k\}$ is a martingale, then $\{|X_k|\}$ is a submartingale and that if $\{X_k\}$ is a submartingale and $\phi$ is convex and increasing, then $\{\phi(X_k)\}$ is a submartingale.

An upcrossing occurs when a sequence goes from $a$ up to $b$. Thus it crosses the interval, $[a, b]$ in the up direction, hence upcrossing. More precisely,

**Definition 58.2.2** Let $\{x_i\}_{i=1}^I$ be any sequence of real numbers, $I \leq \infty$. Define an increasing sequence of integers $\{m_k\}$ as follows. $m_1$ is the first integer $\geq 1$ such that $x_{m_1} \leq a$, $m_2$ is the first integer larger than $m_1$ such that $x_{m_2} \geq b$, $m_3$ is the first integer larger than $m_2$ such that $x_{m_3} \leq a$, etc. Then each sequence,$$
\{x_{m_{2k-1}}, \ldots, x_{m_{2k}}\},$$
is called an upcrossing of $[a, b]$.

Here is a picture of an upcrossing.

\[
\begin{array}{c}
\hline
b \\
\hline
a \\
s_{1} \\
s_{2} \\
s_{3} \\
\vdots \\
\hline
\end{array}
\]

**Proposition 58.2.3** Let $\{X_i\}_{i=1}^n$ be a finite sequence of real random variables defined on $\Omega$ where $(\Omega, S, P)$ is a probability space. Let $U_{[a,b]}(\omega)$ denote the number of upcrossings of $X_i(\omega)$ of the interval $[a, b]$. Then $U_{[a,b]}$ is a random variable.

**Proof:** Let $X_0(\omega) \equiv a+1$, let $Y_0(\omega) \equiv 0$, and let $Y_k(\omega)$ remain 0 for $k = 0, \ldots, l$ until $X_l(\omega) \leq a$. When this happens (if ever), $Y_{l+1}(\omega) \equiv 1$. Then let $Y_i(\omega)$ remain 1 for $i = l+1, \ldots, r$ until $X_r(\omega) \geq b$ when $Y_{r+1}(\omega) \equiv 0$. Let $Y_k(\omega)$ remain 0 for $k \geq r+1$ until $X_k(\omega) \leq a$ when $Y_k(\omega) \equiv 1$ and continue in this way. Thus the upcrossings of $X_i(\omega)$ are identified as unbroken strings of ones for $Y_k$ with a zero
at each end, with the possible exception of the last string of ones which may be missing the zero at the upper end and may or may not be an upcrossing.

Note also that \( Y_0 \) is measurable because it is identically equal to 0 and that if \( Y_k \) is measurable, then \( Y_{k+1} \) is measurable because the only change in going from \( k \) to \( k+1 \) is a change from 0 to 1 or from 1 to 0 on a measurable set determined by \( X_k \). In particular,

\[
Y_{k+1}^{-1}(1) = ([Y_k = 1] \cap [X_k < b]) \cup ([Y_k = 0] \cap [X_k \leq a])
\]

This set is in \( S \) by induction. Of course, \( Y_{k+1}^{-1}(0) \) is just the complement of this set. Thus \( Y_{k+1} \) is \( S \) measurable since 0, 1 are the only two values possible. Now let

\[
Z_k(\omega) = \begin{cases} 
1 & \text{if } Y_k(\omega) = 1 \text{ and } Y_{k+1}(\omega) = 0, \\
0 & \text{otherwise,}
\end{cases}
\]

if \( k < n \) and

\[
Z_n(\omega) = \begin{cases} 
1 & \text{if } Y_n(\omega) = 1 \text{ and } X_n(\omega) \geq b, \\
0 & \text{otherwise.}
\end{cases}
\]

Thus \( Z_k(\omega) = 1 \) exactly when an upcrossing has been completed and each \( Z_i \) is a random variable.

\[
U_{[a,b]}(\omega) = \sum_{k=1}^{n} Z_k(\omega)
\]

so \( U_{[a,b]} \) is a random variable as claimed.

The following corollary collects some key observations found in the above construction.

**Corollary 58.2.4** Let \( \phi(a, b) \leq \text{the number of unbroken strings of ones in the sequence, } \{Y_k(\omega)\} \text{ there being at most one unbroken string of ones which produces no upcrossing. Also}

\[
Y_i(\omega) = \psi_i \left( \{X_j(\omega)\}_{j=1}^{i-1} \right),
\]

(58.2.4)

where \( \psi_i \) is some function of the past values of \( X_j(\omega) \).

**Lemma 58.2.5** Let \( \phi \) be a convex and increasing function and suppose

\[
\{(X_n, S_n)\}
\]

is a submartingale. Then if \( E(\phi(X_n)) < \infty \), it follows

\[
\{(\phi(X_n), S_n)\}
\]

is also a submartingale.

**Proof:** It is given that \( E(X_{n+1}, S_n) \geq X_n \) and so

\[
\phi(X_n) \leq \phi(E(X_{n+1}|S_n)) \leq E(\phi(X_{n+1})|S_n)
\]

by Jensen’s inequality.

The following is called the upcrossing lemma.
58.2.1 Upcrossings

Lemma 58.2.6 (upcrossing lemma) Let \( \{(X_i, S_i)\}_{i=1}^n \) be a submartingale and let \( U_{[a,b]}(\omega) \) be the number of upcrossings of \([a,b]\). Then

\[
E(U_{[a,b]}) \leq \frac{E(|X_n|)}{b-a}.
\]

Proof: Let \( \phi(x) \equiv a + (x-a)^+ \) so that \( \phi \) is an increasing convex function always at least as large as \( a \). By Lemma 58.2.5 it follows that \( \{(\phi(X_k), S_k)\} \) is also a submartingale.

\[
\phi(X_{k+r}) - \phi(X_k) = \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1}))
\]

\[
= \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1})) Y_i + \sum_{i=k+1}^{k+r} (\phi(X_i) - \phi(X_{i-1})) (1 - Y_i).
\]

Observe that \( Y_i \) is \( S_{i-1} \) measurable from its construction in Proposition 58.2.3, \( Y_i \) depending only on \( X_j \) for \( j < i \).

Now let the unbroken strings of ones for \( \{Y_i(\omega)\} \) be

\[
\{k_1, \cdots , k_1 + r_1\}, \{k_2, \cdots , k_2 + r_2\}, \cdots , \{k_m, \cdots , k_m + r_m\}
\]

(58.2.5)

where \( m = V(\omega) \equiv \) the number of unbroken strings of ones in the sequence \( \{Y_i(\omega)\} \).

By Corollary 58.2.4 \( V(\omega) \geq U_{[a,b]}(\omega) \).

\[
\phi(X_n(\omega)) - \phi(X_1(\omega))
\]

\[
= \sum_{k=1}^n (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) Y_k(\omega)
\]

\[
+ \sum_{k=1}^n (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) (1 - Y_k(\omega)).
\]

The first sum in the above reduces to summing over the unbroken strings of ones because the terms in which \( Y_i(\omega) = 0 \) contribute nothing. Therefore,

\[
\phi(X_n(\omega)) - \phi(X_1(\omega))
\]

\[
\geq U_{[a,b]}(\omega) (b-a) + 0 + \sum_{k=1}^n (\phi(X_k(\omega)) - \phi(X_{k-1}(\omega))) (1 - Y_k(\omega))
\]

(58.2.6)

where the zero on the right side results from a string of ones which does not produce an upcrossing. It is here that it is important that \( \phi(x) \geq a \). Such
a string begins with $\phi(X_k(\omega)) = a$ and results in an expression of the form $\phi(X_{k+m}(\omega)) - \phi(X_k(\omega)) \geq 0$ since $\phi(X_{k+m}(\omega)) \geq a$. If $X_k$ had not been replaced with $\phi(X_k)$, it would have been possible for $\phi(X_{k+m}(\omega))$ to be less than $a$ and the zero in the above could have been a negative number. This would have been inconvenient.

Next take the expected value of both sides in 58.2.6. This results in

$$E(\phi(X_n) - \phi(X_1)) \geq (b-a)E(U_{[a,b]})$$

$$+ E\left(\sum_{k=1}^{n} (\phi(X_k) - \phi(X_{k-1}))(1-Y_k)\right)$$

$$\geq (b-a)E(U_{[a,b]})$$

The reason for the last inequality where the term at the end was dropped is

$$E((\phi(X_k) - \phi(X_{k-1}))(1-Y_k))$$

$$= E(E((\phi(X_k) - \phi(X_{k-1}))(1-Y_k)|F_{k-1}))$$

$$= E((1-Y_k)E(\phi(X_k)|F_{k-1}) - (1-Y_k)E(\phi(X_{k-1})|F_{k-1}))$$

$$\geq E((1-Y_k)(\phi(X_{k-1}) - \phi(X_{k-1}))) = 0.$$}

Recall that $Y_k$ is $S_{k-1}$ measurable and that $(\phi(X_k), S_k)$ is a submartingale. 

The reason for this lemma is to prove the amazing submartingale convergence theorem.

### 58.2.2 The Submartingale Convergence Theorem

**Theorem 58.2.7 (submartingale convergence theorem)** Let

$$\{(X_i, S_i)\}_{i=1}^{\infty}$$

be a submartingale with $K \equiv \sup E(|X_n|) < \infty$. Then there exists a random variable, $X$, such that $E(|X|) \leq K$ and

$$\lim_{n \to \infty} X_n(\omega) = X(\omega) \text{ a.e.}$$

**Proof:** Let $a, b \in \mathbb{Q}$ and let $a < b$. Let $U^n_{[a,b]}(\omega)$ be the number of upcrossings of $\{X_i(\omega)\}_{i=1}^{n}$. Then let

$$U^n_{[a,b]}(\omega) \equiv \lim_{n \to \infty} U^n_{[a,b]}(\omega) = \text{number of upcrossings of } \{X_i\}.$$  

By the upcrossing lemma,

$$E\left(U^n_{[a,b]}\right) \leq \frac{E(|X_n|) + |a|}{b-a} \leq \frac{K + |a|}{b-a}$$
and so by the monotone convergence theorem,
\[ E(U_{[a,b]}) \leq \frac{K + |a|}{b - a} < \infty \]
which shows \( U_{[a,b]}(\omega) \) is finite a.e., for all \( \omega \notin S_{[a,b]} \) where \( P(S_{[a,b]}) = 0 \). Define
\[ S \equiv \cup \{ S_{[a,b]} : a, b \in \mathbb{Q}, a < b \}. \]
Then \( P(S) = 0 \) and if \( \omega \notin S \), \( \{X_k\}_{k=1}^{\infty} \) has only finitely many upcrossings of every interval having rational endpoints. For such \( \omega \) it cannot be the case that
\[ \limsup_{k \to \infty} X_k(\omega) > \liminf_{k \to \infty} X_k(\omega) \]
because then you could pick rational \( a, b \) such that \([a, b]\) is between the \( \limsup \) and the \( \liminf \) and there would be infinitely many upcrossings of \([a, b]\). Thus, for \( \omega \notin S \),
\[ \limsup_{k \to \infty} X_k(\omega) = \liminf_{k \to \infty} X_k(\omega) = \lim_{k \to \infty} X_k(\omega) = X_\infty(\omega). \]
Letting \( X_\infty(\omega) \equiv 0 \) for \( \omega \in S \), Fatou’s lemma implies
\[ \int_{\Omega} |X_\infty| dP = \int_{\Omega} \liminf_{n \to \infty} |X_n| dP \leq \liminf_{n \to \infty} \int_{\Omega} |X_n| dP \leq K \]

58.2.3 Doob Submartingale Estimate

Another very interesting result about submartingales is the Doob submartingale estimate.

**Theorem 58.2.8** Let \( \{(X_i,S_i)\}_{i=1}^{\infty} \) be a submartingale. Then for \( \lambda > 0 \),
\[ P\left(\max_{1 \leq k \leq n} X_k \geq \lambda\right) \leq \frac{1}{\lambda} \int_{\Omega} X_n^+ dP \]

**Proof:** Let
\[ A_1 \equiv [X_1 \geq \lambda], A_2 \equiv [X_2 \geq \lambda] \setminus A_1, \]
\[ \cdots, A_k \equiv [X_k \geq \lambda] \setminus (\cup_{i=1}^{k-1} A_i) \cdots \]
Thus each \( A_k \) is \( S_k \) measurable, the \( A_k \) are disjoint, and their union equals \( \max_{1 \leq k \leq n} X_k \geq \lambda \).
Therefore from the definition of a submartingale and Jensen’s inequality,

\[
P\left(\max_{1 \leq k \leq n} X_k \geq \lambda\right) = \sum_{k=1}^{n} P(A_k) \leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_k} X_k dP
\]

\[
\leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_k} E(X_n | S_k) dP
\]

\[
\leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_k} E(X_n^+ | S_k) dP
\]

\[
\leq \frac{1}{\lambda} \sum_{k=1}^{n} \int_{A_k} E(X_n^+ | S_k) dP + \int_{\Omega} E(X_n^+ | \Omega) dP \leq \frac{1}{\lambda} \int_{\Omega} X_n^+ dP. \quad \blacksquare
\]

58.3 Optional Sampling And Stopping Times

58.3.1 Stopping Times And Their Properties

First it is necessary to define the notion of a stopping time.

**Definition 58.3.1** Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \(\{\mathcal{F}_n\}_{n=1}^{\infty}\) be an increasing sequence of \(\sigma\) algebras each contained in \(\mathcal{F}\). A stopping time is a measurable function, \(T\) which maps \(\Omega\) to \(\mathbb{N}\),

\[
T^{-1}(A) \in \mathcal{F} \quad \text{for all } A \in \mathcal{P}(\mathbb{N}),
\]

such that for all \(n \in \mathbb{N}\),

\[
[T \leq n] \in \mathcal{F}_n.
\]

Note this is equivalent to saying

\[
[T = n] \in \mathcal{F}_n
\]

because

\[
[T = n] = [T \leq n] \setminus [T \leq n - 1].
\]

For \(T\) a stopping time define \(\mathcal{F}_T\) as follows.

\[
\mathcal{F}_T \equiv \{ A \in \mathcal{F} : A \cap [T \leq n] \in \mathcal{F}_n \text{ for all } n \in \mathbb{N}\}
\]

These sets in \(\mathcal{F}_T\) are referred to as “prior” to \(T\).

The following lemma is fundamental to understand.

**Lemma 58.3.2** In the situation of Definition 58.3.1, if \(S \leq T\) for two stopping times, \(S\) and \(T\), then \(\mathcal{F}_S \subseteq \mathcal{F}_T\). Also \(\mathcal{F}_T\) is a \(\sigma\) algebra.
**Proof:** Let $A \in \mathcal{F}_S$. Then this means

$$A \cap [S \leq n] \in \mathcal{F}_n$$

for all $n$. Then

$$A \cap [T \leq n] = \bigcup_{i=1}^{n} (A \cap [S \leq i]) \cap [T \leq n]$$

(58.3.7)

Suppose $\omega$ is in the set on the left. Then if $T(\omega) < n$, it is clearly in the set on the right. If $T(\omega) = n$, then $\omega \in [S \leq i]$ for some $i \leq n$ and it is also in $[T \leq n]$. Thus the set on the left is contained in the set on the right. Next suppose $\omega$ is in the set on the right. Then $\omega \in [T \leq n]$ and it only remains to verify $\omega \in A$. However, $\omega \in A \cap [S \leq i]$ for some $i$ and so $\omega \in A$ also.

Now from (58.3.7) it follows $A \cap [T \leq n] \in \mathcal{F}_n$ because

$$A \cap [S \leq i] \in \mathcal{F}_i \subseteq \mathcal{F}_n$$

and $[T \leq n] \in \mathcal{F}_n$ because $T$ is a stopping time. Since $n$ is arbitrary, this shows $\mathcal{F}_S \subseteq \mathcal{F}_T$.

It remains to verify $\mathcal{F}_T$ is a $\sigma$ algebra. Suppose $\{A_i\}$ is a sequence of sets in $\mathcal{F}_T$. Then I need to show that $(\bigcup_{i=1}^{\infty} A_i) \cap [T \leq j] \in \mathcal{F}_j$ for all $j$.

$$\bigcup_{i=1}^{\infty} A_i \cap [T \leq j] = \bigcup_{i=1}^{\infty} (A_i \cap [T \leq j])$$

Now each $(A_i \cap [T \leq j])$ is in $\mathcal{F}_j$ and so the countable union of these sets is also in $\mathcal{F}_j$. Next suppose $A \in \mathcal{F}_T$. I need to verify $A^C \cap [T \leq j] \in \mathcal{F}_j$ for all $j$. However, $[T \leq j] \in \mathcal{F}_j$ and $\Omega \in \mathcal{F}_j$ so $\Omega \in \mathcal{F}_T$. Thus

$$\Omega \cap [T \leq j] = (A \cap [T \leq j]) \cup (A^C \cap [T \leq j])$$

and so

$$(A^C \cap [T \leq j]) = \Omega \cap [T \leq j] \setminus (A \cap [T \leq j]) \in \mathcal{F}_j.$$

This proves the lemma.

**Lemma 58.3.3** Let $T$ be a stopping time and let $\{X_n\}$ be a sequence of random variables such that $X_n$ is $\mathcal{F}_n$ measurable. Then $X_T(\omega) \equiv X_{T(\omega)}(\omega)$ is also a random variable and it is measurable with respect to $\mathcal{F}_T$.

**Proof:** I assume the $X_n$ have values in some topological space and each is measurable because the inverse image of an open set is in $\mathcal{F}_n$. I need to show $X_T^{-1}(U) \cap [T \leq n] \in \mathcal{F}_n$ for all $n$ whenever $U$ is open.

$$X_T^{-1}(U) = \bigcup_{i=1}^{\infty} X_i^{-1}(U) \cap [T = i].$$

It follows $X_T^{-1}(U) \in \mathcal{F}$. Furthermore,

$$X_T^{-1}(U) \cap [T \leq n] = \bigcup_{i=1}^{\infty} X_i^{-1}(U) \cap [T = i] \cap [T \leq n]$$

$$= \bigcup_{i=1}^{n} X_i^{-1}(U) \cap [T = i] \cap [T \leq n]$$

$$= \bigcup_{i=1}^{n} \left[ X_i^{-1}(U) \cap [T = i] \in \mathcal{F}_i \right] \in \mathcal{F}_n$$

and so $X_T$ is $\mathcal{F}_T$ is measurable as claimed. This proves the lemma.
Lemma 58.3.4 Let $S \leq T$ be two stopping times such that $T$ is bounded above and let $\{X_n\}$ be a submartingale (martingale) adapted to the increasing sequence of $\sigma$ algebras, $\{F_n\}$. Then

$$E(X_T|F_S) \geq X_S$$

in the case where $\{X_n\}$ is a submartingale and

$$E(X_T|F_S) = X_S$$

in the case where $\{X_n\}$ is a martingale.

Proof: I will prove the case where $\{X_n\}$ is a submartingale and note the other case will only involve replacing $\geq$ with $=$. First recall that from Lemma 58.3.2 $F_S \subseteq F_T$. Also let $m$ be an upper bound for $T$. Then it follows from this that

$$E(|X_T|) = \sum_{i=1}^{m} \int_{[T=i]} |X_i| dP < \infty$$

with a similar formula holding for $E(|X_S|)$. Thus it makes sense to speak of $E(X_T|F_S)$.

I need to show that if $B \in F_S$, so that $B \cap [S \leq n] \in F_n$ for all $n$, then

$$\int_B X_T dP \geq \int_B X_S dP.$$  \tag{58.3.8}

It suffices to do this for $B$ of the special form

$$B = A \cap [S = i]$$

because if this is done, then the result follows from summing over all possible values of $S$. Note that if $B = A \cap [S = m]$, then $X_T = X_S = X_m$ and there is nothing to prove in this case so it can be assumed $i \leq m - 1$. Then let $B$ be of this form.

$$\int_{A \cap [S = i]} X_T dP = \sum_{j=1}^{m} \int_{A \cap [S = i] \cap [T = j]} X_T dP$$

$$= \sum_{j=1}^{m-1} \int_{A \cap [S = i] \cap [T = j]} X_T dP + \int_{A \cap [S = i] \cap [T \geq m]} X_m dP$$

And so

$$\int_{A \cap [S = i]} X_T dP = \sum_{j=1}^{m-1} \int_{A \cap [S = i] \cap [T = j]} X_T dP + \int_{A \cap [S = i] \cap [T \geq m]} X_m dP \tag{58.3.9}$$
except repeat this process till you get the following inequality

which is exactly the same form as \( \text{OPTIMAL SAMPLING AND STOPPING TIMES} \) except \( m \) is replaced with \( m - 1 \). Now repeat this process till you get the following inequality

\[
\int_{A \cap \{S = i\}} X_T dP \geq \sum_{j=i}^{i+1} \int_{A \cap \{S = i\} \cap \{T = j\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T \geq i + 2\}} X_{i+2} dP
\]

The right hand side equals

\[
\sum_{j=i}^{i+1} \int_{A \cap \{S = i\} \cap \{T = j\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T \leq i + 1\}^C} X_{i+2} dP
\]

\[
\geq \sum_{j=i}^{i+1} \int_{A \cap \{S = i\} \cap \{T = j\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T \leq i + 1\}^C} X_{i+1} dP
\]

\[
= \int_{A \cap \{S = i\} \cap \{T = i\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T = i + 1\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T \leq i + 1\}^C} X_{i+1} dP
\]

\[
= \int_{A \cap \{S = i\} \cap \{T = i\}} X_i dP + \int_{A \cap \{S = i\} \cap \{T = i + 1\}} X_i dP + \int_{A \cap \{S = i\} \cap \{T \geq i + 1\}} X_{i+1} dP
\]

\[
= \int_{A \cap \{S = i\} \cap \{T = i\}} X_i dP + \int_{A \cap \{S = i\} \cap \{T \geq i + 1\}} X_{i+1} dP
\]

\[
= \int_{A \cap \{S = i\} \cap \{T = i\}} X_i dP + \int_{A \cap \{S = i\} \cap \{T \leq i\}^C} X_{i+1} dP
\]

provided \( m - 1 \geq i \) because \( \{X_n\} \) is a submartingale and

\[
A \cap \{S = i\} \cap \{T \leq m - 1\}^C \in \mathcal{F}_{m-1}
\]

Now combine the top term of the sum with the term on the right to obtain

\[
\int_{A \cap \{S = i\}} X_T dP = \sum_{j=i}^{m-1} \int_{A \cap \{S = i\} \cap \{T = j\}} X_T dP + \int_{A \cap \{S = i\} \cap \{T \geq m - 1\}^C} X_{m-1} dP
\]
\[ \int_{A \cap [S=i] \cap [T=i]} X_i dP + \int_{A \cap [S=i] \cap [T \leq i]^c} X_i dP = \int_{A \cap [S=i] \cap [T=i]} X_i dP + \int_{A \cap [S=i] \cap [T > i]} X_i dP = \int_{A \cap [S=i] \cap [T \geq i]} X_i dP = \int_{A \cap [S=i]} \int_{A \cap [S=i] \cap [T=i]} X_i dP = \int_{A \cap [S=i]} X_S dP \]

In the case where \( \{X_n\} \) is a martingale, you replace every occurrence of \( \geq \) in the above argument with \( = \). This proves the lemma.

This lemma is called the optional sampling theorem. Another version of this theorem is the case where you have an increasing sequence of stopping times, \( \{T_n\}_{n=1}^{\infty} \). Thus if \( \{X_n\} \) is a sequence of random variables each \( \mathcal{F}_n \) measurable, the sequence \( \{X_{T_n}\} \) is also a sequence of random variables such that \( X_{T_n} \) is measurable with respect to \( \mathcal{F}_{T_n} \) where \( \mathcal{F}_{T_n} \) is an increasing sequence of \( \sigma \) fields. In the case where \( X_n \) is a submartingale (martingale) it is reasonable to ask whether \( \{X_{T_n}\} \) is also a submartingale (martingale). The optional sampling theorem says this is often the case.

**Theorem 58.3.5** Let \( \{T_n\} \) be an increasing bounded sequence of stopping times and let \( \{X_n\} \) be a submartingale (martingale) adapted to the increasing sequence of \( \sigma \) algebras, \( \{\mathcal{F}_n\} \). Then \( \{X_{T_n}\} \) is a submartingale (martingale) adapted to the increasing sequence of \( \sigma \) algebras \( \{\mathcal{F}_{T_n}\} \).

**Proof:** This follows from Lemma 58.3.4.

**Example 58.3.6** Let \( \{X_n\} \) be a sequence of real random variables such that \( X_n \) is \( \mathcal{F}_n \) measurable and let \( A \) be a Borel subset of \( \mathbb{R} \). Let \( T(\omega) \) denote the first time \( X_n(\omega) \) is in \( A \). Then \( T \) is a stopping time. It is called the first hitting time.

To see this is a stopping time,

\[ [T \leq l] = \bigcup_{i=1}^{l} X_i^{-1}(A) \in \mathcal{F}_i. \]

### 58.4 Optional Stopping Times And Martingales

#### 58.4.1 Stopping Times And Their Properties

The purpose of this section is to consider a special optional sampling theorem for martingales which is superior to the one presented earlier. I have presented a different treatment of the fundamental properties of stopping times also. See Kallenberg [70] for more.

**Definition 58.4.1** Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \( \{\mathcal{F}_n\}_{n=1}^{\infty} \) be an increasing sequence of \( \sigma \) algebras each contained in \( \mathcal{F} \). A stopping time is a measurable function, \( \tau \) which maps \( \Omega \) to \( \mathbb{N} \),

\[ \tau^{-1}(A) \in \mathcal{F} \text{ for all } A \in \mathcal{P}(\mathbb{N}), \]
such that for all \( n \in \mathbb{N} \),

\[ [\tau \leq n] \in \mathcal{F}_n. \]

Note this is equivalent to saying

\[ [\tau = n] \in \mathcal{F}_n \]

because

\[ [\tau = n] = [\tau \leq n] \setminus [\tau \leq n - 1]. \]

For \( \tau \) a stopping time define \( \mathcal{F}_\tau \) as follows.

\[ \mathcal{F}_\tau \equiv \{ A \in \mathcal{F} : A \cap [\tau \leq n] \in \mathcal{F}_n \text{ for all } n \in \mathbb{N} \} \]

These sets in \( \mathcal{F}_\tau \) are referred to as “prior” to \( \tau \).

First note that for \( \tau \) a stopping time, \( \mathcal{F}_\tau \) is a \( \sigma \) algebra. This is in the next proposition.

**Proposition 58.4.2** For \( \tau \) a stopping time, \( \mathcal{F}_\tau \) is a \( \sigma \) algebra and if \( Y(k) \) is \( \mathcal{F}_k \) measurable for all \( k \), then

\[ \omega \to Y(\tau(\omega)) \]

is \( \mathcal{F}_\tau \) measurable.

**Proof:** Let \( A_n \in \mathcal{F}_\tau \). I need to show \( \cup_n A_n \in \mathcal{F}_\tau \). In other words, I need to show that

\[ \cup_n A_n \cap [\tau \leq k] \in \mathcal{F}_k \]

The left side equals

\[ \cup_n (A_n \cap [\tau \leq k]) \]

which is a countable union of sets of \( \mathcal{F}_k \) and so \( \mathcal{F}_\tau \) is closed with respect to countable unions. Next suppose \( A \in \mathcal{F}_\tau \).

\[ (A^C \cap [\tau \leq k]) \cup (A \cap [\tau \leq k]) = \Omega \cap [\tau \leq k] \]

and \( \Omega \cap [\tau \leq k] \in \mathcal{F}_k \). Therefore, so is \( A^C \cap [\tau \leq k] \). It remains to verify the last claim.

\[ [Y(\tau) \leq a] = \cup_k [\tau = k] \cap [Y(k) \leq a] \]

Thus

\[ [Y(\tau) \leq a] \cap [\tau \leq l] = \cup_k [\tau = k] \cap [Y(k) \leq a] \cap [\tau \leq l] \]

Consider a term in the union. If \( l \geq k \) the term reduces to \( [\tau = k] \cap [Y(k) \leq a] \in \mathcal{F}_k \) while if \( l < k \), this term reduces to \( \emptyset \), also a set of \( \mathcal{F}_k \). Therefore, \( Y(\tau) \) must be \( \mathcal{F}_\tau \) measurable. This proves the proposition.

The following lemma contains the fundamental properties of stopping times.

**Lemma 58.4.3** In the situation of Definition 58.4.1, let \( \sigma, \tau \) be two stopping times. Then
1. \( \tau \) is \( \mathcal{F}_\tau \) measurable

2. \( \mathcal{F}_\sigma \cap [\sigma \leq \tau] \subseteq \mathcal{F}_{\sigma \wedge \tau} = \mathcal{F}_\sigma \cap \mathcal{F}_\tau \)

3. \( \mathcal{F}_\tau = \mathcal{F}_k \) on \( [\tau = k] \) for all \( k \). That is if \( A \in \mathcal{F}_k \), then \( A \cap [\tau = k] \in \mathcal{F}_\tau \) and if \( A \in \mathcal{F}_\tau \), then \( A \cap [\tau = k] \in \mathcal{F}_k \). Also if \( A \in \mathcal{F}_\tau \),

\[
\int_{A \cap [\tau = k]} E (Y | \mathcal{F}_\tau) \, dP = \int_{A \cap [\tau = k]} E (Y | \mathcal{F}_k) \, dP
\]

and

\[ E (Y | \mathcal{F}_\tau) = E (Y | \mathcal{F}_k) \text{ a.e.} \]
on \( [\tau = k] \).

**Proof:** Consider the first claim. I need to show that \( [\tau \leq a] \cap [\tau \leq k] \in \mathcal{F}_k \) for every \( k \). However, this is easy if \( a \geq k \) because the left side is then \( [\tau \leq k] \) which is given to be in \( \mathcal{F}_k \) since \( \tau \) is a stopping time. If \( a < k \), it is also easy because then the left side is \( [\tau \leq a] \in \mathcal{F}_{[a]} \) where \([a]\) is the greatest integer less than or equal to \( a \).

Next consider the second claim. Let \( A \in \mathcal{F}_\sigma \). I want to show first that

\[ A \cap [\sigma \leq \tau] \in \mathcal{F}_\tau \]  \hspace{1cm} (58.4.10)

In other words, I want to show

\[ A \cap [\sigma \leq \tau] \cap [\tau \leq k] \in \mathcal{F}_k \]

for all \( k \). This will be done if I can show

\[ A \cap [\sigma \leq j] \cap [\tau \leq k] \in \mathcal{F}_k \]

for each \( j \leq k \) because

\[ \bigcup_{j \leq k} A \cap [\sigma \leq j] \cap [\tau \leq k] = A \cap [\sigma \leq \tau] \cap [\tau \leq k] \]

However, since \( \sigma \in \mathcal{F}_\sigma \), it follows \( A \cap [\sigma \leq j] \in \mathcal{F}_j \subseteq \mathcal{F}_k \) for each \( j \leq k \) and \( [\tau \leq k] \in \mathcal{F}_k \) and so this has shown what I wanted to show, \( A \cap [\sigma \leq \tau] \in \mathcal{F}_\tau \).

Now replace the stopping time, \( \tau \) with the stopping time \( \tau \wedge \sigma \) in what was just shown. Note

\[ [\tau \wedge \sigma \leq n] = [\tau \leq n] \cup [\sigma \leq n] \in \mathcal{F}_n \]

so \( \tau \wedge \sigma \) really is a stopping time. This yields

\[ A \cap [\sigma \leq \tau \wedge \sigma] \in \mathcal{F}_{\tau \wedge \sigma} \]

However the left side equals \( A \cap [\sigma \leq \tau] \). Thus

\[ A \cap [\sigma \leq \tau] \in \mathcal{F}_{\tau \wedge \sigma} \]
This has shown the first part of 2.), \( \mathcal{F}_\sigma \cap [\sigma \leq \tau] \subseteq \mathcal{F}_{\tau \wedge \sigma} \). Now \( \text{(8.4.10)} \) implies if \( A \in \mathcal{F}_{\sigma \wedge \tau} \),

\[
A = A \cap [\sigma \wedge \tau \leq \tau] \in \mathcal{F}_\tau
\]

and so \( \mathcal{F}_{\sigma \wedge \tau} \subseteq \mathcal{F}_\tau \). Similarly, \( \mathcal{F}_{\sigma \wedge \tau} \subseteq \mathcal{F}_\sigma \) which shows

\[ \mathcal{F}_{\sigma \wedge \tau} \subseteq \mathcal{F}_\tau \cap \mathcal{F}_\sigma. \]

Next let \( A \in \mathcal{F}_\tau \cap \mathcal{F}_\sigma \). Then is it in \( \mathcal{F}_{\sigma \wedge \tau} \)? Is \( A \cap [\sigma \wedge \tau \leq k] \in \mathcal{F}_k \)? Of course this is so because

\[
A \cap [\sigma \wedge \tau \leq k] = A \cap ([\sigma \leq k] \cup [\tau \leq k])
\]

\[
= (A \cap [\sigma \leq k]) \cup (A \cap [\tau \leq k]) \in \mathcal{F}_k
\]

since both \( \sigma, \tau \) are stopping times. This proves part 2.).

Now consider part 3.). Note that \([\tau = k]\) is in both \( \mathcal{F}_k \) and \( \mathcal{F}_\tau \). Let \( A \in \mathcal{F}_k \). I need to show

\[
\mathcal{F}_\tau \cap [\tau = k] = \mathcal{F}_k \cap [\tau = k]
\]

where \( \mathcal{G} \cap [\tau = k] \) means all sets of the form \( A \cap [\tau = k] \) where \( A \in \mathcal{G} \). Let \( A \in \mathcal{F}_\tau \). Then

\[
A \cap [\tau = k] = (A \cap [\tau \leq k]) \setminus (A \cap [\tau \leq k - 1]) \in \mathcal{F}_k
\]

Therefore, there exists \( B \in \mathcal{F}_k \) such that \( B = A \cap [\tau = k] \) and so

\[
B \cap [\tau = k] = A \cap [\tau = k]
\]

which shows \( \mathcal{F}_\tau \cap [\tau = k] \subseteq \mathcal{F}_k \cap [\tau = k] \). Now let \( A \in \mathcal{F}_k \) so that

\[
A \cap [\tau = k] \in \mathcal{F}_k \cap [\tau = k]
\]

Then

\[
A \cap [\tau = k] \cap [\tau \leq j] \in \mathcal{F}_j
\]

because in case \( j < k \), the set on the left is \( \emptyset \) and if \( j \geq k \) it reduces to \( A \cap [\tau = k] \) and both \( A \) and \( [\tau = k] \) are in \( \mathcal{F}_k \subseteq \mathcal{F}_j \). Therefore, the two \( \sigma \) algebras of subsets of \( [\tau = k] \),

\[
\mathcal{F}_\tau \cap [\tau = k], \mathcal{F}_k \cap [\tau = k]
\]

are equal. Thus for \( A \) in either \( \mathcal{F}_\tau \) or \( \mathcal{F}_k \), \( A \cap [\tau = k] \) is a set of both \( \mathcal{F}_\tau \) and \( \mathcal{F}_k \) because if \( A \in \mathcal{F}_k \), then from the above, there exists \( B \in \mathcal{F}_\tau \) such that

\[
A \cap [\tau = k] = B \cap [\tau = k] \in \mathcal{F}_\tau
\]

with similar reasoning holding if \( A \in \mathcal{F}_\tau \). In other words, if \( g \) is \( \mathcal{F}_\tau \) or \( \mathcal{F}_k \) measurable, then the restriction of \( g \) to \( [\tau = k] \) is measurable with respect to \( \mathcal{F}_\tau \cap [\tau = k] \) and \( \mathcal{F}_k \cap [\tau = k] \). Let \( Y \) be an arbitrary random variable in \( L^1(\Omega, \mathcal{F}) \). It follows

\[
\int_{A \cap [\tau = k]} E(Y | \mathcal{F}_\tau) \, dP = \int_{A \cap [\tau = k]} Y \, dP = \int_{A \cap [\tau = k]} E(Y | \mathcal{F}_k) \, dP
\]
Since this holds for an arbitrary set in $\mathcal{F}_\tau \cap [\tau = k] = \mathcal{F}_k \cap [\tau = k]$, it follows

$$E (Y | \mathcal{F}_\tau) = E (Y | \mathcal{F}_k) \text{ a.e. on } [\tau = k]$$

This proves the third claim and the Lemma.

With this lemma, here is a major theorem, the optional sampling theorem of Doob. This one is special for martingales.

**Theorem 58.4.4** Let $\{M (k)\}$ be a real valued martingale with respect to the increasing sequence of $\sigma$-algebras, $\{\mathcal{F}_k\}$ and let $\sigma, \tau$ be two stopping times such that $\tau$ is bounded. Then $M (\tau)$ defined as

$$\omega \rightarrow M (\tau (\omega))$$

is integrable and

$$M (\sigma \wedge \tau) = E (M (\tau) | \mathcal{F}_\sigma).$$

**Proof:** By Proposition $\mathbb{MLX}$, $M (\tau)$ is $\mathcal{F}_\tau$ measurable.

Next note that since $\tau$ is bounded by some $l$,

$$\int_\Omega \|M (\tau (\omega))\| \, dP \leq \sum_{i=1}^l \int_{[\tau = i]} \|M (i)\| \, dP < \infty.$$  

This proves the first assertion and makes possible the consideration of conditional expectation.

Let $l \geq \tau$ as described above. Then for $k \leq l$, by Lemma $\mathbb{MLX}$,

$$\mathcal{F}_k \cap [\tau = k] = \mathcal{F}_\tau \cap [\tau = k] \equiv \mathcal{G}$$

implying that if $g$ is either $\mathcal{F}_k$ measurable or $\mathcal{F}_\tau$ measurable, then its restriction to $[\tau = k]$ is $\mathcal{G}$ measurable and so if $A \in \mathcal{F}_k \cap [\tau = k] = \mathcal{F}_\tau \cap [\tau = k]$,

$$\int_A E (M (l) | \mathcal{F}_\tau) \, dP = \int_A M (l) \, dP$$

$$= \int_A E (M (l) | \mathcal{F}_k) \, dP$$

$$= \int_A M (k) \, dP$$

$$= \int_A M (\tau) \, dP \text{ (on } A, \tau = k)$$

Therefore, since $A$ was arbitrary,

$$E (M (l) | \mathcal{F}_\tau) = M (\tau) \text{ a.e.}$$

on $[\tau = k]$ for every $k \leq l$. It follows

$$E (M (l) | \mathcal{F}_\tau) = M (\tau) \text{ a.e.} \quad (58.4.11)$$
since it is true on each $[\tau = k]$ for all $k \leq l$.

Now consider $E(M(\tau) | F_\sigma)$ on the set $[\sigma = i] \cap [\tau = j]$. By Lemma 58.4.3 on this set,

$$E(M(\tau) | F_\sigma) = E(M(\tau) | F_i) = E(E(M(l) | F_\tau) | F_i) = E(E(M(l) | F_j) | F_i)$$

If $j \leq i$, this reduces to

$$E(M(l) | F_j) = M(j) = M(\sigma \wedge \tau).$$

If $j > i$, this reduces to

$$E(M(l) | F_i) = M(i) = M(\sigma \wedge \tau)$$

and since this exhausts all possibilities for values of $\sigma$ and $\tau$, it follows

$$E(M(\tau) | F_\sigma) = M(\sigma \wedge \tau) \text{ a.e.}$$

This proves the theorem.

This is a really amazing theorem. Note it says $M(\sigma \wedge \tau) = E(M(\tau) | F_\sigma)$. This would not be so surprising if it had said

$$M(\sigma \wedge \tau) = E(M(\tau) | F_{\sigma \wedge \tau}).$$

What about submartingales? Recall $\{X(k)\}_{k=1}^\infty$ is a submartingale if

$$E(X(k+1) | F_k) \geq X(k)$$

where the $F_k$ are an increasing sequence of $\sigma$ algebras in the usual way. The following is a very interesting result.

**Lemma 58.4.5** Let $\{X(k)\}_{k=0}^\infty$ be a submartingale adapted to the increasing sequence of $\sigma$ algebras, $\{F_k\}$. Then there exists a unique increasing process $\{A(k)\}_{k=0}^\infty$ such that $A(0) = 0$ and $A(k+1)$ is $F_k$ measurable for all $k$ and a martingale, $\{M(k)\}_{k=0}^\infty$ such that

$$X(k) = A(k) + M(k).$$

Furthermore, for $\tau$ a stopping time, $A(\tau)$ is $F_\tau$ measurable.

**Proof:** Define $\sum_{k=0}^{n-1} \neq 0$. First consider the uniqueness assertion. Suppose $A$ is a process which does what is supposed to do.

$$\sum_{k=0}^{n-1} E(X(k+1) - X(k) | F_k) = \sum_{k=0}^{n-1} E(A(k+1) - A(k) | F_k)$$

$$+ \sum_{k=0}^{n-1} E(M(k+1) - M(k) | F_k)$$
Then since \( \{M(k)\} \) is a martingale,
\[
\sum_{k=0}^{n-1} E(X(k+1) - X(k) | \mathcal{F}_k) = \sum_{k=0}^{n-1} A(k + 1) - A(k) = A(n)
\]
This shows uniqueness and gives a formula for \( A(n) \) assuming it exists. It is only a matter of verifying this does work. Define
\[
A(n) = \sum_{k=0}^{n-1} E(X(k+1) - X(k) | \mathcal{F}_k), \quad A(0) = 0.
\]
Then \( A \) is increasing because from the definition,
\[
A(n + 1) - A(n) = E(X(n + 1) - X(n) | \mathcal{F}_n) \geq 0.
\]
Also from the definition above, \( A(n) \) is \( \mathcal{F}_{n-1} \) measurable, consider
\[
\{X(k) - A(k)\}.
\]
Why is this a martingale?
\[
E(X(k+1) - A(k+1) | \mathcal{F}_k) = E(X(k+1) | \mathcal{F}_k) - A(k+1)
\]
\[
= E(X(k+1) | \mathcal{F}_k) - \sum_{j=0}^{k} E(X(j+1) - X(j) | \mathcal{F}_j)
\]
\[
= E(X(k+1) | \mathcal{F}_k) - E(X(k+1) - X(k) | \mathcal{F}_k) - \sum_{j=0}^{k-1} E(X(j+1) - X(j) | \mathcal{F}_j)
\]
\[
= X(k) - \sum_{j=0}^{k-1} E(X(j+1) - X(j) | \mathcal{F}_j) = X(k) - A(k)
\]
Let \( M(k) \equiv X(k) - A(k) \). \( A(\tau) \) is \( \mathcal{F}_\tau \) measurable by Proposition 60.6.3.

Note the nonnegative integers could be replaced with any finite set or ordered countable set of numbers with no change in the conclusions of this lemma or the above optional sampling theorem.

Next consider the case of a submartingale.

**Theorem 58.4.6** Let \( \{X(k)\} \) be a submartingale with respect to the increasing sequence of \( \sigma \) algebras, \( \{\mathcal{F}_k\} \) and let \( \sigma, \tau \) be two stopping times such that \( \tau \) is bounded. Then \( X(\tau) \) defined as
\[
\omega \to X(\tau(\omega))
\]
is integrable and
\[
X(\sigma \land \tau) \leq E(X(\tau) | \mathcal{F}_\sigma).
\]
58.5. **Submartingale Convergence Theorem**

**Proof:** The claim about \( X(\tau) \) being integrable is the same as in Theorem 60.6.5.

If \( \tau \leq l \),

\[
E\left( |X(\omega)| \right) = \sum_{i=1}^{l} \int_{[\tau=i]} |X(i)| \, dP < \infty
\]

By Lemma 58.4.5 there is a martingale, \( \{ M(k) \} \) and an increasing process \( \{ A(k) \} \) such that \( A(k+1) \) is \( \mathcal{F}_k \) measurable such that

\[
X(k) = M(k) + A(k).
\]

Then using Theorem 60.6.5 on the martingale and the fact \( A \) is increasing

\[
E\left( X(\tau) \middle| \mathcal{F}_\sigma \right) = E\left( M(\tau) + A(\tau) \middle| \mathcal{F}_\sigma \right) = M(\tau \wedge \sigma) + E( A(\tau \wedge \sigma) \middle| \mathcal{F}_\sigma )
\]

\[
\geq M(\tau \wedge \sigma) + E( A(\tau \wedge \sigma) \middle| \mathcal{F}_\sigma )
\]

\[
= M(\tau \wedge \sigma) + A(\tau \wedge \sigma) = X(\tau \wedge \sigma).
\]

because in the above, it follows from Lemma 58.4.5, \( A(\tau \wedge \sigma) \) is \( \mathcal{F}_{\tau \wedge \sigma} \) measurable and from Lemma 60.6.4, \( \mathcal{F}_{\tau \wedge \sigma} = \mathcal{F}_\tau \cap \mathcal{F}_\sigma \subseteq \mathcal{F}_\sigma \)

and so

\[
E( A(\tau \wedge \sigma) \middle| \mathcal{F}_\sigma ) = A(\tau \wedge \sigma).
\]

### 58.5.1 Upcrossings

Let \( \{ X(k) \} \) be an adapted stochastic process, \( k = 0, 1, 2, \ldots, M \) adapted to the increasing \( \sigma \) algebras \( \mathcal{F}_k \). Also let \( [a, b] \) be an interval. An upcrossing occurs when \( X(k) < a \) and you have \( X(k+l) > b \) while \( X(r) < b \) for all \( r \in [k, k+l-1] \).

In order to understand upcrossings, consider the following:

\[
\tau_0 = \min \left( \inf \left\{ k : X(k) \leq a \right\}, M \right),
\]

\[
\tau_1 = \min \left( \inf \left\{ k : (X(k \vee \tau_0) - X(\tau_0))_+ \geq b - a \right\}, M \right),
\]

\[
\tau_2 = \min \left( \inf \left\{ k : (X(\tau_1) - X(k))_+ \geq b - a \right\}, M \right),
\]

\[
\tau_3 = \min \left( \inf \left\{ k : (X(k \vee \tau_2) - X(\tau_2))_+ \geq b - a \right\}, M \right),
\]

\[
\tau_4 = \min \left( \inf \left\{ k : (X(\tau_3) - X(k))_+ \geq b - a \right\}, M \right),
\]

\[
\vdots
\]

As usual, \( \inf (\emptyset) \equiv \infty \). Are the above stopping times? If \( \alpha \geq 0 \), and \( \tau \) is a stopping time, is \( k \rightarrow (X(\tau) - X(k \vee \tau))_+ \) adapted?

\[
[(X(\tau) - X(k \vee \tau))_+ > \alpha] = [(X(\tau) - X(k))_+ > \alpha] \cap [\tau \leq k]
\]
Now

\[ ((X(\tau) - X(k))_+ > a) \cap [\tau \leq k] = \bigcup_{i=0}^{k} ((X(i) - X(k))_+ > a) \cap [\tau \leq k] \in \mathcal{F}_k \]

If \( \alpha < 0 \), then \( ((X(\tau_1) - X(k \vee \tau_1))_+ > a) = \Omega \) and so \( k \to (X(\tau) - X(k \vee \tau))_+ \) is adapted. Similarly \( k \to (X(k \vee \tau) - X(\tau))_+ \) is adapted. Therefore, all those \( \tau_k \) are stopping times.

Now consider the following random variable for odd \( M, 2n + 1 = M \)

\[ U_M^{[a,b]} = \lim_{\varepsilon \to 0} \sum_{k=0}^{n} \frac{X(\tau_{2k+1}) - X(\tau_{2k})}{\varepsilon + X(\tau_{2k+1}) - X(\tau_{2k})} \leq \frac{1}{b-a} \sum_{k=0}^{n} X(\tau_{2k+1}) - X(\tau_{2k}) \]

Now suppose \( \{X(k)\} \) is a nonnegative submartingale. Then since \( E(X(2\tau) | \mathcal{F}_{2\tau-1}) \geq X(\tau_{2\tau-1}) \)

\[ E \left( \sum_{k=1}^{n} X(\tau_{2k}) - X(\tau_{2k-1}) \right) \geq 0 \]

Hence

\[ E \left( U_M^{[a,b]} \right) \leq \frac{1}{b-a} \sum_{k=0}^{n} E(X(\tau_{2k+1}) - X(\tau_{2k})) \]

\[ \leq \frac{1}{b-a} \sum_{k=0}^{n} E(X(\tau_{2k+1}) - X(\tau_{2k})) + \frac{1}{b-a} \sum_{k=1}^{n} E(X(\tau_{2k}) - X(\tau_{2k-1})) \]

\[ = \frac{1}{b-a} \sum_{k=0}^{n} E(X(\tau_k) - X(\tau_{k-1})) \leq \frac{1}{b-a} E(X(M)) \]

Now by the optional sampling theorem \( X(0), X(\tau_k), X(M) \) is a submartingale. Therefore, the above is no larger than

\[ \frac{1}{b-a} E(|X(M)|) \]

Now note that \( U_M^{[a,b]} \) is at least as large as the number of upcrossings of \( \{X(k)\} \) for \( k \leq M \). This is because every time an upcrossing occurs, it will follow that \( X(\tau_{2k+1}) - X(\tau_{2k}) > 0 \) and so a one will occur in the above sum which defines \( U_M^{[a,b]} \). However, this might be larger than the number of upcrossings. The above discussion has proved the following upcrossing lemma.

**Lemma 58.5.1** Let \( \{X(k)\} \) be a nonnegative submartingale. Let

\[ U_M^{[a,b]} = \lim_{\varepsilon \to 0} \sum_{k=0}^{n} \frac{X(\tau_{2k+1}) - X(\tau_{2k})}{\varepsilon + X(\tau_{2k+1}) - X(\tau_{2k})}, \quad 2n + 1 = M \]

Then

\[ E \left( U_M^{[a,b]} \right) \leq \frac{1}{b-a} E(X(M)) \]
Suppose that there exists a constant $C \geq E(X(M))$ for all $M$. That is, $\{X(k)\}$ is bounded in $L^1(\Omega)$. Then letting

$$U^{[a,b]} = \lim_{M \to \infty} U_{M}^{[a,b]},$$

it follows that

$$E\left(U^{[a,b]}\right) \leq C \frac{1}{b-a}$$

The second half follows from the first part and the monotone convergence theorem.

Now with this estimate, it is easy to prove the submartingale convergence theorem.

**Theorem 58.5.2** Let $\{X(k)\}$ be a submartingale which is bounded in $L^1(\Omega)$,

$$\|X(k)\|_{L^1(\Omega)} \leq C$$

Then there is a set of measure zero $N$ such that for $\omega \notin N$, $\lim_{k \to \infty} X(k) (\omega)$ exists. If $X(\omega) = \lim_{k \to \infty} X(k) (\omega)$, then $X \in L^1(\Omega)$.

**Proof:** Let $a < b$ and consider the submartingale $(X(k) - a)_+$. Let $U^{[0,b-a]}$ be the random variable of the above lemma which is associated with this submartingale. Thus

$$E\left(U^{[0,b-a]}\right) \leq \frac{C}{b-a}$$

It follows that $U^{[0,b-a]}$ is finite for a.e. $\omega$. As noted above, $U^{[0,b-a]}$ is an upper bound to the number of upcrossings of $(X(k) - a)_+$ and each of these corresponds to an upcrossing of $[a,b]$ by $X(k)$. Thus for all $\omega \notin N_{a,b}$ where $P(N_{a,b}) = 0$, it follows that

$$U^{[0,b-a]} < \infty.$$  

If $\lim_{k \to \infty} X(k) (\omega)$ fails to exist, then there exists $a < b$ both rational such that

$$\lim_{k \to \infty} \sup X(k) > b > a > \lim_{k \to \infty} \inf X(k)$$

Thus $\omega \in N_{a,b}$ because there are infinitely many upcrossings of $[a,b]$. Let $N = \cup \{N_{a,b} : a, b \in \mathbb{Q}\}$. Then for $\omega \notin N$, the limit just discussed must exist. Letting $X(\omega) = \lim_{k \to \infty} X(k) (\omega)$ for $\omega \notin N$ and letting $X(\omega) = 0$ on $N$, it follows from Fatou’s lemma that $X$ is in $L^1(\Omega)$.

58.5.2 Maximal Inequalities

Next I will show that stopping times and the optional sampling theorem, Lemma 58.3.4, can be used to establish maximal inequalities for submartingales very easily.
Lemma 58.5.3 Let \( \{X(k)\} \) be real valued and adapted to the increasing sequence of \( \sigma \) algebras \( \{F_k\} \). Let
\[
T(\omega) \equiv \inf \{k : X(k) \geq \lambda\}
\]
Then \( T \) is a stopping time. Similarly,
\[
T(\omega) \equiv \inf \{k : X(k) \leq \lambda\}
\]
is a stopping time.

**Proof:** Is \( [T \leq p] \in F_p \) for all \( p \)?
\[
[T = p] = \bigcap_{i=1}^{p-1} [X(i) < \lambda] \cap [X(p) \geq \lambda]
\]
Therefore,
\[
[T \leq p] = \bigcup_{i=1}^{p} \{T = i\} \in F_p
\]

Theorem 58.5.4 Let \( \{X_k\} \) be a real valued submartingale with respect to the \( \sigma \) algebras \( \{F_k\} \). Then for \( \lambda > 0 \)
\[
\lambda P\left( \left[ \max_{1 \leq k \leq n} X_k \geq \lambda \right] \right) \leq E\left( X_n^+ \right), \tag{58.5.12}
\]
\[
\lambda P\left( \left[ \min_{1 \leq k \leq n} X_k \leq -\lambda \right] \right) \leq E\left( |X_n| + |X_1| \right), \tag{58.5.13}
\]
\[
\lambda P\left( \left[ \max_{1 \leq k \leq n} |X_k| \geq \lambda \right] \right) \leq 2E\left( |X_n| + |X_1| \right). \tag{58.5.14}
\]

**Proof:** Let \( T(\omega) \) be the first time \( X_k(\omega) \) is \( \geq \lambda \) or if this does not happen for \( k \leq n \), then \( T(\omega) \equiv n \). Thus
\[
T(\omega) \equiv \min(\min \{k : X_k(\omega) \geq \lambda\}, n)
\]
Note
\[
[T > k] = \bigcap_{i=1}^{k} [X_i < \lambda] \in F_k
\]
and so the complement, \( [T \leq k] \) is also in \( F_k \) which shows \( T \) is indeed a stopping time.

Then \( 1, T(\omega), n \) are stopping times, \( 1 \leq T(\omega) \leq n \). Therefore, from the optional sampling theorem, Lemma 58.3.4, \( X_1, X_T, X_n \) is a submartingale. It follows
\[
E(X_n) \geq E(X_T) = \int_{[\max_k X_k \geq \lambda]} X_TdP + \int_{[\max_k X_k < \lambda]} X_TdP
\]
\[
= \int_{[\max_k X_k \geq \lambda]} X_TdP + \int_{[\max_k X_k < \lambda]} X_n dP
\]
and so, subtracting the last term on the right from both sides,

\[ E(X_n^+) \geq \int_{[\max_k X_k \geq \lambda]} X_n dP = \int_{[\max_k X_k \geq \lambda]} X_T dP \geq \lambda P\left(\max_k X_k \geq \lambda\right) \]

because \( X_T(\omega) \geq \lambda \) on \([\max_k X_k \geq \lambda]\) from the definition of \( T \). This establishes 58.5.12.

Next let \( T(\omega) \) be the first time \( X_k(\omega) \) is \( \leq -\lambda \) or if this does not happen for \( k \leq n \), then \( T(\omega) \equiv n \). Then this is a stopping time by similar reasoning and \( 1 \leq T(\omega) \leq n \) are stopping times and so by the optional stopping theorem, \( X_1, X_T, X_n \) is a submartingale. Therefore, on

\[ \left[ \min_k X_k \leq -\lambda \right], \quad X_T(\omega) \leq -\lambda \]

and \( E(X_T|\mathcal{F}_1) \geq X_1 \) and so

\[ E(X_1) \leq E(E(X_T|\mathcal{F}_1)) = E(X_T) \]

which implies

\[ E(X_1) \leq E(X_T) = \int_{[\min_k X_k \leq -\lambda]} X_T dP + \int_{[\min_k X_k > -\lambda]} X_T dP = \int_{[\min_k X_k \leq -\lambda]} X_T dP + \int_{[\min_k X_k > -\lambda]} X_n dP \]

and so

\[ E(X_1) - \int_{[\min_k X_k > -\lambda]} X_n dP \leq \int_{[\min_k X_k \leq -\lambda]} X_T dP \leq -\lambda P\left(\min_k X_k \leq -\lambda\right) \]

which implies

\[ \lambda P\left(\min_k X_k \leq -\lambda\right) \leq \int_{[\min_k X_k > -\lambda]} X_n dP - E(X_1) \leq \int_{\Omega} (|X_n| + |X_1|) dP \]

and this proves 58.5.13.

The last estimate follows from these. Here is why.

\[ \left(\max_{1 \leq k \leq n} |X_k| \geq \lambda\right) \subseteq \left[\max_{1 \leq k \leq n} X_k \geq \lambda\right] \cup \left[\min_{1 \leq k \leq n} X_k \leq -\lambda\right] \]
and so
\[
\lambda P\left(\max_{1 \leq k \leq n} |X_k| \geq \lambda \right) \leq \lambda P\left(\max_{1 \leq k \leq n} X_k \geq \lambda \right) \cup \min_{1 \leq k \leq n} X_k \leq -\lambda \right) 
\]
\[
\leq \lambda P\left(\max_{1 \leq k \leq n} X_k \geq \lambda \right) + \lambda P\left(\min_{1 \leq k \leq n} X_k \leq -\lambda \right) 
\]
\[
\leq 2E (|X_1| + |X_n|)
\]
and this proves the last estimate.

58.5.3 The Upcrossing Estimate

A very interesting example of stopping times is next. It has to do with upcrossings. First here is a lemma.

**Lemma 58.5.5** Let \( \{F_k\} \) be an increasing sequence of \( \sigma \) algebras and let \( \{X (k)\} \) be adapted to this sequence. Suppose that \( X (k) \) has all values in \([a, b]\) and suppose \( \sigma \) is a stopping time with the property that \( X (\sigma) = a \). Let \( \tau (\omega) \) be the first \( k > \sigma \) such that \( X (k) = b \). If no such \( k \) exists, then \( \tau \equiv \infty \). Then \( \tau \) is a stopping time. Also, you can switch \( a, b \) in the above and obtain the same conclusion that \( \tau \) is a stopping time.

**Proof:** Let \( I \) be an interval and consider \( X (k \lor \sigma) \). Is \( k \rightarrow X (k \lor \sigma) \) adapted? Let \( I \) be an interval. Is
\[
A \equiv X (k \lor \sigma)^{-1} (I) \in F_k
\]
We know that this set is in \( F_{k\lor\sigma} \).
\[
A = A \cap [\sigma \leq k] \cup \left( X (k \lor \sigma)^{-1} (I) \cap [\sigma > k] \right)
\]
(♠)

Consider the second set in ♥. There are two cases, \( a \in I \) and \( a \notin I \). First suppose \( a \notin I \). Then if \( \omega \in [\sigma > k] \), it follows that \( X (k \lor \sigma) = X (\sigma) = a \). Therefore, in this case, the set on the right in ♥ is empty and the empty set is in \( F_k \). Next suppose \( a \in I \). Then for \( \omega \in [\sigma > k] \),
\[
X (k \lor \sigma (\omega)) = X (\sigma (\omega)) = a \in I
\]
and so each \( \omega \in [\sigma > k] \) is in the set \( X (k \lor \sigma)^{-1} (I) \) and so, in this case, the set on the right equals
\[
[\sigma > k] \in F_k
\]
Now consider the first set in ♥,
\[
A \cap [\sigma \leq k] = A \cap [\sigma \lor k \leq k] \in F_k
\]
by the definition of what it means for the set \( A \) to be in \( F_{k\lor\sigma} \). The argument proceeds in the same way when you switch \( a, b \).
Definition 58.5.6 Let \( \{X_k\} \) be a sequence of random variables adapted to the increasing sequence of \( \sigma \) algebras, \( \{\mathcal{F}_k\} \). Let \([a,b]\) be an interval. An upcrossing is a sequence \( X_n (\omega), \ldots, X_{n+p} (\omega) \) such that \( X_n (\omega) \leq a, X_{n+i} (\omega) < b \) for \( i < p \), and \( X_{n+p} (\omega) \geq b \).

Example 58.5.7 Let \( \{\mathcal{F}_n\} \) be an increasing sequence of \( \sigma \) algebras contained in \( \mathcal{F} \) where \((\Omega, \mathcal{F}, P)\) is a probability space and let \( \{X_n\} \) be a sequence of real valued random variables such that \( X_n \) is \(\mathcal{F}_n\) measurable. Also let \( a < b \). Define

\[
T_0 = \inf \{ n : X(n) \leq a \}
\]

\[
T_1 = \inf \{ n > T_0 : X(n) \geq b \}
\]

\[
T_2 = \inf \{ n > T_1 : X(n) \leq a \}
\]

...\[
T_{2k-2} = \inf \{ n > T_{2k-3} : X(n) \geq b \}
\]

\[
T_{2k} = \inf \{ n > T_{2k-1} : X(n) \leq a \}
\]

If \( X_n(\omega) \) is never in the desired interval for any \( n > T_j(\omega) \), then define \( T_{j+1}(\omega) = \infty \). Then this is an increasing sequence of stopping times.

It happens that the above gives an increasing sequence of stopping times.

Lemma 58.5.8 The above example gives an increasing sequence of stopping times.

Proof: You could consider the modified random variables

\[
Y(k) = (X(k) \vee a) \wedge b
\]

Then these new random variables stay in \([a,b]\) and if you replace \( X(n) \) in the above with \( Y(n) \), you get the same sequence of stopping times. Now apply Lemma 58.5.6.

Now there is an interesting application of these stopping times to the concept of upcrossings. Let \( \{X_n\} \) be a submartingale such that \( X_n \) is \(\mathcal{F}_n\) measurable and let \( a < b \). Assume \( X_0(\omega) \leq a \). The function, \( x \to (x-a)^+ \) is increasing and convex so \( \{(X_n-a)^+\} \) is also a submartingale. Furthermore, \( \{X_n\} \) goes from \( \leq a \) to \( \geq b \) if and only if \( \{(X_n - a)^+\} \) goes from \( 0 \) to \( \geq b -a \). That is, a subsequence of the form \( Y_n(\omega), Y_{n+1}(\omega), \ldots, Y_{n+r}(\omega) \) for \( Y \) equal to either \( X \) or \( (X-a)^+ \) starts out below \( a \) \((0)\) and ends up above \( b \) \((b-a)\). Such a sequence is called an upcrossing of \([a,b]\). The idea is to estimate the expected number of upcrossings for \( n \leq N \). For the stopping times defined in Example 58.5.7, let \( T_k' = \min(T_k, N) \). Thus \( T_k' \) a continuous function of the stopping time, is also a stopping time which is bounded. Moreover, \( T_k' \leq T_{k+1}' \). Now pick \( n \) such that \( 2n > N \). Then for each \( \omega \in \Omega \)

\[
(X_N(\omega) - a)^+ - (X_0(\omega) - a)^+
\]
must equal the sum of all successive terms of the form
\[
\left( (X_{T_{k+1}}(\omega) - a)^+ - (X_{T_k}(\omega) - a)^+ \right)
\]
for \( k = 1, 2, \cdots, 2n \). This is because \( \{T_k(\omega)\} \) is a strictly increasing sequence which starts with 0 due to the assumption \( X_0(\omega) \leq a \) and ends with \( N < 2n \). Therefore,
\[
(X_N - a)^+ - (X_0 - a)^+ = \sum_{k=1}^{2n} \left( (X_{T_k'} - a)^+ - (X_{T_{k-1}'} - a)^+ \right)
\]
which due to the definition of \( X_T \) is a submartingale and so
\[
\sum_{k=0}^{n-1} \left( (X_{T_{2k+1}} - a)^+ - (X_{T_{2k}} - a)^+ \right) + \sum_{k=1}^{n} \left( (X_{T_{2k}} - a)^+ - (X_{T_{2k-1}} - a)^+ \right).
\]
Now denote by \( U^N_{[a,b]} \) the number of upcrossings. When \( T'_k \) is such that \( k \) is odd, \( (X_{T'_k} - a)^+ \) is above \( b - a \) and when \( k \) is even, it equals 0. Therefore, in the first sum \( X_{T_{2k+1}} - X_{T_{2k}} \geq b - a \) and there are \( U^N_{[a,b]} \) terms which are nonzero in this sum. (Note this might not be \( n \) because many of the terms in the sum could be 0 due to the definition of \( T'_k \).) Hence
\[
(X_N - a)^+ - (X_0 - a)^+ = (X_N - a)^+
\]
\[
\geq (b - a) U^N_{[a,b]} + \sum_{k=1}^{n} \left( (X_{T_{2k}} - a)^+ - (X_{T_{2k-1}} - a)^+ \right). \quad (58.5.15)
\]
Now \( U^N_{[a,b]} \) is a random variable. To see this, let \( Z_k(\omega) = 1 \) if \( T_{2k+1}' > T_{2k}' \) and 0 otherwise. Thus \( U^N_{[a,b]}(\omega) = \sum_{k=0}^{n-1} Z_k(\omega) \). Therefore, it makes sense to take the expected value of both sides of (58.5.15). By the optional sampling theorem,
\[
\left\{ (X_{T'_k} - a)^+ \right\}
\]
is a submartingale and so
\[
E \left( (X_{T_{2k}} - a)^+ - (X_{T_{2k-1}} - a)^+ \right)
\]
\[
= \int_{\Omega} E \left( (X_{T_{2k}} - a)^+ | \mathcal{F}_{T_{2k-1}} \right) dP - \int_{\Omega} (X_{T_{2k-1}} - a)^+ dP \geq 0.
\]
Therefore,
\[
E \left( (X_N - a)^+ \right) \geq (b - a) E \left( U^N_{[a,b]} \right). \quad (58.5.16)
\]
This proves most of the following fundamental upcrossing estimate.

**Theorem 58.5.9** Let \( \{X_n\} \) be a real valued submartingale such that \( X_n \) is \( \mathcal{F}_n \) measurable. Then letting \( U^N_{[a,b]} \) denote the upcrossings of \( \{X_n\} \) from a to b for \( n \leq N \),
\[
E \left( U^N_{[a,b]} \right) \leq \frac{1}{b-a} E \left( (X_N - a)^+ \right).
\]
58.6. THE SUBMARTINGALE CONVERGENCE THEOREM

Proof: The estimate was based on the assumption that $X_0(\omega) \leq a$. If this is not so, modify $X_0$. Change it to $\min(X_0, a)$. Then the inequality holds for the modified submartingale which has at least as many upcrossings. Therefore, the inequality remains. $
abla$

Note this theorem holds if the submartingale starts at the index 1 rather than 0. Just adjust the argument.

58.6 The Submartingale Convergence Theorem

With this estimate it is now possible to prove the amazing submartingale convergence theorem.

Theorem 58.6.1 Let $\{X_n\}$ be a real valued submartingale such that

$$E(|X_n|) < M$$

for all $n$. Then there exists $X \in L^1(\Omega, F)$ such that $X_n(\omega)$ converges to $X(\omega)$ a.e. $\omega$ and $X \in L^1(\Omega)$.

Proof: Let $a < b$ be two rational numbers. From Theorem it follows that for all $N$,

$$\int_{\Omega} U_{[a,b]}^N dP \leq \frac{1}{b-a} E((X_N - a)^+)$$

$$\leq \frac{1}{b-a} (E(|X_N|) + |a|) \leq \frac{M + |a|}{b-a}.$$

Therefore, letting $N \to \infty$, it follows that for a.e. $\omega$, there are only finitely many upcrossings of $[a,b]$. Denote by $S_{[a,b]}$ the exceptional set. Then letting $S \equiv \cup_{a,b \in Q} S_{[a,b]}$, it follows that $P(S) = 0$ and for $\omega \not\in S, \{X_n(\omega)\}$ is a Cauchy sequence because if

$$\limsup_{n \to \infty} X_n(\omega) > \liminf_{n \to \infty} X_n(\omega)$$

then you can pick $\liminf_{n \to \infty} X_n(\omega) < a < b < \limsup_{n \to \infty} X_n(\omega)$ with $a,b$ rational and conclude $\omega \in S_{[a,b]}$.

Let $X(\omega) = \lim_{n \to \infty} X_n(\omega)$ if $\omega \not\in S$ and let $X(\omega) = 0$ if $\omega \in S$. Then it only remains to verify $X \in L^1(\Omega)$. Since $X$ is the pointwise limit of measurable functions, it follows $X$ is measurable. By Fatou’s lemma,

$$\int_{\Omega} |X(\omega)| dP \leq \liminf_{n \to \infty} \int_{\Omega} |X_n(\omega)| dP$$

Thus $X \in L^1(\Omega)$. This proves the theorem.

As a simple application, here is an easy proof of a nice theorem about convergence of sums of independent random variables.
Theorem 58.6.2 Let \( \{X_k\} \) be a sequence of independent real valued random variables such that \( E(|X_k|) < \infty, E(X_k) = 0 \), and
\[
\sum_{k=1}^{\infty} E(X_k^2) < \infty.
\]
Then \( \sum_{k=1}^{\infty} X_k \) converges a.e.

**Proof:** Let \( \mathcal{F}_n \equiv \sigma(X_1, \ldots, X_n) \). Consider \( S_n \equiv \sum_{k=1}^{n} X_k \).
\[
E(S_{n+1}|\mathcal{F}_n) = S_n + E(X_{n+1}|\mathcal{F}_n).
\]
Letting \( A \in \mathcal{F}_n \) it follows from independence that
\[
\int_A E(X_{n+1}|\mathcal{F}_n) \, dP = \int_A X_{n+1} \, dP = \int_\Omega X_A X_{n+1} \, dP = P(A) \int_\Omega X_{n+1} \, dP = 0
\]
and so \( E(X_{n+1}|\mathcal{F}_n) = 0 \). Therefore, \( \{S_n\} \) is a martingale. Now using independence again,
\[
E(|S_n|) \leq E(|S_n^2|) = \sum_{k=1}^{n} E(X_k^2) \leq \sum_{k=1}^{\infty} E(X_k^2) < \infty
\]
and so \( \{S_n\} \) is an \( L^1 \) bounded martingale. Therefore, it converges a.e. and this proves the theorem.

**Corollary 58.6.3** Let \( \{X_k\} \) be a sequence of independent real valued random variables such that \( E(|X_k|) < \infty, E(X_k) = m_k \), and
\[
\sum_{k=1}^{\infty} E\left(|X_k - m_k|^2\right) < \infty.
\]
Then \( \sum_{k=1}^{\infty} (X_k - m_k) \) converges a.e.

This can be extended to the case where the random variables have values in a separable Hilbert space.

Theorem 58.6.4 Let \( \{X_k\} \) be a sequence of independent \( H \) valued random variables where \( H \) is a real separable Hilbert space such that \( E(|X_k|_H) < \infty, E(X_k) = 0 \), and
\[
\sum_{k=1}^{\infty} E\left(|X_k|_H^2\right) < \infty.
\]
Then \( \sum_{k=1}^{\infty} X_k \) converges a.e.
Proof: Let \( \{e_k\} \) be an orthonormal basis for \( H \). Then \( \{(X_n, e_k)_H\}_{n=1}^{\infty} \) are real valued, independent, and their mean equals 0. Also

\[
\sum_{n=1}^{\infty} E \left( |(X_n, e_k)_H|^2 \right) \leq \sum_{n=1}^{\infty} E \left( |X_n|_H^2 \right) < \infty
\]

and so from Theorem 58.6.2, the series,

\[
\sum_{n=1}^{\infty} (X_n, e_k)_H
\]

converges a.e. Therefore, there exists a set of measure zero such that for \( \omega \) not in this set, \( \sum_n (X_n(\omega), e_k)_H \) converges for each \( k \). For \( \omega \) not in this exceptional set, define

\[
Y_k(\omega) \equiv \sum_{n=1}^{\infty} (X_n(\omega), e_k)_H
\]

Next define

\[
S(\omega) \equiv \sum_{k=1}^{\infty} Y_k(\omega) e_k.
\]  

(58.6.17)

Of course it is not clear this even makes sense. I need to show \( \sum_{k=1}^{\infty} |Y_k(\omega)|^2 < \infty \). Using the independence of the \( X_n \)

\[
E \left( |Y_k|^2 \right) = E \left( \left( \sum_{n=1}^{\infty} (X_n, e_k)_H \right)^2 \right)
\]

\[
= E \left( \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} (X_n, e_k)_H (X_m, e_k)_H \right)
\]

\[
\leq \liminf_{N \to \infty} E \left( \sum_{n=1}^{N} \sum_{m=1}^{N} (X_n, e_k)_H (X_m, e_k)_H \right)
\]

\[
= \liminf_{N \to \infty} E \left( \sum_{n=1}^{N} (X_n, e_k)_H^2 \right)
\]

\[
= \sum_{n=1}^{\infty} E \left( (X_n, e_k)_H^2 \right)
\]

Hence from the above,

\[
E \left( \sum_k |Y_k|^2 \right) = \sum_k E \left( |Y_k|^2 \right) \leq \sum_k \sum_n E \left( (X_n, e_k)_H^2 \right)
\]
and by the monotone convergence theorem or Fubini’s theorem,

\[ E \left( \sum_n \sum_k (X_n, e_k)_H^2 \right) = E \left( \sum_k \sum_n (X_n, e_k)_H^2 \right) = E \left( \sum_n \sum_k |X_n|_H^2 \right) < \infty \]  
(58.6.18)

Therefore, for \( \omega \) off a set of measure zero, and for

\[ Y_k(\omega) \equiv \sum_{n=1}^{\infty} (X_n(\omega), e_k)_H, \]

\[ \sum_k |Y_k(\omega)|^2 < \infty \]

and also for these \( \omega \),

\[ \sum_n \sum_k (X_n(\omega), e_k)_H^2 < \infty. \]

It follows from the estimate 58.6.18 that for \( \omega \) not on a suitable set of measure zero, \( S(\omega) \) defined by 58.6.17.

\[ S(\omega) \equiv \sum_k Y_k(\omega) e_k \]

makes sense. Thus for these \( \omega \)

\[ S(\omega) = \sum_l (S(\omega), e_l) e_l = \sum_l Y_l(\omega) e_l = \sum_l \sum_n (X_n(\omega), e_l)_H e_l = \sum_n \sum_l (X_n(\omega), e_l)_H e_l = \sum_n X_n(\omega). \]

This proves the theorem.

Now with this theorem, here is a strong law of large numbers.

**Theorem 58.6.5** Suppose \( \{X_k\} \) are independent random variables and \( E(|X_k|) < \infty \) for each \( k \) and \( E(X_k) = m_k \). Suppose also

\[ \sum_{j=1}^{\infty} \frac{1}{j^2} E \left( |X_j - m_j|^2 \right) < \infty. \]  
(58.6.19)

Then

\[ \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} (X_j - m_j) = 0 \text{ a.e.} \]
Proof: Consider the sum
\[ \sum_{j=1}^{\infty} \frac{X_j - m_j}{j}. \]
This sum converges a.e. because of Theorem 58.6.1 and Theorem 58.6.3 applied to the random vectors \( \{ \frac{X_j - m_j}{j} \} \). Therefore, from Lemma 57.7.2 it follows that for a.e. \( \omega \),
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} (X_j(\omega) - m_j) = 0 \]
This proves the theorem.

The next corollary is often called the strong law of large numbers. It follows immediately from the above theorem.

Corollary 58.6.6 Suppose \( \{ X_j \}_{j=1}^{\infty} \) are independent random vectors, \( \lambda_{X_i} = \lambda_{X_j} \) for all \( i, j \) having mean \( m \) and variance equal to
\[ \sigma^2 = \int_{\Omega} |X_j - m|^2 dP < \infty. \]
Then for a.e. \( \omega \in \Omega \)
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} X_j(\omega) = m \]

58.7 A Reverse Submartingale Convergence Theorem

Definition 58.7.1 Let \( \{ X_n \}_{n=0}^{\infty} \) be a sequence of real random variables such that \( E(|X_n|) < \infty \) for all \( n \) and let \( \{ \mathcal{F}_n \} \) be a sequence of \( \sigma \) algebras such that \( \mathcal{F}_n \supseteq \mathcal{F}_{n+1} \) for all \( n \). Then \( \{ X_n \} \) is called a reverse submartingale if for all \( n \),
\[ E(X_n | \mathcal{F}_{n+1}) \geq X_{n+1}. \]

Note it is just like a submartingale only the indices are going the other way. Here is an interesting lemma. This lemma gives uniform integrability for a reverse submartingale.

Lemma 58.7.2 Suppose \( E(|X_n|) < \infty \) for all \( n \), \( X_n \) is \( \mathcal{F}_n \) measurable, \( \mathcal{F}_{n+1} \subseteq \mathcal{F}_n \) for all \( n \in \mathbb{N} \), and there exist \( X_\infty \) \( \mathcal{F}_\infty \) measurable such that \( \mathcal{F}_\infty \subseteq \mathcal{F}_n \) for all \( n \) and \( X_0 \) \( \mathcal{F}_0 \) measurable such that \( \mathcal{F}_0 \supseteq \mathcal{F}_n \) for all \( n \) such that for all \( n \in \{ 0, 1, \cdots \} \),
\[ E(X_n | \mathcal{F}_{n+1}) \geq X_{n+1}, \quad E(X_n | \mathcal{F}_\infty) \geq X_\infty, \]
where \( E(|X_\infty|) < \infty \). Then \( \{ X_n : n \in \mathbb{N} \} \) is uniformly integrable.
Proof:

\[ E(X_{n+1}) \leq E(E(X_n | \mathcal{F}_{n+1})) = E(X_n) \]

Therefore, the sequence \( \{E(X_n)\} \) is a decreasing sequence bounded below by \( E(X_\infty) \) so it has a limit. I am going to show the functions are equiintegrable. Let \( k \) be large enough that

\[ |E(X_k) - \lim_{m \to \infty} E(X_m)| < \varepsilon \]  

(58.7.20)

and suppose \( n > k \). Then if \( \lambda > 0 \),

\[
\int |X_n| dP = \int_{|X_n| \geq \lambda} X_n dP + \int_{|X_n| < \lambda} (-X_n) dP
\]

\[
= \int_{|X_n| \geq \lambda} X_n dP + \int_{\Omega} (-X_n) dP - \int_{|X_n| < \lambda} (-X_n) dP
\]

\[
= \int_{|X_n| \geq \lambda} X_n dP - \int_{\Omega} X_n dP + \int_{|X_n| < \lambda} X_n dP
\]

From \[58.7.20\]

\[
\leq \int_{|X_n| \geq \lambda} X_n dP - \int_{\Omega} X_k dP + \varepsilon + \int_{|X_n| < \lambda} X_n dP
\]

By assumption,

\[ E(X_k | \mathcal{F}_n) \geq X_n \]

and so the above

\[
\leq \int_{|X_n| \geq \lambda} E(X_k | \mathcal{F}_n) dP - \int_{\Omega} X_k dP + \varepsilon + \int_{|X_n| < \lambda} E(X_k | \mathcal{F}_n) dP
\]

\[
= \int_{|X_n| \geq \lambda} X_k dP - \int_{\Omega} X_k dP + \varepsilon + \int_{|X_n| < \lambda} X_k dP
\]

\[
= \int_{|X_n| \geq \lambda} X_k dP - \int_{\Omega} X_k dP + \varepsilon + \int_{|X_n| < \lambda} X_k dP
\]

\[
= \int_{|X_n| \geq \lambda} X_k dP + \left( \int_{|X_n| < \lambda} (-X_k) dP - \int_{|X_n| < \lambda} (-X_k) dP \right) + \varepsilon
\]

\[
= \int_{|X_n| \geq \lambda} X_k dP + \left( \int_{|X_n| \geq \lambda} (-X_k) dP + \varepsilon \right)
\]

Applying the maximal inequality for submartingales, Theorem \[58.5.3\],

\[ P(\max \{|X_j| : j = n, \cdots, 1\} \geq \lambda) \leq \frac{1}{\lambda} (E(|X_0|) + E(|X_\infty|)) \leq \frac{C}{\lambda} \]

and taking sup for all \( n \),

\[ P(\sup \{|X_j| \geq \lambda\}) \leq \frac{C}{\lambda} \]
58.7. A REVERSE SUBMARTINGALE CONVERGENCE THEOREM

It follows since the single function, $X_k$ is equiintegrable that for all $\lambda$ and $k$ large enough,
\[\int_{|X_n| \geq \lambda} |X_n| \, dP \leq 2\varepsilon\]
and since $\varepsilon$ is arbitrary, this shows $\{X_n\}$ for $n > k$ is equiintegrable. Since there are only finitely many $X_j$ for $j \leq k$, this shows $\{X_n\}$ is equiintegrable. Hence $\{X_n\}$ is uniformly integrable. This proves the lemma.

Now with this lemma and the upcrossing lemma it is easy to prove an important convergence theorem.

**Theorem 58.7.3** Let $\{X_n, \mathcal{F}_n\}_{n=0}^\infty$ be a backwards submartingale as described above and suppose $\sup_{n \geq 0} E(|X_n|) < \infty$. Then $\{X_n\}$ converges a.e. and in $L^1(\Omega)$ to a function, $X_\infty$.

**Proof:** By the upcrossing lemma applied to the submartingale $\{X_k, \mathcal{F}_n\}_{n=0}^N$, the number of upcrossings (Downcrossings is probably a better term. They are upcrossings as $n$ gets smaller.) of the interval $[a, b]$ satisfies the inequality
\[E\left(U_{[a, b]}^N\right) \leq \frac{1}{b-a} E\left((X_0 - a)^+\right)\]
Letting $N \to \infty$, it follows the expected number of upcrossings, $E\left(U_{[a, b]}\right)$ is bounded. Therefore, there exists a set of measure 0 $N_{ab}$ such that if $\omega \notin N_{ab}$, $U_{[a, b]}(\omega) < \infty$. Let $N = \bigcup \{N_{ab} : a, b \in \mathbb{Q}\}$. Then for $\omega \notin N$,
\[\limsup_{n \to \infty} X_n(\omega) = \liminf_{n \to \infty} X_n(\omega)\]
because if inequality holds, then letting
\[\liminf_{n \to \infty} X_n(\omega) < a < b < \limsup_{n \to \infty} X_n(\omega)\]
it would follow $U_{[a, b]}(\omega) = \infty$, contrary to $\omega \notin N_{ab}$.

Let $X_\infty(\omega) \equiv \lim_{n \to \infty} X_n(\omega)$. Then by Fatou’s lemma,
\[\int_{\Omega} |X_\infty(\omega)| \, dP \leq \liminf_{n \to \infty} \int_{\Omega} |X_n| \, dP < \infty.\]
and so $X_\infty$ is in $L^1(\Omega)$. By the Vitali convergence theorem and Lemma 58.7.13 which shows $\{|X_n|\}$ is uniformly integrable, it follows
\[\lim_{n \to \infty} \int_{\Omega} |X_\infty(\omega) - X_n(\omega)| \, dP = 0.\]
This proves the theorem.
58.8 Strong Law Of Large Numbers

There is a version of the strong law of large numbers which does not depend on the random variables having finite variance. First are some preparatory lemmas. The approach followed here is from Ash [4].

**Lemma 58.8.1** Let \( \{X_n\}\) be a sequence of independent random variables such that \( E(|X_k|) < \infty \) for all \( k \) and let \( S_n \equiv \sum_{k=1}^{n} X_k \). Then for \( k \leq n \),

\[
E(X_k|\sigma(S_n)) = E(X_k|\sigma(S_n, Y)) \text{ a.e.}
\]

where \( Y = (X_{n+1}, X_{n+2}, \cdots) \in \mathbb{R}^N \). Also for \( k \leq n \) as above,

\[
\sigma(S_n, Y) = \sigma(S_n, S_{n+1}, \cdots).
\]

**Proof:** Note that \( \mathbb{R}^N \) with the usual product topology has a countable basis. Here it is. Let \( B_N \) denote sets of the form \( \prod_{i=1}^{\infty} D_i \) where for \( i \leq N, D_i \in \mathcal{B} \), a countable basis for \( \mathbb{R} \) and for \( i > N, D_i = \mathbb{R} \). Then \( \mathcal{B}_N \) is countable and so is \( \mathcal{D} \equiv \bigcup_{N=1}^{\infty} \mathcal{B}_N \). From the definition of the product topology, this is a countable basis for the product topology.

Let \( V \in \mathcal{D} \) and \( U \) be an open set of \( \mathbb{R} \). Then if \( A \in (S_n, Y)^{-1}(U \times V)\), by independence of the \( \{X_n\} \),

\[
\int_{(S_n, Y)^{-1}(U \times V)} E(X_k|\sigma(S_n, Y)) \, dP = \int_{(S_n, Y)^{-1}(U \times V)} X_k \, dP
\]

\[
= \int_{\Omega} X_{S_n(U)}(\omega) X_{Y^{-1}(V)}(\omega) \, X_k \, dP = P(Y^{-1}(V)) \int_{\Omega} X_{S_n(U)}(\omega) \, X_k \, dP
\]

\[
= P(Y^{-1}(V)) \int_{S_n^{-1}(U)} E(X_k|\sigma(S_n)) \, dP.
\]

Now by independence again, \( \{S_n, X_{n+1}, X_{n+2}, \cdots\} \) are independent and so the above equals

\[
\int_{S_n^{-1}(U)} X_{Y^{-1}(V)} E(X_k|\sigma(S_n)) \, dP = \int_{(S_n, Y)^{-1}(U \times V)} E(X_k|\sigma(S_n)) \, dP.
\]

Letting

\[
S = \left\{ A \in \mathcal{B} \left( \mathbb{R} \times \mathbb{R}^N \right) : \int_{(S_n, Y)^{-1}(A)} E(X_k|\sigma(S_n)) \, dP \right\}
\]

the above has shown this is true for all \( A \) in a countable basis. Therefore, it is true for all \( A \) open in \( \mathbb{R} \times \mathbb{R}^N \). Finally, it is clear that \( S \) is a \( \sigma \) algebra which shows the above holds for all \( A \) Borel in \( \mathbb{R} \times \mathbb{R}^N \). Thus, for all \( B \in \sigma(S_n, Y) \),

\[
\int_B E(X_k|\sigma(S_n)) \, dP = \int_B E(X_k|\sigma(S_n, Y)) \, dP
\]
and thus \( E(X_k | \sigma(S_n)) = E(X_k | \sigma(S_n, Y)) \) a.e.

It only remains to prove the last assertion. For \( k > 0 \),

\[ X_{n+k} = S_{n+k} - S_{n+k-1} \]

Thus

\[
\sigma(S_n, Y) = \sigma(S_n, X_{n+1}, \ldots) \\
= \sigma(S_n, (S_{n+1} - S_n), (S_{n+2} - S_{n+1}), \ldots) \\
\subseteq \sigma(S_n, S_{n+1}, \ldots)
\]

On the other hand,

\[
\sigma(S_n, S_{n+1}, \ldots) = \sigma(S_n, X_{n+1} + S_n, X_{n+2} + X_{n+1} + S_n, \ldots) \\
= \sigma(S_n, X_{n+1}, X_{n+2}, \ldots)
\]

To see this, note that for an open set, and hence for a Borel set, \( B \),

\[
(S_n + \sum_{k=n+1}^m X_k)^{-1}(B) = (S_n, X_{n+1}, \ldots, X_m)^{-1}(B')
\]

for some \( B' \in \mathbb{R}^{m+1} \). Thus \( (S_n + \sum_{k=n+1}^m X_k)^{-1}(B) \) for \( B \) a Borel set is contained in \( \sigma(S_n, X_{n+1}, X_{n+2}, \ldots) \). Similar considerations apply to the other inclusion stated earlier. This proves the lemma.

**Lemma 58.8.2** Let \( \{X_k\} \) be a sequence of independent identically distributed random variables such that \( E(|X_k|) < \infty \). Then letting \( S_n = \sum_{k=1}^n X_k \), it follows that for \( k \leq n \)

\[ E(X_k | \sigma(S_n, S_{n+1}, \ldots)) = E(X_k | \sigma(S_n)) = \frac{S_n}{n}. \]

**Proof:** It was shown in Lemma 58.8.1 the first equality holds. It remains to show the second. Letting \( A = S_n^{-1}(B) \) where \( B \) is Borel, it follows there exists \( B' \subseteq \mathbb{R}^n \) a Borel set such that

\[ S_n^{-1}(B) = (X_1, \ldots, X_n)^{-1}(B'). \]

Then

\[
\int_A E(X_k | \sigma(S_n)) \, dP = \int_{S_n^{-1}(B)} X_k \, dP \\
= \int_{(X_1, \ldots, X_n)^{-1}(B')} X_k \, dP = \int_{(X_1, \ldots, X_n)^{-1}(B')} x_k \, d\lambda(x_1, \ldots, x_n) \\
= \int \cdots \int x_k \, d\lambda x_1 \, d\lambda x_2 \cdots d\lambda x_n \\
= \int \cdots \int x_l \, d\lambda x_1 \, d\lambda x_2 \cdots d\lambda x_n
\]
\[ E(X_l \mid \sigma(S_n)) = \int_A E(X_l \mid \sigma(S_n)) \, dP \]

and so since \( A \in \sigma(S_n) \) is arbitrary,

\[ E(X_l \mid \sigma(S_n)) = E(X_k \mid \sigma(S_n)) \]

for each \( k, l \leq n \). Therefore,

\[ S_n = E(S_n \mid \sigma(S_n)) = \sum_{j=1}^{n} E(X_j \mid \sigma(S_n)) = nE(X_k \mid \sigma(S_n)) \text{ a.e.} \]

and so

\[ E(X_k \mid \sigma(S_n)) = \frac{S_n}{n} \text{ a.e.} \]

as claimed. This proves the lemma.

With this preparation, here is the strong law of large numbers for identically distributed random variables.

**Theorem 58.8.3** Let \( \{X_k\} \) be a sequence of independent identically distributed random variables such that \( E(|X_k|) < \infty \) for all \( k \). Letting \( m = E(X_k) \),

\[ \lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} X_k(\omega) = m \text{ a.e.} \]

and convergence also takes place in \( L^1(\Omega) \).

**Proof:** Consider the reverse submartingale \( \{E(X_1 \mid \sigma(S_n, S_{n+1}, \cdots))\} \). By Theorem 58.7.3, this converges a.e. and in \( L^1(\Omega) \) to a random variable, \( X_\infty \). However, from Lemma 58.8.2, \( E(X_1 \mid \sigma(S_n, S_{n+1}, \cdots)) = S_n/n \). Therefore, \( S_n/n \) converges a.e. and in \( L^1(\Omega) \) to \( X_\infty \). I need to argue that \( X_\infty \) is constant and also that it equals \( m \). For \( a \in \mathbb{R} \) let

\[ E_a \equiv [X_\infty \geq a] \]

For \( a \) small enough, \( P(E_a) \neq 0 \). Then since \( E_a \) is a tail event for the independent random variables, \( \{X_k\} \) it follows from the Kolmogorov zero one law, Theorem 57.6.4, that \( P(E_a) = 1 \). Let \( b = \sup \{a : P(E_a) = 1\} \). The sets, \( E_a \), are decreasing as \( a \) increases. Let \( \{a_n\} \) be a strictly increasing sequence converging to \( b \). Then

\[ [X_\infty \geq b] = \cap_n [X_\infty \geq a_n] \]

and so

\[ 1 = P(E_b) = \lim_{n \to \infty} P(E_{a_n}) \text{.} \]

On the other hand, if \( c > b \), then \( P(E_c) < 1 \) and so \( P(E_c) = 0 \). Hence \( P([X = b]) = 1 \). It remains to show \( b = m \). This is easy because by the \( L^1 \) convergence,

\[ b = \int_{\Omega} X_\infty dP = \lim_{n \to \infty} \int_{\Omega} \frac{S_n}{n} dP = \lim_{n \to \infty} m = m. \]

This proves the theorem.
Chapter 59

Probability In Infinite Dimensions

59.1 Conditional Expectation In Banach Spaces

Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \(X \in L^1(\Omega; \mathbb{R})\). Also let \(\mathcal{G} \subseteq \mathcal{F}\) where \(\mathcal{G}\) is also a \(\sigma\) algebra. Then the usual conditional expectation is defined by

\[
\int_A X dP = \int_A E(X|\mathcal{G}) dP
\]

where \(E(X|\mathcal{G})\) is \(\mathcal{G}\) measurable and \(A \in \mathcal{G}\) is arbitrary. Recall this is an application of the Radon Nikodym theorem. Also recall \(E(X|\mathcal{G})\) is unique up to a set of measure zero.

I want to do something like this here. Denote by \(L^1(\Omega; E, \mathcal{G})\) those functions in \(L^1(\Omega; E)\) which are measurable with respect to \(\mathcal{G}\).

Theorem 59.1.1 Let \(E\) be a separable Banach space and let \(X \in L^1(\Omega; E, \mathcal{F})\) where \(X\) is measurable with respect to \(\mathcal{F}\) and let \(\mathcal{G}\) be a \(\sigma\) algebra which is contained in \(\mathcal{F}\). Then there exists a unique \(Z \in L^1(\Omega; E, \mathcal{G})\) such that for all \(A \in \mathcal{G}\),

\[
\int_A X dP = \int_A Z dP
\]

Denoting this \(Z\) as \(E(X|\mathcal{G})\), it follows

\[
\|E(X|\mathcal{G})\| \leq E(\|X\| |\mathcal{G})\).
\]

Proof: First consider uniqueness. Suppose \(Z'\) is another in \(L^1(\Omega; E, \mathcal{G})\) which works. Consider a dense subset of \(E \{a_n\}_{n=1}^\infty\). Then the balls \(\left\{B \left(a_n, \frac{\|a_n\|}{2}\right)\right\}_{n=1}^\infty\) must cover \(E \setminus \{0\}\). Here is why. If \(y \neq 0\), pick \(a_n \in B \left(y, \frac{\|y\|}{5}\right)\).
Then \( \|a_n\| \geq 4 \|y\|/5 \) and so \( \|a_n - y\| < \|y\|/5 \). Thus

\[
y \in B(a_n, \|y\|/5) \subseteq B\left(a_n, \frac{\|a_n\|}{4}\right)
\]

Now suppose \( Z \) is \( \mathcal{G} \) measurable and

\[
\int_A Z dP = 0
\]

for all \( A \in \mathcal{G} \). The letting \( A = Z^{-1}\left(B\left(a_n, \frac{\|a_n\|}{4}\right)\right) \) it follows

\[
0 = \int_A Z - a_n + a_n dP
\]

and so

\[
\|a_n\| P(A) = \left\| \int_A a_n dP \right\| = \left\| \int_A (a_n - Z) dP \right\|
\leq \int_{Z^{-1}\left(B\left(a_n, \frac{\|a_n\|}{4}\right)\right)} \|a_n - Z\| dP \leq \frac{\|a_n\|}{4} P(A)
\]

which is a contradiction unless \( P(A) = 0 \). Therefore, letting

\[
N = \bigcup_{n=1}^\infty Z^{-1}\left(B\left(a_n, \frac{\|a_n\|}{4}\right)\right) = Z^{-1}(E \setminus \{0\})
\]

it follows \( N \) has measure zero and so \( Z = 0 \) a.e. This proves uniqueness because if \( Z, Z' \) both hold, then from the above argument, \( Z - Z' = 0 \) a.e.

Next I will show \( Z \) exists. To do this recall Theorem 19.2.5 on Page 636 which is stated below for convenience.

**Theorem 59.1.2** An \( E \) valued function, \( X \), is Bochner integrable if and only if \( X \) is strongly measurable and

\[
\int_{\Omega} \|X(\omega)\| dP < \infty. \tag{59.1.1}
\]

In this case there exists a sequence of simple functions \( \{X_n\} \) satisfying

\[
\int_{\Omega} \|X_n(\omega) - X_m(\omega)\| dP \to 0 \text{ as } m, n \to \infty. \tag{59.1.2}
\]
59.1. CONDITIONAL EXPECTATION IN BANACH SPACES

Let \( X_n(\omega) \) converging pointwise to \( X(\omega) \),

\[
||X_n(\omega)|| \leq 2 \|X(\omega)||
\]

and

\[
\lim_{n \to \infty} \int_{\Omega} ||X(\omega) - X_n(\omega)|| \, dP = 0.
\]

Now let \( \{X_n\} \) be the simple functions just defined and let

\[
X_n(\omega) = \sum_{k=1}^{m} x_k \mathcal{X}_{F_k}(\omega)
\]

where \( F_k \in \mathcal{F} \), the \( F_k \) being disjoint. Then define

\[
Z_n = \sum_{k=1}^{m} x_k E(\mathcal{X}_{F_k}|\mathcal{G})
\]

Thus, if \( A \in \mathcal{G} \),

\[
\int_A Z_n \, dP = \sum_{k=1}^{m} x_k \int_A E(\mathcal{X}_{F_k}|\mathcal{G}) \, dP
\]

\[
= \sum_{k=1}^{m} x_k \int_A \mathcal{X}_{F_k} \, dP
\]

\[
= \sum_{k=1}^{m} x_k P(F_k \cap A) = \int_A X_n \, dP
\]

Then since \( E(\mathcal{X}_{F_k}|\mathcal{G}) \geq 0 \),

\[
||Z_n|| \leq \sum_{k=1}^{m} ||x_k|| E(\mathcal{X}_{F_k}|\mathcal{G})
\]

Thus if \( A \in \mathcal{G} \),

\[
E(||Z_n|| \mathcal{X}_A) \leq E\left( \sum_{k=1}^{m} ||x_k|| \mathcal{X}_A E(\mathcal{X}_{F_k}|\mathcal{G}) \right) = \sum_{k=1}^{m} ||x_k|| \int_A E(\mathcal{X}_{F_k}|\mathcal{G}) \, dP
\]

\[
= \sum_{k=1}^{m} ||x_k|| \int_A \mathcal{X}_{F_k} \, dP = E(\mathcal{X}_A ||X_n||).
\]

Note the use of \( \leq \) in the first step in the above. Although the \( F_k \) are disjoint, all that is known about \( E(\mathcal{X}_{F_k}|\mathcal{G}) \) is that it is nonnegative. Similarly,

\[
E(||Z_n - Z_m||) \leq E(||X_n - X_m||)
\]
and this last term converges to 0 as \( n, m \to \infty \) by the properties of the \( X_n \). Therefore, \( \{Z_n\} \) is a Cauchy sequence in \( L^1(\Omega; E; \mathcal{G}) \). It follows it converges to some \( Z \) in \( L^1(\Omega; E; \mathcal{G}) \). Then letting \( A \in \mathcal{G} \), and using 

\[
\int_A Z dP = \int X_A Z dP = \lim_{n \to \infty} \int X_A Z_n dP = \lim_{n \to \infty} \int A Z_n dP = \lim_{n \to \infty} \int A X_n dP = \int A X dP.
\]

Then define \( Z \equiv E(X|\mathcal{G}) \).

It remains to verify \( ||E(X|\mathcal{G})|| \equiv ||Z|| \leq E(||X|| |\mathcal{G}) \). This follows because, from the above,

\( ||Z_n|| \to ||Z||, \ |X_n|| \to ||X|| \) in \( L^1(\Omega) \)

and so if \( A \in \mathcal{G} \), then from 

\[
\frac{1}{P(A)} \int_A ||Z_n|| dP \leq \frac{1}{P(A)} \int_A ||X_n|| dP
\]

and so, passing to the limit,

\[
\frac{1}{P(A)} \int_A ||Z|| dP \leq \frac{1}{P(A)} \int_A ||X|| dP = \frac{1}{P(A)} \int_A E(||X|| |\mathcal{G}) dP
\]

Since \( A \) is arbitrary, this shows that

\( ||E(X|\mathcal{G})|| \equiv ||Z|| \leq E(||X|| |\mathcal{G}) \). 

In the case where \( E \) is reflexive, one could also use Corollary on Page to get the above result. You would define a vector measure on \( \mathcal{G} \),

\[
\nu(F) = \int_F X dP
\]

and then you would use the fact that reflexive separable Banach spaces have the Radon Nikodym property to obtain \( Z \in L^1(\Omega; E, \mathcal{G}) \) such that

\[
\nu(F) = \int_F X dP = \int_F Z dP.
\]

The function, \( Z \) whose existence and uniqueness is guaranteed by Theorem is called \( E(X|\mathcal{G}) \).

### 59.2 Probability Measures And Tightness

Here and in what remains, \( \mathcal{B}(E) \) will denote the Borel sets of \( E \) where \( E \) is a topological space, usually at least a Banach space. Because of the fact that probability measures are finite, you can use a simpler definition of what it means for a measure
59.2. PROBABILITY MEASURES AND TIGHTNESS

59.2. PROBABILITY MEASURES AND TIGHTNESS

59.2. PROBABILITY MEASURES AND TIGHTNESS

to be regular. Recall that there were two ingredients, inner regularity which said that the measure of a set is the supremum of the measures of compact subsets and outer regularity which says that the measure of a set is the infimum of the measures of the open sets which contain the given set. Here the definition will be similar but instead of using compact sets, closed sets are substituted. Thus the following definition is a little different than the earlier one. I will show, however, that in many interesting cases, this definition of regularity is actually the same as the earlier one.

Definition 59.2.1 A measure, \( \mu \) defined on \( \mathcal{B}(E) \) will be called inner regular if for all \( F \in \mathcal{B}(E) \),

\[
\mu(F) = \sup \{ \mu(K) : K \subseteq F \text{ and } K \text{ is closed} \}
\]

A measure, \( \mu \) defined on \( \mathcal{B}(E) \) will be called outer regular if for all \( F \in \mathcal{B}(E) \),

\[
\mu(F) = \inf \{ \mu(V) : V \supseteq F \text{ and } V \text{ is open} \}
\]

When a measure is both inner and outer regular, it is called regular.

For probability measures, regularity tends to come free.

Lemma 59.2.2 Let \( \mu \) be a finite measure defined on \( \mathcal{B}(E) \) where \( E \) is a metric space. Then \( \mu \) is regular.

Proof: First note every open set is the countable union of closed sets and every closed set is the countable intersection of open sets. Here is why. Let \( V \) be an open set and let

\[
K_k \equiv \{ x \in V : \text{dist} \,(x, V^C) \geq 1/k \}.
\]

Then clearly the union of the \( K_k \) equals \( V \). Next, for \( K \) closed let

\[
V_k \equiv \{ x \in E : \text{dist} \,(x, K) < 1/k \}.
\]

Clearly the intersection of the \( V_k \) equals \( K \). Therefore, letting \( V \) denote an open set and \( K \) a closed set,

\[
\mu(V) = \sup \{ \mu(K) : K \subseteq V \text{ and } K \text{ is closed} \}
\]

\[
\mu(K) = \inf \{ \mu(V) : V \supseteq K \text{ and } V \text{ is open} \}.
\]

Also since \( V \) is open and \( K \) is closed,

\[
\mu(V) = \inf \{ \mu(U) : U \supseteq V \text{ and } V \text{ is open} \}
\]

\[
\mu(K) = \sup \{ \mu(L) : L \subseteq K \text{ and } L \text{ is closed} \}.
\]

In words, \( \mu \) is regular on open and closed sets. Let

\[
\mathcal{F} \equiv \{ F \in \mathcal{B}(E) \text{ such that } \mu \text{ is regular on } F \}.
\]
Then $\mathcal{F}$ contains the open sets. I want to show $\mathcal{F}$ is a $\sigma$ algebra and then it will follow $\mathcal{F} = \mathcal{B}(E)$.

First I will show $\mathcal{F}$ is closed with respect to complements. Let $F \in \mathcal{F}$. Then since $\mu$ is finite and $\mathcal{F}$ is inner regular, there exists $K \subset F$ such that $\mu(F \setminus K) < \varepsilon$. But $K^C \setminus F^C = F \setminus K$ and so $\mu(K^C \setminus F^C) < \varepsilon$ showing that $F^C$ is outer regular. I have just approximated the measure of $F^C$ with the measure of $K^C$, an open set containing $F^C$. A similar argument works to show $\mathcal{F}$ is outer regular. You start with $V \supseteq F$ such that $\mu(V \setminus F) < \varepsilon$, note $F^C \setminus V^C = V \setminus F$, and then conclude $\mu(F^C \setminus V^C) < \varepsilon$, thus approximating $F^C$ with the closed subset, $V^C$.

Next I will show $\mathcal{F}$ is closed with respect to taking countable unions. Let $\{F_k\}$ be a sequence of sets in $\mathcal{F}$. Then $\mu$ is inner regular on each of these so there exist $\{K_k\}$ such that $K_k \subset F_k$ and $\mu(F_k \setminus K_k) < \varepsilon/2^{k+1}$. First choose $m$ large enough that

$$\mu\left(\bigcup_{k=1}^{\infty} F_k \setminus \bigcup_{k=1}^{m} K_k\right) < \varepsilon/2.$$ 

Then

$$\mu\left(\bigcup_{k=1}^{m} F_k \setminus \bigcup_{k=1}^{m} K_k\right) \leq \sum_{k=1}^{m} \frac{\varepsilon}{2^{k+1}} < \frac{\varepsilon}{2},$$

and so

$$\mu\left(\bigcup_{k=1}^{\infty} F_k \setminus \bigcup_{k=1}^{m} K_k\right) \leq \mu\left(\bigcup_{k=1}^{\infty} F_k \setminus \bigcup_{k=1}^{m} F_k\right) \leq \mu\left(\bigcup_{k=1}^{\infty} F_k \setminus \bigcup_{k=1}^{m} F_k\right) + \mu\left(\bigcup_{k=1}^{m} F_k \setminus \bigcup_{k=1}^{m} K_k\right) \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon$$

showing $\mu$ is inner regular on $\bigcup_{k=1}^{\infty} F_k$. Since $\mu$ is outer regular on $F_k$, there exists $V_k$ such that $\mu(V_k \setminus F_k) < \varepsilon/2^k$. Then

$$\mu\left(\bigcup_{k=1}^{\infty} V_k \setminus \bigcup_{k=1}^{\infty} F_k\right) \leq \sum_{k=1}^{\infty} \mu(V_k \setminus F_k) \leq \sum_{k=1}^{\infty} \frac{\varepsilon}{2^k} = \varepsilon$$

and this shows $\mu$ is outer regular on $\bigcup_{k=1}^{\infty} F_k$ and this proves the lemma.

**Lemma 59.2.3** Let $\mu$ be a finite measure on $\mathcal{B}(E)$, the Borel sets of $E$, a separable complete metric space. Then if $C$ is a closed set,

$$\mu(C) = \sup \{\mu(K) : K \subseteq C \text{ and } K \text{ is compact}\}.$$ 

**Proof:** Let $\{a_k\}$ be a countable dense subset of $C$. Thus $\bigcup_{k=1}^{\infty} B\left(a_k, \frac{1}{n}\right) \supseteq C$. Therefore, there exists $m_n$ such that

$$\mu\left(C \setminus \bigcup_{k=1}^{m_n} B\left(a_k, \frac{1}{n}\right)\right) \equiv \mu(C \setminus C_n) < \frac{\varepsilon}{2^n}.$$
Now let \( K = C \cap (\cap_{n=1}^{\infty} C_n) \). Then \( K \) is a subset of \( C_n \) for each \( n \) and so for each \( \varepsilon > 0 \) there exists an \( \varepsilon \) net for \( K \) since \( C_n \) has a \( 1/n \) net, namely \( a_1, \ldots, a_{m_n} \). Since \( K \) is closed, it is complete and so it is also compact. Now

\[
\mu (C \setminus K) = \mu (\bigcup_{n=1}^{\infty} (C \setminus C_n)) < \sum_{n=1}^{\infty} \frac{\varepsilon}{2^n} = \varepsilon.
\]

Thus \( \mu (C) \) can be approximated by \( \mu (K) \) for \( K \) a compact subset of \( C \). This proves the lemma.

This shows that for a finite measure on the Borel sets of a separable metric space, the above definition of regular coincides with the earlier one.

### 59.3 Tight Measures

Now here is a definition of what it means for a set of measures to be tight.

**Definition 59.3.1** Let \( \Lambda \) be a set of probability measures defined on the Borel sets of a topological space. Then \( \Lambda \) is “tight” if for all \( \varepsilon > 0 \) there exists a compact set, \( K_\varepsilon \) such that

\[
\mu ([x \notin K_\varepsilon]) < \varepsilon
\]

for all \( \mu \in \Lambda \).

Lemma \[59.3.3\] implies a single probability measure on the Borel sets of a separable metric space is tight. The proof of that lemma generalizes slightly to give a simple criterion for a set of measures to be tight.

**Lemma 59.3.2** Let \( E \) be a separable complete metric space and let \( \Lambda \) be a set of Borel probability measures. Then \( \Lambda \) is tight if and only if for every \( \varepsilon > 0 \) and \( r > 0 \) there exists a finite collection of balls, \( \{B(a_i, r)\}_{i=1}^{m} \) such that

\[
\mu \left( \bigcup_{i=1}^{m} B(a_i, r) \right) > 1 - \varepsilon
\]

for every \( \mu \in \Lambda \).

**Proof:** If \( \Lambda \) is tight, then there exists a compact set, \( K_\varepsilon \) such that

\[
\mu (K_\varepsilon) > 1 - \varepsilon
\]

for all \( \mu \in \Lambda \). Then consider the open cover, \( \{B(x, r) : x \in K_\varepsilon\} \). Finitely many of these cover \( K_\varepsilon \) and this yields the above condition.

Now suppose the above condition and let

\[
C_n = \bigcup_{i=1}^{m_n} B(a_i^n, 1/n)
\]
satisfy $\mu(C_n) > 1 - \varepsilon/2^n$ for all $\mu \in \Lambda$. Then let $K_\varepsilon = \cap_{n=1}^\infty C_n$. This set $K_\varepsilon$ is a compact set because it is a closed subset of a complete metric space and is therefore complete, and it is also totally bounded by construction. For $\mu \in \Lambda$,

$$
\mu(K_\varepsilon^C) = \mu(\cup_n C_n^C) \leq \sum_n \mu(C_n^C) < \sum_n \frac{\varepsilon}{2^n} = \varepsilon
$$

Therefore, $\Lambda$ is tight.  

Prokhorov’s theorem is an important result which also involves tightness. In order to give a proof of this important theorem, it is necessary to consider some simple results from topology which are interesting for their own sake.

**Theorem 59.3.3** Let $H$ be a compact metric space. Then there exists a compact subset of $[0,1]$, $K$ and a continuous function, $\theta$ which maps $K$ onto $H$.

**Proof:** Without loss of generality, it can be assumed $H$ is an infinite set since otherwise the conclusion is trivial. You could pick finitely many points of $[0,1]$ for $K$.

Since $H$ is compact, it is totally bounded. Therefore, there exists a 1 net for $H$ \{${h_i}$\}$_{i=1}^{m_1}$. Letting $H_1^1 = \overline{B}(h_1, 1)$, it follows $H_1^1$ is also a compact metric space and so there exists a 1/2 net for each $H_1^1$, \{${h_j}$\}$_{j=1}^{m_1}$. Then taking the intersection of $B(h_j, 1/2)$ with $H_1^1$ to obtain sets denoted by $H_2^j$ and continuing this way, one can obtain compact subsets of $H$, \{${H_1^j}$\} which satisfies: each $H_1^j$ is contained in some $H_k^{i-1}$, each $H_j^1$ is compact with diameter less than $i^{-1}$, each $H_j^i$ is the union of sets of the form $H_k^{i+1}$ which are contained in it. Denoting by \{${H_j^i}$\}$_{j=1}^{m_i}$ those sets corresponding to a superscript of $i$, it can also be assumed $m_i < m_{i+1}$. If this is not so, simply add in another point to the $i^{-1}$ net. Now let \{${I_j^i}$\}$_{j=1}^{m_i}$ be disjoint closed intervals in $[0,1]$ each of length no longer than $2^{-m_i}$ which have the property that $I_j^i$ is contained in $I_k^{i-1}$ for some $k$. Letting $K_i = \cup_{j=1}^{m_i} I_j^i$, it follows $K_i$ is a sequence of nested compact sets. Let $K = \cap_{i=1}^\infty K_i$. Then each $x \in K$ is the intersection of a unique sequence of these closed intervals, \{${I_{jk}}$\}$_{k=1}^{j}$. Define $\theta x = \cap_{k=1}^\infty H_{jk}^i$. Since the diameters of the $H_{jk}^i$ converge to 0 as $i \to \infty$, this function is well defined. It is continuous because if $x_n \to x$, then ultimately $x_n$ and $x$ are both in $I_{jk}^i$, the $k^{th}$ closed interval in the sequence whose intersection is $x$. Hence, $d(\theta x_n, \theta x) \leq \text{diameter}(H_{jk}^i) \leq 1/k$. To see the map is onto, let $h \in H$. Then from the construction, there exists a sequence \{${H_{jk}^i}$\}$_{k=1}^{j}$ of the above sets whose intersection equals $h$. Then $\theta (\cap_{k=1}^\infty H_{jk}^i) = h$.  

Note $\theta$ is maybe not one to one.

As an important corollary, it follows that the continuous functions defined on any compact metric space is separable.

**Corollary 59.3.4** Let $H$ be a compact metric space and let $C(H)$ denote the continuous functions defined on $H$ with the usual norm,

$$
||f||_\infty = \max \{|f(x)| : x \in H\}
$$

Then $C(H)$ is separable.
Proof: The proof is by contradiction. Suppose \( C(H) \) is not separable. Let \( \mathcal{H}_k \) denote a maximal collection of functions of \( C(H) \) with the property that if \( f, g \in \mathcal{H}_k \), then \( ||f - g||_\infty \geq 1/k \). The existence of such a maximal collection of functions is a consequence of a simple use of the Hausdorff maximality theorem. Then \( \cup_{k=1}^\infty \mathcal{H}_k \) is dense. Therefore, it cannot be countable by the assumption that \( C(H) \) is not separable. It follows that for some \( k, \mathcal{H}_k \) is uncountable. Now by Theorem 59.3.3 there exists a continuous function, \( \theta \) defined on a compact subset, \( K \) of \([0,1]\) which maps \( K \) onto \( H \). Now consider the functions defined on \( K \)

\[
\mathcal{G}_k = \{ f \circ \theta : f \in \mathcal{H}_k \}.
\]

Then \( \mathcal{G}_k \) is an uncountable set of continuous functions defined on \( K \) with the property that the distance between any two of them is at least as large as \( 1/k \). This contradicts separability of \( C(K) \) which follows from the Weierstrass approximation theorem in which the separable countable set of functions is the restrictions of polynomials that involve only rational coefficients. \( \square \)

Now here is Prokhorov’s theorem.

**Theorem 59.3.5** Let \( \Lambda = \{ \mu_n \}_{n=1}^\infty \) be a sequence of probability measures defined on \( \mathcal{B}(E) \) where \( E \) is a separable complete metric space. If \( \Lambda \) is tight then there exists a probability measure, \( \lambda \) and a subsequence of \( \{ \mu_n \}_{n=1}^\infty \), still denoted by \( \{ \mu_n \}_{n=1}^\infty \) such that whenever \( \phi \) is a continuous bounded complex valued function defined on \( E \),

\[
\lim_{n \to \infty} \int \phi d\mu_n = \int \phi d\lambda.
\]

Proof: By tightness, there exists an increasing sequence of compact sets, \( \{ K_n \} \) such that

\[
\mu(K_n) > 1 - \frac{1}{n}
\]

for all \( \mu \in \Lambda \). Now letting \( \mu \in \Lambda \) and \( \phi \in C(K_n) \) such that \( ||\phi||_\infty \leq 1 \), it follows

\[
\left| \int_{K_n} \phi d\mu \right| \leq \mu(K_n) \leq 1
\]

and so the restrictions of the measures of \( \Lambda \) to \( K_n \) are contained in the unit ball of \( C(K_n)' \). Recall from the Riesz representation theorem, the dual space of \( C(K_n) \) is a space of complex Borel measures. Theorem 15.5.5 on Page 445 implies the unit ball of \( C(K_n)' \) is weak * sequentially compact. This follows from the observation that \( C(K_n) \) is separable which is proved in Corollary 59.3.4 and leads to the fact that the unit ball in \( C(K_n)' \) is actually metrizable by Theorem 15.5.5 on Page 445. Therefore, there exists a subsequence of \( \Lambda, \{ \mu_{1k} \} \) such that their restrictions to \( K_1 \) converge weak * to a measure, \( \lambda_1 \in C(K_1)' \). That is, for every \( \phi \in C(K_1) \),

\[
\lim_{k \to \infty} \int_{K_1} \phi d\mu_{1k} = \int_{K_1} \phi d\lambda_1
\]
CHAPTER 59. PROBABILITY IN INFINITE DIMENSIONS

By the same reasoning, there exists a further subsequence \( \{ \mu_{2k} \} \) such that the restrictions of these measures to \( K_2 \) converge weak * to a measure \( \lambda_2 \in C(K_2)' \) etc. Continuing this way,

\[
\begin{align*}
\mu_{11}, \mu_{12}, \mu_{13}, \ldots & \to \text{Weak * in } C(K_1)' \\
\mu_{21}, \mu_{22}, \mu_{23}, \ldots & \to \text{Weak * in } C(K_2)' \\
\mu_{31}, \mu_{32}, \mu_{33}, \ldots & \to \text{Weak * in } C(K_3)' \\
\vdots
\end{align*}
\]

Here the \( j^{th} \) sequence is a subsequence of the \( (j-1)^{th} \). Let \( \lambda_n \) denote the measure in \( C(K_n)' \) to which the sequence \( \{ \mu_{nk} \}_{k=1}^\infty \) converges weak *. Let \( \{ \mu_n \} = \{ \mu_{nn} \} \), the diagonal sequence. Thus this sequence is ultimately a subsequence of every one of the above sequences and so \( \mu_n \) converges weak * in \( C(K_m)' \) to \( \lambda_m \) for each \( m \). Note that this is all happening on different sets so there is no contradiction with something converging to two different things.

Claim: For \( p > n \), the restriction of \( \lambda_p \) to the Borel sets of \( K_n \) equals \( \lambda_n \).

Proof of claim: Let \( H \) be a compact subset of \( K_n \). Then there are sets, \( V_l \) open in \( K_n \) which are decreasing and whose intersection equals \( H \). This follows because this is a metric space. Then let \( H \prec \phi_l \prec V_l \). It follows

\[
\lambda_n(V_l) = \int_{K_n} \phi_l \, d\lambda_n = \lim_{k \to \infty} \int_{K_n} \phi_l \, d\mu_k
\]

\[
= \lim_{k \to \infty} \int_{K_p} \phi_l \, d\mu_k = \int_{K_p} \phi_l \, d\lambda_p \geq \lambda_p(H).
\]

Now considering the ends of this inequality, let \( l \to \infty \) and pass to the limit to conclude

\[
\lambda_n(H) \geq \lambda_p(H).
\]

Similarly,

\[
\lambda_n(H) \leq \int_{K_n} \phi_l \, d\lambda_n = \lim_{k \to \infty} \int_{K_n} \phi_l \, d\mu_k
\]

\[
= \lim_{k \to \infty} \int_{K_p} \phi_l \, d\mu_k = \int_{K_p} \phi_l \, d\lambda_p \leq \lambda_p(V_l).
\]

Then passing to the limit as \( l \to \infty \), it follows

\[
\lambda_n(H) \leq \lambda_p(H).
\]

Thus the restriction of \( \lambda_p, \lambda_p|_{K_n} \) to the compact sets of \( K_n \) equals \( \lambda_n \). Then by inner regularity it follows the two measures, \( \lambda_p|_{K_n} \), and \( \lambda_n \) are equal on all Borel sets of \( K_n \). Recall that for finite measures on separable metric spaces, regularity is obtained for free.

It is fairly routine to exploit regularity of the measures to verify that \( \lambda_m(F) \geq 0 \) for all \( F \) a Borel subset of \( K_m \). Note that \( \phi \to \int_{K_n} \phi \, d\lambda_n \) is a positive linear functional.
and so $\lambda_n \geq 0$. Also, letting $\phi \equiv 1$,

$$1 \geq \lambda_m (K_m) \geq 1 - \frac{1}{m}.$$  \hfill (59.3.7)

Define for $F$ a Borel set,

$$\lambda (F) \equiv \lim_{n \to \infty} \lambda_n (F \cap K_n).$$

The limit exists because the sequence on the right is increasing due to the above observation that $\lambda_n = \lambda_m$ on the Borel subsets of $K_m$ whenever $n > m$. Thus for $n > m$

$$\lambda_n (F \cap K_n) \geq \lambda_m (F \cap K_m) = \lambda_n (F \cap K_m).$$

Now let $\{F_k\}$ be a sequence of disjoint Borel sets. Then

$$\lambda (\bigcup_{k=1}^\infty F_k) = \lim_{n \to \infty} \lambda_n (\bigcup_{k=1}^n F_k \cap K_n) = \lim_{n \to \infty} \lambda_n (\bigcup_{k=1}^n (F_k \cap K_n))$$

$$= \lim_{n \to \infty} \sum_{k=1}^n \lambda_n (F_k \cap K_n) = \sum_{k=1}^\infty \lambda (F_k)$$

the last equation holding by the monotone convergence theorem.

It remains to verify

$$\lim_{k \to \infty} \int \phi d\mu_k = \int \phi d\lambda$$

for every $\phi$ bounded and continuous. This is where tightness is used again. Then as noted above,

$$\lambda_n (K_n) = \lambda (K_n)$$

because for $p > n$, $\lambda_p (K_n) = \lambda_n (K_n)$ and so letting $p \to \infty$, the above is obtained.

Also, from 59.3.7

$$\lambda (K_n^C) = \lim_{p \to \infty} \lambda_p (K_n^C \cap K_p)$$

$$\leq \limsup_{p \to \infty} (\lambda_p (K_p) - \lambda_p (K_n))$$

$$\leq \limsup_{p \to \infty} (\lambda_p (K_p) - \lambda_n (K_n))$$

$$\leq \limsup_{p \to \infty} \left( 1 - \left( 1 - \frac{1}{n} \right) \right) = \frac{1}{n}$$

Suppose $||\phi||_\infty < M$. Then

$$\left| \int \phi d\mu_k - \int \phi d\lambda \right| \leq \left| \int_{K_n^C} \phi d\mu_k + \int_{K_n} \phi d\mu_k - \left( \int_{K_n} \phi d\lambda + \int_{K_n^C} \phi d\lambda \right) \right|$$

$$\leq \left| \int_{K_n} \phi d\mu_k - \int_{K_n} \phi d\lambda \right| + \left| \int_{K_n^C} \phi d\mu_k - \int_{K_n^C} \phi d\lambda \right|$$
CHAPTER 59. PROBABILITY IN INFINITE DIMENSIONS

First let \( n \) be so large that \( 2M/n < \varepsilon/2 \) and then pick \( k \) large enough that the above expression is less than \( \varepsilon \). \( \blacksquare \)

**Definition 59.3.6** Let \( E \) be a complete separable metric space and let \( \mu \) and the sequence of probability measures, \( \{\mu_n\} \) defined on \( \mathcal{B}(E) \) satisfy

\[
\lim_{n \to \infty} \int \phi \, d\mu_n = \int \phi \, d\mu.
\]

for every \( \phi \) a bounded continuous function. Then \( \mu_n \) is said to converge weakly to \( \mu \).

59.4 A Major Existence And Convergence Theorem

Here is an interesting lemma about weak convergence.

**Lemma 59.4.1** Let \( \mu_n \) converge weakly to \( \mu \) and let \( U \) be an open set with \( \mu(\partial U) = 0 \). Then

\[
\lim_{n \to \infty} \mu_n(U) = \mu(U).
\]

**Proof:** Let \( \{\psi_k\} \) be a sequence of bounded continuous functions which decrease to \( X_{\mathbb{R}} \). Also let \( \{\phi_k\} \) be a sequence of bounded continuous functions which increase to \( X_U \). For example, you could let

\[
\psi_k(x) \equiv (1 - k \text{dist}(x, U))^+,
\]

\[
\phi_k(x) \equiv 1 - (1 - k \text{dist}(x, U^C))^+.
\]

Let \( \varepsilon > 0 \) be given. Then since \( \mu(\partial U) = 0 \), the dominated convergence theorem implies there exists \( \psi = \psi_k \) and \( \phi = \phi_k \) such that

\[
\varepsilon > \int \psi \, d\mu - \int \phi \, d\mu.
\]

Next use the weak convergence to pick \( N \) large enough that if \( n \geq N \),

\[
\int \psi \, d\mu_n \leq \int \psi \, d\mu + \varepsilon, \quad \int \phi \, d\mu_n \geq \int \phi \, d\mu - \varepsilon.
\]

Therefore, for \( n \) this large,

\[
\mu(U), \mu_n(U) \in \left[ \int \phi \, d\mu - \varepsilon, \int \psi \, d\mu + \varepsilon \right]
\]
and so
\[ |\mu(U) - \mu_n(U)| < 3\varepsilon. \]
since \(\varepsilon\) is arbitrary, this proves the lemma.

**Definition 59.4.2** Let \((\Omega, F, P)\) be a probability space and let \(X : \Omega \to E\) be a random variable where here \(E\) is some topological space. Then one can define a probability measure, \(\lambda_X\) on \(\mathcal{B}(E)\) as follows:

\[ \lambda_X(F) \equiv P([X \in F]). \]

More generally, if \(\mu\) is a probability measure on \(\mathcal{B}(E)\), and \(X\) is a random variable defined on a probability space, \(\mathcal{L}(X) = \mu\) means

\[ \mu(F) \equiv P([X \in F]). \]

The following amazing theorem is due to Skorokhod. It starts with a measure, \(\mu\) on \(\mathcal{B}(E)\) and produces a random variable, \(X\) for which \(\mathcal{L}(X) = \mu\). It also has something to say about the convergence of a sequence of such random variables.

**Theorem 59.4.3** Let \(E\) be a separable complete metric space and let \(\{\mu_n\}\) be a sequence of Borel probability measures defined on \(\mathcal{B}(E)\) such that \(\mu_n\) converges weakly to \(\mu\) another probability measure on \(\mathcal{B}(E)\). Then there exist random variables, \(X_n, X\) defined on the probability space, \(([0, 1], \mathcal{B}([0, 1]), m)\) where \(m\) is one dimensional Lebesgue measure such that

\[ \mathcal{L}(X) = \mu, \mathcal{L}(X_n) = \mu_n, \quad (59.4.8) \]
each random variable, \(X, X_n\) is continuous off a set of measure zero, and

\[ X_n(\omega) \to X(\omega) \text{ m.a.e.} \]

**Proof:** Let \(\{a_k\}\) be a countable dense subset of \(E\).

**Construction of sets in \(E\)**

First I will describe a construction. Letting \(C \in \mathcal{B}(E)\) and \(r > 0\),

\[ C^r_1 \equiv C \cap B(a_1, r), C^r_2 \equiv B(a_2, r) \cap C \setminus C^r_1, \ldots, \]

\[ C^r_n \equiv B(a_n, r) \cap C \setminus \left(\bigcup_{k=1}^{n-1} C^r_k\right). \]

Thus the sets, \(C^r_k\) for \(k = 1, 2, \ldots\) are disjoint Borel sets whose union is all of \(C\). Of course many may be empty.

\[ C^r_n(\text{index of the } \{a_k\} \text{ it is close to}) \]

Now let \(C = E\), the whole metric space. Also let \(\{r_k\}\) be a decreasing sequence of positive numbers which converges to 0. Let

\[ A_k \equiv E^{r_k}_k, k = 1, 2, \ldots \]
Thus \( \{A_k\} \) is a sequence of Borel sets, \( A_k \subseteq B(a_k, r_k) \), and the union of the \( A_k \) equals \( E \). For \((i_1, \cdots, i_m) \in \mathbb{N}^m\), suppose \( A_{i_1, \cdots, i_m} \) has been defined. Then for \( k \in \mathbb{N} \),

\[
A_{i_1, \cdots, i_m, k} = ((A_{i_1, \cdots, i_m})_{k-1})_{k+1}
\]

Thus \( A_{i_1, \cdots, i_m, k} \subseteq B(a_k, r_{m+1}) \), is a Borel set, and

\[
\bigcup_{k=1}^{\infty} A_{i_1, \cdots, i_m, k} = A_{i_1, \cdots, i_m}. \tag{59.4.9}
\]

Also note that \( A_{i_1, \cdots, i_m} \) could be empty. This is because \( A_{i_1, \cdots, i_m, k} \subseteq B(a_k, r_{m+1}) \) but \( A_{i_1, \cdots, i_m} \subseteq B(a_m, r_m) \) which might have empty intersection with \( B(a_k, r_{m+1}) \). However, applying (59.4.9) repeatedly,

\[
E = \bigcup_{i_1} \cdots \bigcup_{i_m} A_{i_1, \cdots, i_m}
\]

and also, the construction shows the Borel sets, \( A_{i_1, \cdots, i_m} \) are disjoint. Note that to get \( A_{i_1, \cdots, i_m, k} \), you do to \( A_{i_1, \cdots, i_m} \) what was done for \( E \) but you consider smaller sized pieces.

**Construction of intervals depending on the measure**

Next I will construct intervals, \( I'_{i_1, \cdots, i_n} \) in \( [0, 1) \) corresponding to these \( A_{i_1, \cdots, i_n} \). In what follows, \( \nu = \mu_\nu \) or \( \mu \). These intervals will depend on the measure chosen as indicated in the notation.

\[
I'_i = [0, \nu(A_1)), \cdots, I'_j = \left[ \sum_{k=1}^{j-1} \nu(A_k), \sum_{k=1}^{j} \nu(A_k) \right]
\]

for \( j = 1, 2, \cdots \). Note these are disjoint intervals whose union is \([0, 1)\). Also note

\[
m(I'_j) = \nu(A_j).
\]

The endpoints of these intervals as well as their lengths depend on the measures of the sets \( A_k \). Now supposing \( I'_{i_1, \cdots, i_m} = [\alpha, \beta] \) where \( \beta - \alpha = \nu(A_{i_1, \cdots, i_m}) \), define

\[
I'_{i_1, \cdots, i_m, j} = \left[ \alpha + \sum_{k=1}^{j-1} \nu(A_{i_1, \cdots, i_m, k}), \alpha + \sum_{k=1}^{j} \nu(A_{i_1, \cdots, i_m, k}) \right]
\]

Thus \( m(I'_{i_1, \cdots, i_m, j}) = \nu(A_{i_1, \cdots, i_m, j}) \) and

\[
\nu(A_{i_1, \cdots, i_m}) = \sum_{k=1}^{\infty} \nu(A_{i_1, \cdots, i_m, k}) = \sum_{k=1}^{\infty} m(I'_{i_1, \cdots, i_m, k}) = \beta - \alpha,
\]

the intervals, \( I'_{i_1, \cdots, i_m, j} \) being disjoint and

\[
I'_{i_1, \cdots, i_m} = \bigcup_{j=1}^{\infty} I'_{i_1, \cdots, i_m, j}.
\]

These intervals satisfy the same inclusion properties as the sets \( \{A_{i_1, \cdots, i_m}\} \). They are just on \([0, 1)\) rather than on \( E \). The intervals \( I'_{i_1, \cdots, i_m, k} \) correspond to the sets \( A_{i_1, \cdots, i_m, k} \) and in fact the Lebesgue measure of the interval is the same as \( \nu(A_{i_1, \cdots, i_m, k}) \).
59.4. A MAJOR EXISTENCE AND CONVERGENCE THEOREM

Choosing the sequence \( \{r_k\} \) in an auspicious manner

There are at most countably many positive numbers, \( r \) such that for \( \nu = \mu_n \) or \( \mu, \nu (\partial B(a_i, r)) > 0 \). This is because \( \nu \) is a finite measure. Taking the countable union of these countable sets, there are only countably many \( r \) such that \( \nu (\partial B(a_i, r)) > 0 \) for some \( a_i \). Let the sequence avoid all these bad values of \( r \). Thus for

\[
F \equiv \bigcup_{m=1}^{\infty} \bigcup_{k=1}^{\infty} \partial B(a_k, r_m)
\]

and \( \nu = \mu \) or \( \mu_n, \nu (F) = 0 \). Here the \( r_m \) are all good values such that for all \( k, m \), \( \partial B(a_k, r_m) \) has \( \mu \) measure zero and \( \mu_n \) measure zero. The next claim is illustrated in the following picture. In the picture, \( A \) represents one of those \( A_{i_1, \ldots, i_m} \) and \( A_1 \) and \( A_2 \) are two of the sets \( A_{i_1, \ldots, i_m} \) which partition \( A_{i_1, \ldots, i_m} \).

![Picture of sets]

**Claim 1:** \( \partial A_{i_1, \ldots, i_k} \subseteq F \). This really follows from the construction. However, the details follow.

**Proof of claim:** Suppose \( C \) is a Borel set for which \( \partial C \subseteq F \). I need to show \( \partial C \subseteq F \). First consider \( k = 1 \). Then \( C_1 = B(a_1, r_1) \cap C \). If \( x \in \partial C_1 \), then \( B(x, \delta) \) contains points of \( B(a_1, r_1) \cap C \) and points of \( B(a_1, r_1)^C \cup C^C \) for every \( \delta > 0 \). First suppose \( x \in B(a_1, r_1) \). Then a small enough neighborhood of \( x \) has no points of \( B(a_1, r_1)^C \) and so every \( B(x, \delta) \) has points of \( C \) and points of \( C^C \) so that \( x \in \partial C \subseteq F \) by assumption. If \( x \in \partial C_1 \), then it can’t happen that \( ||x - a_1|| > r_1 \) because then there would be a neighborhood of \( x \) having no points of \( C_1 \). The only other case to consider is that \( ||x - a_1|| = r_1 \) but this says \( x \in F \). Now assume \( \partial C_j \subseteq F \) for \( j \leq k - 1 \) and consider \( \partial C_j \).

\[
C_k \equiv B(a_k, r_i) \cap C \setminus \bigcup_{j=1}^{k-1} C_j
= B(a_k, r_i) \cap C \cap \left( \bigcap_{j=1}^{k-1} C_j \right)^C
\]

(59.4.10)

Consider \( x \in \partial C_k \). If \( x \in \text{int} (B(a_k, r_i) \cap C) \) (int \( \equiv \) **interior**) then a small enough ball about \( x \) contains no points of \( (B(a_k, r_i) \cap C)^C \) and so every ball about \( x \) must contain points of

\[
\left( \bigcap_{j=1}^{k-1} C_j \right)^C = \bigcup_{j=1}^{k-1} C_j
\]

Since there are only finitely many sets in the union, there exists \( s \leq k - 1 \) such that every ball about \( x \) contains points of \( C_s \) but from \( \text{ ** **} \), every ball about \( x \) contains points of \( (C_s)^C \) which implies \( x \in \partial C_s \subseteq F \) by induction. It is not
possible that \( d(x, a_k) > r_i \) and yet have \( x \) in \( \partial C_k \). This follows from the description in [9.4.10]. If \( d(x, a_k) = r_i \) then by definition, \( x \in F \). The only other case to consider is that \( x \notin \operatorname{int}(B(a_k, r_i) \cap C) \) but \( x \in B(a_k, r_i) \). From [9.4.10], every ball about \( x \) contains points of \( C \). However, since \( x \in B(a_k, r_i) \), a small enough ball is contained in \( B(a_k, r_i) \). Therefore, every ball about \( x \) must also contain points of \( C \) since otherwise, \( x \notin \operatorname{int}(B(a_k, r_i) \cap C) \). Thus \( x \notin \partial C \subseteq F \) by assumption. Now apply what was just shown to the case where \( C = E \), the whole space. In this case, \( \partial E \subseteq F \) because \( \partial E = \emptyset \). Then keep applying what was just shown to the \( A_{i_1, \ldots, i_n} \). This proves the claim.

From the claim, \( \nu(\operatorname{int}(A_{i_1, \ldots, i_n})) = \nu(A_{i_1, \ldots, i_n}) \) whenever \( \nu = \mu \) or \( \mu_n \). This is because that in \( A_{i_1, \ldots, i_n} \), which is not in \( \operatorname{int}(A_{i_1, \ldots, i_n}) \) is in \( F \) which has measure zero.

**Some functions on \([0, 1]\)**

By the axiom of choice, there exists \( x_{i_1, \ldots, i_m} \in \operatorname{int}(A_{i_1, \ldots, i_m}) \) whenever

\[
\operatorname{int}(A_{i_1, \ldots, i_n}) \neq \emptyset.
\]

For \( \nu = \mu_n \) or \( \mu \), define the following functions. For \( \omega \in I_{i_1, \ldots, i_m}^n \)

\[
Z_m^n(\omega) \equiv x_{i_1, \ldots, i_m}.
\]

This defines the functions, \( Z_m^n \) and \( Z_m^n \). Note these functions have the same values but on slightly different intervals. Here is an important claim.

**Claim 2 (Limit on \( \mu_n \)):** For a.e. \( \omega \in [0, 1) \), \( \lim_{n \to \infty} Z_m^n(\omega) = Z_m^n(\omega) \).

**Proof of the claim:** This follows from the weak convergence of \( \mu_n \) to \( \mu \) and Lemma [9.4.10]. This lemma implies \( \mu_n(\operatorname{int}(A_{i_1, \ldots, i_m})) \to \mu(\operatorname{int}(A_{i_1, \ldots, i_m})) \). Thus by the construction described above, \( \mu_n(A_{i_1, \ldots, i_m}) \to \mu(A_{i_1, \ldots, i_m}) \) because of claim 1 and the construction of \( F \) in which it is always a set of measure zero. It follows that if \( \omega \in \operatorname{int}(I_{i_1, \ldots, i_m}^n) \), then for all \( n \) large enough, \( \omega \in \operatorname{int}(I_{i_1, \ldots, i_m}^n) \) and so \( Z_m^n(\omega) = Z_m^n(\omega) \). Note this convergence is very far from being uniform.

**Claim 3 (Limit on size of sets, fixed measure):** For \( \nu = \mu_n \) or \( \mu \), \( \{Z_m^n\}_{m=1}^\infty \) is uniformly Cauchy independent of \( \nu \).

**Proof of the claim:** For \( \omega \in I_{i_1, \ldots, i_m}^n \), then by the construction, \( \omega \in I_{i_1, \ldots, i_m, i_{m+1}, \ldots, i_n} \) for some \( i_{m+1}, \ldots, i_n \). Therefore, \( Z_m^n(\omega) \) and \( Z_m^n(\omega) \) are both contained in \( A_{i_1, \ldots, i_m} \) which is contained in \( B(a_k, r_i) \). Since \( \omega \in [0, 1) \) was arbitrary, and \( r_m \to 0 \), it follows these functions are uniformly Cauchy as claimed.

Let \( X^n(\omega) = \lim_{n \to \infty} Z_m^n(\omega) \). Since each \( Z_m^n \) is continuous off a set of measure zero, it follows from the uniform convergence that \( X^n \) is also continuous off a set of measure zero.

**Claim 4:** For a.e. \( \omega \),

\[
\lim_{n \to \infty} X^n(\omega) = X(\omega).
\]

**Proof of the claim:** From Claim 3 and letting \( \varepsilon > 0 \) be given, there exists \( n \) large enough that for all \( n \),

\[
\sup_{\omega} d(Z_m^n(\omega), X^n(\omega)) < \varepsilon/3, \quad \sup_{\omega} d(Z_m^n(\omega), X(\omega)) < \varepsilon/3.
\]
for \(\omega\) off a set of measure zero. Now pick \(\omega \in [0, 1)\) such that \(\omega\) is not equal to any of the end points of any of the intervals, \(\{I_{i_1, \ldots, i_m}\}\), this countable set of endpoints, a set of Lebesgue measure zero. Then by Claim 2, there exists \(N\) such that if \(n \geq N\), then \(d(Z_m^\mu (\omega), Z_m^\nu (\omega)) < \varepsilon/3\). Therefore, for such \(n\) and this \(\omega\),

\[
d(X^\mu (\omega), X^\nu (\omega)) \leq d(X^\mu (\omega), Z_m^\mu (\omega)) + d(Z_m^\mu (\omega), Z_m^\nu (\omega)) + d(Z_m^\nu (\omega), X^\nu (\omega)) < \varepsilon/3 + \varepsilon/3 + \varepsilon/3 = \varepsilon.
\]

This proves the claim.

**Showing \(\mathcal{L}(X^\nu) = \nu.\)**

This has mostly proved the theorem except for the claim that \(\mathcal{L}(X^\nu) = \nu\) for \(\nu = \mu_n\) and \(\mu\). To do this, I will first show \(m\left((X^\nu)^{-1}(\partial A_{i_1, \ldots, i_m})\right) = 0\). By the construction, \(\nu(\partial A_{i_1, \ldots, i_m}) = 0\). Let \(\varepsilon > 0\) be given and let \(\delta > 0\) be small enough that

\[
H_\delta \equiv \{x \in E : \text{dist}(x, \partial A_{i_1, \ldots, i_m}) \leq \delta\}
\]

is a set of measure less than \(\varepsilon/2\). Denote by \(G_k\) the sets of the form \(A_{i_1, \ldots, i_k}\) where \((i_1, \ldots, i_k) \in \mathbb{N}^k\). Recall also that corresponding to \(A_{i_1, \ldots, i_k}\) is an interval, \(I_{i_1, \ldots, i_k}\) having length equal to \(\nu(A_{i_1, \ldots, i_k})\). Denote by \(B_k\) those sets of \(G_k\) which have nonempty intersection with \(H_\delta\) and let the corresponding intervals be denoted by \(I^\nu_k\). If \(\omega \notin \cup I^\nu_k\), then from the construction, \(Z^\nu_k(\omega)\) is at a distance of at least \(\delta\) from \(\partial A_{i_1, \ldots, i_m}\) for all \(p \geq k\). (If \(Z^\nu_k(\omega)\) were in some set of \(B_k\), this would require \(\omega\) to be in the corresponding \(I^\nu_k\) and it is assumed this does not happen. Then for any \(p > k\), \(Z^\nu_k(\omega)\) cannot be in any set of \(G_p\) which intersects \(H_\delta\) either. If it did, you would need to have \(\omega \notin \cup I^\nu_k\) but all of these intervals are inside the intervals \(I^\nu_k\).) Passing to the limit as \(p \to \infty\), it follows \(X^\nu(\omega) \notin \partial A_{i_1, \ldots, i_m}\). Therefore,

\[
(X^\nu)^{-1}(\partial A_{i_1, \ldots, i_m}) \subseteq \cup I^\nu_k
\]

Recall that \(A_{i_1, \ldots, i_k} \subseteq B(a_{i_k}, r_k)\) and the \(r_k \to 0\). Therefore, if \(k\) is large enough,

\[
\nu(\cup B_k) < \varepsilon
\]

because \(\cup B_k\) approximates \(H_\delta\) closely (In fact, \(\cap_{k=1}^{\infty} (\cup B_k) = H_\delta\)). Therefore,

\[
m\left((X^\nu)^{-1}(\partial A_{i_1, \ldots, i_m})\right) \leq m(\cup I^\nu_k) = \sum_{I^\nu_{i_1, \ldots, i_k} \in I^\nu_k} m(I^\nu_{i_1, \ldots, i_k}) = \sum_{A_{i_1, \ldots, i_k} \in B_k} \nu(A_{i_1, \ldots, i_k}) = \nu(\cup B_k) < \varepsilon.
\]
CHAPTER 59. PROBABILITY IN INFINITE DIMENSIONS

Since $\varepsilon > 0$ is arbitrary, this shows $m \left( (X^\nu)^{-1} (\partial A_{i_1, \ldots, i_m}) \right) = 0.$

If $\omega \in I_{i_1, \ldots, i_m}^\nu,$ then from the construction, $Z_p^\nu (\omega) \in \text{int} (A_{i_1, \ldots, i_m})$ for all $p \geq k.$ Therefore, taking a limit, as $p \to \infty,$

$$X^\nu (\omega) \in \text{int} (A_{i_1, \ldots, i_m}) \cup \partial A_{i_1, \ldots, i_m}$$

and so

$$I_{i_1, \ldots, i_m}^\nu \subseteq (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m}) \cup \partial A_{i_1, \ldots, i_m})$$

but also, if $X^\nu (\omega) \in \text{int} (A_{i_1, \ldots, i_m}),$ then $Z_p^\nu (\omega) \in \text{int} (A_{i_1, \ldots, i_m})$ for all $p$ large enough and so

$$(X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \subseteq I_{i_1, \ldots, i_m}^\nu \subseteq (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m}) \cup \partial A_{i_1, \ldots, i_m})$$

Therefore,

$$m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right)$$

$$\leq m \left( I_{i_1, \ldots, i_m}^\nu \right)$$

$$\leq m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right) + m \left( (X^\nu)^{-1} (\partial A_{i_1, \ldots, i_m}) \right)$$

$$= m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right)$$

which shows

$$m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right) = m \left( I_{i_1, \ldots, i_m}^\nu \right) = \nu (A_{i_1, \ldots, i_m}). \quad (59.4.11)$$

Also

$$m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right)$$

$$\leq m \left( (X^\nu)^{-1} (A_{i_1, \ldots, i_m}) \right)$$

$$\leq m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m}) \cup \partial A_{i_1, \ldots, i_m}) \right)$$

$$= m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right)$$

Hence from (59.4.11)

$$\nu (A_{i_1, \ldots, i_m}) = m \left( (X^\nu)^{-1} (\text{int} (A_{i_1, \ldots, i_m})) \right)$$

$$= m \left( (X^\nu)^{-1} (A_{i_1, \ldots, i_m}) \right) \quad (59.4.12)$$

Now let $U$ be an open set in $E.$ Then letting

$$H_k = \{ x \in U : \text{dist} (x, U^C) \geq r_k \}$$
it follows

$$\bigcup_k H_k = U.$$  

Next consider the sets of $G_k$ which have nonempty intersection with $H_k, H_k$. Then $H_k$ is covered by $H_k$ and every set of $H_k$ is contained in $U$, the sets of $H_k$ also being disjoint. Then from 59.4.12,

$$m \left( (X')^{-1} \left( \bigcup H_k \right) \right) = \sum_{A \in H_k} m \left( (X')^{-1} (A) \right) = \sum_{A \in H_k} \nu (A) = \nu \left( \bigcup H_k \right).$$

Therefore, letting $k \to \infty$ and passing to the limit in the above,

$$m \left( (X')^{-1} (U) \right) = \nu (U).$$

Since this holds for every open set, it is routine to verify using regularity that it holds for every Borel set and so $\mathcal{L} (X') = \nu$ as claimed. 

### 59.5 Bochner’s Theorem In Infinite Dimensions

Let $X$ be a real vector space and let $X^*$ denote the space of real valued linear mappings defined on $X$. Then you can consider each $x \in X$ as a linear transformation defined on $X$ by the convention $x^* \mapsto x^* (x)$. Now let $\Lambda$ be a Hamel basis. For a description of what one of these is, see Page 2785. It is just the usual notion of a basis. Thus every vector of $X$ is a finite linear combination of vectors of $\Lambda$ in a unique way.

Now consider $\mathbb{R}^\Lambda$ the space of all mappings from $\Lambda$ to $\mathbb{R}$. In different notation, this is of the form

$$\mathbb{R}^\Lambda = \prod_{y \in \Lambda} \mathbb{R}.$$  

Since $\Lambda$ is a Hamel basis, there exists a one to one and onto mapping, $\theta : X^* \to \mathbb{R}^\Lambda$ defined as

$$\theta (x^*) = \prod_{y \in \Lambda} x^* (y).$$

Now denote by $\sigma (X)$ the smallest $\sigma$ algebra of sets of $X^*$ such that each $x$ is measurable with respect to this $\sigma$ algebra. Thus

$$\{ x^* : x^* (x) \in B \} \in \sigma (X)$$

whenever $B$ is a Borel set in $\mathbb{R}$.

Let $\mathcal{E}$ denote the algebra of disjoint unions of sets of $\mathbb{R}^\Lambda$ of the form

$$\prod_{y \in \Lambda} A_y$$

where $A_y = \mathbb{R}$ except for finitely many $y$. 
Lemma 59.5.1 Let $\mathcal{A}$ denote sets of the form

$$\{x^*: \theta (x^*) \in U\}$$

where $U \in \mathcal{E}$. Then $\mathcal{A}$ is an algebra and $\sigma (\mathcal{A}) = \sigma (X)$. Also

$$\{\theta^{-1} (U): U \in \sigma (\mathcal{E})\} = \sigma (X)$$

Proof: Since $\mathcal{E}$ is an algebra it is clear $\mathcal{A}$ is also an algebra. Also, $\mathcal{A} \subseteq \sigma (X)$ because you could let $U$ have only one $A_y$ not equal to $\mathbb{R}$ and all the others equal to $\mathbb{R}$ and then

$$\{x^*: \theta (x^*) \in U\} = \{x^*: y (x^*) \equiv x^* (y) \in A_y\} \in \sigma (X).$$

Therefore, $\sigma (\mathcal{A}) \subseteq \sigma (X)$. I need to verify that for an arbitrary $x$, it is measurable with respect to $\sigma (\mathcal{A})$. However, this is true because if $x$ is arbitrary, it is a linear combination of $\{y_1, \cdots, y_n\}$, some finite set of functions in $\Lambda$ and so, $x$ being a linear combination of measurable functions implies it is itself measurable.

By definition, $\theta^{-1} (U)$ is in $\mathcal{A}$ whenever $U \in \mathcal{E}$. Now let $\mathcal{G}$ denote those sets, $U$ in $\sigma (\mathcal{E})$ such that $\theta^{-1} (U) \in \sigma (\mathcal{A})$. Then $\mathcal{G}$ is a $\sigma$ algebra which contains $\mathcal{E}$ and so $\mathcal{G} \supseteq \sigma (\mathcal{E}) \supseteq \mathcal{G}$. This proves the last claim. This proves the lemma.

Definition 59.5.2 Let $\psi : X \to \mathbb{C}$. Then $\psi$ is said to be pseudo continuous if whenever $\{x_1, \cdots, x_n\}$ is a finite subset of $X$ and $a = (a_1, \cdots, a_n) \in \mathbb{R}^n$,

$$a \to \psi \left( \sum_{k=1}^{n} a_k x_k \right)$$

is continuous. $\psi$ is said to be positive definite if

$$\sum_{j,k} \psi (x_k - x_j) a_k \bar{a_j} \geq 0$$

$\psi$ is said to be a characteristic function if there exists a probability measure, $\mu$ defined on $\sigma (X)$ such that

$$\psi (x) = \int_{X^*} e^{ix^* (x)} d\mu (x^*)$$

Note that $x^* \to e^{ix^* (x)}$ is $\sigma (X)$ measurable.

Using Kolmogorov’s extension theorem on Page 223, there exists a generalization of Bochner’s theorem found in [113]. For convenience, here is Kolmogorov’s theorem.

Theorem 59.5.3 (Kolmogorov extension theorem) For each finite set

$$J = (t_1, \cdots, t_n) \subseteq I,$$
suppose there exists a Borel probability measure, \( \nu = \nu_{t_1 \cdots t_n} \) defined on the Borel sets of \( \prod_{t \in I} M_t \) for \( M_t = \mathbb{R}^{n_t} \) for \( n_t \) an integer, such that the following consistency condition holds. If

\[
(t_1, \cdots, t_n) \subseteq (s_1, \cdots, s_p),
\]

then

\[
\nu_{t_1 \cdots t_n} (F_{t_1} \times \cdots \times F_{t_n}) = \nu_{s_1 \cdots s_p} (G_{s_1} \times \cdots \times G_{s_p})
\]

(59.5.13)

where if \( s_i = t_j \), then \( G_{s_i} = F_{t_j} \) and if \( s_i \) is not equal to any of the indices, \( t_k \), then \( G_{s_i} = M_{s_i} \). Then for \( E \) defined as in Definition [2.2.3.1], adjusted so that \( \pm \infty \) never appears as any endpoint of any interval, there exists a probability measure, \( P \) and a \( \sigma \) algebra \( \mathcal{F} = \sigma (\mathcal{E}) \) such that

\[
\left( \prod_{t \in I} M_t, P, \mathcal{F} \right)
\]

is a probability space. Also there exist measurable functions, \( X_s : \prod_{t \in I} M_t \to M_s \) defined as

\[
X_s \equiv x_s
\]

for each \( s \in I \) such that for each \( (t_1 \cdots t_n) \subseteq I \),

\[
\nu_{t_1 \cdots t_n} (F_{t_1} \times \cdots \times F_{t_n}) = P \left( [X_{t_1} \in F_{t_1}] \cap \cdots \cap [X_{t_n} \in F_{t_n}] \right)
\]

\[
= P \left( (X_{t_1}, \cdots, X_{t_n}) \in \prod_{j=1}^{n} F_{t_j} \right) = P \left( \prod_{t \in I} F_t \right)
\]

(59.5.14)

where \( F_t = M_t \) for every \( t \notin \{ t_1 \cdots t_n \} \) and \( F_{t_i} \) is a Borel set. Also if \( f \) is a nonnegative function of finitely many variables, \( x_{t_1}, \cdots, x_{t_n} \), measurable with respect to \( \mathcal{B} \left( \prod_{j=1}^{n} M_{t_j} \right) \), then \( f \) is also measurable with respect to \( \mathcal{F} \) and

\[
\int_{M_{t_1} \times \cdots \times M_{t_n}} f(x_{t_1}, \cdots, x_{t_n}) \, d\nu_{t_1 \cdots t_n} = \int_{\prod_{t \in I} M_t} f(x_{t_1}, \cdots, x_{t_n}) \, dP
\]

(59.5.15)

**Theorem 59.5.4** Let \( X \) be a real vector space and let \( X^* \) be the space of linear functionals defined on \( X \). Also let \( \psi : X \to \mathbb{C} \). Then \( \psi \) is a characteristic function if and only if \( \psi (0) = 1 \) and \( \psi \) is pseudo continuous at 0.

**Proof:** Suppose first \( \psi \) is a characteristic function as just described. I need to show it is positive definite and pseudo continuous. It is obvious \( \psi (0) = 1 \) in this case. Also

\[
\psi \left( \sum_k a_k x_k \right) = \int_{X^*} \exp \left( ix^* \left( \sum_k a_k x_k \right) \right) \, d\mu (x^*)
\]
and this is obviously a continuous function of $a$ by the dominated convergence theorem. It only remains to verify the function is positive definite. However,

$$\sum_{k,j} \exp \left( ix^* (x_k - x_j) \right) \alpha_k \alpha_j = \sum_{k,j} e^{ix^* (x_k)} \alpha_k \alpha_j \geq 0$$

as in the earlier discussion of what it means to be positive definite given on Page 1986.

Next suppose the conditions hold. Define for $t \in \mathbb{R}^n$ and $\{y_1, \ldots, y_n\} \subseteq \Lambda$

$$\psi_{\{y_1, \ldots, y_n\}} (t) \equiv \psi \left( \sum_{j=1}^n t_j y_j \right).$$

Then $\psi_{\{y_1, \ldots, y_n\}}$ is continuous at $0$, equals 1 there, and is positive definite. It follows from Bochner’s theorem, Theorem 57.21.7 on Page 1990 there exists a measure $\mu_{\{y_1, \ldots, y_n\}}$ defined on the Borel sets of $\mathbb{R}^n$ such that

$$\psi \left( \sum_{j=1}^n t_j y_j \right) = \psi_{\{y_1, \ldots, y_n\}} (t) = \int_{\mathbb{R}^n} e^{it^* x} d\mu_{\{y_1, \ldots, y_n\}} (x). \quad (59.5.16)$$

Thus if $\{y_1, \ldots, y_n, y_{n+1}, \ldots, y_p\} \subseteq \Lambda$,

$$\psi \left( \sum_{j=1}^n t_j y_j + \sum_{j=1}^{p-n} s_j y_{j+n} \right) = \psi_{\{y_1, \ldots, y_p\}} (t, s) = \int_{\mathbb{R}^{p-n}} e^{is^* x} \int_{\mathbb{R}^n} e^{it^* x} d\mu_{\{y_1, \ldots, y_p\}} (x)$$

I need to verify the measures are consistent to use Kolmogorov’s theorem. Specifically, I need to show

$$\mu_{\{y_1, \ldots, y_p\}} (A \times \mathbb{R}^{p-n}) = \mu_{\{y_1, \ldots, y_n\}} (A).$$

Letting

$$\lambda (A) = \mu_{\{y_1, \ldots, y_p\}} (A \times \mathbb{R}^{p-n})$$
it follows
\[
\int_{\mathbb{R}^n} e^{it\cdot x} d\lambda = \int_{\mathbb{R}^p \times \mathbb{R}^n} e^{it\cdot x} d\mu_{\{y_1, \ldots, y_p\}}(x) = \int_{\mathbb{R}^{p-n}} e^{it\cdot x} d\mu_{\{y_{p-n+1}, \ldots, y_n\}}(x)
\]
\[
= \psi \left( \sum_{j=1}^{n} t_j y_j + \sum_{j=1}^{p-n} 0 y_{j+n} \right) = \psi \left( \sum_{j=1}^{n} t_j y_j \right)
\]
\[
= \int_{\mathbb{R}^n} e^{it\cdot x} d\mu_{\{y_1, \ldots, y_n\}}(x)
\]
and so, by uniqueness of characteristic functions,
\[
\lambda = \mu_{\{y_1, \ldots, y_n\}}
\]
which verifies the necessary consistency condition for Kolmogorov’s theorem.

It follows there exists a probability measure \( \mu \) defined on \( \sigma(\mathcal{E}) \) and random variables, \( X_y \) for each \( y \in \Lambda \) such that whenever \( \{y_1, \ldots, y_p\} \subseteq \Lambda \),
\[
\mu_{\{y_1, \ldots, y_p\}}(A_{y_1} \times \cdots \times A_{y_n}) = \mu \left( \prod_{y \in \Lambda} A_y \right)
\]
where \( A_y = \mathbb{R} \) whenever \( y \notin \{y_1, \ldots, y_p\} \). This defines a measure on \( \sigma(\mathcal{E}) \) which consists of sets of \( \mathbb{R}^\Lambda \).

By Lemma 59.5.1 it follows \( \{\theta^{-1}(U) : U \in \sigma(\mathcal{E})\} = \sigma(\mathcal{A}) \) which equals \( \sigma(X) \).
Define \( \nu \) on \( \sigma(X) \) by
\[
\nu(F) = \mu(\theta F).
\]
Thus \( \nu \) is a measure because \( \mu \) is and \( \theta \) is one to one.

I need to check whether \( \nu \) works. Let \( x = \sum_{k=1}^{m} t_k y_k \) and let a typical element of \( \mathbb{R}^\Lambda \) be denoted by \( z \). Then by Kolmogorov’s theorem above,
\[
\int_{\mathbb{R}^m} \exp \left( i x^* \left( \sum_{k=1}^{m} t_k y_k \right) \right) d\nu = \int_{\mathbb{R}^m} \exp \left( i \left( \sum_{k=1}^{m} t_k x^*(y_k) \right) \right) d\nu = \int_{\mathbb{R}^\Lambda} \exp \left( i \left( \sum_{k=1}^{m} t_k \pi y_k z \right) \right) d\mu = \int_{\mathbb{R}^m} \exp \left( i (t \cdot x) \right) d\mu_{\{y_1, \ldots, y_m\}}(x) = \psi \left( \sum_{k=1}^{m} t_k y_k \right)
\]
where the last equality comes from \( \text{Eq. } 59.5.16 \). Since \( \Lambda \) is a Hamel basis, it follows that for every \( x \in X \),
\[
\psi(x) = \int_X \exp (ix^* (x)) \, d\nu
\]
This proves the theorem.

### 59.6 The Multivariate Normal Distribution

Here I give a review of the main theorems and definitions about multivariate normal random variables. Recall that for a random vector (variable), \( X \) having values in \( \mathbb{R}^p \), \( \lambda_X \) is the law of \( X \) defined by
\[
P ([X \in E]) = \lambda_X (E)
\]
for all \( E \) a Borel set in \( \mathbb{R}^p \). In different notation, \( \mathcal{L}(X) = \lambda_X \). Then the following definitions and theorems are proved and presented starting on Page 1956.

**Definition 59.6.1** A random vector, \( X \), with values in \( \mathbb{R}^p \) has a multivariate normal distribution written as \( X \sim N_p (m, \Sigma) \) if for all Borel \( E \subset \mathbb{R}^p \),
\[
\lambda_X (E) = \int_{\mathbb{R}^p} \chi_E (x) \frac{1}{(2\pi)^{p/2} \det (\Sigma)^{1/2}} e^{-\frac{1}{2} (x - m)^* \Sigma^{-1} (x - m)} \, dx
\]
for \( \mu \) a given vector and \( \Sigma \) a given positive definite symmetric matrix.

**Theorem 59.6.2** For \( X \sim N_p (m, \Sigma) \), \( m = E(X) \) and
\[
\Sigma = E ((X - m) (X - m)^*)
\]

**Theorem 59.6.3** Suppose \( X_1 \sim N_p (m_1, \Sigma_1) \), \( X_2 \sim N_p (m_2, \Sigma_2) \) and the two random vectors are independent. Then
\[
X_1 + X_2 \sim N_p (m_1 + m_2, \Sigma_1 + \Sigma_2).
\]
Also, if \( X \sim N_p (m, \Sigma) \) then \( -X \sim N_p (-m, \Sigma) \). Furthermore, if \( X \sim N_p (m, \Sigma) \) then
\[
E (e^{itX}) = e^{it^* m} e^{-\frac{1}{2} t^* \Sigma t}
\]
Also if a is a constant and \( X \sim N_p (m, \Sigma) \) then \( aX \sim N_p (am, a^2 \Sigma) \).

Following \( [13] \) a random vector has a generalized normal distribution if its characteristic function is given as
\[
e^{it^* m} e^{-\frac{1}{2} t^* \Sigma t}
\]
where \( \Sigma \) is symmetric and has nonnegative eigenvalues. For a random real valued variable, \( m \) is scalar and so is \( \Sigma \) so the characteristic function of such a generalized normally distributed random variable is
\[
e^{itm} e^{-\frac{1}{2} t^2 \sigma^2}
\]
These generalized normal distributions do not require $\Sigma$ to be invertible, only that the eigenvalues be nonnegative. In one dimension this would correspond the characteristic function of a dirac measure having point mass 1 at $m$. In higher dimensions, it could be a mixture of such things with more familiar things. I will often not bother to distinguish between generalized normal and normal distributions.

Here are some other interesting results about normal distributions found in [94].

Theorem 59.6.4 Let $\mathbf{X} = (X_1, \cdots, X_p)$ where each $X_i$ is a real valued random variable. Then $\mathbf{X}$ is normally distributed in the above generalized sense if and only if every linear combination, $\sum_{j=1}^{p} a_j X_i$ is normally distributed. In this case the mean of $\mathbf{X}$ is

$$m = (E(X_1), \cdots, E(X_p))$$

and the covariance matrix for $\mathbf{X}$ is

$$\Sigma_{jk} = E((X_j - m_j)(X_k - m_k))$$

where $m_j = E(X_j)$.

Also proved there is the interesting corollary listed next.

Corollary 59.6.5 Let $\mathbf{X} = (X_1, \cdots, X_p), \mathbf{Y} = (Y_1, \cdots, Y_p)$ where each $X_i, Y_i$ is a real valued random variable. Suppose also that for every $a \in \mathbb{R}^p$, $a \cdot \mathbf{X}$ and $a \cdot \mathbf{Y}$ are both normally distributed with the same mean and variance. Then $\mathbf{X}$ and $\mathbf{Y}$ are both multivariate normal random vectors with the same mean and variance.

Theorem 59.6.6 Suppose $\mathbf{X} = (X_1, \cdots, X_p)$ is normally distributed with mean $\mathbf{m}$ and covariance $\Sigma$. Then if $X_1$ is uncorrelated with any of the $X_i$, $E((X_1 - m_1)(X_j - m_j)) = 0$ for $j > 1$

then $X_1$ and $(X_2, \cdots, X_p)$ are both normally distributed and the two random vectors are independent. Here $m_j = E(X_j)$.

Next I will consider the question of existence of independent random variables having a given law.

Lemma 59.6.7 Let $\mu$ be a probability measure on $\mathcal{B}(E)$, the Borel subsets of a separable real Banach space. Then there exists a probability space $(\Omega, \mathcal{F}, P)$ and two independent random variables, $X, Y$ mapping $\Omega$ to $E$ such that $\mathcal{L}(X) = \mathcal{L}(Y) = \mu$.

Proof: First note that if $A, B$ are Borel sets of $E$ then $A \times B$ is a Borel set in $E \times E$ where the norm on $E \times E$ is given by

$$||(x, y)|| = \max(||x||, ||y||).$$
This can be proved by letting $A$ be open and considering
\[ \mathcal{G} \equiv \{ B \in \mathcal{B}(E) : A \times B \in \mathcal{B}(A \times B) \} . \]

Show $\mathcal{G}$ is a $\sigma$ algebra and it contains the open sets. Therefore, this will show $A \times B$ is in $\mathcal{B}(A \times B)$ whenever $A$ is open and $B$ is Borel. Next repeat a similar argument to show that this is true whenever either set is Borel. Since $E$ is separable, it is completely separable and so is $E \times E$. Thus every open set in $E \times E$ is the union of balls from a countable set. However, these balls are of the form $B^1_1 \times B^2_2$ where $B^1_i$ is a ball in $E$.

Now let
\[ \mathcal{K} \equiv \{ A \times B : A, B \text{ are Borel} \} \]

Then $\mathcal{K} \subseteq \mathcal{B}(E \times E)$ as was just shown and also every open set from $E \times E$ is in $\sigma(\mathcal{K})$. It follows $\sigma(\mathcal{K})$ equals the $\sigma$ algebra of product measurable sets, $\mathcal{B}(E) \times \mathcal{B}(E)$ and you can consider the product measure, $\mu \times \mu$. By Skorokhod’s theorem, Theorem (59.4.8), there exists $(\xi, \zeta)$ a random variable with values in $E \times E$ and a probability space, $(\Omega, \mathcal{F}, P)$ such that $L((X, Y)) = \mu \times \mu$. Then for $A, B$ Borel sets in $E$
\[ P(X \in A, Y \in B) = (\mu \times \mu)(A \times B) = \mu(A) \mu(B) . \]

Also, $P(X \in A) = P(X \in A, Y \in E) = \mu(A)$ and similarly, $P(Y \in B) = \mu(B)$ showing $L(X) = L(Y) = \mu$ and $X, Y$ are independent.

Now here is an interesting theorem in [34].

**Theorem 59.6.8** Suppose $\nu$ is a probability measure on the Borel sets of $\mathbb{R}$ and suppose that $\xi$ and $\zeta$ are independent random variables such that $L(\xi) = L(\zeta) = \nu$ and whenever $\alpha^2 + \beta^2 = 1$ it follows $L(\alpha \xi + \beta \zeta) = \nu$. Then
\[ L(\xi) = N(0, \sigma^2) \]

for some $\sigma \geq 0$. Also if $L(\xi) = L(\zeta) = N(0, \sigma^2)$ where $\xi, \zeta$ are independent, then if $\alpha^2 + \beta^2 = 1$, it follows $L(\alpha \xi + \beta \zeta) = N(0, \sigma^2)$.

**Proof:** Let $\xi, \zeta$ be independent random variables with $L(\xi) = L(\zeta) = \nu$ and whenever $\alpha^2 + \beta^2 = 1$ it follows $L(\alpha \xi + \beta \zeta) = \nu$.

By independence of $\xi$ and $\zeta$,
\[ \phi_\nu(t) = \phi_{\alpha \xi + \beta \zeta}(t) = E(e^{it(\alpha \xi + \beta \zeta)}) = E(e^{ita \xi}) E(e^{itb \zeta}) = \phi_\xi(\alpha t) \phi_\zeta(\beta t) = \phi_\nu(\alpha t) \phi_\nu(\beta t) . \]

In simpler terms and suppressing the subscript,
\[ \phi(t) = \phi(\cos(\theta) t) \phi(\sin(\theta) t) . \] (59.6.21)
Since $\nu$ is a probability measure, $\phi(0) = 1$. Also, letting $\theta = \pi/4$, this yields
\[ \phi(t) = \phi \left( \frac{\sqrt{2}}{2} t \right)^2 \] (59.6.22)
and so if $\phi$ has real values, then $\phi(t) \geq 0$.

Next I will show $\phi$ is real. To do this, it follows from the definition of $\phi$, $\phi(-t) = \int_{\mathbb{R}} e^{-itx} \, d\nu = \int_{\mathbb{R}} e^{itx} \, d\nu = \phi(t)$.

Then letting $\theta = \pi$, $\phi(t) = \phi(-t) \cdot \phi(0) = \phi(-t) = \phi(t)$ showing $\phi$ has real values. It is positive near 0 because $\phi(0) = 1$ and $\phi$ is a continuous function of $t$ thanks to the dominated convergence theorem. However, this and 59.6.22 implies it is positive everywhere. Here is why. If not, let $t_m$ be the smallest positive value of $t$ where $\phi(t) = 0$. Then $t_m > 0$ by continuity. Now from 59.6.22, an immediate contradiction results. Therefore, $\phi(t) > 0$ for all $t > 0$.

Similar reasoning yields the same conclusion for $t < 0$.

Next note that $\phi(t) = \phi(-t)$ also implies $\phi$ depends only on $|t|$ because it takes the same value for $t$ as for $-t$. More simply, $\phi$ depends only on $t^2$. Thus one can define a new function of the form $\phi(t) = f(t^2)$ and 59.6.21 implies the following for $\alpha \in [0,1]$.
\[ f(t^2) = f(\alpha^2 t^2) f \left( (1 - \alpha^2) t^2 \right). \]

Taking $\ln$ of both sides, one obtains the following.
\[ \ln f(t^2) = \ln f(\alpha^2 t^2) + \ln f \left( (1 - \alpha^2) t^2 \right). \]
Now let $x, y \geq 0$. Then choose $t$ such that $t^2 = x + y$. Then for some $\alpha \in [0, 1]$, $x = \alpha^2 t^2$ and so $y = t^2 (1 - \alpha^2)$. Thus for $x, y \geq 0$,
\[ \ln f(x + y) = \ln f(x) + \ln f(y). \]
Hence $\ln f(x) = kx$ and so $\ln f(t^2) = kt^2$ and so $\phi(t) = f(t^2) = e^{kt^2}$ for all $t$. The constant, $k$ must be nonpositive because $\phi(t)$ is bounded due to its definition. Therefore, the characteristic function of $\nu$ is
\[ \phi_{\nu}(t) = e^{-\frac{1}{2} t^2 \sigma^2} \]
for some $\sigma \geq 0$. That is, $\nu$ is the law of a generalized normal random variable.

Note the other direction of the implication is obvious. If $\xi, \zeta \sim N(0, \sigma)$ and they are independent, then if $\alpha^2 + \beta^2 = 1$, it follows
\[ \alpha \xi + \beta \zeta \sim N(0, \sigma^2) \]
because
\[
E \left( e^{it(\alpha \xi + \beta \zeta)} \right) = E \left( e^{it\alpha \xi} \right) E \left( e^{it\beta \zeta} \right) \\
= e^{-\frac{1}{2}(\alpha t)^2 \sigma^2} e^{-\frac{1}{2}(\beta t^2 \sigma^2)} \\
= e^{-\frac{1}{2}t^2 \sigma^2},
\]
the characteristic function for a random variable which is \( N(0, \sigma) \). This proves the theorem.

The next theorem is a useful gimmick for showing certain random variables are independent in the context of normal distributions.

**Theorem 59.6.9** Let \( X \) and \( Y \) be random vectors having values in \( \mathbb{R}^p \) and \( \mathbb{R}^q \) respectively. Suppose also that \((X, Y)\) is multivariate normally distributed and
\[
E \left( (X-E(X)) (Y-E(Y))^* \right) = 0.
\]
Then \( X \) and \( Y \) are independent random vectors.

**Proof:** Let \( Z = (X, Y) \), \( m = p + q \). Then by hypothesis, the characteristic function of \( Z \) is of the form
\[
E \left( e^{it \Sigma} \right) = e^{it \cdot m - \frac{1}{2}it^* \Sigma t}
\]
where \( m = (m_X, m_Y) = E(Z) = E(X, Y) \) and
\[
\Sigma = \begin{pmatrix} E \left( (X-E(X)) (X-E(X))^* \right) & 0 \\
0 & E \left( (Y-E(Y)) (Y-E(Y))^* \right) \end{pmatrix}
= \begin{pmatrix} \Sigma_X & 0 \\
0 & \Sigma_Y \end{pmatrix}.
\]
Therefore, letting \( t = (u, v) \) where \( u \in \mathbb{R}^p \) and \( v \in \mathbb{R}^q \)
\[
E \left( e^{it \Sigma} \right) = E \left( e^{i(u, v) \cdot (X, Y)} \right) = E \left( e^{i(u \cdot X + v \cdot Y)} \right) \\
= e^{iu \cdot m_X} e^{-\frac{1}{2}u^* \Sigma_X u} e^{iv \cdot m_Y} e^{-\frac{1}{2}v^* \Sigma_Y v} \\
= E \left( e^{iu \cdot X} \right) E \left( e^{iv \cdot Y} \right). \tag{59.6.23}
\]
Where the last equality needs to be justified. When this is done it will follow from Proposition 57.11.1 on Page 1936 which is proved on Page 1936 that \( X \) and \( Y \) are independent. Thus all that remains is to verify
\[
E \left( e^{iu \cdot X} \right) = e^{iu \cdot m_X} e^{-\frac{1}{2}u^* \Sigma X u}, \quad E \left( e^{iv \cdot Y} \right) = e^{iv \cdot m_Y} e^{-\frac{1}{2}v^* \Sigma Y v}.
\]
However, this follows from Proposition 59.6.23. To get the first formula, let \( v = 0 \). To get the second, let \( u = 0 \). This proves the Theorem.

Note that to verify the conclusion of this theorem, it suffices to show
\[
E \left( (X_i - E(X_i)) (Y_j - E(Y_j)) \right) = 0.
\]
59.7 Gaussian Measures

59.7.1 Definitions And Basic Properties

First suppose $X$ is a random vector having values in $\mathbb{R}^n$ and its distribution function is $N(\mathbf{m}, \Sigma)$ where $\mathbf{m}$ is the mean and $\Sigma$ is the covariance. Then the characteristic function of $X$ or equivalently, the characteristic function of its distribution is

$$e^{it \cdot \mathbf{m} e^{-\frac{1}{2} t^t \Sigma t}}$$

What is the distribution of $a \cdot X$ where $a \in \mathbb{R}^n$? In other words, if you take a linear functional and do it to $X$ to get a scalar valued random variable, what is the distribution of this scalar valued random variable? Let $Y = a \cdot X$. Then

$$E(e^{itY}) = E(e^{itaX})$$

which from the above formula is

$$e^{ia \cdot \mathbf{m} e^{-\frac{1}{2} a^t \Sigma a^t}}$$

which is the characteristic function of a random variable whose distribution is $N(a \cdot \mathbf{m}, a^* \Sigma a)$. In other words, it is normally distributed having mean equal to $a \cdot \mathbf{m}$ and variance equal to $a^* \Sigma a$. Obviously such a concept generalizes to a Banach space in place of $\mathbb{R}^n$ and this motivates the following definition.

**Definition 59.7.1** Let $E$ be a real separable Banach space. A probability measure, $\mu$ defined on $\mathcal{B}(E)$ is called a Gaussian measure if for every $h \in E'$, the law of $h$ considered as a random variable defined on the probability space, $(E, \mathcal{B}(E), \mu)$ is normal. That is, for $A \subseteq \mathbb{R}$ a Borel set,

$$\lambda_h(A) \equiv \mu(h^{-1}(A))$$

is given by

$$\int_{\mathbb{R}} \frac{1}{\sqrt{2\pi \sigma}} e^{-\frac{1}{2} \sigma^2 (x-m)^2} dx$$

for some $\sigma$ and $m$. A Gaussian measure is called symmetric if $m$ is always equal to 0.

There is another definition of symmetric. First here are a few simple conventions. For $f \in E'$, $x \rightarrow f(x)$ is normally distributed. In particular,

$$\int_E |f(x)| d\mu < \infty$$

and so it makes sense to define

$$m_\mu(f) \equiv \int_E f(x) d\mu.$$
Thus \( m_\mu (f) \) is the mean of the random variable \( x \to f(x) \). It is obvious that \( f \to m_\mu (f) \) is linear. Also define the variance \( \sigma^2 (f) \) by

\[
\sigma^2 (f) \equiv \int_E (f(x) - m_\mu (f))^2 \, d\mu
\]

This is finite because \( x \to f(x) \) is normally distributed. The following lemma gives such an equivalent condition for \( \mu \) to be symmetric.

**Lemma 59.7.2** Let \( \mu \) be a Gaussian measure defined on \( B(E) \). Then \( \mu (F) = \mu (-F) \) for all \( F \) Borel if and only if \( m_\mu (f) = 0 \) for all \( f \in E' \). Such a Gaussian measure is called symmetric.

**Proof:** Suppose first \( m_\mu (f) = 0 \) for all \( f \in E' \). Let

\[
G = f_1^{-1} (F_1) \cap f_2^{-1} (F_2) \cap \cdots \cap f_m^{-1} (F_m)
\]

where \( F_i \) is a Borel set of \( \mathbb{R} \) and each \( f_i \in E' \). Since every linear combination of the \( f_i \) is in \( E' \), every such linear combination is normally distributed and so \( f \equiv (f_1, \ldots, f_m) \) is multivariate normal. That is, \( \lambda_T \) the distribution measure, is multivariate normal. Since each \( m_\mu (f) = 0 \), it follows

\[
\mu (G) = \lambda_T \left( \prod_{i=1}^m F_i \right) = \lambda_T \left( \prod_{i=1}^m F_i \right) = \mu (-G)
\]  

(59.7.24)

By Lemma 19.1.4 on Page 627 there exists a countable subset, \( D \equiv \{ f_k \}_{k=1}^\infty \) of the closed unit ball such that for every \( x \in E \),

\[
||x|| = \sup_{f \in D} |f(x)|.
\]

Therefore, letting \( D(a,r) \) denote the closed ball centered at \( a \) having radius \( r \), it follows

\[
D(a,r) = \bigcap_{k=1}^\infty f_k^{-1} \left( D(f_k(a), r) \right)
\]

Let

\[
D_n (a,r) = \bigcap_{k=1}^n f_k^{-1} \left( D(f_k(a), r) \right)
\]

Then by 59.7.24

\[
\mu (D_n (a,r)) = \mu (-D_n (a,r))
\]

and letting \( n \to \infty \), it follows

\[
\mu (D(a,r)) = \mu (-D(a,r))
\]

Therefore the same is true with \( D(a,r) \) replaced with an open ball. Now consider

\[
D(a,r_1) \cap D(b,r_2) = \bigcap_{k=1}^\infty f_k^{-1} \left( D(f_k(a), r_1) \right) \cap \bigcap_{k=1}^\infty f_k^{-1} \left( D(f_k(b), r_2) \right)
\]
The intersection of these two closed balls is the intersection of sets of the form
\[ \bigcap_{k=1}^{n} f_k^{-1} \left( D \left( f_k(a), r_1 \right) \right) \bigcap \bigcap_{k=1}^{n} f_k^{-1} \left( D \left( f_k(b), r_2 \right) \right) \]
to which 59.7.24 applies. Therefore, by continuing this way it follows that if \( G \) is any finite intersection of closed balls,
\[ \mu(G) = \mu(-G). \]

Let \( \mathcal{K} \) denote the set of finite intersections of closed balls, a \( \pi \) system. Thus for \( G \in \mathcal{K} \) the above holds. Now let
\[ \mathcal{G} \equiv \{ F \in \sigma(\mathcal{K}) : \mu(F) = \mu(-F) \} \]
Thus \( \mathcal{G} \) contains \( \mathcal{K} \) and it is clearly closed with respect to complements and countable disjoint unions. By the \( \pi \) system lemma, \( \mathcal{G} \supseteq \sigma(\mathcal{K}) \) but \( \sigma(\mathcal{K}) \) clearly contains the open sets since every open ball is the countable union of closed disks and every open set is the countable union of open balls. Therefore, \( \mu(G) = \mu(-G) \) for all Borel \( G \).

Conversely suppose \( \mu(G) = \mu(-G) \) for all \( G \) Borel. If for some \( f \in E', m \mu(f) \neq 0 \), then
\[ \mu\left( f^{-1}(0, \infty) \right) \equiv \lambda_f(0, \infty) \neq \lambda_f(-\infty, 0) \]
\[ \equiv \mu\left( f^{-1}(-\infty, 0) \right) = \mu\left( -f^{-1}(0, \infty) \right) \]
a contradiction. This proves the lemma.

**Lemma 59.7.3** Let \( \mu = \mathcal{L}(X) \) where \( X \) is a random variable defined on a probability space, \((\Omega, \mathcal{F}, \mathbb{P})\) which has values in \( E \), a Banach space. Suppose also that for all \( \phi \in E' \), \( \phi \circ X \) is normally distributed. Then \( \mu \) is a Gaussian measure. Conversely, suppose \( \mu \) is a Gaussian measure on \( \mathcal{B}(E) \) and \( X \) is a random variable having values in \( E \) such that \( \mathcal{L}(X) = \mu \). Then for every \( h \in E' \), \( h \circ X \) is normally distributed.

**Proof:** First suppose \( \mu \) is a Gaussian measure and \( X \) is a random variable such that \( \mathcal{L}(X) = \mu \). Then if \( F \) is a Borel set in \( \mathbb{R} \), and \( h \in E' \)
\[ P\left( (h \circ X)^{-1}(F) \right) = P\left( X^{-1}(h^{-1}(F)) \right) = \mu(h^{-1}(F)) = \frac{1}{\sqrt{2\pi} \sigma} \int_{F} e^{-\frac{|x-m|^2}{2\sigma^2}} dx \]
for some \( m \) and \( \sigma^2 \) showing that \( h \circ X \) is normally distributed.

Next suppose \( h \circ X \) is normally distributed whenever \( h \in E' \) and \( \mathcal{L}(X) = \mu \). Then letting \( F \) be a Borel set in \( \mathbb{R} \), I need to verify
\[ \mu(h^{-1}(F)) = \frac{1}{\sqrt{2\pi} \sigma} \int_{F} e^{-\frac{|x-m|^2}{2\sigma^2}} dx. \]
However, this is easy because
\[
\mu(h^{-1}(F)) = P\left(X^{-1}(h^{-1}(F))\right) = P\left((h \circ X)^{-1}(F)\right)
\]
which is given to equal
\[
\frac{1}{\sqrt{2\pi}\sigma} \int_F e^{-\frac{|x-m|^2}{2\sigma^2}} dx
\]
for some \(m\) and \(\sigma^2\). This proves the lemma.

Here is another important observation. Suppose \(X\) is as just described, a random variable having values in \(E\) such that \(L(X) = \mu\) and suppose \(h_1, \ldots, h_n\) are each in \(E'\); then for scalars, \(t_1, \ldots, t_n\),
\[
t_1 h_1 \circ X + \cdots + t_n h_n \circ X = (t_1 h_1 + \cdots + t_n h_n) \circ X
\]
and this last is assumed to be normally distributed because \((t_1 h_1 + \cdots + t_n h_n) \in E'\). Therefore, by Theorem 59.6.4
\[
(h_1 \circ X, \ldots, h_n \circ X)
\]
is distributed as a multivariate normal.

Obviously there exist examples of Gaussian measures defined on \(E\), a Banach space. Here is why. Let \(\xi\) be a random variable defined on a probability space, \((\Omega, \mathcal{F}, P)\) which is normally distributed with mean 0 and variance \(\sigma^2\). Then let \(X(\omega) = \xi(\omega)e\) where \(e \in E\). Then let \(\mu = L(X)\). For \(A\) a Borel set of \(\mathbb{R}\) and \(h \in E'\),
\[
\mu([h(x) \in A]) = P([X(\omega) \in [x : h(x) \in A]]) = P([h \circ X \in A]) = P([\xi(\omega) h(e) \in A]) = \frac{1}{|h(e)|\sigma\sqrt{2\pi}} \int_A e^{-\frac{|h(e)|\sigma^2 x^2}{2}} dx
\]
because \(h(e)\xi\) is a random variable which has variance \(|h(e)|^2\sigma^2\) and mean 0. Thus \(\mu\) is indeed a Gaussian measure. Similarly, one can consider finite sums of the form
\[
\sum_{i=1}^n \xi_i(\omega)e_i
\]
where the \(\xi_i\) are independent normal random variables having mean 0 for convenience. However, this is a rather trivial case.

### 59.7.2 Fernique’s Theorem

The following is an interesting lemma.
Lemma 59.7.4 Suppose \( \mu \) is a symmetric Gaussian measure on the real separable Banach space, \( E \). Then there exists a probability space, \( (\Omega, F, P) \) and independent random variables, \( X \) and \( Y \) mapping \( \Omega \) to \( E \) such that \( L(X) = L(Y) = \mu \). Also, the two random variables,

\[
\frac{1}{\sqrt{2}}(X - Y), \quad \frac{1}{\sqrt{2}}(X + Y)
\]

are independent and

\[
L \left( \frac{1}{\sqrt{2}}(X - Y) \right) = L \left( \frac{1}{\sqrt{2}}(X + Y) \right) = \mu.
\]

Proof: Letting \( X' = \frac{1}{\sqrt{2}}(X + Y) \) and \( Y' = \frac{1}{\sqrt{2}}(X - Y) \), it follows from Theorem 59.6.4 that \( X' \) and \( Y' \), whenever \( h_1, \ldots, h_m \in E' \) and \( g_1, \ldots, g_k \in E' \), the two random vectors,

\[
(h_1 \circ X', \ldots, h_m \circ X') \quad \text{and} \quad (g_1 \circ Y', \ldots, g_k \circ Y')
\]

are independent. Now consider linear combinations

\[
\sum_{j=1}^{m} t_j h_j \circ X' + \sum_{i=1}^{k} s_i g_i \circ Y'.
\]

This equals

\[
\frac{1}{\sqrt{2}} \sum_{j=1}^{m} t_j h_j (X) + \frac{1}{\sqrt{2}} \sum_{j=1}^{m} t_j h_j (Y)
\]

\[
+ \frac{1}{\sqrt{2}} \sum_{i=1}^{k} s_i g_i (X) - \frac{1}{\sqrt{2}} \sum_{i=1}^{k} s_i g_i (Y)
\]

\[
= \frac{1}{\sqrt{2}} \left( \sum_{j=1}^{m} t_j h_j + \sum_{i=1}^{k} s_i g_i \right) (X)
\]

\[
+ \frac{1}{\sqrt{2}} \left( \sum_{j=1}^{m} t_j h_j - \sum_{i=1}^{k} s_i g_i \right) (Y)
\]

and this is the sum of two independent normally distributed random variables so it is also normally distributed. Therefore, by Theorem 59.6.9,

\[
(h_1 \circ X', \ldots, h_m \circ X', g_1 \circ Y', \ldots, g_k \circ Y')
\]

is a random variable with multivariate normal distribution and by Theorem 59.6.9 the two random vectors

\[
(h_1 \circ X', \ldots, h_m \circ X') \quad \text{and} \quad (g_1 \circ Y', \ldots, g_k \circ Y')
\]
are independent if
\[ E \left( (h_i \circ X') (g_j \circ Y') \right) = 0 \]
for all \( i, j \). This is what I will show next.

\[
E \left( (h_i \circ X') (g_j \circ Y') \right) \\
= \frac{1}{4} E \left( (h_i (X) + h_i (Y)) (g_j (X) - g_j (Y)) \right) \\
= \frac{1}{4} E \left( h_i (X) g_j (X) \right) - \frac{1}{4} E \left( h_i (X) g_j (Y) \right) \\
+ \frac{1}{4} E \left( h_i (Y) g_j (X) \right) - \frac{1}{4} E \left( h_i (Y) g_j (Y) \right) \\
(59.7.25)
\]

Now from the above observation after the definition of Gaussian measure \( h_i (X) g_j (X) \) and \( h_i (Y) g_j (Y) \) are both in \( L^1 \) because each term in each product is normally distributed. Therefore, by Lemma 57.15.2

\[
E \left( h_i (X) g_j (X) \right) = \int_{\Omega} h_i (Y) g_j (Y) dP \\
= \int_{E} h_i (y) g_j (y) d\mu \\
= \int_{\Omega} h_i (X) g_j (X) dP \\
= E \left( h_i (Y) g_j (Y) \right)
\]

and so (59.7.25) reduces to

\[
\frac{1}{4} \left( E \left( h_i (Y) g_j (X) - h_i (X) g_j (Y) \right) \right) = 0
\]

because \( h_i (X) \) and \( g_j (Y) \) are independent due to the assumption that \( X \) and \( Y \) are independent. Thus

\[
E \left( h_i (X) g_j (Y) \right) = E \left( h_i (X) \right) E \left( g_j (Y) \right) = 0
\]
due to the assumption that \( \mu \) is symmetric which implies the mean of these random variables equals 0. The other term works out similarly. This has proved the independence of the random variables, \( X' \) and \( Y' \).

Next consider the claim they have the same law and it equals \( \mu \). To do this, I will use Theorem 57.12.9 on Page 1942. Thus I need to show

\[
E \left( e^{ih(X')} \right) = E \left( e^{ih(Y')} \right) = E \left( e^{ih(X)} \right) \\
(59.7.26)
\]

for all \( h \in E' \). Pick such an \( h \). Then \( h \circ X \) is normally distributed and has mean 0. Therefore, for some \( \sigma \),

\[
E \left( e^{ih \circ X} \right) = e^{-\frac{1}{2} h^2 \sigma^2}.
\]
Now since $X$ and $Y$ are independent,

$$E\left(e^{ith\circ X'}\right) = E\left(e^{ith\left(\frac{1}{\sqrt{2}}(X+Y)\right)}\right) = E\left(e^{ith\left(\frac{1}{\sqrt{2}}X\right)}\right)E\left(e^{ith\left(\frac{1}{\sqrt{2}}Y\right)}\right)$$

the product of two characteristic functions of two random variables, $\frac{1}{\sqrt{2}}X$ and $\frac{1}{\sqrt{2}}Y$. The variance of these two random variables which are normally distributed with zero mean is $\frac{1}{2}\sigma^2$ and so

$$E\left(e^{ith\circ X'}\right) = e^{-\frac{1}{2}\left(\frac{1}{2}\sigma^2\right)}e^{-\frac{1}{2}\left(\frac{1}{2}\sigma^2\right)} = e^{-\frac{1}{2}\sigma^2} = E\left(e^{ith\circ X}\right).$$

Similar reasoning shows $E\left(e^{ith\circ Y'}\right) = E\left(e^{ith\circ Y}\right) = E\left(e^{ith\circ X}\right)$. Letting $t = 1$, this yields 59.7.26. This proves the lemma.

With this preparation, here is an incredible theorem due to Fernique.

**Theorem 59.7.5** Let $\mu$ be a symmetric Gaussian measure on $B(E)$ where $E$ is a real separable Banach space. Then for $\lambda$ sufficiently small and positive,

$$\int_E e^{\lambda||x||^2} d\mu < \infty.$$ 

More specifically, if $\lambda$ and $r$ are chosen such that

$$\ln\left(\frac{\mu(\{x : ||x|| > r\})}{\mu(B(0,r))}\right) + 25\lambda r^2 < -1,$$

then

$$\int_E e^{\lambda||x||^2} d\mu \leq \exp(\lambda r^2) + \frac{e^2}{e^2-1}.$$

**Proof:** Let $X, Y$ be independent random variables having values in $E$ such that $\mathcal{L}(X) = \mathcal{L}(Y) = \mu$. Then by Lemma 59.7.3 and

$$\frac{1}{\sqrt{2}} (X - Y), \frac{1}{\sqrt{2}} (X + Y)$$

are also independent and have the same law. Now let $0 \leq s \leq t$ and use independence of the above random variables along with the fact they have the same law as $X$ and $Y$ to obtain

$$P(||X|| \leq s, ||Y|| > t) = P(||X|| \leq s) P(||Y|| > t)$$
\[
\begin{align*}
&= P \left( \left\| \frac{1}{\sqrt{2}}(X - Y) \right\| \leq s \right) P \left( \left\| \frac{1}{\sqrt{2}}(X + Y) \right\| > t \right) \\
&= P \left( \left\| \frac{1}{\sqrt{2}}(X - Y) \right\| \leq s, \left\| \frac{1}{\sqrt{2}}(X + Y) \right\| > t \right) \\
&\leq P \left( \frac{1}{\sqrt{2}} \left\| X \right\| - \left\| Y \right\| \leq s, \frac{1}{\sqrt{2}} \left( \left\| X \right\| + \left\| Y \right\| \right) > t \right).
\end{align*}
\]

Now consider the following picture in which the region, \( R \) represents the points, \((\left\| X \right\|, \left\| Y \right\|)\) such that
\[
\frac{1}{\sqrt{2}} \left\| X \right\| - \left\| Y \right\| \leq s \text{ and } \frac{1}{\sqrt{2}} \left( \left\| X \right\| + \left\| Y \right\| \right) > t.
\]

Therefore, continuing with the chain of inequalities above,
\[
P \left( \left\| X \right\| \leq s \right) P \left( \left\| Y \right\| > t \right)
\]
\[
\leq P \left( \left\| X \right\| > \frac{t - s}{\sqrt{2}}, \left\| Y \right\| > \frac{t - s}{\sqrt{2}} \right)
\]
\[
= P \left( \left\| X \right\| > \frac{t - s}{\sqrt{2}} \right)^2.
\]

Since \( X, Y \) have the same law, this can be written as
\[
P \left( \left\| X \right\| > t \right) \leq \frac{P \left( \left\| X \right\| > \frac{t - s}{\sqrt{2}} \right)^2}{P \left( \left\| X \right\| \leq s \right)}.
\]

Now define a sequence as follows. \( t_0 \equiv r > 0 \text{ and } t_{n+1} \equiv r + \sqrt{2}t_n. \) Also, in the above inequality, let \( s \equiv r \) and then it follows
\[
P \left( \left\| X \right\| > t_{n+1} \right) \leq \frac{P \left( \left\| X \right\| > \frac{t_{n+1} - r}{\sqrt{2}} \right)^2}{P \left( \left\| X \right\| \leq r \right)}
\]
\[
= \frac{P \left( \left\| X \right\| > t_n \right)^2}{P \left( \left\| X \right\| \leq r \right)}.
\]
Let
\[ \alpha_n (r) = \frac{P (||X|| > t_n)}{P (||X|| \leq r)} . \]
Then it follows
\[ \alpha_{n+1} (r) \leq \alpha_n (r)^2, \quad \alpha_0 (r) = \frac{P (||X|| > r)}{P (||X|| \leq r)}. \]
Consequently, \( \alpha_n (r) \leq \alpha_0 (r)^{2^n} \) and also
\[ P (||X|| > t_n) = \alpha_n (r) P (||X|| \leq r) \leq P (||X|| \leq r) \alpha_0 (r)^{2^n} = P (||X|| \leq r) e^{\ln (\alpha_0 (r)) 2^n}. \quad (59.7.27) \]
Now using the distribution function technique and letting \( \lambda > 0 \),
\[ \int_E e^{\lambda ||x||^2} d\mu = \int_0^\infty \mu \left( \left[ e^{\lambda ||x||^2} > t \right] \right) dt \]
\[ = 1 + \int_1^\infty \mu \left( \left[ e^{\lambda ||x||^2} > t \right] \right) dt \]
\[ = 1 + \int_1^\infty P \left( \left[ e^{\lambda ||X||^2} > t \right] \right) dt. \quad (59.7.28) \]
From (59.7.28)
\[ P \left( \left[ \exp (\lambda ||X||^2) > \exp (\lambda t_n^2) \right] \right) \leq P (||X|| \leq r) e^{\ln (\alpha_0 (r)) 2^n}. \]
Now split the above improper integral into intervals, \( (\exp (\lambda t_n^2), \exp (\lambda t_{n+1}^2)) \) for \( n = 0, 1, \ldots \) and note that \( P \left( \left[ e^{\lambda ||X||^2} > t \right] \right) \) is decreasing in \( t \). Then from (59.7.28),
\[ \int_E e^{\lambda ||x||^2} d\mu \leq \exp (\lambda r^2) + \sum_{n=0}^\infty \int_{\exp (\lambda t_n^2)}^{\exp (\lambda t_{n+1}^2)} P \left( \left[ e^{\lambda ||X||^2} > t \right] \right) dt \]
\[ \leq \exp (\lambda r^2) + \sum_{n=0}^\infty P \left( \left[ ||X|| \leq r \right] \right) \left( \exp (\lambda t_n^2) - \exp (\lambda t_{n+1}^2) \right) \]
\[ \leq \exp (\lambda r^2) + \sum_{n=0}^\infty P \left( ||X|| \leq r \right) \exp (\lambda t_{n+1}^2) e^{\ln (\alpha_0 (r)) 2^n} \]
\[ \leq \exp (\lambda r^2) + \sum_{n=0}^\infty e^{\ln (\alpha_0 (r)) 2^n} \exp (\lambda t_{n+1}^2). \]
It remains to estimate \( t_{n+1} \). From the description of the \( t_n \),
\[ t_n = \left( \sum_{k=0}^n (\sqrt{2})^k \right) r = r \frac{(\sqrt{2})^{n+1} - 1}{\sqrt{2} - 1} \leq \frac{\sqrt{2}}{\sqrt{2} - 1} r (\sqrt{2})^n \]
and so
\[ t_{n+1} \leq 5r \left( \sqrt{2} \right)^n \]
Therefore,
\[ \int_E e^{\lambda ||x||^2} d\mu \leq \exp (\lambda r^2) + \sum_{n=0}^{\infty} e^{\ln(\alpha_0(r))2^n + \lambda 25r^22^n}. \]
Now first pick \( r \) large enough that \( \ln (\alpha_0(r)) < -2 \) and then let \( \lambda \) be small enough that \( 25\lambda r^2 < 1 \) or some such scheme and you obtain \( \ln (\alpha_0(r)) + \lambda 25r^2 < -1 \). Then for this choice of \( r \) and \( \lambda \), or for any other choice which makes \( \ln (\alpha_0(r)) + \lambda 25r^2 < -1 \),
\[ \int_E e^{\lambda ||x||^2} d\mu \leq \exp (\lambda r^2) + \sum_{n=0}^{\infty} e^{-2^n} \]
\[ \leq \exp (\lambda r^2) + \sum_{n=0}^{\infty} e^{-2^n} \]
\[ = \exp (\lambda r^2) + \frac{e^2}{e^2 - 1}. \]
This proves the theorem.

59.8 Gaussian Measures For A Separable Hilbert Space

First recall the Kolmogorov extension theorem, Theorem 57.2.3 on Page 1904 which is stated here for convenience. In this theorem, \( I \) is an ordered index set, possibly infinite, even uncountable.

**Theorem 59.8.1** (Kolmogorov extension theorem) For each finite set \( J = (t_1, \ldots, t_n) \subseteq I \), suppose there exists a Borel probability measure, \( \nu_J = \nu_{t_1 \cdots t_n} \) defined on the Borel sets of \( \prod_{t \in J} M_t \) where \( M_t = \mathbb{R}^{n_t} \) such that if
\[ (t_1, \ldots, t_n) \subseteq (s_1, \ldots, s_p), \]
then
\[ \nu_{t_1 \cdots t_n}(F_{t_1} \times \cdots \times F_{t_n}) = \nu_{s_1 \cdots s_p}(G_{s_1} \times \cdots \times G_{s_p}) \]
where if \( s_i = t_j \), then \( G_{s_i} = F_{t_j} \) and if \( s_i \) is not equal to any of the indices, \( t_k \), then \( G_{s_i} = M_{s_i} \). Then there exists a probability space, \( (\Omega, P, \mathcal{F}) \) and measurable functions, \( X_t : \Omega \to M_t \) for each \( t \in I \) such that for each \( (t_1 \cdots t_n) \subseteq I \),
\[ \nu_{t_1 \cdots t_n}(F_{t_1} \times \cdots \times F_{t_n}) = P \left( [X_{t_1} \in F_{t_1}] \cap \cdots \cap [X_{t_n} \in F_{t_n}] \right). \]
Lemma 59.8.2 There exists a sequence, \( \{\xi_k\}_{k=1}^{\infty} \) of random variables such that
\[
\mathcal{L}(\xi_k) = N(0, 1)
\]
and \( \{\xi_k\}_{k=1}^{\infty} \) is independent.

Proof: Let \( i_1 < i_2 \cdots < i_n \) be positive integers and define
\[
\mu_{i_1 \cdots i_n} (F_1 \times \cdots \times F_n) \equiv \frac{1}{(\sqrt{2\pi})^n} \int_{F_1 \times \cdots \times F_n} e^{-|x|^2/2} dx.
\]

Then for the index set equal to \( \mathbb{N} \) the measures satisfy the necessary consistency condition for the Kolmogorov theorem above. Therefore, there exists a probability space, \((\Omega, \mathcal{F}, P)\) and measurable functions, \( \xi_k : \Omega \to \mathbb{R} \) such that
\[
P \left( [\xi_{i_1} \in F_{i_1}] \cap [\xi_{i_2} \in F_{i_2}] \cdots \cap [\xi_{i_n} \in F_{i_n}] \right) = \mu_{i_1 \cdots i_n} (F_1 \times \cdots \times F_n) = P \left( [\xi_{i_1} \in F_{i_1}] \right) \cdots P \left( [\xi_{i_n} \in F_{i_n}] \right)
\]
which shows the random variables are independent as well as normal with mean 0 and variance 1. This proves the Lemma.

A random variable \( X \) defined on a probability space \((\Omega, \mathcal{F}, P)\) is called Gaussian if
\[
P \left( [X \in A] \right) = \frac{1}{\sqrt{2\pi \sigma(v)^2}} \int_A e^{-\frac{1}{2\sigma(v)^2} (x-m(v))^2} dx
\]
for all \( A \) a Borel set in \( \mathbb{R} \). Therefore, for the probability space \((X, \mathcal{B}(X), \mu)\) it is natural to say \( \mu \) is a Gaussian measure if every \( x^* \) in the dual space \( X' \) is a Gaussian random variable. That is, normally distributed.

Definition 59.8.3 Let \( \mu \) be a measure defined on \( \mathcal{B}(X) \), the Borel sets of \( X \), a separable Banach space. It is called a Gaussian measure if each of the functions in the dual space \( X' \) is normally distributed. As a special case, when \( X = U \) a separable real Hilberts space, \( \mu \) is called a Gaussian measure if for each \( v \in U \), the function \( u \to (u, v)_U \) is normally distributed. That is, denoting this random variable as \( v' \), it follows for \( A \) a Borel set in \( \mathbb{R} \)
\[
\lambda_{v'} (A) \equiv \mu ([u : v' (u) \in A]) = \frac{1}{\sqrt{2\pi \sigma(v)^2}} \int_A e^{-\frac{1}{2\sigma(v)^2} (x-m(v))^2} dx
\]
in case \( \sigma(v) > 0 \). In case \( \sigma(v) = 0 \)
\[
\lambda_{v'} \equiv \delta_{m(v)}
\]
In other words, the random variables \( v' \) for \( v \in U \) are all normally distributed on the probability space \((U, \mathcal{B}(U), \mu)\).
Also recall the definition of the characteristic function of a measure.  

**Definition 59.8.4** The Borel sets in a topological space $X$ will be denoted by $B(X)$. For a Borel probability measure $\mu$ defined on $B(U)$ for $U$ a real separable Hilbert space, define its characteristic function as follows.

\[
\phi_\mu(u) \equiv \widehat{\mu}(u) \equiv \int_U e^{i(u,v)}d\mu(v) \quad (59.8.31)
\]

More generally, if $\mu$ is a probability measure defined on $B(X)$ where $X$ is a separable Banach space, then the characteristic function is defined as

\[
\phi_\mu(x^*) = \widehat{\mu}(x^*) \equiv \int_U e^{ix^*(x)}d\mu(x)
\]

One can tell whether $\mu$ is a Gaussian measure by looking at its characteristic function. In fact you can show the following theorem. One part of this theorem is that if $\mu$ is Gaussian, then $m$ and $\sigma^2$ have a certain form.

**Theorem 59.8.5** A measure $\mu$ on $B(U)$ is Gaussian if and only if there exists $m \in U$ and $Q \in \mathcal{L}(U)$ such that $Q$ is nonnegative symmetric with finite trace,

\[
\sum_k (Qe_k, e_k) < \infty
\]

for a complete orthonormal basis for $U$, and

\[
\phi_\mu(u) = \widehat{\mu}(u) = e^{it(m,u) - \frac{1}{2}(Qu,u)} \quad (59.8.32)
\]

In this case $\mu$ is called $N(m, Q)$ where $m$ is the mean and $Q$ is called the covariance.

The measure $\mu$ is uniquely determined by $m$ and $Q$. Also for all $h, g \in U$

\[
\int (x, h)_U \, d\mu(x) = (m, h)_U \quad (59.8.33)
\]

\[
\int ((x, h) - (m, h)) \, ((x, g) - (m, g)) \, d\mu(x) = (Qh, g) \quad (59.8.34)
\]

\[
\int \|x - m\|_U^2 \, d\mu(x) = \text{trace}(Q) . \quad (59.8.35)
\]

**Proof:** First of all suppose $59.8.32$ holds. Why is $\mu$ Gaussian? Consider the random variable $u'$ defined by $u'(v) \equiv (v, u)$. Why is $\lambda_{u'}$ a Gaussian measure on $\mathbb{R}$? By the definition in $59.8.31$,

\[
\int_U e^{it u'(v)} \, d\mu(v) = \int_U e^{it(v, u)} \, d\mu(v) = \int_{\mathbb{R}} e^{ix} \, d\lambda_{u'}(x) = \int_U e^{i(v, tu)} \, d\mu(v) = e^{it(m, u) - \frac{1}{2}t^2(Qu, u)}
\]
59.8. GAUSSIAN MEASURES FOR A SEPARABLE HILBERT SPACE

and this is the characteristic equation for a random variable having mean \((m, u)\) and variance \((Q u, u)\). In case \((Q u, u) = 0\), you get \(e^{i t (m, u)}\) which is the characteristic function for a random variable having distribution \(\delta_{(m, u)}\). Thus if \(\delta_{(m, u)}\) holds, then \(u'\) is normally distributed as desired. Thus \(\mu\) is Gaussian by definition.

The next task is to suppose \(\mu\) is Gaussian and show the existence of \(m, Q\) which have the desired properties. This involves the following lemma.

Lemma 59.8.6 Let \(U\) be a real separable Hilbert space and let \(\mu\) be a probability measure defined on \(B(U)\). Suppose for some positive integer, \(k\)

\[
\int_U |(x, z)|^k \, d\mu(x) < \infty
\]

for all \(z \in U\). Then the transformation,

\[
(h_1, \cdots, h_k) \rightarrow \int_U (h_1, x) \cdots (h_k, x) \, d\mu(x)
\]

(59.8.36)

is a continuous \(k\)-linear form.

Proof: I need to show that for each \(h \in U^k\), the integral in (59.8.36) exists. From this it is obvious it is \(k\)-linear, meaning linear in each argument. Then it is shown it is continuous.

First note

\[
|(h_1, x) \cdots (h_k, x)| \leq |(h_1, x)|^k + \cdots + |(h_k, x)|^k
\]

This follows from observing that one of \(|(h_j, x)|\) is largest. Then the left side is smaller than \(|(h_j, x)|^k\). Therefore, the above inequality is valid. This inequality shows the integral in (59.8.36) makes sense.

I need to establish an estimate of the form

\[
\int_U |(x, h)|^k \, d\mu(x) < C < \infty
\]

for every \(h \in U\) such that \(||h||\) is small enough.

Let

\[
U_n = \left\{ z \in U : \int_U |(x, z)|^k \, d\mu(x) \leq n \right\}
\]

Then by assumption \(U = \cup_{n=1}^{\infty} U_n\) and it is also clear from Fatou’s lemma that each \(U_n\) is closed. Therefore, by the Bair category theorem, at least one of these \(U_{n_0}\) contains an open ball, \(B(z_0, r)\). Then letting \(|y| < r\),

\[
\int_U |(x, z_0 + y)|^k \, d\mu(x), \int_U |(x, z_0)|^k \, d\mu(x) \leq n_0,
\]

and so for such \(y\),

\[
\int_U |(x, y)|^k \, d\mu = \int_U |(x, z_0 + y) - (x, z_0)|^k \, d\mu
\]

\[
\leq \int_U 2^k |(x, z_0 + y)|^k + 2^k |(x, z_0)|^k \, d\mu(x)
\]

\[
\leq 2^k (n_0 + n_0) = 2^{k+1} n_0.
\]
It follows that for arbitrary nonzero \( y \in U \)

\[
\int_U \left| \left( x, \frac{(r/2) y}{||y||} \right)^k \right| d\mu \leq 2^{k+1} n_0
\]

and so

\[
\int_U |(x, y)|^k d\mu \leq (2^{k+2}/r) n_0 ||y||^k \equiv C ||y||^k.
\]

Thus by Holder’s inequality,

\[
\int_U |(h_1, x) \cdots (h_k, x)| d\mu (x) \leq \prod_{j=1}^k \left( \int_U |(h_j, x)|^k d\mu (x) \right)^{1/k} \leq C \prod_{j=1}^k ||h_j||
\]

This proves the lemma.

Now continue with the proof of the theorem. I need to identify \( m \) and \( Q \). It is assumed \( \mu \) is Gaussian. Recall this means \( h' \) is normally distributed for each \( h \in U \). Then using

\[
|x| \leq |x - m(h)| + |m(h)|
\]

\[
\int_U |(x, h)|_{U} d\mu (x) = \int_{\mathbb{R}} |x| d\lambda_{h'} (x)
= \frac{1}{\sqrt{2\pi\sigma^2 (h)}} \int_{\mathbb{R}} |x| e^{-\frac{1}{2\sigma^2} (x - m(h))^2} dx
\leq \frac{1}{\sqrt{2\pi\sigma^2 (h)}} \int_{\mathbb{R}} |x - m(h)| e^{-\frac{1}{2\sigma^2} (x - m(h))^2} dx + |m(h)|
\]

Then using the Cauchy Schwarz inequality, with respect to the probability measure

\[
\frac{1}{\sqrt{2\pi\sigma^2 (h)}} e^{-\frac{1}{2\sigma^2} (x - m(h))^2} dx,
\]

\[
\leq \frac{1}{\sqrt{2\pi\sigma^2 (h)}} \left( \int_{\mathbb{R}} |x - m(h)|^2 e^{-\frac{1}{2\sigma^2} (x - m(h))^2} dx \right)^{1/2} + |m(h)| < \infty
\]

Thus by Lemma 59.8.6

\[
h \rightarrow \int_U (x, h) d\mu (x)
\]

is a continuous linear transformation and so by the Riesz representation theorem, there exists a unique \( m \in U \) such that

\[
(h, m)_U = \int_U (h, x) d\mu (x)
\]
Also the above says \((h, m)\) is the mean of the random variable \(x \to (x, h)\) so in the above,
\[
m(h) = (h, m)_U.
\]

Next it is necessary to find \(Q\). To do this let \(Q\) be given by \(59.8.34\).
Thus
\[
(Qh, g) = \int_U ((x, h) - (m, h)) ((x, g) - (m, g)) d\mu(x)
\]
\[
= \int_U (x - m, h) (x - m, g) d\mu(x)
\]
It is clear \(Q\) is linear and the above is a bilinear form (The integral makes sense because of the assumption that \(h', g'\) are normally distributed.) but is it continuous?

Does \((Qh, h) = \sigma^2(h)\)?

First, the above equals
\[
\int_U (x, h) (x - m, g) d\mu(x) - \int_U (m, h) (x - m, g) d\mu(x)
\]
\[
= \int_U (x, h) (x - m, g) d\mu(x) \quad (59.8.37)
\]

because from the first part,
\[
\int_U (x - m, g) d\mu(x) = \int_U (x, g) d\mu(x) - (m, g)_U = 0.
\]

Now by the first part, the term in \(59.8.37\) is
\[
\int_U (x, h) (x, g) d\mu(x) - (m, g) \int_U (x, h) d\mu(x)
\]
\[
= \int_U (x, h) (x, g) d\mu(x) - (m, g) (m, h).
\]

Thus
\[
|(Qh, g)| \leq \int_U |(x, h) (x, g)| d\mu(x) + \|m\|^2 \|h\| \|g\|
\]
and since the random variables \(h'\) and \(g'\) given by \(x \to (x, h)\) and \(x \to (x, g)\) respectively are given to be normally distributed with variance \(\sigma^2(h)\) and \(\sigma^2(g)\) respectively, the above integral is finite. Also for all \(h\),
\[
\int_U |(x, h)|^2 d\mu(x) < \infty
\]
because the random variable \(h'\) is given to be normally distributed. Therefore from Lemma \(59.8.4\), there exists some constant \(C\) such that
\[
|(Qh, g)| \leq C \|h\| \|g\|
\]
which shows \(Q\) is continuous as desired.
Why is $\sigma^2(h) = (Qh, h)$? This follows because from the above

\[
(Qh, h) = \int_U (h, x - m)^2 d\mu(x) = \int_U ((x, h) - (h, m))^2 d\mu(x) = \int_{\mathbb{R}} (t - (h, m))^2 d\lambda_{h'}(t)
\]

\[
= \frac{1}{\sqrt{2\pi\sigma^2(h)}} \int_{\mathbb{R}} (t - (h, m))^2 e^{-\frac{1}{2\sigma^2(h)}(t-(h, m))^2} dt = \sigma^2(h)
\]

from a standard result for the normal distribution function which follows from an easy change of variables argument.

Why must $Q$ have finite trace? For $h \in U$, it follows from the above that $h'$ is normally distributed with mean $(h, m)$ and variance $(Qh, h)$. Therefore, the characteristic function of $h'$ is known. In fact

\[
\int_U e^{it(x, h)} d\mu(x) = e^{it(h, m)} e^{-\frac{1}{2}t^2 (Qh, h)}
\]

Thus also

\[
\int_U e^{it(x-m, h)} d\mu(x) = e^{-\frac{1}{2}t^2 (Qh, h)}
\]

and letting $t = 1$ this yields

\[
\int_U e^{i(x-m, h)} d\mu(x) = e^{-\frac{1}{2} (Qh, h)}
\]

From this it follows

\[
\int_U \left(1 - e^{i(x-m, h)}\right) d\mu(x) = 1 - e^{-\frac{1}{2} (Qh, h)}
\]

and since the right side is real, this implies

\[
\int_U \left(1 - \cos(x - m, h)\right) d\mu(x) = 1 - e^{-\frac{1}{2} (Qh, h)}
\]

Thus

\[
1 - e^{-\frac{1}{2} (Qh, h)} \leq \int_{||x-m|| \leq c} (1 - \cos(x - m, h)) d\mu(x) + 2 \int_{||x-m|| > c} d\mu(x)
\]

Now it is routine to show

\[
1 - \cos t \leq \frac{1}{2} t^2
\]

and so

\[
1 - e^{-\frac{1}{2} (Qh, h)} \leq \frac{1}{2} \int_{||x-m|| \leq c} ||(x - m, h)||^2 d\mu(x) + 2\mu(||x-m|| > c))
\]
59.8. GAUSSIAN MEASURES FOR A SEPARABLE HILBERT SPACE  2073

Pick $c$ large enough that the last term is smaller than $1/8$. This can be done because the sets decrease to $\emptyset$ as $c \to \infty$ and $\mu$ is given to be a finite measure. Then with this choice of $c$,

$$
\frac{7}{8} - \frac{1}{2} \int_{||x-m|| \leq c} |(x-m,h)|^2 \, d\mu(x) \leq e^{-\frac{1}{2}(Qh,h)}
$$

(59.8.38)

For each $h$ the integral in the above is finite. In fact

$$
\int_{||x-m|| \leq c} |(x-m,h)|^2 \, d\mu(x) \leq c^2 ||h||^2
$$

Let

$$(Q_c h, h_1) \equiv \int_{||x-m|| \leq c} (x-m,h)(x-m,h_1) \, d\mu(x)$$

and let $A$ denote those $h \in U$ such that

$$(Q_c h, h) < 1.$$  

Then from (59.8.38) it follows that for $h \in A$,

$$\frac{3}{8} = \frac{7}{8} - \frac{1}{2} \leq \frac{7}{8} - \frac{1}{2} (Q_c h, h) \leq e^{-\frac{1}{2}(Qh,h)}$$

Therefore, for such $h$,

$$\frac{8}{3} \geq e^{\frac{1}{2}(Qh,h)} \geq 1 + \frac{1}{2} (Qh,h)$$

and so for $h \in A$,

$$(Qh,h) \leq \left( \frac{8}{3} - 1 \right)^2 = \frac{10}{3}$$

Now let $h$ be arbitrary. Then for each $\varepsilon > 0$

$$\frac{h}{\varepsilon + \sqrt{(Q_c h, h)}} \in A$$

and so

$$
\left( Q \left( \frac{h}{\varepsilon + \sqrt{(Q_c h, h)}} \right), \frac{h}{\varepsilon + \sqrt{(Q_c h, h)}} \right) \leq \frac{10}{3}
$$

which implies

$$(Qh,h) \leq \frac{10}{3} \left( \varepsilon + \sqrt{(Q_c h, h)} \right)^2$$

Since $\varepsilon$ is arbitrary,

$$(Qh,h) \leq \frac{10}{3} (Q_c h, h).$$

(59.8.39)

However, $Q_c$ has finite trace. To see this, let $\{e_k\}$ be an orthonormal basis in $U$. Then

$$
\sum_k (Q_c e_k, e_k) = \sum_k \int_{||x-m|| \leq c} |(x-m,e_k)|^2 \, d\mu(x)
$$
\[ = \int_{||x-m|| \leq c} \sum_k |(x-m,e_k)|^2 d\mu(x) = \int_{||x-m|| \leq c} ||x-m||^2 d\mu(x) \leq c^2 \]

It follows from \[59.8.39\] that \(Q\) must also have finite trace.

That \(\mu\) is uniquely determined by \(m\) and \(Q\) follows from Theorem \[57.12.9\]. This proves the theorem.

Suppose you have a given \(Q\) having finite trace and \(m \in U\). Does there exist a Gaussian measure on \(B(U)\) having these as the covariance and mean respectively?

**Proposition 59.8.7** Let \(U\) be a real separable Hilbert space and let \(m \in U\) and \(Q\) be a positive, symmetric operator defined on \(U\) which has finite trace. Then there exists a Gaussian measure with mean \(m\) and covariance \(Q\).

**Proof:** By Lemma \[59.8.2\] which comes from Kolmogorov’s extension theorem, there exists a probability space \((\Omega, F, P)\) and a sequence \(\{\xi_i\}\) of independent random variables which are normally distributed with mean 0 and variance 1. Then let

\[ X(\omega) = m + \sum_{j=1}^{\infty} \sqrt{\lambda_j} \xi_j(\omega) e_j \]

where the \(\{e_j\}\) are the eigenvectors of \(Q\) such that \(Qe_j = \lambda_j e_j\). The series in the above converges in \(L^2(\Omega; U)\) because

\[ \left\| \sum_{j=m}^{n} \sqrt{\lambda_j} \xi_j(\omega) e_j \right\|_{L^2(\Omega; U)}^2 = \int_{\Omega} \sum_{j=m}^{n} \lambda_j \xi_j^2(\omega) dP = \sum_{j=m}^{n} \lambda_j \]

and so the partial sums form a Cauchy sequence in \(L^2(\Omega; U)\).

Now if \(h \in U\), I need to show that \(\omega \rightarrow (X(\omega), h)\) is normally distributed. From this it will follow that \(L(X)\) is Gaussian. A subsequence

\[ \left\{ m + \sum_{j=1}^{n_k} \sqrt{\lambda_j} \xi_j(\omega) e_j \right\} = \{S_{n_k}(\omega)\} \]

of the above sequence converges pointwise a.e. to \(X\).

\[
    E\left(\exp(it(X,h))\right) = \lim_{k \to \infty} E\left(\exp(it(S_{n_k},h))\right) \\
    = \exp(it(m,h)) \lim_{k \to \infty} E\left(\exp\left(it \sum_{j=1}^{n_k} \sqrt{\lambda_j} \xi_j(\omega)(e_j, h)\right)\right) \\
\]

Since the \(\xi_j\) are independent,

\[
    = \exp(it(m,h)) \lim_{k \to \infty} \prod_{j=1}^{n_k} E\left(\exp\left(it\sqrt{\lambda_j}(e_j, h)\right)\xi_j\right) \\
\]
\[ = \exp(it (m, h)) \lim_{k \to \infty} \prod_{j=1}^{n_k} e^{-\frac{1}{2}t^2 \lambda_j (e_j, h)^2} \]

\[ = \exp(it (m, h)) \lim_{k \to \infty} \exp\left(-\frac{1}{2}t^2 \sum_{j=1}^{n_k} \lambda_j (e_j, h)^2\right). \quad (59.8.40) \]

Now

\[ (Qh, h) = \left( \sum_{k=1}^{\infty} (e_k, h) e_k, \sum_{j=1}^{\infty} (e_j, h) e_j \right) \]
\[ = \left( \sum_{k=1}^{\infty} (e_k, h) \lambda_k e_k; \sum_{j=1}^{\infty} (e_j, h) e_j \right) \]
\[ = \sum_{j=1}^{\infty} \lambda_j (e_j, h)^2 \]

and so, passing to the limit in (59.8.40) yields

\[ \exp(it (m, h)) \exp\left(-\frac{1}{2}t^2 (Qh, h)\right) \quad (59.8.41) \]

which implies that \( \omega \to (X (\omega), h) \) is normally distributed with mean \( (m, h) \) and variance \( (Qh, h) \).

Now let \( \mu = \mathcal{L}(X) \). That is, for all \( B \in \mathcal{B}(U) \),

\[ \mu (B) \equiv P ([X \in B]) \]

In particular, \( B \) could be the cylindrical set

\[ B \equiv [x : (x, h) \in A] \]

for \( A \) a Borel set in \( \mathbb{R} \). Then by definition, if \( h \in U \), and \( A \) is a Borel set in \( \mathbb{R} \),

\[ \mu (B) = \mu ([x : (x, h) \in A]) \equiv P ([\omega : (X (\omega), h) \in A]) \]
\[ = \int_{A} \frac{1}{\sqrt{2\pi} (Qh, h)} e^{-\frac{(\mu - (m, h))^2}{2(Qh, h)}} \, dt \]

and so \( x \to (x, h) \) is normally distributed. Therefore by definition, \( \mu \) is a Gaussian measure.

Letting \( t = 1 \) in (59.8.41) it follows

\[ \int_{U} e^{i(x,h)} d\mu (x) = \int_{\Omega} e^{i(X(\omega),h)} dP = \exp (i (m, h)) \exp \left(-\frac{1}{2} (Qh, h)\right) \]

which is the characteristic function of a Gaussian measure on \( U \) having covariance \( Q \) and mean \( m \). This proves the proposition.
CHAPTER 59. PROBABILITY IN INFINITE DIMENSIONS

59.9 Abstract Wiener Spaces

This material follows [20], [53] and [55]. More can be found on this subject in these references. Here $H$ will be a separable real Hilbert space.

**Definition 59.9.1** Cylinder sets in $H$ are of the form

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n)) \in F \}$$

where $F \in \mathcal{B}(\mathbb{R}^n)$, the Borel sets of $\mathbb{R}^n$ and $\{e_k\}$ are given vectors in $H$. Denote this collection of cylinder sets as $C$.

**Proposition 59.9.2** The cylinder sets form an algebra of sets.

**Proof:** First note the complement of a cylinder set is a cylinder set.

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n)) \in F \}^C = \{ x \in H : ((x, e_1), \cdots, (x, e_n)) \in F^C \}.$$  

Now consider the intersection of two of these cylinder sets. Let the cylinder sets be

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n)) \in E \},$$

$$\{ x \in H : ((x, f_1), \cdots, (x, f_m)) \in F \}$$

The first of these equals

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n), (x, f_1), \cdots, (x, f_m)) \in E \times \mathbb{R}^m \}$$

and the second equals

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n), (x, f_1), \cdots, (x, f_m)) \in \mathbb{R}^n \times F \}$$

Therefore, their intersection equals

$$\{ x \in H : ((x, e_1), \cdots, (x, e_n), (x, f_1), \cdots, (x, f_m)) \in E \times \mathbb{R}^m \cap \mathbb{R}^n \times F \}$$

a cylinder set.

Now it is clear the whole of $H$ and $\emptyset$ are cylinder sets given by

$$\{ x \in H : (e, x) \in \mathbb{R} \}, \{ x \in H : (e, x) \in \emptyset \}$$

respectively and so if $C_1, C_2$ are two cylinder sets,

$$C_1 \setminus C_2 \equiv C_1 \cap C_2^C,$$

which was just shown to be a cylinder set. Hence

$$C_1 \cup C_2 = (C_1^C \cap C_2^C)^C,$$
a cylinder set. This proves the proposition.

It is good to have a more geometrical description of cylinder sets. Letting $A$ be a cylinder set as just described, let $P$ denote the orthogonal projection onto span $(e_1, \cdots, e_n)$. Also let $\alpha : PH \to \mathbb{R}^n$ be given by

$$\alpha(x) = ((x, e_1), \cdots, (x, e_n)).$$

This is continuous but might not be one to one if the $e_i$ are not a basis for example. Then consider $\alpha^{-1}(F)$, those $x \in PH$ such that

$$(x, e_1), \cdots, (x, e_n)) \in F.$$ 

For any $x \in H$,

$$((I - P)x, e_k) = 0$$

for each $k$ and so

$$(x, e_1), \cdots, (x, e_n)) = ((Px, e_1), \cdots, (Px, e_n)) \in F$$

Thus $Px \in \alpha^{-1}(F)$, which is a Borel set of $PH$ and

$$x = Px + (I - P)x$$

so the cylinder set is contained in

$$\alpha^{-1}(F) + (PH)^\perp$$

which is of the form

$$(\text{Borel set of } PH) + (PH)^\perp$$

On the other hand, consider a set of the form

$$G + (PH)^\perp$$

where $G$ is a Borel set in $PH$. There is a basis for $PH$ consisting of a subset of \{e_1, \cdots, e_n\}. For simplicity, suppose it is $\{e_1, \cdots, e_k\}$. Then let $\alpha_1 : PH \to \mathbb{R}^k$ be given by

$$\alpha_1(x) = ((x, e_1), \cdots, (x, e_k))$$

Thus $\alpha$ is a homeomorphism of $PH$ and $\mathbb{R}^k$ so $\alpha_1(G)$ is a Borel set of $\mathbb{R}^k$. Now

$$\alpha^{-1}(\alpha_1(G) \times \mathbb{R}^{n-k}) = G$$

and $\alpha_1(G) \times \mathbb{R}^{n-k}$ is a Borel set of $\mathbb{R}^n$. This has proved the following important Proposition illustrated by the following picture.

\[
\begin{tikzpicture}
    \node (A) at (0,0) {$B$};
    \node (B) at (0,-2) {$B + M_\perp$};
    \draw[->] (A) -- (B);
\end{tikzpicture}
\]
**Proposition 59.9.3** The cylinder sets are sets of the form

\[ B + M^\perp \]

where \( M \) is a finite dimensional subspace and \( B \) is a Borel subset of \( M \). Furthermore, the collection of cylinder sets is an algebra.

**Lemma 59.9.4** \( \sigma(C) \), the smallest \( \sigma \) algebra containing \( C \), contains the Borel sets of \( H, B(H) \).

**Proof:** It follows from the definition of these cylinder sets that if \( f_i(x) \equiv (x, e_i) \), so that \( f_i \in H' \), then with respect to \( \sigma(C) \), each \( f_i \) is measurable. It follows that every linear combination of the \( f_i \) is also measurable with respect to \( \sigma(C) \). However, this set of linear combinations is dense in \( H' \) and so the conclusion of the lemma follows from Lemma 57.4.2 on Page 1913. This proves the lemma.

Also note that the mapping

\[ x \rightarrow ((x, e_1), \cdots, (x, e_n)) \]

is a \( \sigma(C) \) measurable map. Restricting it to span \( (e_1, \cdots, e_n) \), it is Borel measurable. Next is a definition of a Gaussian measure defined on \( C \). While this is what it is called, it is a fake measure in general because it cannot be extended to a countably additive measure on \( \sigma(C) \). This will be shown below.

**Definition 59.9.5** Let \( Q \in \mathcal{L}(H, H) \) be self adjoint and satisfy

\[ (Qx, x) > 0 \]

for all \( x \in H, x \neq 0 \). Define \( \nu \) on the cylinder sets, \( C \) by the following rule. For \( \{e_k\}_{k=1}^n \) an orthonormal set in \( H \),

\[ \nu \left( \{x \in H : ((x, e_1), \cdots, (x, e_n)) \in F\} \right) = \frac{1}{(2\pi)^{n/2} (\det(\theta^*Q\theta))^{1/2}} \int_F e^{-\frac{1}{2}t^*\theta^*Q\theta t} \, dt. \]

where here

\[ \theta t = \sum_{i=1}^n t_i e_i. \]

Note that the cylinder set is of the form

\[ \theta F + \text{span} (e_1, \cdots, e_n)^\perp. \]

Thus if \( B + M^\perp \) is a typical cylinder set, choose an orthonormal basis for \( M, \{e_k\}_{k=1}^n \) and do the above definition with \( F = \theta^{-1}B \).
To see this last claim which is like what was done earlier, let
\[(x, e_1), \ldots, (x, e_n) \in F.\]
Then \(\theta ((x, e_1), \ldots, (x, e_n)) = \sum_i (x, e_i) e_i = Px\) and so
\[x = x - Px + Px = x - Px + \theta ((x, e_1), \ldots, (x, e_n)) \in \theta F + \text{span} \{e_1, \ldots, e_n\}^\perp.\]
Thus
\[
\{x \in H : ((x, e_1), \ldots, (x, e_n)) \in F\} \subseteq \theta F + \text{span} \{e_1, \ldots, e_n\}^\perp \]
To see the other inclusion, if \(t \in F\) and \(y \in \text{span} \{e_1, \ldots, e_n\}^\perp\), then if \(x = \theta t\), it follows
\[t_i = (x, e_i)\]
and so \(((x, e_1), \ldots, (x, e_n)) \in F\). But \((y, e_k) = 0\) for all \(k\) and so \(x + y\) is in
\[
\{x \in H : ((x, e_1), \ldots, (x, e_n)) \in F\}.\]

**Lemma 59.9.6** The above definition is well defined.

**Proof:** Let \(\{f_k\}\) be another orthonormal set such that for \(F, G\) Borel sets in \(\mathbb{R}^n\),
\[
A = \{x \in H : ((x, e_1), \ldots, (x, e_n)) \in F\} = \{x \in H : ((x, f_1), \ldots, (x, f_n)) \in G\}
\]
I need to verify \(\nu (A)\) is the same using either \(\{f_k\}\) or \(\{e_k\}\). Let \(a \in G\). Then
\[
x = \sum_{i=1}^n a_i f_i \in A
\]
because \((x, f_k) = a_k\). Therefore, for this \(x\) it is also true that \(((x, e_1), \ldots, (x, e_n)) \in F\).
In other words for \(a \in G\),
\[
\left(\sum_{i=1}^n (e_1, f_i) a_i, \cdots, \sum_{i=1}^n (e_n, f_i) a_i\right) \in F
\]
Let \(L \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)\) be defined by
\[
La = \sum_i L_{ji} a_i, \quad L_{ji} = (e_j, f_i).
\]
Since the \(\{e_j\}\) and \(\{f_k\}\) are orthonormal, this mapping is unitary. Also this has shown that
\[LG \subseteq F.\]
Similarly
\[L^* F \subseteq G.\]
where $L^*$ has the $ij^{th}$ entry $L^*_{ij} = (f_i, e_j)$ as above and $L^*$ is the inverse of $L$ because $L$ is unitary. Thus

$$F = L(L^*(F)) \subseteq L(G) \subseteq F$$

showing that $LG = F$ and $L^*F = G$.

Now let $\theta_t \equiv \sum_i t_i e_i$ with $\theta_f$ defined similarly. Then the definition of $\nu(A)$ corresponding to $\{e_i\}$ is

$$\nu(A) = \frac{1}{(2\pi)^{n/2} \left( \det (\theta^*_e Q \theta_e) \right)^{1/2}} \int_F e^{-\frac{1}{2} \theta^*_e Q^{-1} \theta_e \cdot t} dt$$

Now change the variables letting $t = Ls$ where $s \in G$.

From the definition,

$$\theta^*_e Ls = \sum_j \sum_i (e_j, f_i) s_i e_j$$

$$= \sum_j \left( e_j, \sum_i f_i s_i \right) e_j = \sum_j (e_j, \theta_f s) e_j$$

and so

$$Ls = ((e_1, \theta_f s), \ldots, (e_n, \theta_f s)) = \theta^*_e \theta_f s$$

where from the definition,

$$(\theta^*_e \theta_f s, t) = \sum_i t_i \left( \sum_j s_j e_j, e_i \right)$$

$$= \sum_i t_i s_i = (s, t)$$

and so $\theta^*_e \theta_f$ is the identity on $\mathbb{R}^n$ and similar reasoning yields $\theta_f \theta^*_e$ is the identity on $\theta_e (\mathbb{R}^n)$. Then using the change of variables formula and the fact $|\det(L)| = 1$,

$$\frac{1}{(2\pi)^{n/2} \left( \det (\theta^*_e Q \theta_e) \right)^{1/2}} \int_F e^{-\frac{1}{2} \theta^*_e Q^{-1} \theta_e \cdot t} dt$$

$$= \frac{1}{(2\pi)^{n/2} \left( \det (\theta^*_e Q \theta_e) \right)^{1/2}} \int_G e^{-\frac{1}{2} s^* L^* \theta^*_e Q^{-1} \theta_e Ls} ds$$

$$= \frac{1}{(2\pi)^{n/2} \left( \det (\theta^*_f Q \theta_f) \right)^{1/2}} \int_G e^{-\frac{1}{2} s^* \theta^*_e \theta^*_f \theta^*_e Q^{-1} \theta_e \theta_f \theta^*_f s} ds$$

$$= \frac{1}{(2\pi)^{n/2} \left( \det (\theta^*_f Q \theta_f) \right)^{1/2}} \int_G e^{-\frac{1}{2} s^* \theta^*_f \theta^*_e Q^{-1} \theta_f \theta_e \theta^*_e \theta_f s} ds$$

where part of the justification is as follows.

$$\det (\theta^*_f Q \theta_f) = \det (\theta^*_f \theta^*_e Q \theta_e \theta^*_f \theta_f)$$
\[
\det (\theta_1^* \theta_e) \det (\theta_2^* Q \theta_e) \det (\theta_1^* \theta_f) = \det (\theta_1^* Q \theta_e)
\]

because
\[
\det (\theta_1^* \theta_e) \det (\theta_1^* \theta_f) = \det (\theta_1^* \theta_e \theta_1^* \theta_f) = \det (\theta_1^* \theta_f) = 1.
\]

This proves the lemma.

It would be natural to try to extend \( \nu \) to the \( \sigma \) algebra determined by \( C \) and obtain a measure defined on this \( \sigma \) algebra. However, this is always impossible in the case where \( Q = I \).

**Proposition 59.9.7** For \( Q = I \), \( \nu \) cannot be extended to a measure defined on \( \sigma (C) \) whenever \( H \) is infinite dimensional.

**Proof:** Let \( \{e_n\} \) be a complete orthonormal set of vectors in \( H \). Then first note that \( H \) is a cylinder set.

\[
H = \{ x \in H : (x, e_1) \in \mathbb{R} \}
\]

and so
\[
\nu(H) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} e^{-\frac{1}{2} t^2} dt = 1.
\]

However, \( H \) is also equal to the countable union of the sets,
\[
A_n = \{ x \in H : (x, e_1)_H, \cdots, (x, e_{a_n})_H \in B(0, n) \}
\]

where \( a_n \to \infty \).

\[
\nu(A_n) = \frac{1}{(\sqrt{2\pi})^{a_n}} \int_{B(0,n)} e^{-\frac{1}{2} |t|^2} dt 
\leq \frac{1}{(\sqrt{2\pi})^{a_n}} \int_{-n}^{n} \cdots \int_{-n}^{n} e^{-|t|^2/2} dt_1 \cdots dt_{a_n} 
= \left( \frac{\int_{-n}^{n} e^{-x^2/2} dx}{\sqrt{2\pi}} \right)^{a_n}
\]

Now pick \( a_n \) so large that the above is smaller than \( 1/2^{n+1} \). This can be done because for no matter what choice of \( n \),
\[
\int_{-n}^{n} e^{-x^2/2} dx < 1.
\]

Then
\[
\sum_{n=1}^{\infty} \nu (A_n) \leq \sum_{n=1}^{\infty} \frac{1}{2^{n+1}} = \frac{1}{2}.
\]

This proves the proposition and shows something else must be done to get a countably additive measure from \( \nu \).

However, let \( \mu (C) = \nu_M (C) \) where \( C \) is a cylinder set of the form \( C = B + M \) for \( M \) a finite dimensional subspace.
Proposition 59.9.8 \( \mu \) is finitely additive on \( C \) the algebra of cylinder sets.

**Proof:** Let

\[
A \equiv \{ x \in H : ((x, e_1), \cdots, (x, e_n)) \in E \},
B \equiv \{ x \in H : ((x, f_1), \cdots, (x, f_m)) \in F \}
\]

be two disjoint cylinder sets. Then writing them differently as was done earlier they are

\[
\{ x \in H : ((x, e_1), \cdots, (x, e_n), (x, f_1), \cdots, (x, f_m)) \in E \times \mathbb{R}^m \}
\]

and

\[
\{ x \in H : ((x, e_1), \cdots, (x, e_n), (x, f_1), \cdots, (x, f_m)) \in \mathbb{R}^n \times F \}
\]

respectively. Hence the two sets \( E \times \mathbb{R}^m, \mathbb{R}^n \times F \) must be disjoint. Then the definition yields \( \mu (A \cup B) = \mu (A) + \mu (B) \). This proves the proposition.

**Definition 59.9.9** Let \( H \) be a separable Hilbert space and let \( ||| \cdot ||| \) be a norm defined on \( H \) which has the following property. Whenever \( \{e_n\} \) is an orthonormal sequence of vectors in \( H \) and \( \mathcal{F}(\{e_n\}) \) consists of the set of all orthogonal projections onto the span of finitely many of the \( e_k \) the following condition holds. For every \( \varepsilon > 0 \) there exists \( P_\varepsilon \in \mathcal{F}(\{e_n\}) \) such that if \( P \in \mathcal{F}(\{e_n\}) \) and \( PP_\varepsilon = 0 \), then

\[
\nu \{ x \in H : \|Px\| > \varepsilon \} < \varepsilon.
\]

Then \( ||| \cdot ||| \) is called Gross measurable.

The following lemma is a fundamental result about Gross measurable norms. It is about the continuity of \( ||| \cdot ||| \). It is obvious that with respect to the topology determined by \( ||| \cdot ||| \) that \( x \to ||x|| \) is continuous. However, it would be interesting if this were the case with respect to the topology determined by the norm on \( H, |\cdot| \). This lemma shows this is the case and so the funny condition above implies \( x \to ||x|| \) is a continuous, hence Borel measurable function.

**Lemma 59.9.10** Let \( ||| \cdot ||| \) be Gross measurable. Then there exists \( c > 0 \) such that

\[
||x|| \leq c |x|
\]

for all \( x \in H \). Furthermore, the above definition is well defined.

**Proof:** First it is important to consider the question whether the above definition is well defined. To do this note that on \( PH \), the two norms are equivalent because \( PH \) is a finite dimensional space. Let \( G = \{ y \in PH : ||y|| > \varepsilon \} \) so \( G \) is an open set in \( PH \). Then

\[
\{ x \in H : ||Px|| > \varepsilon \}
\]

equals

\[
\{ x \in H : Px \in G \} \]
which equals a set of the form
\[ \{ x \in H : ((x, e_1)_H, \ldots, (x, e_m)_H) \in G' \} \]
for \( G' \) an open set in \( \mathbb{R}^m \) and so everything makes sense in the above definition.

Now it is necessary to verify \( jjj c jj \). If it is not so, there exists \( e_1 \) such that
\[ jj e_1 jj_1 = jj e_1 jj = 1. \]

Suppose \( \{ e_k \}_{k=1}^n \) have been chosen such that each is a unit vector in \( H \) and \( jj e_k jj \geq k \).
Then considering \( \text{span} (e_1, \ldots, e_n) \perp \) if for every \( x \in \text{span} (e_1, \ldots, e_n) \), then if \( z \in H \) is arbitrary, \( z = x + y \) where \( y \in \text{span} (e_1, \ldots, e_n) \) and so since the two norms are equivalent on a finite dimensional subspace, there exists \( e' \) corresponding to \( \text{span} (e_1, \ldots, e_n) \) such that
\[ jj z jj_2 \leq 2 jj x jj + 2 jj y jj \]
\[ = (2c^2 + 2c') (jj x jj^2 + jj y jj^2) \]
and the lemma is proved. Therefore it can be assumed, there exists
\[ e_{n+1} \in \text{span} (e_1, \ldots, e_n) \perp \]
such that \( |e_{n+1}| = 1 \) and \( |e_{n+1}| \geq n + 1. \)

This constructs an orthonormal set of vectors, \( \{ e_k \} \). Letting \( 0 < \varepsilon < \frac{1}{2} \), it follows since \( jj \cdot jj \) is measurable, there exists \( P_\varepsilon \in \mathcal{F} (\{ e_n \}) \) such that if \( PP_\varepsilon = 0 \) where \( P \in \mathcal{F} (\{ e_n \}) \), then
\[ \nu (\{ x \in H : jj P x jj > \varepsilon \}) < \varepsilon. \]

Say \( P_\varepsilon \) is the projection onto the span of finitely many of the \( e_k \), the last one being \( e_N \). Then for \( n > N \) and \( P_n \) the projection onto \( e_n \), it follows \( P_\varepsilon P_n = 0 \) and from the definition of \( \nu \),
\[ \varepsilon > \nu (\{ x \in H : jj P_n x jj > \varepsilon \}) \]
\[ = \nu (\{ x \in H : (x, e_n) |e_{n+1}| > \varepsilon \}) \]
\[ = \nu (\{ x \in H : (x, e_n) > \varepsilon / |e_{n+1}| \}) \]
\[ \geq \nu (\{ x \in H : (x, e_n) > \varepsilon / (n + 1) \}) \]
\[ > \frac{1}{\sqrt{2\pi}} \int_{\varepsilon/(n+1)}^\infty e^{-x^2/2} dx \]
which yields a contradiction for all \( n \) large enough. This proves the lemma.

What are examples of Gross measurable norms defined on a separable Hilbert space, \( H \)? The following lemma gives an important example.
Lemma 59.9.11 Let $H$ be a separable Hilbert space and let $A \in \mathcal{L}_2(H,H)$, a Hilbert Schmidt operator. Thus $A$ is a continuous linear operator with the property that for any orthonormal set, $\{e_k\}$,

$$\sum_{k=1}^{\infty} |Ae_k|^2 < \infty.$$  

Then define $||\cdot||$ by

$$||x|| \equiv |Ax|_H.$$  

Then if $||\cdot||$ is a norm, it is measurable\footnote{If it is only a seminorm, it satisfies the same conditions.}.

Proof: Let $\{e_k\}$ be an orthonormal sequence. Let $P_n$ denote the orthogonal projection onto span $(e_1, \cdots, e_n)$. Let $\epsilon > 0$ be given. Since $A$ is a Hilbert Schmidt operator, there exists $N$ such that

$$\sum_{k=N}^{\infty} |Ae_k|^2 < \alpha$$

where $\alpha$ is chosen very small. In fact, $\alpha$ is chosen such that $\alpha < \epsilon^2/r^2$ where $r$ is sufficiently large that

$$\frac{2}{\sqrt{2\pi}} \int_r^{\infty} e^{-t^2/2} dt < \epsilon. \quad (59.9.42)$$

Let $P$ denote an orthogonal projection in $\mathcal{F}(\{e_k\})$ such that $PP_N = 0$. Thus $P$ is the projection on to span $(e_{i_1}, \cdots, e_{i_m})$ where each $i_k > N$. Then

$$\nu\{x \in H : ||Px|| > \epsilon\} = \nu\{x \in H : |APx| > \epsilon\}$$

Now $Px = \sum_{j=1}^{m} (x, e_{i_j}) e_{i_j}$ and the above reduces to

$$\nu\left( \left\{ x \in H : \left| \sum_{j=1}^{m} (x, e_{i_j}) A e_{i_j} \right| > \epsilon \right\} \right) \leq$$
59.9. ABSTRACT WIENER SPACES

\[ \nu \left( \left\{ x \in H : \left( \sum_{j=1}^{m} |(x, e_i)|^2 \right)^{1/2} \left( \sum_{j=1}^{m} |Ae_i|^2 \right)^{1/2} > \varepsilon \right\} \right) \]

\[ \leq \nu \left( \left\{ x \in H : \left( \sum_{j=1}^{m} |(x, e_i)|^2 \right)^{1/2} \alpha^{1/2} > \varepsilon \right\} \right) \]

\[ = \nu \left( \left\{ x \in H : \left( \sum_{j=1}^{m} |(x, e_i)|^2 \right)^{1/2} > \frac{\varepsilon}{\alpha^{1/2}} \right\} \right) \]

\[ = \nu \left( \left\{ x \in H : ((x, e_{i_1}), \ldots, (x, e_{i_m})) \in B \left( 0, \frac{\varepsilon}{\alpha^{1/2}} \right)^{C} \right\} \right) \]

\[ \leq \nu \left( \left\{ x \in H : \max \left\{ |(x, e_i)| \right\} > \frac{\varepsilon}{\sqrt{ma^{1/2}}} \right\} \right) \]

This is no larger than

\[ \frac{1}{(\sqrt{2\pi})^m} \int_{|t_1| > \sqrt{ma^{1/2}}} \cdots \int_{|t_m| > \sqrt{ma^{1/2}}} e^{-t_1^2/2} dt_m \cdots dt_1 \]

\[ = \left( \frac{2 \int_{\varepsilon/(\sqrt{ma^{1/2}})}^{\infty} e^{-t^2/2} dt}{\sqrt{2\pi}} \right)^m \]

which by Jensen’s inequality is no larger than

\[ \frac{2 \int_{\varepsilon/(\sqrt{ma^{1/2}})}^{\infty} e^{-mt^2/2} dt}{\sqrt{2\pi}} = \frac{2 \frac{1}{\sqrt{m}} \int_{\varepsilon/(\alpha^{1/2})}^{\infty} e^{-t^2/2} dt}{\sqrt{2\pi}} \]

\[ \leq \frac{2 \int_{\varepsilon/(\sqrt{\alpha})}^{\infty} e^{-t^2/2} dt}{\sqrt{2\pi}} \]

\[ = \frac{2 \int_{\varepsilon}^{\infty} e^{-t^2/2} dt}{\sqrt{2\pi}} < \varepsilon \]

By \textbf{[59.9.12]} This proves the lemma.

\textbf{Definition 59.9.12} A triple, \((i, H, B)\) is called an abstract Wiener space if \(B\) is a separable Banach space and \(H\) is a separable Hilbert space such that \(H\) is dense and continuously embedded in \(B\) and the norm \(||\cdot||\) on \(B\) is Gross measurable.

Next consider a weaker norm for \(H\) which comes from the inner product

\[ (x, y)_E \equiv \sum_{k=1}^{\infty} \frac{1}{k^2} (x, e_k)_H (y, e_k)_H. \]
Then let $E$ be the completion of $H$ with respect to this new norm. Thus $\{k e_k\}$ is a complete orthonormal basis for $E$. This follows from the density of $H$ in $E$ along with the obvious observation that in the above inner product, $\{k e_k\}$ is an orthonormal set of vectors.

**Lemma 59.9.13** There exists a countably additive Gaussian measure, $\lambda$ defined on $B(E)$. This measure is the law of the random variable,

$$X(\omega) = \sum_{k=1}^{\infty} \xi_k(\omega) e_k,$$

where $\{\xi_k\}$ denotes a sequence of independent normally distributed random variables having mean 0 and variance 1, the series converging pointwise a.e. in $E$. Also

$$k^2 (X(\omega), e_k)_E = \xi_k(\omega) \text{ a.e.}$$

**Proof:** Observe that $\sum_{k=1}^{\infty} \frac{1}{k^2} (ke_k) \otimes (ke_k)$ is a nuclear operator on the Hilbert space, $E$. Letting $\{\xi_k\}$ be a sequence of independent random variables each normally distributed with mean 0 and variance 1, that

$$X(\omega) = \sum_{k=1}^{\infty} \frac{1}{k} \xi_k(\omega) ke_k = \sum_{k=1}^{\infty} \xi_k(\omega) e_k$$

(59.9.43)

is a random variable with values in $E$ and $L(X)$ is a Gaussian measure on $B(E)$, the series converging pointwise a.e. in $E$. Let $\lambda$ be the name of this Gaussian measure and denote the probability space on which the $\xi_k$ are defined as $(\Omega, \mathcal{F}, P)$. Thus for $F \in B(E)$,

$$\lambda(F) = P(\{\omega \in \Omega : X(\omega) \in F\})$$

Finally, denoting by $X_N$, the partial sum,

$$X_N(\omega) = \sum_{k=1}^{N} \xi_k(\omega) e_k,$$

the definition of $\langle \cdot, \cdot \rangle_E$ on $H$ and a simple computation yields

$$\xi_k(\omega) = \lim_{N \to \infty} k^2 (X_N(\omega), e_k)_E$$

$$= k^2 (X(\omega), e_k)_E.$$  (59.9.44)

One can pass to the limit because $X_N(\omega)$ converges to $X(\omega)$ in $E$. This proves the lemma.

**Theorem 59.9.14** Let $(i, H, B)$ be an abstract Wiener space. Then there exists a Gaussian measure on the Borel sets of $B$.  

Proof: Let $E$ be defined above as the completion of $H$ with respect to that weaker norm. Then from Lemma 59.9.13 and $X(\omega)$ given above in 59.9.43, $k^2 (X (\omega), e_k)_E = \xi_k (\omega)$ a.e. $\omega$.

Let $\{e_n\}$ be a complete orthonormal set for $H$. There exists an increasing sequence of projections, $\{Q_n\} \subseteq \mathcal{F}(\{e_n\})$ such that $Q_n x \to x$ in $H$ for each $x \in H$. Say $Q_n$ is the orthogonal projection onto span $(e_1, \cdots, e_{p_n})$. Then since $||\cdot||$ is measurable, these can be chosen such that if $Q$ is the orthogonal projection onto span $(e_1, \cdots, e_k)$ for some $k > p_n$ then

$$\nu \left( \{ x : ||Qx - Q_n x|| > 2^{-n} \} \right) < 2^{-n}. $$

In particular,

$$\nu \left( \{ x : ||Q_n x - Q_m x|| > 2^{-m} \} \right) < 2^{-m}$$

whenever $n \geq m$.

I would like to consider the infinite series,

$$S(\omega) = \sum_{k=1}^\infty k^2 (X (\omega), e_k)_E e_k \in B.$$ 

converging in $B$ but of course this might make no sense because the series might not converge. It was shown above that the series converges in $E$ but it has not been shown to converge in $B$.

Suppose the series did converge a.e. Then let $f \in B'$ and consider the random variable $f \circ S$ which maps $\Omega$ to $\mathbb{R}$. I would like to verify this is normally distributed. First note that the following finite sum is weakly measurable and separably valued so it is strongly measurable with values in $B$.

$$S_{p_n}(\omega) = \sum_{k=1}^{p_n} k^2 (X (\omega), e_k)_E e_k,$$

Since $f \in B'$ which is a subset of $H'$ due to the assumption that $H$ is dense in $B$, there exists a unique $v \in H$ such that $f(x) = (x, v)$ for all $x \in H$. Then from the above sum,

$$f(S_{p_n}(\omega)) = (S_{p_n}(\omega), v) = \sum_{k=1}^{p_n} k^2 (X (\omega), e_k)_E (e_k, v)$$

which by Lemma 59.9.13 equals

$$\sum_{k=1}^{p_n} (e_k, v)_H \xi_k (\omega)$$

a finite linear combination of the independent $N(0,1)$ random variables, $\xi_k (\omega)$. Then it follows

$$\omega \to f(S_{p_n}(\omega))$$
is also normally distributed and has mean 0 and variance equal to
\[ \sum_{k=1}^{p_n} (e_k, v)_H^2. \]

Then it seems reasonable to suppose
\[
E \left( e^{itf \circ S} \right) = \lim_{n \to \infty} E \left( e^{itf \circ S_{p_n}} \right) \\
= \lim_{n \to \infty} e^{-t^2 \sum_{k=1}^{p_n} (e_k, v)_H^2} \\
= e^{-t^2 \sum_{k=1}^{p_m} (e_k, v)_H^2} \\
= e^{-t^2 |v|^2_H} \tag{59.9.45}
\]

the characteristic function of a random variable which is \( N \left( 0, |v|^2_H \right) \). Thus at least formally, this would imply for all \( f \in B', f \circ S \) is normally distributed and so if \( \mu = \mathcal{L}(S) \), then by Lemma 59.7.3 it follows \( \mu \) is a Gaussian measure.

What is missing to make the above a proof? First of all, there is the issue of the sum. Next there is the problem of passing to the limit in the little argument above in which the characteristic function is used.

First consider the sum. Note that \( Q_n X (\omega) \in H \). Then for any \( n > p_m \),
\[
P \left( \{ \omega \in \Omega : \| S_n (\omega) - S_{p_m} (\omega) \| > 2^{-m} \} \right)
= P \left\{ \omega \in \Omega : \left\| \sum_{k=p_m+1}^{n} k^2 (X(\omega), e_k)_E e_k \right\| > 2^{-m} \right\}
= P \left\{ \omega \in \Omega : \left\| \sum_{k=p_m+1}^{n} \xi_k (\omega) e_k \right\| > 2^{-m} \right\} \tag{59.9.46}
\]

Let \( Q \) be the orthogonal projection onto span \((e_1, \cdots, e_n)\). Define
\[
F \equiv \{ x \in (Q - Q_m) H : \| x \| > 2^{-m} \}
\]

Then continuing the chain of equalities ending with 59.9.46,
\[
P \left\{ \omega \in \Omega : \left\| \sum_{k=p_m+1}^{n} \xi_k (\omega) e_k \in F \right\| \right\}
= P \left( \{ \omega \in \Omega : (\xi_n (\omega), \cdots, \xi_{p_m+1} (\omega)) \in F' \} \right)
= \nu \left( \{ x \in H : \langle x, e_n \rangle_H, \cdots, \langle x, e_{p_m+1} \rangle_H \} \in F' \} \right)
= \nu \left( \{ x \in H : Q (x) - Q_m (x) \in F \} \right)
= \nu \left( \{ x \in H : \| Q (x) - Q_m (x) \| > 2^{-m} \} \right) < 2^{-m}.
\]
This has shown that
\[ P \left( \{ \omega \in \Omega : \| S_n (\omega) - S_{p_m} (\omega) \| > 2^{-m} \} \right) < 2^{-m} \] (59.9.47)
for all \( n > p_m \). In particular, the above is true if \( n = p_n \) for \( n > m \).

If \( \{ S_{p_n} (\omega) \} \) fails to converge, then \( \omega \) must be contained in the set,
\[ A \equiv \cap_{m=1}^{\infty} \cup_{n=m}^{\infty} \{ \omega \in \Omega : \| S_{p_n} (\omega) - S_{p_m} (\omega) \| > 2^{-m} \} \] (59.9.48)
because if \( \omega \) is in the complement of this set,
\[ \cup_{m=1}^{\infty} \cap_{n=m}^{\infty} \{ \omega \in \Omega : \| S_{p_n} (\omega) - S_{p_m} (\omega) \| \leq 2^{-m} \} , \]
it follows \( \{ S_{p_n} (\omega) \}_{n=1}^{\infty} \) is a Cauchy sequence and so it must converge. However, the set in (59.9.48) is a set of measure 0 because of (59.9.47) and the observation that for all \( m \),
\[ P (A) \leq \sum_{n=m}^{\infty} P \left( \{ \omega \in \Omega : \| S_{p_n} (\omega) - S_{p_m} (\omega) \| > 2^{-m} \} \right) \leq \sum_{n=m}^{\infty} \frac{1}{2^m} \]
Thus the subsequence \( \{ S_{p_n} \} \) of the sequence of partial sums of the above series does converge pointwise in \( B \) and so the dominated convergence theorem also verifies that the computations involving the characteristic function in (59.9.45) are correct.

The random variable obtained as the limit of the partial sums, \( \{ S_{p_n} (\omega) \} \) described above is strongly measurable because each \( S_{p_n} (\omega) \) is strongly measurable due to each of these being weakly measurable and separably valued. Thus the measure given as the law of \( S \) defined as
\[ S (\omega) \equiv \lim_{n \to \infty} S_{p_n} (\omega) \]
is defined on the Borel sets of \( B \). This proves the theorem.

Also, there is an important observation from the proof which I will state as the following corollary.

**Corollary 59.9.15** Let \((i, H, B)\) be an abstract Wiener space. Then there exists a Gaussian measure on the Borel sets of \( B \). This Gaussian measure equals \( L(S) \) where \( S(\omega) \) is the a.e. limit of a subsequence of the sequence of partial sums,
\[ S_{p_n} (\omega) \equiv \sum_{k=1}^{p_n} \xi_k (\omega) e_k \]
for \( \{ \xi_k \} \) a sequence of independent random variables which are normal with mean 0 and variance 1 which are defined on a probability space, \((\Omega, F, P)\). Furthermore, for any \( k > p_n \),
\[ P \left( \{ \omega \in \Omega : \| S_k (\omega) - S_{p_n} (\omega) \| > 2^{-n} \} \right) < 2^{-n} \].
59.10 White Noise

In an abstract Wiener space as discussed above there is a Gaussian measure, \( \mu \) defined on the Borel sets of \( B \). This measure is the law of a random variable having values in \( B \) which is the limit of a subsequence of a sequence of partial sums. I will show here that the sequence of partial sums also converges pointwise a.e.

Now with this preparation, here is the theorem about white noise.

**Theorem 59.10.1** Let \((i, H, B)\) be an abstract Wiener space and \( \{e_k\} \) is a complete orthonormal sequence in \( H \). Then there exists a Gaussian measure on the Borel sets of \( B \). This Gaussian measure equals \( L(S) \) where \( S(\omega) \) is the a.e. limit of the sequence of partial sums,

\[
S_n(\omega) = \sum_{k=1}^{n} \xi_k(\omega) e_k
\]

for \( \{\xi_k\} \) a sequence of independent random variables which are normal with mean 0 and variance 1, defined on a probability space, \((\Omega, \mathcal{F}, P)\)

**Proof:** By Corollary 59.9.15 there is a subsequence, \( \{S_{p_n}\} \) of these partial sums which converge pointwise a.e. to \( S(\omega) \). However, this corollary also states that

\[
P(\{\omega \in \Omega : \|S_k(\omega) - S_{p_n}(\omega)\| > 2^{-n}\}) < 2^{-n}
\]

whenever \( k > p_n \) and so by Lemma 59.11.6 the original sequence of partial sums also converges uniformly of a set of measure zero. The reason this lemma applies is that \( \xi_k(\omega) e_k \) has symmetric distribution. This proves the theorem.

59.11 Existence Of Abstract Wiener Spaces

It turns out that if \( E \) is a separable Banach space, then it is the top third of an abstract Wiener space. This is what will be shown in this section. Therefore, it follows from the above that there exists a Gaussian measure on \( E \) which is the law of an a.e. convergent series as discussed above. First recall Lemma 15.4.2 on Page 441.

**Lemma 59.11.1** Let \( E \) be a separable Banach space. Then there exists an increasing sequence of subspaces, \( \{F_n\} \) such that \( \dim(F_{n+1}) - \dim(F_n) \leq 1 \) and equals 1 for all \( n \) if the dimension of \( E \) is infinite. Also \( \bigcup_{n=1}^{\infty} F_n \) is dense in \( E \).

**Lemma 59.11.2** Let \( E \) be a separable Banach space. Then there exists a sequence \( \{e_n\} \) of points of \( E \) such that whenever \( |\beta| \leq 1 \) for \( \beta \in \mathbb{F}^n \),

\[
\sum_{k=1}^{n} \beta_k e_k \in B(0,1)
\]

the unit ball in \( E \).
59.11. EXISTENCE OF ABSTRACT WIENER SPACES

**Proof:** By Lemma 59.11.1, let \( \{z_1, \ldots, z_n\} \) be a basis for \( F_n \) where \( \cup_{n=1}^{\infty} F_n \) is dense in \( E \). Then let \( \alpha_1 \) be such that \( e_1 = \alpha_1 z_1 \in B(0,1) \). Thus \( \beta_1 e_1 \in B(0,1) \) whenever \( |\beta_1| \leq 1 \). Suppose \( \alpha_i \) has been chosen for \( i = 1, 2, \ldots, n \) such that for all \( \beta \in D_n \equiv \{\alpha \in \mathbb{F}^n : |\alpha| \leq 1\} \), it follows

\[
\sum_{k=1}^{n} \beta_k \alpha_k z_k \in B(0,1)
\]

Then

\[
C_n = \left\{ \sum_{k=1}^{n} \beta_k \alpha_k z_k : \beta \in D_n \right\}
\]

is a compact subset of \( B(0,1) \) and so it is at a positive distance from the complement of \( B(0,1) \), \( \delta \). Now let \( 0 < \alpha_{n+1} < \delta / \|z_{n+1}\| \). Then for \( \beta \in D_{n+1} \),

\[
\sum_{k=1}^{n} \beta_k \alpha_k z_k \in C_n
\]

and so

\[
\left\| \sum_{k=1}^{n+1} \beta_k \alpha_k z_k - \sum_{k=1}^{n} \beta_k \alpha_k z_k \right\| = \| \beta_{n+1} \alpha_{n+1} z_{n+1} \| < \| \alpha_{n+1} z_{n+1} \| < \delta
\]

which shows

\[
\sum_{k=1}^{n+1} \beta_k \alpha_k z_k \in B(0,1).
\]

This proves the lemma. Let \( e_k = \alpha_k z_k \).

Now the main result is the following. It says that any separable Banach space is the upper third of some abstract Wiener space.

**Theorem 59.11.3** Let \( E \) be a real separable Banach space with norm \( \| \cdot \| \). Then there exists a separable Hilbert space, \( H \) such that \( H \) is dense in \( E \) and the inclusion map is continuous. Furthermore, if \( \nu \) is the Gaussian measure defined earlier on the cylinder sets of \( H, \| \cdot \| \) is Gross measurable.

**Proof:** Let \( \{e_k\} \) be the points of \( E \) described in Lemma 59.11.1. Then let \( H_0 \) denote the subspace of all finite linear combinations of the \( \{e_k\} \). It follows \( H_0 \) is dense in \( E \). Next decree that \( \{e_k\} \) is an orthonormal basis for \( H_0 \). Thus for

\[
\sum_{k=1}^{n} c_k e_k, \sum_{j=1}^{n} d_j e_j \in H_0,
\]

\[
\left( \sum_{k=1}^{n} c_k e_k, \sum_{j=1}^{n} d_j e_j \right)_{H_0} = \sum_{k=1}^{n} c_k d_k
\]
this being well defined because the \( \{e_k\} \) are independent. Let the norm on \( H_0 \) be denoted by \(|\cdot|_{H_0}\). Let \( H_1 \) be the completion of \( H_0 \) with respect to this norm.

I want to show that \(|\cdot|_{H_0}\) is stronger than \(|\cdot|\). Suppose then that

\[
\sum_{k=1}^{n} \beta_k e_k \leq 1.
\]

It follows then from the definition of \(|\cdot|_{H_0}\) that

\[
\left\| \sum_{k=1}^{n} \beta_k e_k \right\|_{H_0}^2 = \sum_{k=1}^{n} \beta_k^2 \leq 1
\]

and so from the construction of the \( e_k \), it follows that

\[
\left\| \sum_{k=1}^{n} \beta_k e_k \right\| < 1
\]

Stated more simply, this has just shown that if \( h \in H_0 \) then since \( |h|/|h|_{H_0}|_{H_0} \leq 1 \), it follows that

\[
||h||/|h|_{H_0} < 1
\]

and so

\[
||h|| < |h|_{H_0}.
\]

It follows that the completion of \( H_0 \) must lie in \( E \) because this shows that every Cauchy sequence in \( H_0 \) is a Cauchy sequence in \( E \). Thus \( H_1 \) embeds continuously into \( E \) and is dense in \( E \). Denote its norm by \(|\cdot|_{H_1}\).

Now consider the nuclear operator,

\[
A = \sum_{k=1}^{\infty} \lambda_k e_k \otimes e_k
\]

where each \( \lambda_k > 0 \) and \( \sum_k \lambda_k < \infty \). This operator is clearly one to one. Also it is clear the operator is Hilbert Schmidt because \( \sum_k \lambda_k^2 < \infty \). Let

\[
H \equiv AH_1.
\]

and for \( x \in H \), define

\[
|x|_H \equiv |A^{-1}x|_{H_1}.
\]

Since each \( e_k \) is in \( H \) it follows that \( H \) is dense in \( E \). Note also that \( H \subseteq H_1 \) because \( A \) maps \( H_1 \) to \( H_1 \).

\[
Ax \equiv \sum_{k=1}^{\infty} \lambda_k (x, e_k) e_k
\]
and the series converges in $H_1$ because

$$
\sum_{k=1}^{\infty} \lambda_k |(x, e_k)| \leq \left( \sum_{k=1}^{\infty} \lambda_k^2 \right)^{1/2} \left( \sum_{k=1}^{\infty} |(x, e_k)|^2 \right)^{1/2} < \infty.
$$

Also $H$ is a Hilbert space with inner product given by

$$(x, y)_H \equiv (A^{-1}x, A^{-1}y)_{H_1}.$$ 

$H$ is complete because if $\{x_n\}$ is a Cauchy sequence in $H$, this is the same as $\{A^{-1}x_n\}$ being a Cauchy sequence in $H_1$ which implies $A^{-1}x_n \to y$ for some $y \in H_1$. Then it follows $x_n = A(A^{-1}x_n) \to Ay$ in $H$.

For $x \in H \subseteq H_1$,

$$
||x|| \leq |x|_{H_1} = |AA^{-1}x|_{H_1} \leq ||A|| |A^{-1}x|_{H_1} = ||A|| |x|_H
$$

and so the embedding of $H$ into $E$ is continuous. Why is $||\cdot||$ a measurable norm on $H$? Note first that for $x \in H \subseteq H_1$,

$$
|Ax|_H = |A^{-1}Ax|_{H_1} = |x|_{H_1} \geq ||x||_E. \quad (59.11.49)
$$

Therefore, if it can be shown $A$ is a Hilbert Schmidt operator on $H$, the desired measurability will follow from Lemma 59.9.11 on Page 2084.

**Claim:** $A$ is a Hilbert Schmidt operator on $H$.

**Proof of the claim:** From the definition of the inner product in $H$, it follows an orthonormal basis for $H$ is $\{\lambda_k e_k\}$. This is because

$$(\lambda_k e_k, \lambda_j e_j)_{H} = (\lambda_k A^{-1}e_k, \lambda_j A^{-1}e_j)_{H_1} = (e_k, e_j)_{H_1} = \delta_{jk}.$$ 

To show that $A$ is Hilbert Schmidt, it suffices to show that

$$
\sum_k |A(\lambda_k e_k)|_H^2 < \infty
$$

because this is the definition of an operator being Hilbert Schmidt. However, the above equals

$$
\sum_k |A^{-1}A(\lambda_k e_k)|_{H_1}^2 = \sum_k \lambda_k^2 < \infty.
$$

This proves the claim.

Now consider $\lambda_k e_k$. By Lemma 59.9.11 it follows the norm $||x||'_e \equiv |Ax|_H$ is Gross measurable on $H$. Therefore, $||\cdot||'_E$ is also Gross measurable because it is smaller. This proves the theorem.

Using Theorem 59.11.3 and Theorem 59.10.1 this proves most of the following important corollary.
Corollary 59.11.4 Let $E$ be any real separable Banach space. Then there exists a sequence, $\{e_k\} \subseteq E$ such that for any $\{\xi_k\}$ a sequence of independent random variables such that $\mathcal{L}(\xi_k) = N(0,1)$, it follows

$$X(\omega) \equiv \sum_{k=1}^{\infty} \xi_k(\omega)e_k$$

converges a.e. and its law is a Gaussian measure defined on $\mathcal{B}(E)$. Furthermore, $\|e_k\|_E \leq \lambda_k$ where $\sum_k \lambda_k < \infty$.

Proof: From the proof of Theorem 59.11.4, a basis for $H$ is $\{\lambda_k e_k\}$. Therefore, by Theorem 59.10.1 if $\{\xi_k\}$ is a sequence of independent $N(0,1)$ random variables, then $\sum_{k=1}^{\infty} \xi_k(\omega)\lambda_k e_k$ converges a.e. to a random variable whose law is Gaussian. Also from the proof of Theorem 59.10.1, each $e_k$ in that proof has the property that $\|e_k\| \leq 1$ because if $\|e_k\| > 1$, then you could consider $\beta \equiv (0,0,\cdots,1)$ and from the construction of the $e_k$, you would need $1e_k \in B(0,1)$ which is a contradiction. Thus $\|\lambda_k e_k\| \leq \lambda_k$ and changing the notation, replacing $\lambda_k e_k$ with $e_k$, this proves the corollary.
Chapter 60

Stochastic Processes

60.1 Fundamental Definitions And Properties

Here $E$ will be a separable Banach space and $B(E)$ will be the Borel sets of $E$. Let $(\Omega, \mathcal{F}, P)$ be a probability space and $I$ will be an interval of $\mathbb{R}$. A set of $E$ valued random variables, one for each $t \in I$, $\{X(t) : t \in I\}$ is called a stochastic process. Thus for each $t$, $X(t)$ is a measurable function of $\omega \in \Omega$. Set $X(t, \omega) \equiv X(t)(\omega)$. Functions $t \to X(t, \omega)$ are called trajectories. Thus there is a trajectory for each $\omega \in \Omega$. A stochastic process, $Y$ is called a version or a modification of a stochastic process, $X$ if for all $t \in I$,

$$X(t, \omega) = Y(t, \omega) \text{ a.e. } \omega$$

There are several descriptions of stochastic processes.

1. $X$ is measurable if $X(\cdot, \cdot) : I \times \Omega \to E$ is $B(I) \times \mathcal{F}$ measurable. Note that a stochastic process, $X$ is not necessarily measurable.

2. $X$ is stochastically continuous at $t_0 \in I$ means: for all $\varepsilon > 0$ and $\delta > 0$ there exists $\rho > 0$ such that

$$P (\|X(t) - X(t_0)\| \geq \varepsilon) \leq \delta \text{ whenever } |t - t_0| < \rho, t \in I.$$ 

Note the above condition says that for each $\varepsilon > 0$,

$$\lim_{t \to t_0} P (\|X(t) - X(t_0)\| \geq \varepsilon) = 0.$$

3. $X$ is stochastically continuous if it is stochastically continuous at every $t \in I$.

4. $X$ is stochastically uniformly continuous if for every $\varepsilon, \delta > 0$ there exists $\rho > 0$ such that whenever $s, t \in I$ with $|s - t| < \rho$, it follows

$$P (\|X(t) - X(s)\| \geq \varepsilon) \leq \delta.$$
5. $X$ is mean square continuous at $t_0 \in I$ if
\[
\lim_{t \to t_0} E\left(\left\|X(t) - X(t_0)\right\|^2\right) = \lim_{t \to t_0} \int_\Omega \left\|X(t)(\omega) - X(t_0)(\omega)\right\|^2 dP = 0.
\]

6. $X$ is mean square continuous in $I$ if it is mean square continuous at every point of $I$.

7. $X$ is continuous with probability 1 or continuous if $t \to X(t, \omega)$ is continuous for all $\omega$ outside some set of measure 0.

8. $X$ is Hölder continuous if $t \to X(t, \omega)$ is Hölder continuous for a.e. $\omega$.

**Lemma 60.1.1** A stochastically continuous process on $[a, b] \equiv I$ is uniformly stochastically continuous on $[a, b] \equiv I$.

**Proof:** If this is not so, there exists $\varepsilon, \delta > 0$ and points of $I, s_n, t_n$ such that even though
\[
|t_n - s_n| < \frac{1}{n},
\]
\[
P\left(\left\|X(s_n) - X(t_n)\right\| \geq \varepsilon\right) > \delta.
\]
Taking a subsequence, still denoted by $s_n$ and $t_n$ there exists $t \in I$ such that the above hold and
\[
\lim_{n \to \infty} s_n = \lim_{n \to \infty} t_n = t.
\]
Then
\[
P\left(\left\|X(s_n) - X(t_n)\right\| \geq \varepsilon\right)
\leq P\left(\left\|X(s_n) - X(t)\right\| \geq \varepsilon/2\right) + P\left(\left\|X(t) - X(t_n)\right\| \geq \varepsilon/2\right).
\]
But the sum of the last two terms converges to 0 as $n \to \infty$ by stochastic continuity of $X$ at $t$, violating $|t_n - s_n| < \frac{1}{n}$ for all $n$ large enough. This proves the lemma.

For a stochastically continuous process defined on a closed and bounded interval, there always exists a measurable version. This is significant because then you can do things with product measure and iterated integrals.

**Proposition 60.1.2** Let $X$ be a stochastically continuous process defined on a closed interval, $I \equiv [a, b]$. Then there exists a measurable version of $X$.

**Proof:** By Lemma 60.1.1 $X$ is uniformly stochastically continuous and so there exists a sequence of positive numbers, $\{\rho_n\}$ such that if $|s - t| < \rho_n$, then
\[
P\left(\left\|X(t) - X(s)\right\| \geq \frac{1}{2^n}\right) \leq \frac{1}{2^n}.
\]
Then let \( \{t^n_0, t^n_1, \cdots, t^n_m\} \) be a partition of \([a, b]\) in which \( |t^n_i - t^n_{i-1}| < \rho_n \). Now define \( X_n \) as follows:

\[
X_n (t) = \sum_{i=1}^{m_n} X (t^n_{i-1}) X_{[t^n_{i-1}, t^n_i)} (t)
\]

Then \( X_n \) is obviously \( B(I) \times \mathcal{F} \) measurable because it is the sum of functions which are. Consider the set, \( A \) on which \( \{X_n (t, \omega)\} \) is a Cauchy sequence. This set is of the form

\[
A = \cap_{n=1}^{\infty} \cup_{m=1}^{\infty} \cap_{p, q \geq m} \left[ \|X_p - X_q\| < \frac{1}{n} \right]
\]

and so it is a \( B(I) \times \mathcal{F} \) measurable set. Now define

\[
Y (t, \omega) = \begin{cases} 
\lim_{n \to \infty} X_n (t, \omega) & \text{if } (t, \omega) \in A \\
0 & \text{if } (t, \omega) \notin A
\end{cases}
\]

I claim \( Y (t, \omega) = X (t, \omega) \) for a.e. \( \omega \). To see this, consider \( \text{lllll} \). From the construction of \( X_n \), it follows that for each \( t \),

\[
P \left( \left\{ \|X_n (t) - X (t)\| \geq \frac{1}{2^n} \right\} \right) \leq \frac{1}{2^n}
\]

Also, for a fixed \( t \), if \( X_n (t, \omega) \) fails to converge to \( X (t, \omega) \), then \( \omega \) must be in infinitely many of the sets,

\[
B_n = \left[ \|X_n (t) - X (t)\| \geq \frac{1}{2^n} \right]
\]

which is a set of measure zero by the Borel Cantelli lemma. Recall why this is so.

\[
P \left( \cap_{k=1}^{\infty} \cup_{n=k}^{\infty} B_n \right) \leq \sum_{n=k}^{\infty} P (B_n) < \frac{1}{2^{k-1}}
\]

Therefore, for each \( t, (t, \omega) \in A \) for a.e. \( \omega \). Hence \( X (t) = Y (t) \) a.e. and so \( Y \) is a measurable version of \( X \).

**Lemma 60.1.3** Let \( D \) be a dense subset of an interval, \( I = [0, T] \) and suppose \( X : D \to E \) satisfies

\[
\|X (d) - X (d')\| \leq C |d - d'|^\gamma
\]

for all \( d', d \in D \). Then \( X \) extends uniquely to a continuous \( Y \) defined on \([0, T]\) such that

\[
\|Y (t) - Y (t')\| \leq C |t - t'|^\gamma
\]
**Proof:** Let \( t \in I \) and let \( d_k \to t \) where \( d_k \in D \). Then \( \{X(d_k)\} \) is a Cauchy sequence because \( \|X(d_k) - X(d_m)\| \leq C|d_k - d_m|^\gamma \). Therefore, \( X(d_k) \) converges. The thing it converges to will be called \( Y(t) \). Note this is well defined, giving \( X(t) \) if \( t \in D \). Also, if \( d_k \to t \) and \( d'_k \to t \), then \( \|X(d_k) - X(d'_k)\| \leq C|d_k - d'_k|^\gamma \) and so \( X(d_k) \) and \( X(d'_k) \) converge to the same thing. Therefore, it makes sense to define \( Y(t) = \lim_{d \to t} X(d) \). It only remains to verify the estimate. But letting \( |d - t| \) and \( |d' - t'| \) be small enough,

\[
\|Y(t) - Y(t')\| = \|X(d) - X(d')\| + \varepsilon \\
\leq C|d - d'| + \varepsilon \leq |t - t'| + 2\varepsilon.
\]

Since \( \varepsilon \) is arbitrary, this proves the existence part of the lemma. Uniqueness follows from observing that \( Y(t) \) must equal \( \lim_{d \to t} X(d) \). This proves the lemma.

### 60.2 Kolmogorov Čentsov Continuity Theorem

**Lemma 60.2.1** Let \( r_j^m \) denote \( j \left( \frac{T}{2^m} \right) \) where \( j \in \{0, 1, \ldots, 2^m\} \). Also let \( D_m = \{ r_j^m \}_{j=1}^{2^m} \) and \( D = \cup_{m=1}^{\infty} D_m \). Suppose \( X(t) \) satisfies

\[
\|X(r_j^{k+1}) - X(r_j^k)\| \leq 2^{-\gamma k}
\]  

(60.2.3)

for all \( k \geq M \). Then if \( d, d' \in D_m \) for \( m > n \geq M \) such that \(|d - d'| \leq T2^{-n}\), then

\[
\|X(d') - X(d)\| \leq 2 \sum_{j=n+1}^{m} 2^{-\gamma j}.
\]

Also, there exists a constant \( C \) depending on \( M \) such that for all \( d, d' \in D \),

\[
\|X(d) - X(d')\| \leq C|d - d'|^\gamma.
\]

**Proof:** Suppose \( d' < d \). Suppose first \( m = n + 1 \). Then \( d = (k + 1)T2^{-(n+1)} \) and \( d' = kT2^{-(n+1)} \). Then from (60.2.3)

\[
\|X(d') - X(d)\| \leq 2^{-\gamma(n+1)} \leq 2 \sum_{j=n+1}^{n+1} 2^{-\gamma j}.
\]

Suppose the claim is true for some \( m > n \) and let \( d, d' \in D_{m+1} \) with \(|d - d'| < T2^{-n}\). If there is no point of \( D_m \) between these, then \( d', d \) are adjacent points either in \( D_m \) or in \( D_{m+1} \). Consequently,

\[
\|X(d') - X(d)\| \leq 2^{-\gamma m} < 2 \sum_{j=n+1}^{m+1} 2^{-\gamma j}.
\]

Assume therefore, there exist points of \( D_m \) between \( d' \) and \( d \). Let \( d' \leq d_1' \leq d_1 \leq d \) where \( d_1, d_1' \) are in \( D_m \) and \( d_1' \) is the smallest element of \( D_m \) which is at least
as large as $d'$ and $d_1$ is the largest element of $D_m$ which is no larger than $d$. Then $|d' - d'_1| \leq T2^{-(m+1)}$ and $|d_1 - d| \leq T2^{-(m+1)}$ while all of these points are in $D_{m+1}$ which contains $D_m$. Therefore, from (60.2.3) and induction,

$$
|X(d') - X(d)| 
\leq |X(d') - X(d'_1)| + |X(d'_1) - X(d)|
\leq 2 \times 2^{-\gamma(m+1)} + 2 \sum_{j=n+1}^{m} 2^{-\gamma j} = 2 \sum_{j=n+1}^{m+1} 2^{-\gamma j}
\leq 2 \left( \frac{2^{-\gamma(n+1)}}{1 - 2^{-\gamma}} \right) \left( \frac{T2^{-(n+1)}}{1 - 2^{-\gamma}} \right) \gamma
$$

(60.2.4)

It follows the above holds for any $d, d' \in D$ such that $|d - d'| \leq T2^{-n}$ because they are both in some $D_m$ for $m > n$.

Consider the last claim. Let $d, d' \in D$, $|d - d'| \leq T2^{-M}$. Then $d, d'$ are both in some $D_m$ for $m > M$. The number $|d - d'|$ satisfies

$$
T2^{-(n+1)} < |d - d'| \leq T2^{-n}
$$

for large enough $n \geq M$. Just pick the first $n$ such that $T2^{-(n+1)} < |d - d'|$. Then from (60.2.3),

$$
|X(d') - X(d)| \leq \left( \frac{T2^{-\gamma}}{1 - 2^{-\gamma}} \right) (T2^{-(n+1)}) \gamma
\leq \left( \frac{T2^{-\gamma}}{1 - 2^{-\gamma}} \right) (|d - d'|) \gamma
$$

Now $[0, T]$ is covered by $2^M$ intervals of length $T2^{-M}$ and so for any pair $d, d' \in D,$

$$
|X(d) - X(d')| \leq C |d - d'| \gamma
$$

where $C$ is a suitable constant depending on $2^M$. ■

For $\gamma \leq 1$, you can show, using convexity arguments, that it suffices to have

$$
C = \left( \frac{2T^{-\gamma}}{1 - 2^{-\gamma}} \right)^{\frac{1}{\gamma}} (2^M)^{1-\gamma}.
$$

Of course the case where $\gamma > 1$ is not interesting because it would result in $X$ being a constant.

The following is the amazing Kolmogorov Čentsov continuity theorem [41].

**Theorem 60.2.2** Suppose $X$ is a stochastic process on $[0, T]$. Suppose also that there exists a constant, $C$ and positive numbers, $\alpha, \beta$ such that

$$
E(||X(t) - X(s)||^\alpha) \leq C |t - s|^{1+\beta}
$$

(60.2.5)

Then there exists a stochastic process $Y$ such that for a.e. $\omega, t \rightarrow Y(t)(\omega)$ is Hölder continuous with exponent $\gamma < \frac{\beta}{\alpha}$ and for each $t$, $P(||X(t) - Y(t)|| > 0) = 0$. ($Y$ is a version of $X$.)

**Proof:** Let \( r^m_j \) denote \( j \left( \frac{T}{2^m} \right) \) where \( j \in \{0, 1, \cdots, 2^m\} \). Also let \( D_m = \{r^m_j\}_{j=1}^{2^m} \) and \( D = \bigcup_{m=1}^{\infty} D_m \). Consider the set,

\[
||X(t) - X(s)|| > \delta
\]

By \( 60.2.5 \),

\[
P(||X(t) - X(s)|| > \delta) \delta^\alpha \leq \int_{||X(t) - X(s)|| > \delta}||X(t) - X(s)||^\alpha dP \\
\leq C|t-s|^{1+\beta}.
\]

(60.2.6)

Letting \( t = r^k_j+1 \), \( s = r^k_j \), and \( \delta = 2^{-\gamma k} \) where

\[
\gamma \in \left(0, \frac{\beta}{\alpha}\right),
\]

this yields

\[
P\left(||X\left(r^k_{j+1}\right) - X\left(r^k_j\right)|| > 2^{-\gamma k}\right) \leq C2^{\alpha \gamma k} (T2^{-k})^{1+\beta} = CT^{1+\beta}2^{k(\alpha \gamma - (1+\beta))}
\]

There are \( 2^k \) of these differences and so letting

\[
N_k = \bigcup_{j=1}^{2^k} \left[ ||X\left(r^k_{j+1}\right) - X\left(r^k_j\right)|| > 2^{-\gamma k}\right]
\]

it follows

\[
P(N_k) \leq C2^{\alpha \gamma k} (T2^{-k})^{1+\beta} 2^k = C2^{k(\alpha \gamma - (1+\beta))}T^{1+\beta}.
\]

Since \( \gamma < \beta/\alpha \),

\[
\sum_{k=1}^{\infty} P(N_k) \leq CT^{1+\beta} \sum_{k=1}^{\infty} 2^{k(\alpha \gamma - (1+\beta))} < \infty
\]

and so by the Borel Cantelli lemma, Lemma 57.1.2, there exists a set of measure zero \( N \), such that if \( \omega \notin N \), then \( \omega \) is in only finitely many \( N_k \). In other words, for \( \omega \notin N \), there exists \( M(\omega) \) such that if \( k \geq M(\omega) \), then for each \( j \),

\[
||X\left(r^k_{j+1}\right)(\omega) - X\left(r^k_j\right)(\omega)|| \leq 2^{-\gamma k}.
\]

(60.2.7)

It follows from Lemma 57.1.3 that \( t \to X(t)(\omega) \) is Holder continuous on \( D \) with Holder exponent \( \gamma \). Note the constant is a measurable function of \( \omega \), depending on how many measurable \( N_k \) which contain \( \omega \).

By Lemma 57.1.3, one can define \( Y(t)(\omega) \) to be the unique function which extends \( d \to X(d)(\omega) \) off \( D \) for \( \omega \notin N \) and let \( Y(t)(\omega) = 0 \) if \( \omega \in N \). Thus by Lemma 57.1.3 \( t \to Y(t)(\omega) \) is Holder continuous. Also, \( \omega \to Y(t)(\omega) \) is measurable because it is the pointwise limit of measurable functions

\[
Y(t)(\omega) = \lim_{d \to t} X(d)(\omega)X_{NC}(\omega).
\]

(60.2.8)
It remains to verify the claim that \( Y(t)(\omega) = X(t)(\omega) \) a.e.

\[
\mathcal{X}_{||Y(t) - X(t)|| > \varepsilon \cap N^C}(\omega) \leq \liminf_{d \to t} \mathcal{X}_{||X(d) - X(t)|| > \varepsilon \cap N^C}(\omega)
\]

because if \( \omega \in N \) both sides are 0 and if \( \omega \in N^C \) then the above limit in [10.2.8] holds and so if \( ||Y(t)(\omega) - X(t)(\omega)|| > \varepsilon \), the same is true of \( ||X(d)(\omega) - X(t)(\omega)|| \) whenever \( d \) is close enough to \( t \) and so by Fatou’s lemma,

\[
P(\{||Y(t) - X(t)|| > \varepsilon\}) = \int \mathcal{X}_{||Y(t) - X(t)|| > \varepsilon \cap N^C}(\omega) \, dP
\]
\[
\leq \liminf_{d \to t} \int \mathcal{X}_{||X(d) - X(t)|| > \varepsilon}(\omega) \, dP
\]
\[
\leq \liminf_{d \to t} \int \mathcal{X}_{||X(d) - X(t)|| > \varepsilon}(\omega) \, dP
\]
\[
\leq \liminf_{d \to t} P\left(||X(d) - X(t)|| > \varepsilon \right)\]
\[
\leq \liminf_{d \to t} \int_{||X(d) - X(t)|| > \varepsilon} ||X(d) - X(t)|| \, dP
\]
\[
\leq \liminf_{d \to t} \frac{C}{\varepsilon} |d - t|^{1+\beta} = 0.
\]

Therefore,

\[
P(\{||Y(t) - X(t)|| > 0\}) = \sum_{k=1}^{\infty} P\left(||Y(t) - X(t)|| > \frac{1}{k}\right)
\]
\[
\leq \sum_{k=1}^{\infty} P\left(||Y(t) - X(t)|| > \frac{1}{k}\right) = 0. \quad \square
\]

A few observations are interesting. In the proof, the following inequality was obtained.

\[
||X(d')(\omega) - X(d)(\omega)|| \leq \frac{2}{T^\gamma (1 - 2^{-\gamma})} \left(T 2^{-(\alpha+1)}\right)^\gamma
\]
\[
\leq \frac{2}{T^\gamma (1 - 2^{-\gamma})} (|d - d'|)^\gamma
\]

which was so for any \( d', d \in D \) with \( |d' - d| < T 2^{-(M(\omega)+1)} \). Thus the Holder continuous version of \( X \) will satisfy

\[
||Y(t)(\omega) - Y(s)(\omega)|| \leq \frac{2}{T^\gamma (1 - 2^{-\gamma})} (|t - s|)^\gamma
\]

provided \( |t - s| < T 2^{-(M(\omega)+1)} \). Does this translate into an inequality of the form

\[
||Y(t)(\omega) - Y(s)(\omega)|| \leq \frac{2}{T^\gamma (1 - 2^{-\gamma})} (|t - s|)^\gamma
\]
for any pair of points \( t, s \in [0, T] \)? It seems it does not for any \( \gamma < 1 \) although it does yield

\[
||Y(t)(\omega) - Y(s)(\omega)|| \leq C (|t-s|)^\gamma
\]

where \( C \) depends on the number of intervals having length less than \( T^{-2(M(\omega)+1)} \) which it takes to cover \([0, T]\). First note that if \( \gamma > 1 \), then the Holder continuity will imply \( t \to Y(t)(\omega) \) is a constant. Therefore, the only case of interest is \( \gamma < 1 \).

Let \( s, t \) be any pair of points and let \( s = x_0 < \cdots < x_n = t \) where \( |x_i - x_{i-1}| < T^{-2(M(\omega)+1)} \).

Then

\[
||Y(t)(\omega) - Y(s)(\omega)|| \leq \sum_{i=1}^{n} ||Y(x_i)(\omega) - Y(x_{i-1})(\omega)||
\]

\[
\leq \frac{2}{T^\gamma (1 - 2^{-\gamma})} \sum_{i=1}^{n} (|x_i - x_{i-1}|)^\gamma \tag{60.2.9}
\]

How does this compare to

\[
\left( \sum_{i=1}^{n} |x_i - x_{i-1}| \right)^\gamma = |t-s|^\gamma?
\]

This last expression is smaller than the right side of (60.2.9) for any \( \gamma < 1 \). Thus for \( \gamma < 1 \), the constant in the conclusion of the theorem depends on both \( T \) and \( \omega \notin N \).

In the case where \( \alpha \geq 1 \), here is another proof of this theorem. It is based on the one in the book by Stroock [109].

Theorem 60.2.3 Suppose \( X \) is a stochastic process on \([0, T]\) having values in the Banach space \( E \). Suppose also that there exists a constant, \( C \) and positive numbers \( \alpha, \beta, \alpha \geq 1 \), such that

\[
E(||X(t) - X(s)||^\alpha) \leq C |t-s|^{1+\beta}
\tag{60.2.10}
\]

Then there exists a stochastic process \( Y \) such that for a.e. \( \omega \), \( t \to Y(t)(\omega) \) is Hölder continuous with exponent \( \gamma < \frac{\beta}{\alpha} \) and for each \( t \), \( P(||X(t) - Y(t)|| > 0) = 0 \). \( Y \) is a version of \( X \). Also

\[
E \left( \sup_{0 \leq s < t \leq T} \frac{||Y(t) - Y(s)||}{(t-s)^\gamma} \right) \leq C
\]

where \( C \) depends on \( \alpha, \beta, T, \gamma \).

Proof: The proof considers piecewise linear approximations of \( X \) which are automatically continuous. These are shown to converge to \( Y \) in \( L^\alpha(\Omega; C([0,T], E)) \) so it follows that \( Y \) must be continuous for a.e. \( \omega \). Finally, it is shown that \( Y \) is a version of \( X \) and is Hölder continuous. In the proof, I will use \( C \) to denote a constant which depends on the quantities \( \gamma, \alpha, \beta, T \). Let \( \{t^n_k\}_{k=0}^{2^n} \) be a uniform partition of the interval \([0, T]\) so that \( t^n_{k+1} - t^n_k = T 2^{-n} \). Now let

\[
M_n = \max_{k \leq 2^n} ||X(t^n_k) - X(t^n_{k-1})||
\]
Then it follows that
\[ M_n^\alpha \leq \sum_{k=1}^{2^n} \| X(t^n_k) - X(t^n_{k-1}) \|^\alpha \]
and so
\[ E(M_n^\alpha) \leq \sum_{k=1}^{2^n} C(T2^{-n})^{1+\beta} = C2^n2^{-n(1+\beta)} = C2^{-n\beta} \quad (60.2.11) \]

Next denote by \( X_n \) the piecewise linear function which results from the values of \( X \) at the points \( t^n_k \). Consider the following picture which illustrates a part of the graphs of \( X_n \) and \( X_{n+1} \).

Then
\[
\max_{t \in [0, T]} \| X_{n+1}(t) - X_n(t) \| \leq \max_{1 \leq k \leq 2^n+1} \left\| X(t_{2k-1}^{n+1}) - \frac{X(t^n_k) + X(t^n_{k-1})}{2} \right\|
\]
\[
\leq \max_{k \leq 2^{n+1}} \left( \frac{1}{2} \| X(t_{2k-1}^{n+1}) - X(t_{2k}^{n+1}) \| + \frac{1}{2} \| X(t_{2k-1}^{n+1}) - X(t_{2k-2}^{n+1}) \| \right) \leq M_{n+1}
\]

Denote by \( \| \cdot \|_\infty \) the usual norm in \( C([0, T], E) \),
\[
\max_{t \in [0, T]} \| Z(t) \| = \| Z \|_\infty,
\]
then from what was just established,
\[
E(\| X_{n+1} - X_n \|_\infty^\alpha) = \int_{\Omega} \| X_{n+1} - X_n \|_\infty^\alpha dP \leq E(M_{n+1}^\alpha) = C2^{-n\beta}
\]
which shows that
\[
\| X_{n+1} - X_n \|_{L^\alpha(\Omega; C([0, T], E))} = \left( \int_{\Omega} \| X_{n+1} - X_n \|_\infty^\alpha dP \right)^{1/\alpha} \leq C \left( 2^{(\beta/\alpha)} \right)^{-n}
\]
Also, for \( m > n \), it follows from the assumption that \( \alpha \geq 1 \),
\[
\| X_m - X_n \|_{L^\alpha(\Omega; C([0, T], E))} \leq
\]
Thus $\{X_n\}$ is a Cauchy sequence in $L^\alpha (\Omega; C([0,T], E))$ and so it converges to some $Y$ in this space, a subsequence converging pointwise. Then from Fatou’s lemma,

$$\|Y - X_n\|_{L^\alpha(\Omega; C([0,T], E))} \leq C \left(2^{(\beta/\alpha)}\right)^{-n} \quad \text{(60.2.13)}$$

Also, for a.e. $\omega$, $t \to Y(t)$ is in $C([0,T], E)$. It remains to verify that $Y(t) = X(t)$ a.e.

From the construction, it follows that for any $n$ and $m \geq n$

$$Y(t^n) = X_m(t^n) = X(t^n)$$

Thus

$$\|Y(t) - X(t)\| \leq \|Y(t) - Y(t^n)\| + \|Y(t^n) - X(t)\|$$

$$= \|Y(t) - Y(t^n)\| + \|X(t^n) - X(t)\|$$

Now from the hypotheses of the theorem,

$$P (\|X(t^n) - X(t)\|^\alpha > \varepsilon) \leq \frac{1}{\varepsilon} E (\|X(t^n) - X(t)\|^\alpha) \leq \frac{C}{\varepsilon} |t^n_k - t|^{1+\beta}$$

Thus, there exists a sequence of mesh points $\{s_n\}$ converging to $t$ such that

$$P (\|X(s_n) - X(t)\|^\alpha > 2^{-n}) \leq 2^{-n}$$

Then by the Borel Cantelli lemma, there is a set of measure zero $N$ such that for $\omega \notin N$,

$$\|X(s_n) - X(t)\|^\alpha \leq 2^{-n}$$

for all $n$ large enough. Then

$$\|Y(t) - X(t)\| \leq \|Y(t) - Y(s_n)\| + \|X(s_n) - X(t)\|$$

which shows that, by continuity of $Y$, for $\omega$ not in an exceptional set of measure zero, $\|Y(t) - X(t)\| = 0$.

It remains to verify the assertion about Holder continuity of $Y$. Let $0 \leq s < t \leq T$. Then for some $n$,

$$2^{-(\alpha+1)}T \leq t - s \leq 2^{-n}T \quad \text{(60.2.14)}$$

Thus

$$\|Y(t) - Y(s)\| \leq \|Y(t) - X_n(t)\| + \|X_n(t) - X_n(s)\| + \|X_n(s) - Y(s)\|$$

$$\leq 2 \sup_{\tau \in [0,T]} \|Y(\tau) - X_n(\tau)\| + \|X_n(t) - X_n(s)\| \quad \text{(60.2.15)}$$
60.2. KOLMOGOROV ČENTSOV CONTINUITY THEOREM

Now
\[ \frac{\|X_n(t) - X_n(s)\|}{t - s} \leq \frac{\|X_n(t) - X_n(s)\|}{2^{-(n+1)T}} \]

From a picture like the following must hold.

\[ \begin{array}{cccc}
  t_{k+1} & s & t_k & t_{k+1} \\
  t_{k-1} & & & \\
 \end{array} \]

Therefore, from the above,
\[ \frac{\|X_n(t) - X_n(s)\|}{t - s} \leq \frac{\|X(t_{k+1}) - X(t_k)\| + \|X(t_k) - X(t_{k+1})\|}{2^{-(n+1)T}} \leq C2^n M_{n+1} \]

It follows from
\[ \|Y(t) - Y(s)\| \leq 2 \|Y - X_n\| + C2^n M_{n+1} (t - s) \]

Next, letting \( \gamma < \beta/\alpha \), and using
\[ \frac{\|Y(t) - Y(s)\|}{(t - s)\gamma} \leq 2 (T^{-1}2^{n+1})^\gamma \|Y - X_n\| + C2^{n} (2^{-n})^{1-\gamma} M_{n+1} \]
\[ = C2^{n\gamma} (\|Y - X_n\| + M_{n+1}) \]

The above holds for any \( s, t \) satisfying. Then
\[ \sup_{0 \leq s < t \leq T, |t - s| \in [2^{-(n+1)}T, 2^{-n}T]} \left\{ \frac{\|Y(t) - Y(s)\|}{(t - s)\gamma} \right\} \leq C2^{n\gamma} (\|Y - X_n\| + M_{n+1}) \]

Denote by \( P_n \) the ordered pairs \((s, t)\) satisfying the above condition that
\[ 0 \leq s < t \leq T, |t - s| \in [2^{-(n+1)}T, 2^{-n}T] \]

Thus for a.e. \( \omega \), and for all \( n \),
\[ \left( \sup_{(s, t) \in P_n} \frac{\|Y(t) - Y(s)\|}{(t - s)^\gamma} \right)^\alpha \leq C \sum_{k=0}^{\infty} 2^{k\alpha\gamma} (\|Y - X_n\|^\alpha + M_{k+1}^\alpha) \]

Note that \( n \) is arbitrary. Hence
\[ \sup_{0 \leq s < t \leq T} \left( \frac{\|Y(t) - Y(s)\|}{(t - s)^\gamma} \right)^\alpha \leq \]
\[ \sup_{n} \sup_{(s,t) \in P_n} \left( \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \right)^{\alpha} \leq \sup_{n} \left( \sup_{(s,t) \in P_n} \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \right)^{\alpha} \]
\[ \leq \sum_{k=0}^{\infty} C^{2^k\gamma} \left( \|Y - X_k\|_{\infty}^{\alpha} + M_{k+1}^\alpha \right) \]

By continuity of \( Y \), the result on the left is unchanged if the ordered pairs are restricted to lie in \( Q \setminus [0,T] \times Q \setminus [0,T] \), a countable set. Thus the left side is measurable. It follows from \ref{60.2.11} and \ref{60.2.13} which say
\[ \|Y - X_k\|_{L^\alpha(\Omega; C([0,T],E))} \leq C \left( 2^{(\beta/\alpha)} \right)^{-k}, \quad E \left( M_k^\alpha \right) \leq C 2^{-k\beta} \]
that
\[ E \left( \sup_{0 \leq s < t \leq T} \left( \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \right)^{\alpha} \right) \leq \sum_{k=0}^{\infty} C^{2^k\alpha\gamma} 2^{-\beta k} \equiv C < \infty \]
because \( \alpha\gamma - \beta < 0 \). By continuity of \( Y \), there are no measurability concerns in taking the above expectation. Note that this implies, since \( \alpha \geq 1 \),
\[ E \left( \sup_{0 \leq s < t \leq T} \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \right) \leq \left( E \left( \sup_{0 \leq s < t \leq T} \left( \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \right)^{\alpha} \right) \right)^{1/\alpha} \leq C^{1/\alpha} \equiv C \]
Now
\[ P \left( \sup_{0 \leq s < t \leq T} \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} > 2^{ak} \right) \leq \frac{1}{2^{ak} C} \]
and so there exists a set of measure zero \( N \) such that for \( \omega \notin N \),
\[ \sup_{0 \leq s < t \leq T} \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \leq 2^{ak} \]
for all \( k \) large enough. Pick such a \( k \), depending on \( \omega \notin N \). Then for any \( s, t \),
\[ \frac{\|Y(t) - Y(s)\|}{(t-s)\gamma} \leq 2^k \]
and so, this has shown that for \( \omega \notin N \),
\[ \|Y(t) - Y(s)\| \leq C (\omega) (t-s)\gamma \]

Note that if \( X(t) \) is known to be continuous off a set of measure zero, then the piecewise linear approximations converge to \( X(t) \) in \( C([0,T],E) \) off this set of measure zero. Therefore, it must be that off a set of measure zero, \( Y(t) = X(t) \) and so in fact \( X(t) \) is Holder continuous off a set of measure zero and the condition on expectation also must hold, that is
\[ E \left( \sup_{0 \leq s < t \leq T} \frac{\|X(t) - X(s)\|}{(t-s)\gamma} \right) \leq C. \]
60.3 Filtrations

Instead of having a sequence of $\sigma$ algebras, one can consider an increasing collection of $\sigma$ algebras indexed by $t \in \mathbb{R}$. This is called a filtration.

**Definition 60.3.1** Let $X$ be a stochastic process defined on an interval, $I = [0,T]$ or $[0, \infty)$. Suppose the probability space, $(\Omega, \mathcal{F}, P)$ has an increasing family of $\sigma$ algebras, $\{\mathcal{F}_t\}$. This is called a filtration. If for arbitrary $t \in I$ the random variable $X(t)$ is $\mathcal{F}_t$ measurable, then $X$ is said to be adapted to the filtration $\{\mathcal{F}_t\}$. Denote by $\mathcal{F}_{t+}$ the intersection of all $\mathcal{F}_s$ for $s > t$. The filtration is normal if

1. $\mathcal{F}_0$ contains all $A \in \mathcal{F}$ such that $P(A) = 0$
2. $\mathcal{F}_t = \mathcal{F}_{t+}$ for all $t \in I$.

$X$ is called progressively measurable if for every $t \in I$, the mapping

$$(s, \omega) \in [0, t] \times \Omega, \quad (s, \omega) \mapsto X(s, \omega)$$

is $B([0, t]) \times \mathcal{F}_t$ measurable.

Thus $X$ is progressively measurable means

$$(s, \omega) \mapsto X_{[0, t]}(s) X(s, \omega)$$

is $B([0, t]) \times \mathcal{F}_t$ measurable. As an example of a normal filtration, here is an example.

**Example 60.3.2** For example, you could have a stochastic process, $X(t)$ and you could define

$$\mathcal{G}_t \equiv \sigma(X(s) : s \leq t),$$

the completion of the smallest $\sigma$ algebra such that each $X(s)$ is measurable for all $s \leq t$. This gives an example of a filtration to which $X(t)$ is adapted which satisfies $\mathfrak{H}$. More generally, suppose $X(t)$ is adapted to a filtration, $\mathcal{G}_t$. Define

$$\mathcal{F}_t \equiv \cap_{s>t} \mathcal{G}_s$$

Then

$$\mathcal{F}_{t+} \equiv \cap_{s>t} \mathcal{F}_s = \cap_{s>t} \cap_{r>s} \mathcal{G}_r = \cap_{s>t} \mathcal{G}_s \equiv \mathcal{F}_t.$$

and each $X(t)$ is measurable with respect to $\mathcal{F}_t$. Thus there is no harm in assuming a stochastic process adapted to a filtration can be modified so the filtration is normal. Also note that $\mathcal{F}_t$ defined this way will be complete so if $A \in \mathcal{F}_t$ has $P(A) = 0$ and if $B \subseteq A$, then $B \in \mathcal{F}_t$ also. This is because this relation between the sets and the probability of $A$ being zero, holds for this pair of sets when considered as elements of each $\mathcal{G}_s$ for $s > t$. Hence $B \in \mathcal{G}_s$ for each $s > t$ and is therefore one of the sets in $\mathcal{F}_t$. 
What is the description of a progressively measurable set?

\[ Q \cap [0, t] \times \Omega \]

It means that for \( Q \) progressively measurable, \( Q \cap [0, t] \times \Omega \) as shown in the above picture is \( \mathcal{B}([0, t]) \times \mathcal{F}_t \) measurable. It is like saying a little more descriptively that the function is progressively product measurable.

I shall generally assume the filtration is normal.

**Observation 60.3.3** If \( X \) is progressively measurable, then it is adapted. Furthermore the progressively measurable sets, those \( E \cap [0, T] \times \Omega \) for which \( \mathcal{X}_E \) is progressively measurable form a \( \sigma \) algebra.

To see why this is, consider \( X \) progressively measurable and \( t \): Then \((s, \omega) \to X(s, \omega)\) for \((s, \omega) \in [0, t] \times \Omega\) is given to be \( \mathcal{B}([0, t]) \times \mathcal{F}_t \) measurable, the ordinary product measure and so fixing any \( s \in [0, t] \), it follows the resulting function of \( \omega \) is \( \mathcal{F}_t \) measurable. In particular, this is true upon fixing \( s = t \). Thus \( \omega \to X(t, \omega) \) is \( \mathcal{F}_t \) measurable and so \( X(t) \) is adapted.

A set \( E \subseteq [0, T] \times \Omega \) is progressively measurable means that \( \mathcal{X}_E \) is progressively measurable. That is \( \mathcal{X}_E \) restricted to \([0, t] \times \Omega\) is \( \mathcal{B}([0, t]) \times \mathcal{F}_t \) measurable. In other words, \( E \) is progressively measurable if

\[ E \cap ([0, t] \times \Omega) \in \mathcal{B}([0, t]) \times \mathcal{F}_t. \]

If \( E_i \) is progressively measurable, does it follow that \( E \equiv \bigcup_{i=1}^{\infty} E_i \) is also progressively measurable? Yes.

\[ E \cap ([0, t] \times \Omega) = \bigcup_{i=1}^{\infty} E_i \cap ([0, t] \times \Omega) \in \mathcal{B}([0, t]) \times \mathcal{F}_t \]

because each set in the union is in \( \mathcal{B}([0, t]) \times \mathcal{F}_t \). If \( E \) is progressively measurable, is \( E^C \)?

\[
E^C \cap ([0, t] \times \Omega) \cup (E \cap ([0, t] \times \Omega)) = [0, t] \times \Omega
\]

and so \( E^C \cap ([0, t] \times \Omega) \in \mathcal{B}([0, t]) \times \mathcal{F}_t \). Thus the progressively measurable sets are a \( \sigma \) algebra.

Another observation of interest is in the following lemma.

**Lemma 60.3.4** Suppose \( Q \) is in \( \mathcal{B}([0, a]) \times \mathcal{F}_r \). Then if \( b \geq a \) and \( t \geq r \), then \( Q \) is also in \( \mathcal{B}([0, b]) \times \mathcal{F}_t \).
Proof: Consider a measurable rectangle $A \times B$ where $A \in \mathcal{B}([0,a])$ and $B \in \mathcal{F}_t$. Is it true that $A \times B \in \mathcal{B}((0,b)] \times \mathcal{F}_t$? This reduces to the question whether $A \in \mathcal{B}((0,b])$. If $A$ is an interval, it is clear that $A \in \mathcal{B}([0,a])$. Consider the $\pi$ system of intervals and let $\mathcal{G}$ denote those Borel sets $A \in \mathcal{B}([0,a])$ such that $A \in \mathcal{B}((0,b])$. If $A \in \mathcal{G}$, then $[0,b] \setminus A \in \mathcal{B}((0,b])$ by assumption (the difference of Borel sets is surely Borel). However, this set equals 

\[ ([0,a] \setminus A) \cup (a,b) \]

and so

\[ [0,b] = ([0,a] \setminus A) \cup (a,b] \cup A \]

The set on the left is in $\mathcal{B}([0,b])$ and the sets on the right are disjoint and two of them are also in $\mathcal{B}([0,b])$. Therefore, the third, $([0,a] \setminus A)$ is in $\mathcal{B}([0,b])$. It is obvious that $\mathcal{G}$ is closed with respect to countable disjoint unions. Therefore, by Lemma 10.12.3, Dynkin’s lemma, $\mathcal{G} \supseteq \sigma$ (Intervals) = $\mathcal{B}([0,a])$.

Therefore, such a measurable rectangle $A \times B$ where $A \in \mathcal{B}([0,a])$ and $B \in \mathcal{F}_t$ is in $\mathcal{B}([0,b]) \times \mathcal{F}_t$ and in fact it is a measurable rectangle in $\mathcal{B}((0,b]) \times \mathcal{F}_t$. Let $\mathcal{G}$ (new $\mathcal{G}$) denote those sets $Q$ of $\mathcal{B}([0,a]) \times \mathcal{F}_{t'}$ which are in $\mathcal{B}((0,b]) \times \mathcal{F}_t$. Then if $Q \in \mathcal{G}$,

\[ Q \cup ([0,a] \times \Omega \setminus Q) \cup (a,b] \times \Omega = [a,b] \times \Omega \]

Then the sets are disjoint and all but $[0,a] \times \Omega \setminus Q$ are in $\mathcal{B}([0,b]) \times \mathcal{F}_t$. Therefore, this one is also in $\mathcal{B}([0,b]) \times \mathcal{F}_t$. If $Q_i \in \mathcal{G}$ and the $Q_i$ are disjoint, then $\cup Q_i$ is also in $\mathcal{B}([0,b]) \times \mathcal{F}_t$ and so $\mathcal{G}$ is closed with respect to countable disjoint unions and complements. Hence $\mathcal{G} \supseteq \sigma (\mathcal{K}) = \mathcal{B}([0,a]) \times \mathcal{F}_t$ which shows

\[ \mathcal{B}([0,a]) \times \mathcal{F}_t \subseteq \mathcal{B}([0,b]) \times \mathcal{F}_t \]

A significant observation is the following which states that the integral of a progressively measurable function is progressively measurable.

**Proposition 60.3.5** Suppose $X : [0,T] \times \Omega \to E$ where $E$ is a separable Banach space. Also suppose that $X (\cdot, \omega) \in L^1 ([0,T], E)$ for each $\omega$. Here $\mathcal{F}_t$ is a filtration and with respect to this filtration, $X$ is progressively measurable. Then

\[ (t, \omega) \to \int_0^t X(s, \omega) \, ds \]

is also progressively measurable.

Proof: Suppose $Q \in [0,T] \times \Omega$ is progressively measurable. This means for each $t$,

\[ Q \cap [0,t] \times \Omega \in \mathcal{B}([0,t]) \times \mathcal{F}_t \]

What about

\[ (s, \omega) \in [0,t] \times \Omega, (s, \omega) \to \int_0^s X_Q \, dr? \]
Is that function on the right \( B([0, t]) \times \mathcal{F}_t \) measurable? We know that \( Q \cap [0, s] \times \Omega \) is \( B([0, s]) \times \mathcal{F}_s \) measurable and hence \( B([0, t]) \times \mathcal{F}_t \) measurable. When you integrate a product measurable function, you do get one which is product measurable. Therefore, this function must be \( B([0, t]) \times \mathcal{F}_t \) measurable. This shows that \( (t, \omega) \rightarrow \int_0^t X_Q(s, \omega) \, ds \) is progressively measurable. Here is a claim which was just used.

**Claim:** If \( Q \) is \( B([0, t]) \times \mathcal{F}_t \) measurable, then \( (s, \omega) \rightarrow \int_0^s X_Q(r, \omega) \, dr \) is also \( B([0, t]) \times \mathcal{F}_t \) measurable.

**Proof of claim:** First consider \( A \times B \) where \( A \in B([0, t]) \) and \( B \in \mathcal{F}_t \). Then

\[
\int_0^s X_{A \times B} \, dr = \int_0^s X_A X_B \, dr = X_B(\omega) \int_0^s X_A(s) \, dr
\]

This is clearly \( B([0, t]) \times \mathcal{F}_t \) measurable. It is the product of a continuous function of \( s \) with the indicator function of a set in \( \mathcal{F}_t \). Now let

\[
\mathcal{G} = \left\{ Q \in B([0, t]) \times \mathcal{F}_t : (s, \omega) \rightarrow \int_0^s X_Q(r, \omega) \, dr \text{ is } B([0, t]) \times \mathcal{F}_t \text{ measurable} \right\}
\]

Then it was just shown that \( \mathcal{G} \) contains the measurable rectangles. It is also clear that \( \mathcal{G} \) is closed with respect to countable disjoint unions and complements. Therefore, \( \mathcal{G} \supseteq \sigma(\mathcal{K}_t) = B([0, t]) \times \mathcal{F}_t \) where \( \mathcal{K}_t \) denotes the measurable rectangles \( A \times B \) where \( B \in \mathcal{F}_t \) and \( A \in B([0, t]) = B([0, T]) \cap [0, t] \). This proves the claim.

Thus if \( Q \) is progressively measurable, it follows that \( (s, \omega) \rightarrow \int_0^s X_Q(r, \omega) \, dr \equiv f(s, \omega) \) is progressively measurable because for \( (s, \omega) \in [0, t] \times \Omega \), \( (s, \omega) \rightarrow f(s, \omega) \) is \( B([0, t]) \times \mathcal{F}_t \) measurable. This is what was to be proved in this special case.

Now consider the conclusion of the proposition. By considering the positive and negative parts of \( \phi(X) \) for \( \phi \in E' \), and using Pettis theorem, it suffices to consider the case where \( X \geq 0 \). Then there exists an increasing sequence of progressively measurable simple functions \( \{X_n\} \) converging pointwise to \( X \). From what was just shown,

\[
(t, \omega) \rightarrow \int_0^t X_n \, ds
\]

is progressively measurable. Hence, by the monotone convergence theorem, \( (t, \omega) \rightarrow \int_0^t X \, ds \) is also progressively measurable.

What else can you do to something which is progressively measurable and obtain something which is progressively measurable? It turns out that shifts in time can preserve progressive measurability. Let \( \mathcal{F}_t \) be a filtration on \([0, T]\) and extend the filtration to be equal to \( \mathcal{F}_0 \) and \( \mathcal{F}_T \) for \( t < 0 \) and \( t > T \), respectively. Recall the following definition of progressively measurable sets.

**Definition 60.3.6** Denote by \( \mathcal{P} \) those sets \( Q \) in \( \mathcal{F}_T \times B([0, T]) \) such that for \( t \in [-\infty, T] \)

\[
\Omega \times (-\infty, t] \cap Q \in \mathcal{F}_t \times B((-, t])
\]
Lemma 60.3.7 Define $Q + h$ as

$$Q + h \equiv \{(t + h, \omega) : (t, \omega) \in Q\}.$$

Then if $Q \in \mathcal{P}$, it follows that $Q + h \in \mathcal{P}$.

**Proof**: This is most easily seen through the use of the following diagram. In this diagram, $Q$ is in $\mathcal{P}$ so it is progressively measurable.

By definition, $S$ in the picture is $\mathcal{B}((\infty, t - h]) \times \mathcal{F}_{t-h}$ measurable. Hence $S + h \equiv Q + h \cap \Omega \times (\infty, t]$ is $\mathcal{B}((\infty, t]) \times \mathcal{F}_{t-h}$ measurable. To see this, note that if $B \times A \in \mathcal{B}((\infty, t - h]) \times \mathcal{F}_{t-h}$, then translating it by $h$ gives a set in $\mathcal{B}((\infty, t]) \times \mathcal{F}_{t-h}$. Then if $G$ consists of sets $S$ in $\mathcal{B}((\infty, t - h]) \times \mathcal{F}_{t-h}$ for which $S + h$ is in $\mathcal{B}((\infty, t]) \times \mathcal{F}_{t-h}$, $G$ is closed with respect to countable disjoint unions and complements. Thus, $G$ equals $\mathcal{B}((\infty, t - h]) \times \mathcal{F}_{t-h}$. In particular, it contains the set $S$ just described. ■

Now for $h > 0$,

$$\tau_h f(t) \equiv \begin{cases} f(t - h) & \text{if } t \geq h, \\ 0 & \text{if } t < h. \end{cases}$$

Lemma 60.3.8 Let $Q \in \mathcal{P}$. Then $\tau_h X_Q$ is $\mathcal{P}$ measurable.

**Proof**: If $\tau_h X_Q(t, \omega) = 1$, then you need to have $(t - h, \omega) \in Q$ and so $(t, \omega) \in Q + h$. Thus

$$\tau_h X_Q = X_{Q+h},$$

which is $\mathcal{P}$ measurable since $Q \in \mathcal{P}$. In general,

$$\tau_h X_Q = X_{[h,T] \times \Omega} X_{Q+h},$$

which is $\mathcal{P}$ measurable. ■

This lemma implies the following.

Lemma 60.3.9 Let $f(t, \omega)$ have values in a separable Banach space and suppose $f$ is $\mathcal{P}$ measurable. Then $\tau_h f$ is $\mathcal{P}$ measurable.

**Proof**: Taking values in a separable Banach space and being $\mathcal{P}$ measurable, $f$ is the pointwise limit of $\mathcal{P}$ measurable simple functions. If $s_n$ is one of these, then from the above lemmas, $\tau_h s_n$ is $\mathcal{P}$ measurable. Then, letting $n \to \infty$, it follows that $\tau_h f$ is $\mathcal{P}$ measurable. ■

The following is similar to Proposition 60.1.2. It shows that under pretty weak conditions, an adapted process has a progressively measurable adapted version.
Proposition 60.3.10 Let $X$ be a stochastically continuous adapted process for a normal filtration defined on a closed interval, $I \equiv [0, T]$. Then $X$ has a progressively measurable adapted version.

Proof: By Lemma 60.1.1 $X$ is uniformly stochastically continuous and so there exists a sequence of positive numbers, $\{\rho_n\}$ such that if $|s-t| < \rho_n$, then

$$P \left( \left| |X(t) - X(s)| \right| \geq \frac{1}{2^n} \right) \leq \frac{1}{2^n}. \quad (60.3.16)$$

Then let $\{t^n_0, t^n_1, \cdots, t^n_{m_n}\}$ be a partition of $[0, T]$ in which $|t^n_i - t^n_{i-1}| < \rho_n$. Now define $X_n$ as follows:

$$X_n(t)(\omega) = \sum_{i=1}^{m_n} X(t^n_{i-1})(\omega) X_{[t^n_{i-1}, t^n_i]}(t)$$

Then let $Y(t, \omega)$ be

$$Y(t, \omega) = \begin{cases} \lim_{n \to \infty} X_n(t, \omega) & \text{if } (t, \omega) \in A \\ 0 & \text{if } (t, \omega) \notin A \end{cases}$$

I claim that for each $t$, $Y(t, \omega) = X(t, \omega)$ for a.e. $\omega$. To see this, consider 60.3.10. From the construction of $X_n$, it follows that for each $t$,

$$P \left( \left| |X_n(t) - X(t)| \right| \geq \frac{1}{2^n} \right) \leq \frac{1}{2^n}$$

Also, for a fixed $t$, if $X_n(t, \omega)$ fails to converge to $X(t, \omega)$, then $\omega$ must be in infinitely many of the sets,$

$$B_n = \left| |X_n(t) - X(t)| \right| \geq \frac{1}{2^n}$$

which is a set of measure zero by the Borel Cantelli lemma. Recall why this is so.

$$P \left( \bigcap_{k=1}^{\infty} \bigcup_{n=k}^{\infty} B_n \right) \leq \sum_{n=k}^{\infty} P(B_n) < \frac{1}{2^{k-1}}$$

Therefore, for each $t, (t, \omega) \in A$ for a.e. $\omega$. Hence $X(t) = Y(t)$ a.e. and so $Y$ is a measurable version of $X$. $Y$ is adapted because the filtration is normal and hence
\( \mathcal{F}_t \) contains all sets of measure zero. Therefore, \( Y(t) \) differs from \( X(t) \) on a set which is \( \mathcal{F}_t \) measurable. \( \blacksquare \)

There is a more specialized situation in which the measurability of a stochastic process automatically implies it is adapted. Furthermore, this can be defined easily in terms of a \( \pi \) system of sets.

**Definition 60.3.11** Let \( \mathcal{F}_t \) be a filtration on \((\Omega, \mathcal{F}, P)\) and denote by \( \mathcal{P}_\infty \) the smallest \( \sigma \) algebra of sets of \([0, \infty) \times \Omega \) containing the sets

\[
(s, t] \times F, F \in \mathcal{F}_s \quad \{0\} \times F, F \in \mathcal{F}_0.
\]

This is called the predictable \( \sigma \) algebra, and the sets in this \( \sigma \) algebra are called the predictable sets. Denote by \( \mathcal{P}_T \) the intersection of \( \mathcal{P}_\infty \) to \([0, T] \times \Omega \). A stochastic process \( X \) which maps either \([0, T] \times \Omega \) or \([0, \infty) \times \Omega \) to \( E \), a separable real Banach space is called predictable if for every Borel set \( A \in \mathcal{B}(E) \), it follows \( X^{-1}(A) \in \mathcal{P}_T \) or \( \mathcal{P}_\infty \).

This is a lot like product measure except one of the \( \sigma \) algebras is changing.

**Proposition 60.3.12** Let \( \mathcal{F}_t \) be a filtration as above and let \( X \) be a predictable stochastic process. Then \( X \) is \( \mathcal{F}_t \) adapted.

**Proof:** Let \( s_0 > 0 \) and define

\[
\mathcal{G}_{s_0} \equiv \{ S \in \mathcal{P}_\infty : S_{s_0} \in \mathcal{F}_{s_0} \}
\]

where

\[
S_{s_0} \equiv \{ \omega \in \Omega : (s_0, \omega) \in S \}.
\]

It is clear \( \mathcal{G}_{s_0} \) is a \( \sigma \) algebra. The next step is to show \( \mathcal{G}_{s_0} \) contains the sets

\[
(s, t] \times F, F \in \mathcal{F}_s \quad (60.3.17)
\]

and

\[
\{0\} \times F, F \in \mathcal{F}_0. \quad (60.3.18)
\]

It is clear \( \{0\} \times F \) is contained in \( \mathcal{G}_{s_0} \) because \( \{(0) \times F\}_{s_0} = \emptyset \in \mathcal{F}_{s_0} \). Similarly, if \( s \geq s_0 \) or if \( s, t < s_0 \) then \( \{(s, t] \times F\}_{s_0} = \emptyset \in \mathcal{F}_{s_0} \). The only case left is for \( s < s_0 \) and \( t \geq s_0 \). In this case, letting \( A_s \in \mathcal{F}_s \), \( \{(s, t] \times A_s\}_{s_0} = A_s \in \mathcal{F}_s \subseteq \mathcal{F}_{s_0} \). Therefore, \( \mathcal{G}_{s_0} \) contains all the sets of the form given in (60.3.17) and (60.3.18) and so
CHAPTER 60. STOCHASTIC PROCESSES

since $\mathcal{P}_\infty$ is the smallest $\sigma$-algebra containing these sets, it follows $\mathcal{P}_\infty = \mathcal{G}_{s_0}$. The case where $s_0 = 0$ is entirely similar but shorter.

Therefore, if $X$ is predictable, letting $A \in \mathcal{B}(E)$, $X^{-1}(A) \in \mathcal{P}_\infty$ or $\mathcal{P}_T$ and so

$$(X^{-1}(A))_s = \{\omega \in \Omega : X(s, \omega) \in A\} = X(s)^{-1}(A) \in \mathcal{F}_s$$

showing $X(t)$ is $\mathcal{F}_t$ adapted. This proves the proposition.

Another way to see this is to recall the progressively measurable functions are adapted. Then show the predictable sets are progressively measurable.

**Proposition 60.3.13** Let $\mathcal{P}$ denote the predictable $\sigma$-algebra and let $\mathcal{R}$ denote the progressively measurable $\sigma$-algebra. Then $\mathcal{P} \subseteq \mathcal{R}$.

**Proof:** Let $\mathcal{G}$ denote those sets of $\mathcal{P}$ such that they are also in $\mathcal{R}$. Then $\mathcal{G}$ clearly contains the $\pi$ system of sets $\{0\} \times A, A \in \mathcal{F}_0$, and $(s, t] \times A, A \in \mathcal{F}_s$. Furthermore, $\mathcal{G}$ is closed with respect to countable disjoint unions and complements. It follows $\mathcal{G}$ contains the $\sigma$-algebra generated by this $\pi$ systems which is $\mathcal{P}$. This proves the proposition.

**Proposition 60.3.14** Let $X(t)$ be a stochastic process having values in $E$ a complete metric space and let it be $\mathcal{F}_t$ adapted and left continuous. Then it is predictable. Also, if $X(t)$ is stochastically continuous and adapted on $[0, T]$, then it has a predictable version.

**Proof:** Define $I_{m,k} \equiv ((k - 1)2^{-m}T, k2^{-m}T]$ if $k \geq 1$ and $I_{m,0} = \{0\}$ if $k = 1$. Then define

$$X_m(t) = \sum_{k=1}^{2^m} X(T(k - 1)2^{-m}) \chi_{((k - 1)2^{-m}T, k2^{-m}T]}(t) + X(0) \chi_{[0,0]}(t)$$

Here the sum means that $X_m(t)$ has value $X(T(k - 1)2^{-m})$ on the interval $((k - 1)2^{-m}T, k2^{-m}T]$.

Thus $X_m$ is predictable because each term in the sum is. Thus

$$X_m^{-1}(U) = \cup_{k=1}^{2^m} \left(X(T(k - 1)2^{-m}) \chi_{((k - 1)2^{-m}T, k2^{-m}T]}^{-1}(U) \right) = \cup_{k=1}^{2^m} ((k - 1)2^{-m}T, k2^{-m}T] \times \left(X(T(k - 1)2^{-m})^{-1}(U) \right),$$

a finite union of predictable sets. Since $X$ is left continuous,

$$X(t, \omega) = \lim_{m \to \infty} X_m(t, \omega)$$

and so $X$ is predictable.
Next consider the other claim. Since $X$ is stochastically continuous on $[0, T]$, it is uniformly stochastically continuous on this interval by Lemma 60.1. Therefore, there exists a sequence of partitions of $[0, T]$, the $m^{th}$ being

$$0 = t_{m,0} < t_{m,1} < \cdots < t_{m,n(m)} = T$$

such that for $X_m$ defined as above, then for each $t$

$$P \left( \left| d\left(X_m(t), X(t)\right) \right| \geq 2^{-m} \right) \leq 2^{-m} \quad (60.3.19)$$

Then as above, $X_m$ is predictable. Let $A$ denote those points of $\mathcal{P}_T$ at which $X_m(t, \omega)$ converges. Thus $A$ is a predictable set because it is just the set where $X_m(t, \omega)$ is a Cauchy sequence. Now define the predictable function $Y$

$$Y(t, \omega) = \begin{cases} \lim_{m \to \infty} X_m(t, \omega) & \text{if } (t, \omega) \in A \\ 0 & \text{if } (t, \omega) \notin A \end{cases}$$

From it follows from the Borel Cantelli lemma that for fixed $t$, the set of $\omega$ which are in infinitely many of the sets,

$$\left[d\left(X_m(t), X(t)\right) \geq 2^{-m}\right]$$

has measure zero. Therefore, for each $t$, there exists a set of measure zero, $N(t)$ such that for $\omega \notin N(t)$ and all $m$ large enough

$$d\left(X_m(t, \omega), X(t, \omega)\right) < 2^{-m}$$

Hence for $\omega \notin N(t)$, $(t, \omega) \in A$ and so $X_m(t, \omega) \to Y(t, \omega)$ which shows

$$d\left(Y(t, \omega), X(t, \omega)\right) = 0 \text{ if } \omega \notin N(t).$$

The predictable version of $X(t)$ is $Y(t)$. ■

Here is a summary of what has been shown above.

adapted and left continuous
\[\downarrow\]
predictable
\[\downarrow\]

stochastically continuous and adapted $\implies$ progressively measurable version
60.4 Martingales

Definition 60.4.1 Let \(X\) be a stochastic process defined on an interval, \(I\) with values in a separable Banach space, \(E\). It is called integrable if \(E(||X(t)||) < \infty\) for each \(t \in I\). Also let \(\mathcal{F}_t\) be a filtration. An integrable and adapted stochastic process \(X\) is called a martingale if for \(s \leq t\)

\[
E(X(t)|\mathcal{F}_s) = X(s) \text{ a.e. } \omega.
\]

Recalling the definition of conditional expectation this says that for \(F \in \mathcal{F}_s\)

\[
\int_F X(t) \, d\mathbb{P} = \int_F E(X(t)|\mathcal{F}_s) \, d\mathbb{P} = \int_F X(s) \, d\mathbb{P}
\]

for all \(F \in \mathcal{F}_s\). A real valued stochastic process is called a submartingale if whenever \(s < t\),

\[
E(X(t)|\mathcal{F}_s) \geq X(s) \text{ a.e.}
\]

and a supermartingale if

\[
E(X(t)|\mathcal{F}_s) \leq X(s) \text{ a.e.}
\]

Example 60.4.2 Let \(\mathcal{F}_t\) be a filtration and let \(Z\) be in \(L^1(\Omega, \mathcal{F}_T, \mathbb{P})\). Then let \(X(t) = E(Z|\mathcal{F}_t)\).

This works because for \(s < t\), \(E(X(t)|\mathcal{F}_s) = E(E(Z|\mathcal{F}_t)|\mathcal{F}_s) = E(Z|\mathcal{F}_s) = X(s)\).

Proposition 60.4.3 The following statements hold for a stochastic process defined on \([0,T]\times \Omega\) having values in a real separable Banach space, \(E\).

1. If \(X(t)\) is a martingale then \(||X(t)||, t \in [0,T]\) is a submartingale.
2. If \(g\) is an increasing convex function from \([0, \infty)\) to \([0, \infty)\) and \(E(g(||X(t)||)) < \infty\) for all \(t \in [0,T]\) then \(g(||X(t)||), t \in [0,T]\) is a submartingale.

Proof: Let \(s \leq t\)

\[
||X(s)|| = ||E(X(s) - X(t)|\mathcal{F}_s) + E(X(t)|\mathcal{F}_s)|| \\
\leq ||E(X(s) - X(t)|\mathcal{F}_s)|| + ||E(X(t)|\mathcal{F}_s)|| \\
\leq ||E(X(t)|\mathcal{F}_s)||.
\]

Now by Theorem 59.1.1 on Page 2029

\[
||E(X(t)|\mathcal{F}_s)|| \leq E(||X(t)|||\mathcal{F}_s).
\]

Thus \(||X(s)|| \leq E(||X(t)|||\mathcal{F}_s)\) which shows \(||X||\) is a submartingale as claimed.
Consider the second claim. Recall Jensen’s inequality for submartingales, Theorem 58.1.6 on Page 1994. From the first part \[ jjX(s)jj \leq E(jjX(t)||F_s) \] a.e. and so from Jensen’s inequality, \[ g(jjX(s)||) \leq g(E(jjX(t)||F_s)) \leq E(g(jjX(t)||)|F_s) \] a.e., showing that \( g(jjX(t)||) \) is also a submartingale. This proves the proposition.

60.5 Some Maximal Estimates

Martingales and submartingales have some very interesting maximal estimates. I will present some of these here. The proofs are fairly general and do not require the filtration to be normal.

**Lemma 60.5.1** Let \( \{\mathcal{F}_t\} \) be a filtration and let \( \{X(t)\} \) be a nonnegative valued submartingale for \( t \in [S, T] \). Then for \( \lambda > 0 \) and any \( p \geq 1 \), if \( A_t \) is a \( \mathcal{F}_t \) measurable subset of \( \{X(t) \geq \lambda\} \), then
\[
P(A_t) \leq \frac{1}{\lambda^p} \int_{A_t} X(T)^p \, dP.
\]

**Proof:** From Jensen’s inequality,
\[
\lambda^p P(A_t) \leq \int_{A_t} X(t)^p \, dP \leq \int_{A_t} E(X(T)|\mathcal{F}_t)^p \, dP \leq \int_{A_t} E(X(T|^F_t)) \, dP = \int_{A_t} X(T)^p \, dP
\]
and this proves the lemma.

The following theorem is the main result.

**Theorem 60.5.2** Let \( \{\mathcal{F}_t\} \) be a filtration and let \( \{X(t)\} \) be a nonnegative valued right continuous submartingale for \( t \in [S, T] \). Then for all \( \lambda > 0 \) and \( p \geq 1 \), for
\[
X^* \equiv \sup_{t \in [S, T]} X(t),
\]
\[
P([X^* \geq \lambda]) \leq \frac{1}{\lambda^p} \int_{\Omega} \lambda^{[X^* \geq \lambda]} X(T)^p \, dP
\]
In the case that \( p > 1 \), it is also true that
\[
E((X^*)^p) \leq \left( \frac{p}{p-1} \right) E(X(T)^p)^{1/p} (E((X^*)^p))^{1/p'}
\]
Also there are no measurability issues related to the above \( \sup_{t \in [S, T]} X(t) \equiv X^* \)
\[ ^1 t \to M(t)(\omega) \) is continuous from the right for a.e. \( \omega \).
Proof: Let $S \leq t_0^m < t_1^m < \cdots < t_N^m = T$ where $t_{j+1}^m - t_j^m = (T - S) 2^{-m}$.

First consider $m = 1$.

Define

$$A_{t_0^m} \equiv \{ \omega \in \Omega : X (t_0^m) (\omega) \geq \lambda \}, \quad A_{t_1^m} \equiv \{ \omega \in \Omega : X (t_1^m) (\omega) \geq \lambda \} \setminus A_{t_0^m}$$

$$A_{t_0^m} \equiv \{ \omega \in \Omega : X (t_0^m) (\omega) \geq \lambda \} \setminus (A_{t_0^m} \cup A_{t_1^m})$$

Do this type of construction for $m = 2, 3, 4, \cdots$ yielding disjoint sets, $\{ A_{t_j^m} \}_{j=0}^{2^m}$ whose union equals

$$\cup_{t \in D_m} [X (t) \geq \lambda]$$

where $D_m = \{ t_j^m \}_{j=0}^{2^m}$. Thus $D_m \subseteq D_{m+1}$. Then also, $D \equiv \cup_{m=1}^{\infty} D_m$ is dense and countable. From Lemma 60.5.1

$$P (\cup_{t \in D_m} [X (t) \geq \lambda]) = P \left( \sup_{t \in D_m} X (t) \geq \lambda \right) = \sum_{j=0}^{2^m} P (A_{t_j^m})$$

$$\leq \frac{1}{\lambda^p} \sum_{j=0}^{2^m} \int_{A_{t_j^m}} X_{\{\sup_{t \in D_m} X (t) \geq \lambda \}} X (T)^p \, dP$$

$$\leq \frac{1}{\lambda^p} \int_{\Omega} X_{\{\sup_{t \in D} X (t) \geq \lambda \}} X (T)^p \, dP.$$

Let $m \to \infty$ in the above to obtain

$$P (\cup_{t \in D} [X (t) \geq \lambda]) = P \left( \sup_{t \in D} X (t) \geq \lambda \right) \leq \frac{1}{\lambda^p} \int_{\Omega} X_{\{\sup_{t \in D} X (t) \geq \lambda \}} X (T)^p \, dP.$$

From now on, assume that for a.e. $\omega \in \Omega$, $t \to X (t) (\omega)$ is right continuous. Then with this assumption, the following claim holds.

$$\sup_{t \in [S, T]} X (t) \equiv X^* = \sup_{t \in D} X (t)$$

which verifies that $X^*$ is measurable. Then from

$$P (\{X^* \geq \lambda\}) = P \left( \left[\sup_{t \in D} X (t) \geq \lambda \right] \right) \leq \frac{1}{\lambda^p} \int_{\Omega} X_{\{\sup_{t \in D} X (t) \geq \lambda \}} X (T)^p \, dP$$

$$= \frac{1}{\lambda^p} \int_{\Omega} X_{\{X^* \geq \lambda\}} X (T)^p \, dP.$$

Now consider the other inequality. Using the distribution function technique and the above estimate obtained in the first part,

$$E ((X^*)^p) = \int_0^\infty p \alpha^{p-1} P (\{X^* > \alpha\}) \, d\alpha$$

$$\leq \int_0^\infty p \alpha^{p-1} P (\{X^* \geq \alpha\}) \, d\alpha.$$
Of course it would be nice to divide both sides by $E (\sup_{t \in I} ||X (t)||^{p})$ but we don’t know that this is finite. One can use a stopped submartingale which will have $X (t)$ bounded, divide, and then let the stopping time increase to $\infty$. However, this is discussed later.

With Theorem 60.5.2, here is an important maximal estimate for martingales having values in $E$, a real separable Banach space.

**Theorem 60.5.3** Let $X (t)$ for $t \in I = [0, T]$ be an $E$ valued right continuous martingale with respect to a filtration, $\mathcal{F}_t$. Then for $p \geq 1$,

$$P \left( \sup_{t \in I} ||X (t)|| \geq \lambda \right) \leq \frac{1}{X^p} E (||X (T)||^p). \quad (60.5.21)$$

If $p > 1$,

$$E \left( \left( \sup_{t \in [S, T]} ||X (t)|| \right)^p \right) \leq \left( \frac{p}{p-1} \right) E (||X (T)||^p)^{1/p} \left( \left( \sup_{t \in [S, T]} ||X (t)|| \right)^p \right)^{1/p}. \quad (60.5.22)$$

**Proof:** By Proposition 60.5.2, $||X (t)||, t \in I$ is a submartingale and so from Theorem 60.5.2, it follows 60.5.21 and 60.5.22 hold. ■

**Definition 60.5.4** Let $K$ be a set of functions of $L^1 (\Omega, \mathcal{F}, P)$. Then $K$ is called equi integrable if

$$\lim_{\lambda \to \infty} \sup_{f \in K} \int_{||f|| \geq \lambda} |f| dP = 0.$$ 

Recall that from Corollary 60.5.3 on Page 241 such an equi integrable set of functions is weakly sequentially precompact in $L^1 (\Omega, \mathcal{F}, P)$ in the sense that if $\{f_n\} \subseteq K$, there exists a subsequence, $\{f_{n_k}\}$ and a function, $f \in L^1 (\Omega, \mathcal{F}, P)$ such that for all $g \in L^1 (\Omega, \mathcal{F}, P)$,

$$g (f_{n_k}) \to g (f).$$
60.6 Optional Sampling Theorems

60.6.1 Stopping Times And Their Properties

The optional sampling theorem is very useful in the study of martingales and submartingales as will be shown.

First it is necessary to define the notion of a stopping time.

**Definition 60.6.1** Let $(\Omega, \mathcal{F}, P)$ be a probability space and let $\{\mathcal{F}_n\}_{n=1}^{\infty}$ be an increasing sequence of $\sigma$-algebras each contained in $\mathcal{F}$, called a discrete filtration. A stopping time is a measurable function, $\tau$ which maps $\Omega$ to $\mathbb{N}$, such that for all $n \in \mathbb{N}$,

$$[\tau \leq n] \in \mathcal{F}_n.$$ 

Note this is equivalent to saying

$$[\tau = n] \in \mathcal{F}_n$$

because

$$[\tau = n] = [\tau \leq n] \setminus [\tau \leq n - 1].$$

For $\tau$ a stopping time define $\mathcal{F}_\tau$ as follows.

$$\mathcal{F}_\tau \equiv \{A \in \mathcal{F} : A \cap [\tau \leq n] \in \mathcal{F}_n \text{ for all } n \in \mathbb{N}\}$$

These sets in $\mathcal{F}_\tau$ are referred to as “prior” to $\tau$.

The most important example of a stopping time is the first hitting time.

**Example 60.6.2** The first hitting time of an adapted process $X(n)$ of a Borel set $G$ is a stopping time. This is defined as

$$\tau \equiv \min \{k : X(k) \in G\}$$

To see this, note that

$$[\tau = n] = \bigcap_{k < n} [X(k) \in G^c] \cap [X(n) \in G] \in \mathcal{F}_n.$$ 

**Proposition 60.6.3** For $\tau$ a stopping time, $\mathcal{F}_\tau$ is a $\sigma$-algebra and if $Y(k)$ is $\mathcal{F}_k$ measurable for all $k$, $Y(k)$ having values in a separable Banach space $E$, then

$$\omega \mapsto Y(\tau(\omega))$$

is $\mathcal{F}_\tau$ measurable.
Proof: Let $A_n \in \mathcal{F}_\tau$. I need to show $\bigcup_n A_n \in \mathcal{F}_\tau$. In other words, I need to show that
$$\bigcup_n A_n \cap [\tau \leq k] \in \mathcal{F}_k$$
The left side equals
$$\bigcup_n \left( A_n \cap [\tau \leq k] \right)$$
which is a countable union of sets of $\mathcal{F}_k$ and so $\mathcal{F}_\tau$ is closed with respect to countable unions. Next suppose $A \in \mathcal{F}_\tau$.

$$(A^C \cap [\tau \leq k]) \cup (A \cap [\tau \leq k]) = \Omega \cap [\tau \leq k]$$
and $\Omega \cap [\tau \leq k] \in \mathcal{F}_k$. Therefore, so is $A^C \cap [\tau \leq k]$.

It remains to verify the last claim. Let $B$ be an open set in $E$. Is
$$|Y(\tau) \in B| \in \mathcal{F}_\tau?$$
Is
$$|Y(\tau) \in B| \cap [\tau \leq k] \in \mathcal{F}_k \text{ for all } k?$$
This equals
$$\bigcup_{i=1}^k |Y(\tau) \in B| \cap [\tau = i] = \bigcup_{i=1}^k |Y(i) \in B| \cap [\tau = i] \in \mathcal{F}_k$$
Therefore, $Y(\tau)$ must be $\mathcal{F}_\tau$ measurable. ■

The following lemma contains the fundamental properties of stopping times for discrete filtrations.

Lemma 60.6.4 In the situation of Definition 60.6.1, let $\sigma, \tau$ be two stopping times. Then

1. $\tau$ is $\mathcal{F}_\tau$ measurable
2. $\mathcal{F}_\sigma \cap [\sigma \leq \tau] \subseteq \mathcal{F}_\sigma \cap \mathcal{F}_\tau$
3. $\mathcal{F}_\tau = \mathcal{F}_k$ on $[\tau = k]$ for all $k$. That is if $A \in \mathcal{F}_k$, then $A \cap [\tau = k] \in \mathcal{F}_\tau$ and if $A \in \mathcal{F}_\tau$, then $A \cap [\tau = k] \in \mathcal{F}_k$. In other words, the two $\sigma$ algebras

$$[\tau = k] \cap \mathcal{F}_\tau, [\tau = k] \cap \mathcal{F}_k$$

are equal. Letting $\mathcal{G}$ denote this $\sigma$ algebra, if $g$ is either $\mathcal{F}_\tau$ or $\mathcal{F}_k$ measurable then its restriction to $[\tau = k]$ is $\mathcal{G}$ measurable. Also if $A \in \mathcal{F}_\tau$, and $Y \in L^1(\Omega;E)$,

$$\int_{A \cap [\tau = k]} E(Y|\mathcal{F}_\tau) \, dP = \int_{A \cap [\tau = k]} E(Y|\mathcal{F}_k) \, dP$$

and

$$E(Y|\mathcal{F}_\tau) = E(Y|\mathcal{F}_k) \text{ a.e.}$$
on $[\tau = k]$. 

**Proof:** Consider the first claim. \([\sigma \leq l] \cap [\tau \leq m] = [\sigma \leq |l| \wedge m] \in \mathcal{F}_|l| \wedge m \subseteq \mathcal{F}_m\) and so \(\tau\) is \(\mathcal{F}_\tau\) measurable. Here \(|l|\) is the greatest integer less than or equal to \(l\). Next note that \(\tau \wedge \sigma\) is a stopping time because

\[
[\sigma \wedge \tau \leq k] = [\sigma \leq k] \cup [\tau \leq k] \in \mathcal{F}_k
\]

Next consider the second claim. Let \(A \in \mathcal{F}_\sigma\). I want to show

\[
A \cap [\sigma \leq \tau] \in \mathcal{F}_{\tau \wedge \sigma}
\]

(60.6.23)

In other words, I want to show

\[
A \cap [\sigma \leq \tau] \cap [\tau \wedge \sigma \leq k] \in \mathcal{F}_k
\]

(60.6.24)

for all \(k\). However, the set on the left equals

\[
A \cap [\sigma \leq \tau] \cap [\sigma \leq k] = \bigcup_{j=1}^{k} A \cap [\sigma = j] \cap [\tau \geq j] \cap [\sigma \leq k]
\]

\[
= \bigcup_{j=1}^{k} A \cap [\sigma = j] \cap [\tau \wedge \sigma \leq j \wedge \sigma \leq k] \in \mathcal{F}_k
\]

Now let \(A \in \mathcal{F}_{\sigma \wedge \tau}\). I want to show it is in both \(\mathcal{F}_\tau\) and \(\mathcal{F}_\sigma\). To show it is in \(\mathcal{F}_\tau\) I need to show that

\[
A \cap [\tau \leq k] \in \mathcal{F}_k
\]

for all \(k\). However,

\[
A \cap [\tau = k] = \bigcup_{i=1}^{\infty} A \cap [\tau = i] \cap [\sigma = i] \cap [\tau = k]
\]

\[
= \bigcup_{i=1}^{k-1} A \cap [\sigma \wedge \tau = i] \cap [\tau = k] \cup \bigcup_{i=k}^{\infty} A \cap [\sigma = i] \cap [\tau = k]
\]

\[
= \bigcup_{i=1}^{k-1} A \cap [\sigma \wedge \tau = i] \cap [\tau = k] \cup A \cap [\sigma \wedge \tau = k] \cap [\tau = k]
\]

and so this is in \(\mathcal{F}_k\). Thus \(A \cap [\tau \leq k] \in \mathcal{F}_k\) being the finite union of sets which are. Similarly \(A \cap [\sigma \leq k] \in \mathcal{F}_k\) for all \(k\) and so \(A \in \mathcal{F}_\tau \cap \mathcal{F}_\sigma\).

Next let \(A \in \mathcal{F}_\tau \cap \mathcal{F}_\sigma\). Then is it in \(\mathcal{F}_{\sigma \wedge \tau}\)? Is \(A \cap [\sigma \wedge \tau \leq k] \in \mathcal{F}_k\)? Of course this is so because

\[
A \cap [\sigma \wedge \tau \leq k] = A \cap ([\sigma \leq k] \cup [\tau \leq k])
\]

\[
= (A \cap [\sigma \leq k]) \cup (A \cap [\tau \leq k]) \in \mathcal{F}_k
\]

since both \(\sigma, \tau\) are stopping times. This proves part 2.).

Now consider part 3.). Note that \([\tau = k]\) is in both \(\mathcal{F}_k\) and \(\mathcal{F}_\tau\). First consider the claim it is in \(\mathcal{F}_\tau\).

\[
[\tau = k] \cap [\tau \leq l] = \emptyset \text{ if } l < k
\]
which is in \( \mathcal{F}_l \). If \( l \geq k \), it reduces to \([\tau = k] \in \mathcal{F}_k \subseteq \mathcal{F}_l \) so it is in \( \mathcal{F}_\tau \). \([\tau = k] \) is obviously in \( \mathcal{F}_k \).

I need to show
\[
\mathcal{F}_\tau \cap \{\tau = k\} = \mathcal{F}_k \cap \{\tau = k\}
\]
where \( \mathcal{H} \cap \{\tau = k\} \) means all sets of the form \( A \cap \{\tau = k\} \) where \( A \in \mathcal{H} \). Let \( A \in \mathcal{F}_\tau \). Then
\[
A \cap \{\tau = k\} = (A \cap \{\tau \leq k\}) \setminus (A \cap \{\tau \leq k - 1\}) \in \mathcal{F}_k
\]
Therefore, there exists \( B \in \mathcal{F}_k \) such that \( B = A \cap \{\tau = k\} \) and so
\[
B \cap \{\tau = k\} = A \cap \{\tau = k\}
\]
which shows \( \mathcal{F}_\tau \cap \{\tau = k\} \subseteq \mathcal{F}_k \cap \{\tau = k\} \). Now let \( A \in \mathcal{F}_k \) so that
\[
A \cap \{\tau = k\} \in \mathcal{F}_k \cap \{\tau = k\}
\]
Then
\[
A \cap \{\tau = k\} \cap \{\tau \leq j\} \in \mathcal{F}_j
\]
because in case \( j < k \), the set on the left is \( \emptyset \) and if \( j \geq k \) it reduces to \( A \cap \{\tau = k\} \) and both \( A \) and \( \{\tau = k\} \) are in \( \mathcal{F}_j \subseteq \mathcal{F}_j \). Thus \( A \cap \{\tau = k\} = B \in \mathcal{F}_\tau \) and so
\[
A \cap \{\tau = k\} = B \cap \{\tau = k\} \in \mathcal{F}_\tau \cap \{\tau = k\}.
\]
Therefore, the two \( \sigma \) algebras of subsets of \( \{\tau = k\} \),
\[
\mathcal{F}_\tau \cap \{\tau = k\}, \mathcal{F}_k \cap \{\tau = k\}
\]
are equal. Thus for \( A \) in either \( \mathcal{F}_\tau \) or \( \mathcal{F}_k \), \( A \cap \{\tau = k\} \) is a set of both \( \mathcal{F}_\tau \) and \( \mathcal{F}_k \) because if \( A \in \mathcal{F}_k \), then from the above, there exists \( B \in \mathcal{F}_\tau \) such that
\[
\in \mathcal{F}_\tau \cap \mathcal{F}_k
A \cap \{\tau = k\} = B \cap \{\tau = k\} \in \mathcal{F}_\tau
\]
with similar reasoning holding if \( A \in \mathcal{F}_\tau \). In other words, if \( g \) is \( \mathcal{F}_\tau \) or \( \mathcal{F}_k \) measurable, then the restriction of \( g \) to \( \{\tau = k\} \) is measurable with respect to \( \mathcal{F}_\tau \cap \{\tau = k\} \) and \( \mathcal{F}_k \cap \{\tau = k\} \). Let \( Y \) be an arbitrary random variable in \( L^1(\Omega, \mathcal{F}) \). It follows, since
\[
A \cap \{\tau = k\} \in both \mathcal{F}_\tau \text{ and } \mathcal{F}_k,
\]
\[
\int_{A \cap \{\tau = k\}} E(Y|\mathcal{F}_\tau) \, dP = \int_{A \cap \{\tau = k\}} Y \, dP
\]
\[
= \int_{A \cap \{\tau = k\}} E(Y|\mathcal{F}_k) \, dP
\]
Since this holds for an arbitrary set in \( \mathcal{F}_\tau \cap \{\tau = k\} = \mathcal{F}_k \cap \{\tau = k\} \), it follows
\[
E(Y|\mathcal{F}_\tau) = E(Y|\mathcal{F}_k) \text{ a.e. on } \{\tau = k\}.
\]
CHAPTER 60. STOCHASTIC PROCESSES

The assertion that

\[ E(Y|\mathcal{F}_\tau) = E(Y|\mathcal{F}_k) \quad \text{a.e.} \]

on \([\tau = k]\) and that a function \(g\) which is \(\mathcal{F}_\tau\) or \(\mathcal{F}_k\) measurable when restricted to \([\tau = k]\) is \(\mathcal{G}\) measurable for

\[ \mathcal{G} = [\tau = k] \cap \mathcal{F}_\tau = [\tau = k] \cap \mathcal{F}_k \]

is the main result in the above lemma and this fact leads to the amazing Doob optional sampling theorem below. Also note that if \(Y(k)\) is any process defined on the positive integers \(k\), then by definition, \(Y(k)(\omega) = Y(\tau(\omega))(\omega)\) on the set \([\tau = k]\) because \(\tau\) is constant on this set.

60.6.2 Doob Optional Sampling Theorem

With this lemma, here is a major theorem, the optional sampling theorem of Doob. This one is for martingales having values in a Banach space. To begin with, consider the case of a martingale defined on a countable set.

**Theorem 60.6.5** Let \(\{M(k)\}\) be a martingale having values in \(E\) a separable real Banach space with respect to the increasing sequence of \(\sigma\) algebras, \(\{\mathcal{F}_k\}\) and let \(\sigma, \tau\) be two stopping times such that \(\tau\) is bounded. Then \(M(\tau)\) defined as

\[ \omega \rightarrow M(\tau(\omega)) \]

is integrable and

\[ M(\sigma \wedge \tau) = E(M(\tau)|\mathcal{F}_\tau). \]

**Proof:** By Proposition 60.6.3, \(M(\tau)\) is \(\mathcal{F}_\tau\) measurable.

Next note that since \(\tau\) is bounded by some \(l\),

\[ \int_{\Omega} \|M(\tau(\omega))\| dP \leq \sum_{i=1}^{l} \int_{[\tau=i]} \|M(i)\| dP < \infty. \]

This proves the first assertion and makes possible the consideration of conditional expectation.

Let \(l \geq \tau\) as described above. Then for \(k \leq l\), by Lemma 60.6.2,

\[ \mathcal{F}_k \cap [\tau = k] = \mathcal{F}_\tau \cap [\tau = k] \equiv \mathcal{G} \]

implying that if \(g\) is either \(\mathcal{F}_k\) measurable or \(\mathcal{F}_\tau\) measurable, then its restriction to \([\tau = k]\) is \(\mathcal{G}\) measurable and so if \(A \in \mathcal{F}_k \cap [\tau = k] = \mathcal{F}_\tau \cap [\tau = k]\),

\[ \int_A E(M(l)|\mathcal{F}_\tau) dP = \int_A M(l) dP \]

\[ = \int_A E(M(l)|\mathcal{F}_k) dP \]

\[ = \int_A M(k) dP \]

\[ = \int_A M(\tau) dP \quad (\text{on } A, \tau = k) \]
Therefore, since $A$ was arbitrary,

$$E(M(l) | F_\tau) = M(\tau) \text{ a.e.}$$

on $[\tau = k]$ for every $k \leq l$. It follows

$$E(M(l) | F_\tau) = M(\tau) \text{ a.e.}$$

since it is true on each $[\tau = k]$ for all $k \leq l$.

Now consider $E(M(\tau) | F_\sigma)$ on the set $[\sigma = i] \cap [\tau = j]$. By Lemma 60.6.4, on this set,

$$E(M(\tau) | F_\sigma) = E(M(\tau) | F_i) = E(E(M(l) | F_\tau) | F_i) = E(E(M(l) | F_j) | F_i)$$

If $j \leq i$, this reduces to

$$E(M(l) | F_j) = M(j) = M(\sigma \wedge \tau).$$

If $j > i$, this reduces to

$$E(M(l) | F_i) = M(i) = M(\sigma \wedge \tau)$$

and since this exhausts all possibilities for values of $\sigma$ and $\tau$, it follows

$$E(M(\tau) | F_\sigma) = M(\sigma \wedge \tau) \text{ a.e.} \blacksquare$$

You can also give a version of the above to submartingales. This requires the following very interesting decomposition of a submartingale into the sum of an increasing stochastic process and a martingale.

**Theorem 60.6.6** Let $\{X_n\}$ be a submartingale. Then there exists a unique stochastic process, $\{A_n\}$ and martingale, $\{M_n\}$ such that

1. $A_n(\omega) \leq A_{n+1}(\omega)$, $A_1(\omega) = 0$,

2. $A_n$ is $F_{n-1}$ adapted for all $n \geq 1$ where $F_0 \equiv F_1$.

and also $X_n = M_n + A_n$.

**Proof:** Let $A_1 \equiv 0$ and define

$$A_n \equiv \sum_{k=2}^{n} E(X_k - X_{k-1} | F_{k-1}).$$

It follows $A_n$ is $F_{n-1}$ measurable. Since $\{X_k\}$ is a submartingale, $A_n$ is increasing because

$$A_{n+1} - A_n = E(X_{n+1} - X_n | F_n) \geq 0 \quad (60.6.25)$$
It is a submartingale because
\[
E(A_n|\mathcal{F}_{n-1}) = E\left(\sum_{k=2}^{n} E(X_k - X_{k-1}|\mathcal{F}_{k-1})|\mathcal{F}_{n-1}\right)
\]
\[
= \sum_{k=2}^{n} E(X_k - X_{k-1}|\mathcal{F}_{k-1}) \equiv A_n \geq A_{n-1}
\]
Now let \(M_n\) be defined by
\[
X_n = M_n + A_n.
\]
Then from 60.6.25,
\[
E(M_{n+1}|\mathcal{F}_n) = E(X_{n+1}|\mathcal{F}_n) - E(A_{n+1}|\mathcal{F}_n)
\]
\[
= E(X_{n+1}|\mathcal{F}_n) - E(A_{n+1} - A_n|\mathcal{F}_n) - A_n
\]
\[
= E(X_{n+1}|\mathcal{F}_n) - E(E(X_{n+1} - X_n|\mathcal{F}_n)|\mathcal{F}_n) - A_n
\]
\[
= E(X_{n+1}|\mathcal{F}_n) - E(X_{n+1} - X_n|\mathcal{F}_n) - A_n
\]
\[
= E(X_n|\mathcal{F}_n) - A_n
\]
\[
= X_n - A_n \equiv M_n
\]
This proves the existence part.
It remains to verify uniqueness. Suppose then that
\[
X_n = M_n + A_n = M'_n + A'_n
\]
where \(\{A_n\}\) and \(\{A'_n\}\) both satisfy the conditions of the theorem and \(\{M_n\}\) and \(\{M'_n\}\) are both martingales. Then
\[
M_n - M'_n = A'_n - A_n
\]
and so, since \(A'_n - A_n\) is \(\mathcal{F}_{n-1}\) measurable and \(\{M_n - M'_n\}\) is a martingale,
\[
M_{n-1} - M'_{n-1} = E(M_n - M'_n|\mathcal{F}_{n-1})
\]
\[
= E(A'_n - A_n|\mathcal{F}_{n-1})
\]
\[
= A'_n - A_n = M_n - M'_n.
\]
Continuing this way shows \(M_n - M'_n\) is a constant. However, since \(A'_1 - A_1 = 0 = M_1 - M'_1\), it follows \(M_n = M'_n\) and this proves uniqueness. 

Now here is a version of the optional sampling theorem for submartingales.

**Theorem 60.6.7** Let \(\{X(k)\}\) be a real valued submartingale with respect to the increasing sequence of \(\sigma\) algebras, \(\{\mathcal{F}_k\}\) and let \(\sigma \leq \tau\) be two stopping times such that \(\tau\) is bounded. Then \(M(\tau)\) defined as
\[
\omega \rightarrow X(\tau(\omega))
\]
is integrable and

\[ X(\sigma) \leq E(X(\tau) \mid \mathcal{F}_\sigma). \]

Without assuming \( \sigma \leq \tau \), one can write

\[ X(\sigma \wedge \tau) \leq E(X(\tau) \mid \mathcal{F}_\sigma) \]

**Proof:** That \( \omega \rightarrow X(\tau(\omega)) \) is integrable follows right away as in the optional sampling theorem for martingales. You just consider the finitely many values of \( \tau \).

Use Theorem 60.6.6 above to write

\[ X(n) = M(n) + A(n) \]

where \( M \) is a martingale and \( A \) is increasing with \( A(n) \) being \( \mathcal{F}_{n-1} \) measurable and \( A(0) = 0 \) as discussed in Theorem 60.6.6. Then

\[ E(X(\tau) \mid \mathcal{F}_\tau) = E(M(\tau) + A(\tau) \mid \mathcal{F}_\sigma) \]

Now since \( A \) is increasing, you can use the optional sampling theorem for martingales, Theorem 60.6.5 to conclude that, since \( \mathcal{F}_{\sigma \wedge \tau} \subseteq \mathcal{F}_\sigma \) and \( A(\sigma \wedge \tau) \) is \( \mathcal{F}_{\sigma \wedge \tau} \) measurable,

\[ \geq E(M(\tau) + A(\sigma \wedge \tau) \mid \mathcal{F}_\sigma) = E(M(\tau) \mid \mathcal{F}_\sigma) + A(\sigma \wedge \tau) \]

\[ = M(\sigma \wedge \tau) + A(\sigma \wedge \tau) = X(\sigma \wedge \tau). \]

In summary, the main results for stopping times for discrete filtrations are the following definitions and theorems.

\[ [\tau \leq m] \in \mathcal{F}_m \]

\[ A \in \mathcal{F}_\tau \text{ means } A \cap [\tau \leq m] \in \mathcal{F}_m \text{ for any } m \]

\( X \) adapted implies \( X(\tau) \) is \( \mathcal{F}_\tau \) measurable

\[ \mathcal{F}_{\sigma \wedge \tau} = \mathcal{F}_\sigma \cap \mathcal{F}_\tau \]

\[ [\tau = k] \cap \mathcal{F}_k = [\tau = k] \cap \mathcal{F}_\tau \]

This last theorem implies the following amazing result. From these fundamental properties, we obtain the optional sampling theorem for martingales and submartingales.

\[ E(Y \mid \mathcal{F}_\tau) = E(Y \mid \mathcal{F}_k) \text{ a.e. on } [\tau = k] \]

### 60.7 Doob Optional Sampling Continuous Case

#### 60.7.1 Stopping Times

With continuous processes, the discrete filtration is replaced by a normal filtration. Also we tend to feature right continuous or continuous processes. As in the case of discrete martingales, there is something called a stopping time.
Definition 60.7.1 Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \(\mathcal{F}_t\) be a filtration. A measurable function, \(\tau : \Omega \to [0, \infty]\) is called a stopping time if
\[
[\tau \leq t] \in \mathcal{F}_t
\]
for all \(t \geq 0\). Associated with a stopping time is the \(\sigma\) algebra, \(\mathcal{F}_\tau\) defined by
\[
\mathcal{F}_\tau \equiv \{ A \in \mathcal{F} : A \cap [\tau \leq t] \in \mathcal{F}_t \text{ for all } t \}\,.
\]
These sets are also called those “prior” to \(\tau\).

Note that \(\mathcal{F}_\tau\) is obviously closed with respect to countable unions. If \(A \in \mathcal{F}_\tau\), then
\[
A^C \cap [\tau \leq t] = [\tau \leq t] \setminus (A \cap [\tau \leq t]) \in \mathcal{F}_t
\]
Thus \(\mathcal{F}_\tau\) is a \(\sigma\) algebra.

Proposition 60.7.2 Let \(B\) be an open subset of topological space \(E\) and let \(X(t)\) be a right continuous \(\mathcal{F}_t\) adapted stochastic process such that \(\mathcal{F}_t\) is normal. Then define
\[
\tau(\omega) \equiv \inf \{ t > 0 : X(t)(\omega) \in B \}
\]
This is called the first hitting time. Then \(\tau\) is a stopping time. If \(X(t)\) is continuous and adapted to \(\mathcal{F}_t\), a normal filtration, then if \(H\) is a nonempty closed set such that \(H = \cap_{n=1}^\infty B_n\) for \(B_n\) open, \(B_n \supseteq B_{n+1}\),
\[
\tau(\omega) \equiv \inf \{ t > 0 : X(t)(\omega) \in H \}
\]
is also a stopping time.

Proof: Consider the first claim. \(\omega \in [\tau = a]\) implies that for each \(n \in \mathbb{N}\), there exists \(t \in [a, a + \frac{1}{n}]\) such that \(X(t) \in B\). Also for \(t < a\), you would need \(X(t) \notin B\).

By right continuity, this is the same as saying that \(X(d) \notin B\) for all rational \(d < a\). (If \(t < a\), you could let \(d_n \downarrow t\) where \(X(d_n) \in B^C\), a closed set. Then it follows that \(X(t)\) is also in the closed set \(B^C\).) Thus, aside from a set of measure zero, for each \(m \in \mathbb{N}\),
\[
[\tau = a] = \left( \cap_{n=m}^\infty \cup_{t \in [a, a + \frac{1}{n}]} [X(t) \in B] \right) \cap (\cap_{t \in [0, a]} [X(t) \in B^C])
\]
Since \(X(t)\) is right continuous, this is the same as
\[
\left( \cap_{n=m}^\infty \cup_{d \in \mathbb{Q} \cap [a, a + \frac{1}{n}]} [X(d) \in B] \right) \cap (\cap_{d \in \mathbb{Q} \cap [0, a]} [X(d) \in B^C]) \in \mathcal{F}_{a + \frac{1}{m}}
\]
Thus, since the filtration is normal,
\[
[\tau = a] \in \cap_{m=1}^\infty \mathcal{F}_{a + \frac{1}{m}} = \mathcal{F}_{a+} = \mathcal{F}_a
\]
Now what of $[\tau < a]$? This is equivalent to saying that $X(t) \in B$ for some $t < a$. Since $X$ is right continuous, this is the same as saying that $X(t) \in B$ for some $t \in \mathbb{Q}$, $t < a$. Thus

$$[\tau < a] = \bigcup_{d \in \mathbb{Q}, d < a} [X(d) \in B] \in \mathcal{F}_a$$

It follows that $[\tau \leq a] = [\tau < a] \cup [\tau = a] \in \mathcal{F}_a$.

Now consider the claim involving the additional assumption that $X(t)$ is continuous and it is desired to hit a closed set $H = \bigcap_{n=1}^{\infty} B_n$ where $B_n$ is open, $B_n \supseteq B_{n+1}$. (Note that if the topological space is a metric space, this is always possible so this is not a big restriction.) Then let $\tau_n$ be the first hitting time of $B_n$ by $X(t)$. Then it can be shown that

$$[\tau \leq a] = \bigcap_n [\tau_n \leq a] \in \mathcal{F}_a$$

To show this, first note that $\omega \in [\tau \leq a]$ if and only if there exists $t \leq a$ such that $X(t)(\omega) \in H$. This follows from continuity and the fact that $H$ is closed. Thus $\tau_n \leq a$ for all $n$ because for some $t \leq a$, $X(t) \in H \subseteq B_n$ for all $n$. Next suppose $\omega \in [\tau_n \leq a]$ for all $n$. Then for $\delta_n \downarrow 0$, there exists $t_n \in [0, a + \delta_n]$ such that $X(t_n)(\omega) \in B_n$. It follows there is a subsequence, still denoted by $t_n$ such that $t_n \to t \in [0, a]$. By continuity of $X$, it must be the case that $X(t)(\omega) \in H$ and so $\omega \in [\tau \leq a]$. This shows the above formula. Now by the first part, each $[\tau_n \leq a] \in \mathcal{F}_a$ and so $[\tau \leq a] \in \mathcal{F}_a$ also. 

Another useful result for real valued stochastic process is the following.

**Proposition 60.7.3** Let $X(t)$ be a real valued stochastic process which is $\mathcal{F}_t$ adapted for a normal filtration $\mathcal{F}_t$, with the property that off a set of measure zero in $\Omega$, $t \to X(t)$ is lower semicontinuous. Then

$$\tau \equiv \inf \{ t : X(t) > a \}$$

is a stopping time.

**Proof:** As above

$$[\tau = a] = \left( \bigcap_{n=m}^{\infty} \bigcup_{t \in [a, a + \frac{1}{n}]} [X(t) > a] \right) \cap \left( \bigcap_{t \in [0, a]} [X(t) \leq a] \right)$$

Now

$$\bigcap_{t \in [0, a]} [X(t) \leq a] \subseteq \bigcap_{t \in [0, a], t \in \mathbb{Q}} [X(t) \leq a]$$

If $\omega$ is in the right side, then for arbitrary $t < a$, let $t_n \downarrow t$ where $t_n \in \mathbb{Q}$ and $t < a$. Then $X(t) \leq \liminf_{n \to \infty} X(t_n) \leq a$ and so $\omega$ is in the left side also. Thus

$$\bigcap_{t \in [0, a]} [X(t) \leq a] = \bigcap_{t \in [0, a], t \in \mathbb{Q}} [X(t) \leq a]$$

$$\cup_{t \in [a, a + \frac{1}{n}]} [X(t) > a] = \bigcup_{t \in [a, a + \frac{1}{n}], t \in \mathbb{Q}} [X(t) > a]$$

If $\omega$ is in the left side, then for some $t$ in the given interval, $X(t) > a$. If for all $s \in [a, a + \frac{1}{n}] \cap \mathbb{Q}$ you have $X(s) \leq a$, then you could take $s_n \to t$ where
Let \( \{a \} \) and conclude that \( X(t) \leq a \) also by lower semicontinuity. Thus there is some rational \( s \) where \( X(s) > a \) and so the two sides are equal. Hence,
\[
[\tau = a] = \left( \bigcap_{n=m}^{\infty} \cup_{t \in [a, a + \frac{1}{n}]} [X(t) > a] \right) \cap \left( \cap_{t \in [0,a)} [X(t) \leq a] \right)
\]
The first set on the right is in \( \mathcal{F}_{a+1/m} \) and so is the next set on the right. Hence \([\tau = a] \in \cap_{m} \mathcal{F}_{a+1/m} = \mathcal{F}_a\). What of \([\tau < a]? \) This equals \( \cup_{t \in [0,a]} [X(t) > a] = \cup_{t \in [0,a]} [X(t) > a] \in \mathcal{F}_a\), the equality following from lower semicontinuity. Thus \([\tau \leq a] = [\tau = a] \cup [\tau < a] \in \mathcal{F}_a\).

Thus there do exist stopping times, the first hitting time above being an example. When dealing with continuous stopping times on a normal filtration, one uses the following discrete stopping times
\[
\tau_n = \sum_{k=1}^{\infty} X_{[r \in (t^n_{k}, t^{n+1}_{k})]} t^n_{k+1}
\]
where here \([t^n_{k} - t^{n+1}_{k}] = r_n\) for all \( k \) where \( r_n \to 0 \). Then here is an important lemma.

Lemma 60.7.4 \( \tau_n \) is a stopping time \([\tau_n \leq t] \in \mathcal{F}_t\). Also \( \mathcal{F}_\tau \subseteq \mathcal{F}_{\tau_n} \) and for each \( \omega, \tau_n(\omega) \downarrow \tau(\omega) \).

Proof: Say \( t \in (t^n_{k-1}, t^n_{k}) \). Then \([\tau_n \leq t] = [\tau \leq t^{n}_{k-1}] \) if \( t < t^n_{k} \) and it equals \([\tau \leq t^n_{k}] \) if \( t = t^n_{k} \). Either way \([\tau_n \leq t] \in \mathcal{F}_t \) so it is a stopping time. Also from the definition, it follows that \( \tau_n \geq \tau \) and \( |\tau_n(\omega) - \tau(\omega)| \leq r_n \) which is given to converge to 0. Now suppose \( A \in \mathcal{F}_\tau \) and say \( t \in (t^n_{k-1}, t^n_{k}) \) as above. Then
\[
A \cap [\tau_n \leq t] = A \cap [\tau \leq t^{n}_{k-1}] \in \mathcal{F}^{t^n}_{k-1} \subseteq \mathcal{F}_t \text{ if } t < t^n_{k}
\]
and
\[
A \cap [\tau_n \leq t] = A \cap [\tau \leq t^n_{k}] \in \mathcal{F}^{t^n}_{k} = \mathcal{F}_t \text{ if } t = t^n_{k}
\]
Thus \( \mathcal{F}_\tau \subseteq \mathcal{F}_{\tau_n} \) as claimed. ■

Next is the claim that if \( X(t) \) is adapted to \( \mathcal{F}_t \), then \( X(\tau) \) is adapted to \( \mathcal{F}_\tau \) just like the discrete case.

Proposition 60.7.5 Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \( \sigma \leq \tau \) be two stopping times with respect to a filtration, \( \mathcal{F}_t \). Then \( \mathcal{F}_\sigma \subseteq \mathcal{F}_\tau \). If \( X(t) \) is a right continuous stochastic process adapted to a normal filtration \( \mathcal{F}_t \) and \( \tau \) is a stopping time, \( \omega \to X(\tau(\omega)) \) is \( \mathcal{F}_\tau \) measurable.

Proof: Let \( A \in \mathcal{F}_\sigma \). Then \( A \cap [\sigma \leq t] \in \mathcal{F}_t \) for all \( t \geq 0 \). Since \( \sigma \leq \tau \),
\[
A \cap [\tau \leq t] = A \cap [\sigma \leq t] \cap [\tau \leq t] \in \mathcal{F}_t
\]
Thus \( A \in \mathcal{F}_\tau \) and so \( \mathcal{F}_\sigma \subseteq \mathcal{F}_\tau \).
Consider the following approximation of \( \tau \) in which \( t_k^n = k2^{-n} \).

\[
\tau_n = \sum_{k=1}^{\infty} X_{[r \in (t_k^n, t_{k+1}^n)]} t_{k+1}^n
\]

Thus \( \tau_n \downarrow \tau \). Consider for \( U \) an open set, \( X(\tau_n)^{-1}(U) \cap [\tau_n < t] \). Say \( t \in (t_k^n, t_{k+1}^n) \).

Then from the above definition of \( \tau_n \),

\[
[\tau_n < t] = [\tau \leq t_k^n] \in \mathcal{F}_{t_k^n} \subseteq \mathcal{F}_t
\]

It follows that

\[
X(\tau_n)^{-1}(U) \cap [\tau_n < t] = \bigcup_{j=1}^{k} X(t_j^n)^{-1}(U) \cap [\tau_n = t_j^n]
\]

and so this set is in \( \mathcal{F}_{t_k^n} \subseteq \mathcal{F}_t \). The reason \( [\tau_n = t_j^n] \in \mathcal{F}_{t_j^n} \) is that it equals \( [r \in (t_{j-1}^n, t_j^n)] \in \mathcal{F}_{t_j^n} \) by assumption that \( \tau \) is a stopping time.

By right continuity of \( X \), it follows that

\[
X(\tau)^{-1}(U) \cap [\tau < t] = \bigcap_{m=1}^{\infty} \bigcap_{n \geq m} X(\tau_n)^{-1}(U) \cap \left[ \tau < t + \frac{1}{n} \right] \in \mathcal{F}_{t + \frac{1}{m}}
\]

Since the filtration is normal, it follows that

\[
X(\tau)^{-1}(U) \cap [\tau \leq t] \in \mathcal{F}_{t+} = \mathcal{F}_t.
\]

Now consider an increasing family of stopping times, \( \tau(t) (\omega \rightarrow \tau(t)(\omega)) \). It turns out this is a submartingale.

**Example 60.7.6** Let \( \{ \tau(t) \} \) be an increasing family of stopping times. Then \( \tau(t) \) is adapted to the \( \sigma \) algebras \( \mathcal{F}_{\tau(t)} \) and \( \{ \tau(t) \} \) is a submartingale adapted to these \( \sigma \) algebras.

First I need to show that a stopping time, \( \tau \) is \( \mathcal{F}_\tau \) measurable. Consider \([\tau \leq s]\). Is this in \( \mathcal{F}_\tau \)? Is \([\tau \leq s] \cap [\tau \leq r] \in \mathcal{F}_\tau \) for each \( r \)? This is obviously so if \( s \leq r \) because the intersection reduces to \([\tau \leq s] \in \mathcal{F}_s \subseteq \mathcal{F}_\tau \). On the other hand, if \( s > r \) then the intersection reduces to \([\tau \leq r] \in \mathcal{F}_r \) and so it is clear that \( \tau \) is \( \mathcal{F}_\tau \) measurable. It remains to verify it is a submartingale.

Let \( s < t \) and let \( A \in \mathcal{F}_{\tau(s)} \)

\[
\int_A E(\tau(t) | \mathcal{F}_{\tau(s)}) \, dP = \int_A \tau(t) \, dP \geq \int_A \tau(s) \, dP
\]

and this shows \( E(\tau(t) | \mathcal{F}_{\tau(s)}) \geq \tau(s) \).

Now here is an important example. First note that for \( \tau \) a stopping time, so is \( t \vee \tau \). Here is why.

\[
[t \vee \tau \leq s] = [t \leq s] \cap [\tau \leq s] \in \mathcal{F}_s.
\]
Example 60.7.7 Let $\tau$ be a stopping time and let $X$ be continuous and adapted to the filtration $\mathcal{F}_t$. Then for $a > 0$, define $\sigma$ as

$$
\sigma(\omega) \equiv \inf \{ t > \tau(\omega) : ||X(t)(\omega) - X(\tau(\omega))|| = a \}
$$

Then $\sigma$ is also a stopping time.

To see this is so, let

$$
Y(t)(\omega) = ||X(t \land \tau)(\omega) - X(\tau(\omega))||
$$

Then $Y(t)$ is $\mathcal{F}_{t \land \tau}$ measurable. It is desired to show that $Y$ is $\mathcal{F}_t$ adapted. Hence if $U$ is open in $\mathbb{R}$, then

$$
Y^{-1}(U) = \left( Y^{-1}(U) \cap [\tau \leq t] \right) \cup \left( Y^{-1}(U) \cap [\tau > t] \right)
$$

The second set in the above union on the right equals either $\emptyset$ or $[\tau > t]$ depending on whether $0 \in U$. If $\tau > t$, then $Y(t) = 0$ and so the second set equals $[\tau > t]$ if $0 \in U$. If $0 \notin U$, then the second set equals $\emptyset$. Thus the second set above is in $\mathcal{F}_t$. It is necessary to show the first set is also in $\mathcal{F}_t$. The first set equals

$$
Y^{-1}(U) \cap [\tau \leq t] = Y^{-1}(U) \cap [\tau \land t \leq t]
$$

because $[\tau \land t \leq t] = [\tau \leq t]$. However, $Y^{-1}(U) \in \mathcal{F}_{t \land \tau}$ and so the set on the right in the above is in $\mathcal{F}_t$. Therefore, $Y(t)$ is adapted. Then $\sigma$ is just the first hitting time for $Y(t)$ to equal the closed set $a$. Therefore, $\sigma$ is a stopping time by Proposition 60.7.2.

60.7.2 The Optional Sampling Theorem Continuous Case

Next I want a version of the Doob optional sampling theorem which applies to martingales defined on $[0, L], L \leq \infty$. First recall Theorem 60.7.2, part of which is stated as the following lemma.

Lemma 60.7.8 Let $f \in L^1(\Omega; E, \mathcal{F})$ where $E$ is a separable Banach space. Then if $\mathcal{G}$ is a $\sigma$ algebra $\mathcal{G} \subseteq \mathcal{F}$,

$$
||E(f|\mathcal{G})|| \leq E(||f|||\mathcal{G}).
$$

Here is a lemma which is the main idea for the proofs of the optional sampling theorem for the continuous case.

Lemma 60.7.9 Let $X(t)$ be a right continuous nonnegative submartingale such that the filtration $\{\mathcal{F}_t\}$ is normal. Recall this includes

$$
\mathcal{F}_t = \cap_{s>t} \mathcal{F}_s.
$$
Also let \( \tau \) be a stopping time with values in \([0, T]\). Let \( \mathcal{P}_n = \{t_k^n\}_{k=1}^{m_n+1} \) be a sequence of partitions of \([0, T]\) which have the property that

\[
\mathcal{P}_n \subseteq \mathcal{P}_{n+1}, \quad \lim_{n \to \infty} ||\mathcal{P}_n|| = 0,
\]

where

\[
||\mathcal{P}_n|| \equiv \sup \left\{ |t^n_k - t^n_{k+1}| : k = 1, 2, \cdots, m_n \right\}
\]

Then let

\[
\tau_n(\omega) \equiv \sum_{k=0}^{m_n} t^n_{k+1} \mathcal{X}_{\tau^{-1}(t^n_k, t^n_{k+1}]}(\omega)
\]

It follows that \( \tau_n \) is a stopping time and also the functions \( |X(\tau_n)| \) are uniformly integrable. Furthermore, \( |X(\tau)| \) is integrable.

**Proof:** First of all, say \( t \in (t^n_k, t^n_{k+1}] \). If \( t < t^n_{k+1} \), then

\[
[\tau_n \leq t] = [\tau \leq t^n_k] \in \mathcal{F}_t^n \subseteq \mathcal{F}_t
\]

and if \( t = t^n_{k+1} \), then

\[
[\tau_n \leq t^n_{k+1}] = [\tau \leq t^n_{k+1}] \in \mathcal{F}_{t_{k+1}}^n = \mathcal{F}_t
\]

and so \( \tau_n \) is a stopping time. It follows from Proposition 60.7.5 that \( X(\tau_n) \) is \( \mathcal{F}_{\tau_n} \)-measurable.

Now from Lemma 58.3.4 or Theorem 60.6.7, \( X(0) , X(\tau_n) , X(T) \) is a submartingale. Then

\[
\int_{[X(\tau_n) \geq \lambda]} X(\tau_n) dP \leq \int_{[X(\tau_n) \geq \lambda]} E(X(T)|\mathcal{F}_{\tau_n}) dP = \int_{[X(\tau_n) \geq \lambda]} E(X|\mathcal{X}(\tau_n) \geq \lambda) X(T)|\mathcal{F}_{\tau_n}) dP = \int_{[X(\tau_n) \geq \lambda]} X(T) dP
\]

From maximal estimates, for example Theorem 58.2.8,

\[
P([X(\tau_n) \geq \lambda]) \leq \frac{1}{\lambda} \int_{\Omega} X(T)^+ dP = \frac{1}{\lambda} \int_{\Omega} X(T) dP
\]

and now it follows from the above that the random variables \( X(\tau_n) \) are equiintegrable. Recall this means that

\[
\lim_{\lambda \to \infty} \sup_n \int_{[X(\tau_n) \geq \lambda]} X(\tau_n) dP = 0
\]

Hence they are uniformly integrable.
To verify that $|X(\tau)|$ is integrable, note that by right continuity, $X(\tau_n) \to X(\tau)$ pointwise. Apply the Vitali convergence theorem to obtain

$$\int_{\Omega} |X(\tau)| \, dP = \lim_{n \to \infty} \int_{\Omega} |X(\tau_n)| \, dP \leq \int_{\Omega} X(T) \, dP < \infty. \quad \blacksquare$$

In fact, you do not need to assume $X$ is nonnegative.

**Lemma 60.7.10** Let $X(t)$ be a right continuous submartingale such that the filtration $\{\mathcal{F}_t\}$ is normal. Recall this includes

$$\mathcal{F}_t = \cap_{s>t} \mathcal{F}_s.$$ 

Also let $\tau$ be a stopping time with values in $[0,T]$. Let $\mathcal{P}_n = \{t_k^n\}_{k=1}^{m_n+1}$ be a sequence of partitions of $[0,T]$ which have the property that

$$\mathcal{P}_n \subseteq \mathcal{P}_{n+1}, \quad \lim_{n \to \infty} ||\mathcal{P}_n|| = 0,$$

where

$$||\mathcal{P}_n|| = \sup \{ |t_k^n - t_{k+1}^n| : k = 1, 2, \ldots, m_n \}.$$ 

Then let

$$\tau_n(\omega) = \sum_{k=0}^{m_n} t_{k+1}^n \mathcal{X}_{\tau^{-1}(t_k^n, t_{k+1}^n)}(\omega).$$

It follows that $\tau_n$ is a stopping time and also the functions $|X(\tau_n)|$ are uniformly integrable. Furthermore, $|X(\tau)|$ is integrable.

**Proof:** It was shown above that $\tau_n$ is a stopping time. Also, $t_k^n \to X(t_k^n)$ is a discrete submartingale. Then by Theorem [2.38], there is a martingale $t_k^n \to M(t_k^n)$ and an increasing submartingale $t_k^n \to A(t_k^n)$ such that $A \geq 0$ and is increasing

$$X(t_k^n) = M(t_k^n) + A(t_k^n).$$

You define $A(t_0^n) = 0$ and for $n \geq 1$,

$$A(t_n^m) = \sum_{k=1}^{m_n} E \left( X(t_n^m) - X(t_{k-1}^m) \mid \mathcal{F}_{t_{k-1}^m} \right)$$

and repeat the arguments in that theorem. You know that $A(0), A(\tau_n), A(T)$ is a submartingale by the optional sampling theorem given earlier, Theorem [5.6.6], and so

$$P(A(\tau_n) > \lambda) \leq \lambda \int_{[A(\tau_n) > \lambda]} A(\tau_n) \, dP \leq \lambda \int_{[A(\tau_n) > \lambda]} A(T) \, dP \leq \frac{\|A(T)\|_{L_1}}{\lambda}$$

It also follows from the definition of $A$ that

$$\|A(T)\|_{L_1} = \int_{\Omega} X(T) - X(0) \, dP < \infty.$$
Hence
\[ \lim_{\lambda \to \infty} \int_{[A(\tau_n) > \lambda]} A(\tau_n) \, dP \leq \lim_{\lambda \to \infty} \int_{[A(\tau_n) > \lambda]} A(T) \, dP = 0 \]
Because \( P(A(\tau_n) > \lambda) \to 0 \) and a single function in \( L^1 \) is uniformly integrable. Thus these functions \( A(\tau_n) \) are equi-integrable. Hence they are uniformly integrable. Now \( t_k^n \to [M(t_k^n)] \) is also a nonnegative submartingale. Thus
\[ |M(0)|, |A(\tau_n)|, |M(T)| \]
is a submartingale by the optional sampling theorem for discrete submartingales given earlier. Therefore,
\[ P(|M(\tau_n)| > \lambda) \leq \frac{1}{\lambda} \int_{|M(\tau_n)| > \lambda} |M(\tau_n)| \, dP \leq \frac{1}{\lambda} \int_{|M(\tau)| > \lambda} |M(T)| \, dP \leq \frac{\|M(T)\|_{L^1}}{\lambda} \]
Of course \( \|M(T)\|_{L^1} \) is finite because it is dominated by
\[ \int_{\Omega} A(T) + |X(T)| \, dP < \infty \]
Hence
\[ \limsup_{\lambda \to \infty} \frac{1}{\lambda} \int_{|M(\tau_n)| > \lambda} |M(\tau_n)| \, dP \leq \limsup_{\lambda \to \infty} \frac{1}{\lambda} \int_{|M(\tau)| > \lambda} |M(T)| \, dP = 0 \]
because a single function in \( L^1 \) is uniformly integrable and the above estimate shows that \( P(|M(\tau_n)| > \lambda) \to 0 \) uniformly in \( n \). Thus, in fact \( X(\tau_n) \) must be uniformly integrable since it is the sum of two which are.

**Theorem 60.7.11** Let \( \{M(t)\} \) be a right continuous martingale having values in \( E \) a separable real Banach space with respect to the increasing sequence of \( \sigma \) algebras, \( \{\mathcal{F}_t\} \) which is assumed to be a normal filtration satisfying,
\[ \mathcal{F}_t = \cap_{s > t} \mathcal{F}_s, \]
for \( t \in [0, L], L \leq \infty \) and let \( \sigma, \tau \) be two stopping times with \( \tau \) bounded. Then \( M(\tau) \) defined as
\[ \omega \to M(\tau(\omega)) \]
is integrable and
\[ M(\sigma \wedge \tau) = E(M(\tau)|\mathcal{F}_\sigma). \]

**Proof:** Since \( M(t) \) is a martingale, \( \|M(t)\| \) is a submartingale. Let
\[ \tau_n(\omega) \equiv \sum_{k=0}^{\infty} 2^{-n} (k + 1) T \chi_{\tau > 1, (k_2-1, k+1) \in \mathcal{T}_2^n}(\omega). \]
By Lemma \[\text{Lemma 60.7.10}\], \(\tau_n\) is a stopping time and the functions \(|| M (\tau_n) ||\) are uniformly integrable. Also \(|| M (\tau) ||\) is integrable. Similarly \(|| M (\tau_n \wedge \sigma_n) ||\) are uniformly integrable where \(\sigma_n\) is defined similarly to \(\tau_n\).

Consider the main claim now. Letting \(\sigma, \tau\) be stopping times with \(\tau\) bounded, it follows that for \(\sigma_n\) and \(\tau_n\) as above, it follows from Theorem \[\text{Theorem 60.6.7}\]

\[M (\sigma_n \wedge \tau_n) = E (M (\tau_n) | F_{\sigma_n})\]

Thus, taking \(A \in F_{\sigma}\) and recalling \(\sigma \leq \sigma_n\) so that by Proposition \[\text{Proposition 60.7.5}\], \(F_{\sigma} \subseteq F_{\sigma_n}\),

\[\int_A M (\sigma_n \wedge \tau_n) \, dP = \int_A E (M (\tau_n) | F_{\sigma_n}) \, dP = \int_A M (\tau_n) \, dP.\]

Now passing to a limit as \(n \to \infty\), the Vitali convergence theorem, Theorem \[\text{Theorem 6.5.3}\] on Page \[\text{Page 244}\] and the right continuity of \(M\) implies one can pass to the limit in the above and conclude

\[\int_A M (\sigma \wedge \tau) \, dP = \int_A M (\tau) \, dP.\]

By Proposition \[\text{Proposition 60.7.5}\], \(M (\sigma \wedge \tau)\) is \(F_{\sigma \wedge \tau} \subseteq F_{\sigma}\) measurable showing

\[E (M (\tau) | F_{\sigma}) = M (\sigma \wedge \tau). \quad \Box\]

A similar theorem is available for submartingales defined on \([0, L], L \leq \infty\).

**Theorem 60.7.12** Let \(\{X (t)\}\) be a right continuous submartingale with respect to the increasing sequence of \(\sigma\) algebras, \(\{F_t\}\) which is assumed to be a normal filtration,

\[F_t = \cap_{s \geq t} F_s,\]

for \(t \in [0, L], L \leq \infty\) and let \(\sigma, \tau\) be two stopping times with \(\tau\) bounded. Then \(X (\tau)\) defined as

\[\omega \to X (\tau (\omega))\]

is integrable and

\[X (\sigma \wedge \tau) \leq E (X (\tau) | F_{\sigma}).\]

**Proof:** Let

\[\tau_n (\omega) \equiv \sum_{k \geq 0} 2^{-n} (k + 1) T X_{\tau - 1((k2^{-n} T, (k+1)2^{-n}])} (\omega).\]

Then by Lemma \[\text{Lemma 60.7.11}\] \(\tau_n\) is a stopping time, the functions \(|X (\tau_n)|\) are uniformly integrable, and \(|X (\tau)|\) is also integrable. For \(\sigma_n\) defined similarly to \(\tau_n\), it also follows \(|X (\tau_n \wedge \sigma_n)|\) are uniformly integrable.

Let \(A \in F_{\sigma}\). Since \(\sigma \leq \sigma_n\), it follows that \(F_{\sigma} \subseteq F_{\sigma_n}\). By the discrete optional sampling theorem for submartingales, Theorem \[\text{Theorem 60.6.7}\],

\[X (\sigma_n \wedge \tau_n) \leq E (X (\tau_n) | F_{\sigma_n})\]
and so
\[ \int_A X (\sigma_n \wedge \tau_n) \, dP \leq \int_A E(X(\tau_n) | \mathcal{F}_{\sigma_n}) \, dP = \int_A X(\tau_n) \, dP \]
and now taking \( \lim_{n \to \infty} \) of both sides and using the Vitali convergence theorem along with the right continuity of \( X \), it follows
\[ \int_A X (\sigma \wedge \tau) \, dP \leq \int_A X(\tau) \, dP = \int_A E(X(\tau) | \mathcal{F}_\sigma) \, dP \]
By Proposition 60.7.5, \( \mathcal{F}_{\sigma \wedge \tau} \subseteq \mathcal{F}_\sigma \), and so since \( A \in \mathcal{F}_\sigma \) was arbitrary,
\[ E(X(\tau) | \mathcal{F}_\sigma) \geq X(\sigma \wedge \tau) \ a.e. \]

Note that a function defined on a countable ordered set such as the integers or equally spaced points is right continuous.

Here is an interesting lemma.

**Lemma 60.7.13** Suppose \( E(|X_n|) < \infty \) for all \( n \), \( X_n \) is \( \mathcal{F}_n \) measurable, \( \mathcal{F}_{n+1} \subseteq \mathcal{F}_n \) for all \( n \in \mathbb{N} \), and there exist \( X_\infty \mathcal{F}_\infty \) measurable such that \( \mathcal{F}_\infty \subseteq \mathcal{F}_n \) for all \( n \) and \( X_0 \mathcal{F}_0 \) measurable such that \( \mathcal{F}_0 \supseteq \mathcal{F}_n \) for all \( n \) such that for all \( n \in \{0,1,\cdots\} \),
\[ E(X_n | \mathcal{F}_{n+1}) \geq X_{n+1}, \ E(X_n | \mathcal{F}_\infty) \geq X_\infty. \]
Then \( \{X_n : n \in \mathbb{N}\} \) is uniformly integrable.

**Proof:**
\[ E(X_{n+1}) \leq E(E(X_n | \mathcal{F}_{n+1})) = E(X_n) \]
Therefore, the sequence \( E(X_n) \) is a decreasing sequence bounded below by \( E(X_\infty) \) so it has a limit. Let \( k \) be large enough that
\[ \left| E(X_k) - \lim_{m \to \infty} E(X_m) \right| < \varepsilon \quad (60.7.26) \]
and suppose \( n > k \). Then if \( \lambda > 0 \),
\[ \int_{|X_n| \geq \lambda} |X_n| \, dP = \int_{|X_n| \geq \lambda} X_n \, dP + \int_{|X_n| \leq \lambda} (-X_n) \, dP \]
\[ = \int_{|X_n| \geq \lambda} X_n \, dP + \int_{|X_n| \leq \lambda} (-X_n) \, dP - \int_{X_n < \lambda} (-X_n) \, dP \]
\[ = \int_{|X_n| \geq \lambda} X_n \, dP - \int_{\Omega} X_n \, dP + \int_{X_n < \lambda} X_n \, dP \]
From (60.7.26)
\[ \leq \int_{|X_n| \geq \lambda} X_n \, dP - \int_{\Omega} X_k \, dP + \varepsilon + \int_{X_n < \lambda} X_n \, dP \]
By assumption,
\[ E(X_k|\mathcal{F}_n) \geq X_n \]
and so
\[
\int_{\Omega} X_k dP - \int_{\Omega} X_k dP + \varepsilon + \int_{\Omega} E(X_k|\mathcal{F}_n) dP
\]
\[
= \int_{[X_n \geq \lambda]} X_k dP - \int_{[X_n < \lambda]} X_k dP + \varepsilon + \int_{[X_n < \lambda]} X_k dP
\]
\[
= \int_{[X_n \geq \lambda]} X_k dP + \left( \int_{\Omega} (-X_k) dP - \int_{[X_n > -\lambda]} (-X_k) dP \right) + \varepsilon
\]
\[
= \int_{[X_n \geq \lambda]} X_k dP + \int_{[X_n \leq -\lambda]} (-X_k) dP + \varepsilon = \int_{[X_n \geq \lambda]} \left| X_k \right| dP + \varepsilon
\]

Applying the maximal inequality for submartingales, Theorem 58.5.4,
\[
P(\max \{|X_j| : j = n, \cdots, 1\} \geq \lambda) \leq \frac{1}{\lambda} (E(|X_0|) + E(|X_{\infty}|)) \leq \frac{C}{\lambda}
\]
and taking sup for all \(n\),
\[
P(\sup \{|X_j| \geq \lambda\}) \leq \frac{C}{\lambda}
\]
It follows that for all \(\lambda\) large enough,
\[
\int_{|X_n| \geq \lambda} |X_n| dP \leq 2\varepsilon
\]
and since \(\varepsilon\) is arbitrary, this shows \(\{X_n\}\) for \(n > k\) is equiintegrable. Since there are only finitely many \(X_j\) for \(j \leq k\), this shows \(\{X_n\}\) is equiintegrable. Hence \(\{X_n\}\) is uniformly integrable.

### 60.8 Right Continuity Of Submartingales

The following theorem is an attempt to consider the question of right continuity. It turns out that you can always assume right continuity of a submartingale by going to a suitable version and this theorem is a first step in this direction.

**Theorem 60.8.1** Let \(\{X(t)\}\) be a real valued submartingale adapted to the filtration \(\mathcal{F}_t\). Then there exists a set of measure zero \(N\), \(P(N) = 0\), such that if \(\omega \notin N\) then,
\[
\lim_{r \to t^+, r \in \mathbb{Q}} X(r, \omega), \quad \lim_{r \to t^-, r \in \mathbb{Q}} X(r, \omega)
\]
both exist. There also exists a set of measure zero \( N \) such that for \( \mathbb{Q}^+ \) the nonnegative rationals and \( \omega \not\in N \),

\[
\sup_{t \in \mathbb{Q}^+ \cap [0,M]} |X(t,\omega)| < \infty
\]

is bounded for each \( M \in \mathbb{N} \). \( \mathbb{Q} \) can be replaced with any countable dense subset of \( \mathbb{R} \).

**Proof:** Let \( \{r_k\}_{k=1}^\infty \) be an enumeration of the nonnegative rationals. Let \( t > 0 \) be given. Then let \( \{s_1, s_2, \ldots, s_n\} \) be such that these are in order and \( \{s_2, \ldots, s_{n-1}\} \) are the first \( n-2 \) rationals less than \( t \) listed in order and \( s_1 = 0 \) while \( s_n = t \). Then let \( Y_k = X(s_k) \). It follows \( \{Y_k\} \) is a submartingale and so from the maximal inequality in Theorem 58.5.4,

\[
\mathbb{P}\left( \max_{1 \leq k \leq n} |Y_k| \geq 2^m \right) \leq \frac{1}{2^m} (2\mathbb{E}(|Y_n| + |Y_1|)) = 2^{-m} (2\mathbb{E}(|X(t)| + |X(0)|))
\]

Then letting \( n \to \infty \), it follows upon letting \( C_t = 2\mathbb{E}(|X(t)| + |X(0)|) \),

\[
\mathbb{P}\left( \sup_{r \in \mathbb{Q}^+ \cap [0,t]} |X(r)| \geq 2^m \right) \leq 2^{-m} C_t.
\]

By the Borel Cantelli lemma, there exists a set of measure 0, \( N_t \) such that for \( \omega \not\in N_t, \omega \) is contained in only finitely many of the sets

\[
\left[ \sup_{r \in \mathbb{Q}^+ \cap [0,t]} |X(r)| \geq 2^m \right]
\]

which shows that for \( \omega \not\in N_t, \sup_{r \in \mathbb{Q}^+ \cap [0,t]} |X(r)| \) is bounded. Now let \( N = \cup_{j=1}^\infty N_j \). This proves the second claim.

Next consider the first claim. By the upcrossing estimate, Theorem 58.5.9 or Lemma 58.2.6 and letting \( a < b \) and \( U_{[a,b]}^n [c,d] \) the upcrossings of \( Y_k \) from \( a \) to \( b \) on \( [c,d] \) for \( d \leq t \) and \( c \geq 0 \),

\[
\mathbb{E}\left( U_{[a,b]}^n [0,t] \right) \leq \frac{1}{b-a} \mathbb{E}\left( (Y_n - a)^+ \right) = \frac{1}{b-a} \mathbb{E}\left( (X(t) - a)^+ \right).
\]

Hence

\[
\mathbb{P}\left( U_{[a,b]}^n [0,t] \geq M \right) \leq \frac{1}{M} \left( \frac{1}{b-a} \mathbb{E}\left( (X(t) - a)^+ \right) \right).
\]  \hspace{1cm} (60.8.27)

Suppose for some \( s < t \),

\[
\lim_{r \to s^+, r \in \mathbb{Q}} \sup_{r \in \mathbb{Q}} X(r,\omega) > b > a > \lim_{r \to s^+, r \in \mathbb{Q}} \inf_{r \in \mathbb{Q}} X(r,\omega).
\]  \hspace{1cm} (60.8.28)
CHAPTER 60. STOCHASTIC PROCESSES

If this is so, then in \((s, t) \cap \mathbb{Q}\) there must be infinitely many values of \(r \in \mathbb{Q}\) such that \(X(r, \omega) \geq b\) as well as infinitely many values of \(r \in \mathbb{Q}\) such that \(X(r, \omega) \leq a\). Note this involves the consideration of a limit from one side. Thus, since it is a limit from one side only, there are an arbitrarily large number of upcrossings between \(s\) and \(t\). Therefore, letting \(M\) be a large positive number, it follows that for all \(n\) sufficiently large,

\[ U^n_{[a,b]} [0,t] (\omega) \geq M \]

which implies

\[ \omega \in \left[ U^n_{[a,b]} [0,t] \geq M \right] \]

which from \(60.8.27\) is a set of measure no more than

\[ \frac{1}{M} \left( \frac{1}{b-a} E \left( (X(t) - a)^+ \right) \right) \]

This has shown that the set of \(\omega\) such that for some \(s \in [0,t)\) \(60.8.28\) holds is contained in the set

\[ N_{[a,b]} \equiv \cap_{M=1}^{\infty} \cup_{n=1}^{\infty} U^n_{[a,b]} [0,t] \geq M \]

Now the sets,

\[ U^n_{[a,b]} [0,t] \geq M \]

are increasing in \(n\) and each has measure less than

\[ \frac{1}{M} \left( \frac{1}{b-a} E \left( (X(t) - a)^+ \right) \right) \]

and so

\[ P \left( \cup_{n=1}^{\infty} U^n_{[a,b]} [0,t] \geq M \right) \leq \frac{1}{M} \left( \frac{1}{b-a} E \left( (X(t) - a)^+ \right) \right) \]

which shows that

\[ P \left( N_{[a,b]} \right) \leq \frac{1}{M} \left( \frac{1}{b-a} E \left( (X(t) - a)^+ \right) \right) \]

for every \(M\) and therefore, \(P(N_{[a,b]}) = 0\).

Therefore, corresponding to \(a < b\), there exists a set of measure 0, \(N_{[a,b]}\) such that for \(\omega \not\in N_{[a,b]}\) \(60.8.28\) is not true for any \(s \in [0,t)\). Let \(N \equiv \cup_{a,b \in \mathbb{Q}} N_{[a,b]}\), a set of measure 0 with the property that if \(\omega \not\in N\), then \(60.8.28\) fails to hold for any pair of rational numbers, \(a < b\) for any \(s \in [0,t)\). Thus for \(\omega \not\in N\),

\[ \lim_{r \to s^+, r \in \mathbb{Q}} X(r, \omega) \]

exists for all \(s \in [0,t)\). Similar reasoning applies to show the existence of the limit

\[ \lim_{r \to s^-, r \in \mathbb{Q}} X(r, \omega) . \]
for all $s \in (0, t]$ whenever $\omega$ is outside of a set of measure zero. Of course, this exceptional set depends on $t$. However, if this exceptional set is denoted as $N_t$, one could consider $N \equiv \bigcup_{n=1}^{\infty} N_n$. It is obvious there is no change if $\mathbb{Q}$ is replaced with any countable dense subset. This proves the theorem.

Of course the above theorem does not say the left and right limits are equal, just that they exist in some way for $\omega$ not in some set of measure zero. Also it has not been shown that $\lim_{r \to s+} X(r, \omega) = X(s, \omega)$ for a.e. $\omega$.

**Corollary 60.8.2** In the situation of Theorem 60.8.1, let $s > 0$ and let $D_1$ and $D_2$ be two countable dense subsets of $\mathbb{R}$. Then

$$\lim_{r \to s-} X(r, \omega) = \lim_{r \to s-} X(r, \omega) \ a.e. \ \omega$$

$$\lim_{r \to s+} X(r, \omega) = \lim_{r \to s+} X(r, \omega) \ a.e. \ \omega$$

**Proof:** Let $\{r_n\}$ be an increasing sequence from $D_1$ converging to $s$ and let $N$ be the exceptional set corresponding to the countable dense set $D_1 \cup D_2$. Then for $\omega \notin N$, and $i = 1, 2$,

$$\lim_{r \to s-} X(r, \omega) = \lim_{n \to \infty} X(r_n, \omega) = \lim_{r \to s-} X(r, \omega)$$

The other claim is similar. This proves the corollary.

Now here is an impressive lemma about submartingales and uniform integrability.

**Lemma 60.8.3** Let $X(t)$ be a submartingale adapted to a filtration $\mathcal{F}_t$. Let $\{r_k\} \subseteq [s, t)$ be a decreasing sequence converging to $s$. Then $\{X(r_j)\}_{j=1}^{\infty}$ is uniformly integrable.

**Proof:** First I will show the sequence is equiintegrable. I need to show that for all $\varepsilon > 0$ there exists $\lambda$ large enough that for all $n$

$$\int_{|X(r_n)| \geq \lambda} |X(r_n)| dP < \varepsilon.$$  

Let $\varepsilon > 0$ be given. Since $\{X(r)\}_{r \geq 0}$ is a submartingale, $E(X(r_n))$ is a decreasing sequence bounded below by $E(X(s))$. This is because for $r_n < r_k$,

$$E(X(r_n)) \leq E(E(X(r_k) | \mathcal{F}_n)) = E(X(r_k))$$

Pick $k$ such that

$$E(X(r_k)) - \lim_{n \to \infty} E(X(r_n))$$

$$= \left| E(X(r_k)) - \lim_{n \to \infty} E(X(r_n)) \right| < \varepsilon/2.$$
Then for \( n > k \),

\[
\int_{[|X(r_n)| \geq \lambda]} |X(r_n)| \, dP = \int_{[X(r_n) \geq \lambda]} X(r_n) \, dP + \int_{[X(r_n) \leq -\lambda]} -X(r_n) \, dP
\]

\[
= \int_{[X(r_n) \geq \lambda]} X(r_n) \, dP + \int_{[X(r_n) > -\lambda]} X(r_n) \, dP - \int_{\Omega} X(r_n) \, dP
\]

\[
\leq \int_{[X(r_n) \geq \lambda]} X(r_n) \, dP + \int_{[X(r_n) > -\lambda]} E(X(r_k) | \mathcal{F}_n) \, dP - \int_{\Omega} X(r_n) \, dP
\]

\[
\leq \int_{[X(r_n) \geq \lambda]} X(r_k) \, dP + \int_{[X(r_n) > -\lambda]} X(r_k) \, dP - \int_{\Omega} X(r_k) + \varepsilon/2 \, dP
\]

\[
= \int_{[X(r_n) \geq \lambda]} X(r_k) \, dP + \int_{[X(r_n) \leq -\lambda]} (-X(r_k)) \, dP + \varepsilon/2
\]

\[
= \int_{\sup \{ X(r) | r \in \{ r_j \}_{j=1}^\infty \}} |X(r_k)| \, dP + \varepsilon/2
\]

(60.8.29)

From maximal inequalities of Theorem 58.5.4

\[
P \left( \sup_{r \in \{ r_n, r_{n+1}, \ldots, r_1 \}} \left| X(r) \right| \geq \lambda \right) \leq \frac{2E(|X(t)| + |X(0)|)}{\lambda} \equiv C
\]

and so, letting \( n \to \infty \),

\[
P \left( \sup_{r \in \{ r_n \}_{n=1}^\infty} \left| X(r) \right| \geq \lambda \right) \leq \frac{C}{\lambda}
\]

It follows that for \( \lambda \) sufficiently large the first term in (60.8.29) is smaller than \( \varepsilon/2 \) because \( k \) is fixed. Now this shows there is a choice of \( \lambda \) such that for all \( n > k \),

\[
\int_{\{ |X(r_n)| \geq \lambda \}} |X(r_n)| \, dP < \varepsilon
\]

There are only finitely many \( r_n \) for \( n \leq k \) and by choosing \( \lambda \) sufficiently large the above formula can be made to hold for these also, thus showing \( \{ X(r_n) \} \) is equi integrable.

Now this implies the sequence of random variables is uniformly integrable as well. Let \( \varepsilon > 0 \) be given and choose \( \lambda \) large enough that for all \( n \),

\[
\int_{\{ |X(r_n)| \geq \lambda \}} |X(r_n)| \, dP < \varepsilon/2
\]
Then let $A$ be a measurable set.

$$\int_A |X(r_n)| dP = \int_{A \cap [X(r_n) \geq \lambda]} |X(r_n)| dP + \int_{A \cap [X(r_n) < \lambda]} |X(r_n)| dP$$

$$< \frac{\varepsilon}{2} + \int_{A \cap [X(r_n) < \lambda]} |X(r_n)| dP \leq \frac{\varepsilon}{2} + \lambda P(A)$$

and now you see that if $P(A)$ is sufficiently small then for all $n$,

$$\int_A |X(r_n)| dP < \varepsilon$$

which shows the set of functions is uniformly integrable as claimed. This proves the lemma.

You can often consider a submartingale to be right continuous. This is the importance of the following theorem.

**Theorem 60.8.4** Let $\{X(t)\}$ be a submartingale adapted to a normal filtration $F_t$. There exists a right continuous submartingale having left limits, $\{Y(t)\}$ such that $Y(t) = X(t)$ a.e. for every $t \in \mathbb{Q}^+$. Furthermore $\{X(t)\}$ has a right continuous left limits version if and only if

$$t \rightarrow E(X(t))$$

is right continuous. More generally, $Y(t) = X(t)$ a.e. at every point where the above function is right continuous.

**Proof:** From Theorem 60.8.1, there exists a set of measure zero, $N$ such that for $\omega \notin N$, left and right limits of the following form exist.

$$\lim_{r \rightarrow t+, r \in \mathbb{Q}} X(r, \omega), \lim_{r \rightarrow t-, r \in \mathbb{Q}} X(r, \omega).$$

Then define for each $t$ and $\omega \notin N$,

$$Y(t, \omega) \equiv \lim_{r \rightarrow t+, r \in \mathbb{Q}} X(r, \omega).$$

and for $\omega \in N$,

$$Y(t, \omega) \equiv 0$$

Thus $Y(t)(\omega) = X(t)(\omega)$ a.e. for $t \in \mathbb{Q}^+$. For each $\omega \notin N$, there exists $\delta > 0$ such that if $r \in \mathbb{Q}$, $t < r < t + 2\delta$, then

$$|Y(t, \omega) - X(r, \omega)| < \varepsilon/2.$$

Now suppose $s \in (t, t + \delta)$. Then there exists $\delta_1 < \delta$ such that if $s < r < s + \delta_1$ then

$$|Y(s, \omega) - X(r, \omega)| < \varepsilon/2.$$
pick \( r \in \mathbb{Q} \cap (s, t + \delta) \). Then both of the above two inequalities hold and so it follows

\[
|Y(t, \omega) - Y(s, \omega)| \leq |Y(t, \omega) - X(r, \omega)| + |X(r, \omega) - Y(s, \omega)| < \varepsilon/2 + \varepsilon/2 = \varepsilon.
\]

Therefore, \( t \to Y(t, \omega) \) is right continuous as claimed.

From the definition of \( Y(t, \omega) \), it follows \( \omega \to Y(t, \omega) \) is measurable in \( \mathcal{F}_{t+} \) because it is the limit of a sequence, \( X(r_n, \omega) \mathcal{X}_{Nn} \) where \( r_n \to t + \). Now each \( X(r_n, \cdot) \) is \( \mathcal{F}_{r_n} \) measurable and so \( Y(t, \cdot) \) is \( \mathcal{F}_{r_n} \) measurable also for each \( r_n \). Thus \( Y(t, \cdot) \) is \( \mathcal{F}_{t+} \) measurable. Since the filtration is normal, \( \mathcal{F}_t = \mathcal{F}_{t+} \) and it follows \( Y(t, \cdot) \) is \( \mathcal{F}_t \) measurable. Why is \( Y(t, \cdot) \in L^1(\Omega) \)?

From Lemma 60.8.3, the collection \( \{X(r_n)\} \) is uniformly integrable. Therefore, from the Vitali convergence theorem, Theorem 9.5.3 on Page 244.

\[
\lim_{n \to \infty} \int_{\Omega} |Y(s) - X(r_n)| dP = 0 \tag{60.8.30}
\]

and \( Y(s) \in L^1(\Omega) \).

It remains to verify \( \{Y(s)\} \) is a submartingale. For \( s < t \), is it true that

\[
E(Y(t) \lvert \mathcal{F}_s) \geq Y(s).
\]

Fix \( A \in \mathcal{F}_s \). From the above construction, there exists \( w \in \mathbb{Q} \) and \( w \geq t \) such that

\[
\int_A Y(t) dP \geq \int_A X(w) dP - \varepsilon.
\]

Then also, there exists \( r \in \mathbb{Q} \cap (s, t) \) such that

\[
\int_A X(r) dP \geq \int_A Y(s) dP - \varepsilon.
\]

Now

\[
\int_A E(Y(t) \lvert \mathcal{F}_s) dP = \int_A Y(t) dP \geq \int_A X(w) dP - \varepsilon
\]

\[
= \int_A E(X(w) \lvert \mathcal{F}_r) dP - \varepsilon
\]

\[
\geq \int_A X(r) dP - \varepsilon \geq \int_A Y(s) dP - 2\varepsilon.
\]

Since \( \varepsilon \) was arbitrary, this shows

\[
\int_A E(Y(t) \lvert \mathcal{F}_s) dP \geq \int_A Y(s) dP
\]

for any \( A \in \mathcal{F}_s \) and so this verifies since \( A \) is arbitrary that

\[
E(Y(t) \lvert \mathcal{F}_s) \geq Y(s)
\]
so $Y$ is a submartingale.

By Theorem 60.8.1 there exists a set of measure 0, $N$ such that the left limits of $Y(r, \omega)$ exist through rational numbers if $\omega \notin N$.

Is $\{Y(t)\}$ a version of $\{X(t)\}$? This is where the assumption $t \to E(X(t))$ is continuous is used. We know $E(X(r_n)|F_s) \geq X(s)$ and also for $A \in \mathcal{F}_s$

$$\int_A X(r_n) dP = \int_A E(X(r_n)|F_s) dP \geq \int_A X(s) dP.$$ 

Hence taking a limit yields

$$\int_A Y(s) dP \geq \int_A X(s) dP$$

and since $A$ is arbitrary, $Y(s) \geq X(s)$. Now since $t \to E(X(t))$ is continuous,

$$\int_\Omega |Y(s) - X(s)| dP = E(Y(s)) - E(X(s)) = \lim_{n \to \infty} (E(X(r_n)) - E(X(r_n))) = 0.$$

It only remains to verify the only way $X(t)$ has a right continuous version is for $t \to E(X(t))$ to be continuous. Suppose then that $\{X(t)\}$ has a right continuous version, $\{Y(t)\}$. Letting $r_n \downarrow s$, Lemma 60.8.1 implies $\{Y(r_n)\}$ is uniformly integrable. Also $Y(s)(\omega) = \lim_{n \to \infty} Y(r_n)(\omega)$ a.e. and so by the Vitali convergence theorem,

$$\lim_{n \to \infty} \int_\Omega |X(r_n) - X(s)| dP = \lim_{n \to \infty} \int_\Omega |Y(r_n) - Y(s)| dP = 0.$$ 

This proves the theorem.

Note that the condition $t \to E(X(t))$ being continuous holds for any martingale. Therefore, every martingale has a right continuous version. The condition that $t \to E(X(t))$ is right continuous is not a very stringent assumption. For $\{X(t)\}$ a submartingale, this is an increasing function. Therefore, the only points where the condition might not hold comprise a countable set.

### 60.9 Some Maximal Inequalities

As in the case of discrete martingales and submartingales, there are maximal inequalities available.

**Lemma 60.9.1** Let $X$ be right continuous and adapted such that the given filtration is complete in the sense that $\mathcal{F}_0$ contains all sets $A$ of $\mathcal{F}$ such that $P(A) = 0$. Then there exists a set of measure zero $N$ and a $\mathcal{F} \times \mathcal{B}(\mathbb{R})$ measurable function $Y$ such that if $\omega \notin N$, then $Y(t)(\omega) = X(t)(\omega)$. Also, if $f$ is $\mathcal{F}$ measurable and nonnegative then $(\lambda, \omega) \to X_{[f > \lambda]}$ is $\mathcal{F} \times \mathcal{B}(\mathbb{R})$ measurable.
Proof: Let \( \{t^n_0, t^n_1, \ldots, t^n_m_n\} \) be a partition of \([0, T]\) in which \( |t^n_i - t^n_{i-1}| < \rho_n \) where \( \rho_n \to 0 \). Now define \( X_n \) as follows:

\[
X_n(t)(\omega) = \sum_{i=1}^{m_n} X(t^n_i)(\omega) X_{(t^n_{i-1}, t^n_i]}(t)
\]

\[
X_n(0) = X(0).
\]

then each \( X_n \) is obviously product measurable because it is the sum of functions which are. By right continuity, \( X_n \) converges pointwise to \( X \) for \( \omega \notin N \) where \( N \) is a set of measure zero and so if \( Y(t)(\omega) \equiv X(t)(\omega) \) for all \( \omega \notin N \) and \( Y(t)(\omega) = 0 \) for all \( \omega \in N \), this is the desired product measurable function.

To see the last claim, let \( s \) be a nonnegative simple function, \( s(\omega) = \sum_{k=1}^{n} c_k \chi_{E_k}(\omega) \) where the \( c_k \) are strictly increasing in \( k \). Also let \( F_k = \bigcup_{i=k}^{n} E_i \). Then

\[
\chi_{[s > \lambda]} = \sum_{k=1}^{n} \chi_{[c_k-c_{k-1}, c_k)} \chi_{F_k}(\omega)
\]

which is clearly product measurable. For arbitrary \( f \geq 0 \) and measurable, there is an increasing sequence of simple functions \( s_n \) converging pointwise to \( f \). Therefore,

\[
\lim_{n \to \infty} \chi_{[s_n > \lambda]} = \chi_{[f > \lambda]}
\]

and so \( \chi_{[f > \lambda]} \) is product measurable. \( \blacksquare \)

Definition 60.9.2 Let \( X(t) \) be a right continuous submartingale for \( t \in I \) and let \( \{\tau_n\} \) be a sequence of stopping times such that \( \lim_{n \to \infty} \tau_n = \infty \). Then \( X^{\tau_n} \) is called the stopped submartingale and it is defined by

\[
X^{\tau_n}(t) \equiv X(t \land \tau_n).
\]

Proposition 60.9.3 The stopped submartingale just defined is a submartingale.

Proof: By the optional sampling theorem for submartingales, Theorem 60.7.2, it follows that for \( s < t \),

\[
E(X^{\tau_n}(t) | \mathcal{F}_s) = E(X(t \land \tau_n) | \mathcal{F}_s) \geq X(t \land \tau_n \land s) = X(\tau_n \land s) \equiv X^{\tau_n}(s).
\]

Theorem 60.9.4 Let \( \{X(t)\} \) be a right continuous nonnegative submartingale adapted to the normal filtration \( \mathcal{F}_t \) for \( t \in [0, T] \). Let \( p \geq 1 \). Define

\[
X^*(t) \equiv \sup \{X(s) : 0 < s < t\}, \quad X^*(0) \equiv 0.
\]

Then for \( \lambda > 0 \), if \( X(t)^p \) is in \( L^1(\Omega) \) for each \( t \),

\[
P(|X^*(T) > \lambda|) \leq \frac{1}{\lambda^p} \int \chi_{[X^*(T) > \lambda]} X(T)^p \, dP \quad (60.9.31)
\]
If \( X(t) \) is continuous, the above inequality holds without this assumption. In case \( p > 1 \), and \( X(t) \) continuous, then for each \( t \leq T \),

\[
\left( \int_\Omega |X^*(t)|^p \, dP \right)^{1/p} \leq \frac{p}{p-1} \left( \int_\Omega X(T)^p \, dP \right)^{1/p}
\]  

(60.9.32)

**Proof:** The first inequality follows from Theorem 60.7.2. However, it can also be obtained a different way using stopping times.

Define the stopping time

\[
\tau \equiv \inf \{ t > 0 : X(t) > \lambda \} \wedge T.
\]

(The infimum over an empty set will equal \( \infty \).) This is a stopping time by 60.7.2 because it is just a continuous function of the first hitting time of an open set. Also from the definition of \( X^* \) in which the supremum is taken over an open interval,

\[ [\tau < t] = [X^*(t) > \lambda] \]

Note this also shows \( X^*(t) \) is \( \mathcal{F}_t \) measurable. Then it follows that \( X^p(t) \) is also a submartingale since \( r^p \) is increasing and convex. By the optional sampling theorem, \( X(0)^p, X(\tau)^p, X(T)^p \) is a submartingale. Also \([\tau < T] \in \mathcal{F}_\tau \) and so

\[
\int_{[\tau < T]} X(\tau)^p \, dP \leq \int_{[\tau < T]} E(X(T)^p | \mathcal{F}_\tau) \, dP = \int_{[\tau < T]} X(T)^p \, dP
\]

By right continuity, on \([\tau < T] \), \( X(\tau) \geq \lambda \). Therefore,

\[
\lambda^p P([X^*(T) > \lambda]) = \lambda^p P([\tau < T]) \\
\leq \int_{[\tau < T]} X(\tau)^p \, dP \leq \int_{[X^*(T) > \lambda]} X(T)^p \, dP
\]

Next suppose \( X(t) \) is continuous and let \( \{\tau_n\} \) be a localizing sequence,

\[
\tau_n \equiv \inf \{ t : X(t) > n \}.
\]

Then by continuity, \( X^{\tau_n} \) is bounded because \( X(\tau_n \wedge t) \leq n \), and so from what was just shown,

\[
\lambda^p P\left( [(X^{\tau_n})^*(T) > \lambda]\right) \leq \int_{[(X^{\tau_n})^*(T) > \lambda]} (X^{\tau_n})(T)^p \, dP
\]

Then \( (X^{\tau_n})(T) \) is increasing as \( \tau_n \to \infty \) so the result follows from the monotone convergence theorem. This proves the first part.

Let \( X^{\tau_n} \) be as just defined. Thus it is a bounded submartingale. To save on notation, the \( X \) in the following argument is really \( X^{\tau_n} \). This is done so that all the integrals are finite. If \( p > 1 \), then from the first part using the case of \( p = 1 \),

\[
\int_\Omega |X^*(t)|^p \, dP \leq \int_\Omega |X^*(T)|^p \, dP = \int_0^\infty p \lambda^{p-1} \tilde{P}(\{X^*(T) > \lambda\}) \, d\lambda
\]
\[ p \int_0^\infty \lambda^{p-1} \lambda^{p-2} d\lambda \]

\[ = p \int_0^\infty X(T)X^{*}(T) dP \]

\[ = p \int_\Omega X(T)X^{*}(T)^{p-1} dP \]

\[ \leq \frac{p}{p-1} \left( \int_\Omega X^{*}(T)^p dP \right)^{1/p} \left( \int_\Omega X^p dP \right)^{1/p} \]

Now divide both sides by \( (\int_\Omega X^{*}(T)^p dP)^{1/p} \). Substituting \( X^* \) for \( X \)

\[ \left( \int_\Omega |X^{\tau_n+}(t)|^p dP \right)^{1/p} \leq \left( \int_\Omega X^{\tau_n+}(T)^p dP \right)^{1/p} \leq \frac{p}{p-1} \left( \int_\Omega X^{\tau_n}(T)^p dP \right)^{1/p} \]

Now let \( n \to \infty \) and use the monotone convergence theorem to obtain the inequality of the theorem. This establishes \[ 60.9.32 \]. The use of Fubini’s theorem follows from Lemma \[ 60.9.1 \].

Here is another sort of maximal inequality in which \( X(t) \) is not assumed non-negative.

**Theorem 60.9.5** Let \( \{X(t)\} \) be a right continuous submartingale adapted to the normal filtration \( F_t \) for \( t \in [0,T] \) and \( X^{*}(t) \) defined as in Theorem \[ 60.9.4 \].

\[ X^{*}(t) \equiv \sup \{X(s) : 0 < s < t \}, \quad X^{*}(0) \equiv 0, \]

For \( t > 0 \), let

\[ X_{\ast}(t) = \inf \{X(s) : s < t \}. \]

Then

\[ P([X^{*}(T) > \lambda]) \leq \frac{1}{\lambda} E(|X(T)|) \] (60.9.33)

For \( t > 0 \), let

\[ X_{\ast}(t) = \inf \{X(s) : s < t \}. \]

Then

\[ P([X_{\ast}(T) < -\lambda]) \leq \frac{1}{\lambda} E(|X(T)| + |X(0)|) \] (60.9.34)

Also

\[ P([\sup \{X(s) : s < T \} > \lambda]) \]

\[ \leq \frac{2}{\lambda} E(|X(T)| + |X(0)|) \] (60.9.35)

**Proof:** The function \( f(r) = r^+ \equiv \frac{1}{2} (|r| + r) \) is convex and increasing. Therefore, \( X^+(t) \) is also a submartingale but this one is nonnegative. Also

\[ |X^{*}(T) > \lambda| = \left[ (X^+)^*(T) > \lambda \right] \]

and so from Theorem \[ 60.9.4 \],

\[ P([X^{*}(T) > \lambda]) = P\left( [(X^+)^*(T) > \lambda] \right) \leq \frac{1}{\lambda} E(X^+(T)) \leq \frac{1}{\lambda} E(|X(T)|). \]
Next let
\[ \tau = \min \left( \inf \{ t : X(t) < -\lambda \} , T \right) \]
then as before, \( X(0), X(\tau), X(T) \) is a submartingale and so
\[
\int_{[\tau < T]} X(\tau) \, dP + \int_{[\tau = T]} X(\tau) \, dP = \int_{\Omega} X(\tau) \, dP \geq \int_{\Omega} X(0) \, dP
\]
Now for \( \omega \in [\tau < T], X(t)(\omega) < -\lambda \) for some \( t < T \) and so by right continuity, \( X(t)(\omega) \leq -\lambda \). Therefore,
\[
-\lambda \int_{[\tau < T]} dP \geq -\int_{[\tau = T]} X(T) \, dP + \int_{\Omega} X(0) \, dP
\]
If \( X_*(T) < -\lambda \), then from the definition given above, there exists \( t < T \) such that \( X(t) < -\lambda \) and so \( \tau < T \). If \( \tau < T \), then by definition, there exists \( t < T \) such that \( X(t) < -\lambda \) and so \( X_*(T) < -\lambda \). Hence \( [\tau < T] = [X_*(T) < -\lambda] \). It follows that
\[
P([X_*(T) < -\lambda]) = P([\tau < T])
\]
\[
\leq \frac{1}{\lambda} \int_{[\tau = T]} X(T) \, dP - \frac{1}{\lambda} \int_{\Omega} X(0) \, dP
\]
\[
\leq \frac{1}{\lambda} E(|X(T)| + |X(0)|)
\]
and this proves [MUNCH].

Finally, combining the above two inequalities,
\[
P(\sup \{ |X(s)| : s < T \} > \lambda)
\]
\[
= P([X_*(T) < -\lambda]) + P([X^*(T) > \lambda])
\]
\[
\leq \frac{2}{\lambda} E(|X(T)| + |X(0)|).
\]

60.10 Continuous Submartingale Convergence Theorem

In this section, \( \{X(t)\} \) will be a right continuous submartingale.

The next task is to consider an upcrossing estimate as was done before for discrete submartingales. Let \( a < b \) and define
\[
\tau_0 = \min \left( \inf \{ t > 0 : X(t) < a \} , M \right),
\]
\[
\tau_1 = \min \left( \inf \{ t > 0 : (X(t \land \tau_0) - X(\tau_0))_+ > b - a \} , M \right),
\]
\[
\tau_2 = \min \left( \inf \{ t > 0 : (X(\tau_1) - X(t \land \tau_1))_+ > b - a \} , M \right),
\]
\[
\tau_3 = \min \left( \inf \{ t > 0 : (X(t \land \tau_2) - X(\tau_2))_+ > b - a \} , M \right),
\]
\[
\tau_4 = \min \left( \inf \{ t > 0 : (X(\tau_3) - X(t \land \tau_3))_+ > b - a \} , M \right),
\]
\[
\vdots
\]
Lemma 60.10.1 The above $\tau_i$ are stopping times for $t \in [0, M]$.

Proof: It is obvious that $\tau_0$ is a stopping time because it is the minimum of $M$ and the first hitting time of an open set by a right continuous adapted process. Consider a stopping time $\eta \leq M$ and let

$$\sigma \equiv \inf \{ t > 0 : (X(t \lor \eta) - X(\eta))^+ > b - a \}$$

I claim that $t \mapsto X(t \lor \eta) - X(\eta)$ is adapted to $\mathcal{F}_t$. Suppose $\alpha \geq 0$ and consider

$$(X(t \lor \eta) - X(\eta))^+ > \alpha$$

The above set equals

$$\{(X(t \lor \eta) - X(\eta))^+ > \alpha \cap [\eta \leq t]\} \cap \{(X(t \lor \eta) - X(\eta))^+ > \alpha \cap [\eta > t]\}$$

Consider the second of the above two sets. Since $\alpha > 0$, this set is $\emptyset$. This is because for $\eta > t$, $X(t \lor \eta) - X(\eta) = 0$. Now consider the first. It equals

$$[(X(t \lor \eta) - X(\eta))^+ > \alpha] \cap [\eta \lor t \leq t],$$

a set of $\mathcal{F}_{t \lor \eta}$ intersected with $[\eta \lor t \leq t]$ and so it is in $\mathcal{F}_t$.

If $\alpha < 0$, then $X(t \lor \eta) - X(\eta)$ reduces to $\Omega$, also in $\mathcal{F}_t$. Therefore, by Proposition 60.7.2, $\sigma$ is a stopping time because it is the first hitting time of an open set of a right continuous adapted process. It follows that $\sigma \land M$ is also a stopping time. Similarly $t \mapsto X(\eta) - X(t \lor \eta)$ is adapted and

$$\sigma \equiv \inf \{ t > 0 : (X(\eta) - X(t \lor \eta))^+ > b - a \}$$

is also a stopping time from the same reasoning. It follows that the $\tau_i$ defined above are all stopping times. ■

Note that in the above, if $\eta = M$, then $\sigma = M$ also. Thus in the definition of the $\tau_i$, if any $\tau_i = M$, it follows that also $\tau_{i+1} = M$ and so there is no change in the stopping times. Also note that these stopping times $\tau_i$ are increasing as $i$ increases.

Let

$$U_{[a,b]}^{n,M} = \lim_{\varepsilon \to 0} \sum_{k=0}^{n} \frac{X(\tau_{2k+1}) - X(\tau_{2k})}{\varepsilon + X(\tau_{2k+1}) - X(\tau_{2k})} \leq \frac{1}{b - a} \sum_{k=0}^{n} X(\tau_{2k+1}) - X(\tau_{2k})$$

(60.10.37)

Note that if an upcrossing occurs after $\tau_{2k}$ on $[0, M]$, then $\tau_{2k+1} > \tau_{2k}$ because there exists $t$ such that

$$(X(t \lor \tau_{2k}) - X(\tau_{2k}))^+ > b - a$$

However, you could have $\tau_{2k+1} > \tau_{2k}$ without an upcrossing occurring. This happens when $\tau_{2k} < M$ and $\tau_{2k+1} = M$ which may mean that $X(t)$ never again climbs above $b$. 
Then $U^M_{\lfloor a,b \rfloor}$ is clearly a random variable which is at least as large as the number of upcrossings occurring for $t \leq M$ using only $2n + 1$ of the stopping times. From the optional sampling theorem,

$$E (X (\tau_{2k})) - E (X (\tau_{2k-1})) = \int_{\Omega} X (\tau_{2k}) - X (\tau_{2k-1}) dP$$

$$= \int_{\Omega} E (X (\tau_{2k}) | \mathcal{F}_{\tau_{2k-1}}) - X (\tau_{2k-1}) dP$$

$$\geq \int_{\Omega} X (\tau_{2k-1}) - X (\tau_{2k-1}) dP = 0$$

Note that from right continuity, $X (\tau_{2k}) \leq a$ while $X (\tau_{2k-1}) \geq b$ so the above may seem surprising. However, the two stopping times can both equal $M$ so this is actually possible. For example, it could happen that $X (t) > a$ for all $t \in [0, M]$.

Next, take the expectation of both sides of \ref{60.10.37},

$$E \left( U^M_{\lfloor a,b \rfloor} \right) \leq \frac{1}{b-a} \sum_{k=0}^{n} E (X (\tau_{2k+1})) - E (X (\tau_{2k}))$$

$$\leq \frac{1}{b-a} \sum_{k=0}^{n} E (X (\tau_{2k+1})) - E (X (\tau_{2k})) + \frac{1}{b-a} \sum_{k=1}^{n} E (X (\tau_{2k})) - E (X (\tau_{2k-1}))$$

$$= \frac{1}{b-a} (E (X (\tau_1)) - E (X (0))) + \frac{1}{b-a} \sum_{k=1}^{n} E (X (\tau_{2k+1})) - E (X (\tau_{2k-1}))$$

$$\leq \frac{1}{b-a} (E (X (\tau_{2n+1})) - E (X (\tau_0)))$$

$$\leq \frac{1}{b-a} (E (X (M)) - E (X (0)))$$

which does not depend on $n$. The last inequality follows because $0 \leq \tau_{2n+1} \leq M$ and $X (t)$ is a submartingale. Let $n \rightarrow \infty$ to obtain

$$E \left( U^M_{\lfloor a,b \rfloor} \right) \leq \frac{1}{b-a} (E (X (M)) - E (X (0)))$$

where $U^M_{\lfloor a,b \rfloor}$ is an upper bound to the number of upcrossings of $\{X (t)\}$ on $[0, M]$. This proves the following interesting upcrossing estimate.

**Lemma 60.10.2** Let $\{X (t)\}$ be a right continuous submartingale adapted to a normal filtration $\mathcal{F}_t$ for $t \in [0, M]$. Then if $U^M_{\lfloor a,b \rfloor}$ is defined as the above upper bound to the number of upcrossings of $\{X (t)\}$ for $t \in [0, M]$, then this is a random variable and

$$E \left( U^M_{\lfloor a,b \rfloor} \right) \leq \frac{1}{b-a} (E (X (M)) - E (X (0))).$$

With this it is easy to prove a continuous submartingale convergence theorem.
**Theorem 60.10.3** Let \( \{X(t)\} \) be a right continuous submartingale adapted to a normal filtration such that

\[
\sup_t \{E(\|X(t)\|)\} = C < \infty.
\]

Then there exists \( X_\infty \in L^1(\Omega) \) such that

\[
\lim_{t \to \infty} X(t)(\omega) = X_\infty(\omega) \text{ a.e. } \omega.
\]

**Proof:** Let \( U_{[a,b]} \) be defined by

\[
U_{[a,b]} = \lim_{M \to \infty} U_{[a,b]}^M.
\]

Thus the random variable \( U_{[a,b]} \) is an upper bound for the number of upcrossings. From Lemma 60.10.2 and the assumption of this theorem, there exists a constant \( C \) independent of \( M \) such that

\[
E(U_{[a,b]}^M) \leq \frac{2C}{b-a}.
\]

Letting \( M \to \infty \), it follows from monotone convergence theorem that

\[
E(U_{[a,b]}) \leq \frac{2C}{b-a}
\]

also. Therefore, there exists a set of measure 0 \( N_{ab} \) such that if \( \omega \notin N_{ab} \), then \( U_{[a,b]}(\omega) < \infty \). That is, there are only finitely many upcrossings. Now let

\[
N = \cup \{N_{ab} : a, b \in \mathbb{Q}\}.
\]

It follows that for \( \omega \notin N \), it cannot happen that

\[
\limsup_{t \to \infty} X(t)(\omega) - \liminf_{t \to \infty} X(t)(\omega) > 0
\]

because if this expression is positive, there would be arbitrarily large values of \( t \) where \( X(t)(\omega) > b \) and arbitrarily large values of \( t \) where \( X(t)(\omega) < a \) where \( a, b \) are rational numbers chosen such that

\[
\limsup_{t \to \infty} X(t)(\omega) > b > a > \liminf_{t \to \infty} X(t)(\omega)
\]

Thus there would be infinitely many upcrossings which is not allowed for \( \omega \notin N \). Therefore, the limit \( \lim_{t \to \infty} X(t)(\omega) \) exists for a.e. \( \omega \). Let \( X_\infty(\omega) \) equal this limit for \( \omega \notin N \) and let \( X_\infty(\omega) = 0 \) for \( \omega \in N \). Then \( X_\infty \) is measurable and by Fatou’s lemma,

\[
\int_\Omega \|X_\infty(\omega)\|dP \leq \liminf_{n \to \infty} \int_\Omega \|X(n)(\omega)\|dP < C.
\]

Now here is an interesting result due to Doob.
Theorem 60.10.4 Let \( \{ M(t) \} \) be a right continuous real martingale adapted to the normal filtration \( \mathcal{F}_t \). Then the following are equivalent.

1. The random variables \( M(t) \) are equiintegrable.
2. There exists \( M(\infty) \in L^1(\Omega) \) such that \( \lim_{t \to \infty} \| M(\infty) - M(t) \|_{L^1(\Omega)} = 0 \).

In this case, \( M(t) = E(M(\infty) | \mathcal{F}_t) \) and convergence also takes place pointwise.

Proof: Suppose the equiintegrable condition. Then there exists \( \lambda \) large enough such that for all \( t \),

\[
\int_{\{ |M(t)| \geq \lambda \}} |M(t)| \, dt < 1.
\]

It follows that for all \( t \),

\[
\int_{\Omega} |M(t)| \, dP = \int_{\{ |M(t)| \geq \lambda \}} |M(t)| \, dP + \int_{\{ |M(t)| < \lambda \}} |M(t)| \, dP \leq 1 + \lambda.
\]

Since the martingale is bounded in \( L^1 \), by Theorem 60.10.3 there exists \( M(\infty) \in L^1(\Omega) \) such that \( \lim_{t \to \infty} M(t)(\omega) = M(\infty)(\omega) \) pointwise a.e. By the assumption \( \{ M(t) \} \) are equiintegrable, it follows these functions are uniformly integrable. Letting \( \delta > 0 \) be such that if \( P(E) < \delta \), then

\[
\int_E |M(t)| \, dP < \frac{\varepsilon}{5},
\]

and \( t_n \to \infty \), Egoroff’s theorem implies that there exists a set \( E \) of measure less than \( \delta \) such that on \( E^C \), the convergence of the \( M(t_n) \) is uniform. Thus

\[
\int_{\Omega} |M(t_m) - M(t_n)| \, dP = \int_E |M(t_m) - M(t_n)| \, dP + \int_{E^C} |M(t_m) - M(t_n)| \, dP \leq \frac{2\varepsilon}{5} + \int_{E^C} |M(t_m) - M(t_n)| \, dP < \varepsilon
\]

whenever \( m, n \) are large enough. Therefore, the sequence \( \{ M(t_n) \} \) is Cauchy in \( L^1(\Omega) \) which implies it converges to something in \( L^1(\Omega) \) which must equal \( M(\infty) \) a.e.

Next suppose there is a function \( M(\infty) \) to which \( M(t) \) converges in \( L^1(\Omega) \). Then for \( t \) fixed and \( A \in \mathcal{F}_t \), then as \( s \to \infty, s > t \)

\[
\int_A M(t) \, dP = \int_A E(M(s) | \mathcal{F}_t) \, dP \equiv \int_A M(s) \, dP \to \int_A M(\infty) \, dP = \int_A E(M(\infty) | \mathcal{F}_t)
\]
which shows $E(M(\infty)|\mathcal{F}_t) = M(t)$ a.e. since $A \in \mathcal{F}_t$ is arbitrary. By Lemma 60.7.8,

$$\int_{[|M(t)| \geq \lambda]} |M(t)| \, dP = \int_{[|M(t)| \geq \lambda]} E(M(\infty)|\mathcal{F}_t) \, dP \leq \int_{[|M(t)| \geq \lambda]} E(|M(\infty)|\mathcal{F}_t) \, dP = \int_{[|M(t)| \geq \lambda]} |M(\infty)| \, dP \quad (60.10.38)$$

Now from this,

$$\lambda P(|M(t)| \geq \lambda) \leq \int_{[|M(t)| \geq \lambda]} |M(t)| \, dP \leq \int_{\Omega} |M(\infty)| \, dP = \int_{\Omega} E(|M(\infty)|\mathcal{F}_t) \, dP = \int_{[|M(t)| \geq \lambda]} |M(\infty)| \, dP$$

and so

$$P(|M(t)| \geq \lambda) \leq \frac{C}{\lambda}$$

From this, this shows $\{M(t)\}$ is uniformly integrable because this is true of the single function $|M(\infty)|$. By the submartingale convergence theorem, the convergence to $M(\infty)$ also takes place pointwise.

### 60.11 Hitting This Before That

Let $\{M(t)\}$ be a real valued martingale for $t \in [0, T]$ where $T \leq \infty$ and $M(0) = 0$. In case $T = \infty$, assume the conditions of Theorem 60.10.3 are satisfied. Thus there exists $M(\infty)$ and the $M(t)$ are equiintegrable. With the Doob optional sampling theorem it is possible to estimate the probability that $M(t)$ hits $a$ before it hits $b$ where $a < 0 < b$. There is no loss of generality in assuming $T = \infty$ since if it is less than $\infty$, you could just let $M(t) \equiv M(T)$ for all $t > T$. In this case, the equiintegrability of the $M(t)$ follows because for $t < T$,

$$\int_{[|M(t)| > \lambda]} |M(t)| \, dP = \int_{[|M(t)| > \lambda]} |E(M(T)|\mathcal{F}_t)| \, dP \leq \int_{[|M(t)| > \lambda]} |M(T)| \, dP$$

and from Theorem 60.11.2,

$$P(|M(t)| > \lambda) \leq P(|M^* (t) > \lambda|) \leq \frac{1}{\lambda} \int_{\Omega} |M(T)| \, dP.$$

**Definition 60.11.1** Let $M$ be a process adapted to the filtration $\mathcal{F}_t$ and let $\tau$ be a stopping time. Then $M^\tau$, called the stopped process is defined by

$$M^\tau(t) \equiv M(\tau \land t).$$
With this definition, here is a simple lemma.

**Lemma 60.11.2** Let $M$ be a right continuous martingale adapted to the normal filtration $\mathcal{F}_t$ and let $\tau$ be a stopping time. Then $M^\tau$ is also a martingale adapted to the filtration $\mathcal{F}_t$.

**Proof:** Let $s < t$. By the Doob optional sampling theorem,

$$E (M^\tau (t) | \mathcal{F}_s) = E (M (\tau \wedge t) | \mathcal{F}_s) = M (\tau \wedge t \wedge s) = M^\tau (s).$$

**Theorem 60.11.3** Let \{ $M (t)$ \} be a continuous real valued martingale adapted to the normal filtration $\mathcal{F}_t$ and let

$$M^\ast \equiv \sup \{ |M (t)| : t \geq 0 \}$$

and $M (0) = 0$. Letting

$$\tau_x \equiv \inf \{ t > 0 : M (t) = x \}$$

Then if $a < 0 < b$ the following inequalities hold.

$$(b - a) P ([\tau_b \leq \tau_a]) \geq -a P ([M^\ast > 0]) \geq (b - a) P ([\tau_b < \tau_a])$$

and

$$(b - a) P ([\tau_a < \tau_b]) \leq b P ([M^\ast > 0]) \leq (b - a) P ([\tau_a \leq \tau_b]).$$

In words, $P ([\tau_a \leq \tau_b])$ is the probability that $M (t)$ hits $b$ no later than when it hits $a$. (Note that if $\tau_a = \infty = \tau_b$ then you would have $[\tau_a = \tau_b]$.)

**Proof:** For $x \in \mathbb{R}$, define

$$\tau_x \equiv \inf \{ t \in \mathbb{R} \text{ such that } M (t) = x \}$$

with the usual convention that $\inf (\emptyset) = \infty$. Let $a < 0 < b$ and let

$$\tau = \tau_a \wedge \tau_b$$

Then the following claim will be important.

**Claim:** $E (M (\tau)) = 0$.

**Proof of the claim:** Let $t > 0$. Then by the Doob optional sampling theorem,

$$E (M (\tau \wedge t)) = E (E (M (t) | \mathcal{F}_\tau)) = E (M (t)) = E (E (M (t) | \mathcal{F}_0)) = E (M (0)) = 0.$$  

Observe the martingale $M^\tau$ must be bounded because it is stopped when $M (t)$ equals either $a$ or $b$. There are two cases according to whether $\tau = \infty$. If $\tau = \infty$, then $M (t)$ never hits $a$ or $b$ so $M (t)$ has values between $a$ and $b$. In this case $M^\tau (t) = M (t) \in [a, b]$. On the other hand, you could have $\tau < \infty$. Then in this case $M^\tau (t)$ is eventually equal to either $a$ or $b$ depending on which it hits first.
In either case, the martingale $M^\tau$ is bounded and by the martingale convergence theorem, Theorem 60.10.3, there exists $M^\tau(\infty)$ such that

$$\lim_{t \to \infty} M^\tau(t)(\omega) = M^\tau(\infty)(\omega) = M(\tau)(\omega)$$

and since the $M^\tau(t)$ are bounded, the dominated convergence theorem implies

$$E(M(\tau)) = \lim_{t \to \infty} E(M(\tau \wedge t)) = 0.$$ 

This proves the claim.

Recall

$M^\tau(\omega) \equiv \sup \{ |M(t)(\omega)| : t \in [0, \infty] \}.$

Also note that $[\tau_a = \tau_b] = [\tau = \infty]$. Now from the claim,

$$0 = E(M(\tau)) = \int_{[\tau_a < \tau_b]} M(\tau) \, dP + \int_{[\tau_a < \tau_a]} M(\tau) \, dP + \int_{[\tau_a = \tau_b] \cap [M^\tau > 0]} M(\infty) \, dP + \int_{[\tau_a = \tau_b] \cap [M^\tau = 0]} M(\infty) \, dP$$

(60.11.41)

The last term equals 0. By continuity, $M(\tau)$ is either equal to $a$ or $b$ depending on whether $\tau_a < \tau_b$ or $\tau_b < \tau_a$. Thus

$$0 = E(M(\tau)) = aP([\tau_a < \tau_b]) + bP([\tau_a = \tau_a]) + \int_{[\tau_a = \tau_b] \cap [M^\tau > 0]} M(\infty) \, dP$$

(60.11.42)

Consider this last term. By the definition, $[\tau_a = \tau_b]$ corresponds to $M(t)$ never hitting either $a$ or $b$. Since $M(0) = 0$, this can only happen if $M(t)$ has values in $[a, b]$. Therefore, this last term satisfies

$$aP([\tau_a = \tau_b] \cap [M^\tau > 0]) \leq \int_{[\tau_a = \tau_b] \cap [M^\tau > 0]} M(\infty) \, dP$$

$$\leq bP([\tau_a = \tau_b] \cap [M^\tau > 0])$$

(60.11.43)

It follows

$$aP([\tau_a = \tau_b] \cap [M^\tau > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_b < \tau_a]) \leq 0 \leq bP([\tau_a = \tau_b] \cap [M^\tau > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_b < \tau_a])$$

(60.11.44)
Note that $[\tau_b < \tau_a] \cup [\tau_a < \tau_b] \subseteq [M^* > 0]$ and so

$$[\tau_b < \tau_a] \cup [\tau_a < \tau_b] \cup ([\tau_a = \tau_b] \cap [M^* > 0]) = [M^* > 0] \tag{60.11.45}$$

The following diagram may help in keeping track of the various substitutions.

$$\begin{array}{c}
 [M^* > 0] \\
 [\tau_a < \tau_b] \\
 [\tau_b < \tau_a] \\
 [\tau_b = \tau_a] \cap [M^* > 0]
\end{array}$$

**Left side of 60.11.45**

From 60.11.45, this yields on substituting for $P([\tau_a < \tau_b])$

$$0 \geq aP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b] \cap [M^* > 0])
\geq bP([\tau_a < \tau_b])$$

and so since $[\tau_a \neq \tau_b] \subseteq [M^* > 0]$,

$$0 \geq a[P([M^* > 0]) - P([\tau_a > \tau_b])] + bP([\tau_a < \tau_b])$$

$$= -aP([M^* > 0]) \geq (b-a)P([\tau_b < \tau_a]) \tag{60.11.46}$$

Next use 60.11.45 to substitute for $P([\tau_b < \tau_a])$

$$0 \geq aP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_b < \tau_a])$$

$$= aP([\tau_a = \tau_b] \cap [M^* > 0]) + bP([\tau_a < \tau_b])
+ bP([M^* > 0]) - P([\tau_a \leq \tau_b] \cap [M^* > 0])$$

$$= aP([\tau_a \leq \tau_b] \cap [M^* > 0]) + bP([M^* > 0]) - P([\tau_a \leq \tau_b] \cap [M^* > 0])$$

and so

$$(b-a)P([\tau_a \leq \tau_b]) \geq bP([M^* > 0]) \tag{60.11.47}$$

**Right side of 60.11.45**

From 60.11.45, used to substitute for $P([\tau_a < \tau_b])$ this yields

$$0 \leq bP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_b < \tau_a])$$

$$= bP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([M^* > 0]) - P([\tau_a \geq \tau_b] \cap [M^* > 0])
+ bP([\tau_b < \tau_a])$$

$$= bP([\tau_a \geq \tau_b] \cap [M^* > 0]) + aP([M^* > 0]) - P([\tau_a \geq \tau_b] \cap [M^* > 0])$$

and so

$$(b-a)P([\tau_a \geq \tau_b]) \geq -aP([M^* > 0]) \tag{60.11.48}$$
Next use \( bP([\tau_b = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_a < \tau_a]) \)

\[
0 \leq bP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_a < \tau_a])
\]

\[
= bP([\tau_a = \tau_b] \cap [M^* > 0]) + aP([\tau_a < \tau_b]) + bP([\tau_a \leq \tau_b] \cap [M^* > 0])
\]

\[
= aP([\tau_a < \tau_b]) + bP([M^* > 0]) - bP([\tau_a < \tau_b] \cap [M^* > 0])
\]

\[
= aP([\tau_a < \tau_b]) + bP([M^* > 0]) - bP([\tau_a < \tau_b])
\]

and so

\[
(b - a)P([\tau_a < \tau_b]) \leq bP([M^* > 0])
\] (60.11.49)

Now the boxed in formulas in 60.11.46 - 60.11.49 yield the conclusion of the theorem. This proves the theorem.

Note \( P([\tau_a < \tau_b]) \) means \( M(t) \) hits \( a \) before it hits \( b \) with other occurrences of similar expressions being defined similarly.

### 60.12 The Space \( \mathcal{M}^p_T (E) \)

Here \( p \geq 1 \).

**Definition 60.12.1** Let \( M \) be an \( E \) valued martingale. Then \( M \in \mathcal{M}^p_T (E) \) if \( t \rightarrow M(t)(\omega) \) is continuous for a.e. \( \omega \) and

\[
E \left( \sup_{t \in [0,T]} ||M(t)||^p \right)^{1/p} < \infty
\]

Here \( E \) is a separable Banach space.

**Proposition 60.12.2** Define a norm on \( \mathcal{M}^p_T (E) \) by

\[
||M||_{\mathcal{M}^p_T (E)} \equiv E \left( \sup_{t \in [0,T]} ||M(t)||^p \right)^{1/p}
\]

Then with this norm, \( \mathcal{M}^p_T (E) \) is a Banach space.

**Proof:** First it is good to observe that \( \sup_{t \in [0,T]} ||M(t)||^p \) is measurable. This follows because of the continuity of \( t \rightarrow M(t) \). Let \( D \) be a dense countable set in \([0,T]\). Then by continuity,

\[
\sup_{t \in [0,T]} ||M(t)||^p = \sup_{t \in D} ||M(t)||^p
\]

and the expression on the right is measurable because \( D \) is countable.
Next it is necessary to show this is a norm. It is clear that
\[ ||M||_{\mathcal{M}_T^p(E)} \geq 0 \]
and equals 0 only if
\[ 0 = E \left( \sup_{t \in [0,T]} ||M(t)||^p \right) \]
which requires \( M(t) = 0 \) for all \( t \) for \( \omega \) off a set of measure zero so that \( M = 0 \). It is also clear that
\[ ||\alpha M||_{\mathcal{M}_T^p(E)} = ||\alpha|| \cdot ||M||_{\mathcal{M}_T^p(E)} \cdot \]
It remains to check the triangle inequality. Let \( M, N \in \mathcal{M}_T^p(E) \).
\[ ||M + N||_{\mathcal{M}_T^p(E)} = E \left( \sup_{t \in [0,T]} ||M(t) + N(t)||^p \right)^{1/p} \]
\[ \leq E \left( \sup_{t \in [0,T]} (||M(t)|| + ||N(t)||)^p \right)^{1/p} \]
\[ \leq E \left( \left( \sup_{t \in [0,T]} ||M(t)|| + \sup_{t \in [0,T]} ||N(t)|| \right)^p \right)^{1/p} \]
\[ = \left( \int_\Omega \left( \sup_{t \in [0,T]} ||M(t)|| + \sup_{t \in [0,T]} ||N(t)|| \right)^p \, dP \right)^{1/p} \]
\[ \leq \left( \int_\Omega \left( \sup_{t \in [0,T]} ||M(t)|| \right)^p \, dP \right)^{1/p} + \left( \int_\Omega \left( \sup_{t \in [0,T]} ||N(t)|| \right)^p \, dP \right)^{1/p} \]
\[ = ||M||_{\mathcal{M}_T^p(E)} + ||N||_{\mathcal{M}_T^p(E)} \]
Next consider the claim that \( \mathcal{M}_T^p(E) \) is a Banach space. Let \( \{M_n\} \) be a Cauchy sequence. Then
\[ E \left( \sup_{t \in [0,T]} ||M_n(t) - M_m(t)||^p \right) \to 0 \] (60.12.50)
as \( m, n \to \infty \). From continuity,
\[ \sup_{t \in [0,T]} ||M_n(t) - M_m(t)|| = \sup_{t \in (0,T)} ||M_n(t) - M_m(t)|| \]
Then from theorem 60.5.3 or 60.9.4
\[ P \left( \sup_{t \in [0,T]} ||M_n(t) - M_m(t)|| > \lambda \right) \leq \frac{1}{\lambda^p} E \left( ||M_n(T) - M_m(T)||^p \right) \]
Therefore, one can extract a subsequence \( \{ M_{n_k} \} \) such that

\[
P \left( \sup_{t \in [0,T]} \left| M_{n_k} (t) - M_{n_{k+1}} (t) \right| > 2^{-k} \right) \leq 2^{-k}.
\]

By the Borel Cantelli lemma, it follows \( \{ M_{n_k} (t) (\omega) \} \) converges uniformly on \([0, T]\) for a.e. \( \omega \). Denote by \( M (t) (\omega) \) the thing to which it converges, a continuous process because of the uniform convergence. Also, because it is the pointwise limit off a set of measure zero, \( \omega \to M (t) (\omega) \) is \( \mathcal{F}_t \) measurable. Also, from Proposition 60.12.50 and Fatou’s lemma

\[
\int \sup_{t \in [0,T]} \left| M_n (t) - M (t) \right|^p dP 
\leq \lim inf_{k \to \infty} \int \sup_{t \in [0,T]} \left| M_n (t) - M_{n_k} (t) \right|^p dP \leq \varepsilon
\]

whenever \( n \) is large enough, this from the assumption that \( \{ M_n \} \) is Cauchy. Thus

\[
\lim_{n \to \infty} E \left( \sup_{t \in [0,T]} \left| M_n (t) - M (t) \right|^p \right) = 0
\]

and so for each \( t, M_n (t) \to M (t) \) in \( L^p (\Omega) \). This also shows that for large, \( n \)

\[
E \left( \sup_{t \in [0,T]} \left| M (t) \right|^p \right) \leq E \left( \sup_{t \in [0,T]} \left( \left| M (t) - M_n (t) \right| + \left| M_n (t) \right| \right)^p \right)
\]

\[
\leq 2^{p-1} E \left( \sup_{t \in [0,T]} \left| M (t) - M_n (t) \right|^p + \sup_{t \in [0,T]} \left( \left| M_n (t) \right| \right)^p \right) < \infty
\]

It only remains to verify \( M \) is a martingale. Let \( s \leq t \) and let \( B \in \mathcal{F}_s \). For each \( s \), \( M_n (s) \to M (s) \) in \( L^p (\Omega) \). Then from the above, \( \omega \to M (s) (\omega) \) is \( \mathcal{F}_s \) measurable. Then it follows that

\[
\int_B M (s) dP = \lim_{n \to \infty} \int_B M_n (s) dP = \lim_{n \to \infty} \int_B E (M_n (t) | \mathcal{F}_s) dP
\]

\[
= \lim_{n \to \infty} \int_B M_n (t) dP = \int_B M (t) dP
\]

and so by definition, \( E (M (t) | \mathcal{F}_s) = M (s) \) which shows \( M \) is a martingale. \( \blacksquare \)

**Proposition 60.12.3** The functions \( M (t) \) for each \( M \in \mathcal{M}_T^p (E) \) are equi integrable.

**Proof:** This follows because

\[
\int_{\{ ||M(t)|| \geq \lambda \}} ||M (t)||^p dP \leq \int_{\{ \sup_{t \in [0,T]} ||M(t)|| \geq \lambda \}} \left( \sup_{t \in [0,T]} ||M (t)||^p \right) dP \quad (60.12.51)
\]
which converges to 0 due to the definition of $\mathcal{M}_T^p(E)$ which requires that

$$\sup_{t \in [0, T]} \| M(t) \|^p \in L^1(\Omega, \mathcal{F}, P).$$

Since the sets $\left[ \sup_{t \in [0, T]} \| M(t) \| \geq \lambda \right]$ decrease to $\emptyset$ as $\lambda \to \infty$, the dominated convergence theorem implies the integral on the right in [60.12.51] converges to 0. ☐
Chapter 61

The Quadratic Variation Of A Martingale

61.1 How To Recognize A Martingale

The main ideas are most easily understood in the special case where it is assumed the martingale is bounded. Then one can extend to more general situations.

Let \( \{M(t)\} \) be a continuous martingale having values in a separable Hilbert space. The idea is to consider the submartingale, \( \{||M(t)||^2\} \) and write it as the sum of a martingale and a submartingale. An important part of the argument is the following lemma which gives a checkable criterion for a stochastic process to be a martingale.

**Lemma 61.1.1** Let \( \{X(t)\} \) be a stochastic process adapted to the filtration \( \mathcal{F}_t \) for \( t \geq 0 \). Then it is a martingale for the given filtration if for every stopping time \( \sigma \) it follows

\[
E(X(t)) = E(X(\sigma)).
\]

In fact, it suffices to check this on stopping times which have two values.

**Proof:** Let \( s < t \) and \( A \in \mathcal{F}_s \). Define a stopping time

\[
\sigma(\omega) \equiv s\chi_A(\omega) + t\chi_{A^c}(\omega)
\]

This is a stopping time because \( [\sigma \leq l] = \Omega \) if \( l \geq t \). Also \( [\sigma \leq l] = A \in \mathcal{F}_s \) if \( l \in [s, t) \) and \( [\sigma \leq l] = \emptyset \) if \( l < s \). Then by assumption,

\[
\int_A X(t) \, dP + \int_{A^c} X(t) \, dP = \int_X X(s) \, dP + \int_{A^c} X(t) \, dP
\]

by assumption

\[
\int X(t) \, dP = \int X(\sigma) \, dP = \int_A X(s) \, dP + \int_{A^c} X(t) \, dP
\]

2163
Therefore, \[
\int_A X(t) \, dP = \int_A X(s) \, dP
\]
and since \(X(s)\) is \(\mathcal{F}_s\) measurable, it follows \(E(X(t) | \mathcal{F}_s) = X(s)\) a.e. and this shows \(\{X(t)\}\) is a martingale. ■

Note that if \(t \in [0, T]\), it suffices to check the expectation condition for stopping times which have two values no larger than \(T\).

The following lemma will be useful.

**Lemma 61.1.2** Suppose \(X_n \to X\) in \(L^1(\Omega, \mathcal{F}, P; E)\) where \(E\) is a separable Banach space. Then letting \(\mathcal{G}\) be a \(\sigma\) algebra contained in \(\mathcal{F}\),

\[
E(X_n | \mathcal{G}) \to E(X | \mathcal{G})
\]
in \(L^1(\Omega)\).

**Proof:** This follows from the definitions and Theorem 59.1.1 on Page 2029.

\[
\int_\Omega ||E(X | \mathcal{G}) - E(X_n | \mathcal{G})|| \, dP = \int_\Omega ||E(X_n - X | \mathcal{G})|| \, dP \\
\leq \int_\Omega E(||X_n - X|| | \mathcal{G}) \, dP \\
= \int_\Omega ||X_n - X|| \, dP \quad \blacksquare
\]

**Corollary 61.1.3** Let \(X, Y\) be in \(L^2(\Omega, \mathcal{F}, P; H)\) where \(H\) is a separable Hilbert space and let \(X\) be \(\mathcal{G}\) measurable where \(\mathcal{G} \subseteq \mathcal{F}\). Then

\[
E((X, Y) | \mathcal{G}) = (X, E(Y | \mathcal{G})) \quad \text{a.e.}
\]

**Proof:** First let \(X = a \chi_B\) where \(B \in \mathcal{G}\). Then for \(A \in \mathcal{G}\),

\[
\int_A E((a \chi_B, Y) | \mathcal{G}) \, dP = \int_A \chi_B E((a, Y) | \mathcal{G}) \, dP = \int_A \chi_B (a, Y) \, dP = \int_{A \cap B} (a, Y) \, dP = \left( a, \int_{A \cap B} Y \, dP \right)
\]

\[
\int_A (a \chi_B, E(Y | \mathcal{G})) \, dP = \int_A \chi_B (a, E(Y | \mathcal{G})) \, dP = \left( a, \int_A \chi_B E(Y | \mathcal{G}) \, dP \right) = \left( a, \int_{A \cap B} Y \, dP \right)
\]

It follows that the formula holds for \(X\) simple.

Therefore, letting \(X_n\) be a sequence of \(\mathcal{G}\) measurable simple functions converging pointwise to \(X\) and also in \(L^2(\Omega)\),

\[
E((X_n, Y) | \mathcal{G}) = (X_n, E(Y | \mathcal{G}))
\]
Now the desired formula holds from Lemma \ref{lemma:desired_formula}. The following is related to something called a martingale transform. It is a lot like what will happen later with the Ito integral.

**Proposition 61.1.4** Let \( \{\tau_k\} \) be an increasing sequence of stopping times for the normal filtration \( \{\mathcal{F}_t\} \) such that

\[
\lim_{k \to \infty} \tau_k = \infty, \quad \tau_0 = 0.
\]

Also let \( \xi_k \) be \( \mathcal{F}_{\tau_k} \) measurable with values in \( H \), a separable Hilbert space and let \( M(t) \) be a right continuous martingale adapted to the normal filtration \( \mathcal{F}_t \) which has the property that \( M(t) \in L^2(\Omega; H) \) for all \( t, M(0) = 0 \). Then if \( |\xi_k| \leq C \),

\[
E \left( \left( \sum_{k \geq 0} \left( \xi_k, (M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t)) \right) \right)^2 \right) \leq C^2 E \left( ||M(t)||^2 \right)
\]

(61.1.1)

**Proof:** First of all, the sum converges because eventually \( \tau_k \wedge t = t \). Therefore, for large enough \( k \), \( M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t) \equiv \Delta M_k = 0 \). Consider first the finite sum, \( k \leq q \).

\[
E \left( \left( \sum_{k=0}^{q} (\xi_k, \Delta M_k) \right)^2 \right)
\]

(61.1.2)

When the sum is multiplied out, you get mixed terms. Consider one of these mixed terms, \( j < k \)

\[
E \left( (\xi_k, \Delta M_k)(\xi_j, \Delta M_j) \right)
\]

Using Corollary \ref{corollary:martingale_transform} and Doob’s optional sampling theorem, Theorem \ref{theorem:optionalsampling}, this equals

\[
E \left( E \left( (\xi_k, \Delta M_k)(\xi_j, \Delta M_j)|\mathcal{F}_{\tau_k} \right) \right) = E \left( (\xi_k, \Delta M_k)E \left( (\xi_j, \Delta M_j)|\mathcal{F}_{\tau_k} \right) \right)
\]

\[
= E \left( (\xi_j, \Delta M_j)(\xi_k,E \left( M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t)|\mathcal{F}_{\tau_k} \right)) \right) = E \left( (\xi_j, \Delta M_j)(\xi_k,0) \right) = 0
\]

Note that in using the optional sampling theorem, the stopping time \( \tau_{k+1} \wedge t \) is bounded.

Therefore, the only terms which survive are the non mixed terms and so this expression reduces to

\[
\sum_{k=0}^{q} E \left( (\xi_k, \Delta M_k)^2 \right) \leq C^2 \sum_{k=0}^{q} E \left( ||\Delta M_k||^2 \right)
\]

\[
= C^2 \sum_{k=0}^{q} E \left( ||M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t)||^2 \right)
\]
\[ C^2 \sum_{k=0}^{q} E \left( \|M(\tau_{k+1} \wedge t)\|^2 \right) + E \left( \|M(\tau_k \wedge t)\|^2 \right) - 2E (\langle M(\tau_k \wedge t), M(\tau_{k+1} \wedge t) \rangle) \]  
\hspace*{1cm} (61.1.3)

Consider the term \( E (\langle M(\tau_k \wedge t), M(\tau_{k+1} \wedge t) \rangle) \). By Doob’s optional sampling theorem for martingales and Corollary 61.1.3 again, this equals

\[ E \left( E \left( \langle M(\tau_k \wedge t), M(\tau_{k+1} \wedge t) \rangle | \mathcal{F}_{\tau_k} \right) \right) = E \left( \langle M(\tau_k \wedge t), E(M(\tau_{k+1} \wedge t) | \mathcal{F}_{\tau_k}) \rangle \right) = E \left( \langle M(\tau_k \wedge t), M(\tau_{k+1} \wedge t \wedge \tau_k) \rangle \right) = E \left( \|M(\tau_k \wedge t)\|^2 \right) \]

It follows equals

\[ C^2 \sum_{k=0}^{q} E \left( \|M(\tau_{k+1} \wedge t)\|^2 \right) - E \left( \|M(\tau_k \wedge t)\|^2 \right) \leq C^2 E \left( \|M(t)\|^2 \right). \]

Then from Fatou’s lemma,

\[ E \left( \left( \sum_{k \geq 0} (\xi_k, (M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t))) \right)^2 \right) \leq \lim \inf_{q \to \infty} E \left( \left( \sum_{k=0}^{q} (\xi_k, (M(\tau_{k+1} \wedge t) - M(\tau_k \wedge t))) \right)^2 \right) \leq C^2 E \left( \|M(t)\|^2 \right) \]

Now here is an interesting lemma which will be used to prove uniqueness in the main result.

**Lemma 61.1.5** Let \( \mathcal{F}_t \) be a normal filtration and let \( A(t), B(t) \) be adapted to \( \mathcal{F}_t \), continuous, and increasing with \( A(0) = B(0) = 0 \) and suppose \( A(t) - B(t) \) is a martingale. Then \( A(t) - B(t) = 0 \) for all \( t \).

**Proof:** I shall show \( A(l) = B(l) \) where \( l \) is arbitrary. Let \( M(t) \) be the name of the martingale. Define a stopping time

\[ \tau \equiv \inf \left\{ t > 0 : |M(t)| > C \right\} \wedge l \wedge \inf \left\{ t > 0 : A(t) > C \right\} \wedge \inf \left\{ t > 0 : B(t) > C \right\} \]

where \( \inf(\emptyset) \equiv \infty \) and denote the stopped martingale

\[ M^\tau(t) \equiv M(t \wedge \tau). \]
Then I claim this is also a martingale with respect to the filtration $\mathcal{F}_t$ because by Doob’s optional sampling theorem for martingales, if $s < t,$

$$E (M^\tau (t) | \mathcal{F}_s) = E (M (\tau \wedge t) | \mathcal{F}_s) = M (\tau \wedge t \wedge s) = M (\tau \wedge s) = M^\tau (s)$$

Note the bounded stopping time is $\tau \wedge t$ and the other one is $\sigma = s$ in this theorem. Then $M^\tau$ is a continuous martingale which is also uniformly bounded. It equals $A^\tau - B^\tau$. The stopping time ensures $A^\tau$ and $B^\tau$ are uniformly bounded by $C$. Thus all of $|M^\tau (t)|, B^\tau (t), A^\tau (t)$ are bounded by $C$ on $[0, l]$. Now let $\mathcal{P}_n = \{t_k\}_{k=1}^n$ be a uniform partition of $[0, l]$ and let $M^\tau (\mathcal{P}_n)$ denote

$$M^\tau (\mathcal{P}_n) = \max \{|M^\tau (t_{i+1}) - M^\tau (t_i)|\}_{i=1}^n.$$  

Then

$$E \left( M^\tau (l)^2 \right) = E \left( \left( \sum_{k=0}^{n-1} M^\tau (t_{k+1}) - M^\tau (t_k) \right)^2 \right)$$

Now consider a mixed term in the sum where $j < k$.

$$E ((M^\tau (t_{k+1}) - M^\tau (t_k)) (M^\tau (t_{j+1}) - M^\tau (t_j)))$$

$$= E (E ((M^\tau (t_{k+1}) - M^\tau (t_k)) (M^\tau (t_{j+1}) - M^\tau (t_j)) | \mathcal{F}_{t_k}))$$

$$= E ((M^\tau (t_{j+1}) - M^\tau (t_j)) E ((M^\tau (t_{k+1}) - M^\tau (t_k)) | \mathcal{F}_{t_k}))$$

$$= E ((M^\tau (t_{j+1}) - M^\tau (t_j)) (M^\tau (t_k) - M^\tau (t_h))) = 0$$

It follows

$$E \left( M^\tau (l)^2 \right) \leq E \left( \sum_{k=0}^{n-1} (M^\tau (t_{k+1}) - M^\tau (t_k))^2 \right)$$

$$\leq E \left( \sum_{k=0}^{n-1} M^\tau (\mathcal{P}_n) |M^\tau (t_{k+1}) - M^\tau (t_k)| \right)$$

$$\leq E \left( \sum_{k=0}^{n-1} M^\tau (\mathcal{P}_n) (|A^\tau (t_{k+1}) - A^\tau (t_k)| + |B^\tau (t_{k+1}) - B^\tau (t_k)|) \right)$$

$$\leq E \left( M^\tau (\mathcal{P}_n) \sum_{k=0}^{n-1} (|A^\tau (t_{k+1}) - A^\tau (t_k)| + |B^\tau (t_{k+1}) - B^\tau (t_k)|) \right)$$

$$\leq E (M^\tau (\mathcal{P}_n) 2C)$$

the last step holding because $A$ and $B$ are increasing. Now letting $n \to \infty$, the right side converges to 0 by the dominated convergence theorem and the observation that for a.e. $\omega$, 

$$\lim_{n \to \infty} M^\tau (\mathcal{P}_n) (\omega) = 0$$
because of continuity of $M$. Thus for $\tau = \tau_C$ given above,

$$M (l \land \tau_C) = 0 \text{ a.e.}$$

Now let $C \in \mathbb{N}$ and let $N_C$ be the exceptional set off which $M (l \land \tau_C) = 0$. Then letting $N_1$ denote the union of all these exceptional sets for $C \in \mathbb{N}$, it is also a set of measure zero and for $\omega$ not in this set, $M (l \land \tau_C) = 0$ for all $C$. Since the martingale is continuous, it follows for each such $\omega$, eventually $\tau_C > l$ and so $M (l) = 0$. Thus for $\omega \notin N_1$,

$$M (l) (\omega) = 0$$

Now let $N = \cup_{l \in \mathbb{Q} \cap [0, \infty)} N_l$. Then for $\omega \notin N, M (l) (\omega) = 0$ for all $l \in \mathbb{Q} \cap [0, \infty)$ and so by continuity, this is true for all positive $l$. ■

Note this shows a continuous martingale is not of bounded variation unless it is a constant.

### 61.2 The Quadratic Variation

This section is on the quadratic variation of a martingale. Actually, you can also consider the quadratic variation of a local martingale which is more general. Therefore, this concept is defined first. We will generally assume $M (0) = 0$ since there is no real loss of generality in doing so. One can simply subtract $M (0)$ otherwise.

**Definition 61.2.1** Let $\{M (t)\}$ be adapted to the normal filtration $\mathcal{F}_t$ for $t > 0$. Then $\{M (t)\}$ is a local martingale (submartingale) if there exist stopping times $\tau_n$ increasing to infinity such that for each $n$, the process $M^\tau_n (t) \equiv M (t \land \tau_n)$ is a martingale (submartingale) with respect to the given filtration. The sequence of stopping times is called a localizing sequence. The martingale $M^\tau_n$ is called the stopped martingale. Exactly the same convention applies to a localized submartingale.

**Proposition 61.2.2** If $M (t)$ is a continuous local martingale (submartingale) for a normal filtration as above, $M (0) = 0$, then there exists a localizing sequence $\tau_n$ such that for each $n$ the stopped martingale(submartingale) $M^\tau_n$ is uniformly bounded. Also if $M$ is a martingale, then $M^\tau$ is also a martingale (submartingale). If $\tau_n$ is an increasing sequence of stopping times such that $\lim_{n \to \infty} \tau_n = \infty$, and for each $\tau_n$ and real valued stopping time $\delta$, there exists a function $X$ of $\tau_n \land \delta$ such that $X (\tau_n \land \delta)$ is $\mathcal{F}_{\tau_n \land \delta}$ measurable, then $\lim_{n \to \infty} X (\tau_n \land \delta) \equiv X (\delta)$ exists for each $\omega$ and $X (\delta)$ is $\mathcal{F}_\delta$ measurable.

**Proof:** First consider the claim about $M^\tau$ being a martingale (submartingale) when $M$ is. By optional sampling theorem,

$$E (M^\tau (t) | \mathcal{F}_s) = E (M (t \land \tau) | \mathcal{F}_s) = M (\tau \land t \land s) = M^\tau (s).$$

The case where $M$ is a submartingale is similar.

Next suppose $\sigma_n$ is a localizing sequence for the local martingale(submartingale) $M$. Then define

$$\eta_n \equiv \inf \{t > 0 : ||M (t)|| > n\}.$$
61.2. THE QUADRATIC VARIATION

Therefore, by continuity of \( M \), \( ||M (\eta_n)|| \leq n \). Now consider \( \tau_n \equiv \eta_n \land \sigma_n \). This is an increasing sequence of stopping times. By continuity of \( M \), it must be the case that \( \eta_n \to \infty \). Hence \( \sigma_n \land \eta_n \to \infty \).

Finally, consider the last claim. Pick \( \omega \). Then \( X (\tau_n (\omega) \land \delta (\omega)) (\omega) \) is eventually constant as \( n \to \infty \) because for all \( n \) large enough, \( \tau_n (\omega) > \delta (\omega) \) and so this sequence of functions converges pointwise. That which it converges to, denoted by \( X (\delta) \), is \( \mathcal{F}_\delta \) measurable because each function \( \omega \to X (\tau_n (\omega) \land \delta (\omega)) (\omega) \) is \( \mathcal{F}_{\delta \land \tau_n} \subseteq \mathcal{F}_\delta \) measurable. ■

One can also give a generalization of Lemma 61.2.4 to conclude a local martingale must be constant or else they must fail to be of bounded variation.

**Corollary 61.2.3** Let \( \mathcal{F}_t \) be a normal filtration and let \( A (t) \), \( B (t) \) be adapted to \( \mathcal{F}_t \), continuous, and increasing with \( A (0) = B (0) = 0 \) and suppose \( A (t) - B (t) \equiv M (t) \) is a local martingale. Then \( M (t) = A (t) - B (t) = 0 \) a.e. for all \( t \).

**Proof:** Let \( \{ \tau_n \} \) be a localizing sequence for \( M \). For given \( n \), consider the martingale,

\[
M^{\tau_n} (t) = A^{\tau_n} (t) - B^{\tau_n} (t)
\]

Then from Lemma 61.2.3, it follows \( M^{\tau_n} (t) = 0 \) for all \( t \) for all \( \omega \notin N_n \), a set of measure 0. Let \( N = \bigcup_n N_n \). Then for \( \omega \notin N \), \( M (\tau_n (\omega) \land t) (\omega) = 0 \). Let \( n \to \infty \) to conclude that \( M (t) (\omega) = 0 \). Therefore, \( M (t) (\omega) = 0 \) for all \( t \). ■

Recall Example 60.7.6 on Page 2432. For convenience, here is a version of what it says.

**Lemma 61.2.4** Let \( X (t) \) be continuous and adapted to a normal filtration \( \mathcal{F}_t \) and let \( \eta \) be a stopping time. Then if \( K \) is a closed set with \( 0 \notin K \),

\[
\tau \equiv \inf \{ t > \eta : X (t) \in K \}
\]

is also a stopping time.

**Proof:** First consider \( Y (t) = X (t \lor \eta) - X (\eta) \). I claim that \( Y (t) \) is adapted to \( \mathcal{F}_t \). Consider \( U \) and open set and \( [Y (t) \in U] \). Is it in \( \mathcal{F}_t \)? We know it is in \( \mathcal{F}_{t \lor \eta} \). It equals \( ([Y (t) \in U] \cap [\eta \leq t]) \cup ([Y (t) \in U] \cap [\eta > t]) \). Consider the second of these sets. It equals \( ([X (\eta) - X (\eta) \in U] \cap [\eta > t]) \). If \( 0 \in U \), then it reduces to \( [\eta > t] \in \mathcal{F}_t \). If \( 0 \notin U \), then it reduces to \( \emptyset \) still in \( \mathcal{F}_t \).

Next consider the first set. It equals \( [X (t \lor \eta) - X (\eta) \in U] \cap [\eta \leq t] \) and so when this is intersected with \( [t \lor \eta \leq t] \) one obtains a set in \( \mathcal{F}_t \). This is what it means to be in \( \mathcal{F}_{t \lor \eta} \). Now \( \tau \) is just the first hitting time of \( Y (t) \) of the closed set. ■
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

Proposition 61.2.5 Let \( M(t) \) be a continuous local martingale for \( t \in [0,T] \) having values in \( H \) a separable Hilbert space adapted to the normal filtration \( \{ \mathcal{F}_t \} \) such that \( M(0) = 0 \). Then there exists a unique continuous, increasing, nonnegative, local submartingale \([M](t)\) called the quadratic variation such that

\[
\|M(t)\|^2 - [M](t)
\]

is a real local martingale and \([M](0) = 0\). Here \( t \in [0,T] \). If \( \delta \) is any stopping time

\[
[M] = [M]_{\delta}
\]

Proof: First it is necessary to define some stopping times. Define stopping times \( \eta_{k+1}^n = \inf \{ s > \eta_k^n : \|M(s) - M(\eta_k^n)\| = 2^{-n} \} \),

\[
\tau_k^n = \eta_k^n \land T
\]

where \( \inf \emptyset = \infty \). These are stopping times by Example 60.7.7 on Page 2132. See also Lemma 61.2.4. Then for \( t > 0 \) and \( \delta \) any stopping time, and fixed \( \omega \), for some \( k \),

\[
t \land \delta \in I_k(\omega), \ I_0(\omega) = [\tau_0^n(\omega), \tau_1^n(\omega)], \ I_k(\omega) = (\tau_k^n(\omega), \tau_{k+1}^n(\omega)) \text{ some } k
\]

Here is why. The sequence \( \{\tau_k^n(\omega)\}_{k=1}^\infty \) eventually equals \( T \) for all \( n \) sufficiently large. This is because if it did not, it would converge, being bounded above by \( T \) and then by continuity of \( M \), \( \{M(\tau_k^n(\omega))\}_{k=1}^\infty \) would be a Cauchy sequence contrary to the requirement that

\[
\|M(\tau_{k+1}^n(\omega)) - M(\tau_k^n(\omega))\| = \|M(\eta_{k+1}^n(\omega)) - M(\eta_k^n(\omega))\| = 2^{-n}.
\]

Note that if \( \delta \) is any stopping time, then

\[
\|M(t \land \delta \land \tau_{k+1}^n) - M(t \land \delta \land \tau_k^n)\| = \|M^\delta(t \land \tau_{k+1}^n) - M^\delta(t \land \tau_k^n)\| \leq 2^{-n}
\]

You can see this is the case by considering the cases, \( t \land \delta \geq \tau_{k+1}^n, t \land \delta \in [\tau_k^n, \tau_{k+1}^n) \), and \( t \land \delta < \tau_k^n \). It is only this approximation property and the fact that the \( \tau_k^n \) partition \([0,T]\) which is important in the following argument.

Now let \( \alpha_n \) be a localizing sequence such that \( M^{\alpha_n} \) is bounded as in Proposition 61.2.4. Thus \( M^{\alpha_n}(t) \in L^2(\Omega) \) and this is all that is needed. In what follows, let \( \delta \) be a stopping time and denote \( M^{\delta \land} \) by \( M \) to save notation. Thus \( M \) will be uniformly bounded and from the definition of the stopping times \( \tau_k^n \), for \( t \in [0,T] \),

\[
M(t) = \sum_{k \geq 0} M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n), \quad (61.2.4)
\]
and the terms of the series are eventually 0, as soon as \( \eta_k^n = \infty \).

Therefore,

\[
\| M(t) \|^2 = \left\| \sum_{k \geq 0} M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n) \right\|^2
\]

Then this equals

\[
= \sum_{k \geq 0} \left\| M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n) \right\|^2
+ \sum_{j \neq k} \left( (M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n), M(t \land \tau_{j+1}^n) - M(t \land \tau_j^n)) \right) \quad (61.2.5)
\]

Consider the second sum. It equals

\[
2 \sum_{k \geq 0} \sum_{j=0}^{k-1} \left( (M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n), M(t \land \tau_{j+1}^n) - M(t \land \tau_j^n)) \right)
\]

This last sum equals \( P_n(t) \) defined as

\[
2 \sum_{k \geq 0} \left( (M(t \land \tau_k^n), M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n)) \right) \equiv P_n(t) \quad (61.2.6)
\]

This is because in the \( k^{th} \) term, if \( t \geq \tau_k^n \), then it reduces to

\[
(M(t \land \tau_k^n), (M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n))
\]

while if \( t < \tau_k^n \), then the term reduces to 0 which is also the same as

\[
(M(t \land \tau_k^n), (M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n))
\]

This is a finite sum because eventually, for large enough \( k \), \( \tau_k^n = T \). However the number of nonzero terms depends on \( \omega \). This is not a good thing. However, a little more can be said. In fact the sum also converges in \( L^2(\Omega) \). Say \( \| M(t, \omega) \| \leq C \).

\[
E \left( \left( \sum_{k \geq p} (M(t \land \tau_k^n), (M(t \land \tau_{k+1}^n) - M(t \land \tau_k^n)) \right)^2 \right)
\]
\[
= \sum_{k \geq p}^q E \left( \left( M (\tau_k^n), (M (t \land \tau_{k+1}^n) - M (t \land \tau_k^n))^2 \right) \right) + \text{mixed terms (61.2.7)}
\]

Consider one of these mixed terms for \( j < k \):

\[
E \left( \left( \left( \left( M \left( \tau_j^n \right), \left( M (t \land \tau_{j+1}^n) - M (t \land \tau_j^n) \right) \right) \right) \right) \right).
\]

Then it equals

\[
E \left( E \left( \left( M \left( \tau_j^n \right), \left( M (t \land \tau_{j+1}^n) - M (t \land \tau_j^n) \right) \right) \right) \right) \cdot E \left( \left( \left( M \left( \tau_k^n \right), \left( M (t \land \tau_{k+1}^n) - M (t \land \tau_k^n) \right) \right) \right) \right).
\]

Now since the mixed terms equal 0, it follows from (61.2.7), that expression is dominated by

\[
C^2 \sum_{k \geq p}^q E \left( |M (t \land \tau_{k+1}^n) - M (t \land \tau_k^n)|^2 \right)
\]

Using a similar manipulation to what was just done to show the mixed terms equal 0, this equals

\[
C^2 \sum_{k = p}^q E \left( |M (t \land \tau_{k+1}^n)|^2 - E \left( |M (t \land \tau_k^n)|^2 \right) \right) \leq C^2 E \left( |M (t \land \tau_{q+1}^n)|^2 - |M (t \land \tau_p^n)|^2 \right)
\]

The integrand converges to 0 as \( p, q \to \infty \) and the uniform bound on \( M \) allows a use of the dominated convergence theorem. Thus the partial sums of the series of

\[
\text{61.2.6}
\]

converge in \( L^2 (\Omega) \) as claimed.

By adding in the values of \( \{\tau_{k+1}^n\} \), \( P_n (t) \) can be written in the form

\[
2 \sum_{k \geq 0} (M (\tau_{k+1}^{n+1}), (M (t \land \tau_{k+1}^{n+1}) - M (t \land \tau_k^{n+1}))
\]

where \( \tau_{k+1}^{n+1} \) has some repeats. From the construction,

\[
|M (\tau_{k+1}^{n+1}) - M (\tau_k^{n+1})| \leq 2^{-(n+1)}
\]

Thus

\[
P_n (t) - P_{n+1} (t) = 2 \sum_{k \geq 0} (M (\tau_{k+1}^{n+1}) - M (\tau_k^{n+1}), (M (t \land \tau_{k+1}^{n+1}) - M (t \land \tau_k^{n+1}))
\]
and so from Proposition 61.1.4 applied to $\xi_k \equiv M (\tau^{n+1}_k) - M (\tau^{n+1}_k)$,

$$E \left( \| P_n (t) - P_{n+1} (t) \|^2 \right) \leq 2^{-2n} E \left( \| M (t) \|^2 \right), \quad (61.2.8)$$

Now $t \to P_n (t)$ is continuous because it is a finite sum of continuous functions. It is also the case that $\{P_n (t)\}$ is a martingale. To see this use Lemma 61.1.1. Let $\sigma$ be a stopping time having two values. Then using Corollary 61.1.3 and the Doob optional sampling theorem, Theorem 60.7.11

$$E \left( \sum_{k=0}^q (M (\tau^n_k), (M (\sigma \land \tau^n_{k+1}) - M (\sigma \land \tau^n_k))) \right)$$

$$= \sum_{k=0}^q E \left( E (M (\tau^n_k), (M (\sigma \land \tau^n_{k+1}) - M (\sigma \land \tau^n_k))) | \mathcal{F}_{\tau^n_k} \right)$$

$$= \sum_{k=0}^q E \left( (M (\tau^n_k), E (M (\sigma \land \tau^n_{k+1}) - M (\sigma \land \tau^n_k))) | \mathcal{F}_{\tau^n_k} \right)$$

$$= \sum_{k=0}^q E \left( (M (\tau^n_k), E (M (\sigma \land \tau^n_{k+1} \land \tau^n_k) - M (\sigma \land \tau^n_k))) \right) = 0$$

Note the Doob theorem applies because $\sigma \land \tau^n_{k+1}$ is a bounded stopping time due to the fact $\sigma$ has only two values. Similarly

$$E \left( \sum_{k=0}^q (M (\tau^n_k), (M (t \land \tau^n_{k+1}) - M (t \land \tau^n_k))) \right)$$

$$= \sum_{k=0}^q E \left( E (M (\tau^n_k), (M (t \land \tau^n_{k+1}) - M (t \land \tau^n_k))) | \mathcal{F}_{\tau^n_k} \right)$$

$$= \sum_{k=0}^q E \left( (M (\tau^n_k), E (M (t \land \tau^n_{k+1}) - M (t \land \tau^n_k))) | \mathcal{F}_{\tau^n_k} \right)$$

$$= \sum_{k=0}^q E \left( (M (\tau^n_k), E (M (t \land \tau^n_{k+1} \land \tau^n_k) - M (t \land \tau^n_k))) \right) = 0$$

It follows each partial sum for $P_n (t)$ is a martingale. As shown above, these partial sums converge in $L^2 (\Omega)$ and so it follows that $P_n (t)$ is also a martingale. Note the Doob theorem applies because $t \land \tau^n_{k+1}$ is a bounded stopping time.
I want to argue that \( P_n \) is a Cauchy sequence in \( \mathcal{M}^2_T(\mathbb{R}) \). By Theorem [11.2.8] and continuity of \( P_n \)

\[
E \left( \left( \sup_{t \leq T} |P_n(t) - P_{n+1}(t)| \right)^2 \right)^{1/2} \leq 2 E \left( |P_n(T) - P_{n+1}(T)|^2 \right)^{1/2}
\]

By [11.2.8]

\[
\leq 2^{-n} E \left( |M(T)|^2 \right)^{1/2}
\]

which shows \( \{P_n\} \) is indeed a Cauchy sequence in \( \mathcal{M}^2_T(\mathbb{R}) \).

Therefore, by Proposition [11.2.9], there exists \( \{N(t)\} \in \mathcal{M}^2_T(\mathbb{R}) \) such that \( P_n \to N \) in \( \mathcal{M}^2_T(H) \). That is

\[
\lim_{n \to \infty} E \left( \sup_{t \in [0,T]} |P_n(t) - N(t)|^2 \right)^{1/2} = 0.
\]

Since \( \{N(t)\} \in \mathcal{M}^2_T(\mathbb{R}) \), it is a continuous martingale and \( N(t) \in L^2(\Omega) \), and \( N(0) = 0 \) because this is true of each \( P_n(0) \). From the above [11.2.9]

\[
||M(t)||^2 = Q_n(t) + P_n(t) \quad (61.2.9)
\]

where

\[
Q_n(t) = \sum_{k \geq 0} ||M(t \wedge \tau^n_{k+1}) - M(t \wedge \tau^n_k)||^2
\]

and \( P_n(t) \) is a martingale. Then from [11.2.9], \( Q_n(t) \) is a submartingale and converges for each \( t \) to something, denoted as \( [M](t) \) in \( L^1(\Omega) \) uniformly in \( t \in [0,T] \). This is because \( P_n(t) \) converges uniformly on \([0,T] \) to \( N(t) \) in \( L^2(\Omega) \) and \( ||M(t)||^2 \) does not depend on \( n \). Then also \( [M] \) is a submartingale which equals 0 at 0 because this is true of \( Q_n \) and because if \( A \in \mathcal{F}_s \) where \( s < t \),

\[
\int_A E ([M](t) | \mathcal{F}_s) \, dP \equiv \int_A [M](t) \, dP = \lim_{n \to \infty} \int_A (||M(t)||^2 - P_n(t)) \, dP
\]

\[
= \lim_{n \to \infty} \int_A E (||M(t)||^2 - P_n(t) | \mathcal{F}_s) \, dP \geq \lim_{n \to \infty} \int_A ||M(s)||^2 - P_n(s) \, dP
\]

\[
= \lim_{n \to \infty} \int_A Q_n(s) \, dP = \int_A [M](s) \, dP.
\]

Note that \( Q_n(t) \) is increasing because as \( t \) increases, the definition allows for the possibility of more nonzero terms in the sum. Therefore, \( [M](t) \) is also increasing in \( t \). The function \( t \to [M](t) \) is continuous because \( ||M(t)||^2 = [M](t) + N(t) \) and \( t \to N(t) \) is continuous as is \( t \to ||M(t)||^2 \). That is, off a set of measure zero, these are both continuous functions of \( t \) and so the same is true of \( [M] \).

Now put back in \( M^{\alpha_p \wedge \delta} \) in place of \( M \). From the above, this has shown

\[
||M^{\alpha_p \wedge \delta}(t)||^2 = [M^{\alpha_p \wedge \delta}](t) + N_p(t)
\]
where $N_p$ is a martingale and
\[
\left[ M^{\alpha_p \wedge \delta} \right] (t) = \lim_{n \to \infty} \sum_{k \geq 0} \left| M^{\alpha_p \wedge \delta} (t \wedge \tau^n_{k+1}) - M^{\alpha_p \wedge \delta} (t \wedge \tau^n_k) \right|^2 \\
= \lim_{n \to \infty} \sum_{k \geq 0} \left| M (t \wedge \tau^n_{k+1} \wedge \alpha_p \wedge \delta) - M (t \wedge \tau^n_k \wedge \alpha_p \wedge \delta) \right|^2 \quad \text{in } L^1(\Omega), \quad (61.2.10)
\]
the convergence being uniform on $[0, T]$. The above formula shows that $\left[ M^{\alpha_p \wedge \delta} \right] (t)$ is a $\mathcal{F}_{t \wedge \delta \wedge \alpha_p}$ measurable random variable which depends on $t \wedge \delta \wedge \alpha_p$ (Note that $t \wedge \delta$ is a real valued stopping time even if $\delta = \infty$.)

Therefore, by Proposition 61.2.3, there exists a random variable, denoted as $\left[ M^\delta \right] (t)$ which is the pointwise limit as $p \to \infty$ of these random variables which is $\mathcal{F}_{t \wedge \delta}$ measurable because, for a given $\omega$, when $\alpha_p$ becomes larger than $t$, the sum in (61.2.10) loses its dependence on $p$. Thus from pointwise convergence in (61.2.10)
\[
\left[ M^\delta \right] (t) \equiv \lim_{n \to \infty} \sum_{k \geq 0} \left| M (t \wedge \delta \wedge \tau^n_{k+1}) - M (t \wedge \delta \wedge \tau^n_k) \right|^2
\]
In case $\delta = \infty$, the above gives an $\mathcal{F}_t$ measurable random variable denoted by $\left[ M \right] (t)$ such that
\[
\left[ M \right] (t) \equiv \lim_{n \to \infty} \sum_{k \geq 0} \left| M (t \wedge \tau^n_{k+1}) - M (t \wedge \tau^n_k) \right|^2
\]
Now stopping with the stopping time $\delta$, this shows that
\[
\left[ M^\delta \right] (t) \equiv \lim_{n \to \infty} \sum_{k \geq 0} \left| M (t \wedge \delta \wedge \tau^n_{k+1}) - M (t \wedge \delta \wedge \tau^n_k) \right|^2 = \left[ M \right]^\delta (t)
\]
That is, the quadratic variation of the stopped local martingale makes sense a.e. and equals the stopped quadratic variation of the local martingale.

This has now shown that
\[
\left| M^{\alpha_n} (t) \right|^2 - \left[ M \right]^{\alpha_n} (t) = \left| M^{\alpha_n} (t) \right|^2 - \left[ M^{\alpha_n} \right] (t) = N_n (t), \quad N_n (t) \quad \text{a martingale}
\]
and both of the random variables on the left converge pointwise as $n \to \infty$ to a function which is $\mathcal{F}_t$ measurable. Hence so does $N_n (t)$. Of course $N_n (t)$ is likewise a function of $\alpha_n \wedge t$ and so by Proposition 61.2.3 again, it converges pointwise to a $\mathcal{F}_t$ measurable function called $N (t)$ and $N (t)$ is a continuous local martingale.

It remains to consider the claim about the uniqueness. Suppose then there are two which work, $\left[ M \right]$, and $\left[ M \right]_1$. Then $\left[ M \right] - \left[ M \right]_1$ equals a local martingale $G$ which is 0 when $t = 0$. Thus the uniqueness assertion follows from Corollary 61.2.3.

Here is a corollary which tells how to manipulate stopping times. It is contained in the above proposition, but it is worth emphasizing it from a different point of view.
Corollary 61.2.6 In the situation of Proposition 61.2.5, let \( \tau \) be a stopping time. Then

\[ [M^\tau] = [M]^{\tau}. \]

Proof:

\[ [M^\tau](t) + N_1(t) = \left(\|M\|^2\right)^\tau(t) = \|M^\tau\|^2(t) = [M^\tau](t) + N_2(t) \]

where \( N_i \) is a local martingale. Therefore,

\[ [M^\tau](t) - [M^\tau](t) = N_2(t) - N_1(t), \]

a local martingale. Therefore, by Corollary 61.2.3, this shows \([M^\tau](t) - [M^\tau](t) = 0\).

\[ \blacksquare \]

61.3 The Covariation

Definition 61.3.1 The covariation of two continuous \( H \) valued local martingales for \( H \) a separable Hilbert space \( M, N, M(0) = 0 = N(0) \), is defined as follows.

\[ [M, N] \equiv \frac{1}{4} ([M + N] - [M - N]) \]

Lemma 61.3.2 The following hold for the covariation.

\[ [M] = [M, M] \]

\[ [M, N] = \text{local martingale} + \frac{1}{4} \left(\|M + N\|^2 - \|M - N\|^2\right) \]

\[ = (M, N) + \text{local martingale}. \]

Proof: From the definition of covariation,

\[ [M] = \|M\|^2 - N_1 \]

\[ [M, M] = \frac{1}{4} ([M + M] - [M - M]) = \frac{1}{4} \left(\|M + M\|^2 - N_2\right) \]

\[ = \|M\|^2 - \frac{1}{4} N_2 \]

where \( N_i \) is a local martingale. Thus \([M] - [M, M]\) is equal to the difference of two increasing continuous adapted processes and it also equals a local martingale. By Corollary 61.2.3, this process must equal 0. Now consider the second claim.

\[ [M, N] = \frac{1}{4} ([M + N] - [M - N]) = \frac{1}{4} \left(\|M + N\|^2 - \|M - N\|^2 + N\right) \]

\[ = (M, N) + \frac{1}{4} N \]

where \( N \) is a local martingale. \( \blacksquare \)
Corollary 61.3.3 Let \( M, N \) be two continuous local martingales, \( M(0) = N(0) = 0 \), as in Proposition 61.2.5. Then \([M, N]\) is of bounded variation and
\[
(M, N)_H - [M, N]
\]
is a local martingale. Also for \( \tau \) a stopping time,
\[
[M, N]^{\tau} = [M^{\tau}, N^{\tau}] = [M^{\tau}, N] = [M, N^{\tau}].
\]
In addition to this,
\[
[M - M^{\tau}] = [M] - [M^{\tau}] \leq [M]
\]
and also
\[
(M, N) \rightarrow [M, N]
\]
is bilinear and symmetric.

**Proof:** Since \([M, N]\) is the difference of increasing functions, it is of bounded variation.

\[
(M, N)_H - [M, N] = \frac{1}{4} \left( \left\| M + N \right\|^2 - \left\| M - N \right\|^2 \right)
\]
\[
= \frac{1}{4} \left( [M + N] - [M - N] \right)
\]
which equals a local martingale from the definition of \([M + N]\) and \([M - N]\). It remains to verify the claim about the stopping time. Using Corollary 61.2.6
\[
[M, N]^{\tau} = \frac{1}{4} \left( [M + N] - [M - N] \right)^{\tau}
\]
\[
= \frac{1}{4} \left( [M + N]^{\tau} - [M - N]^{\tau} \right)
\]
\[
= \frac{1}{4} \left( [M^{\tau} + N^{\tau}] - [M^{\tau} - N^{\tau}] \right) \equiv [M^{\tau}, N^{\tau}].
\]
The really interesting part is the next equality. This will involve Corollary 61.2.8
\[
[M, N]^{\tau} - [M^{\tau}, N] = [M^{\tau}, N^{\tau}] - [M^{\tau}, N]
\]
\[
\equiv \frac{1}{4} \left( [M^{\tau} + N^{\tau}] - [M^{\tau} - N^{\tau}] \right) - \frac{1}{4} \left( [M^{\tau} + N] - [M^{\tau} - N] \right)
\]
\[
= \frac{1}{4} \left( [M^{\tau} + N^{\tau}] + [M^{\tau} - N] \right) - \frac{1}{4} \left( [M^{\tau} + N] + [M^{\tau} - N^{\tau}] \right), (61.3.11)
\]
the difference of two increasing adapted processes. Also, this equals
\[
\text{local martingale} - (M^{\tau}, N) + (M^{\tau}, N^{\tau})
\]
Claim: \((M^\tau, N) - (M^\tau, N^\tau) = (M^\tau, N - N^\tau)\) is a local martingale. Let \(\sigma_n\) be a localizing sequence for both \(M\) and \(M\). Such a localizing sequence is of the form \(\tau_n^M \wedge \tau_n^N\) where these are localizing sequences for the indicated local submartingale. Then obviously,

\[ (- (M^\tau, N) + (M^\tau, N^\tau))^{\sigma_n} = -(M^{\sigma_n \wedge \tau}, N^{\sigma_n}) + (M^{\sigma_n \wedge \tau}, N^{\sigma_n \wedge \tau}) \]

where \(N^{\sigma_n}\) and \(M^{\sigma_n}\) are martingales. To save notation, denote these by \(M\) and \(N\) respectively. Now use Lemma 61.1.1. Let \(\sigma\) be a stopping time with two values.

\[ E\left( (M^\tau (\sigma) , N (\sigma) - N^\tau (\sigma)) \right) = E \left( E \left( (M^\tau (\sigma) , N (\sigma) - N^\tau (\sigma)) \mid \mathcal{F}_\tau \right) \right) \]

Now \(M^\tau (\sigma)\) is \(M (\sigma \wedge \tau)\) which is \(\mathcal{F}_\tau\) measurable and so by the Doob optional sampling theorem,

\[ = E \left( M^\tau (\sigma), E \left( N (\sigma) - N^\tau (\sigma) \mid \mathcal{F}_\tau \right) \right) \]
\[ = E \left( M^\tau (\sigma), N (\sigma \wedge \tau) - N (\tau \wedge \sigma) \right) = 0 \]

while

\[ E \left( ((M^\tau (t), N (t) - N^\tau (t))) \right) = E \left( E \left( ((M^\tau (t), N (t) - N^\tau (t)) \mid \mathcal{F}_\tau \right) \right) \]

Since \(M^\tau (t)\) is \(\mathcal{F}_\tau\) measurable,

\[ = E \left( ((M^\tau (t), E \left( N (t) - N^\tau (t) \mid \mathcal{F}_\tau \right)) \right) \]
\[ = E \left( ((M^\tau (t), E \left( N (t \wedge \tau) - N (t \wedge \tau) \right)) \right) = 0 \]

This shows the claim is true.

Now from 61.3.11 and Corollary 61.3.3, \([M, N]^\tau - [M^\tau, N] = 0\).

Similarly

\([M, N]^\tau - [M, N^\tau] = 0\)

Now consider the next claim that \([M - M^\tau] = [M] - [M^\tau]\). From the definition, it follows

\[ [M - M^\tau] - ([M] + [M^\tau] - 2[M, M^\tau]) \]
\[ = ||M - M^\tau||^2 - \left(||M||^2 + ||M^\tau||^2 - 2 (M, M^\tau) \right) + \text{local martingale} \]
\[ = \text{local martingale} \]

By the first part of the corollary which ensures \([M, M^\tau]\) is of bounded variation, the left side is the difference of two increasing adapted processes and so by Corollary 61.2.3 again, the left side equals 0. Thus from the above,

\[ [M - M^\tau] = [M] + [M^\tau] - 2[M, M^\tau] \]
\[ = [M] + [M^\tau] - 2[M^\tau, M^\tau] \]
\[ = [M] + [M^\tau] - 2[M^\tau] \]
\[ = [M] - [M^\tau] \leq [M] \]
Finally consider the claim that \([M, N]\) is bilinear. From the definition, letting \(M_1, M_2, N\) be \(H\)-valued local martingales,

\[
(aM_1 + bM_2, N) = [aM_1 + bM_2, N] + \text{local martingale}
\]

\[
a (M_1, N) + b (M_2, N) = [aM_1, N] + b [M_2, N] + \text{local martingale}
\]

Hence

\[
[aM_1 + bM_2, N] - (a [M_1, N] + b [M_2, N]) = \text{local martingale}.
\]

The left side can be written as the difference of two increasing functions thanks to \([M, N]\) of bounded variation and so by Lemma 61.1.5 it equals 0. \([M, N]\) is obviously symmetric from the definition. ■

### 61.4 The Burkholder Davis Gundy Inequality

Define

\[
M^* (\omega) \equiv \sup \{||M (t) (\omega)|| : t \in [0, T]\}.
\]

The Burkholder Davis Gundy inequality is an amazing inequality which involves \(M^*\) and \([M] (T)\).

Before presenting this, here is the good lambda inequality, Theorem 10.7.1 on Page 281 listed here for convenience.

**Theorem 61.4.1** Let \((\Omega, F, \mu)\) be a finite measure space and let \(F\) be a continuous increasing function defined on \([0, \infty)\) such that \(F(0) = 0\). Suppose also that for all \(\alpha > 1\), there exists a constant \(C\) such that for all \(x \in [0, \infty)\),

\[
F (\alpha x) \leq C_{\alpha} F (x).
\]

Also suppose \(f, g\) are nonnegative measurable functions and there exists \(\beta > 1, 0 < r \leq 1,\) such that for all \(\lambda > 0\) and \(1 > \delta > 0\),

\[
\mu (\{f > \beta \lambda\} \cap \{g \leq r \delta \lambda\}) \leq \phi (\delta) \mu (\{f > \lambda\})
\]

where \(\lim_{\delta \to 0+} \phi (\delta) = 0\) and \(\phi\) is increasing. Under these conditions, there exists a constant \(C\) depending only on \(\beta, \phi, r\) such that

\[
\int_{\Omega} F (f (\omega)) d\mu (\omega) \leq C \int_{\Omega} F (g (\omega)) d\mu (\omega).
\]

The proof of this important inequality also will depend on the hitting this before that theorem which is listed next for convenience.

**Theorem 61.4.2** Let \(\{M (t)\}\) be a continuous real valued martingale adapted to the normal filtration \(F_t\) and let

\[
M^* \equiv \sup \{|M (t)| : t \geq 0\}
\]
and \( M(0) = 0 \). Letting 
\[
\tau_x \equiv \inf \{ t > 0 : M(t) = x \}
\]
Then if \( a < 0 < b \) the following inequalities hold.
\[
(b - a) \ P ( [\tau_b \leq \tau_a]) \geq -a \ P ( [M^* > 0]) \geq (b - a) \ P ( [\tau_b < \tau_a])
\]
and
\[
(b - a) \ P ( [\tau_a < \tau_b]) \leq b \ P ( [M^* > 0]) \leq (b - a) \ P ( [\tau_a \leq \tau_b]) .
\]
In words, \( P ( [\tau_b \leq \tau_a]) \) is the probability that \( M(t) \) hits \( b \) no later than when it hits \( a \). (Note that if \( a = 1 = b \) then you would have \( [\tau_a = \tau_b] \).

Then the Burkholder Davis Gundy inequality is as follows. Generalizations will be presented later.

**Theorem 61.4.3** Let \( \{ M(t) \} \) be a continuous \( H \) valued martingale which is uniformly bounded, \( M(0) = 0 \), where \( H \) is a separable Hilbert space and \( t \in [0,T] \). Then if \( F \) is a function of the sort described in the good lambda inequality above, there are constants, \( C \) and \( c \) independent of such martingales \( M \) such that
\[
c \int_\Omega F ( [M(T)]^{1/2}) \ dP \leq \int_\Omega F (M^*) dP \leq C \int_\Omega F ( [M(T)]^{1/2}) \ dP
\]
where
\[
M^* (\omega) \equiv \sup \{ ||M(t)(\omega)|| : t \in [0,T] \} .
\]

**Proof:** Using Corollary let
\[
N(t) \equiv ||M(t) - M^* (t)||^2 - [M - M^*] (t)
\]
\[
= ||M(t) - M^* (t)||^2 - [M(t) + M^*] (t)
\]
where
\[
\tau \equiv \inf \{ t \in [0,T] : ||M(t)|| > \lambda \}
\]
Thus \( N \) is a martingale and \( N(0) = 0 \). In fact \( N(t) = 0 \) as long as \( t \leq \tau \). As usual \( \inf (\emptyset) \equiv \infty \). Note
\[
[\tau < \infty] = [M^* > \lambda] \supset [N^* > 0] .
\]
This is because to say \( \tau < \infty \) is to say there exists \( t < T \) such that \( ||M(t)|| > \lambda \) which is the same as saying \( M^* > \lambda \). Thus the first two sets are equal. If \( \tau = \infty \), then from the formula for \( N(t) \) above, \( N(t) = 0 \) for all \( t \in [0,T] \) and so it can’t happen that \( N^* > 0 \). Thus the third set is contained in \( [\tau < \infty] \) as claimed.

Let \( \beta > 2 \) and let \( \delta \in (0,1) \). Then
\[
\beta - 1 > 1 > \delta > 0
\]
Consider the following which is set up to use the good lambda inequality.
\[
S_r \equiv [M^* > \beta \lambda] \cap [([M(T)]^{1/2} \leq r \delta \lambda]
\]
where $0 < r < 1$. It is shown that $S_r$ corresponds to hitting “this before that” and there is an estimate for this which involves $P([N^* > 0])$ which is bounded above by $P([M^* > \lambda])$ as discussed above. This will satisfy the hypotheses of the good lambda inequality.

**Claim:** For $\omega \in S_r$, $N(t)$ hits $\lambda^2 (1 - \delta^2)$.

**Proof of claim:** For $\omega \in S_r$, there exists a $t < T$ such that $||M(t)|| > \beta \lambda$ and so using Corollary 61.3.3.

\[
N(t) \geq ||M(t)|| - ||M^*(t)||^2 - [M - M^*(t)](t) \geq |\beta \lambda - \lambda|^2 - |M(t)|
\]

which shows that $N(t)$ hits $(\beta - 1)^2 \lambda^2 - \delta^2 \lambda^2$ for $\omega \in S_r$. By the intermediate value theorem, it also hits $\lambda^2 (1 - \delta^2)$. This proves the claim.

**Claim:** $N(t)(\omega)$ never hits $-\delta^2 \lambda^2$ for $\omega \in S_r$.

**Proof of claim:** Suppose $t$ is the first time $N(t)$ reaches $-\delta^2 \lambda^2$. Then $t > \tau$ and so

\[
N(t) = -\delta^2 \lambda^2 \geq ||M(t)|| - \lambda^2 - |M(t)| + [M^*(t)](t)
\]

a contradiction since $r < 1$. This proves the claim.

Therefore, for all $\omega \in S_r$, $N(t)(\omega)$ reaches $\lambda^2 (1 - \delta^2)$ before it reaches $-\delta^2 \lambda^2$. It follows

\[
P(S_r) \leq P(N(t) \text{ reaches } \lambda^2 (1 - \delta^2) \text{ before } -\delta^2 \lambda^2)
\]

and because of Theorem 61.3.3 this is no larger than

\[
P([N^* > 0]) \frac{\delta^2 \lambda^2}{\lambda^2 (1 - \delta^2) - (-\delta^2 \lambda^2)} = P([N^* > 0]) \delta^2 \leq \delta^2 P([M^* > \lambda]).
\]

Thus

\[
P\left([M^* > \beta \lambda] \cap \left([M(T)]^{1/2} \leq r \delta \lambda \right)\right) \leq P([M^* > \lambda]) \delta^2
\]

By the good lambda inequality,

\[
\int_{\Omega} F(M^*) dP \leq C \int_{\Omega} F\left([M(T)]^{1/2}\right) dP
\]

which is one half the inequality.

Now consider the other half. This time define the stopping time $\tau$ by

\[
\tau = \inf \left\{ t \in [0,T] : ([M(t)]^{1/2}) > \lambda \right\}
\]

and let

\[
S_r = \left(\left([M(T)]^{1/2} > \beta \lambda\right) \cap [2M^* \leq r \delta \lambda]\right).
\]

Then there exists $t < T$ such that $[M(t)] > \beta^2 \lambda^2$. This time, let

\[
N(t) = [M(t)] - [M^*(t)] - ||M(t) - M^*(t)||^2
\]
This is still a martingale since by Corollary 61.3.3

\[ [M](t) - [M^\tau](t) = [M - M^\tau](t) \]

**Claim:** \( N(t)(\omega) \) hits \( \lambda^2 \left( 1 - \delta^2 \right) \) for some \( t < T \) for \( \omega \in S_r \).

**Proof of claim:** Fix such a \( \omega \in S_r \). Let \( t < T \) be such that \( [M](t) > \beta^2 \lambda^2 \). Then \( t > \tau \) and so for that \( \omega \),

\[
N(t) > \beta^2 \lambda^2 - \lambda^2 - ||M(t) - M(\tau)||^2 \\
\geq (\beta - 1)^2 \lambda^2 - (||M(t)|| + ||M(\tau)||)^2 \\
\geq (\beta - 1)^2 \lambda^2 - r^2 \delta^2 \lambda^2 \geq \lambda^2 - \delta^2 \lambda^2
\]

By the intermediate value theorem, it hits \( \lambda^2 \left( 1 - \delta^2 \right) \). This proves the claim.

**Claim:** \( N(t)(\omega) \) never hits \( -\delta^2 \lambda^2 \) for \( \omega \in S_r \).

**Proof of claim:** By Corollary 61.3.3, if it did at \( t \), then \( t > \tau \) because \( N(t) = 0 \) for \( t \leq \tau \), and so

\[
0 \leq [M](t) - [M^\tau](t) = ||M(t) - M(\tau)||^2 - \delta^2 \lambda^2 \\
\leq (||M(t)|| + ||M(\tau)||)^2 - \delta^2 \lambda^2 \leq r^2 \delta^2 \lambda^2 - \delta^2 \lambda^2 < 0,
\]

a contradiction. This proves the claim.

It follows that for each \( r \in (0,1) \),

\[
P(S_r) \leq P(\text{N(t) hits } \lambda^2 \left( 1 - \delta^2 \right) \text{ before } -\delta^2 \lambda^2)\]

By Theorem \( 60.11.3 \) this is no larger than

\[
P([N^* > 0]) \frac{\delta^2 \lambda^2}{\lambda^2 (1 - \delta^2) + \delta^2 \lambda^2} = P([N^* > 0]) \delta^2 \\
\leq P([\tau < \infty]) \delta^2 = P\left(\left(\left[|M(T)|^{1/2}\right] > \lambda\right)\right) \delta^2
\]

Now by the good lambda inequality, there is a constant \( k \) independent of \( M \) such that

\[
\int_{\Omega} F\left(\left[|M(T)|^{1/2}\right]\right) dP \leq k \int_{\Omega} F(2M^*) dP \leq kC_2 \int_{\Omega} F(M^*) dP
\]

by the assumptions about \( F \). Therefore, combining this result with the first part,

\[
(kC_2)^{-1} \int_{\Omega} F\left(\left[|M(T)|^{1/2}\right]\right) dP \leq \int_{\Omega} F(M^*) dP \\
\leq C \int_{\Omega} F\left(\left[|M(T)|^{1/2}\right]\right) dP
\]

Of course, everything holds for local martingales in place of martingales.
Theorem 61.4.4 Let \( \{ M(t) \} \) be a continuous \( H \) valued local martingale, \( M(0) = 0 \), where \( H \) is a separable Hilbert space and \( t \in [0,T] \). Then if \( F \) is a function of the sort described in the good lambda inequality, that is,

\[
F(0) = 0, \ F \text{ continuous, } F \text{ increasing,}
\]

there are constants, \( C \) and \( c \) independent of such local martingales \( M \) such that

\[
c \int \Omega F \left( [M](T)^{1/2} \right) dP \leq \int \Omega F(M^*) dP \leq C \int \Omega F \left( [M](T)^{1/2} \right) dP
\]

where

\[
M^*(\omega) \equiv \sup \{ [M](t)(\omega) : t \in [0,T] \}.
\]

Proof: Let \( \{ \tau_n \} \) be an increasing localizing sequence for \( M \) such that \( M^{\tau_n} \) is uniformly bounded. Such a localizing sequence exists from Proposition 61.2.2. Then from Theorem 61.4.3 there exist constants \( c, C \) independent of \( n \) such that

\[
c \int \Omega F \left( [M^{\tau_n}](T)^{1/2} \right) dP \leq \int \Omega F \left( (M^{\tau_n})^* \right) dP \leq C \int \Omega F \left( [M^{\tau_n}](T)^{1/2} \right) dP
\]

By Corollary 61.4.5, this implies

\[
c \int \Omega F \left( ([M]^{\tau_n})(T)^{1/2} \right) dP \leq \int \Omega F \left( (M^{\tau_n})^* \right) dP \leq C \int \Omega F \left( ([M]^{\tau_n})(T)^{1/2} \right) dP
\]

and now note that \( (M^{\tau_n})(T)^{1/2} \) and \( (M^{\tau_n})^* \) increase in \( n \) to \( [M](T)^{1/2} \) and \( M^* \) respectively. Then the result follows from the monotone convergence theorem.

Here is a corollary.

Corollary 61.4.5 Let \( \{ M(t) \} \) be a continuous \( H \) valued local martingale and let \( \varepsilon, \delta \in (0, \infty) \). Then there is a constant \( C, \) independent of \( \varepsilon, \delta \) such that

\[
P \left( \sup_{t \in [0,T]} \left\| M(t) \right\| \geq \varepsilon \right) \leq \frac{C}{\varepsilon} E \left( [M]^{1/2}(T) \wedge \delta \right) + P \left( [M]^{1/2}(T) > \delta \right)
\]

Proof: Let the stopping time \( \tau \) be defined by

\[
\tau \equiv \inf \left\{ t > 0 : [M]^{1/2}(t) > \delta \right\}
\]
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

Then

\[ P([M^* \geq \varepsilon]) = P([M^* \geq \varepsilon] \cap [\tau = \infty]) + P([M^* \geq \varepsilon] \cap [\tau < \infty]) \]

On the set where \([\tau = \infty]\), \(M^\tau = M\) and so

\[ P([M^* \geq \varepsilon]) \leq \frac{1}{\varepsilon} \int_{\Omega} (M^\tau)^* dP + P\left([M^* \geq \varepsilon] \cap \left[|M|^{1/2}(T) > \delta\right]\right) \]

By Theorem [61.4.4] and Corollary [61.3.3],

\[ \leq \frac{C}{\varepsilon} \int_{\Omega} |M|^{1/2}(T) dP + P\left([M^* \geq \varepsilon] \cap \left[|M|^{1/2}(T) > \delta\right]\right) \]

\[ = \frac{C}{\varepsilon} \int_{\Omega} (|M|^{1/2}(T)) dP + P\left([M^* \geq \varepsilon] \cap \left[|M|^{1/2}(T) > \delta\right]\right) \]

\[ \leq \frac{C}{\varepsilon} \int_{\Omega} |M|^{1/2}(T) \wedge \delta dP + P\left([M^* \geq \varepsilon] \cap \left[|M|^{1/2}(T) > \delta\right]\right) \]

\[ \leq \frac{C}{\varepsilon} \int_{\Omega} |M|^{1/2}(T) \wedge \delta dP + P\left([|M|^{1/2}(T) > \delta]\right) \]

The Burkholder Davis Gundy inequality along with the properties of the covariation implies the following amazing proposition.

**Proposition 61.4.6** The space \(M^2_T(H)\) is a Hilbert space. Here \(H\) is a separable Hilbert space.

**Proof:** We already know from Proposition [60.12.2] that this space is a Banach space. It is only necessary to exhibit an equivalent norm which makes it a Hilbert space. However, you can let \(F(\lambda) = \lambda^2\) in the Burkholder Davis Gundy theorem and obtain for \(M \in M^2_T(H)\), the two norms

\[ \left(\int_{\Omega} |M|(T) dP\right)^{1/2} = \left(\int_{\Omega} |M|^{1/2}(T) dP\right)^{1/2} \]

and

\[ \left(\int_{\Omega} (M^*)^2 dP\right)^{1/2} \]

are equivalent. The first comes from an inner product since from Corollary [61.3.3], \([\cdot, \cdot]\) is bilinear and symmetric and nonnegative. If \([M, M](T) = |M|(T) = 0\) in \(L^1(\Omega)\), then from the Burkholder Davis Gundy inequality, \(M^* = 0\) in \(L^2(\Omega)\) and so \(M = 0\). Hence

\[ \int_{\Omega} |M, N|(T) dP \]

is an inner product which yields the equivalent norm. \(\blacksquare\)
Example 61.4.7 An example of a real martingale is the Wiener process, $W(t)$. It has the property that whenever $t_1 < t_2 < \cdots < t_n$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent and whenever $s < t$, $W(t) - W(s)$ is normally distributed with mean 0 and variance $(t-s)$. For the Wiener process, we let

$$F_t = \cap_{u>t} \sigma \{W(s) - W(r) : r < s \leq u\}$$

and it is with respect to this normal filtration that $W$ is a continuous martingale. What is the quadratic variation of such a process?

The quadratic variation of the Wiener process is just $t$. This is because if $A = \sigma(W(s))$, then

$$E \left( \mathcal{X}_A \left( |W(t)|^2 - t \right) \right) = E \left( \mathcal{X}_A \left( |W(t) - W(s)|^2 + |W(s)|^2 + 2(W(s), W(t) - W(s)) - (t-s+s) \right) \right)$$

Now

$$E(\mathcal{X}_A(2(W(s), W(t) - W(s)))) = P(A)E(2W(s))E(W(t) - W(s)) = 0$$

by the independence of the increments. Thus the above reduces to

$$E \left( \mathcal{X}_A \left( |W(t) - W(s)|^2 + |W(s)|^2 - (t-s+s) \right) \right)$$

$$= E \left( \mathcal{X}_A \left( |W(t) - W(s)|^2 - (t-s) \right) \right) + E \left( \mathcal{X}_A \left( |W(s)|^2 - s \right) \right)$$

$$= P(A)E \left( |W(t) - W(s)|^2 - (t-s) \right) + E \left( \mathcal{X}_A \left( |W(s)|^2 - s \right) \right)$$

$$= E \left( \mathcal{X}_A \left( |W(s)|^2 - s \right) \right)$$

and so $E(\left|W(t)\right|^2 - t|F_s) = |W(s)|^2 - s$ showing that $t \to |W(t)|^2 - t$ is a martingale. Hence, by uniqueness, $[W](t) = t$.

61.5 The Quadratic Variation And Stochastic Integration

Let $\mathcal{F}_t$ be a normal filtration and let $\{M(t)\}$ be a continuous local martingale adapted to $\mathcal{F}_t$ having values in $U$ a separable real Hilbert space.

Definition 61.5.1 Let $\mathcal{F}_t$ be a normal filtration and let

$$f(t) = \sum_{k=0}^{n-1} f_k \mathcal{X}_{(t_k, t_{k+1}]}(t)$$
where \( \{ t_k \}_{k=0}^n \) is a partition of \([0, T]\) and each \( f_k \) is \( \mathcal{F}_{t_k} \) measurable, \( f_k M^* \in L^2(\Omega) \) where

\[
M^*(\omega) \equiv \sup_{t \in [0, T]} ||M(t)(\omega)||
\]

Such a function is called an elementary function. Also let \( \{M(t)\} \) be a local martingale adapted to \( \mathcal{F}_t \) which has values in a separable real Hilbert space \( U \) such that \( M(0) = 0 \). For such an elementary real valued function define

\[
\int_0^t f \, dM = \sum_{k=0}^{n-1} f_k (M(t \wedge t_{k+1}) - M(t \wedge t_k)).
\]

Then with this definition, here is a wonderful lemma.

**Lemma 61.5.2** For \( f \) an elementary function as above, \( \left\{ \int_0^t f \, dM \right\} \) is a continuous local martingale and

\[
E \left( \left\| \int_0^t f \, dM \right\|^2_U \right) = \int_\Omega \int_0^t f(s)^2 \, d[M](s) \, dP.
\] (61.5.13)

If \( N \) is another continuous local martingale adapted to \( \mathcal{F}_t \) and both \( f, g \) are elementary functions such that for each \( k \),

\[
f_k M^*, g_k N^* \in L^2(\Omega),
\]

then

\[
E \left( \left( \int_0^t f \, dM, \int_0^t g \, dN \right)_U \right) = \int_\Omega \int_0^t f \, g \, d[M, N]
\] (61.5.14)

and both sides make sense.

**Proof:** Let \( \{ \tau_i \} \) be a localizing sequence for \( M \) such that \( M^{\tau_i} \) is a bounded martingale. Then from the definition, for each \( \omega \)

\[
\int_0^t f \, dM = \lim_{i \to \infty} \int_0^t f \, dM^{\tau_i} = \lim_{i \to \infty} \left( \int_0^t f \, dM \right)^{\tau_i}
\]

and it is clear that \( \left\{ \int_0^t f \, dM^{\tau_i} \right\} \) is a martingale because it is just the sum of some martingales. Thus \( \{ \tau_i \} \) is a localizing sequence for \( \int_0^t f \, dM \). It is also clear \( \int_0^t f \, dM \) is continuous because it is a finite sum of continuous random variables.

Next consider the formula which is really a version of the Ito isometry. There is no loss of generality in assuming the mesh points are the same for the two elementary functions because if not, one can simply add in points to make this happen. It suffices to consider 61.5.14 because the other formula is a special case. To begin with, let \( \{ \tau_i \} \) be a localizing sequence which makes both \( M^{\tau_i} \) and \( N^{\tau_i} \) into bounded martingales. Consider the stopped process.

\[
E \left( \left( \int_0^t f \, dM^{\tau_i}, \int_0^t g \, dN^{\tau_i} \right)_U \right)
\]
At this point, recall the definition of the covariation. The above equals

\[
N_k \sum_{k=0}^{n-1} f_k (M^\tau_k (t \wedge t_{k+1}) - M^\tau_k (t \wedge t_k))\quad \text{and} \quad \sum_{k=0}^{n-1} g_k (N^\tau_k (t \wedge t_{k+1}) - N^\tau_k (t \wedge t_k))
\]

To save on notation, write \(M^\tau_k (t \wedge t_{k+1}) - M^\tau_k (t \wedge t_k) \equiv \Delta M_k (t)\), similar for \(\Delta N_k\). Thus
\[
\Delta M_k = M^\tau_{k \wedge t_{k+1}} - M^\tau_{k \wedge t_k},
\]
similar for \(\Delta N_k\). Then the above equals
\[
E \left( \sum_{k=0}^{n-1} f_k \Delta M_k, \sum_{k=0}^{n-1} g_k \Delta N_k \right) = E \left( \sum_{k,j} f_k g_j (\Delta M_k, \Delta N_j) \right)
\]

Now consider one of the mixed terms with \(j < k\).
\[
E ((f_k \Delta M_k, g_j \Delta N_j)) = E (E ((f_k \Delta M_k, g_j \Delta N_j) | \mathcal{F}_{t_k})) = E (g_j \Delta N_j, f_k E (\Delta M_k | \mathcal{F}_{t_k}) = 0
\]
since \(E (\Delta M_k | \mathcal{F}_{t_k}) = E ((M^\tau_k (t \wedge t_{k+1}) - M^\tau_k (t \wedge t_k)) | \mathcal{F}_{t_k}) = 0\) by the Doob optional sampling theorem. Thus
\[
E \left( \left( \int_0^t f dM^\tau, \int_0^t g dN^\tau \right)_U \right) = \sum_{k=0}^{n-1} E (f_k g_k (\Delta M_k, \Delta N_k)) = \sum_{k=0}^{n-1} E (f_k g_k (|\Delta M_k, \Delta N_k| + N_k))
\]
(61.5.15)

where \(N_k\) is a martingale such that \(N_k (t) = 0\) for all \(t \leq t_k\). This is because the martingale \((N^\tau_k)^{t_{k+1}} - (N^\tau_k)^{t_k} = \Delta N_k\) equals zero for such \(t\); and so \(E (N_k (t)) = 0\). Thus \(f_k g_k N_k\) is a martingale which equals zero when \(t = 0\). Therefore, its expectation also equals zero. Consequently the above reduces to
\[
\sum_{k=0}^{n-1} E (f_k g_k [\Delta M_k, \Delta N_k]).
\]

At this point, recall the definition of the covariation. The above equals
\[
\frac{1}{4} \sum_{k=0}^{n-1} E (f_k g_k ([\Delta M_k + \Delta N_k] - [\Delta M_k - \Delta N_k]))
\]

Rewriting this yields
\[
= \frac{1}{4} \sum_{k=0}^{n-1} E \left( f_k g_k \left( ((M^\tau_k)^{t_{k+1}} + (N^\tau_k)^{t_{k+1}}) - (M^\tau_k)^{t_k} + (N^\tau_k)^{t_k}) - ((M^\tau_k)^{t_{k+1}} - (N^\tau_k)^{t_{k+1}}) - ((M^\tau_k)^{t_k} - (N^\tau_k)^{t_k}) \right) \right)
\]
To save on notation, denote

\[(M^{\tau_l})^k + (N^{\tau_l})^k + 1 - (M^{\tau_l})^k + (N^{\tau_l})^k) = \Delta_k (M^{\tau_l} + N^{\tau_l})
\]
\[(M^{\tau_l})^k + (N^{\tau_l})^k + 1 - (M^{\tau_l})^k - (N^{\tau_l})^k) = \Delta_k (M^{\tau_l} - N^{\tau_l})
\]

Thus the above equals

\[
\frac{1}{4} \sum_{k=0}^{n-1} E (f_k g_k ((\Delta_k (M^{\tau_l} + N^{\tau_l})) - [\Delta_k (M^{\tau_l} - N^{\tau_l}))])
\]

Now from Corollary 61.3.3,

\[
= \frac{1}{4} \sum_{k=0}^{n-1} E (f_k g_k ((\Delta_k (M + N))^{\tau_l} - [\Delta_k (M - N)]^{\tau_l}))
\]

Letting \(l \to \infty\), this reduces to

\[
= \frac{1}{4} \sum_{k=0}^{n-1} E (f_k g_k ([\Delta_k (M + N)] - [\Delta_k (M - N)])
\]
\[
= \frac{1}{4} \left( \int_0^t \int_0 \int_0^t f g (d [M + N] - d [M - N]) \right)
\]
\[
= \int_0^t \int_0 f g d [M, N]
\]

Now consider the left side of 61.3.16,

\[E \left( \left( \int_0^t f dM^{\tau_l}, \int_0^t g dN^{\tau_l} \right) \right)
\]

\[
= \int_0^t \sum_{k,j} f_k g_j ((M^{\tau_l} (t \land t_{k+1}) - M^{\tau_l} (t \land t_k)), (N^{\tau_l} (t \land t_{j+1}) - N^{\tau_l} (t \land t_j)) dP
\]

Then for each \(\omega\), the integrand converges as \(l \to \infty\) to

\[
\sum_{k,j} f_k g_j ((M (t \land t_{k+1}) - M (t \land t_k)), (N (t \land t_{j+1}) - N (t \land t_j)))
\]

But also you can do a sloppy estimate which will allow the use of the dominated convergence theorem,
61.5. THE QUADRATIC VARIATION AND STOCHASTIC INTEGRATION

\[ \sum_{i,j} f_k g_j (M(t \wedge t_{k+1}) - M(t \wedge t_k), N(t \wedge t_{j+1}) - N(t \wedge t_j)) dP \]

by assumption. Thus the left side of 61.5.10 converges as \( l \to \infty \) to

\[ \int_{\Omega} \left( \int_0^t f dM, \int_0^t g dN \right)_{U} dP \]

Note for each \( \omega \), the inside integral in 61.5.14 is just a Stieltjes integral taken with respect to the increasing integrating function \([M]\).

Of course, with this estimate it is obvious how to extend the integral to a larger class of functions.

**Definition 61.5.3** Let \( \nu(\omega) \) denote the Radon measure representing the functional

\[ \Lambda(\omega)(g) \equiv \int_0^T g d[M](t)(\omega) \]

\((t \to [M](t)(\omega)\) is a continuous increasing function and \( \nu(\omega) \) is the measure representing the Stieltjes integral, one for each \( \omega \).) Then let \( \mathcal{G}_M \) denote functions \( f(s,\omega) \) which are the limit of such elementary functions in the space \( L^2(\Omega; L^2([0,T], \nu(\cdot))) \), the norm of such functions being

\[ ||f||^2_2 \equiv \int_{\Omega} \int_0^T f(s)^2 d[M](s) dP \]

For \( f \in \mathcal{G} \) just defined,

\[ \int_0^t f dM \equiv \lim_{n \to \infty} \int_0^t f_n dM \]

where \( \{f_n\} \) is a sequence of elementary functions converging to \( f \) in

\[ L^2(\Omega; L^2([0,T], \nu(\cdot))) \]

Now here is an interesting lemma.

**Lemma 61.5.4** Let \( M, N \) be continuous local martingales, \( M(0) = N(0) = 0 \) having values in a separable Hilbert space, \( U \). Then

\[ [M + N]^{1/2} \leq \left( [M]^{1/2} + [N]^{1/2} \right) \]  

\[ [M + N] \leq 2([M] + [N]) \]  

Also, letting \( \nu_{M+N} \) denote the measure obtained from the increasing function \([M + N]\) and \( \nu_N, \nu_M \) defined similarly,

\[ \nu_{M+N} \leq 2(\nu_M + \nu_N) \]  

on all Borel sets.
Proof: Since $(M,N) \to [M,N]$ is bilinear and satisfies
\[
[M,N] = [N,M] \\
[aM + bM_1, N] = a[M,N] + b[M_1,N] \\
[M,M] \geq 0
\]
which follows from Corollary 61.3.3, the usual Cauchy Schwarz inequality holds and so
\[
|[M,N]| \leq [M]^{1/2} [N]^{1/2}
\]
Thus
\[
[M + N] = [M + N,M + N] = [M,M] + [N,N] + 2[M,N] \\
\leq [M] + [N] + 2[M]^{1/2} [N]^{1/2} = ([M]^{1/2} + [N]^{1/2})^2
\]
This proves 61.5.17. Now square both sides. Then the right side is no larger than
\[
2 ([M] + [N])
\]
and this shows 61.5.18.

Now consider the claim about the measures. It was just shown that
\[
[(M + N) - (M + N)^s] \leq 2 ([M - M^s] + [N - N^s])
\]
and from Corollary 61.5.19 this implies that for $t > s$
\[
[M + N](t) - [M + N](s \land t) \\
= [M + N](t) - [M + N]^s(t) \\
= [M + N - (M^s + N^s)](t) \\
= [M - M^s + (N - N^s)](t) \\
\leq 2 [M - M^s](t) + 2 [N - N^s](t)
\]
Thus
\[
\nu_{M+N}([s,t]) \leq 2 (\nu_M([s,t]) + \nu_N([s,t]))
\]
By regularity of the measures, this continues to hold with any Borel set $F$ in place of $[s,t]$.

Theorem 61.5.5 The integral is well defined and has a continuous version which is a local martingale. Furthermore it satisfies the Ito isometry,
\[
E \left( \left\| \int_0^t f dM \right\|_V^2 \right) = \int_\Omega \int_0^t f(s)^2 d[M](s) dP
\]
Let the norm on \( \mathcal{G}_N \cap \mathcal{G}_M \) be the maximum of the norms on \( \mathcal{G}_N \) and \( \mathcal{G}_M \) and denote by \( \mathcal{E}_N \) and \( \mathcal{E}_M \) the elementary functions corresponding to the martingales \( N \) and \( M \) respectively. Define \( \mathcal{G}_{NM} \) as the closure in \( \mathcal{G}_N \cap \mathcal{G}_M \) of \( \mathcal{E}_N \) and \( \mathcal{E}_M \) respectively. Define

\[
E \left( \left( \int_0^t f \, dM, \int_0^t g \, dN \right) \right) = \int_{\Omega} \int_0^t f g \, d[M, N] \tag{61.5.20}
\]

**Proof:** It is clear the definition is well defined because if \( \{f_n\} \) and \( \{g_n\} \) are two sequences of elementary functions converging to \( f \) in \( L^2(\Omega; L^2([0,T], \nu(\cdot))) \) and if \( \int_0^T f \, dM \) is the integral which comes from \( \{g_n\} \),

\[
\int_{\Omega} \left\| \int_0^T f \, dM - \int_0^t f \, dM \right\|^2 \, dP = \lim_{n \to \infty} \int_{\Omega} \left\| \int_0^T g_n \, dM - \int_0^t f_n \, dM \right\|^2 \, dP \leq \lim_{n \to \infty} \int_{\Omega} \int_0^T \left\| g_n - f_n \right\|^2 \, dP = 0.
\]

Consider the claim the integral has a continuous version. Recall Theorem 60.9.4, part of which is listed here for convenience.

**Theorem 61.5.6** Let \( \{X(t)\} \) be a right continuous nonnegative submartingale adapted to the normal filtration \( \mathcal{F}_t \) for \( t \in [0,T] \). Let \( p \geq 1 \). Define

\[
X^*(t) \equiv \sup \{X(s) : 0 < s < t\}, \quad X^*(0) \equiv 0.
\]

Then for \( \lambda > 0 \)

\[
P \left( \left| X^*(T) \right| > \lambda \right) \leq \frac{1}{\lambda^p} \int_{\Omega} X(T)^p \, dP \tag{61.5.21}
\]

Let \( \{f_n\} \) be a sequence of elementary functions converging to \( f \) in \( L^2(\Omega; L^2([0,T], \nu(\cdot))) \).

Then letting

\[
X_{n,m}^\tau(t) = \left\| \int_0^t (f_n - f_m) \, dM^\tau \right\|_U,
\]

\[
X_{n,m}(t) = \left\| \int_0^t (f_n - f_m) \, dM \right\|_U = \left\| \int_0^t f_n \, dM - \int_0^t f_m \, dM \right\|_U
\]

It follows \( X_{n,m}^\tau(t) \) is a continuous nonnegative submartingale and from Theorem 60.5.6 just listed,

\[
P \left( \left| X_{n,m}^\tau(T) \right| > \lambda \right) \leq \frac{1}{\lambda^p} \int_{\Omega} X_{n,m}^\tau(T)^p \, dP
\]
\[ \frac{1}{\lambda^2} \int_{\Omega} \int_0^T |f_n - f_m|^2 \, d[M^t] \, dP \]
\[ \leq \frac{1}{\lambda^2} \int_{\Omega} \int_0^T |f_n - f_m|^2 \, d[M] \, dP \]

Letting \( l \to \infty \),
\[ P \left( [X^*_n m(T) > \lambda] \right) \leq \frac{1}{\lambda^2} \int_{\Omega} \int_0^T |f_n - f_m|^2 \, d[M] \, dP \]

Therefore, there exists a subsequence, still denoted by \( \{f_n\} \) such that
\[ P \left( [X^*_n, n+1(T) > 2^{-n}] \right) < 2^{-n} \]

Then by the Borel Cantelli lemma, the \( \omega \) in infinitely many of the sets
\[ [X^*_n, n+1(T) > 2^{-n}] \]
has measure 0. Denoting this exceptional set as \( N \), it follows that for \( \omega \notin N \), there exists \( n(\omega) \) such that for \( n > n(\omega) \),
\[ \sup_{t \in [0, T]} \left\| \int_0^t f_n dM - \int_0^t f_{n+1} dM \right\| \leq 2^{-n} \]

and this implies uniform convergence of \( \left\{ \int_0^t f_n dM \right\} \). Letting
\[ G(t) = \lim_{n \to \infty} \int_0^t f_n dM, \]
for \( \omega \notin N \) and \( G(t) = 0 \) for \( \omega \in N \), it follows that for each \( t \), the continuous adapted process \( G(t) \) equals \( \int_0^t f dM \) a.e. Thus \( \left\{ \int_0^t f dM \right\} \) has a continuous version.

It suffices to verify \[ \text{(61.5.2)} \]. Let \( \{f_n\} \) and \( \{g_n\} \) be sequences of elementary functions converging to \( f \) and \( g \) in \( G_M \cap G_N \). By Lemma \[ \text{(61.5.1)} \],
\[ E \left( \left( \int_0^t f_n dM, \int_0^t g_n dN \right)_{U} \right) = \int_\Omega \int_0^t f_n g_n d[M, N] \]

Then by the Holder inequality and the above definition,
\[ \lim_{n \to \infty} E \left( \left( \int_0^t f_n dM, \int_0^t g_n dN \right)_{U} \right) = E \left( \left( \int_0^t f dM, \int_0^t g dN \right)_{U} \right) \]

Consider the right side which equals
\[ \frac{1}{4} \int_\Omega \int_0^t f_n g_n d[M + N] \, dP - \frac{1}{4} \int_\Omega \int_0^t f_n g_n d[M - N] \, dP \]

\[ \text{CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE} \]
Now from Lemma 61.5.4,
\[
\left| \int_\Omega \int_0^t f_n g_n d[M + N] dP - \int_\Omega \int_0^t f g d[M + N] dP \right|
\leq 2 \left( \int_\Omega \int_0^t |f_n g_n - f g| d\nu dP + \int_\Omega \int_0^t |f_n g_n - f g| d\nu dP \right)
\]
and by the choice of the \( f_n \) and \( g_n \), these both converge to 0. Similar considerations apply to
\[
\left| \int_\Omega \int_0^t f_n g_n d[M - N] dP - \int_\Omega \int_0^t f g d[M - N] dP \right|
\]
and show
\[
\lim_{n \to \infty} \int_\Omega \int_0^t f_n g_n d[M, N] = \int_\Omega \int_0^t f g d[M, N]
\]

### 61.6 Another Limit For Quadratic Variation

The problem to consider first is to define an integral
\[
\int_0^t f dM
\]
where \( f \) has values in \( H' \) and \( M \) is a continuous martingale having values in \( H \). For the sake of simplicity assume \( M(0) = 0 \). The process of definition is the same as before. First consider an elementary function
\[
f (t) \equiv \sum_{k=0}^{m-1} f_k \chi_{(t_k, t_{k+1}]} (t)
\]
where \( f_k \) is measurable into \( H' \) with respect to \( \mathcal{F}_{t_k} \). Then define
\[
\int_0^t f dM \equiv \sum_{k=0}^{m-1} f_k (M (t \land t_{k+1}) - M (t \land t_k)) \in \mathbb{R}
\]

**Lemma 61.6.1** The \( k^{th} \) term in the above sum is a martingale and the integral is also a martingale.

**Proof:** Let \( \sigma \) be a stopping time with two values. Then
\[
E (f_k (M (\sigma \land t_{k+1}) - M (\sigma \land t_k))) = E (f_k E ((M (\sigma \land t_{k+1}) - M (\sigma \land t_k)) | \mathcal{F}_{t_k})) = 0
\]
and it works the same with $\sigma$ replaced with $t$. Hence by the lemma about recognizing martingales, Lemma 61.1.1, each term is a martingale and so it follows that the integral $\int_0^t f dM$ is also a martingale. 

Note also that, since $M$ is continuous, this is a continuous martingale.

As before, it is important to estimate this.

$$E \left( \int_0^t f dM \right)^2 \leq ?$$

Consider a mixed term. For $j < k$, it follows from measurability considerations that

$$E \left( (f_k(M(t \wedge t_{k+1}) - M(t \wedge t_k))) (f_j(M(t \wedge t_{j+1}) - M(t \wedge t_j))) \right)$$

$$= E \left( E \left( (f_k(M(t \wedge t_{k+1}) - M(t \wedge t_k))) (f_j(M(t \wedge t_{j+1}) - M(t \wedge t_j))) | F_{t_k} \right) \right)$$

$$= E \left( (f_j(M(t \wedge t_{j+1}) - M(t \wedge t_j))) f_k E \left( (M(t \wedge t_{k+1}) - M(t \wedge t_k)) | F_{t_k} \right) \right) = 0$$

Therefore,

$$E \left( \left| \int_0^t f dM \right|^2 \right) = E \left( \sum_{k=0}^{m-1} |f_k(M(t \wedge t_{k+1}) - M(t \wedge t_k))|^2 \right)$$

$$\leq E \left( \sum_{k=0}^{m-1} \|f_k\|^2 |M(t \wedge t_{k+1}) - M(t \wedge t_k)|^2 \right)$$

$$= E \left( \sum_{k=0}^{m-1} \|f_k\|^2 \left( [M^{t_{k+1}}] - [M^{t_k}] \left( t \right) + N_k(t) \right) \right)$$

$$= E \left( \sum_{k=0}^{m-1} \|f_k\|^2 \left( [M^{t_{k+1}}] - [M^{t_k}] \left( t \right) + N_k(t) \right) \right)$$

$$= E \left( \sum_{k=0}^{m-1} \|f_k\|^2 \left( [M] \left( t \wedge t_{k+1} \right) - [M] \left( t \wedge t_k \right) + N_k(t) \right) \right)$$

where $N_k$ is a martingale which equals 0 for $t \leq t_k$. The above equals

$$E \left( \int_0^t \|f\|^2 d[M] \right) \equiv E \left( \int_0^t \|f\|^2 d\nu \right)$$

the integral inside being the ordinary Lebesgue Stieltjes integral for the step function

where $\nu$ is the measure determined by the positive linear functional

$$\Lambda g = \int_0^T g d[M]$$
61.6. ANOTHER LIMIT FOR QUADRATIC VARIATION

where the integral on the right is the ordinary Stieltjes integral. Thus, the following inequality is obtained.

\[
E \left( \left| \int_0^t f dM \right|^2 \right) \leq E \left( \int_0^t \|f\|^2 d[M] \right) \tag{61.6.24}
\]

Now what would it take for

\[
E \left( \left| \int_0^t f dM \right|^2 \right) \tag{61.6.25}
\]

to be well defined? A convenient condition would be to insist that each \(\|f_k\| M^*\) is in \(L^2(\Omega)\) where

\[
M^*(\omega) \equiv \sup_{t \in [0,T]} |M(t)(\omega)|_H
\]

Is this condition also sufficient for the above integral to be finite? From the above, that integral equals

\[
E \left( \sum_{k=0}^{m-1} \|f_k\|^2 |M(t \wedge t_{k+1}) - M(t \wedge t_k)|^2 \right)
\]

\[
\leq E \left( 4 \sum_{k=0}^{m-1} \|f_k\|^2 (M^*)^2 \right)
\]

Thus the condition that for each \(k, \|f_k\| M^* \in L^2(\Omega)\) is sufficient for all of the above to consist of real numbers and be well defined.

**Definition 61.6.2** A function \(f\) is called an elementary function if it is a step function of the form given in (61.6.22) where each \(f_k\) is \(\mathcal{F}_{t_k}\) measurable and for each \(k, \|f_k\| M^* \in L^2(\Omega)\). Define \(\mathcal{G}_M\) to be the collection of functions \(f\) having values in \(H'\) which have the property that there exists a sequence of elementary functions \(\{f_n\}\) with \(f_n \to f\) in the space

\[
L^2(\Omega; L^2([0,T], \nu))
\]

Then picking such an approximating sequence,

\[
\int_0^t f dM \equiv \lim_{n \to \infty} \int_0^t f_n dM
\]

the convergence happening in \(L^2(\Omega)\).

The inequality shows that this definition is well defined. So what are the properties of the integral just defined? Each \(\int_0^t f_n dM\) is a continuous martingale because it is the sum of continuous martingales. Since convergence happens in
It follows that \( \int_0^t f dM \) is also a martingale. Is it continuous? By the maximal inequality Theorem 60.9.4, it follows that
\[
P \left( \sup_{t \in [0,T]} \left| \int_0^t f_{n+p} dM - \int_0^t f_n dM \right| > \lambda \right) \leq \frac{1}{\lambda^2} E \left( \int_0^T (f_{m} - f_n) dM \right)^2
\]
and it follows that there exists a subsequence, still called \( n \) such that for all \( p \) positive,
\[
P \left( \sup_{t \in [0,T]} \left| \int_0^t f_{n+p} dM - \int_0^t f_n dM \right| > \frac{1}{n} \right) < 2^{-n}
\]
By the Borel Cantelli lemma, there exists a set of measure zero \( N \) such that for \( \omega \in N \), \( \{ \int_0^t f_n dM \} \) is a Cauchy sequence. Thus, what it converges to is continuous in \( t \) for each \( \omega \in N \) and for each \( t \), it equals \( \int_0^t f dM \) a.e. Hence we can regard \( \int_0^t f dM \) as this continuous version.

What is an example of such a function in \( G_M \)?

**Lemma 61.6.3** Let \( R : H \to H' \) be the Riesz map.
\[
\langle Rf, g \rangle \equiv (f, g)_H.
\]
Also, suppose \( M \) is a uniformly bounded continuous martingale with values in \( H \). Then \( RM \in G_M \).

**Proof:** I need to exhibit an approximating sequence of elementary functions as described above. Consider
\[
M_n(t) = \sum_{i=0}^{m_n-1} M(t_i) \mathcal{X}_{(t_i, t_{i+1}]}(t)
\]
Then clearly \( RM_n(t_i) M^* \in L^\infty(\Omega) \) and so in particular it is in \( L^2(\Omega) \). Here
\[
\lim_{n \to \infty} \max \{ |t_i^n - t_{i+1}^n|, i = 0, \ldots, m_n \} = 0.
\]
Say \( M^*(\omega) \leq C \). Furthermore, I claim that
\[
\lim_{n \to \infty} E \left( \int_0^T \|RM_n - RM\|^2 d[M] \right) = 0. \tag{61.6.26}
\]
This requires a little proof. Recall the description of \( [M](t) \). It was as follows. You considered
\[
P_n(t) = 2 \sum_{k \geq 0} (\{ M(t \wedge \tau_{k+1}^n) - M(t \wedge \tau_k^n) \}, \{ M(t \wedge \tau_k^n) \})
\]
where the stopping times were defined such that $\tau_{k+1}^n$ is the first time $t > \tau_k^n$ such that $|M(t) - M(\tau_k^n)|^2 = 2^{-n}$ and $\tau_0^n = 0$. Recall that $\lim_{k \to \infty} \tau_k^n = \infty$ or $T$ in the way it was formulated earlier. Then it was shown that $P_n(t)$ converged to a martingale $P(t)$ in $L^1(\Omega)$. Then by the usual procedure using the Borel Cantelli lemma, a subsequence converges to $P(t)$ uniformly off a set of measure zero. It is easy to estimate $P_n(t)$:

$$|P_n(t)| \leq \sum_{k \geq 0} |M(t \wedge \tau_{k+1}^n)|^2 - |M(t \wedge \tau_k^n)|^2 = |M(t)|^2 \leq M^*$$

This follows from the observation that

$$(M(t \wedge \tau_{k+1}^n), M(t \wedge \tau_k^n)) \leq \frac{1}{2} \left( |M(t \wedge \tau_{k+1}^n)|^2 + |M(t \wedge \tau_k^n)|^2 \right)$$

Then it follows that $\sup_{t \in [0,T]} |P(t)(\omega)| \leq M^*(\omega) \leq C$ for a.e. $\omega$. The quadratic variation $[M]$ was defined as

$$|M(t)|^2 = P(t) + [M](t)$$

Thus $[M](t) \leq 2(M^*)^2$. Now consider the above limit in 61.6.26. From the assumption that $M$ is uniformly bounded,

$$\int_0^T \|RM_n - RM\|^2 d[M] \leq \int_0^T 4C^2 d[M] = 4C^2 [M](T) \leq 4C^2 (2C^2) < \infty$$

Also, by the continuity of the martingale, for each $\omega$,

$$\lim_{n \to \infty} \|RM_n - RM\|^2 = 0$$

By the dominated convergence theorem, and the fact that the integrand is bounded,

$$\lim_{n \to \infty} \int_0^T \|RM_n - RM\|^2 d[M] = 0.$$ 

Then from the above estimate and the dominated convergence theorem again, 61.6.26 follows. Thus $RM \in G_M$. 

From the above lemma, it makes sense to speak of

$$\int_0^t (RM) dM$$

and this is a continuous martingale having values in $\mathbb{R}$. Also from the above argument, if $\{t_i^m\}_{k=0}^{m_n}$ is a sequence of partitions such that

$$\lim_{n \to \infty} \max \{|t_i^m - t_{i+1}^m|, i = 0, \cdots, m_n\} = 0,$$

then it follows that

$$\sum_{i=0}^{m_n-1} RM(t_i)(M(t \wedge t_{k+1}) - M(t \wedge t_k)) \to \int_0^t (RM) dM$$

in $L^2(\Omega)$, this for each $t \in [0,T]$. 

Now here is the main result.
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

Theorem 61.6.4 Let $H$ be a Hilbert space and suppose $(M, \mathcal{F}_t), t \in [0,T]$ is a uniformly bounded continuous martingale with values in $H$. Also let $\{t^n_k\}_{k=1}^{m_n}$ be a sequence of partitions satisfying

$$\lim_{n \to \infty} \max \{ |t^n_i - t^n_{i+1}|, i = 0, \cdots, m_n \} = 0, \quad \{t^n_k\}_{k=1}^{m_n} \subseteq \{t^{n+1}_k\}_{k=1}^{m_{n+1}}.$$

Then

$$\lfloor M \rfloor (t) = \lim_{n \to \infty} \sum_{k=0}^{m_n-1} |M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k)|^2_H$$

the limit taking place in $L^2(\Omega)$. In case $M$ is just a continuous local martingale, the above limit happens in probability.

Proof: First suppose $M$ is uniformly bounded.

$$\sum_{k=0}^{m_n-1} |M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k)|^2_H$$

$$= \sum_{k=0}^{m_n-1} |M (t \wedge t^n_{k+1})|^2 - |M (t \wedge t^n_k)|^2 - 2 \sum_{k=0}^{m_n-1} (M (t \wedge t^n_k), M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k))$$

$$= |M (t)|^2_H - 2 \sum_{k=0}^{m_n-1} (M (t \wedge t^n_k), M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k))$$

$$= |M (t)|^2_H - 2 \sum_{k=0}^{m_n-1} RM (t^n_k) (M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k))$$

Then by Lemma 61.6.3, the right side converges to

$$|M (t)|^2_H - 2 \int_0^t (RM) dM$$

Therefore, in $L^2(\Omega)$,

$$\lim_{n \to \infty} \sum_{k=0}^{m_n-1} |M (t \wedge t^n_{k+1}) - M (t \wedge t^n_k)|^2_H + 2 \int_0^t (RM) dM = |M (t)|^2_H$$

That term on the left involving the limit is increasing and equal to 0 when $t = 0$. Therefore, it must equal $\lfloor M \rfloor (t)$.

Next suppose $M$ is only a continuous local martingale. By Proposition 61.2.2 there exists an increasing localizing sequence $\{\tau_k\}$ such that $M^{\tau_k}$ is a uniformly bounded martingale. Then

$$P (\cup_{k=1}^{\infty} [\tau_k = \infty]) = 1$$
To save notation, let

\[ Q_n(t) \equiv \sum_{k=0}^{m_n-1} \left[ M(t \land t^*_{k+1}) - M(t \land t^*_k) \right]^2_H \]

Let \( \eta, \varepsilon > 0 \) be given. Then there exists \( k \) large enough that \( P(\{\tau_k = \infty\}) > 1 - \eta/2 \). This is because the sets \( \{\tau_k = \infty\} \) increase to \( \Omega \) other than a set of measure zero. Then,

\[ |Q^*_n - [M]^*_k (t)| > \varepsilon \cap [\tau_k = \infty] = |Q_n - [M] (t)| > \varepsilon \cap [\tau_k = \infty] \]

Thus

\[ P(\{|Q_n - [M] (t)| > \varepsilon\}) \leq P(\{|Q_n - [M] (t)| > \varepsilon \cap [\tau_k = \infty]\}) + P(\{\tau_k < \infty\}) \]

\[ \leq P(\{|Q^*_n - [M]^*_k (t)| > \varepsilon\}) + \eta/2 \]

From the first part, the convergence in probability of \( Q^*_n (t) \) to \( [M]^*_k (t) \) follows from the convergence in \( L^2 (\Omega) \) and so if \( n \) is large enough, the right side of the above inequality is less than \( \eta/2 + \eta/2 = \eta \). Since \( \eta \) was arbitrary, this proves convergence in probability. \( \Box \)

### 61.7 Doob Meyer Decomposition

This section is on the Doob Meyer decomposition which is a way of starting with a submartingale and writing it as the sum of a martingale and an increasing adapted stochastic process of a certain form. This is more general than what was done above with the submartingales \( |M(t)|^2 \) for \( M(t) \in \mathcal{M}_L^2 (H) \) where \( M \) is a continuous martingale. There are two forms for this theorem, one for discrete martingales and one for martingales defined on an interval of the real line which is much harder. According to \([64]\), this material is found in \([61]\) however, I am following \([64]\) for the continuous version of this theorem.

**Theorem 61.7.1** Let \( \{X_n\} \) be a submartingale. Then there exists a unique stochastic process, \( \{A_n\} \) and martingale, \( \{M_n\} \) such that

1. \( A_n(\omega) \leq A_{n+1}(\omega), \ A_1(\omega) = 0 \),

2. \( A_n \) is \( \mathcal{F}_{n-1} \) adapted for all \( n \geq 1 \) where \( \mathcal{F}_0 \equiv \mathcal{F}_1 \).

and also \( X_n = M_n + A_n \).

**Proof:** Let \( A_1 \equiv 0 \) and define

\[ A_n \equiv \sum_{k=2}^{n} E \left( X_k - X_{k-1} | \mathcal{F}_{k-1} \right). \]
2200  CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

It follows \( A_n \) is \( \mathcal{F}_{n-1} \) measurable. Since \( \{X_k\} \) is a submartingale, \( A_n \) is increasing because

\[
A_{n+1} - A_n = E(X_{n+1} - X_n | \mathcal{F}_n) \geq 0 \tag{61.7.27}
\]

It is a submartingale because

\[
E(A_n | \mathcal{F}_{n-1}) = A_n \geq A_{n-1}.
\]

Now let \( M_n \) be defined by

\[
X_n = M_n + A_n.
\]

Then from (61.7.27),

\[
E(M_{n+1} | \mathcal{F}_n) = E(X_{n+1} | \mathcal{F}_n) - E(A_{n+1} | \mathcal{F}_n)
\]

\[
= E(X_{n+1} | \mathcal{F}_n) - E(A_{n+1} - A_n | \mathcal{F}_n) - A_n
\]

\[
= E(X_{n+1} | \mathcal{F}_n) - E(E(X_{n+1} - X_n | \mathcal{F}_n) | \mathcal{F}_n) - A_n
\]

\[
= E(X_{n+1} | \mathcal{F}_n) - E(X_{n+1} - X_n | \mathcal{F}_n) - A_n
\]

\[
= E(X_n | \mathcal{F}_n) - A_n
\]

\[
= X_n - A_n \equiv M_n
\]

This proves the existence part.

It remains to verify uniqueness. Suppose then that

\[
X_n = M_n + A_n = M'_n + A'_n
\]

where \( \{A_n\} \) and \( \{A'_n\} \) both satisfy the conditions of the theorem and \( \{M_n\} \) and \( \{M'_n\} \) are both martingales. Then

\[
M_n - M'_n = A'_n - A_n
\]

and so, since \( A'_n - A_n \) is \( \mathcal{F}_{n-1} \) measurable and \( \{M_n - M'_n\} \) is a martingale,

\[
M_{n-1} - M'_{n-1} = E(M_n - M'_n | \mathcal{F}_{n-1})
\]

\[
= E(A'_n - A_n | \mathcal{F}_{n-1})
\]

\[
= A'_n - A_n = M_n - M'_n.
\]

Continuing this way shows \( M_n - M'_n \) is a constant. However, since \( A'_1 - A_1 = 0 = M_1 - M'_1 \), it follows \( M_n = M'_n \) and this proves uniqueness. This proves the theorem.

**Definition 61.7.2** A stochastic process, \( \{A_n\} \) which satisfies the conditions of Theorem [61.7.1].

\[
A_n (\omega) \leq A_{n+1} (\omega)
\]

and
61.7. DOOB MEYER DECOMPOSITION

\[ A_n \text{ is } \mathcal{F}_{n-1} \text{ adapted for all } n \geq 1 \]

where \( \mathcal{F}_0 \equiv \mathcal{F}_1 \) is said to be natural.

The Doob Meyer theorem needs to be extended to continuous submartingales and this will require another description of what it means for a stochastic process to be natural. To get an idea of what this condition should be, here is a lemma.

**Lemma 61.7.3** Let a stochastic process, \( \{A_n\} \), be natural. Then for every martingale, \( \{M_n\} \),

\[
E (M_n A_n) = E \left( \sum_{j=1}^{n-1} M_j (A_{j+1} - A_j) \right)
\]

**Proof:** Start with the right side.

\[
E \left( \sum_{j=1}^{n-1} M_j (A_{j+1} - A_j) \right) = E \left( \sum_{j=2}^{n} M_{j-1}A_j - \sum_{j=1}^{n-1} M_jA_j \right)
\]

\[
= E \left( \sum_{j=2}^{n-1} A_j (M_{j-1} - M_j) \right) + E (M_{n-1}A_n)
\]

Then the first term equals zero because since \( A_j \) is \( \mathcal{F}_{j-1} \) measurable,

\[
\int_{\Omega} A_jM_{j-1}dP - \int_{\Omega} A_jM_j = \int_{\Omega} A_jE (M_j|\mathcal{F}_{j-1}) dP - \int_{\Omega} A_jM_jdP
\]

\[
= \int_{\Omega} E (A_jM_j|\mathcal{F}_{j-1}) dP - \int_{\Omega} A_jM_jdP
\]

\[
= \int_{\Omega} A_jM_jdP - \int_{\Omega} A_jM_jdP = 0.
\]

The last term equals

\[
\int_{\Omega} M_{n-1}A_n dP = \int_{\Omega} E (M_n|\mathcal{F}_{n-1}) A_n dP
\]

\[
= \int_{\Omega} E (M_nA_n|\mathcal{F}_{n-1}) dP = E (M_n A_n).
\]

This proves the lemma.

**Definition 61.7.4** Let \( A \) be an increasing function defined on \( \mathbb{R} \). By Theorem 3.3.4 on Page 48 there exists a positive linear functional, \( L \) defined on \( C_c(\mathbb{R}) \) given by

\[
Lf \equiv \int_{a}^{b} f dA \text{ where } \text{spt}(f) \subseteq [a, b]
\]
where the integral is just the Riemann Stieltjes integral. Then by the Riesz representation theorem, Theorem 10.3.2 on Page 269, there exists a unique Radon measure, \( \mu \) which extends this functional, as described in the Riesz representation theorem. Then for \( B \) a measurable set, I will write either

\[
\int_B f \, d\mu \quad \text{or} \quad \int_B f \, dA
\]

to denote the Lebesgue integral,

\[
\int X_B f \, d:\]

Lemma 61.7.5 Let \( f \) be right continuous. Then \( f \) is Borel measurable. Also, if the limit from the left exists, then \( f_-(x) \equiv \lim_{y \to x^-} f(y) \) is also Borel measurable. If \( A \) is an increasing right continuous function and \( f \) is right continuous and \( f_+ \), the left limit function exists, then if \( f \) is bounded, on \( [a,b] \), and if

\[
\left\{ x_0^p, \ldots, x_n^p \right\}_{p=1}^\infty
\]

is a sequence of partitions of \( [a,b] \) such that

\[
\lim_{p \to \infty} \max \left\{ \left| x_k^p - x_{k-1}^p \right| : k = 1, 2, \ldots, n_p \right\} = 0 \quad (61.7.28)
\]

then

\[
\int_{(a,b]} f_+ \, dA = \lim_{p \to \infty} \sum_{k=1}^{n_p} f(x_{k-1}^p) (A(x_k^p) - A(x_{k-1}^p)) \quad (61.7.29)
\]

More generally, let

\[
D \equiv \bigcup_{p=1}^\infty \left\{ x_0^p, \ldots, x_n^p \right\}_{p=1}^\infty
\]

and

\[
f_-(t) = \lim_{s \to t^-, s \in D} f(s).
\]

Then (61.7.29) holds.

**Proof:** For \( x \in f^{-1}((a, \infty)) \), denote by \( I_x \) the union of all intervals containing \( x \) such that \( f(y) \) is larger than \( a \) for all \( y \) in the interval. Since \( f \) is right continuous, each \( I_x \) has positive length. Now if \( I_x \) and \( I_y \) are two of these intervals, then either they must have empty intersection or they are the same interval. Thus \( f^{-1}((a, \infty)) \) is of the form \( \cup_{x \in f^{-1}((a, \infty))} I_x \) and there can only be countably many distinct intervals because each has positive length and \( \mathbb{R} \) is separable. Hence \( f^{-1}((a, \infty)) \) equals the countable union of intervals and is therefore, Borel measurable. Now

\[
f_-(x) = \lim_{n \to \infty} f(x - r_n) \equiv \lim_{n \to \infty} f_{r_n}(x)
\]

where \( r_n \) is a decreasing sequence converging to 0. Now each \( f_{r_n} \) is Borel measurable by the first part of the proof because it is right continuous and so it follows the same is true of \( f_- \).
Finally consider the claim about the integral. Since \( A \) is right continuous, a simple argument involving the dominated convergence theorem and approximating \((c,d]\) with a piecewise linear continuous function nonzero only on \((c,d+h)\) which approximates \( X_{(c,d]} \) will show that for \( \mu \) the measure of Definition 61.7.4

\[ \mu ((c,d]) = A(d) - A(c). \]

Therefore, the sum in 61.7.29 is of the form

\[
\sum_{k=1}^{n_p} f(x_{k-1}^p, x_k^p) = \int_{(a,b]} \sum_{k=1}^{n_p} f(x_{k-1}^p) X_{(x_{k-1}, x_k]} d\mu
\]

and by 61.7.28

\[
\lim_{p \to \infty} \sum_{k=1}^{n_p} f(x_{k-1}^p) X_{(x_{k-1}, x_k]}(x) = f^-(x)
\]

for each \( x \in (a,b] \). Therefore, since \( f \) is bounded, 61.7.29 follows from the dominated convergence theorem. The last claim follows the same way. This proves the lemma.

**Definition 61.7.6** An increasing stochastic process, \( \{A(t)\} \) which is right continuous is said to be natural if \( A(0) = 0 \) and whenever \( \{\xi(t)\} \) is a bounded right continuous martingale,

\[
E(A(t) \xi(t)) = E \left( \int_{(0,t]} \xi^-(s) dA(s) \right).
\]

(61.7.30)

Here

\[ \xi^-(s, \omega) = \lim_{r \to s-} \xi(r, \omega) \]

a.e. where \( D \) is a countable dense subset of \([0,t] \). By Corollary 60.8.2 the right side of 61.7.30 is not dependent on the choice of \( D \) since if \( \xi^- \) is computed using two different dense subsets, the two random variables are equal a.e.

Some discussion is in order for this definition. Pick \( \omega \in \Omega \). Then since \( A \) is right continuous, the function \( t \to A(t, \omega) \) is increasing and right continuous. Therefore, one can do the Lebesgue Stieltjes integral defined in Definition 61.7.4 for each \( \omega \) whenever \( f \) is Borel measurable and bounded. Now it is assumed \( \{\xi(t)\} \) is bounded and right continuous. By Lemma 61.7.5 \( \xi^-(t) = \lim_{r \to t-} \xi(r) \) is measurable and by this lemma,

\[
\int_{(0,t]} \xi^-(s) dA(s) = \lim_{p \to \infty} \sum_{k=1}^{n_p} \xi^p(t_{k-1}^p) (A(t_k^p) - A(t_{k-1}^p))
\]

where \( \{t_k^p\}_{k=1}^{n_p} \) is a sequence of partitions of \([0,t] \) such that

\[
\lim_{p \to \infty} \max \{ |t_k^p - t_{k-1}^p| : k = 1, 2, \ldots, n_p \} = 0.
\]

(61.7.31)
and $D \equiv \bigcup_{p=1}^{\infty} \bigcup_{k=1}^{n_p} \{ t_k^p \}^{n_p}$.

Also, if $t \to A(t, \omega)$ is right continuous, hence Borel measurable, then for $\xi(t)$ the above bounded right continuous martingale, it follows it makes sense to write

$$\int_{(0,t]} \xi(s) \, dA(s).$$

Consider the right sum,

$$\sum_{k=1}^{n_p} \xi(t_k^p) \left( A(t_k^p) - A(t_{k-1}^p) \right)$$

This equals

$$\int_{(0,t]} \sum_{k=1}^{n_p} \xi(t_k^p) \mathcal{X}_{(t_{k-1}^p, t_k^p]}(s) \, dA(s)$$

and by right continuity, it follows

$$\lim_{p \to \infty} \sum_{k=1}^{n_p} \xi(t_k^p) \mathcal{X}_{(t_{k-1}^p, t_k^p]}(s) = \xi(s)$$

and so the dominated convergence theorem applies and it follows

$$\lim_{p \to \infty} \sum_{k=1}^{n_p} \xi(t_k^p) \left( A(t_k^p) - A(t_{k-1}^p) \right) = \int_{(0,t]} \xi(s) \, dA(s)$$

where this is a random variable. Thus

$$E \left( \int_{(0,t]} \xi(s) \, dA(s) \right) = \int_{\Omega} \left( \lim_{p \to \infty} \int_{(0,t]} \sum_{k=1}^{n_p} \xi(t_k^p) \mathcal{X}_{(t_{k-1}^p, t_k^p]}(s) \, dA(s) \right) \, dP$$

(61.7.32)

Now as mentioned above,

$$\int_{(0,t]} \sum_{k=1}^{n_p} \xi(t_k^p) \mathcal{X}_{(t_{k-1}^p, t_k^p]}(s) \, dA(s) = \sum_{k=1}^{n_p} \xi(t_k^p) \left( A(t_k^p) - A(t_{k-1}^p) \right)$$

and since $A$ is increasing, this is bounded above by an expression of the form $CA(t)$, a function in $L^1$. Therefore, by the dominated convergence theorem, (61.7.32) reduces
to

\[
\lim_{p \to \infty} \int \int_{(0,t]} \sum_{k=1}^{n_p} \xi(t^p_k) \chi_{(t^p_{k-1}, t^p_k]} (s) \, dA(s) \, dP
\]

\[
= \lim_{p \to \infty} \int \sum_{k=1}^{n_p} \xi(t^p_k) (A(t^p_k) - A(t^p_{k-1})) \, dP
\]

\[
= \lim_{p \to \infty} \int \left( \sum_{k=1}^{n_p} \xi(t^p_k) A(t^p_k) - \sum_{k=0}^{n_p-1} \xi(t^p_{k+1}) A(t^p_k) \right) \, dP
\]

\[
= \lim_{p \to \infty} \sum_{k=1}^{n_p-1} \int \xi(t^p_k) - \xi(t^p_{k+1}) A(t^p_k) \, dP + \int \xi(t) A(t) \, dP.(61.7.33)
\]

Since \(\xi\) is a martingale,

\[
\int \xi(t^p_k) A(t^p_k) \, dP = \int \Omega E \left( \xi(t^p_{k+1}) A(t^p_k) \mid \mathcal{F}_{t_k^p} \right) \, dP
\]

\[
= \int \Omega A(t^p_k) E \left( \xi(t^p_{k+1}) \mid \mathcal{F}_{t_k^p} \right) \, dP
\]

\[
= \int \Omega A(t^p_k) \xi(t^p_k) \, dP
\]

and so in \(\text{(61.7.33)}\) the term with the sum equals 0 and it reduces to

\[
E(\xi(t) A(t)).
\]

This is sufficiently interesting to state as a lemma.

**Lemma 61.7.7** Let \(A\) be an increasing adapted stochastic process which is right continuous. Also let \(\xi(t)\) be a bounded right continuous martingale. Then

\[
E(\xi(t) A(t)) = E \left( \int_{(0,t]} \xi(s) \, dA(s) \right)
\]

and \(A\) is natural, if and only if for all such bounded right continuous martingales,

\[
E(\xi(t) A(t)) = E \left( \int_{(0,t]} \xi_+(s) \, dA(s) \right) = E \left( \int_{(0,t]} \xi_-(s) \, dA(s) \right)
\]

**Lemma 61.7.8** Let \((\Omega, \mathcal{F}, P)\) be a probability space and let \(\mathcal{G}\) be a \(\sigma\) algebra contained in \(\mathcal{F}\). Suppose also that \(\{f_n\}\) is a sequence in \(L^1(\Omega)\) which converges weakly to \(f\) in \(L^1(\Omega)\). That is, for every \(h \in L^\infty(\Omega)\),

\[
\int f_n h dP \to \int f h dP.
\]

Then \(E(f_n \mid \mathcal{G})\) converges weakly in \(L^1(\Omega)\) to \(E(f \mid \mathcal{G})\).
Proof: First note that if \( h \in L^\infty (\Omega, \mathcal{F}) \), then \( E (h|\mathcal{G}) \in L^\infty (\Omega, \mathcal{G}) \) because if \( A \in \mathcal{G} \),
\[
\int_A |E (h|\mathcal{G})| \, dP \leq \int_A E (|h| |\mathcal{G}) \, dP = \int_A |h| \, dP
\]
and so if \( A = [|E (h|\mathcal{G})| > ||h||_\infty] \), then if \( P (A) > 0 \),
\[
||h||_\infty P (A) < \int_A |E (h|\mathcal{G})| \, dP \leq \int_A |h| \, dP \leq ||h||_\infty P (A),
\]
a contradiction. Hence \( P (A) = 0 \) and so \( E (h|\mathcal{G}) \in L^\infty (\Omega, \mathcal{G}) \) as claimed. Let \( h \in L^\infty (\Omega, \mathcal{G}) \).
\[
\int_{\Omega} E (f_n|\mathcal{G}) \, h \, dP = \int_{\Omega} E (E (f_n|\mathcal{G}) \, h|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (f_n|\mathcal{G}) \, E (h|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (f_n E (h|\mathcal{G}) \, |\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} f_n E (h|\mathcal{G}) \, dP
\]
and so
\[
\lim_{n \to \infty} \int_{\Omega} E (f_n|\mathcal{G}) \, h \, dP = \lim_{n \to \infty} \int_{\Omega} f_n E (h|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} f E (h|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (f E (h|\mathcal{G}) \, |\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (h|\mathcal{G}) \, E (f|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (E (f|\mathcal{G}) \, h|\mathcal{G}) \, dP
\]
\[
= \int_{\Omega} E (f|\mathcal{G}) \, h \, dP
\]
and this proves the lemma.

Next suppose \( \{X (t)\} \) is a real submartingale and suppose \( X (t) = M (t) + A (t) \) where \( A (t) \) is an increasing stochastic process adapted to \( \mathcal{F}_t \) such that \( A (0) = 0 \) and \( \{M (t)\} \) is a martingale adapted to \( \mathcal{F}_t \). Also let \( T \) be a stopping time bounded above by \( a \). Then by the optional sampling theorem, and the observation that \( \{|M (t)|\} \)
is a submartingale
\[
\int_{|X(T)| \geq \lambda} |X(T)| \, dP \\
\leq \int_{|X(T)| \geq \lambda} |M(T)| \, dP + \int_{|X(T)| \geq \lambda} A(T) \, dP \\
\leq \int_{|X(T)| \geq \lambda} E(|M(a)| \mid \mathcal{F}_T) \, dP + \int_{|X(T)| \geq \lambda} E(A(a) \mid \mathcal{F}_T) \, dP \\
\leq \int_{|X(T)| \geq \lambda} |M(a)| \, dP + \int_{|X(T)| \geq \lambda} A(a) \, dP
\]
Now by Theorem 58.5.4,
\[
P(|X_T| \geq \lambda) \leq \frac{2}{\lambda} E(|X(0)| + |X(a)|)
\]
and so \(P(|X(T)| \geq \lambda) \rightarrow 0\) uniformly for \(T\) a stopping time bounded by \(a\) as \(\lambda \rightarrow \infty\) and so this shows equi integrability of \(\{X(T)\}\) because \(A(t, \omega) \geq 0\).

This motivates the following definition.

**Definition 61.7.9** A stochastic process, \(\{X(t)\}\) is called DL if for all \(a > 0\), the set of random variables, \(\{X(T)\}\) for \(T\) a stopping time bounded by \(a\) is equi integrable.

**Example 61.7.10** Let \(\{M(t)\}\) be a continuous martingale. Then \(\{M(t)\}\) is of class DL.

To show this, let \(a > 0\) be given and let \(T\) be a stopping time bounded by \(a\). Then by the optional sampling theorem, \(M(0), M(T), M(a)\) is a martingale and so
\[
E(M(a) \mid \mathcal{F}_T) = M(T)
\]
and so by Jensen’s inequality, \(|M(T)| \leq E(|M(a)| \mid \mathcal{F}_T)\). Therefore,
\[
\int_{|M(T)| \geq \lambda} |M(T)| \, dP \leq \int_{|M(T)| \geq \lambda} E(|M(a)| \mid \mathcal{F}_T) \, dP \\
= \int_{|M(T)| \geq \lambda} |M(a)| \, dP.
\]
Now by Theorem 60.5.3,
\[
P(|M(T)| \geq \lambda) \leq \frac{1}{\lambda} E(|M(a)|)
\]
and so since a given \(L^1\) function is uniformly integrable, there exists \(\delta\) such that if \(P(A) < \delta\) then
\[
\int_A |M(a)| \, dP < \varepsilon.
\]
Now choose $\lambda$ large enough that
\[
\frac{1}{\lambda} E (|M(a)|) < \delta.
\]
Then for such $\lambda$, it follows from 61.3.34 that for any stopping time bounded by $a$,
\[
\int_{|M(T)| \geq \lambda} |M(T)| dP < \varepsilon.
\]
This shows $M$ is DL.

**Example 61.7.11** Let \( \{X(t)\} \) be a nonnegative submartingale with \( t \to E(X(t)) \) right continuous so \( \{X(t)\} \) can be considered right continuous. Then \( \{X(t)\} \) is DL.

To show this, let $T$ be a stopping time bounded by $a > 0$. Then by the optional sampling theorem,
\[
\int_{X(T) \geq \lambda} X(T) dP \leq \int_{X(T) \geq \lambda} X(a) dP
\]
and now by Theorem 58.5.4 on Page 2014
\[
P(\{X(T) \geq \lambda\}) \leq \frac{1}{\lambda} E \left( X^+_a \right).
\]
Thus if $\varepsilon > 0$ is given, there exists $\lambda$ large enough that for any stopping time, $T \leq a$,
\[
\int_{X(T) \geq \lambda} X(T) dP \leq \varepsilon
\]
Thus the submartingale is DL.

Now with this preparation, here is the Doob Meyer decomposition.

**Theorem 61.7.12** Let \( \{X(t)\} \) be a submartingale of class DL. Then there exists a martingale, \( \{M(t)\} \) and an increasing submartingale, \( \{A(t)\} \) such that for each $t$,
\[
X(t) = M(t) + A(t).
\]
If \( \{A(t)\} \) is chosen to be natural and $A(0) = 0$, then with this condition, \( \{M(t)\} \) and \( \{A(t)\} \) are unique.

**Proof:** First I will show uniqueness. Suppose then that
\[
X(t) = M(t) + A(t) = M'(t) + A'(t)
\]
where $M, M'$ and $A, A'$ satisfy the given conditions. Let $t > 0$ and consider $s \in [0,t]$. Then
\[
A(s) - A'(s) = M'(s) - M(s)
\]
Since $A, A'$ are natural, it follows that for $\xi(t)$ a right continuous bounded martingale,

$$E(\xi(t)(A(t) - A'(t))) = E\left(\int_{[0,t]} \xi_-(s) \, dA(s)\right) - E\left(\int_{[0,t]} \xi_-(s) \, dA'(s)\right)$$

$$= E\left(\lim_{n \to \infty} \sum_{k=1}^{m_n} \xi(t^n_k) \left(A(t^n_k) - A(t^n_{k-1})\right) - \sum_{k=1}^{m_n} \xi(t^n_{k-1}) \left(A'(t^n_k) - A'(t^n_{k-1})\right)\right)$$

where $\{t^n_k\}_{k=0}^{m_n}$ is a sequence of partitions of $[0,t]$ such that these are equally spaced points, $\lim_{n \to \infty} t^n_{k+1} - t^n_k = 0$, and $\{t^n_k\}_{k=0}^{m_n} \subseteq \{t^{n+1}_k\}_{k=0}^{m_{n+1}}$. Then since $A(t)$ and $A'(t)$ are increasing, the absolute value of each sum is bounded above by an expression of the form

$$CA(t) \text{ or } CA'(t)$$

and so the dominated convergence theorem can be applied to get the above expression to equal

$$\lim_{n \to \infty} E\left(\sum_{k=1}^{m_n} \xi(t^n_k) \left(M(t^n_k) - M(t^n_{k-1})\right) - \sum_{k=1}^{m_n} \xi(t^n_{k-1}) \left(M'(t^n_k) - M'(t^n_{k-1})\right)\right).$$

Now using $X = A + M$ and $X = A' + M'$

$$= \lim_{n \to \infty} E\left(\sum_{k=1}^{m_n} \xi(t^n_k) \left(M(t^n_k) - M(t^n_{k-1})\right) - \sum_{k=1}^{m_n} \xi(t^n_{k-1}) \left(M'(t^n_k) - M'(t^n_{k-1})\right)\right).$$

Both terms in the above equal 0. Here is why.

$$E\left(\xi(t^n_{k-1}) M(t^n_k)\right) = E\left(E\left(\xi(t^n_{k-1}) M(t^n_k) | F_{t^n_{k-1}}\right)\right)$$

$$= E\left(\xi(t^n_{k-1}) E\left(M(t^n_k) | F_{t^n_{k-1}}\right)\right)$$

$$= E\left(\xi(t^n_{k-1}) M(t^n_{k-1})\right).$$

Thus the expected value of the first sum equals 0. Similarly, the expected value of the second sum equals 0. Hence this has shown that for any bounded right continuous martingale, $\{\xi(s)\}$ and $t > 0$,

$$E(\xi(t) (A(t) - A'(t))) = 0.$$

Now let $\xi$ be a bounded random variable and let $\xi(t)$ be a right continuous version of the martingale $E(\xi | F_t)$ . Then

$$0 = E\left(E(\xi | F_t) (A(t) - A'(t))\right) = E\left(E(\xi (A(t) - A'(t)) | F_t)\right)$$

$$= E\left(\xi (A(t) - A'(t))\right)$$

and since $\xi$ is arbitrary, it follows that $A(t) = A'(t)$ a.e. which proves uniqueness.
Because of the uniqueness assertion, it suffices to prove the theorem on an arbitrary interval, [0, a].

Without loss of generality, it can be assumed \( X(0) = 0 \) since otherwise, you could simply consider \( X(t) - X(0) \) in its place and then at the end, add \( X(0) \) to \( M(t) \). Let \( \{t_k^n\}_{k=0}^{m_n} \) be a sequence of partitions of \([0, a]\) such that these are equally spaced points, \( \lim_{n \to \infty} t_{k+1}^n - t_k^n = 0 \), and \( \{t_k^n\}_{k=0}^{m_n} \subseteq \{t_{k+1}^{n+1}\}_{k=0}^{m_{n+1}} \). Then consider the submartingale, \( \{X(t_k^n)\}_{k=0}^{m_n} \). Theorem 61.7.1 implies there exists a unique martingale, and increasing submartingale, \( \{M(t_k^n)\}_{k=0}^{m_n} \) and \( \{A(t_k^n)\}_{k=0}^{m_n} \) respectively such that \( M(0) = 0 = A(0) \),

\[
X(t_k^n) = M^n(t_k^n) + A^n(t_k^n).
\]

and \( A^n(t_k^n) \) is \( \mathcal{F}_{t_k^n} \) measurable. Recall how these were defined.

\[
A^n(t_k^n) = \sum_{j=1}^{k-1} E \left( X(t_j^n) - X(t_{j-1}^n) \mid \mathcal{F}_{t_{j-1}^n} \right), \quad A^n(0) = 0
\]

\[
M^n(t_k^n) = X(t_k^n) - A^n(t_k^n).
\]

I want to show that \( \{A^n(a)\} \) is equi integrable. From this there will be a weakly convergent subsequence and nice things will happen. Define \( T^n(\omega) \) to equal \( t_{j-1}^n \) where \( t_j^n \) is the first time where \( A^n(t_j^n, \omega) \geq \lambda \) or \( T^n(\omega) = a \) if this never happens. I want to say that \( T^n \) is a stopping time and so I need to verify that \( [T^n \leq t_j^n] \in \mathcal{F}_{t_j^n} \) for each \( j \). If \( \omega \in [T^n \leq t_j^n] \), then this means the first time, \( t_k^n \), where \( A^n(t_k^n, \omega) \geq \lambda \) is such that \( t_k^n \leq t_{j+1}^n \). Since \( A^n \) is increasing in \( k \),

\[
[T^n \leq t_j^n] = \bigcup_{k=0}^{j+1} [A^n(t_k^n) \geq \lambda] = [A^n(t_{j+1}^n) \geq \lambda] \in \mathcal{F}_{t_j^n}.
\]

Note \( T^n \) only has the values \( t_k^n \). Thus for \( t \in [t_{j-1}^n, t_j^n) \),

\[
[T^n \leq t] = [T^n \leq t_{j-1}^n] \in \mathcal{F}_{t_{j-1}^n} \subseteq \mathcal{F}_t.
\]

Thus \( T^n \) is one of those stopping times bounded by \( a \). Since \( \{X(t)\} \) is \( DL \), this shows \( \{X(T^n)\} \) is equi integrable. Now from the definition of \( T^n \), it follows

\[
A^n(T^n) \leq \lambda
\]

Recall \( T^n(\omega) = t_{j-1}^n \) where \( t_j^n \) is the first time where \( A^n(t_j^n, \omega) \geq \lambda \) or \( T^n(\omega) = a \) if this never happens. Thus \( T^n \) is such that it is before \( A^n \) gets larger than \( \lambda \). Thus,

\[
\int_{[A^n(a) \geq 2\lambda]} \frac{1}{2} A^n(a) dP \leq \int_{[A^n(a) \geq 2\lambda]} (A^n(a) - \lambda) dP
\]

\[
\leq \int_{[A^n(a) \geq 2\lambda]} (A^n(a) - A^n(T^n)) dP
\]
there exists a subsequence it also follows that

Thus it is obvious from properties of conditional expectation that

Because by the discrete optional sampling theorem,

Remember \( \{M^n(t^k)\}_{k=0}^{m_n} \) was a martingale.

\[
\int_{\Omega} (X(a) - X(T^n)) dP = \int_{[A^n(a) \geq \lambda]} (X(a) - X(T^n)) dP \\
+ \int_{[A^n(a) < \lambda]} (X(a) - X(T^n)) dP.
\]

The second of the integrals on the right is such that for \( \omega \) in this set, \( T^n(\omega) = a \) and so the second integral equals 0. Hence from the above,

\[
\int_{[A^n(a) \geq \lambda]} \frac{1}{2} A^n(a) dP \leq \int_{[A^n(a) \geq \lambda]} (X(a) - X(T^n)) dP
\]

and since \( \{X(t)\} \) is \( DL \), this shows \( \{A^n(a)\}_{n=1}^{\infty} \) is equi integrable.

By Corollary 11.6.1 on Page 624 there exists a subsequence \( \{A^{n_k}(a)\}_{k=1}^{\infty} \) which converges weakly in \( L^1(\Omega) \) to \( A(a) \). By Lemma 11.6.2 it also follows that \( E(A^{n_k}(a)|\mathcal{F}_t) \) converges weakly to \( E(A(a)|\mathcal{F}_t) \) in \( L^1(\Omega) \). Now define

\[
M(t) \equiv E(X(a) - A(a)|\mathcal{F}_t).
\]

Thus it is obvious from properties of conditional expectation that \( \{M(t)\} \) is a martingale adapted to \( \mathcal{F}_t \) and without loss of generality, it is a right continuous version. Let

\[
A(t) \equiv X(t) - M(t).
\]

Then since \( \{X(t)\} \) is a submartingale, it follows \( \{A(t)\} \) is also a submartingale.

It remains to show several things. First, it is necessary to show \( A(t) \) is increasing in \( t \) and \( A(0) = 0 \). To see this, let \( s < t, s, t \in \bigcup_{n=1}^{\infty} \bigcup_{k=0}^{m_n} t^k_n \). Then letting \( n \) large enough both \( s, t \) are in \( \bigcup_{k=0}^{m_n} t^k_n \). Only consider such \( n \). Let \( t = t^k_{n(t)}, s = t^k_{n(s)} \) and let \( h \in L^\infty(\Omega), h \geq 0 \). Then

\[
\int_{\Omega} (A(t) - A(s)) hdP = \int_{\Omega} (X(t) - M(t) - (X(s) - M(s))) hdP
\]

\[
\int_{\Omega} (X(t) - E(X(a) - A(a)|\mathcal{F}_t) - (X(s) - E(X(a) - A(a)|\mathcal{F}_s))) hdP.
\]

(61.7.35)
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

Now by Lemma 61.7.8, the following weak limit holds.

\[
E \left( X (a) - A (a) \mid \mathcal{F}_t \right) = \lim_{k \to \infty} E \left( \frac{M^{nk} (a)}{X (a) - A^{nk} (a)} \mid \mathcal{F}_t \right)
\]

\[
= \lim_{k \to \infty} M^{nk} (t)
\]

A similar formula holds for \( s \) in place of \( t \). Then the expression in 61.7.35 equals

\[
\lim_{k \to \infty} \int_{\Omega} (X (t) - M^{nk} (t) - (X (s) - M^{nk} (s))) h dP
\]

\[
= \lim_{k \to \infty} \int_{\Omega} (A^{nk} (t) - A^{nk} (s)) h dP \geq 0
\]

Since \( h \geq 0 \) is arbitrary, this shows \( A (t) - A (s) \geq 0 \) a.e. Not requiring \( h \geq 0 \), the above argument also shows that for \( s, t \in \bigcup_{n=1}^{\infty} \bigcup_{k=0}^{m_n} t_k \),

\[
A (t) - A (s) = \text{weak lim}_{p \to \infty} A^{nk} (t) - A^{nk} (s). \tag{61.7.36}
\]

Now consider the claim that \( A (0) = 0 \). Recall

\[
A (0) = X (0) - E \left( X (a) - A (a) \mid \mathcal{F}_0 \right) = -E \left( X (a) - A (a) \mid \mathcal{F}_0 \right)
\]

and so

\[
A (0) = \lim_{k \to \infty} -E \left( X (a) - A^{nk} (a) \mid \mathcal{F}_0 \right)
\]

\[
= \lim_{k \to \infty} -E \left( M^{nk} (a) \mid \mathcal{F}_0 \right) = \lim_{k \to \infty} -M^{nk} (0) = 0.
\]

This proves the theorem except for the claim that \( A (t) \) is natural. Let \( \xi (t) \) be a bounded right continuous martingale. I need to consider

\[
E \left( \int_{(0,t]} \xi_- (s) dA (s) \right)
\]

and show it equals \( \xi (t) A (t) \). First consider the case \( t = a \). By Lemma 61.7.9,

\[
E \left( \int_{(0,a]} \xi_- (s) dA (s) \right) \equiv E \left( \lim_{k \to \infty} \sum_{j=1}^{m_{nk}} \xi \left( t_{j-1}^{nk} \right) \left( A \left( t_{j}^{nk} \right) - A \left( t_{j-1}^{nk} \right) \right) \right) \tag{61.7.37}
\]

Since \( \xi \) is bounded, you can take the limit outside. This follows from the dominated convergence theorem and the fact, shown above that \( A \) is increasing and nonnegative. Here is why.

\[
0 \leq \left| \xi \left( t_{j-1}^{nk} \right) \right| A \left( t_{j}^{nk} \right) \leq A (a) C
\]
where $C$ is a constant larger than the values of $\xi$. Thus the above equals

$$\lim_{k \to \infty} E \left( \sum_{j=1}^{m_n} \xi (t_{j-1}^n) (A (t_j^n) - A (t_{j-1}^n)) \right)$$

$$= \lim_{k \to \infty} E \left( \sum_{j=1}^{m_n} \xi (t_{j-1}^n) (X (t_j^n) - M (t_j^n) - (X (t_{j-1}^n) - M (t_{j-1}^n))) \right)$$

$$= \lim_{k \to \infty} E \left( \sum_{j=1}^{m_n} \xi (t_{j-1}^n) (X (t_j^n) - X (t_{j-1}^n)) \right)$$  \hspace{1cm} (61.7.38)

because

$$E (\xi (t_{j-1}^n) M (t_j^n)) = E \left( E (\xi (t_{j-1}^n) M (t_j^n) | F_{t_{j-1}^n}) \right)$$

$$= E \left( \xi (t_{j-1}^n) E (M (t_j^n) | F_{t_{j-1}^n}) \right)$$

$$= E \left( \xi (t_{j-1}^n) M (t_j^n) \right)$$

since $M$ is a martingale. Now by a similar trick, this time using that $\{M^{n_k} (t_j^n)\}_{j=0}^{m_n}$ is a martingale, equals

$$\lim_{k \to \infty} E \left( \sum_{j=1}^{m_n} \xi (t_{j-1}^n) (A^{n_k} (t_j^n) - A^{n_k} (t_{j-1}^n)) \right)$$  \hspace{1cm} (61.7.39)

and now recall that $A^{n_k} (t_j^n)$ is $F_{t_{j-1}^n}$-measurable. This will now be used to change the subscript of $t_{j-1}^n$ in $\xi (t_{j-1}^n)$ to a $j$. \hspace{1cm} (61.7.39) equals

$$= \lim_{k \to \infty} \sum_{j=1}^{m_n} E \left( E (\xi (t_j^n) | F_{t_{j-1}^n}) (A^{n_k} (t_j^n) - A^{n_k} (t_{j-1}^n)) \right)$$

$$= \lim_{k \to \infty} \sum_{j=1}^{m_n} E \left( E (\xi (t_j^n) (A^{n_k} (t_j^n) - A^{n_k} (t_{j-1}^n)) | F_{t_{j-1}^n}) \right)$$

$$= \lim_{k \to \infty} \sum_{j=1}^{m_n} E (\xi (t_j^n) (A^{n_k} (t_j^n) - A^{n_k} (t_{j-1}^n)))$$

$$= \lim_{k \to \infty} E \left( \sum_{j=1}^{m_n} \xi (t_j^n) (A^{n_k} (t_j^n) - A^{n_k} (t_{j-1}^n)) \right)$$
From this all that remains is to write the above as

\[
\lim_{k \to \infty} E \left( \sum_{j=1}^{m_{n_k}} \xi (t_{j}^{n_k}) A^{n_k} (t_{j}^{n_k}) - \sum_{j=0}^{m_{n_k}-1} \xi (t_{j+1}^{n_k}) A^{n_k} (t_{j}^{n_k}) \right)
\]

\[
= \lim_{k \to \infty} \left( E (\xi (a) A^{n_k} (a)) + E \left( \sum_{j=1}^{m_{n_k}-1} (\xi (t_{j}^{n_k}) - \xi (t_{j+1}^{n_k})) A^{n_k} (t_{j}^{n_k}) \right) \right)
\]

Now using the fact \( \xi \) is a martingale, this last term equals 0. Here is why.

\[
E (\xi (t_{j+1}^{n_k}) A^{n_k} (t_{j}^{n_k})) = E \left( E (\xi (t_{j+1}^{n_k}) A^{n_k} (t_{j}^{n_k}) | \mathcal{F}_{t_{j}^{n_k}}) \right)
\]

\[
= E \left( A^{n_k} (t_{j}^{n_k}) E (\xi (t_{j+1}^{n_k}) | \mathcal{F}_{t_{j}^{n_k}}) \right)
\]

\[
= E \left( A^{n_k} (t_{j}^{n_k}) \xi (t_{j}^{n_k}) \right)
\]

The first term converges to \( E (\xi (a) A (a)) \) because this was how \( A (a) \) was obtained, as a weak limit in \( L^1 (\Omega) \) of \( A^{n_k} (a) \). Also by Lemma 61.7.7, \( E (\xi (a) A (a)) = E \left( \int_{[0,a]} (s) dA (s) \right) \)

From this has now shown that

\[
E (\xi (a) A (a)) = E \left( \int_{(0,a]} (s) dA (s) \right)
\]

To get the desired result on \((0,t]\), apply what was just shown to a “stopped martingale”,

\[
\xi^t (s) = \begin{cases} 
\xi (s) & \text{if } s \leq t \\
\xi (t) & \text{if } s > t
\end{cases}
\]

\[
E \left( \int_{[0,t]} (s) dA (s) \right) + (A (a) - A (t)) E (\xi (t))
\]

\[
= E \left( \int_{(0,a]} (s) dA (s) \right)
\]

From what was shown above,

\[
= E \left( \int_{(0,a]} (s) dA (s) \right)
\]

\[
= E \left( \int_{(0,t]} (s) dA (s) + \int_{(t,a]} (s) dA (s) \right)
\]

\[
= E \left( \int_{(0,t]} (s) dA (s) \right) + (A (a) - A (t)) E (\xi (t))
\]
and so
\[ E \left( \int_{(0,t]} \xi(s) dA(s) \right) = E \left( \int_{(0,t]} \xi^-(s) dA(s) \right) \]
which shows \( A \) is natural by Lemma 61.7.7. This proves the theorem.

There is another interesting variation of the above theorem. It involves the following definition.

**Definition 61.7.13** A submartingale, \( \{ X(t) \} \) is said to be \( D \) if
\[ \{ X_T : T < \infty \text{ is a stopping time} \} \]
is equi integrable.

In this case, you can consider partitions of the entire positive real line and the martingales, \( \{ M(t^n_k) \}_{k=0}^\infty \) and \( \{ A(t^n_k) \}_{k=0}^\infty \) as before. This time you don’t stop at \( m \). By the submartingale convergence theorem, you can argue there exists \( A^n_m = \lim_{k \to \infty} A(t^n_k) \). Then repeat the above argument using \( A^n_m \) in place of \( A^n(a) \). This time you get \( \{ A(t) \} \) equi integrable. Thus the following corollary is obtained.

**Corollary 61.7.14** Let \( \{ X(t) \} \) be a right continuous submartingale of class \( D \). Then there exists a right continuous martingale, \( \{ M(t) \} \) and a right continuous increasing submartingale, \( \{ A(t) \} \) such that for each \( t \),
\[ X(t) = M(t) + A(t). \]
If \( \{ A(t) \} \) is chosen to be natural and \( A(0) = 0 \), then with this condition, \( \{ M(t) \} \) and \( \{ A(t) \} \) are unique. Furthermore \( \{ M(t) \} \) and \( \{ A(t) \} \) are equi integrable on \([0, \infty)\).

In the above theorem, \( \{ X(t) \} \) was a submartingale and so it has a right continuous version. What if \( \{ X(t) \} \) is actually continuous? Can one conclude that \( A(t) \) and \( M(t) \) are also continuous? The answer is yes.

**Theorem 61.7.15** Let \( \{ X(t) \} \) be a right continuous submartingale of class \( DL \). Then there exists a right continuous martingale, \( \{ M(t) \} \) and a right continuous increasing submartingale, \( \{ A(t) \} \) such that for each \( t \),
\[ X(t) = M(t) + A(t). \]
If \( \{ A(t) \} \) is chosen to be natural and \( A(0) = 0 \), then with this condition, \( \{ M(t) \} \) and \( \{ A(t) \} \) are unique. Also, if \( \{ X(t) \} \) is continuous, \( t \to X(t, \omega) \) is continuous for a.e. \( \omega \) then the same is true of \( \{ A(t) \} \) and \( \{ M(t) \} \).

**Proof:** The first part is done above. Let \( \{ X(t) \} \) be continuous. As before, let \( \{ t^n_k \}_{k=0}^{m_0} \) be a sequence of partitions of \([0, a] \) such that these are equally spaced points, \( \lim_{n \to \infty} t^n_{k+1} - t^n_k = 0 \), and \( \{ t^n_0 \}_{k=0}^{m_0} \subseteq \{ t^n_{m+1} \}_{k=0}^{m_n+1} \) where here \( a > 0 \) is an arbitrary positive number and let \( \lambda > 0 \) be an arbitrary positive number. Define
\[ \xi^n(t) = E \left( \min \left( \lambda, A(t^n_j) \right) \right) \mid F_t \] for \( t^n_{j-1} < t \leq t^n_j \).
Thus on \((t^n_{j-1}, t^n_j] \) \(\xi^n (t)\) is a bounded martingale. Assuming we are dealing with a right continuous version of this martingale so there are no measurability questions, it follows since \(A\) is natural,

\[
E \left( \int_{(t^n_{j-1}, t^n_j]} \xi^n (s) \, dA (s) \right) = E \left( \int_{(t^n_{j-1}, t^n_j]} \xi^n (s) \, dA (s) \right)
\]

where here

\[
\xi^n (s, \omega) \equiv \lim_{r \to s^- \text{ for } r \in D} \xi^n (s, \omega) \quad \text{a.e.}
\]

for \(D \equiv \bigcup_{n=1}^\infty \bigcup_{k=1}^{m_n} \{ t^n_k \}_{k=0}^{m_n} \). Thus, adding these up for all the intervals, \((t^n_{j-1}, t^n_j]\) yields

\[
E \left( \int_{(0,a]} \xi^n (s) \, dA (s) \right) = E \left( \int_{(0,a]} \xi^n (s) \, dA (s) \right)
\]

I want to show that for a.e. \(\omega, \xi^n (t, \omega)\) converges uniformly to

\[
\min (\lambda, A (t, \omega)) \equiv \lambda \wedge A (t, \omega)
\]

on \((0,a]\). From this it will follow

\[
E \left( \int_{(0,a]} \lambda \wedge A (s, \omega) \, dA (s) \right) = E \left( \int_{(0,a]} \lambda \wedge A - (s, \omega) \, dA (s) \right)
\]

Now since \(s \to A (s, \omega)\) is increasing, there is no problem in writing \(A - (s, \omega)\) and the above equation will suffice to show with simple considerations that for a.e. \(\omega, s \to A (s, \omega)\) is left continuous. Since \(\{A (s)\}\) is a submartingale already, it has a right continuous version which we are using in the above. Thus for a.e. \(\omega\) it must be the case that \(s \to A (s, \omega)\) is continuous. Let \(t \in (t^n_{j-1}, t^n_j]\). Then since \(\lambda \wedge A (t)\) is \(\mathcal{F}_t\) measurable,

\[
\xi^n (t) - \lambda \wedge A (t) \equiv E \left( \lambda \wedge A (t^n_j) - \lambda \wedge A (t) \mid \mathcal{F}_t \right) \geq 0
\]

because \(A (t)\) is increasing.

Now define a stopping time, \(T^n (\varepsilon)\) for \(\varepsilon > 0\) by letting \(T^n (\varepsilon)\) be the infimum of all \(t \in [0,a]\) with the property that

\[
\xi^n (t) - \lambda \wedge A (t) > \varepsilon
\]

or if this does not happen, then \(T^n (\varepsilon) = a\). Thus

\[
T^n (\varepsilon) (\omega) = a \wedge \inf \{ t \in [0,a] : \xi^n (t, \omega) - \lambda \wedge A (t, \omega) > \varepsilon \}
\]

I need to verify \(T^n (\varepsilon)\) really is a stopping time. Letting \(s < a\), it follows that if \(\omega \in [T^n (\varepsilon) \leq s]\), then for each \(N\), there exists \(t \in [s, s + \frac{1}{N}]\) such that \(\xi^n (t, \omega) - \lambda \wedge A (t, \omega) > \varepsilon\). Then by right continuity it follows there exists \(r \in D \cap [s, s + \frac{1}{N}]\) such that

\[
\xi^n (r, \omega) - \lambda \wedge A (r, \omega) > \varepsilon
\]
Thus
\[ [T^n (\varepsilon) \leq s] = \cap_{n=1}^{\infty} \cup_{r \in D \cap [s, s+\frac{1}{n}]} [\xi^n (r, \omega) - \lambda \wedge A (r, \omega) > \varepsilon] \]
and each \( \cup_{r \in D \cap [s, s+\frac{1}{n}]} [\xi^n (r, \omega) - \lambda \wedge A (r, \omega) > \varepsilon] \in \mathcal{F}_{s+1/n} \) and so \([T^n (\varepsilon) \leq s] \in \cap_{r \in D, r \geq s} \mathcal{F}_r = \mathcal{F}_s = \mathcal{F}_s^* \) due to the assumption that the filtration is normal.

What if \( s \geq a \)? Then from the definition, \([T^n (\varepsilon) \leq a] = \Omega \in \mathcal{F}_s \). Thus this really is a stopping time.

Now let \( B_j \equiv [t^n_{j-1} < T^n (\varepsilon) \leq t^n_j] \). Note that \( T^n (\varepsilon) \wedge t^n_j \) is also a stopping time.

\[
\int_{\Omega} \xi^n_{T^n(\varepsilon)} dP = \sum_{j=1}^{m_n} \int_{B_j} \xi^n_{T^n(\varepsilon)} dP = \sum_{j=1}^{m_n} \int_{B_j} \xi^n_{T^n(\varepsilon) \wedge t^n_j} dP
\]
\[
= \sum_{j=1}^{m_n} \int_{B_j} E \left( \xi^n_{T^n(\varepsilon) \wedge t^n_j} | \mathcal{F}_{T^n(\varepsilon) \wedge t^n_j} \right) dP.
\]

This is because \( B_j \in \mathcal{F}_{T^n(\varepsilon) \wedge t^n_j} \). Thus from the definition, the above equals
\[
= \sum_{j=1}^{m_n} \int_{B_j} E \left( E \left( \lambda \wedge A (t^n_j) | \mathcal{F}_{T^n(\varepsilon) \wedge t^n_j} \right) | \mathcal{F}_{T^n(\varepsilon) \wedge t^n_j} \right) dP
\]
\[
= \sum_{j=1}^{m_n} \int_{B_j} E \left( \lambda \wedge A (t^n_j) | \mathcal{F}_{T^n(\varepsilon) \wedge t^n_j} \right) dP
\]
\[
= \sum_{j=1}^{m_n} \int_{B_j} \lambda \wedge A (t^n_j) dP = \int_{\Omega} \lambda \wedge A ([T^n (\varepsilon)]) dP \hspace{1cm} (61.7.40)
\]

where on \((t^n_{j-1}, t^n_j)\), \([T^n (\varepsilon)] = t^n_j\). Now \([T^n (\varepsilon)] \) is also a bounded stopping time.

Here is why. Suppose \( s \in (t^n_{j-1}, t^n_j) \). Then
\[
[ [T^n (\varepsilon)] \leq s ] = [ T^n (\varepsilon) \leq t^n_j ] \subset \mathcal{F}_{t^n_j} \subset \mathcal{F}_s.
\]

Now let \( Q_n = \sup_{t \in [0, a]} |\xi^n (t) - \lambda \wedge A (t)| \).

Then first note that
\[
[Q_n > \varepsilon] = \left[ \sup_{t \in [0, a]} |\xi^n (t) - \lambda \wedge A (t)| > \varepsilon \right]
\]
because \( Q_n (a) = 0 \) follows from the definition of \( \xi^n (t) \) as
\[
E \left( \lambda \wedge A (t^n_j) | \mathcal{F}_1 \right) \text{ for } t^n_{j-1} < t \leq t^n_j
\]
and so
\[
\xi^n (a) = E \left( \lambda \wedge A (a) | \mathcal{F}_a \right) = \lambda \wedge A (a).
\]
Thus it suffices to take the supremum over the half open interval, $[0, a)$. It follows

$$[Q_n > \varepsilon] = [T^n (\varepsilon) < a]$$

By right continuity,

$$\xi^n (T^n (\varepsilon)) - \lambda \wedge A (T^n (\varepsilon)) \geq \varepsilon$$

on $[Q_n > \varepsilon]$.

\[ \varepsilon P ([Q_n > \varepsilon]) = \varepsilon P ([T^n (\varepsilon) < a]) \]
\[ \leq \int_{[Q_n > \varepsilon]} (\xi^n (T^n (\varepsilon)) - \lambda \wedge A (T^n (\varepsilon))) dP \]
\[ \leq \int_{\Omega} (\xi^n (T^n (\varepsilon)) - \lambda \wedge A (T^n (\varepsilon))) dP \]

Therefore, from 61.7.40,

\[ P ([Q_n > \varepsilon]) \leq \frac{1}{\varepsilon} \int_{\Omega} (\lambda \wedge A ([T^n (\varepsilon)]) - \lambda \wedge A (T^n (\varepsilon))) dP \]
\[ \leq \frac{1}{\varepsilon} \int_{\Omega} (A ([T^n (\varepsilon)]) - A (T^n (\varepsilon))) dP \quad (61.7.41) \]

By optional sampling theorem,

\[ E (M (T^n (\varepsilon))) = E (M (0)) = 0 \]

and also

\[ E (M ([T^n (\varepsilon)])) = E (M (0)) = 0. \]

Therefore, 61.7.41 reduces to

\[ P ([Q_n > \varepsilon]) \leq \frac{1}{\varepsilon} \int_{\Omega} (X ([T^n (\varepsilon)]) - X (T^n (\varepsilon))) dP \]

By the assumption that $\{X (t)\}$ is $DL$, it follows the functions in the above integrand are equi integrable and so since $\lim_{n \to \infty} X ([T^n (\varepsilon)]) - X (T^n (\varepsilon)) = 0$, the above integral converges to 0 as $n \to \infty$ by Vitali’s convergence theorem, Theorem 6.5.3 on Page 244. It follows that there is a subsequence, $n_k$ such that

\[ P ([Q_{n_k} > 2^{-k}]) \leq 2^{-k} \]

and so from the definition of $Q_n$,

\[ \lim_{k \to \infty} \sup_{\varepsilon \in [0, a]} |\xi^{n_k} (t) - \lambda \wedge A (t)| \]

giving uniform convergence. Now recall that

\[ E \left( \int_{(0, a]} \xi^{n_k} (s) dA (s) \right) = E \left( \int_{(0, a]} \xi^{n_k} (s) dA (s) \right) \]
and so passing to the limit as \( k \to \infty \) with the uniform convergence yields
\[
E \left( \int_{(0,a]} \lambda \wedge A(s) \, dA(s) \right) = E \left( \int_{(0,a]} \lambda \wedge A_- (s) \, dA(s) \right)
\]

Now let \( \lambda \to \infty \). Then from the monotone convergence theorem,
\[
E \left( \int_{(0,a]} A(s) \, dA(s) \right) = E \left( \int_{(0,a]} A_- (s) \, dA(s) \right)
\]
and so for a.e. \( \omega \),
\[
\int_{(0,a]} (A(s) - A_- (s)) \, dA(s) = 0.
\]
Thus letting the measure associated with this Lebesgue integral be denoted by \( \mu \),
\[
A(s) - A_- (s) = 0 \quad \mu \text{ a.e.}
\]
Suppose then that \( A(s) - A_- (s) > 0 \). Then \( \mu (\{s\}) = 0 = A(s) - A(s-) \), a contradiction. Hence \( A(s) - A_- (s) = 0 \) for all \( s \). It is already the case that \( s \to A(s) \) is right continuous. Therefore, this proves the theorem.

**Example 61.7.16** Suppose \( \{M(t)\} \) is a continuous martingale. Assume
\[
\sup_{t \in [0,a]} \|M(t)\|_{L^2(\Omega)} < \infty
\]
Then \( \{|M(t)|\} \) is a submartingale and so is \( \left\{ \|M(t)\|^2 \right\} \). By Example 61.7.14, this is DL. Then there exists a unique Doob Meyer decomposition,
\[
\|M(t)\|^2 = Y(t) + \langle \|M(t)\| \rangle
\]
where \( Y(t) \) is a martingale and \( \{\|M(t)\|\} \) is a submartingale which is continuous, natural, increasing and equal to 0 when \( t = 0 \). This submartingale is called the quadratic variation.

### 61.8 Levy’s Theorem

This remarkable theorem has to do with when a martingale is a Wiener process. The proof I am giving here follows [11].

**Definition 61.8.1** Let \( W(t) \) be a stochastic process which has the properties that whenever \( t_1 < t_2 < \cdots < t_m \), the increments \( \{W(t_i) - W(t_{i-1})\} \) are independent and whenever \( s < t \), it follows \( W(t) - W(s) \) is normally distributed with variance \( t-s \) and mean \( 0 \). Also \( t \to W(t) \) is Holder continuous with every exponent \( \gamma < 1/2 \) and \( W(0) = 0 \). This is called a Wiener process.
First here is a lemma.

**Lemma 61.8.2** Let \( \{X(t)\} \) be a real martingale adapted to the filtration \( \mathcal{F}_t \) for \( t \in [a, b] \) some interval such that for all \( t \in [a, b] \), \( E \left( X(t)^2 \right) < \infty \). Then \( \{X(t)^2 - t\} \) is also a martingale if and only if whenever \( s < t \),
\[
E \left( (X(t) - X(s))^2 | \mathcal{F}_s \right) = t - s.
\]

**Proof:** Suppose first \( \{X(t)^2 - t\} \) is a real martingale. Then since \( \{X(t)\} \) is a martingale,
\[
E \left( (X(t) - X(s))^2 | \mathcal{F}_s \right) = E \left( X(t)^2 - 2X(t)X(s) + X(s)^2 | \mathcal{F}_s \right)
\]
\[
= E \left( X(t)^2 | \mathcal{F}_s \right) - 2E \left( X(t)X(s) | \mathcal{F}_s \right) + X(s)^2
\]
\[
= E \left( X(t)^2 | \mathcal{F}_s \right) - 2X(s)E \left( X(t) | \mathcal{F}_s \right) + X(s)^2
\]
\[
= E \left( X(t)^2 - X(s)^2 | \mathcal{F}_s \right) + t - X(s)^2
\]
\[
= X(s)^2 - s + t - X(s)^2 = t - s
\]
Next suppose \( E \left( (X(t) - X(s))^2 | \mathcal{F}_s \right) = t - s \). Then since \( \{X(t)\} \) is a martingale,
\[
t - s = E \left( X(t)^2 - X(s)^2 | \mathcal{F}_s \right)
\]
\[
= E \left( X(t)^2 - t | \mathcal{F}_s \right) + t - X(s)^2
\]
and so
\[
0 = E \left( X(t)^2 - t | \mathcal{F}_s \right) - \left( X(s)^2 - s \right)
\]
which proves the converse.

**Theorem 61.8.3** Suppose \( \{X(t)\} \) is a real stochastic process which satisfies all the conditions of a real Wiener process except the requirement that it be continuous. Then both \( \{X(t)\} \) and \( \{X(t)^2 - t\} \) are martingales.

**Proof:** First define the filtration to be
\[
\mathcal{F}_t = \sigma \{X(s) - X(r) : r \leq s \leq t \}.
\]

**Claim:** If \( A \in \mathcal{F}_s \), then
\[
\int \Omega \chi_A (X(t) - X(s)) \, dP = P(A) \int \Omega (X(t) - X(s)) \, dP.
\]
**Proof of claim:** Let $\mathcal{G}$ denote those sets of $\mathcal{F}_s$ for which the above formula holds. Then it is clear that $\mathcal{G}$ is closed with respect to countable unions of disjoint sets and complements. Let $\mathcal{K}$ denote those sets which are finite intersections of sets of the form $(X(u) - X(r))^{-1}(B)$ where $B$ is a Borel set and $r \leq u \leq s$. Say a set, $A$ of $\mathcal{K}$ is of the form

$$\bigcap_{i=1}^m (X(u_i) - X(r_i))^{-1}(B_i)$$

Then since disjoint increments are independent, linear combinations of the random variables, $X(u_i) - X(r_i)$ are normally distributed. Consequently,

$$(X(u_1) - X(r_1), \ldots, X(u_m) - X(r_m), X(t) - X(s))$$

is multivariate normal. The covariance matrix is of the form

$$\begin{pmatrix}
A & 0 \\
0 & t - s
\end{pmatrix}$$

and so the random vector, $(X(u_1) - X(r_1), \ldots, X(u_m) - X(r_m))$ and the random variable $X(t) - X(s)$ are independent. Consequently, $\mathcal{X}_A$ is independent of $X(t) - X(s)$ for any $A \in \mathcal{K}$. Then by the lemma on $\pi$ systems, Lemma 10.12.3 on Page 311, $\mathcal{F}_s \supseteq \mathcal{G} \supseteq \sigma(\mathcal{K}) = \mathcal{F}_s$. This proves the claim.

Thus

$$\int_A (X(t) - X(s)) dP = \int_{\Omega} (X(t) - X(s)) \mathcal{X}_A dP$$

$$= P(A) \int_{\Omega} (X(t) - X(s)) dP = 0$$

which shows that since $A \in \mathcal{F}_s$ was arbitrary,

$$E(X(t) | \mathcal{F}_s) = X(s)$$

and $\{X(t)\}$ is a martingale.

Now consider whether $\{X(t)^2 - t\}$ is a martingale. By assumption,

$$\mathcal{L}(X(t) - X(s)) = \mathcal{L}(X(t-s)) = N(0, t - s).$$

Then for $A \in \mathcal{F}_s$, the independence of $\mathcal{X}_A$ and $X(t) - X(s)$ shows

$$\int_A E((X(t) - X(s))^2 | \mathcal{F}_s) dP = \int_A (X(t) - X(s))^2 dP$$

$$= P(A) (t - s) = \int_A (t - s) dP$$

and since $A \in \mathcal{F}_s$ is arbitrary,

$$E((X(t) - X(s))^2 | \mathcal{F}_s) = t - s$$

and so the result follows from Lemma 61.8.2. This proves the theorem.

The next lemma is the main result from which Levy’s theorem will be established.
Lemma 61.8.4 Let \( \{ X (t) \} \) be a real continuous martingale adapted to the filtration \( \mathcal{F}_t \) for \( t \in [a, b] \) some interval such that for all \( t \in [a, b] \), \( E \left( X (t)^2 \right) < \infty \). Suppose also that \( \{ X (t)^2 - t \} \) is a martingale. Then for \( \lambda \) real,
\[
E \left( e^{i \lambda X (b)} \right) = E \left( e^{i \lambda X (a)} \right) e^{-\lambda (b-a)^2 / 2}
\]

**Proof:** Let \( \lambda \in [-p, p] \) where for most of the proof, \( p \) is fixed but arbitrary. Let \( \{ t_k^n \}_{k=0}^{2^n} \) be uniform partitions such that \( t_k^n - t_{k-1}^n = \delta_n \equiv (b-a) / 2^n \). Now for \( \varepsilon > 0 \) define a stopping time \( \tau_{\varepsilon,n} \) to be the first time, \( t \) such that there exist \( s_1, s_2 \in [a, t] \) with \( |s_1 - s_2| < \delta_n \) but

\[
|X (s_1) - X (s_2)| = \varepsilon.
\]

If no such time exists, then \( \tau_{\varepsilon,n} \equiv b \).

Then \( \tau_{\varepsilon,n} \) really is a stopping time because from continuity of \( X (t) \) and denoting by \( r, r_1 \) elements of \( \mathbb{Q} \), then

\[
[\tau_{\varepsilon,n} > t] = \bigcup_{m=1}^{\infty} 0 \leq r_1, r_2 \leq t, |r_1 - r_2| \leq \delta_n \left| X (r_1) - X (r_2) \right| \leq \varepsilon - \frac{1}{m} \in \mathcal{F}_t,
\]

because to be in \([\tau_{\varepsilon,n} > t]\) it means that by \( t \) the absolute value of the differences must always be less than \( \varepsilon \). Hence \([\tau_{\varepsilon,n} \leq t] = \Omega \setminus [\tau_{\varepsilon,n} > t] \in \mathcal{F}_t \).

Now consider \([\tau_{\varepsilon,n} = b]\) for various \( n \). By continuity, it follows that for each \( \omega \in \Omega \),

\[
\tau_{\varepsilon,n} (\omega) = b
\]

for all \( n \) large enough. Thus

\[
\emptyset = \bigcap_{n=1}^{\infty} [\tau_{\varepsilon,n} < b],
\]

the sets in the intersection decreasing. Thus there exists \( n (\varepsilon) \) such that

\[
P \left( [\tau_{\varepsilon,n(\varepsilon)} < b] \right) < \varepsilon. \tag{61.8.42}
\]

Denote \( \tau_{\varepsilon,n(\varepsilon)} \) as \( \tau_{\varepsilon} \) for short and it will always be assumed that \( n (\varepsilon) \) is at least this large and that \( \lim_{\varepsilon \to 0^+} n (\varepsilon) = \infty \). In addition to this, \( n (\varepsilon) \) will also be large enough that

\[
1 - \frac{\lambda^2}{2} \delta_{n(\varepsilon)} > 0
\]

for all \( \lambda \in [-p, p] \). To save on notation, \( t_j \) will take the place of \( t_j^n \). Then consider the stopping times \( \tau_{\varepsilon} \wedge t_j \) for \( j = 0, 1, \ldots, 2^n(\varepsilon) \).

Let \( y_j = X (\tau_{\varepsilon} \wedge t_j) - X (\tau_{\varepsilon} \wedge t_{j-1}) \), it follows from the definition of the stopping time that

\[
|y_j| \leq \varepsilon \tag{61.8.43}
\]
Thus, since $\tau_\varepsilon \land t_j$ and $\tau_\varepsilon \land t_{j-1}$ are less than $\tau_\varepsilon$ and closer together than $\delta_{n(\varepsilon)}$ and so if $|y_j| > \varepsilon$, then $\tau_\varepsilon < t_j, t_{j-1}$ and so $y_j$ would need to equal 0.

By the optional stopping theorem, $\{X(\tau_\varepsilon \land t_j)\}_j$ is a martingale as is also

$$\{X(\tau_\varepsilon \land t_j) - \tau_\varepsilon \land t_j\}_j.$$ 

Thus for $A \in \mathcal{F}_{\tau_\varepsilon \land t_{j-1}},$

$$\int_A E (y_j^2 | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}}) dP = \int_A E \left( (X(\tau_\varepsilon \land t_j) - X(\tau_\varepsilon \land t_{j-1}))^2 | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP$$

$$= \int_A E \left( X(\tau_\varepsilon \land t_j)^2 | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) + X(\tau_\varepsilon \land t_{j-1})^2 - 2X(\tau_\varepsilon \land t_{j-1}) E \left( X(\tau_\varepsilon \land t_j) | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP$$

$$= \int_A E \left( X(\tau_\varepsilon \land t_j)^2 - \tau_\varepsilon \land t_j | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP + \int_A E \left( \tau_\varepsilon \land t_j | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP$$

$$+ \int_A \left( \tau_\varepsilon \land t_{j-1} \right)^2 dP - 2 \int_A X(\tau_\varepsilon \land t_{j-1})^2 dP$$

$$= \int_A X(\tau_\varepsilon \land t_{j-1})^2 dP - \int_A \tau_\varepsilon \land t_{j-1} dP + \int_A E \left( \tau_\varepsilon \land t_j | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP$$

$$+ \int_A X(\tau_\varepsilon \land t_{j-1})^2 dP - 2 \int_A X(\tau_\varepsilon \land t_{j-1})^2 dP$$

$$= \int_A E \left( \tau_\varepsilon \land t_j | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) dP - \int_A \tau_\varepsilon \land t_{j-1} dP$$

$$= \int_A (\tau_\varepsilon \land t_j - \tau_\varepsilon \land t_{j-1}) dP \leq \int_A t_j - t_{j-1} dP.$$ 

Thus, since $A$ is arbitrary,

$$\sigma_j^2 = \int_A E (y_j^2 | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}}) dP =$$

$$E \left( (X(\tau_\varepsilon \land t_j) - X(\tau_\varepsilon \land t_{j-1}))^2 | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) \leq t_j - t_{j-1} = \delta_{n(\varepsilon)} \quad (61.8.44)$$

Also,

$$E (y_j | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}}) = E \left( X(\tau_\varepsilon \land t_j) - X(\tau_\varepsilon \land t_{j-1}) | \mathcal{F}_{\tau_\varepsilon \land t_{j-1}} \right) = 0. \quad (61.8.45)$$

Now it is time to find $E \left( e^{i\lambda X(\tau_\varepsilon \land t_j)} \right),$

$$E \left( e^{i\lambda X(\tau_\varepsilon \land t_j)} \right) = E \left( e^{i\lambda (X(\tau_\varepsilon \land t_{j-1}) + y_j)} \right)$$
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE

\[ = E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} E \left( e^{i\lambda y_j} | \mathcal{F}_{\tau_n \wedge t_{j-1}} \right) \right) . \]  

(61.8.46)

Now let \( o(1) \) denote any quantity which converges to 0 as \( \varepsilon \to 0 \) for all \( \lambda \in [-p, p] \) and \( O(1) \) is a quantity which is bounded as \( \varepsilon \to 0 \). Then from (61.8.45) and (61.8.46) you can consider the power series for \( e^{i\lambda y_j} \) which converges uniformly due to (61.8.43) and write (61.8.46) as

\[ E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} \left( 1 - \frac{\lambda^2}{2} \sigma_j^2 (1 + o(1)) \right) \right) . \]

then noting that from (61.8.44) which shows \( \sigma_j^2 \) is \( o(1) \), it is routine to verify

\[ 1 - \frac{\lambda^2}{2} \sigma_j^2 (1 + o(1)) = e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} . \]

Now this shows

\[ E \left( e^{i\lambda X(\tau_n \wedge t_{j})} \right) = E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} \right) \]

Recall that \( \sigma_j^2 \leq \delta_n = t_j - t_{j-1} \). Consider

\[ \left| E \left( e^{i\lambda X(\tau_n \wedge t_j)} \right) - E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} \right) \right| \]

\[ = \left| E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} \right) - E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \delta_n} \right) \right| \]

\[ = \left| E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} \left( e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} - e^{-\frac{\lambda^2}{2} \delta_n} \right) \right) \right| \]

\[ = \left| E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1))} \left( e^{-\frac{\lambda^2}{2} \sigma_j^2 (1 + o(1)) + \frac{\lambda^2}{2} \delta_n} - 1 \right) \right) \right| \]

Everything in the exponent is \( o(1) \) and so the above expression is bounded by

\[ O(1) E \left( \frac{\lambda^2}{2} (\delta_n - \sigma_j^2) + \sigma_j^2 o(1) \right) \]

\[ \leq O(1) E \left( (\delta_n - \sigma_j^2) + \delta_n |o(1)| \right) \]

\[ = O(1) \left[ \delta_n - E (\sigma_j^2) + \delta_n o(1) \right] . \]

(61.8.47)

Therefore,

\[ \left| E \left( e^{i\lambda X(\tau_n \wedge t_j)} \right) - E \left( e^{i\lambda X(\tau_n \wedge t_{j-1})} e^{-\frac{\lambda^2}{2} \delta_n} \right) \right| \]

\[ \leq O(1) \left[ \delta_n - E (\sigma_j^2) + \delta_n o(1) \right] \]
and so it also follows
\[
\left| E \left( e^{i\lambda X(\tau_x \wedge t_j)} e^{\frac{z^2}{2} t_j} \right) - E \left( e^{i\lambda X(\tau_x \wedge t_{j-1})} e^{\frac{z^2}{2} t_{j-1}} \right) \right| \\
\leq O(1) \left[ \delta_n - E \left( y_j^2 \right) + \delta_n o(1) \right]
\]

Now also remember
\[y_j = X (\tau_x \wedge t_j) - X (\tau_x \wedge t_{j-1})\]
and that \(\{ X (\tau_x \wedge t_j) \}_j\) is a martingale. Therefore it is routine to show,
\[E \left( y_j^2 \right) = E \left( X (\tau_x \wedge t_j)^2 \right) - E \left( X (\tau_x \wedge t_{j-1})^2 \right).
\]
and so
\[
\left| E \left( e^{i\lambda X(\tau_x \wedge t_j)} e^{\frac{z^2}{2} t_j} \right) - E \left( e^{i\lambda X(\tau_x \wedge t_{j-1})} e^{\frac{z^2}{2} t_{j-1}} \right) \right| \\
\leq O(1) \left[ \delta_n - \left( E \left( X (\tau_x \wedge t_j)^2 \right) - E \left( X (\tau_x \wedge t_{j-1})^2 \right) \right) + \delta_n o(1) \right]
\]
and so, summing over all \(j = 1, \ldots, 2^n(\varepsilon)\),
\[
\left| E \left( e^{i\lambda X(\tau_x \wedge b)} e^{\frac{z^2}{2} b} \right) - E \left( e^{i\lambda X(a)} e^{\frac{z^2}{2} a} \right) \right| \\
\leq O(1) \left( (1 + o(1))(b - a) - \left( E \left( X (\tau_x \wedge b)^2 \right) - E \left( X (a)^2 \right) \right) \right) \tag{61.8.48}
\]

Now recall \[61.8.42\] which said
\[P \left( |\tau_x < b| \right) < \varepsilon.\]
Let \(\varepsilon_k \equiv 2^{-k}\) and then by the Borel Cantelli lemma,
\[X (\tau_x \wedge b) \rightarrow X (b)\]
a.e. since if \(\omega\) is such that convergence does not take place, \(\omega\) must be in infinitely many of the sets, \(\{ \tau_{\varepsilon_k} < b \}\), a set of measure 0. Also since \(\{ X (\tau_x \wedge t_j) \}_j\) is a martingale, it follows from optional sampling theorem that \(\{ X (a)^2, X (\tau_x \wedge b)^2, X (b)^2 \}\) is a submartingale and so
\[
\int_{[X(\tau_x \wedge b)^2 \geq \alpha]} X (\tau_x \wedge b)^2 dP \leq \int_{[X(\tau_x \wedge b)^2 \geq \alpha]} X (b)^2 dP
\]
and also from the maximal inequalities, Theorem \[58.5.4\] on Page 2014 it follows
\[P \left( X (\tau_x \wedge b)^2 \geq \alpha \right) \leq \frac{1}{\alpha} E \left( X (b)^2 \right)\]
and so the functions, \( \{ X (\tau_k \wedge b) \}_{\tau_k} \) are uniformly integrable which implies by the Vitali convergence theorem, Theorem 4.5.8.5 on Page 2226, that you can pass to the limit as \( \varepsilon_k \to 0 \) in the inequality. Now letting \( \lambda_k \to 0 \) and conclude

\[
\left| E \left( e^{i\lambda X(b)} \right) - E \left( e^{i\lambda X(a)} e^{\frac{a^2}{2}} \right) \right| \\
\leq O(1) \left( (b-a) - \left( E (X(b)^2) - E (X(a)^2) \right) \right) = 0.
\]

Therefore,

\[
E \left( e^{i\lambda X(b)} \right) = E \left( e^{i\lambda X(a)} \right) e^{-\frac{a^2}{2}(b-a)}
\]

This proves the lemma because \( p \) was arbitrary.

Now from this lemma, it is not hard to establish Levy’s theorem.

**Theorem 61.8.5** Let \( \{ X(t) \} \) be a real continuous martingale adapted to the filtration \( \mathcal{F}_t \) for \( t \in [0,a] \) some interval such that for all \( t \in [0,a], E (X(t)^2) < \infty \).

Suppose also that \( \{ X(t)^2 - t \} \) is a martingale. Then for \( s < t, X(t) - X(s) \) is normally distributed with mean \( 0 \) and variance \( t-s \). Also if \( 0 \leq t_0 < t_1 < \cdots < t_m \leq b \), then the increments \( \{ X(t_j) - X(t_{j-1}) \} \) are independent.

**Proof:** Let the \( t_j \) be as described above and consider the interval \([t_{m-1}, t_m]\) in place of \([a,b]\) in Lemma 61.8.3. Also let \( \lambda_k \) for \( k = 1, 2, \ldots, m \) be given. For \( t \in [t_{m-1}, t_m] \), and \( \lambda_m \neq 0, \)

\[
Z_{\lambda_m}(t) = \frac{1}{\lambda_m} \sum_{j=1}^{m-1} \lambda_j (X(t_j) - X(t_{j-1})) + (X(t) - X(t_{m-1}))
\]

Then it is clear that \( \{ Z_{\lambda_m}(t) \} \) is a martingale on \([t_{m-1}, t_m]\). What is possibly less clear is that \( \{ Z_{\lambda_m}(t)^2 - t \} \) is also a martingale. Note that \( Z_{\lambda_m}(t) = X(t) + Y \) where \( Y \) is measurable in \( \mathcal{F}_{t_{m-1}} \). Therefore, for \( s < t, s \in [t_{m-1}, t_m] \),

\[
E \left( Z_{\lambda_m}(t)^2 - t \mid \mathcal{F}_s \right) = E \left( X(t)^2 + 2X(t)Y + Y^2 - t \mid \mathcal{F}_s \right)
\]

\[
= X(s)^2 - s + 2E(X(t)Y \mid \mathcal{F}_s) + Y^2
\]

\[
= X(s)^2 - s + 2YX(s) + Y^2 = Z_{\lambda_m}(s)^2 - s
\]

and so Lemma 61.8.3 can be applied to conclude

\[
E \left( e^{i\lambda Z_{\lambda_m}(t_m)} \right) = E \left( e^{i\lambda Z_{\lambda_m}(t_{m-1})} \right) e^{-\frac{\lambda^2}{2}(t_m - t_{m-1})}.
\]

Now letting \( \lambda = \lambda_m, \)

\[
E \left( e^{i \sum_{j=1}^{m} \lambda_j (X(t_j) - X(t_{j-1}))} \right) = E \left( e^{i \sum_{j=1}^{m-1} \lambda_j (X(t_j) - X(t_{j-1}))} \right) e^{-\frac{\lambda^2}{2}(t_m - t_{m-1})}.
\]
By continuity, this equation continues to hold for $\lambda_m = 0$. Then iterate this, using a similar argument on the first factor of the right side to eventually obtain

$$E\left(e^{i\sum_{j=1}^{m} \lambda_j (X(t_j) - X(t_{j-1}))}\right) = \prod_{j=1}^{m} e^{-\frac{\lambda_j^2}{2}(t_j - t_{j-1})}.$$ 

Then letting all but one $\lambda_j$ equal zero, this shows the increment, $X(t_j) - X(t_{j-1})$ is a random variable which is normally distributed having variance $t_j - t_{j-1}$ and mean 0. The above formula also shows from Proposition 57.11.1 on Page 1936 that the increments are independent. This proves the theorem.
CHAPTER 61. THE QUADRATIC VARIATION OF A MARTINGALE
Chapter 62

Wiener Processes

A real valued random variable $X$ is normally distributed with mean 0 and variance $\sigma^2$ if

$$P(X \in A) = \frac{1}{\sqrt{2\pi\sigma}} \int_A e^{-\frac{x^2}{2\sigma^2}} dx$$

Consider the characteristic function. By definition it is

$$\phi_X(\lambda) = \int_{\mathbb{R}} e^{ix} d\lambda_X(x)$$

where $\lambda_X$ is the distribution measure for this random variable. Thus the characteristic function of this random variable is

$$\frac{1}{\sqrt{2\pi\sigma}} \int_{-\infty}^{\infty} e^{i\lambda x} e^{-\frac{x^2}{2\sigma^2}} dx$$

One can then show through routine arguments that this equals

$$\exp\left(-\frac{1}{2} \sigma^2 \lambda^2\right)$$

62.1 Real Wiener Processes

Here is the definition of a Wiener process.

**Definition 62.1.1** Let $W(t)$ be a stochastic process which has the properties that whenever $t_1 < t_2 < \cdots < t_m$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent and whenever $s < t$, it follows $W(t) - W(s)$ is normally distributed with variance $t-s$ and mean 0. Also $t \to W(t)$ is Holder continuous with every exponent $\gamma < 1/2$ and $W(0) = 0$. This is called a Wiener process.

Do Wiener processes exist? Yes, they do. First here is a simple lemma which has really been done before. It depends on the Kolmogorov extension theorem, Theorem 57.2.3 on Page 1904.
Lemma 62.1.2 There exists a sequence, \( \{ \xi_k \}_{k=1}^{\infty} \) of random variables such that
\[
\mathcal{L} (\xi_k) = N(0, 1)
\]
and \( \{ \xi_k \}_{k=1}^{\infty} \) is independent.

Proof: Let \( i_1 < i_2 \cdots < i_n \) be positive integers and define
\[
\mu_{i_1 \ldots i_n} (F_1 \times \cdots \times F_n) = \frac{1}{(\sqrt{2\pi})^n} \int_{F_1 \times \cdots \times F_n} e^{-|x|^2/2} dx.
\]
Then for the index set equal to \( \mathbb{N} \) the measures satisfy the necessary consistency condition for the Kolmogorov theorem. Therefore, there exists a probability space, \((\Omega, P, \mathcal{F})\) and measurable functions, \( \xi_k : \Omega \to \mathbb{R} \) such that
\[
P \left( \left\{ \xi_{i_1} \in F_{i_1} \right\} \cap \left\{ \xi_{i_2} \in F_{i_2} \right\} \cdots \cap \left\{ \xi_{i_n} \in F_{i_n} \right\} \right) = \mu_{i_1 \ldots i_n} (F_1 \times \cdots \times F_n)
\]
\[
= P \left( \left\{ \xi_{i_1} \in F_{i_1} \right\} \right) \cdots P \left( \left\{ \xi_{i_n} \in F_{i_n} \right\} \right)
\]
which shows the random variables are independent as well as normal with mean 0 and variance 1. ■

Recall that the sum of independent normal random variables is normal. The Wiener process is just an infinite weighted sum of the above independent normal random variables, the weights depending on \( t \). Therefore, if the sum converges, it is not too surprising that the result will be normally distributed and the variance will depend on \( t \). This is the idea behind the following theorem.

Theorem 62.1.3 There exists a real Wiener process as defined in Definition 62.1.1. Furthermore, the distribution of \( W(t) - W(s) \) is the same as the distribution of \( W(t-s) \) and \( W \) is Holder continuous with exponent \( \gamma \) for any \( \gamma < 1/2 \). Also for each \( \alpha > 1 \),
\[
E \left( |W(t) - W(s)|^\alpha \right) \leq C_\alpha |t-s|^{\alpha/2} E \left( |W(1)|^\alpha \right)
\]

Proof: Let \( \{ g_m \}_{m=1}^{\infty} \) be a complete orthonormal set in \( L^2(0, \infty) \). Thus, if \( f \in L^2(0, \infty) \),
\[
f = \sum_{i=1}^{\infty} (f, g_i)_{L^2} g_i.
\]
The Wiener process is defined as
\[
W(t, \omega) = \sum_{i=1}^{\infty} (X_{(0, t)}, g_i)_{L^2} \xi_i (\omega)
\]
where the random variables, \( \{ \xi_i \} \) are as described in Lemma 62.1.2. The series converges in \( L^2(\Omega) \) where \( (\Omega, \mathcal{F}, P) \) is the probability space on which the random
variables, $\xi_i$ are defined. This will first be shown. Note first that from the independence of the $\xi_i$,
\[ \int_{\Omega} \xi_i \xi_j dP = 0 \]
Therefore,
\[ \int_{\Omega} \left| \sum_{i=m}^{n} (\mathcal{X}(0,t), g_i) \mathcal{L}_2 \xi_i (\omega) \right|^2 dP = \sum_{i=m}^{n} (\mathcal{X}(0,t), g_i)^2 \int_{\Omega} |\xi_i|^2 dP \]
which converges to 0 as $m, n \to \infty$. Thus the partial sums are a Cauchy sequence in $L^2 (\Omega, P)$.

It just remains to verify this definition satisfies the desired conditions. First I will show that $W(t, \omega)$ is normally distributed with mean 0 and variance $t$. That it should be normally distributed is not surprising since it is just a sum of independent random variables which are this way. Selecting a suitable subsequence, \{n_k\} it can be assumed
\[ W(t, \omega) = \lim_{k \to \infty} \sum_{i=1}^{n_k} (\mathcal{X}(0,t), g_i) \mathcal{L}_2 \xi_i (\omega) \text{ a.e.} \]
and so from the dominated convergence theorem and the independence of the $\xi_i$,
\[ E (\exp (i\lambda W(t))) = \lim_{k \to \infty} E \left( \exp \left( i\lambda \sum_{j=1}^{n_k} (\mathcal{X}(0,t), g_j) \mathcal{L}_2 \xi_j (\omega) \right) \right) \]
\[ = \lim_{k \to \infty} E \left( \prod_{j=1}^{n_k} \exp \left( i\lambda (\mathcal{X}(0,t), g_j) \mathcal{L}_2 \xi_j (\omega) \right) \right) \]
\[ = \lim_{k \to \infty} \prod_{j=1}^{n_k} E (\exp (i\lambda (\mathcal{X}(0,t), g_j) \mathcal{L}_2 \xi_j (\omega))) \]
\[ = \lim_{k \to \infty} \prod_{j=1}^{n_k} e^{-\frac{1}{2} \lambda^2 (\mathcal{X}(0,t), g_j)^2} \]
\[ = \lim_{k \to \infty} \exp \left( \sum_{j=1}^{n_k} -\frac{1}{2} \lambda^2 (\mathcal{X}(0,t), g_j)^2 \right) \]
\[ = \exp \left( -\frac{1}{2} \lambda^2 \|\mathcal{X}(0,t)\|_{L^2}^2 \right) = \exp \left( -\frac{1}{2} \lambda^2 t \right) , \]
the characteristic function of a normally distributed random variable having variance $t$ and mean 0.
It is clear \( W(0) = 0 \). It remains to verify the increments are independent. To do this, consider

\[
E \left( \exp \left( i \left[ \lambda (W(t) - W(s)) + \mu (W(s) - W(r)) \right] \right) \right)
\]

(62.1.1)

Is this equal to

\[
E \left( \exp \left( i \lambda (W(t) - W(s)) \right) \right) \cdot E \left( \exp \left( i \mu (W(s) - W(r)) \right) \right)
\]

(62.1.2)

Letting \( n_k \to \infty \) such that convergence happens pointwise for each function of interest, and using the independence of the \( \xi_i \), and the dominated convergence theorem as needed,

\[
E \left( \exp \left( i \left[ \sum_{i=1}^{\infty} \lambda (\mathcal{X}(s,t), g_i) L_2 \xi_i + \sum_{i=1}^{\infty} \mu (\mathcal{X}(r,s), g_i) L_2 \xi_i \right] \right) \right)
\]

\[
= \lim_{k \to \infty} E \left( \exp \left( i \left[ \sum_{j=1}^{n_k} \lambda (\mathcal{X}(s,t), g_j) L_2 + \mu (\mathcal{X}(r,s), g_j) L_2 \right] \xi_j \right) \right)
\]

\[
= \lim_{k \to \infty} \prod_{j=1}^{n_k} E \left( \exp \left( i \left( \lambda (\mathcal{X}(s,t), g_j) L_2 + \mu (\mathcal{X}(r,s), g_j) L_2 \right) \xi_j \right) \right)
\]

\[
= \lim_{k \to \infty} \prod_{j=1}^{n_k} \exp \left( -\frac{1}{2} \left( \lambda \mathcal{X}(s,t) + \mu \mathcal{X}(r,s), g_j \right)^2 \right)
\]

\[
= \lim_{k \to \infty} \exp \left( -\frac{1}{2} \sum_{j=1}^{n_k} \left( \lambda \mathcal{X}(s,t) + \mu \mathcal{X}(r,s), g_j \right)^2 \right)
\]

\[
= \exp \left( -\frac{1}{2} \sum_{j=1}^{\infty} \left( \lambda \mathcal{X}(s,t) + \mu \mathcal{X}(r,s), g_j \right)^2 \right) = \exp \left( -\frac{1}{2} \left( \lambda \mathcal{X}(s,t) + \mu \mathcal{X}(r,s) \right)^2 \right)
\]

because the functions \( \lambda \mathcal{X}(s,t), \mu \mathcal{X}(r,s) \) are orthogonal. Then this equals

\[
= \exp \left( -\frac{1}{2} \left[ \lambda^2 (t-s) + \mu^2 (s-r) \right] \right)
\]

\[
= \exp \left( -\frac{1}{2} (t-s) \lambda^2 \right) \exp \left( -\frac{1}{2} (s-r) \mu^2 \right)
\]
which equals and this shows the increments are independent. Obviously, this same argument shows this holds for any finite set of disjoint increments.

From the definition, if \( t > s \)

\[
W(t - s) = \sum_{k=1}^{\infty} (\mathcal{X}(0, t-s), g_k)_{L^2} \xi_k
\]

while

\[
W(t) - W(s) = \sum_{k=1}^{\infty} (\mathcal{X}_{(s,t)}, g_k)_{L^2} \xi_k.
\]

Then the same argument given above involving the characteristic function to show \( W(t) \) is normally distributed shows both of these random variables are normally distributed with mean 0 and variance \( t - s \) because they have the same characteristic function.

For example, ignoring the limit questions and proceeding formally,

\[
E\left( \exp\left( i \lambda (W(t) - W(s)) \right) \right) = E\left( \exp\left( i \lambda \left( \sum_{k=1}^{\infty} (\mathcal{X}(s,t), g_k)_{L^2} \xi_k \right) \right) \right)
\]

\[
= E\left( \prod_{k=1}^{\infty} \exp\left( i \lambda (\mathcal{X}(s,t), g_k)_{L^2} \xi_k \right) \right)
\]

\[
= \prod_{k=1}^{\infty} E\left( \exp\left( i \lambda (\mathcal{X}(s,t), g_k)_{L^2} \xi_k \right) \right)
\]

\[
= \prod_{k=1}^{\infty} e^{-\frac{1}{2} \lambda^2 (\mathcal{X}_{(s,t)}, g_k)^2_{L^2}}
\]

\[
= \exp\left( -\frac{1}{2} \lambda^2 \sum_{k=1}^{\infty} (\mathcal{X}(s,t), g_k)^2_{L^2} \right)
\]

\[
= \exp\left( -\frac{1}{2} \lambda^2 (t - s) \right)
\]

which is the characteristic function of a random variable having mean 0 and variance \( t - s \).

Finally note the distribution of \( W(t - s) \) is the same as the distribution of

\[
W(1)(t - s)^{1/2} = \sum_{k=1}^{\infty} (\mathcal{X}_{(0,1)}, g_k)_{L^2} \xi_k (t - s)^{1/2}
\]

because the characteristic function of this last random variable is the same as the characteristic function of \( W(t - s) \) which is \( e^{-\frac{1}{2} \lambda^2 (t - s)} \) which follows from a simple computation. Since \( W(1) \) is a normally distributed random variable with mean 0 and variance 1,

\[
E\left( \exp\left( i \lambda W(1)(t - s)^{1/2} \right) \right) = e^{-\frac{1}{2} \lambda^2 (t - s)}
\]
which is the same as the characteristic function of $W(t-s)$.

Hence for any positive $\alpha$,

$$E(|W(t) - W(s)|^\alpha) = E(|W(t-s)|^\alpha) = E \left( |(t-s)^{1/2} W(1)|^\alpha \right) = |t-s|^\alpha E(|W(1)|^\alpha)$$

It follows from Theorem 60.2.2 that $W(t)$ is Holder continuous with exponent $\gamma$ where $\gamma$ is any positive number less than $\beta/\alpha$ where $\alpha/2 = 1 + \beta$. Thus $\gamma$ is any constant less than

$$\frac{\alpha - 1}{\alpha} = \frac{1}{2}$$

Thus $\gamma$ is any constant less than $\frac{1}{2}$. $\blacksquare$

The proof of the theorem, which only depended on $\{\xi_i\}_{i=1}^\infty$ being independent random variables each normal with mean 0 and variance 1, implies the following corollary.

**Corollary 62.1.4** Let $\{\xi_i\}_{i=1}^\infty$ be independent random variables each normal with mean 0 and variance 1. Then

$$W(t, \omega) = \sum_{i=1}^\infty \langle \chi_{[0,t)} ; g_i \rangle_{L^2} \xi_i (\omega)$$

is a real Wiener process. Furthermore, the distribution of $W(t) - W(s)$ is the same as the distribution of $W(t-s)$ and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma < 1/2$. Also for each $\alpha > 1$,

$$E(|W(t) - W(s)|^\alpha) \leq C_\alpha |t - s|^{\alpha/2} E(|W(1)|^\alpha)$$

### 62.2 Nowhere Differentiability Of Wiener Processes

If $W(t)$ is a Wiener process, it turns out that $t \to W(t, \omega)$ is nowhere differentiable for a.e. $\omega$. This fact is based on the independence of the increments and the fact that these increments are normally distributed.

First note that $W(t) - W(s)$ has the same distribution as $(t-s)^{1/2} W(1)$. This is because they have the same characteristic function. Next it follows that because
of the independence of the increments and what was just noted that,

\[ P \left( \bigcap_{r=1}^{5} \left[ |W(t+r\delta) - W(t+(r-1)\delta)| \leq K\delta \right] \right) \]

\[ = \prod_{r=1}^{5} P \left( \left| W(t+r\delta) - W(t+(r-1)\delta) \right| \leq K\delta \right) \]

\[ = \prod_{r=1}^{5} P \left( \left| \delta^{1/2}W(1) \right| \leq K\delta \right) = \left( \frac{1}{\sqrt{2\pi}} \int_{-K\sqrt{\delta}}^{K\sqrt{\delta}} e^{-\frac{1}{2}t^2} dt \right)^5 \]

\[ \leq C\delta^{5/2}. \quad (62.2.4) \]

With this observation, here is the proof which follows [108] and according to this reference is due to Payley, Wiener and Zygmund and the proof is like one given by Dvoretsky, Erdös and Kakutani.

**Theorem 62.2.1** Let \( W(t) \) be a Wiener process. Then there exists a set of measure 0, \( N \) such that for all \( \omega \notin N \),

\[ t \to W(t,\omega) \]

is nowhere differentiable.

**Proof:** Let \([0,a]\) be an interval. If for some \( \omega, t \to W(t,\omega) \) is differentiable at some \( s \), then for some \( n, p > 0 \),

\[ \left| \frac{W(t,\omega) - W(s,\omega)}{t-s} \right| \leq p \]

whenever \( |t-s| < 5a2^{-n} \equiv 5\delta_n \). Define \( C_{np} \) by

\[ \left\{ \omega : \text{for some } s \in [0,a), \left| \frac{W(t,\omega) - W(s,\omega)}{t-s} \right| \leq p \text{ if } |t-s| \leq 5\delta_n \right\}. \quad (62.2.5) \]

Thus \( \bigcup_{n,p\in\mathbb{N}} C_{np} \) contains the set of \( \omega \) such that \( t \to W(t,\omega) \) is differentiable for some \( s \in [0,a] \).

Now define uniform partitions of \([0,a]\), \( \{t_k^n\}_{k=0}^{2^n} \) such that

\[ |t_k^n - t_{k-1}^n| = a2^{-n} \equiv \delta_n \]

Let

\[ D_{np} = \bigcup_{i=0}^{2^n-1} \left( \bigcap_{r=1}^{5} \left[ |W(t_{i}^n + r\delta_n) - W(t_{i}^n + (r-1)\delta_n)| \leq 10p\delta_n \right] \right) \]

If \( \omega \in C_{np} \), then for some \( s \in [0,a) \), the condition of (62.2.5) holds. Suppose \( k \) is the number such that \( s \in [t_{k-1}^n, t_k^n) \). Then for \( r \in \{1, 2, 3, 4, 5\} \),

\[ \left| W(t_{k-1}^n + r\delta_n, \omega) - W(t_{k-1}^n + (r-1)\delta_n, \omega) \right| \leq |W(t_{k-1}^n + r\delta_n, \omega) - W(s,\omega)| + |W(s,\omega) - W(t_{k-1}^n + (r-1)\delta_n, \omega)| \]
\[ 5p_n \delta_n + 5p_n = 10p_n \]

Thus \( C_{np} \subseteq D_{np} \). Now from (62.2.4),
\[ P(D_{np}) \leq 2^n C_n^{5/2} = C_n^{5/2}2^n (2^{-n})^{5/2} = C \left( \sqrt{n} \right)^{5} 2^{-\frac{5}{2}n} \] (62.2.6)

Let
\[ C_p = \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} C_{kp} \subseteq \cup_{n=1}^{\infty} \cap_{k=n}^{\infty} D_{kp}. \]

It was just shown in (62.2.6) that \( P(\cap_{k=n}^{\infty} D_{kp}) = 0 \) and so \( C_p \) has measure 0. Thus \( \cup_{k=1}^{\infty} C_p \), the set of points, \( \omega \) where \( t \to W(t, \omega) \) could have a derivative has measure 0. Taking the union of the exceptional sets corresponding to intervals \([0, n)\) for \( n \in \mathbb{N} \), this proves the theorem.

This theorem on nowhere differentiability is very important because it shows it is doubtful one can define an integral \( \int f(s) dW(s) \) by simply fixing \( \omega \) and then doing some sort of Stieltjes integral in time. The reason for this is that the nowhere differentiability of \( W \) implies it is also not of bounded variation on any interval since if it were, it would equal the difference of two increasing functions and would therefore have a derivative at a.e. point.

I have presented the theorem on nowhere differentiability for one dimensional Wiener processes but the same proof holds with minor modifications if you have defined the Wiener process in \( \mathbb{R}^n \) or you could simply consider the components and apply the above result.

### 62.3 Wiener Processes In Separable Banach Space

Here is an important lemma on which the existence of Wiener processes will be based.

**Lemma 62.3.1** There exists a sequence of real Wiener processes, \( \{ \psi_k(t) \}_{k=1}^{\infty} \), which have the following properties. Let \( t_0 < t_1 < \cdots < t_n \) be an arbitrary sequence. Then the random variables
\[ \{ \psi_k(t_q) - \psi_k(t_{q-1}) : (q,k) \in (1,2,\cdots,n) \times (k_1,\cdots,k_m) \} \] (62.3.7)

are independent. Also each \( \psi_k \) is Holder continuous with exponent \( \gamma \) for any \( \gamma < 1/2 \) and for each \( m \in \mathbb{N} \) there exists a constant \( C_m \) independent of \( k \) such that
\[ \int_{\Omega} |\psi_k(t) - \psi_k(s)|^{2m} \, dP \leq C_m |t - s|^m \] (62.3.8)

**Proof:** First, there exists a sequence \( \{ \xi_{ij} \}_{(i,j) \in \mathbb{N} \times \mathbb{N}} \) such that the \( \{ \xi_{ij} \} \) are independent and each normally distributed with mean 0 and variance 1. This follows from Lemma (62.1.2). Let \( \{ \xi_i \}_{i=1}^{\infty} \) be independent and normally distributed with mean 0 and variance 1. (Let \( \theta \) be a one to one and onto map from \( \mathbb{N} \) to \( \mathbb{N} \times \mathbb{N} \). Then define \( \xi_{ij} = \xi_{\theta^{-1}(i,j)} \).)
Let
\[ \psi_k(t) = \sum_{j=1}^{\infty} \langle X_{[0,t]}, g_j \rangle_{L^2} \xi_{kj} \]  
(62.3.9)
where \( \{g_j\} \) is a orthonormal basis for \( L^2(0, \infty) \). By Corollary 62.3.8, this defines a real Wiener process satisfying 62.3.8. It remains to show that the random variables
\[ \psi_{k_r}(t_q) - \psi_{k_r}(t_{q-1}) \]  
(62.3.10)
are independent.

Let
\[ P = \sum_{q=1}^{n} \sum_{r=1}^{m} s_{qr} (\psi_{k_r}(t_q) - \psi_{k_r}(t_{q-1})) \]
and consider \( E(e^{iP}) \). I want to use Proposition 57.11.1 on Page 1936. To do this, I need to show \( E(e^{iP}) \) equals
\[ \prod_{q=1}^{n} \prod_{r=1}^{m} E\left( \exp\left( i s_{qr} (\psi_{k_r}(t_q) - \psi_{k_r}(t_{q-1})) \right) \right) \.
\]
Using 62.3.8, \( E(e^{iP}) \) equals
\[
E \left( \exp \left( i \sum_{q=1}^{n} \sum_{r=1}^{m} s_{qr} \sum_{j=1}^{\infty} \langle X_{[t_{q-1},t_q]}, g_j \rangle_{L^2} \xi_{kj} \right) \right) \\
= \lim_{N \to \infty} E \left( \exp \left( i \sum_{q=1}^{n} \sum_{r=1}^{m} s_{qr} \sum_{j=1}^{N} \langle X_{[t_{q-1},t_q]}, g_j \rangle_{L^2} \xi_{kj} \right) \right) 
\]
Now the \( \xi_{kj} \) are independent by construction. Therefore, the above equals
\[
= \lim_{N \to \infty} \prod_{q=1}^{n} \prod_{r=1}^{m} \prod_{j=1}^{N} E \left( \exp \left( i s_{qr} \langle X_{[t_{q-1},t_q]}, g_j \rangle_{L^2} \right) \right) \\
= \prod_{q=1}^{n} \prod_{r=1}^{m} \lim_{N \to \infty} \exp \left( -\frac{1}{2} s_{qr}^2 \langle X_{[t_{q-1},t_q]}, g_j \rangle_{L^2}^2 \right) \\
= \prod_{q=1}^{n} \prod_{r=1}^{m} \exp \left( -\frac{1}{2} s_{qr}^2 (t_q - t_{q-1}) \right)
because \( \psi_{k_q} (t_q) - \psi_{k_q} (t_{q-1}) \) is normally distributed with variance \( t_q - t_{q-1} \) and mean 0. By Proposition 57.11.1 on Page 1936, it follows the random variables of 62.3.10 are independent. Note that as a special case, this also shows the random variables, \( \{\psi_k (t)\}_{k=1}^{\infty} \) are independent due to the fact \( \psi_k (0) = 0 \). ■

Recall Corollary 59.11.4 which is stated here for convenience.

**Corollary 62.3.2** Let \( E \) be any real separable Banach space. Then there exists a sequence, \( \{e_k\} \subseteq E \) such that for any \( \{\xi_k\} \) a sequence of independent random variables such that \( \mathcal{L} (\xi_k) = N (0, 1) \), it follows

\[
X (\omega) = \sum_{k=1}^{\infty} \xi_k (\omega) e_k
\]

converges a.e. and its law is a Gaussian measure defined on \( \mathcal{B} (E) \). Furthermore, \( ||e_k||_E \leq \lambda_k \) where \( \sum_k \lambda_k < \infty \).

Now let \( \{\psi_k (t)\} \) be the sequence of Wiener processes described in Lemma 62.3.1. Then define a process with values in \( E \) by

\[
W (t) = \sum_{k=1}^{\infty} \psi_k (t) e_k \tag{62.3.11}
\]

Then \( \psi_k (t) / \sqrt{t} \) is \( N (0, 1) \) and so by Corollary 62.3.2 the law of

\[
W (t) / \sqrt{t} = \sum_{k=1}^{\infty} \left( \psi_k (t) / \sqrt{t} \right) e_k
\]

is a Gaussian measure. Therefore, the same is true of \( W (t) \). Similar reasoning applies to the increments, \( W (t) - W (s) \) to conclude the law of each of these is Gaussian. Consider the question whether the increments are independent. Let \( 0 \leq t_0 < t_1 < \cdots < t_m \) and let \( \phi_j \in E' \). Then by the dominated convergence theorem and the properties of the \( \{\psi_k\} \),

\[
E \left( \exp \left( i \sum_{j=1}^{m} \phi_j (W (t_j) - W (t_{j-1})) \right) \right)
\]

\[
= E \left( \exp \left( i \sum_{j=1}^{m} \left( \sum_{k=1}^{\infty} (\psi_k (t_j) - \psi_k (t_{j-1})) \phi_j (e_k) \right) \right) \right)
\]

\[
= E \left( \prod_{j=1}^{m} \exp \left( i \sum_{k=1}^{\infty} (\psi_k (t_j) - \psi_k (t_{j-1})) \phi_j (e_k) \right) \right)
\]
which shows by Theorem \[\text{[Theorem 57.13.3 on Page 1943]}\] that the random vectors,

\[\{W(t_j) - W(t_{j-1})\}_{j=1}^m\]

are independent.

It is also routine to verify using properties of the \(\psi_k\) and characteristic functions that \(\mathcal{L}(W(t) - W(s)) = \mathcal{L}(W(t-s))\). To see this, let \(\phi \in E'\)

\[E(\exp(i\phi(W(t) - W(s)))) = \lim_{n \to \infty} E\left(\exp\left(i\phi_k(t) - \psi_k(s) e_k\right)\right)\]
\[ \lim_{n \to \infty} \prod_{k=1}^{n} E \left( \exp \left( i \phi (\epsilon_k) (\psi_k (t) - \psi_k (s)) \right) \right) \]

which is the same as the result for

\[ E \left( \exp \left( i \phi (W (t - s)) \right) \right) \]

and

\[ E \left( \exp \left( i \phi (\sqrt{t - s} W (1)) \right) \right) \]

This has proved the following lemma.

**Lemma 62.3.3** Let \( E \) be a real separable Banach space. Then there exists an \( E \) valued stochastic process, \( W (t) \) such that \( L (W (t)) \) and \( L (W (t) - W (s)) \) are Gaussian measures and the increments, \( \{W (t) - W (s)\} \) are independent. Furthermore, the increment \( W (t) - W (s) \) has the same distribution as \( W (t - s) \) and \( W (t) \) has the same distribution as \( \sqrt{t} W (1) \).

Now I want to consider the question of Holder continuity of the functions, \( t \to W (t, \omega) \).

\[
\int_{\Omega} \|W (t) - W (s)\|^\alpha dP = \int_{E} \|x\|^\alpha d\mu_{W (t) - W (s)}
\]

\[
= \int_{E} \|x\|^\alpha d\mu_{W (t - s)} = \int_{E} \|x\|^\alpha d\mu_{\sqrt{t - s} W (1)}
\]

\[
= \int_{\Omega} \|\sqrt{t - s} W (1)\|^\alpha dP
\]

\[
= |t - s|^{\alpha/2} \int_{\Omega} \|W (1)\|^\alpha dP = C_\alpha |t - s|^{\alpha/2}
\]

by Fernique’s theorem, Theorem \( \text{TUTA} \). From the Kolmogorov Čentsov theorem, Theorem \( \text{KOLOS} \), it follows \( \{W (t)\} \) is Holder continuous with exponent \( \gamma < \frac{\alpha}{2} - 1 \) / \( \alpha \).

This completes the proof of the following theorem.

**Theorem 62.3.4** Let \( E \) be a separable real Banach space. Then there exists a stochastic process, \( \{W (t)\} \) such that the distribution of \( W (t) \) and every increment, \( W (t) - W (s) \) is Gaussian. Furthermore, the increments corresponding to disjoint intervals are independent, \( L (W (t) - W (s)) = L (W (t - s)) = L (\sqrt{t - s} W (1)) \).

Also for a.e. \( \omega \), \( t \to W (t, \omega) \) is Holder continuous with exponent \( \gamma < 1/2 \).
62.4 An Example Of Martingales, Independent Increments

Here is an interesting lemma.

**Lemma 62.4.1** Let $(W(t), \mathcal{F}_t)$ be a stochastic process which has independent increments having values in $E$ a real separable Banach space. Let

$$A \in \mathcal{F}_s \equiv \sigma (W(u) - W(r) : 0 \leq r < u \leq s)$$

Suppose $g(W(t) - W(s)) \in L^1(\Omega; E)$. Then the following formula holds.

$$\int_\Omega \chi_A g(W(t) - W(s)) \, dP = P(A) \int_\Omega g(W(t) - W(s)) \, dP \quad (62.4.12)$$

**Proof:** Let $\mathcal{G}$ denote the set, of all $A \in \mathcal{F}_s$ such that (62.4.12) holds. Then it is obvious $\mathcal{G}$ is closed with respect to complements and countable disjoint unions. Let $\mathcal{K}$ denote those sets which are finite intersections of the form

$$A = \cap_{i=1}^m A_i$$

where each $A_i$ is in a set of $\sigma (W(u_i) - W(r_i))$ for some $0 \leq r_i < u_i \leq s$. For such $A_i$ it follows

$$A \in \sigma (W(u_i) - W(r_i), i = 1, \cdots, m).$$

Now consider the random vector having values in $E^{m+1}$,

$$(W(u_1) - W(r_1), \cdots, W(u_m) - W(r_m), g(W(t) - W(s)))$$

Let $t^* \in (E')^m$ and $s^* \in E'$.

$$t^* : (W(u_1) - W(r_1), \cdots, W(u_m) - W(r_m))$$

can be written in the form $g^* \cdot (W(\tau_1) - W(\eta_1), \cdots, W(\tau_j) - W(\eta_j))$ where the intervals, $(\eta_j, \tau_j)$ are disjoint and each $\tau_j \leq s$. For example, suppose you have

$$a(W(2) - W(1)) + b(W(2) - W(0)) + c(W(3) - W(1)),$$

where obviously the increments are not disjoint. Then you would write the above expression as

$$a(W(2) - W(1)) + b(W(2) - W(0)) + b(W(1) - W(0))$$

$$+ c(W(3) - W(2)) + c(W(2) - W(1))$$

and then you would collect the terms to obtain

$$b(W(1) - W(0)) + (a + b + c)(W(2) - W(1)) + c(W(3) - W(2))$$

and now these increments are disjoint.
Therefore, by independence of the increments,
\[
E \left( \exp \left( i (t^* \cdot (W (u_1) - W (r_1)), \cdots, W (u_m) - W (r_m)) + s^* (g (W (t) - W (s))) \right) \right) \\
= E \left( \exp \left( i (g^* \cdot (W (\tau_1) - W (\eta_1)), \cdots, W (\tau_l) - W (\eta_l)) + s^* (g (W (t) - W (s))) \right) \right) \\
= \prod_{j=1}^l E \left( \exp \left( i g_j (W (\tau_j) - W (\eta_j)) \right) \right) E \left( \exp \left( i s^* (g (W (t) - W (s))) \right) \right) \\
= E \left( \exp \left( i (t^* \cdot (W (u_1) - W (r_1)), \cdots, W (u_m) - W (r_m))) \cdot \right) \\
E \left( \exp \left( i s^* (g (W (t) - W (s))) \right) \right).
\]

By Theorem 62.13.3, it follows the vector \((W (u_1) - W (r_1), \cdots, W (u_m) - W (r_m))\)
\(\) is independent of the random variable \(g (W (t) - W (s))\) which shows that for \(A \in \mathcal{K}, \)
\(X_A,\) measurable in \(\sigma (W (u_1) - W (r_1), \cdots, W (u_m) - W (r_m))\) is independent of
\(g (W (t) - W (s)).\)

Thus \(K \subseteq \mathcal{G}\) and so by the lemma on \(\pi\) systems, Lemma 61.1.1.2 on Page 2241 it
follows \(\mathcal{G} \supseteq \sigma (K) \supseteq \mathcal{F}_t \supseteq \mathcal{G}.\)

**Lemma 62.4.2** Let \(\{W (t)\}\) be a stochastic process having values in a separable
Banach space which has the property that if \(t_1 < t_2 \cdots < t_n,\) then the increments,
\(\{W (t_k) - W (t_{k-1})\}\)
\(\) are independent and integrable and \(E (W (t) - W (s)) = 0.\) Suppose also that \(W (t)\)
\(\) is right continuous, meaning that for \(\omega\) off a set of measure zero, \(t \to W (t) (\omega)\)
is right continuous. Also suppose that for some \(q > 1\)
\(\|W (t) - W (s)\|_{L^q(\Omega)}\)
is bounded independent of \(s \leq t.\) Then \(\{W (t)\}\) is also a martingale with respect to
the normal filtration defined by
\(\mathcal{F}_s \equiv \cap_{t > s} \sigma (W (u) - W (r) : 0 \leq r < u - t)\)
where this denotes the intersection of the completions of the \(\sigma\) algebras
\(\sigma (W (u) - W (r) : 0 \leq r < u - t)\)
\(\) Also, in the same situation but without the assumption that \(E (W (t) - W (s)) = 0,\)
if \(t > s\) and \(A \in \mathcal{F}_s\) it follows that if \(g\) is a continuous function such that
\(\|g (W (t) - W (s))\|_{L^q(\Omega)}\)
is bounded independent of \(s \leq t\) for some \(q > 1\) then for \(t > s,\)
\[
\int_\Omega \chi_A g (W (t) - W (s)) dP = P (A) \int_\Omega g (W (t) - W (s)) dP.
\]
62.4. AN EXAMPLE OF MARTINGALES, INDEPENDENT INCREMENTS

Proof: Consider first the claim, \([62.4.14]\). To begin with I show that if \(A \in \mathcal{F}_s\) then for all \(\varepsilon \) small enough that \(t > s + \varepsilon\),

\[
\int_{\Omega} \mathcal{X}_A g(W(t) - W(s + \varepsilon)) dP = P(A) \int_{\Omega} g(W(t) - W(s + \varepsilon)) dP \quad (62.4.15)
\]

This will happen if \(\mathcal{X}_A\) and \(g(W(t) - W(s + \varepsilon))\) are independent. First note that from the definition

\[
A \in \sigma(W(u) - W(r) : 0 \leq r < u \leq s + \varepsilon)
\]

and so from the process of completion of a measure space, there exists

\[
B \subseteq A \text{ and } P(B \setminus A) = 0.
\]

Therefore, letting \(\phi \in E'\),

\[
E(\exp(it\mathcal{X}_A + i\phi(g(W(t) - W(s + \varepsilon)))) = E(\exp(it\mathcal{X}_B + i\phi(g(W(t) - W(s + \varepsilon)))) = E(\exp(it\mathcal{X}_B)) E(\exp(i\phi(g(W(t) - W(s + \varepsilon))))
\]

because \(\mathcal{X}_B\) is independent of \(g(W(t) - W(s + \varepsilon))\) by Lemma \([62.4.1]\) above. Then the above equals

\[
= E(\exp(it\mathcal{X}_A)) E(\exp(i\phi(g(W(t) - W(s + \varepsilon))))
\]

Now by Theorem \([57.13.3]\), \((62.4.15)\) follows. Next pass to the limit in both sides of \((62.4.15)\) as \(\varepsilon \to 0\). One can do this because of \([62.4.13]\) which implies the functions in the integrands are uniformly integrable and Vitali's convergence theorem, Theorem \([19.5.7]\). This yields \([62.4.14]\).

Now consider the part about the stochastic process being a martingale. Let \(g\) be the identity map. If \(A \in \mathcal{F}_s\), the above implies

\[
\int_{A} E(W(t)|\mathcal{F}_s) dP = \int_{A} W(t) dP = \int_{A} (W(t) - W(s)) dP + \int_{A} W(s) dP
\]

\[
= P(A) \int_{\Omega} (W(t) - W(s)) dP + \int_{A} W(s) dP = \int_{A} W(s) dP
\]

and so since \(A\) is arbitrary, \(E(W(t)|\mathcal{F}_s) = W(s)\). \(\blacksquare\)

Note this implies immediately from Lemma \([61.1.5]\) that Wiener process is not of bounded variation on any interval. This is because this lemma implies if it were of bounded variation, then it would be constant which is not the case due to

\[
\mathcal{L}(W(t) - W(s)) = \mathcal{L}(W(t - s)) = \mathcal{L}(\sqrt{t - s}W(1)).
\]

Here is an interesting theorem about approximation.

\(^1\)Note how the \(\sigma\) algebra \(\mathcal{F}_s\) are defined, as the intersection of completions of \(\sigma\) algebras corresponding to \(t\) strictly larger than \(s\).
**Theorem 62.4.3** Let \( \{W(t)\} \) be a Wiener process having values in a separable Banach space as described in Theorem 62.3.4. There exists a set of measure 0, \( N \), such that for \( \omega \in N \), the sum in 62.3.11 converges uniformly to \( W(t, \omega) \) on any interval, \([0, T]\). That is, for each \( \omega \) not in a set of measure zero, the partial sums of the sum in that formula converge uniformly to \( t \mapsto W(t, \omega) \) on \([0, T]\).

**Proof:** By Lemma 62.4.2 the independence of the increments imply

\[
\sum_{k=m}^{n} \psi_k(t) e_k
\]

is a martingale and so by Theorem 62.5.3,

\[
P\left(\left\{ \sup_{t \in [0,T]} \left\| \sum_{k=m}^{n} \psi_k(t) e_k \right\| \geq \alpha \right\} \right) \leq \frac{1}{\alpha} \int_{\Omega} \left\| \sum_{k=m}^{n} \psi_k(T) e_k \right\| dP
\]

From Corollary 62.4.4

\[
\int_{\Omega} \left\| \sum_{k=m}^{n} \psi_k(T) e_k \right\| dP \leq \sum_{k=m}^{n} \int_{\Omega} |\psi_k(T)| dP \lambda_k
\]

which shows that there exists a subsequence, \( m_l \) such that whenever \( n > m_l \),

\[
P\left(\left\{ \sup_{t \in [0,T]} \left\| \sum_{k=m_l}^{n} \psi_k(t) e_k \right\| \geq 2^{-k} \right\} \right) \leq 2^{-k}.
\]

Recall Lemma 62.4.4 stated below for convenience.

**Lemma 62.4.4** Let \( \{\zeta_k\} \) be a sequence of random variables having values in a separable real Banach space, \( E \) whose distributions are symmetric. Letting \( S_k \equiv \sum_{i=1}^{k} \zeta_i \), suppose \( \{S_{n_k}\} \) converges a.e. Also suppose that for every \( m > n_k \),

\[
P\left(\left\{ \left\| S_m - S_{n_k} \right\|_E > 2^{-k} \right\} \right) < 2^{-k}.
\]

Then in fact,

\[
S_k(\omega) \to S(\omega) \text{ a.e. } \omega
\]

Apply this lemma to the situation in which the Banach space, \( E \) is \( C([0, T]; E) \) and \( \zeta_k = \psi_k e_k \). Then you can conclude uniform convergence of the partial sums,

\[
\sum_{k=1}^{m} \psi_k(t) e_k.
\]

This proves the theorem.
Why is $C([0,T];E)$ separable? You can assume without loss of generality that the interval is $[0,1]$ and consider the Bernstein polynomials

$$p_n(t) = \sum_{k=0}^{n} \binom{n}{k} f\left(\frac{k}{n}\right) t^k (1-t)^{n-k}$$

These converge uniformly to $f$. Now look at all polynomials of the form

$$\sum_{k=0}^{n} a_k t^k (1-t)^k$$

where the $a_k$ is one of the countable dense set and $n \in \mathbb{N}$. Each Bernstein polynomial uniformly close to one of these and also uniformly close to $f$. Hence polynomials of this sort are countable and dense in $C([0,T];E)$.

**62.5 Hilbert Space Valued Wiener Processes**

Next I will consider the case of Hilbert space valued Wiener processes. This will include the case of $\mathbb{R}^n$ valued Wiener processes. I will present this material independent of the more general case of $E$ valued Wiener processes.

**Definition 62.5.1** Let $W(t)$ be a stochastic process with values in $H$, a real separable Hilbert space which has the properties that $t \rightarrow W(t,\omega)$ is continuous, whenever $t_1 < t_2 < \cdots < t_m$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent, $W(0) = 0$, and whenever $s < t$,

$$\mathcal{L}(W(t) - W(s)) = N(0, (t-s) Q)$$

which means that whenever $h \in H$,

$$\mathcal{L}(\langle h, W(t) - W(s) \rangle) = N(0, (t-s) \langle Qh, h \rangle)$$

Also

$$E(\langle h_1, W(t) - W(s) \rangle \langle h_2, W(t) - W(s) \rangle) = \langle Qh_1, h_2 \rangle (t-s).$$

Here $Q$ is a nonnegative trace class operator. Recall this means

$$Q = \sum_{i=1}^{\infty} \lambda_i e_i \otimes e_i$$

where $\{e_i\}$ is a complete orthonormal basis, $\lambda_i \geq 0$, and

$$\sum_{i=1}^{\infty} \lambda_i < \infty$$

Such a stochastic process is called a $Q$ Wiener process. In the case where these have values in $\mathbb{R}^n$, $tQ$ ends up being the covariance matrix of $W(t)$. 
Note the characteristic function of a $Q$ Wiener process is
\[ E \left( e^{i(h,W(t))} \right) = e^{-\frac{1}{2} t^2 (Qh,h)} \] (62.5.18)

Note that by Theorem 59.8.5 if you simply say that the distribution measure of $W(t)$ is Gaussian, then it follows there exists a trace class operator $Q_t$ and $m_t \in H$ such that this measure is $N(m_t,Q_t)$. Thus for $W(t)$ a Wiener process, $Q_t = tQ$ and $m_t = 0$. In addition, the increments are independent so this is much more specific than the earlier definition of a Gaussian measure.

What is a $Q$ Wiener process if the Hilbert space is $\mathbb{R}^n$? In particular, what is $Q$? It is given that $L((h,W(t) - W(s))) = N(0,(t-s)(Qh,h))$

In this case everything is a vector in $\mathbb{R}^n$ and so for $h \in \mathbb{R}^n$,
\[ E \left( e^{i\lambda(h,W(t)-W(s))} \right) = e^{-\frac{1}{2} \lambda^2 (t-s)(Qh,h)} \]

In particular, letting $\lambda = 1$ this shows $W(t) - W(s)$ is normally distributed with covariance $(t-s)Q$ because its characteristic function is $e^{-\frac{1}{2} h^*(t-s)Qh}$.

With this and definition, one can describe Hilbert space valued Wiener processes in a fairly general setting.

**Theorem 62.5.2** Let $U$ be a real separable Hilbert space and let $J : U_0 \to U$ be a Hilbert Schmidt operator where $U_0$ is a real separable Hilbert space. Then let $\{g_k\}$ be a complete orthonormal basis for $U_0$ and define for $t \in [0,T]$
\[ W(t) \equiv \sum_{k=1}^{\infty} \psi_k(t) Jg_k \]

Then $W(t)$ is a $Q$ Wiener process for $Q = JJ^*$ as in Definition 52.5.4. Furthermore, the distribution of $W(t) - W(s)$ is the same as the distribution of $W(t-s)$, and $W$ is Holder continuous with exponent $\gamma$ for any $\gamma < 1/2$. There also is a subsequence denoted by $N$ such that the convergence of the series
\[ \sum_{k=1}^{N} \psi_k(t) Jg_k \]
is uniform for all $\omega$ not in some set of measure zero.

**Proof:** First it is necessary to show the series converges in $L^2(\Omega;U)$ for each $t$. For convenience I will consider the series for $W(t) - W(s)$. (Always, it is assumed $t > s$.) Then since $\psi_k(t) - \psi_k(s)$ is normal with mean 0 and variance $(t-s)$ and $\psi_k(t) - \psi_k(s)$ and $\psi_l(t) - \psi_l(s)$ are independent,
\[ \int_{\Omega} \left| \sum_{k=m}^{n} (\psi_k(t) - \psi_k(s)) Jg_k \right|^2 dP = \int_{\Omega} \sum_{k,l=m}^{n} ((\psi_k(t) - \psi_k(s)) Jg_k, (\psi_l(t) - \psi_l(s)) Jg_l) \]
which converges to 0 as \( m, n \to \infty \) thanks to the assumption that \( J \) is Hilbert Schmidt. It follows the above sum converges in \( L^2(\Omega; \mathcal{U}) \). Now letting \( m < n \), it follows by the maximal estimate, Theorem 60.5.3, and the above

\[
P \left( \left| \sup_{t \in [0,T]} \left( \sum_{k=1}^{m} \psi_k(t) Jg_k - \sum_{k=1}^{n} \psi_k(t) Jg_k \right) \right| \geq \lambda \right) \leq \frac{1}{\lambda^2} \mathbb{E} \left( \sum_{k=m+1}^{n} \psi_k(T) Jg_k \right)^2 \leq \frac{1}{\lambda^2 T} \sum_{k=m}^{n} \|Jg_k\|^2_{\mathcal{U}}
\]

and so there exists a subsequence \( n_l \) such that for all \( p \geq 0 \),

\[
P \left( \left| \sup_{t \in [0,T]} \left( \sum_{k=1}^{n_l} \psi_k(t) Jg_k - \sum_{k=1}^{n_l+p} \psi_k(t) Jg_k \right) \right| \geq 2^{-l} \right) < 2^{-l}
\]

Therefore, by Borel Cantelli lemma, there is a set of measure zero such that for \( \omega \) not in this set,

\[
\lim_{l \to \infty} \sum_{k=1}^{n_l} \psi_k(t) Jg_k = \sum_{k=1}^{\infty} \psi_k(t) Jg_k
\]

is uniform on \([0,T]\). From now on denote this subsequence by \( N \) to save on notation.

I need to consider the characteristic function of \((h, W(t) - W(s))_{\mathcal{U}}\) for \( h \in \mathcal{U} \). Then

\[
\mathbb{E} \left( \exp \left( \text{ir} \left( h, (W(t) - W(s))_{\mathcal{U}} \right) \right) \right)
= \lim_{N \to \infty} \mathbb{E} \left( \exp \left( \text{ir} \left( \sum_{j=1}^{N} (\psi_j(t) - \psi_j(s))(h, Jg_j) \right) \right) \right)
= \lim_{N \to \infty} \mathbb{E} \left( \prod_{j=1}^{N} e^{\text{ir}(\psi_j(t) - \psi_j(s))(h, Jg_j)} \right)
\]

Since the random variables \( \psi_j(t) - \psi_j(s) \) are independent,

\[
= \lim_{N \to \infty} \prod_{j=1}^{N} \mathbb{E} \left( e^{\text{ir}(h, Jg_j)(\psi_j(t) - \psi_j(s))} \right)
\]

Since \( \psi_j(t) - \psi_j(s) \) is a Gaussian random variable having mean 0 and variance \((t - s)\), the above equals

\[
= \lim_{N \to \infty} \prod_{j=1}^{N} e^{-\frac{1}{2} \text{ir}^2(h, Jg_j)^2(t-s)}
\]
which shows \((h, W(t) - W(s))_U\) is normally distributed with mean 0 and variance 
\((t-s)(Qh,h)_U\) where \(Q = JJ^*.\) It is obvious from the definition that \(W(0) = 0.\) Note that \(Q\) is of trace class because if 
\(\{e_k\}\) is an orthonormal basis for \(U,\)

\[
\sum_k (Qe_k, e_k)_U = \sum_k ||J^*e_k||^2_U = \sum_k \sum_l (J^*e_k, g_l)_U^2 < \infty
\]

To find the covariance, consider

\[
E \left( (h_1, W(t) - W(s)) (h_2, W(t) - W(s)) \right),
\]

This equals

\[
E \left( \sum_{k=1}^{\infty} (\psi_k(t) - \psi_k(s)) (h_1, Jg_k) \sum_{j=1}^{\infty} (\psi_j(t) - \psi_j(s)) (h_2, Jg_j) \right).
\]

Since the series converge in \(L^2(\Omega; U),\) the independence of the \(\psi_k(t) - \psi_k(s)\) implies the above equals

\[
= \lim_{n \to \infty} E \left( \sum_{k=1}^{n} (\psi_k(t) - \psi_k(s)) (h_1, Jg_k) \sum_{j=1}^{n} (\psi_j(t) - \psi_j(s)) (h_2, Jg_j) \right).
\]
Next consider the claim that the increments are independent. Let \( W^N(t) \) be given by the appropriate partial sum and let \( \{ h_j \}_{j=1}^m \) be a finite list of vectors of \( U \). Then from the independence properties of \( \psi_j \) explained above,

\[
E \left( \exp \sum_{j=1}^m i \left( h_j, W^N (t_j) - W^N (t_{j-1}) \right) \right)
\]

\[
= E \left( \exp \sum_{j=1}^m \sum_{k=1}^N i (h_j, Jg_k (\psi_k (t_j) - \psi_k (t_{j-1}))) \right)
\]

\[
= E \left( \prod_{j,k} \exp \left( i (h_j, Jg_k) (\psi_k (t_j) - \psi_k (t_{j-1})) \right) \right)
\]

This can be done because of the independence of the random variables \( \{ \psi_k (t_j) - \psi_k (t_{j-1}) \}_{j,k} \).

Thus the above equals

\[
\prod_{j,k} \exp \left( -\frac{1}{2} (h_j, Jg_k)^2 (t_j - t_{j-1}) \right)
\]

\[
= \prod_{j=1}^m \exp \left( -\frac{1}{2} \sum_{k=1}^N (h_j, Jg_k)^2 (t_j - t_{j-1}) \right)
\]
because \( \psi_k(t_j) - \psi_k(t_{j-1}) \) is normally distributed having variance \( t_j - t_{j-1} \). Now letting \( N \to \infty \), this implies

\[
E \left( \exp \left( \sum_{j=1}^{m} i \langle h_j, W(t_j) - W(t_{j-1}) \rangle_U \right) \right) = \prod_{j=1}^{m} \exp \left( -\frac{1}{2} \sum_{k=1}^{\infty} (h_j, Jg_k)^2_U (t_j - t_{j-1}) \right)
\]

\[
= \prod_{j=1}^{m} \exp \left( -\frac{1}{2} (t_j - t_{j-1}) \sum_{k=1}^{\infty} (J^* h_j, g_k)^2_U \right)
\]

\[
= \prod_{j=1}^{m} \exp \left( -\frac{1}{2} (t_j - t_{j-1}) ||J^* h_j||^2_U \right)
\]

\[
= \prod_{j=1}^{m} \exp \left( i \langle h_j, W(t_j) - W(t_{j-1}) \rangle_U \right)
\]

(62.5.20)

from 62.5.19, letting \( r = 1 \). By Theorem 57.13 on Page 1938, this shows the increments are independent.

It remains to verify the Holder continuity. Recall

\[
W(t) = \sum_{k=1}^{\infty} Jg_k \psi_k(t)
\]

where \( \psi_k \) is a real Wiener process.

Next consider the claim about Holder continuity. It was shown above that

\[
E \left( \exp \left( i \langle h, (W(t) - W(s)) \rangle_U \right) \right) = \exp \left( -\frac{1}{2} r^2 (t - s) (Qh, h)_U \right)
\]

Therefore, taking a derivative with respect to \( r \) two times yields

\[
E \left( \left( -\langle h, (W(t) - W(s)) \rangle_U \right)^2 \exp \left( i \langle h, (W(t) - W(s)) \rangle_U \right) \right)
\]

\[
= -(t - s)(Qh, h) \exp \left( -\frac{1}{2} r^2 (t - s) (Qh, h)_U \right) +
\]

\[
\quad r^2 (t - s)^2 (Qh, h)^2_U \exp \left( -\frac{1}{2} r^2 (t - s) (Qh, h)_U \right)
\]

Now plug in \( r = 0 \) to obtain

\[
E \left( \langle h, (W(t) - W(s)) \rangle_U^2 \right) = (t - s) (Qh, h).
\]
Similarly, taking 4 derivatives, it follows that an expression of the following form holds:
\[ E \left( \left( h, (W(t) - W(s)) \right)^4 \right) = C_2 (Qh, h)^2 (t - s)^2, \]
and in general,
\[ E \left( \left( h, (W(t) - W(s)) \right)^{2m} \right) = C_m (Qh, h)^m (t - s)^m. \]

Now it follows from Minkowsky’s inequality applied to the two integrals \( \sum_{i=1}^{\infty} \) and \( \int_{\Omega} \) that
\[
\left[ E \left( |W(t) - W(s)|^{2m} \right) \right]^{1/m} = \left[ E \left( \left( \sum_{k=1}^{\infty} (e_k, W(t) - W(s))^2 \right)^m \right) \right]^{1/m} \\
\leq \sum_{k=1}^{\infty} \left[ E \left( (e_k, W(t) - W(s))^{2m} \right) \right]^{1/m} \\
= \sum_{k=1}^{\infty} [C_m (Qe_k, e_k)^m (t - s)^m]^{1/m} \\
= C_m^{1/m} |t - s| \left( \sum_{k=1}^{\infty} (Qe_k, e_k) \right) \equiv C_m |t - s|.
\]

Hence there exists a constant \( C_m \) such that
\[ E \left( |W(t) - W(s)|^{2m} \right) \leq C_m |t - s|^m. \]

By the Kolmogorov Čentsov Theorem, Theorem 60.2.2, it follows that off a set of measure 0, \( t \to W(t, \omega) \) is Hölder continuous with exponent \( \gamma \) such that
\[ \gamma < \frac{m - 1}{2m}, \quad m > 2. \]

Finally, from 62.5.19 with \( r = 1 \),
\[ E \left( \exp i \left( h, (W(t) - W(s))_U \right) \right) = \exp \left( -\frac{1}{2} (t - s) (Qh, h) \right) \]
which is the same as \( E \left( \exp i \left( h, (W(t) - W(s))_U \right) \right) \) due to the fact \( W(0) = 0. \]

The above has shown that \( W(t) \) satisfies the conditions of Lemma 62.4.2 and so it is a martingale with respect to the filtration given there. What is its quadratic variation?
\[ E \left( ||W(t)||^2 \right) = \sum_{k=1}^{\infty} E \left( (W(t), e_k) (W(t), e_k) \right) = \sum_{k=1}^{\infty} (Qe_k, e_k) t = \text{trace} (Q) t \]
Is it the case that \([W](t) = \text{trace}(Q)t\)? Let the filtration be as in Lemma 62.4 and let \(A \in \mathcal{F}_s\). Then using the result of that lemma,

\[
\int_A \left( ||W(t)||^2 - t \text{trace}(Q) \right) |\mathcal{F}_s| dP 
\]

\[
= \int_A \left( ||W(t) - W(s)||^2 + 2(W(t), W(s)) - ||W(s)||^2 
- (t - s) \text{trace } Q - \text{trace } Qs |\mathcal{F}_s| ight) dP
\]

\[
= P(A) \int_\Omega ||W(t) - W(s)||^2 - (t - s) \text{trace } Q dP 
+ \int_A \left( 2(W(t), W(s)) - ||W(s)||^2 - \text{trace } (Q)s |\mathcal{F}_s| ight) dP
\]

\[
= \int_A 2(W(s), E(W(t)|\mathcal{F}_s)) dP - \int_A ||W(s)||^2 dP - \int_A s \text{trace } Q dP 
= \int_A \left( ||W(s)||^2 - s \text{trace } Q \right) dP
\]

and this shows that the quadratic variation \([W](t) = t \text{trace}(Q)\) by uniqueness of the quadratic variation.

Now suppose you start with a nonnegative trace class operator \(Q\). Then in this case also one can define a \(Q\) Wiener process. It is possible to get this theorem from Theorem 62.5.2 but this will not be done here.

**Theorem 62.5.3** Let \(U\) be a real separable Hilbert space and let \(Q\) be a nonnegative trace class operator defined on \(U\). Then there exists a \(Q\) Wiener process as defined in Definition 62.5.1. Furthermore, the distribution of \(W(t) - W(s)\) is the same as the distribution of \(W(t - s)\) and \(W\) is Holder continuous with exponent \(\gamma\) for any \(\gamma < 1/2\).

**Proof:** One can obtain this theorem as a corollary of Theorem 62.5.2 but this will not be done here.

Let

\[
Q = \sum_{i=1}^{\infty} \lambda_i e_i \otimes e_i
\]

where \(\{e_i\}\) is a complete orthonormal set and \(\lambda_i \geq 0\) and \(\sum \lambda_i < \infty\). Now the definition of the \(Q\) Wiener process is

\[
W(t) \equiv \sum_{k=1}^{\infty} \sqrt{\lambda_k} e_k \psi_k(t) \tag{62.5.21}
\]

where \(\{\psi_k(t)\}\) are the real Wiener processes defined in Lemma 62.5.1.
Now consider. From this formula, if \( s < t \)

\[
W(t) - W(s) = \sum_{k=1}^{\infty} \sqrt{\lambda_k} e_k (\psi_k(t) - \psi_k(s)) \tag{62.5.22}
\]

First it is necessary to show this sum converges. Since \( \psi_j(t) \) is a Wiener process,

\[
\int_{\Omega} \left| \sum_{j=m}^{n} \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s)) e_j \right|^2 dP
\]

\[
= \int_{\Omega} \sum_{j=m}^{n} \lambda_j \left(\psi_j(t) - \psi_j(s)\right)^2 dP
\]

\[
= (t - s) \sum_{j=m}^{n} \lambda_j
\]

and this converges to 0 as \( m, n \to \infty \) because it was given that

\[
\sum_{j=1}^{\infty} \lambda_j < \infty
\]

so the series in 62.5.22 converges in \( L^2(\Omega; U) \).

Therefore, there exists a subsequence

\[
\left\{ \sum_{k=1}^{N} \sqrt{\lambda_k} e_k (\psi_k(t) - \psi_k(s)) \right\}
\]

which converges pointwise a.e. to \( W(t) - W(s) \) as well as in \( L^2(\Omega; U) \) as \( N \to \infty \).

Then letting \( h \in U \),

\[
(h, W(t) - W(s))_U = \sum_{k=1}^{\infty} \sqrt{\lambda_k} (\psi_k(t) - \psi_k(s)) (h, e_k) \tag{62.5.23}
\]

Then by the dominated convergence theorem,

\[
E\left(\exp \left( ir (h, (W(t) - W(s)))_U \right) \right)
\]

\[
= \lim_{N \to \infty} E\left( \exp \left( ir \left( \sum_{j=1}^{N} \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s)) (h, e_j) \right) \right) \right)
\]

\[
= \lim_{N \to \infty} E\left( \prod_{j=1}^{N} e^{ir \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s))(h, e_j)} \right)
\]
Since the random variables $\psi_j(t) - \psi_j(s)$ are independent,

$$= \lim_{N \to \infty} \prod_{j=1}^{N} E\left(e^{i r \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s))(h, e_j)}\right)$$

Since $\psi_j(t)$ is a real Wiener process,

$$= \lim_{N \to \infty} \prod_{j=1}^{N} e^{-\frac{1}{2} r^2 \lambda_j (t-s)(h, e_j)^2}$$

$$= \lim_{N \to \infty} \exp \left( \sum_{j=1}^{N} -\frac{1}{2} r^2 \lambda_j (t-s)(h, e_j)^2 \right)$$

$$= \exp \left( -\frac{1}{2} r^2 (t-s) \sum_{j=1}^{\infty} \lambda_j (h, e_j)^2 \right)$$

$$= \exp \left( -\frac{1}{2} r^2 (t-s) (Qh, h) \right) \quad (62.5.24)$$

Thus $(h, W(t) - W(s))$ is normally distributed with mean 0 and variance $(t-s)(Qh, h)$. It is obvious from the definition that $W(0) = 0$. Also to find the covariance, consider

$$E((h_1, W(t) - W(s))(h_2, W(t) - W(s)))$$

and use $(62.5.23)$ to obtain this is equal to

$$E\left( \sum_{k=1}^{\infty} \sqrt{\lambda_k} (\psi_k(t) - \psi_k(s))(h_1, e_k) \sum_{j=1}^{\infty} \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s))(h_2, e_j) \right)$$

$$= \lim_{n \to \infty} E\left( \sum_{k=1}^{n} \sqrt{\lambda_k} (\psi_k(t) - \psi_k(s))(h_1, e_k) \sum_{j=1}^{n} \sqrt{\lambda_j} (\psi_j(t) - \psi_j(s))(h_2, e_j) \right)$$

$$= \lim_{n \to \infty} (t-s) \sum_{k=1}^{n} \lambda_k (h_1, e_k) (h_2, e_j) = (t-s) (Qh_1, h_2)$$

(Recall $Q \equiv \sum_k \lambda_k e_k \otimes e_k$.)

Next I show the increments are independent. Let $N$ be the subsequence defined above and let $W^N(t)$ be given by the appropriate partial sum and let $\{h_j\}_{j=1}^{m}$ be a finite list of vectors of $U$. Then from the independence properties of $\psi_j$ explained above,

$$E\left( \exp \sum_{j=1}^{m} i (h_j, W^N(t_j) - W^N(t_{j-1}))_U \right)$$
62.5. HILBERT SPACE VALUED WIENER PROCESSES

\[ E \left( \exp \sum_{j=1}^{m} \left( \mu_{j} \sum_{k=1}^{N} \lambda_{k} e_{k} (\psi_{k}(t_{j}) - \psi_{k}(t_{j-1})) \right) \right) \]

\[ = E \left( \exp \sum_{j=1}^{m} \sum_{k=1}^{N} \lambda_{k} e_{k} (\psi_{k}(t_{j}) - \psi_{k}(t_{j-1})) \right) \]

\[ = E \left( \prod_{j,k} \exp \left( \lambda_{k} e_{k} (\psi_{k}(t_{j}) - \psi_{k}(t_{j-1})) \right) \right) \]

This can be done because of the independence of the random variables \( \{\psi_{k}(t_{j}) - \psi_{k}(t_{j-1})\}_{j,k} \).

Thus the above equals

\[ = \prod_{j=1}^{m} \exp \left( - \frac{1}{2} \sum_{k=1}^{N} \lambda_{k}^{2} (t_{j} - t_{j-1}) \right) \]

because \( \psi_{k}(t_{j}) - \psi_{k}(t_{j-1}) \) is normally distributed having variance \( t_{j} - t_{j-1} \) and mean 0. Now letting \( N \to \infty \), this implies

\[ E \left( \exp \sum_{j=1}^{m} \mu_{j} (W(t_{j}) - W(t_{j-1}))) \right) \]

\[ = \prod_{j=1}^{m} \exp \left( - \frac{1}{2} \sum_{k=1}^{N} \lambda_{k}^{2} (t_{j} - t_{j-1}) \right) \]

\[ = \prod_{j=1}^{m} \exp \left( - \frac{1}{2} (t_{j} - t_{j-1}) (Qh,h) \right) \]

\[ = \prod_{j=1}^{m} \exp \left( i (h_{j}, W(t_{j}) - W(t_{j-1})) \right) \]

(62.5.25)

because of the fact shown above that \( (h,W(t) - W(s)) \) is normally distributed with mean 0 and variance \( (t - s) (Qh,h) \). By Theorem 57.13.3 on Page 1943, this shows the increments are independent.

Next consider the continuity assertion. Recall

\[ W(t) = \sum_{k=1}^{\infty} \sqrt{\lambda_{k}} e_{k} \psi_{k}(t) \]
where $\psi_k$ is a real Wiener process. Therefore, letting $2m > 2, m \in \mathbb{N}$ and using\footnote{for $\psi_k$ and Jensen’s inequality along with Lemma 62.3.1.} to $E(W(t) - W(s))^{2m}$

\[ E \left( |W(t) - W(s)|^{2m} \right) = E \left( \left( \sum_{k=1}^{\infty} \sqrt{\lambda_k} e_k (\psi_k(t) - \psi_k(s)) \right)^{2m} \right) \]
\[ = E \left( \left( \sum_{k=1}^{\infty} \lambda_k |\psi_k(t) - \psi_k(s)|^2 \right)^m \right) \]
\[ \leq E \left( \left( \sum_{k=1}^{\infty} \lambda_k \right)^{m-1} \sum_{k=1}^{\infty} \lambda_k |\psi_k(t) - \psi_k(s)|^{2m} \right) \]
\[ \leq C_m \sum_{k=1}^{\infty} \lambda_k E \left( |\psi_k(t) - \psi_k(s)|^{2m} \right) \]
\[ \leq C_m |t-s|^m \quad (62.5.26) \]

By the Kolmogorov Čentsov Theorem, Theorem 62.5.4, it follows that off a set of measure 0, $t \rightarrow W(t, \omega)$ is Holder continuous with exponent $\gamma$ such that

\[ \gamma < \frac{m-1}{2m}. \]

Finally, from\footnote{taking $r = 1$,} taking $r = 1$,

\[ E \left( \exp i (h, W(t) - W(s))_U \right) = \exp \left( -\frac{1}{2} (t-s) (Q h, h) \right) \]

which is the same as $E \left( \exp i (h, W(t - s))_U \right)$ due to the fact $W(0) = 0$. This proves the theorem.

The above shows there exists $Q$ Wiener processes in any separable Hilbert space. Next I will show the way described above is the only way it can happen.

**Theorem 62.5.4** Suppose $\{W(t)\}$ is a $Q$ Wiener process in $U$, a real separable Hilbert space. Then letting

\[ Q = \sum_{k=1}^{\infty} \lambda_k e_k \otimes e_k \]

where the $\{e_k\}$ are orthonormal, $\lambda_k \geq 0$, and $\sum_{k=1}^{\infty} \lambda_k < \infty$, it follows

\[ W(t) = \sum_{k=1}^{\infty} \sqrt{\lambda_k} \psi_k(t) e_k \quad (62.5.28) \]

where

\[ \psi_k(t) = \begin{cases} \frac{1}{\sqrt{\lambda_k}} (W(t), e_k)_U & \text{if } \lambda_k \neq 0 \\ 0 & \text{if } \lambda_k = 0 \end{cases} \]
62.5. HILBERT SPACE VALUED WIENER PROCESSES

then \( \{ \psi_k(t) \} \) is a Wiener process and for \( t_0 < t_1 < \cdots < t_n \) the random variables
\[
\{ \psi_k(t_q) - \psi_k(t_{q-1}) : (q,k) \in (1,2,\ldots,n) \times (k_1,\ldots,k_m) \}
\]
are independent. Furthermore, the sum in (62.5.28) converges uniformly for a.e. \( \omega \) on any closed interval, \([0,T]\).

**Proof:** First of all, the fact that \( W(t) \) has values in \( U \) and that \( \{ e_k \} \) is an orthonormal basis implies the sum in (62.5.28) converges for each \( \omega \). Consider
\[
E(\exp(ir\psi_k(t))) = E\left(\exp\left(\frac{1}{\sqrt{\lambda_k}} (W(t),e_k)_U\right)\right)
\]
Since \( W(t) \) is given to be a \( Q \) Wiener process, \((W(t),e_k)_U\) is normally distributed with mean 0 and variance \( t(Qh,h) \). Therefore, the above equals
\[
e^{-r^2 \frac{1}{\lambda_k} t((Qe_k,e_k)} = e^{-r^2 \frac{1}{\lambda_k}} = e^{-r^2 t},
\]
the characteristic function for a random variable which is \( N(0,t) \). The independence of the increments for a given \( \psi_k(t) \) follows right away from the independence of the increments of \( W(t) \) and the distribution of the increments being \( N(0,t-s) \) follows similarly to the above.

For \( t_1 < t_2 < \cdots < t_n \), why are the random variables,
\[
\{ (W(t_q),e_k)_U - (W(t_{q-1}),e_k)_U : (q,k) \in (1,2,\ldots,n) \times (k_1,\ldots,k_m) \}
\]
(62.5.29)
independent? Let
\[
P = \sum_{q=1}^{n} \sum_{j=1}^{m} s_{qj} \left( (W(t_q),e_k)_U - (W(t_{q-1}),e_k)_U \right)
\]
and consider \( E(e^{iP}) \). This equals
\[
e^{iP} = E\left(\exp\left(i \sum_{q=1}^{n} \sum_{j=1}^{m} s_{qj} \left( (W(t_q),e_k)_U - (W(t_{q-1}),e_k)_U \right)\right)\right)
\]
(62.5.30)
\[
= E\left(\exp\left(i \sum_{q=1}^{n} \left( (W(t_q), \sum_{j=1}^{m} s_{qj} e_k)_U - (W(t_{q-1}), \sum_{j=1}^{m} s_{qj} e_k)_U \right)\right)\right)
\]
\[
= E\left(\prod_{q=1}^{n} \exp\left(i \left( W(t_q) - W(t_{q-1}) \sum_{j=1}^{m} s_{qj} e_k \right)_U \right)\right)
\]
Now recall that by assumption the increments \( W(t) - W(s) \) are independent. Therefore, the above equals
\[
\prod_{q=1}^{n} E\left(\exp\left(i \left( W(t_q) - W(t_{q-1}) \sum_{j=1}^{m} s_{qj} e_k \right)_U \right)\right)
\]
Recall that by assumption \((W(t) - W(s), h)_U\) is normally distributed with variance \((t-s)(Qh, h)\) and mean 0. Therefore, the above equals

\[
\prod_{q=1}^{n} \exp \left( -\frac{1}{2} (t_q - t_{q-1}) \left( Q \sum_{j=1}^{m} s_{qj} e_{k_j}, \sum_{j=1}^{m} s_{qj} e_{k_j} \right) \right)
\]

\[
= \prod_{q=1}^{n} \exp \left( -\frac{1}{2} (t_q - t_{q-1}) \sum_{j=1}^{m} s_{qj}^2 \lambda_{k_j} \right)
\]

\[
= \exp \left( -\frac{1}{2} \sum_{q=1}^{n} \sum_{j=1}^{m} (t_q - t_{q-1}) s_{qj}^2 \lambda_{k_j} \right)
\]

Also

\[
\prod_{q=1}^{n} \prod_{j=1}^{n} E \left( \exp \left( i s_{qj} \left( (W(t_q), e_{k_j})_U - (W(t_{q-1}), e_{k_j})_U \right) \right) \right)
\]

\[
= \prod_{q=1}^{n} \prod_{j=1}^{n} E \left( \exp \left( i s_{qj} \left( (W(t_q) - W(t_{q-1}), e_{k_j})_U \right) \right) \right)
\]

\[
= \prod_{q=1}^{n} \prod_{j=1}^{n} \exp \left( -\frac{1}{2} (t_q - t_{q-1}) s_{qj}^2 (Qe_{k_j}, e_{k_j}) \right)
\]

\[
= \prod_{q=1}^{n} \prod_{j=1}^{n} \exp \left( -\frac{1}{2} (t_q - t_{q-1}) s_{qj}^2 \lambda_{k_j} \right)
\]

\[
= \exp \left( -\frac{1}{2} \sum_{q=1}^{n} \sum_{j=1}^{m} (t_q - t_{q-1}) s_{qj}^2 \lambda_{k_j} \right)
\]

Therefore, \(e^{IP}\) equals the expression in (62.5.32) because both equal the expression in (62.5.31) and it follows from Proposition 57.11.1 on Page 1936 that the random variables of 62.5.29 are independent.

What about the claim of uniform convergence? By the independence of the increments, it follows from Lemma 62.4.2 that \(\{W(t)\}\) is a martingale and each real valued function, \((W(t), e_k)_U\) is also a martingale. Therefore, Theorem 60.5.3 can be applied to conclude

\[
P \left( \sup_{t \in [0,T]} \left| \sum_{k=m}^{n} (W(t), e_k)_U e_k \right| \geq \alpha \right) \leq \frac{1}{\alpha} \int_{\Omega} \left| \sum_{k=m}^{n} (W(T), e_k)_U e_k \right| dP
\]
\begin{align*}
&\leq \frac{1}{\alpha} \int_{\Omega} \left| \sum_{k=m}^{n} (W(T), e_k)_U e_k \right|^2 dP = \frac{1}{\alpha} \sum_{k=m}^{n} \int_{\Omega} (W(T), e_k)_U^2 dP \\
&= \frac{1}{\alpha} \sum_{k=m}^{n} (Q e_k, e_k) T = \frac{T}{\alpha} \sum_{k=m}^{n} \lambda_k \leq \frac{T}{\alpha} \sum_{k=m}^{\infty} \lambda_k
\end{align*}

Since \( \sum_{k=1}^{\infty} \lambda_k < \infty \), there exists a sequence, \( \{m_i\} \) such that if \( n > m_i \)

\[
P \left( \sup_{t \in [0, T]} \left| \sum_{k=m_i}^{n} (W(t), e_k)_U e_k \right| > 2^{-k} \right) < 2^{-k}
\]

and so by the Borel Cantelli lemma, off a set of measure 0 the partial sums

\[
\left\{ \sum_{k=1}^{m_i} (W(t), e_k)_U e_k \right\}
\]

converge uniformly on \( [0, T] \). This is very interesting but more can be said. In fact the original partial sums converge.

Recall Lemma stated below for convenience.

**Lemma 62.5.5** Let \( \{\zeta_k\} \) be a sequence of random variables having values in a separable real Banach space, \( E \) whose distributions are symmetric. Letting \( S_k = \sum_{i=1}^{k} \zeta_i \), suppose \( \{S_{n_k}\} \) converges a.e. Also suppose that for every \( m > n_k \),

\[
P \left( \|S_m - S_{n_k}\|_E > 2^{-k} \right) < 2^{-k}. \tag{62.5.33}
\]

Then in fact,

\[
S_k(\omega) \to S(\omega) \text{ a.e.} \omega \tag{62.5.34}
\]

Apply this lemma to the situation in which the Banach space, \( E \) is \( C([0, T]; U) \). Then you can conclude uniform convergence of the partial sums,

\[
\sum_{k=1}^{m} (W(t), e_k)_U e_k.
\]

This proves the theorem.

### 62.6 Wiener Processes, Another Approach

#### 62.6.1 Lots Of Independent Normally Distributed Random Variables

You can use the Kolmogorov extension theorem to prove the following corollary. It is Corollary on Page 1052.
**Corollary 62.6.1** Let $H$ be a real Hilbert space. Then there exist real valued random variables $W(h)$ for $h \in H$ such that each is normally distributed with mean 0 and for every $h, g, (W(f), W(g))$ is normally distributed and

$$E(W(h)W(g)) = (h,g)_H$$

Furthermore, if $\{e_i\}$ is an orthogonal set of vectors of $H$, then $\{W(e_i)\}$ are independent random variables. Also for any finite set $\{f_1, f_2, \cdots, f_n\}$,

$$(W(f_1), W(f_2), \cdots, W(f_n))$$

is normally distributed.

**Corollary 62.6.2** The map $h \to W(h)$ is linear. Also, $\{W(h) : h \in H\}$ is a closed subspace of $L^2(\Omega,F,P)$ where $F = \sigma(W(h) : h \in H)$.

**Proof:** This follows from the above description.

$$E \left( |W(g+h) - (W(g) + W(h))|^2 \right) = E \left( W(g+h)^2 \right)$$

$$+ E \left( (W(g) + W(h))^2 \right) - 2E(W(g+h)(W(g) + W(h)))$$

$$= |g+h|^2 + |g|^2 + |h|^2 + 2(g,h) - 2(g+h,g) - 2(g+h,h)$$

$$= |g|^2 + |h|^2 + 2(g,h) + 2(g,h) + |h|^2$$

$$+ |h|^2 - 2|g|^2 - 2(g,h) - 2(g,h) - 2|h|^2 = 0$$

Hence $W(h+g)-W(g)+W(h)$.

$$E \left( (W(\alpha f) - \alpha W(f))^2 \right) = E \left( W(\alpha f)^2 \right) + E \left( \alpha^2 W(f)^2 \right) - 2E(W(\alpha f) \alpha W(f))$$

$$= \alpha^2 |f|^2 + \alpha^2 |f|^2 - 2\alpha (\alpha f, f) = 0.$$  

Why is $\{W(h) : h \in H\}$ a subspace? This is obvious because $W$ is linear. Why is it closed? Say $W(h_n) \to f \in L^2(\Omega)$. This requires that $\{h_n\}$ is a Cauchy sequence. Thus $h_n \to h$ and so

$$E \left( |f - W(h)|^2 \right) \leq 2 \lim_{n \to \infty} E \left( |f - W(h_n)|^2 \right) + E \left( |W(h_n) - W(h)|^2 \right)$$

$$= 2 \lim_{n \to \infty} E \left( |W(h_n) - W(h)|^2 \right) = 2 \lim_{n \to \infty} |h_n - h|^2_H = 0$$

and so $f = W(h)$ showing that this is indeed a closed subspace. 

Next is a technical lemma which will be of considerable use.
Lemma 62.6.3 Let $X \geq 0$ and measurable. Also define a finite measure on $\mathcal{B}(\mathbb{R}^p)$

$$\nu(B) = \int_{\Omega} X \chi_B(Y) \, dP$$

Then let $f : \mathbb{R}^p \to [0, \infty)$ be Borel measurable. Then

$$\int_{\Omega} f(Y) X \, dP = \int_{\mathbb{R}^p} f(y) \nu(y)$$

where here $Y$ is a given measurable function with values in $\mathbb{R}^p$. Formally, $X \, dP = dv$.

Note that $Y$ is given and $X$ is just some random variable which here has non-negative values. Of course similar things will work without this stipulation.

Proof: First say $X = \chi_D$ and replace $f(Y)$ with $\chi_{Y^{-1}(B)}$. Then

$$\int_{\Omega} \chi_D \chi_{Y^{-1}(B)} \, dP = P(D \cap Y^{-1}(B))$$

$$\int_{\mathbb{R}^p} \chi_B(y) \nu(y) \equiv \nu(B) = \int_{\Omega} \chi_D \chi_B(Y) \, dP$$

$$= \int_{\Omega} \chi_D \chi_{Y^{-1}(B)} \, dP = P(D \cap Y^{-1}(B))$$

Thus

$$\int_{\Omega} \chi_D \chi_{Y^{-1}(B)} \, dP = \int_{\Omega} \chi_D \chi_B(Y) \, dP = \int_{\mathbb{R}^p} \chi_B(y) \nu(y)$$

Now let $s_n(y) \uparrow f(y)$, and let $s_n(y) = \sum_{k=1}^{m} c_k \chi_{B_k}(y)$ where $B_k$ is a Borel set. Then

$$\int_{\mathbb{R}^p} s_n(y) \nu(y) = \int_{\mathbb{R}^p} \sum_{k=1}^{m} c_k \chi_{B_k}(y) \nu(y) = \sum_{k=1}^{m} c_k \int_{\mathbb{R}^p} \chi_{B_k}(y) \nu(y)$$

$$= \sum_{k=1}^{m} c_k P(D \cap Y^{-1}(B_k))$$

$$\int_{\Omega} \chi_D \chi_{Y^{-1}(B)} \, dP = \sum_{k=1}^{m} c_k \int_{\Omega} \chi_D \chi_{B_k}(Y) \, dP = \sum_{k=1}^{m} c_k P(D \cap Y^{-1}(B_k))$$

which is the same thing. Therefore,

$$\int_{\Omega} s_n(Y) \chi_D \, dP = \int_{\mathbb{R}^p} s_n(y) \nu(y)$$

Now pass to a limit using the monotone convergence theorem to obtain

$$\int_{\Omega} f(Y) \chi_D \, dP = \int_{\mathbb{R}^p} f(y) \nu(y)$$
Next replace $X_D$ with $\sum_{k=1}^{m} d_k X_{D_k} \equiv s_n (\omega)$, a simple function.

$$
\int_{\Omega} f (Y) \sum_{k=1}^{m} d_k X_{D_k} dP = \sum_{k=1}^{m} d_k \int_{\Omega} f (Y) X_{D_k} dP
$$

$$
= \sum_{k=1}^{m} d_k \int_{\mathbb{R}^p} f (Y) d\nu_k
$$

where $\nu_k (B) \equiv \int_{\Omega} X_{D_k} X_B (Y) dP$. Now let

$$
\nu_n (B) = \int_{\Omega} \sum_{k=1}^{m} d_k X_{D_k} X_B (Y) = \int_{\Omega} s_n X_B (Y) dP
$$

It is indexed with $n$ thanks to $s_n$. Then

$$
\nu_n (B) = \sum_{k=1}^{m} d_k \int_{\Omega} X_{D_k} X_B (Y) dP = \sum_{k=1}^{m} d_k \nu_k (B)
$$

Hence

$$
\int_{\Omega} f (Y) s_n dP = \int_{\Omega} f (Y) \sum_{k=1}^{m} d_k X_{D_k} dP = \sum_{k=1}^{m} d_k \int_{\mathbb{R}^p} f (Y) d\nu_k
$$

$$
= \int_{\mathbb{R}^p} f (y) \sum_{k=1}^{m} d_k d\nu_k = \int_{\mathbb{R}^p} f (y) d\nu_n
$$

($s_n dP = d\nu_n$ so to speak.) Then let $s_n (\omega) \uparrow X (\omega)$. Clearly $\nu_n \ll \nu$ and so by the Radon Nikodym theorem $d\nu_n = h_n d\nu$ where $h_n \uparrow 1$. It follows from the monotone convergence theorem that one can pass to a limit in the above and obtain

$$
\int_{\Omega} f (Y) X dP = \int_{\mathbb{R}^p} f (y) d\nu \quad \blacksquare
$$

The interest here is to let $f (Y) \equiv e^{\lambda Y}$ so $f (y) = e^{\lambda y}$. To remember this, $X dP = d\nu$ in a sort of sloppy way then the above formula holds.

**Lemma 62.6.4** Each $e^{W(h)}$ is in $L^p (\Omega)$ for every $h \in H$ and for every $p \geq 1$. In fact,

$$
\int_{\Omega} \left( e^{W(h)} \right)^p dP = \int_{\Omega} e^{W(p h)} dP = e^{\frac{1}{2} |p h|^2 H}.
$$

In addition to this,

$$
\sum_{k=0}^{n} \frac{W(h)^k}{k!} \rightarrow e^{W(h)} \text{ in } L^p (\Omega, \mathcal{F}, P), \quad p > 1
$$
62.6. WIENER PROCESSES, ANOTHER APPROACH

**Proof:** It suffices to verify this for all positive integers \( p \). Let \( p \) be such an integer. Note that from the linearity of \( W \), \( (e^{W(h)})^p = e^{pW(h)} = e^{W(ph)} \) and so it suffices to verify that for each \( h \in H \), \( e^{W(h)} \) is in \( L^1(\Omega) \). From Lemma 6.4.1.2,

\[
\int_{\Omega} e^{W(h)}dP = \int_{R} e^{y}d\nu(y)
\]

where \( \nu(B) = \int_{\Omega} \chi_{B}(W(h))dP = \int_{R} \chi_{B}(y)d\nu(y) \). In using this lemma, \( Y = W(h), X = 1 \). Thus

\[
\int_{\Omega} e^{W(h)}dP = \int_{0}^{\infty} \nu(e^y > \lambda) d\lambda = \int_{0}^{\infty} \frac{1}{\sqrt{2\pi|h|}} \int_{[y>\ln(\lambda)]} e^{-\frac{1}{2}\frac{y^2}{|h|}}dyd\lambda, u = \ln(\lambda),
\]

\[
= \frac{1}{\sqrt{2\pi|h|}} \int_{-\infty}^{\infty} e^{u} \int_{u}^{\infty} e^{-\frac{1}{2}\frac{y^2}{|h|}}dydu = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \int_{u/|h|}^{\infty} e^{u} e^{-\frac{1}{2}\frac{v^2}{|h|}}dvdu
\]

\[
= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{u} e^{-\frac{1}{2}\frac{v^2}{|h|}}dvdu = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\frac{1}{2}\frac{v^2}{|h|}}dv
\]

\[
= \frac{1}{\sqrt{2\pi}} \sqrt{2\pi} e^{\frac{1}{2}|h|^2} = e^{\frac{1}{2}|h|^2} < \infty
\]

If \( h = 0 \), \( W(h) \) would be 0 because by the construction, \( E(W(0)^2) = (0, 0)_H = 0 \). Then

\[
\int_{\Omega} e^{W(h)}dP = \int_{\Omega} e^{0}dP = 1
\]

Consider the last claim. It is enough to assume \( p \) is an integer.

\[
\left| \sum_{k=0}^{n} \frac{W(h)^k}{k!} - e^{W(h)} \right| = \left| \sum_{k=n+1}^{\infty} \frac{W(h)^k}{k!} \right| = \left| W(h)^{n+1} \right| \left| \sum_{k=0}^{\infty} \frac{W(h)^k}{(n+1+k)!} \right|
\]

\[
= \left| W(h)^{n+1} \right| \left| \sum_{k=0}^{\infty} \frac{W(h)^k}{k!(n+1+k)!} \right|
\]

\[
\leq \left| W(h)^{n+1} \right| \frac{1}{(n+1)!} \left| \sum_{k=0}^{\infty} \frac{W(h)^k}{k!} \right| = \frac{W(h)^{n+1}}{(n+1)!} e^{W(h)}
\]

This converges to 0 for each \( \omega \) because it says nothing more than that the \( n^{th} \) term of a convergent sequence converges to 0.

\[
\int_{\Omega} \left( \left| \frac{W(h)^{n+1}}{(n+1)!} e^{W(h)} \right| \right)^{2p} dP = \int_{\Omega} \left( \frac{W(h)^{n+1}}{(n+1)!} \right)^{2p} \left( e^{W(h)} \right)^{2p} dP
\]

\[
= \left( \frac{1}{(n+1)!} \right)^{2p} \frac{1}{\sqrt{2\pi|h|}} \int_{R} e^{-\frac{1}{2}\frac{y^2}{|h|}} e^{2px} e^{2p(n+1)}dx
\]
\[ \sum \text{ratio test argument are as follows. The ratio, after simplifying is} \]
\[ \frac{1}{(n+1)!} \int_{\mathbb{R}} e^{-\frac{1}{2|m|}(x-2p|m|^2)^2} x^{2p(m+1)} \, dx \]
\[ \leq \frac{1}{(n+1)!} \int_{\mathbb{R}} e^{-\frac{1}{2|m|}(x-2p|m|^2)^2} \frac{2p(m+1)}{2p} e^{2p|m|^2} \, dx \]
\[ + \frac{1}{(n+1)!} \int_{\mathbb{R}} e^{-\frac{1}{2|m|}(x-2p|m|^2)^2} (2p|m|^2)^{2p(n+1)} \, dx \]

The second term clearly converges to 0 as \( n \to \infty \). Consider the first term. To simplify, let \( t = \frac{x-2p|m|}{|m|} \). Then this term reduces to
\[ \frac{2p}{(n+1)!} \frac{2p(m+1)}{2p} e^{2p|m|^2} \int_{\mathbb{R}} e^{-t^2} t^{2p(n+1)} \, dt \]
\[ = 2 \frac{1}{(n+1)!} \frac{2p(m+1)}{2p} e^{2p|m|^2} \int_{0}^{\infty} e^{-t^2} t^{2p(n+1)} \, dt \]

Now let \( t^2 = u \). Then this becomes
\[ 2 \frac{1}{(n+1)!} \frac{2p(m+1)}{2p} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \frac{1}{2} \, du \]
\[ = C \frac{2p(m+1)}{(n+1)!} \frac{1}{(n+1)!} \frac{1}{(n+1)!} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \, du \]
\[ \leq C \frac{2p(m+1)}{(n+1)!} \frac{1}{(n+1)!} \frac{1}{(n+1)!} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \, du \]
\[ = C(n+1)! \frac{2p(m+1)}{(n+1)!} \frac{1}{(n+1)!} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \, du \]
\[ \leq C(n+1)! \frac{2p(m+1)}{(n+1)!} \frac{1}{(n+1)!} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \, du \]
\[ = C(n+1)! \frac{2p(m+1)}{(n+1)!} \frac{1}{(n+1)!} e^{2p|m|^2} \int_{0}^{\infty} e^{-u} u^{p(n+1) - \frac{1}{2}} \, du \]

this converges to 0 as \( n \to \infty \). This is obvious for \( \frac{(2p)(n+1)!}{(n+1)!} \). Consider \( \frac{(n+1)!}{(n+1)!} \). By the ratio test, \( \sum_{n} \frac{(n+1)!}{(n+1)!} < \infty \) so this also converges to 0. The details of this ratio test argument are as follows. The ratio, after simplifying is
\[ \frac{p(p+1)(p+2)(p+3)}{(n+1)!} \leq \frac{p^{p(n+1)!}(n+1)!}{(n+1)!} \leq \frac{(n+1)!}{(n+1)!} \]
which clearly converges to 0 since $2p - 1 > p$ since $p$ is an integer larger than 1. Therefore, \[
\left\{ \frac{W(h)^{n+1}}{(n+1)!} e^{W(h)} \right\}_{n=1}^{\infty}
\] is bounded in $L^{2p}(\Omega)$. Then
\[
\int_{\Omega} \left| \sum_{k=0}^{n} \frac{W(h)^{k}}{k!} - e^{W(h)} \right|^p dP \to 0
\]
because the integrand is bounded by \[
\left( \frac{W(h)^{n+1}}{(n+1)!} \right)^p e^{W(h)}
\] and it was just shown that these functions are bounded in $L^2(\Omega)$. Therefore, the claimed convergence follows from the Vitali convergence theorem. ■

The following lemma shows that the functions $e^{W(h)}$ are dense in $L^p(\Omega)$ for every $p > 1$.

**Lemma 62.6.5** Let $\mathcal{F}$ be the $\sigma$ algebra determined by the random variables $W(h)$. If $X \in L^p(\Omega, \mathcal{F}, P)$, $p > 1$ and $\int_{\Omega} X e^{W(h)} dP = 0$ for every $h \in H$, then $X = 0$.

**Proof:** Let $h_1, \cdots, h_p$ be given. Then for $t_i \in \mathbb{R}$,
\[
\sum_{i} t_i h_i \in H
\]
and so since $W$ is linear,
\[
\int_{\Omega} X e^{t_i W(h)} dP = 0, \quad W(h) \equiv (W(h_1), \cdots, W(h_p))
\]
Now by Lemma [M4.15],
\[
\int_{\Omega} X^+ e^{t_i (W(h_1), \cdots, W(h_p))} dP = \int_{\mathbb{R}^p} e^{t \cdot y} d\nu_+(y)
\]
where $\nu_+(B) = E(X^+ \chi_B(W(h)))$. From Lemma [M4.13], this function of $t$ is finite for all $t \in \mathbb{R}^p$. Similarly,
\[
\int_{\Omega} X^- e^{t_i (W(h_1), \cdots, W(h_p))} dP = \int_{\mathbb{R}^p} e^{t \cdot y} d\nu_-(y)
\]
where $\nu_-(B) = E(X^- \chi_B(W(h)))$. Thus for $\nu$ equal to the signed measure $\nu \equiv \nu_+ - \nu_-$,
\[
f(t) \equiv \int_{\mathbb{R}^p} e^{t \cdot y} d\nu(y) = 0
\]
for $t \in \mathbb{R}^p$. Also
\[
\int_{\Omega} X^+ e^{i t \cdot (W(h))} dP = \int_{\mathbb{R}^p} e^{i t \cdot y} d\nu_+(y)
\]
with a similar formula holding for $X^-$. Thus
\[
f(t) \equiv \int_{\mathbb{R}^p} e^{i t \cdot y} d\nu(y) \in \mathbb{C}
\]
is well defined for all $t \in \mathbb{C}^p$. Consider
\[
\int_{\mathbb{R}^p} e^{ty} d\nu_+(y)
\]
Is this function analytic in each $t_k$? Take a difference quotient. It equals for $h \in \mathbb{C}$,
\[
\int_{\Omega} X^+ \left( e^{(t+he_k)\cdot(W(h))} - e^{t(W(h))} \right) \frac{h}{h} dP = \int_{\Omega} X^+ e^{tW(h)} \left( e^{he_k\cdot(W(h))} - 1 \right) \frac{h}{h} dP
\]
In case $e_k \cdot W(h) = 0$ there is nothing to show. Assume then that this is not 0. Then this equals
\[
\int_{\Omega} X^+ e_k \cdot (W(h)) e^{tW(h)} \left( e^{he_k\cdot(W(h))} - 1 \right) \frac{h}{h} (e_k \cdot (W(h))) dP
\]
Now
\[
\left| \frac{e^z - 1}{z} \right| = \left| \frac{1}{z} \sum_{k=1}^{\infty} \frac{z^k}{k!} \right| \leq \sum_{k=0}^{\infty} \left| e^z \right|
\]
and so the integrand is dominated by
\[
\left| X^+ e_k \cdot (W(h)) e^{tW(h)} \left( e^{he_k\cdot(W(h))} - 1 \right) \frac{h}{h} (e_k \cdot (W(h))) \right| \leq X^+ \left| e_k \cdot (W(h)) e^{tW(h)} e^{he_k\cdot(W(h))} \right|
\]
From Lemma 62.6.4 which says that $\mathbb{E}^{W(h)}$ is in $L^q(\Omega)$ for each $q > 1$, this is in particular true for $q = mp$ where $m$ is an arbitrary positive integer satisfying
\[
p > \frac{m+1}{m}
\]
Then the integrand is of the form $fg_h$ where $f \in L^p$ and $g_h$ is bounded in $L^{mp}$. Therefore,
\[
\alpha \equiv (pm) / (m+1) > 1
\]
and
\[
\int_{\Omega} |fg_h|^\alpha dP = \int_{\Omega} |f|^\alpha |gh|^\alpha dP \leq \left( \int_{\Omega} |f|^p dP \right)^{m/(m+1)} \left( \int_{\Omega} |gh|^{pm} dP \right)^{1/(m+1)}
\]
which is bounded. By the Vitali convergence theorem,
\[
\lim_{h \to 0} \int_{\Omega} X^+ \left( e^{(t+he_k)\cdot(W(h))} - e^{t(W(h))} \right) \frac{h}{h} dP = \int_{\Omega} X^+ e_k \cdot (W(h)) e^{tW(h)} dP
\]
and so this function of $t_k$ is analytic. Similarly one can do the same thing for the integral involving $X^-$. Thus
\[
0 = \int_{\mathbb{R}^p} e^{ty} d\nu_-(y)
\]
whenever \( t_j \in \mathbb{R} \) for all \( j \) and \( t_1 \to \int_{\mathbb{R}^p} e^{iy \cdot \nu} (y) \) is analytic on \( \mathbb{C} \). Thus this analytic function of \( t_1 \) is zero for all \( t_1 \in \mathbb{C} \) since it is zero on a set which has a limit point, and in particular

\[
\int_{\mathbb{R}^p} e^{it_1 y_1 + t_2 y_2 + \cdots + t_p y_p} d\nu(y) = 0
\]

where each \( t_j \) is real. Now repeat the argument with respect to \( t_2 \) and conclude that

\[
\int_{\mathbb{R}^p} e^{it_1 y_1 + t_2 y_2 + \cdots + t_p y_p} d\nu(y) = 0,
\]

and continue this way to conclude that

\[
0 = \int_{\mathbb{R}^p} e^{it \cdot y} d\nu(y)
\]

which shows that the inverse Fourier transform of \( \nu \) is 0. Thus \( \nu = 0 \). To see this, let \( \psi \in \mathcal{S} \), the Schwartz class. Then neglecting troublesome constants in the Fourier transform,

\[
\int_{\mathbb{R}^p} \psi(t) \int_{\mathbb{R}^p} e^{it \cdot y} d\nu(y) dt = \int_{\mathbb{R}^p} \psi(t) e^{it \cdot y} d\nu(y) = \nu (F^{-1} \psi)
\]

Now \( F^{-1} \) maps \( \mathcal{S} \) onto \( \mathcal{S} \) and so this reduces to

\[
\int_{\mathbb{R}^p} \psi d\nu = 0
\]

for all \( \psi \in \mathcal{S} \). By density of \( \mathcal{S} \) in \( C_0(\mathbb{R}^p) \), it follows that the above holds for all \( \psi \in C_0(\mathbb{R}^p) \) and so \( \nu = 0 \).

It follows that for every \( B \) Borel and for every such description of \( \mathbf{W}(h) \),

\[
0 = \int_{\Omega} X \chi_B(\mathbf{W}(h)) dP = \int_{\Omega} X \chi_{\mathbf{W}(h)^{-1}(B)} dP
\]

Let \( \mathcal{K} \) be sets of the form \( \mathbf{W}(h)^{-1}(B) \) where \( B \) is of the form \( B_1 \times \cdots \times B_p, B_i \) open, this for some \( p \). Then this is clearly a \( \pi \) system because the intersection of any two of them is another one and

\[
0, \Omega = \mathbf{W}(h)^{-1}(\mathbb{R}^p)
\]

are both in \( \mathcal{K} \). Also \( \sigma(\mathcal{K}) = \mathcal{F} \). Let \( \mathcal{G} \) be those sets \( F \) of \( \mathcal{F} \) such that

\[
0 = \int_{\Omega} X \chi_F dP
\]

This is true for \( F \in \mathcal{K} \). Now it is clear that \( \mathcal{G} \) is closed with respect to complements and countable disjoint unions. It is closed with respect to complements because

\[
\int_{\Omega} X \chi_{F \cap C} dP = \int_{\Omega} X (1 - \chi_F) dP = \int_{\Omega} X dP - \int_{\Omega} X \chi_F dP = 0
\]

By Dynkin’s lemma, \( \mathcal{G} = \mathcal{F} \) and so (62.6.35) holds for all \( F \in \mathcal{F} \) which requires \( X = 0 \).
62.6.2 The Wiener Processes

Recall the definition of the Wiener process.

**Definition 62.6.6** Let $W(t)$ be a stochastic process which has the properties that whenever $t_1 < t_2 < \cdots < t_m$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent and whenever $s < t$, it follows $W(t) - W(s)$ is normally distributed with variance $t - s$ and mean 0. Also $t \to W(t)$ is Holder continuous with every exponent $\gamma < 1/2$, $W(0) = 0$. This is called a Wiener process.

Now in the definition of $W$ above, you begin with a Hilbert space $H$. There exists a probability space $(\Omega, \widetilde{\mathcal{F}}, P)$ and a linear mapping $W$ such that

$$E(W(f) W(g)) = (f, g)$$

and $(W(f_1), W(f_2), \cdots, W(f_n))$ is normally distributed with mean 0. Next define $\mathcal{F} = \sigma(W(h) : h \in H)$.

Consider the special example where $H = L^2(0, \infty; \mathbb{R})$, real valued functions which are square integrable with respect to Lebesgue measure. Note that for each $t \in [0, \infty)$, $X_{[0,t]} \in H$. Let

$$W(t) = W(X_{[0,t]})$$

Then from definition, if $t_1 < t_2 < \cdots < t_m$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent. This is because, due to the linearity of $W$, each of these equals $W(X_{[0,t_i]} - X_{[0,t_{i-1}]} = W(X_{[t_{i-1}, t_i]})$ and from Corollary 62.6.1, the random vector $(W(X_{[t_1, t_2]}), \cdots, W(X_{[t_{m-1}, t_m]}))$ is normally distributed with covariance equal to a diagonal matrix. Also $E(W(t)^2) = E(W(X_{[0,t]}))^2 = \int_0^\infty X_{[0,t]}^2 ds = t$. More generally,

$$W(t) - W(s) = W(X_{[0,t]}) - W(X_{[0,s]}) = W(X_{[s,t]})$$

so both $W(t) - W(s)$ and $W(t - s)$ are normally distributed with mean 0 and variance $t - s$. What about the Holder continuity? The characteristic function of $W(t) - W(s)$ is

$$E(e^{i\lambda(W(t-s))}) = e^{\frac{1}{2}\lambda^2 |t-s|}$$

Consider a few derivatives of the right side with respect to $\lambda$ and then let $\lambda = 0$. This will yield $E((W(t) - W(s))^n)$ for $n = 1, 2, 3, 4$.

$$0, |s - t|, 0.3 |s - t|^2$$

You see the pattern. By induction, you can show that $E((W(t) - W(s))^{2m}) = C_m |t-s|^m$. By the Kolmogorov Censtov theorem, Theorem 62.6.3,

$$E\left(\sup_{0 \leq s < t \leq T} \frac{\|W(t) - W(s)\|}{(t-s)^r}\right) \leq C_m$$
whenever \( \gamma < \beta / \alpha = \frac{m-1}{2m} \). Thus the above is true whenever \( \gamma < 1/2 \). It follows that there exists a set of measure zero off which \( t \to W(t) \) is Hölder continuous with exponent \( \gamma < 1/2 \).

Thus this gives a construction of the real Wiener process. Now consider the normal filtration

\[
\mathcal{F}_s = \cap_{t > s} \sigma(W(u) - W(r) : 0 \leq r < u \leq t)
\]

By Lemma 62.6.2, \( \{W(t)\} \) is a martingale with respect to this filtration, because of the independence of the increments.

Of course you could also take an arbitrary \( f \in L^2(0, \infty) \) and consider \( W(t) \equiv W(\mathcal{X}_{(0,t)}f) \). You could consider this as an integral and write it in the notation

\[
W(t) \equiv \int_0^t f \, dW \equiv W(f_{\mathcal{X}_{(0,t)}})
\]

Then from the construction,

\[
E \left( \left( \int_0^t f \, dW \right)^2 \right) = E \left( W(f_{\mathcal{X}_{(0,t)}})^2 \right) = \int_0^T f^2 \mathcal{X}_{(0,t)} \, ds = \int_0^t \left| f \right|^2 \, ds = E \left( \int_0^t \left| f \right|^2 \, ds \right)
\]

because \( f \) does not depend on \( \omega \). This of course is formally the Itô isometry.

### 62.6.3 Q Wiener Processes In Hilbert Space

Now let \( U \) be a real separable Hilbert space. Let an orthonormal basis for \( U \) be \( \{g_i\} \). Now let \( L^2(0, \infty, U) \) be \( H \) in the above construction. For \( h, g \in L^2(0, \infty, U) \).

\[
E(W(h) W(g)) = (h, g)_{L^2(0, \infty, U)} \equiv (h, g)_H
\]

Here each \( W(g) \) will be a real valued normal random variable, the variance of \( W(g) \) is \( |g|^2_{L^2(0, \infty, U)} \) and its mean is 0, every vector \( (W(h_1), \ldots, W(h_n)) \) being generalized multivariate normal. Let

\[
\psi_k(t) = W(\mathcal{X}_{(0,t)}g_k).
\]

Then this is a real valued random variable. Disjoint increments are obviously independent in the same way as before. Also

\[
E(\psi_k(t) \psi_j(s)) = E(W(\mathcal{X}_{(0,t)}g_k) W(\mathcal{X}_{(0,s)}g_j)) \equiv \int_0^\infty \mathcal{X}_{(0,t\land s)}(g_k, g_j)_U \, dt = 0
\]

if \( j \neq k \). Thus the random variables \( \psi_k(t) \) and \( \psi_j(s) \) are independent. This is because, from the construction, \( (\psi_k(t), \psi_j(s)) \) is normally distributed and the covariance is a diagonal matrix. Also

\[
\psi_k(t) - \psi_k(s) = W(\mathcal{X}_{(0,t)}Jg_k) - W(\mathcal{X}_{(0,s)}Jg_k) = W(\mathcal{X}_{(s,t)}Jg_k)
\]
\[ \psi_k(t - s) \equiv W \left( \mathcal{X}_{(0,t-s)} J g_k \right) \]

so \( \psi_k(t - s) \) has the same mean, 0 and variance, \( |t - s| \), as \( \psi_k(t) - \psi_s(s) \). Thus these have the same distribution because both are normally distributed.

Now let \( J \) be a Hilbert Schmidt map from \( U \) to \( H \). Then consider

\[ W(t) = \sum_k \psi_k(t) J g_k. \]  \hspace{1cm} (62.6.37)

This has values in \( H \). It is shown below that the series converges in \( L^2(\Omega; H) \).

Recall the definition of a \( Q \)-Wiener process.

**Definition 62.6.7** Let \( W(t) \) be a stochastic process with values in \( H \), a real separable Hilbert space which has the properties that \( t \to W(t, \omega) \) is continuous, whenever \( t_1 < t_2 < \cdots < t_m \), the increments \( \{W(t_i) - W(t_{i-1})\} \) are independent, \( W(0) = 0 \), and whenever \( s < t \),

\[ \mathcal{L}(W(t) - W(s)) = N(0, (t - s) Q) \]

which means that whenever \( h \in H \),

\[ \mathcal{L}((h, W(t) - W(s))) = N(0, (t - s) (Q h, h)) \]

Also

\[ E((h_1, W(t) - W(s)) (h_2, W(t) - W(s))) = (Q h_1, h_2) (t - s). \]

Here \( Q \) is a nonnegative trace class operator. Recall this means

\[ Q = \sum_{i=1}^{\infty} \lambda_i e_i \otimes e_i \]

where \( \{e_i\} \) is a complete orthonormal basis, \( \lambda_i \geq 0 \), and

\[ \sum_{i=1}^{\infty} \lambda_i < \infty \]

Such a stochastic process is called a \( Q \)-Wiener process. In the case where these have values in \( \mathbb{R}^n \), \( tQ \) ends up being the covariance matrix of \( W(t) \).

**Proposition 62.6.8** The process defined in 62.6.37 is a \( Q \)-Wiener process in \( H \) where \( Q = JJ^* \).

**Proof:** First, why does the sum converge? Consider the sum for an increment in time. Let \( t_i - 1 = 0 \) to obtain the convergence of the sum for a given \( t \). Consider
the difference of two partial sums.

\[ E \left( \sum_{k,l=m}^{n} (\psi_k(t_i) - \psi_k(t_{i-1})) Jg_k, (\psi_l(t_i) - \psi_l(t_{i-1})) Jg_l \right) \]

\[ = E \left( \sum_{k,l=m}^{n} (J^* Jg_k, g_l) (\psi_k(t_i) - \psi_k(t_{i-1})) (\psi_l(t_i) - \psi_l(t_{i-1})) \right) \]

\[ = \sum_{k,l=m}^{n} (J^* Jg_k, g_l) E \left( (\psi_k(t_i) - \psi_k(t_{i-1})) (\psi_l(t_i) - \psi_l(t_{i-1})) \right) \]

\[ = \sum_{k=m}^{n} (J^* Jg_k, g_k) E \left( \psi_k(t_i) - \psi_k(t_{i-1}) \right)^2 = \sum_{k=m}^{n} |Jg_k|^2_H (t_i - t_{i-1}) \]

and this converges to 0 as \( m, n \to \infty \) since \( J \) is Hilbert Schmidt. Thus the sum converges in \( L^2(\Omega, H) \). Why are the disjoint increments independent?

Let \( \lambda_k \in H \). Consider \( t_0 < t_1 < \cdots < t_n \).

\[ E \left( \exp i \sum_{k=1}^{n} (\lambda_k, W(t_k) - W(t_{k-1})) \right) = \prod_{k=1}^{n} E \left( \exp (i (\lambda_k, W(t_k) - W(t_{k-1}))) \right) \]

(62.6.38)

Start with the left. There are finitely many increments concerned and so it can be assumed that for each \( k \) one can have \( m \to \infty \) such that the partial sums up to \( m \) in the definition of \( W(t_k) - W(t_{k-1}) \) converge pointwise a.e. Thus

\[ E \left( \exp i \sum_{k=1}^{n} (\lambda_k, W(t_k) - W(t_{k-1})) \right) \]

\[ = \lim_{m \to \infty} E \left( \exp i \sum_{k=1}^{n} \left( \lambda_k, \sum_{j=1}^{m} (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \]

\[ = \lim_{m \to \infty} E \left( \exp \sum_{k=1}^{n} \sum_{j=1}^{m} i (\lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j) \right) \]

\[ = \lim_{m \to \infty} E \left( \prod_{j=1}^{m} \exp \left( \sum_{k=1}^{n} i (\lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j) \right) \right) \]

Now from (62.6.38) \( \{ \sum_{k=1}^{m} i (\lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j) \}_{j=1}^{m} \) are independent. Hence the above equals

\[ = \lim_{m \to \infty} \prod_{j=1}^{m} E \left( \exp \left( \sum_{k=1}^{n} i (\lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j) \right) \right) \]
\[
\lim_{m \to \infty} \prod_{j=1}^{m} E \left( \prod_{k=1}^{n} \exp \left( i \left( \lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \right)
\]

Now from independence of the increments for the \( \psi_j \), this equals

\[
\lim_{m \to \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E \left( \exp \left( i \left( \lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \right)
\]

\[
= \lim_{m \to \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} E \left( \exp \left( i \left( \lambda_k, (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \right)
\]

\[
= \lim_{m \to \infty} \prod_{j=1}^{m} \prod_{k=1}^{n} e^{-\frac{1}{2} (\lambda_k, Jg_j)^2 (t_k - t_{k-1})} = \lim_{m \to \infty} \prod_{j=1}^{m} e^{-\frac{1}{2} \sum_{k=1}^{n} (\lambda_k, Jg_j)^2 (t_k - t_{k-1})}
\]

\[
= \lim_{m \to \infty} \exp \left( -\frac{1}{2} \sum_{k=1}^{n} \sum_{j=1}^{m} (\lambda_k, Jg_j)^2 (t_k - t_{k-1}) \right)
\]

\[
= \exp \left( -\frac{1}{2} \sum_{k=1}^{n} \sum_{j=1}^{m} (J^* \lambda_k, g_j)^2 (t_k - t_{k-1}) \right)
\]

(62.6.39)

What is the right side of \( \text{(62.6.39)} \)?

\[
\prod_{k=1}^{n} E \left( \exp \left( i \left( \lambda_k, W(t_k) - W(t_{k-1}) \right) \right) \right) = \prod_{k=1}^{n} E \left[ \exp \left( i \left( \lambda_k, \sum_{j=1}^{m} (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \right]
\]

\[
= \lim_{m \to \infty} \prod_{k=1}^{n} E \left[ \exp \left( i \left( \lambda_k, \sum_{j=1}^{m} (\psi_j(t_k) - \psi_j(t_{k-1})) Jg_j \right) \right) \right]
\]

\[
= \lim_{m \to \infty} \prod_{k=1}^{n} E \left[ \exp \left( i \sum_{j=1}^{m} (Jg_j, \lambda_k) (\psi_j(t_k) - \psi_j(t_{k-1})) \right) \right]
\]

\[
= \lim_{m \to \infty} \prod_{k=1}^{n} \left( \prod_{j=1}^{m} i (J^* \lambda_k, g_j) \left( \psi_j(t_k) - \psi_j(t_{k-1}) \right) \right)
\]
62.6. WIENER PROCESSES, ANOTHER APPROACH

and by independence,

\[
\lim_{m \to \infty} \prod_{k=1}^{n} \prod_{j=1}^{m} E \left[ i (J^* \lambda_k, g_j) \left( \psi_j (t_k) - \psi_j (t_{k-1}) \right) \right] = \lim_{m \to \infty} \prod_{k=1}^{n} \exp \left( -\frac{1}{2} \sum_{j=1}^{m} (J^* \lambda_k, g_j)^2 (t_k - t_{k-1}) \right)
\]

which is exactly the same thing as 62.6.39. Thus the disjoint increments are independent.

You could also do something like the following. Let \( W_m (t) \) denote the partial sum for \( W (t) \) and since there are only finitely many increments, we can assume the partial sums converge a.e. Then we need to consider the random variables

\[
\left\{ \left( \sum_{i=1}^{m} \left( \psi_i (t_k - \psi_i (t_{k-1}) \right) J g_i \right) \right\}_{k=1}^{m}
\]

Then for any \( h \in H \), you could consider

\[
\left\{ \left( \sum_{i=1}^{m} \left( \psi_i (t_k - \psi_i (t_{k-1}) \right) (J g_i, h)_H \right) \right\}_{k=1}^{m}
\]

and the vector whose \( k^{th} \) component is \( \sum_{i=1}^{m} \left( \psi_i (t_k - \psi_i (t_{k-1}) \right) (J g_i, h)_H \) for \( k = 1, 2, \cdots, n \) is normally distributed and the covariance is a diagonal matrix. Hence these are independent random variables as hoped. Now you can pass to a limit as \( m \to \infty \). Since this is true for any \( h \in H \) that the random variables \( (W (t_k) - W (t_{k-1}), h)_H \) are independent, it follows that the random variables \( W (t_k) - W (t_{k-1}) \) are also.

What of the Hölder continuity? In the above computation for independence, as a special case, for \( \lambda \in H \),

\[
E (\exp i (\lambda, W (t) - W (s))) = \exp \left( -\frac{1}{2} |J^* \lambda|_{U}^2 (t - s) \right)
\]

(62.6.40)

In particular, replacing \( \lambda \) with \( \lambda r \) for \( r \) real,

\[
E (\exp i r (\lambda, W (t) - W (s))) = \exp \left( -\frac{1}{2} r^2 |J^* \lambda|_{U}^2 (t - s) \right)
\]
CHAPTER 62. WIENER PROCESSES

Now we differentiate with respect to \( r \) and then take \( r = 0 \) as before to obtain finally that

\[
E \left( (\lambda, W(t) - W(s))^{2m} \right) \leq C_m |J^\ast \lambda|^{2m} |t - s|^m = C_m (Q \lambda, \lambda)^m |t - s|^m
\]

Then letting \( \{h_k\} \) be an orthonormal basis for \( H \), and using the above inequality with Minkowski’s inequality,

\[
\left( E \left( |W(t) - W(s)|^{2m} \right) \right)^{1/m} \leq \sum_{k=1}^{\infty} \left[ E \left( (W(t) - W(s), h_k)^{2m} \right) \right]^{1/m} \leq \sum_{k=1}^{\infty} \left( C_m (t - s)^m |J^\ast h_k|_U^{2m} \right)^{1/m} \]

\[
= C_m^{1/m} |t - s| \sum_{k=1}^{\infty} |J^\ast h_k|_U^2 = C_m^{1/m} |t - s| \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} (J^\ast h_k, g_j)^2 \]

\[
= C_m^{1/m} |t - s| \sum_{j=1}^{\infty} \sum_{j=1}^{\infty} (h_k, J g_j)^2 = |t - s| C_m^{1/m} \sum_{j=1}^{\infty} |J g_j|_H^2
\]

and since \( J \) is Hilbert Schmidt, modifying the constant yields

\[
E \left( |W(t) - W(s)|^{2m} \right) \leq C_m |t - s|^m
\]

By the Kolmogorov Centsov theorem, Theorem [60.2.3],

\[
E \left( \sup_{0 \leq s \leq t} \frac{||W(t) - W(s)||}{(t - s)\gamma} \right) \leq C_m
\]

whenever \( \gamma < \beta/\alpha = \frac{m-1}{2m} \). Thus the above is true whenever \( \gamma < 1/2 \). Hence off a set of measure zero, \( t \to W(t) \) is Holder continuous.

What of the covariance condition? From [62.6.40], letting \( f, g \) be two elements of \( H \),

\[
E (\exp i (\alpha f + \beta g, W(t) - W(s))) = \exp \left( -\frac{1}{2} (Q (\alpha f + \beta g), \alpha f + \beta g) (t - s) \right)
\]

Differentiate with respect to \( \alpha \)

\[
E (i (f, W(t) - W(s)) \exp i (\alpha f + \beta g, W(t) - W(s)))
\]

\[
= -[\alpha (Qf, f) + (Qf, \beta g)] (t - s) \exp \left( -\frac{1}{2} (Q (\alpha f + \beta g), \alpha f + \beta g) (t - s) \right)
\]

Let \( \alpha = 0 \).

\[
E (i (f, W(t) - W(s)) \exp i (\beta g, W(t) - W(s)))
\]

\[
= -[(Qf, \beta g)] (t - s) \exp \left( -\frac{1}{2} (Q (\beta g), \beta g) (t - s) \right)
\]
Now differentiate with respect to $\beta$

$$E (- (f, W(t) - W(s)) (g, W(t) - W(s)) \exp i (\beta g, W(t) - W(s)))$$

$$= - [(Qf, g)] (t-s) \exp \left( - \frac{1}{2} (Q (\beta g), \beta g) (t-s) \right) + - [(Qf, \beta g)] (t-s) \text{ (something)}$$

Now let $\beta = 0$.

$$E ((f, W(t) - W(s)) (g, W(t) - W(s))) = (Qf, g) (t-s)$$

Finally, $Q = JJ^*$. It is self adjoint and nonnegative and so there is a complete orthonormal basis $\{e_i\}$ such that $Qe_i = \lambda_i e_i$. Then $\lambda_i = (Qe_i, e_i)_H$ and so

$$\sum \lambda_i = \sum (Qe_i, e_i) = \sum |J^* e_i|_U^2 < \infty$$

because $J$ and hence $J^*$ are both Hilbert Schmidt operators. ■

Recall the notion of the Hilbert space $LU$ in Definition [17.2.1].

What if you have a given $Q \in \mathcal{L}(H, H)$ which is trace class, $Q = Q^*$, and nonnegative. Does there exist a $Q$ Wiener process of the sort just described? It appears this amounts to obtaining a Hilbert Schmidt map $J$ from some Hilbert space $U$ to $H$ such that $Q = JJ^*$.

Since $Q$ is trace class and is self adjoint, it follows that there is an orthonormal basis $\{e_i\}, Qe_i = \lambda_i e_i$, where $\lambda_i$ is positive for $i \leq L$ or positive for all $i$. Then

$$Q^{1/2} = \sum_{i=1}^L \lambda_i^{1/2} e_i \otimes e_i$$

and

$$Q^{1/2} e_i = \sqrt{\lambda_i} e_i.$$  

Then also on $Q^{1/2} H$,

$$\left( Q^{1/2} e_i, Q^{1/2} e_j \right)_{Q^{1/2} H} = (e_i, e_j)_H$$

and so an orthonormal basis in $Q^{1/2} H$ is $\{\sqrt{\lambda_i} e_i\}_{i=1}^L$. Then define $J : Q^{1/2} H \to H$

$$J x = \sum_{k=1}^L \left( x, \sqrt{\lambda_k} e_k \right)_{Q^{1/2} H} \sqrt{\lambda_k} e_k$$

It follows from the above that

$$J e_j = \sum_{k=1}^L \frac{1}{\sqrt{\lambda_j}} \left( \sqrt{\lambda_j} e_j, \sqrt{\lambda_k} e_k \right)_{Q^{1/2} H} \sqrt{\lambda_k} e_k = e_j$$
Then
\[
\sum_{i=1}^{L} \left| J \sqrt{\lambda_i} e_i \right|_H^2 = \sum_{i=1}^{L} \left| \sum_{k=1}^{L} (\sqrt{\lambda_i} e_i, \sqrt{\lambda_k} e_k)_{Q^{1/2}H} \sqrt{\lambda_k} e_k \right|_H^2
\]
\[
= \sum_{i=1}^{L} |\sqrt{\lambda_i} e_i|_H^2 = \sum_{i=1}^{L} \lambda_i < \infty
\]

Thus it is clear that \( J \) is Hilbert Schmidt. Is \( JJ^* = Q \)? For \( y \in Q^{1/2}H, x \in H, \)
\[
(J^* x, y)_{Q^{1/2}H} \equiv (x, J(y))_H = \left( x, \sum_{k=1}^{L} (y, \sqrt{\lambda_k} e_k)_{Q^{1/2}H} \sqrt{\lambda_k} e_k \right)_H
\]
\[
= \sum_{k=1}^{L} (x, \sqrt{\lambda_k} e_k)_H \left( y, \sqrt{\lambda_k} e_k \right)_{Q^{1/2}H}
\]

Thus for \( y \in H, x \in H, \)
\[
(J^* x, J^* y)_{Q^{1/2}H} = \sum_{k=1}^{L} (x, \sqrt{\lambda_k} e_k)_H \left( J^* y, \sqrt{\lambda_k} e_k \right)_{Q^{1/2}H}
\]
\[
= \sum_{k=1}^{L} (x, \sqrt{\lambda_k} e_k)_H \left( y, \sqrt{\lambda_k} e_k \right)_{Q^{1/2}H}
\]
\[
= \sum_{k=1}^{L} \lambda_k (x, e_k)_H (y, e_k)_H = (Q x, y)
\]

and so \((JJ^* x, y) = (Q x, y)\) showing that \( JJ^* = Q \). This shows the following.

**Proposition 62.6.9** Let \( Q \in \mathcal{L}(H, H) \) where \( H \) is a real separable Hilbert space and \((Qx, x) \geq 0\) and is trace class. Then there exists a one to one Hilbert Schmidt map \( J : Q^{1/2}H \to H \) such that \( JJ^* = Q \). Then the \( Q \) Wiener process is \( W(t) = \sum_{k=1}^{\infty} \psi_k(t) J g_k \) where \( \{g_k\} \) is a complete orthonormal basis for the Hilbert space \( Q^{1/2}H \).

Note that in case \( H \) is \( \mathbb{R}^p \) and \( Q \) is any symmetric \( p \times p \) matrix, having non-negative eigenvalues, this is automatically trace class and so the above conclusion holds. In particular, the covariance condition says in this case that
\[
E((e_i, W(t) - W(s))(e_j, W(t) - W(s))) = E((W_i(t) - W_i(s))(W_j(t) - W_j(s))) = (Q e_i, e_j) = Q_{ij}
\]

This is a \( p \) dimensional Wiener process.
62.6. WIENER PROCESSES, ANOTHER APPROACH

62.6.4 Levy’s Theorem In Hilbert Space

Recall the concept of quadratic variation. Let \( W(t) \) be a \( Q \) Wiener process. Does it follow \( f W(t) g^2 \mathcal{M}_T^2(H) \)? The Wiener process is continuous. Furthermore,

\[
E \left( |W(t)|^2_H \right) < \infty
\]

for each \( t \in [0, T] \). Since \( \{W(t)\} \) is a martingale, Theorem 60.5.3 can be applied to conclude

\[
E \left( \sup_{t \in [0,T]} |W(t)| \right)^2 \leq 2E \left( |W(T)|^2_H \right)^{1/2}
\]

and so \( \{W(t)\} \in \mathcal{M}_T^2(H) \). Therefore, by the Doob Meyer decomposition, Theorem 61.7.15, there exists an increasing natural process, \( A(t) \) and a martingale, \( Y(t) \) such that

\[
|W(t)|^2_H = Y(t) + A(t).
\]

What is \( A(t) \)? Consider the process

\[
|W(t)|^2
\]

From Theorem 62.5.4 this equals

\[
\sum_{k=1}^{\infty} \lambda_k \psi_k(t)^2
\]

where \( \psi_k(t) \) is a one dimensional Wiener process and

\[
Q = \sum_{k=1}^{\infty} \lambda_k e_k \otimes e_k, \quad \sum_{k=1}^{\infty} \lambda_k < \infty.
\]

By Lemma 62.4.2 \( \{W(t)\} \) is a martingale. Therefore, for \( s < t \) and \( A \in \mathcal{F}_s \), it follows since \( \mathcal{X}_A \) is independent of \( W(t) - W(s) \) as in the proof of Lemma 62.4.2 that the following holds.

\[
\int_A E \left( |W(t)|^2 \mathcal{F}_s \right) - |W(s)|^2 dP
\]

\[
= \int_A E \left( |W(t)|^2 + |W(s)|^2 - 2W(t) \cdot W(s) \mathcal{F}_s \right) dP
\]

\[
= \int_A E \left( |W(t) - W(s)|^2 \mathcal{F}_s \right) dP = \int_A |W(t) - W(s)|^2 dP
\]
Theorem 62.6.10 Let \( \{ W(t) \} \in \mathcal{M}_2^2(H), E(W(t)) = 0 \), where \( H \) is a real separable Hilbert space. Then for \( Q \) a nonnegative symmetric trace class operator, \( \{ W(t) \} \) is a \( Q \)-Wiener process if and only if both \( \{ W(t), h \}^2 - t (Qh, h) \) are martingales for every \( h \in H \).

Proof: First suppose \( \{ W(t) \} \) is a \( Q \)-Wiener process. Then defining the filtration to be

\[
\mathcal{F}_t \equiv \sigma(W(s) - W(u) : u \leq s \leq t),
\]

it follows from Lemma 62.3.2 that \( \{ W(t) \} \) is a martingale. Consider

\[
\left\{ (W(t), h)^2 - t (Qh, h) \right\}.
\]

Let \( A \in \mathcal{F}_s \) where \( s \leq t \). Then using the fact \( \{ W(t) \} \) is a martingale,

\[
\int_A E \left( (W(t) - W(s), h)^2 | \mathcal{F}_s \right) dP
\]

\[
= \int_A E \left( W(t, h)^2 + W(s, h)^2 - 2 (W(t), h) (W(s), h) | \mathcal{F}_s \right) dP
\]

\[
= \int_A E \left( (W(t), h)^2 | \mathcal{F}_s \right) + (W(s), h)^2 - E (2 (W(t), h) (W(s), h) | \mathcal{F}_s) dP
\]
62.6. WIENER PROCESSES, ANOTHER APPROACH

\[
\begin{align*}
= & \int_A E \left( (W(t), h)^2 \mid \mathcal{F}_s \right) dP + \int_A (W(s), h)^2 dP \\
& - \int_A (W(s), h) E(2(W(t), h) \mid \mathcal{F}_s) dP \\
= & \int_A E \left( (W(t), h)^2 \mid \mathcal{F}_s \right) dP - \int_A (W(s), h)^2 dP.
\end{align*}
\]

Also since \( X_A \) is independent of \((W(t) - W(s), h)^2\) as in the proof of Lemma 62.6.41, and \( \{W(t)\} \) is a \( Q \) Wiener process,

\[
\int_A E \left( (W(t) - W(s), h)^2 \mid \mathcal{F}_s \right) dP \]

\[
= \int_A (W(t) - W(s), h)^2 dP \]

\[
= P(A) \int_\Omega (W(t) - W(s), h)^2 dP \]

\[
= P(A) (t - s)(Qh, h) .
\]

Thus, this has shown that for all \( A \in \mathcal{F}_s \),

\[
\int_A E \left( (W(t), h)^2 \mid \mathcal{F}_s \right) dP - \int_A (W(s), h)^2 dP
\]

\[
= P(A) (t - s)(Qh, h) = \int_A (t - s)(Qh, h) dP
\]

and since \( A \in \mathcal{F}_s \) is arbitrary, this proves

\[
E \left( (W(t), h)^2 - t(Qh, h) \mid \mathcal{F}_s \right) = (W(s), h)^2 - s(Qh, h) .
\]

This proves one half of the theorem.

Next suppose both \( \{W(t)\} \) and \( \{(W(t), h)^2 - t(Qh, h)\} \) are martingales for any \( h \in H \). It follows that both \( \{(W(t), h)\} \) and \( \{(W(t), h)^2 - t(Qh, h)\} \) are martingales also. Therefore, by Levy’s theorem, Theorem 62.6.41, \( \{W(t), h\} \) is a Wiener process with the property that its variance at \( t \) equals \( (Qh, h) t \) instead of \( t \). Thus the time increments are normal and independent. I need to verify that \( \{W(t)\} \) is a \( Q \) Wiener process. One of the things which needs to be shown is that

\[
E \left( (W(t) - W(s), h_1) (W(t) - W(s), h_2) \right) = (Qh_1, h_2)(t - s) . \tag{62.6.41}
\]

I have just shown

\[
E \left( (W(t) - W(s), h)^2 \right) = (t - s)(Qh, h) \tag{62.6.42}
\]

which follows from Levy’s theorem which concludes \( \{(W(t), h)\} \) is a Wiener process. Therefore,

\[
E \left( (W(t) - W(s), h_1 + h_2) (W(t) - W(s), h_2 + h_1) \right)
\]

\[
= (Q(h_1 + h_2), (h_1 + h_2))(t - s)
\]
Now using (24.0.34) it follows from this that

$$E ((W(t) - W(s), h_1) (W(t) - W(s), h_2)) = (Qh_1, h_2)(t - s)$$

which shows (24.0.31). This completes the proof.
Chapter 63

Stochastic Integration

63.1 Integrals Of Elementary Processes

Stochastic integration starts with a $Q$ Wiener process having values in a separable Hilbert space $U$. Thus it satisfies the following definition.

**Definition 63.1.1** Let $W(t)$ be a stochastic process with values in $U$, a real separable Hilbert space which has the properties that $t \to W(t, \omega)$ is continuous. Whenever $t_1 < t_2 < \cdots < t_m$, the increments $\{W(t_i) - W(t_{i-1})\}$ are independent, $W(0) = 0$, and whenever $s < t$,

$$
\mathcal{L}(W(t) - W(s)) = N(0, (t-s) Q)
$$

which means that whenever $h \in H$,

$$
\mathcal{L}((h, W(t) - W(s))) = N(0, (t-s) (Qh, h))
$$

Also

$$
E((h_1, W(t) - W(s)) (h_2, W(t) - W(s))) = (Qh_1, h_2) (t-s).
$$

Here $Q$ is a nonnegative trace class operator. Recall this means

$$
Q = \sum_{i=1}^{\infty} \lambda_i e_i \otimes e_i
$$

where $\{e_i\}$ is a complete orthonormal basis, $\lambda_i \geq 0$, and

$$
\sum_{i=1}^{\infty} \lambda_i < \infty
$$

Such a stochastic process is called a $Q$ Wiener process.
Recall that such Wiener processes are always of the form
\[ \sum_{k=1}^{\infty} \psi_k(t) J g_k \]
where \( J \) is a Hilbert Schmidt operator from a suitable space \( U_0 \) to \( U \) and the \( \psi_k \) are real independent Wiener processes described earlier. This follows from Theorem 62.5.4 where you let \( U_0 \subseteq U \) be such that for \( J \) the inclusion map, \( J e_k = \sqrt{\lambda_k} e_k \) for \( Q = \sum \lambda_k e_k \otimes e_k \), the \( e_k \) an orthonormal set in \( U \). Thus
\[
(Q x, y) = \left( \sum_k \lambda_k e_k (x, e_k), y \right) = \sum_k \left( x, \sqrt{\lambda_k} e_k \right) \left( y, \sqrt{\lambda_k} e_k \right) = \sum_k (x, J e_k) (y, J e_k) = \sum_k (J^* x, e_k) (J^* y, e_k) = (J^* x, J y) = (JJ^* x, y)
\]
so it follows that \( Q = JJ^* \). Of course in finite dimensions, there is no issue because the identity map is Hilbert Schmidt.

Recall the definition of \( \mathcal{L}_2(U, H) \equiv \mathcal{L}_2 \) the space of Hilbert Schmidt operators. \( \Psi \in \mathcal{L}_2(U, H) \) means \( \Psi \) has the property that for some (equivalently all) orthonormal basis of \( U \) \( \{e_k\} \), it follows
\[
\sum_{k=1}^{\infty} ||\Psi(e_k)||^2 < \infty
\]
and the inner product for two of these, \( \Psi, \Phi \) is given by
\[
(\Psi, \Phi)_{\mathcal{L}_2} = \sum_k (\Psi(e_k), \Phi(e_k))
\]
Then for such a Hilbert Schmidt operator, the norm in \( \mathcal{L}_2 \) is given by
\[
\left( \sum_{k=1}^{\infty} ||\Psi(e_k)||^2 \right)^{1/2} \equiv ||\Psi||_{\mathcal{L}_2},
\]
Note this is the same as
\[
\left( \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} (\Psi(e_k), f_j)^2 \right)^{1/2} \quad (63.1.1)
\]
where \( \{f_j\} \) is an orthonormal basis for \( H \). This is the analog of the Frobenius norm for matrices obtained as
\[
\text{trace} (MM^*)^{1/2} = \left( \sum_i (MM^*)_{ii} \right)^{1/2} = \left( \sum_{i,j} M^2_{ij} \right)^{1/2}
\]
Also shows right away that if \( \Psi \in \mathcal{L}_2(U,H) \), then

\[
\| \Psi \|_{\mathcal{L}_2(U,H)}^2 = \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} (e_k, f_j)_H^2
\]

\[
= \sum_{k=1}^{\infty} \sum_{j=1}^{\infty} (e_k, \Psi^* f_j)_U^2 = \| \Psi^* \|_{\mathcal{L}_2(H,U)}^2
\]

and that \( \Psi \) and \( \Psi^* \) are Hilbert Schmidt together.

The filtration will continue to be denoted by \( \mathcal{F}_t \). It will be defined as the following normal filtration in which

\[
\sigma (W(s) - W(r) : 0 \leq r < s \leq u)
\]

is the completion of \( \sigma (W(s) - W(r) : 0 \leq r < s \leq u) \).

\[
\mathcal{F}_t = \cap_{u>0} \sigma (W(s) - W(r) : 0 \leq r < s \leq u). \tag{63.1.2}
\]

and \( \sigma (W(s) - W(r) : 0 \leq r < s \leq u) \) denotes the \( \sigma \) algebra of all sets of the form

\[
(W(s) - W(r))^{-1} \text{ (Borel)}
\]

where \( 0 \leq r < s \leq u \).

**Definition 63.1.2** Let \( \Phi(t) \in \mathcal{L}(U,H) \) be constant on each interval, \((t_m, t_{m+1}]\) determined by a partition of \([a, T]\), \( 0 \leq a = t_0 < t_1 \cdots < t_n = T \). Then \( \Phi(t) \) is said to be elementary if also \( \Phi(t_m) \) is \( \mathcal{F}_{t_m} \) measurable and \( \Phi(t_m) \) equals a sum of the form

\[
\Phi(t_m)(\omega) = \sum_{j=1}^{m} \Phi_j A_j
\]

where \( \Phi_j \in \mathcal{L}(U,H) \), \( A_j \in \mathcal{F}_{t_m} \). What does the measurability assertion mean? It means that if \( O \) is an open (Borel) set in the topological space \( \mathcal{L}(U,H) \), \( \Phi(t_m)^{-1}(O) \in \mathcal{F}_{t_m} \). Thus an elementary function is of the form

\[
\Phi(t) = \sum_{k=0}^{n-1} \Phi(t_k) \mathcal{X}_{(t_k, t_{k+1}]}(t).
\]

Then for \( \Phi \) elementary, the stochastic integral is defined by

\[
\int_a^t \Phi(s) \, dW(s) = \sum_{k=0}^{n-1} \Phi(t_k) (W(t \wedge t_{k+1}) - W(t \wedge t_k)).
\]

It is also sometimes denoted by \( \Phi \cdot W(t) \).
The above definition is the same as saying that for \( t \in (t_m, t_{m+1}] \),

\[
\int_a^t \Phi(s) \, dW(s) = \sum_{k=0}^{m-1} \Phi(t_k) (W(t_{k+1}) - W(t_k)) + \Phi(t_m) (W(t_m) - W(t_m)).
\]

(63.1.3)

The following lemma will be useful.

**Lemma 63.1.3** Let \( f, g \in L^2(\Omega; H) \) and suppose \( g \) is \( \mathcal{G} \) measurable and \( f \) is \( \mathcal{F} \) measurable where \( \mathcal{F} \supseteq \mathcal{G} \). Then

\[
E ((f, g)_H | \mathcal{G}) = (E(f|\mathcal{G}), g)_H \text{ a.e.}
\]

Similarly if \( \Phi \) is \( \mathcal{G} \) measurable as a map into \( L(U, H) \) with

\[
\int \Omega \, \|\Phi\|^2 \, dP < \infty
\]

and \( f \) is \( \mathcal{F} \) measurable as a map into \( U \) such that \( f \in L^2(\Omega; H) \), then

\[
E (\Phi f | \mathcal{G}) = \Phi E(f|\mathcal{G}).
\]

**Proof:** Let \( A \in \mathcal{G} \). Let \( \{g_n\} \) be a sequence of simple functions, measurable with respect to \( \mathcal{G} \),

\[
g_n(\omega) = \sum_{k=1}^{m_n} a^n_k \mathcal{X}_{E^n_k} (\omega)
\]

which converges in \( L^2(\Omega; H) \) and pointwise to \( g \). Then

\[
\int_A (E(f|\mathcal{G}), g)_H \, dP = \lim_{n \to \infty} \int_A (E(f|\mathcal{G}), g_n)_H \, dP
\]

\[
= \lim_{n \to \infty} \int_A \sum_{k=1}^{m_n} (E(f|\mathcal{G}), a^n_k \mathcal{X}_{E^n_k}|_H) \, dP = \lim_{n \to \infty} \int_A \sum_{k=1}^{m_n} E((f, a^n_k \mathcal{X}_{E^n_k}|_H) \, dP
\]

\[
= \lim_{n \to \infty} \int_A \sum_{k=1}^{m_n} E((f, a^n_k \mathcal{X}_{E^n_k}|_H) \, dP = \lim_{n \to \infty} \int_A \left( \sum_{k=1}^{m_n} a^n_k \mathcal{X}_{E^n_k}|_H \right) \, dP
\]

\[
= \lim_{n \to \infty} \int_A E((f, g_n)_H | \mathcal{G}) \, dP = \lim_{n \to \infty} \int_A (f, g_n)_H \, dP = \int_A (f, g)_H \, dP
\]

which shows

\[
(E(f|\mathcal{G}), g)_H = E((f, g)_H | \mathcal{G})
\]

as claimed.

Consider the other claim. Let

\[
\Phi_n(\omega) = \sum_{k=1}^{m_n} \Phi^n_k \mathcal{X}_{E^n_k} (\omega), \quad E^n_k \in \mathcal{G}
\]
where $\Phi^n_k \in \mathcal{L}(U,H)$ be such that $\Phi^n$ converges to $\Phi$ pointwise in $\mathcal{L}(U,H)$ and also

$$\int_\Omega ||\Phi^n - \Phi||^2 dP \to 0.$$  

Then letting $A \in \mathcal{G}$ and using Corollary 63.1.4 as needed,

$$\int_A \Phi E(f|\mathcal{G}) dP = \lim_{n \to \infty} \int_A \Phi^n E(f|\mathcal{G}) E_{E^n_k} dP = \lim_{n \to \infty} \sum_{k=1}^{m_n} \Phi^n_k \int_A E(f|\mathcal{G}) E_{E^n_k} dP = \lim_{n \to \infty} \sum_{k=1}^{m_n} \Phi^n_k \int_A X_{E^n_k} f dP = \lim_{n \to \infty} \int_A \Phi f dP = \int_A \Phi f dP = \int_A E(f|\mathcal{G}) dP$$

Since $A \in \mathcal{G}$ is arbitrary, this proves the lemma. 

**Lemma 63.1.4** Let $J : U_0 \to U$ be a Hilbert Schmidt operator and let $W(t)$ be the resulting Wiener process

$$W(t) = \sum_{k=1}^{\infty} \psi_k(t) Jg_k$$

where $\{g_k\}$ is an orthonormal basis for $U_0$. Let $f \in H$. Then considering one of the terms of the integral defined above,

$$E \left( (\Phi(t_k) (W(t \wedge t_{k+1}) - W(t \wedge t_k)), f) \right)^2$$

$$= E \left( ((W(t \wedge t_{k+1}) - W(t \wedge t_k)), \Phi(t_k)^* f) \right)$$

$$= (t \wedge t_{k+1} - t \wedge t_k) E \left( \|J^* \Phi(t_k)^* f\|_{U_0}^2 \right) .$$

**Proof:** For simplicity, write $\Delta W_k(t)$ for $W(t \wedge t_{k+1}) - W(t \wedge t_k)$ and $\Delta_k(t) = (t \wedge t_{k+1}) - (t \wedge t_k)$. If $\Phi(t_k)$ were a constant, then the result would follow right away from the fact that $W(t)$ is a Wiener process. Therefore, suppose for disjoint $E_i$,

$$\Phi(t_k)(\omega) = \sum_{i=1}^{m} \Phi_i \chi_{E_i} (\omega)$$

where $\Phi_i \in \mathcal{L}(U,H)$ and $E_i \in \mathcal{F}_k$. Then, since the $E_i$ are disjoint,

$$E \left( (\Phi(t_k) (W(t \wedge t_{k+1}) - W(t \wedge t_k)), f) \right)^2$$
= \sum_{i=1}^{m} E \left( (\Delta_k W(t), \Phi_i^* f \mathcal{X}_{E_i})^2 \right) = \sum_{i=1}^{m} \int_{\Omega} \left( \mathcal{X}_{E_i} ((\Delta_k W(t), \Phi_i^* f)^2 \right) dP

Thus each $E_i$ is $\mathcal{F}_{t_k}$ measurable. By Lemma 62.4.2 and the properties of the Wiener process, this equals

$$\sum_{i=1}^{m} P(E_i) \int_{\Omega} ((\Delta_k W(t), \Phi_i^* f)^2) dP = \sum_{i=1}^{m} P(E_i) \Delta_k t (Q \Phi_i^* f, \Phi_i^* f)_{U}$$

where $Q = JJ^*$. Then the above reduces to

$$(t \wedge t_{k+1} - t \wedge t_k) E \left( \|J^* \Phi(t_k)^* f\|_{L^2(U_0)}^2 \right).$$

Now here is a major result on the integral of elementary functions. The last assertion in the following proposition is called the Ito isometry.

**Proposition 63.1.5** Let $\Phi(t)$ be an elementary process as defined in Definition 63.1.2 and let $W(t)$ be a Wiener process.

$$W(t) = \sum_{k=1}^{\infty} \psi_k(t) J g_k$$

where $J : U_0 \rightarrow U$ is Hilbert Schmidt and the $\psi_k$ are real independent Wiener processes as described above.

$$U_0 \xrightarrow{g_k} U \xrightarrow{\Phi} H$$

Then $\int_a^t \Phi(s) dW(s)$ is a continuous square integrable $H$ valued martingale with respect to the $\sigma$ algebras of [63.5.3] on $[0, T]$ and

$$E \left( \left\| \int_a^t \Phi(s) dW(s) \right\|_H^2 \right) = \int_a^t E \left( \| \Phi \circ J \|_{L^2(U_0, H)}^2 \right) ds$$

**Proof:** Start with the left side. Denote by $\Delta_k W(t) \equiv W(t \wedge t_{k+1}) - W(t \wedge t_k)$.

Then

$$E \left( \left\| \int_a^t \Phi(s) dW(s) \right\|_H^2 \right) = E \left( \left\| \sum_{k=0}^{n-1} \Phi(t_k) \Delta_k W(t) \right\|_H^2 \right).$$

Consider a mixed term for $j < k$. Using Lemma 63.1.2 and the fact that $W(t)$ is a martingale,

$$E \left( (\Phi(t_k) \Delta_k W(t), \Phi(t_j) \Delta_j W(t))_H \right)$$

$$= E\left( E \left( (\Phi(t_k) \Delta_k W(t), \Phi(t_j) \Delta_j W(t))_H \right) | \mathcal{F}_{t_k} \right)$$

$$= E \left( (\Phi(t_j) \Delta_j W(t), E \left( \Delta_k W(t) \mathcal{F}_{t_k} \right)) \right)$$

$$= E \left( (\Phi(t_j) \Delta_j W(t), \Phi(t_k) E \left( \Delta_k W(t) \mathcal{F}_{t_k} \right)) \right)$$

$$= E \left( (\Phi(t_j) \Delta_j W(t), \Phi(t_k)) \mathcal{F}_{t_k} \right) = 0.$$
Therefore, from Lemma 63.1.4, and letting \( \{f_j\} \) be an orthonormal basis for \( H \),

\[
E \left( \left| \int_a^t \Phi(s) \, dW \right|_H^2 \right) = \sum_{k=0}^{n-1} E \left( \left( \Phi(t_k) \, \Delta_k W(t) , \Phi(t_k) \, \Delta_k W(t) \right) \right)
\]

\[
= \sum_{k=0}^{n-1} \sum_{j=1}^{\infty} E \left( \left| \Phi(t_k) \, \Delta_k W(t) , f_j \right|_H^2 \right) = \sum_{k=0}^{n-1} \sum_{j=1}^{\infty} E \left( \left( \Phi(t_k) \, \Delta_k W(t) , f_j \right) \right)^2
\]

\[
= \sum_{k=0}^{n-1} \sum_{j=1}^{\infty} (t \wedge t_{k+1} - t \wedge t_k) E \left( \left| \Phi(t_k) \right|_U^2 \right)
\]

\[
= \sum_{k=0}^{n-1} (t \wedge t_{k+1} - t \wedge t_k) E \left( \left| \Phi(t_k) \right|_U^2 \right)
\]

\[
= \sum_{k=0}^{n-1} (t \wedge t_{k+1} - t \wedge t_k) E \left( \left| \Phi(t_k) \right|_{L^2(U,H)}^2 \right)
\]

\[
= \int_a^t E \left( \left| \Phi \circ J \right|_{L^2(U_0,H)}^2 \right) \, ds
\]

It is obvious that \( \int_a^t \Phi(s) \, dW \) is a continuous square integrable martingale from the definition, because it is just a finite sum of such things. 

Of course this is a version of the Itô isometry. The presence of the \( J \) is troublesome but it is hidden in the definition of \( W \) on the left side of the conclusion of the proposition. In finite dimensions one could just let \( J = I \) and this fussy detail would not be there to cause confusion. The next task is to generalize the above integral to a more general class of functions and obtain a process which is not explicitly dependent on \( J \).

### 63.2 Different Definition Of Elementary Functions

What if elementary functions had been defined in terms of \( \mathcal{X}_{[t_k,t_{k+1}]} \)? That is, what if the elementary functions had been of the form

\[
\Phi(t) = \sum_{k=0}^{n-1} \Phi(t_k) \, \mathcal{X}_{[t_k,t_{k+1}]}(t)
\]

Would anything change? If you go over the arguments given, it is clear that nothing would change at all. Furthermore, this elementary function equals the one described above off a finite set of mesh points so the convergence properties in \( L^2([0,T] \times \Omega, L_2(Q^{1/2}U,H)) \), which will be important in what follows are exactly the same. Thus it does not matter whether we give elementary functions in this form or in the form described above. However, some arguments given later about localization depend on it being in the earlier form.
63.3 Approximating With Elementary Functions

Here is a really surprising result about approximating with step functions which is due to Doob. See [71] which is where I found this lemma. This is based on continuity of translation in the $L^p (\mathbb{R}; E)$.

**Lemma 63.3.1** Let $\Phi : [0,T] \times \Omega \to E$, be $\mathcal{B}([0,T]) \times \mathcal{F}$ measurable and suppose

$$\Phi \in K \equiv L^p ([0,T] \times \Omega; E), \quad p \geq 1$$

Then there exists a sequence of nested partitions, $\mathcal{P}_k \subseteq \mathcal{P}_{k+1}$,

$$\mathcal{P}_k \equiv \{ t^k_0, \ldots, t^k_{m_k} \}$$

such that the step functions given by

$$\Phi_k' (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_j) \mathcal{X}_{(t^k_{j-1}, t^k_j]} (t)$$

$$\Phi_k (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_{j-1}) \mathcal{X}_{(t^k_{j-1}, t^k_j]} (t)$$

both converge to $\Phi$ in $K$ as $k \to \infty$ and

$$\lim_{k \to \infty} \max \{ |t^k_j - t^k_{j+1}| : j \in \{0, \ldots, m_k \} \} = 0.$$

Also, each $\Phi (t^k_j)$, $\Phi (t^k_{j-1})$ is in $L^p (\Omega; E)$. One can also assume that $\Phi (0) = 0$.

The mesh points $\{t^k_j\}_{j=0}^{m_k}$ can be chosen to miss a given set of measure zero. In addition to this, we can assume that

$$|t^k_j - t^k_{j-1}| = 2^{-n_k}$$

except for the case where $j = 1$ or $j = m_{n_k}$ when this is so, you could have $|t^k_j - t^k_{j-1}| < 2^{-n_k}$.

Note that it would make no difference in terms of the conclusion of this lemma if you defined

$$\Phi_k' (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_j) \mathcal{X}_{(t^k_{j-1}, t^k_j]} (t)$$

because the modified function equals the one given above off a countable subset of $[0, T]$, the union of the mesh points. One could change $\Phi_k'$ similarly with no change in the conclusion.

**Proof:** For $t \in \mathbb{R}$ let $\gamma_n (t) \equiv k/2^n$, $\delta_n (t) \equiv (k+1)/2^n$, where $t \in (k/2^n, (k+1)/2^n]$, and $2^{-n} < T/4$. Also suppose $\Phi$ is defined to equal 0 on $[0, T]^C \times \Omega$. There exists
a set of measure zero \( N \) such that for \( \omega \notin N, t \to \| \Phi(t, \omega) \| \) is in \( L^p(\mathbb{R}) \). Therefore by continuity of translation, as \( n \to \infty \) it follows that for \( \omega \notin N, \) and \( t \in [0, T] \),

\[
\int_{\mathbb{R}} \| \Phi(\gamma_n(t) + s) - \Phi(t + s) \|^p_E \, ds \to 0
\]

The above is dominated by

\[
\int_{\mathbb{R}} 2^{p-1} (||\Phi(s)||^p + ||\Phi(s)||^p) \chi_{-2T,2T}(s) \, ds
\]

\[
= \int_{-2T}^{2T} 2^{p-1} (||\Phi(s)||^p + ||\Phi(s)||^p) \, ds < \infty
\]

Consider

\[
\int_{\Omega} \int_{-2T}^{2T} \left( \int_{\mathbb{R}} ||\Phi(\gamma_n(t) + s) - \Phi(t + s) \|^p_E \, ds \right) \, dtdP
\]

By the dominated convergence theorem, this converges to 0 as \( n \to \infty \). This is because the integrand with respect to \( \omega \) is dominated by

\[
\int_{-2T}^{2T} \left( \int_{\mathbb{R}} 2^{p-1} (||\Phi(s)||^p + ||\Phi(s)||^p) \chi_{-2T,2T}(s) \, ds \right) \, dt
\]

and this is in \( L^1(\Omega) \) by assumption that \( \Phi \in K \). Now Fubini. This yields

\[
\int_{\Omega} \int_{\mathbb{R}} \int_{-2T}^{2T} ||\Phi(\gamma_n(t) + s) - \Phi(t + s) \|^p_E \, dtds\, dP
\]

Change the variables on the inside.

\[
\int_{\Omega} \int_{\mathbb{R}} \int_{-2T}^{2T+s} ||\Phi(\gamma_n(t-s) + s) - \Phi(t) \|^p_E \, dtds\, dP
\]

Now by definition, \( \Phi(t) \) vanishes if \( t \notin [0,T] \), thus the above reduces to

\[
\int_{\Omega} \int_{\mathbb{R}} \int_{0}^{T} ||\Phi(\gamma_n(t-s) + s) - \Phi(t) \|^p_E \, dtds\, dP
\]

\[
+ \int_{\Omega} \int_{\mathbb{R}} \int_{-2T}^{2T+s} \chi_{[0,T]}(s) ||\Phi(\gamma_n(t-s) + s) \|^p_E \, dtds\, dP
\]

\[
= \int_{\Omega} \int_{\mathbb{R}} \int_{0}^{T} ||\Phi(\gamma_n(t-s) + s) - \Phi(t) \|^p_E \, dtds\, dP
\]

\[
+ \int_{\Omega} \int_{\mathbb{R}} \int_{-2T}^{2T+s} \chi_{[0,T]}(s) ||\Phi(\gamma_n(t-s) + s) - \Phi(t) \|^p_E \, dtds\, dP
\]
Also by definition, \( \gamma_n(t+s) + s \) is within \( 2^{-n} \) of \( t \) and so the integrand in the integral on the right equals 0 unless \( t \in [-2^{-n} - T, T + 2^{-n}] \subseteq [-2T, 2T] \). Thus the above reduces to

\[
\int_{\Omega} \int_{\mathbb{R}} \int_{-2T}^{2T} \| \Phi(\gamma_n(t+s) + s) - \Phi(t) \|_E \, dt \, ds \, dP.
\]

Now Fubini again.

\[
\int_{\mathbb{R}} \int_{\Omega} \int_{-2T}^{2T} \| \Phi(\gamma_n(t+s) + s) - \Phi(t) \|_E \, dt \, ds \, dP
\]

This converges to 0 as \( n \to \infty \) as was shown above. Therefore,

\[
\int_0^T \int_{\Omega} \int_0^T \| \Phi(\gamma_n(t+s) + s) - \Phi(t) \|_E \, dt \, ds \, dP
\]

also converges to 0 as \( n \to \infty \). The only problem is that \( \gamma_n(t+s) + s \geq t - 2^{-n} \) and so \( \gamma_n(t-s) + s \) could be less than 0 for \( t \in [0,2^{-n}] \). Since this is an interval whose measure converges to 0 it follows

\[
\int_0^T \int_{\Omega} \int_0^T \| \Phi(\gamma_n(t+s) + s) - \Phi(t) \|_E \, dt \, ds \, dP
\]

converges to 0 as \( n \to \infty \). Let

\[
m_n(s) = \int_{\Omega} \int_0^T \| \Phi(\gamma_n(t+s) + s) - \Phi(t) \|_E \, dt \, ds
\]

Then letting \( \mu \) denote Lebesgue measure,

\[
\mu([m_n(s) > \lambda]) \leq \frac{1}{\lambda} \int_0^T m_n(s) \, ds.
\]

It follows there exists a subsequence \( n_k \) such that

\[
\mu\left(\left[ m_{n_k}(s) > \frac{1}{k} \right]\right) < 2^{-k}
\]

Hence by the Borel Cantelli lemma, there exists a set of measure zero \( N \) such that for \( s \notin N \),

\[
m_{n_k}(s) \leq 1/k
\]

for all \( k \) sufficiently large. Pick such an \( s \). Then consider \( t \to \Phi(\gamma_{n_k}(t-s) + s)^+ \).

For \( n_k, t \to (\gamma_{n_k}(t-s) + s)^+ \) has jumps at points of the form 0, \( s + l2^{-n_k} \) where \( l \) is an integer. Thus \( P_{n_k} \) consists of points of \([0,T]\) which are of this form and these partitions are nested. Define \( \Phi_k^l(0) \equiv 0, \Phi_k^l(t) \equiv \Phi(\gamma_{n_k}(t-s) + s)^+ \). Now suppose \( N_1 \) is a set of measure zero. Can \( s \) be chosen such that all jumps for all
partitions occur off \( N_1 \)? Let \((a, b)\) be an interval contained in \([0, T]\). Let \( S_j \) be the points of \((a, b)\) which are translations of the measure zero set \( N_1 \) by \( t_j^i \) for some \( j \). Thus \( S_j \) has measure 0. Now pick \( s \in (a, b) \setminus \cup_j S_j \).

It will be assumed that all these mesh points miss the set of all \( t \) such that \( \omega \to \Phi(t, \omega) \) is not in \( L^p(\Omega; E) \). To get the other sequence of step functions, the right step functions, just use a similar argument with \( \delta_n \) in place of \( \gamma_n \). Just apply the argument to a subsequence of \( n_k \) so that the same \( s \) can hold for both. ■

The following proposition says that elementary functions can be used to approximate progressively measurable functions under certain conditions.

**Proposition 63.3.2** Let \( \Phi \in L^p([0, T] \times \Omega, E) \), \( p \geq 1 \), be progressively measurable. Then there exists a sequence of elementary functions which converges to \( \Phi \) in

\[
L^p([0, T] \times \Omega, E).
\]

These elementary functions have values in \( E_0 \), a dense subset of \( E \). If \( \varepsilon_n \to 0 \), and

\[
\Phi_n(t) = \sum_{k=1}^{m_n} \Psi_k^n \chi_{(t_k, t_{k+1}]}(t)
\]

\( \Psi_k^n \) having values in \( E_0 \), it can be assumed that

\[
\sum_{k=1}^{m_n} \|\Psi_k^n - \Phi(t_k)\|_{L^p(\Omega; E)} < \varepsilon_n. \tag{63.3.4}
\]

**Proof:** By Lemma 63.3.1 there exists a sequence of step functions

\[
\Phi_k^l(t) = \sum_{j=1}^{m_k} \Phi(t_{j-1}^k) \chi_{(t_{j-1}^k, t_j^k]}(t)
\]

which converges to \( \Phi \) in \( L^p([0, T] \times \Omega, E) \) where at the left endpoint \( \Phi(0) \) can be modified as described above. Now each \( \Phi(t_{j-1}^k) \) is in \( L^p(\Omega, E) \) and is \( F(t_{j-1}^k) \) measurable and so it can be approximated as closely as desired in \( L^p(\Omega) \) with a simple function

\[
s(t_{j-1}^k) = \sum_{i=1}^{m_k} c_i \chi_{F_i}(\omega), F_i \in F(t_{j-1}^k).
\]

Furthermore, by density of \( E_0 \) in \( E \), it can be assumed each \( c_i \in E_0 \) and the condition 63.3.1 holds. Replacing each \( \Phi(t_{j-1}^k) \) with \( s(t_{j-1}^k) \), the result is an elementary function which approximates \( \Phi_k^l \). ■

Of course everything in the above holds with obvious modifications replacing \([0, T]\) with \([a, T]\) where \( a < T \).

Here is another interesting proposition about the time integral being adapted.
Proposition 63.3.3 Suppose $f \geq 0$ is progressively measurable and $\mathcal{F}_t$ is a filtration. Then
\[
\omega \mapsto \int_a^t f(s, \omega) \, ds
\]
is $\mathcal{F}_t$ adapted.

Proof: This follows right away from the fact $f$ is $\mathcal{B}([a,t]) \times \mathcal{F}_t$ measurable. This is just product measure and so the integral from $a$ to $t$ is $\mathcal{F}_t$ measurable. See also Proposition 60.3.5.

63.4 Some Hilbert Space Theory

Recall the following definition which makes $LU$ into a Hilbert space where $L \in \mathcal{L}(U,H)$.

Definition 63.4.1 Let $L \in \mathcal{L}(U,H)$, the bounded linear maps from $U$ to $H$ for $U,H$ Hilbert spaces. For $y \in L(U)$, let $L^{-1}y$ denote the unique vector in
\[
\{x : Lx = y\} \equiv M_y
\]
which is closest in $U$ to $0$.

Note this is a good definition because $\{x : Lx = y\}$ is closed thanks to the continuity of $L$ and it is obviously convex. Thus Theorem 17.1.8 applies. With this definition define an inner product on $L(U)$ as follows. For $y,z \in L(U)$,
\[
(y,z)_{L(U)} \equiv (L^{-1}y, L^{-1}z)_U
\]
Thus it is obvious that $L^{-1} : LU \to U$ is continuous. The notation is abominable because $L^{-1}(y)$ is the normal notation for $M_y$.

With this definition, here is one of the main results. It is Theorem 17.1.8 proved earlier.

Theorem 63.4.2 Let $U,H$ be Hilbert spaces and let $L \in \mathcal{L}(U,H)$. Then Definition 63.4.1 makes $L(U)$ into a Hilbert space. Also $L : U \to L(U)$ is continuous and $L^{-1} : L(U) \to U$ is continuous. Furthermore there is a constant $C$ independent of $x \in U$ such that
\[
\|L\|_{\mathcal{L}(U,H)} \|Lx\|_{L(U)} \geq \|Lx\|_H \quad (63.4.5)
\]
If $U$ is separable, so is $L(U)$. Also $(L^{-1}(y), x) = 0$ for all $x \in \ker(L)$, and $L^{-1} : L(U) \to U$ is linear. Also, in case that $L$ is one to one, both $L$ and $L^{-1}$ preserve norms.

Let $U$ be a separable Hilbert space and let $Q$ be a positive self adjoint operator. Then consider

$$J : Q^{1/2}U \to U_1,$$

a one to one Hilbert Schmidt operator, where $U_1$ is a separable real Hilbert space. First of all, there is the obvious question whether there are any examples.

**Lemma 63.4.3** Let $A \in \mathcal{L}(U, U)$ be a bounded linear transformation defined on $U$ a separable real Hilbert space. There exists a one to one Hilbert Schmidt operator $J : AU \to U_1$ where $U_1$ is a separable real Hilbert space. In fact you can take $U_1 = U$.

**Proof:** Let $\alpha_k > 0$ and $\sum_{k=1}^{\infty} \alpha_k^2 < \infty$. Then let $\{g_k\}_{k=1}^{L}$ be an orthonormal basis for $AU$, the inner product and norm given in Definition above, and let

$$Jx = \sum_{k=1}^{L} \langle x, g_k \rangle_{AU} \alpha_k g_k.$$

Then it is clear that $J \in \mathcal{L}(AU, U)$. This is because,

$$\|Jx\|_U \leq \sum_{k=1}^{L} |\langle x, g_k \rangle_{AU}| \alpha_k \|g_k\|_U$$

$$\leq C \sum_{k=1}^{L} |\langle x, g_k \rangle_{AU}| \alpha_k \|g_k\|_{AU}$$

$$\leq C \left( \sum_{k=1}^{L} |\langle x, g_k \rangle_{AU}|^2 \right)^{1/2} \left( \sum_{k=1}^{L} \alpha_k^2 \right)^{1/2}$$

$$= C \left( \sum_{k=1}^{L} \alpha_k^2 \right)^{1/2} \|x\|_{AU}$$

Also, from the definition, $Jg_j = \alpha_j g_j$. Say $g_j = Af_j$ where $f_j \in U$ and $1 = \|g_j\|_{AU} = \|f_j\|_U$. Since $A$ is continuous,

$$\|g_j\|_U = \|Af_j\|_U \leq \|A\| \|f_j\|_U = \|A\| \|g_j\|_{AU} = \|A\| \equiv C^{1/2}$$

Thus

$$\sum_{j=1}^{L} \|Jg_j\|_U^2 = \sum_{j=1}^{L} \alpha_j^2 \|g_j\|_U^2 \leq C \sum_{j=1}^{L} \alpha_j^2 < \infty$$

and so $J$ is also a Hilbert Schmidt operator which maps $AU$ to $U$. It is clear that $J$ is one to one because each $\alpha_k > 0$. If $AU$ is finite dimensional, $L < \infty$ and so the above sum is finite. ■
**Definition 63.4.4** Let $U_1, U, H$ be real separable Hilbert spaces and let $Q$ be a nonnegative self adjoint operator, $Q \in \mathcal{L}(U, U)$. Let $Q^{1/2}U$ be the Hilbert space described in Definition 63.4.3. Let $J$ be a one to one Hilbert Schmidt map from $Q^{1/2}U$ to $U_1$.

\[ U_1 \not\negrightarrow Q^{1/2}U \xrightarrow{\Phi} H \]

Then denote by $\mathcal{L}(U_1, H)_0$ the space of restrictions of elements of $\mathcal{L}(U_1, H)$ to the Hilbert space $JQ^{1/2}U \subseteq U_1$.

Here is a diagram to keep this straight.

\[ \begin{array}{ccc}
U & \downarrow & Q^{1/2} \\
U_1 & \xrightarrow{J} & Q^{1/2}U \\
\Phi \downarrow & & \Phi \\
\Phi_n & \lessgtr & H \\
\end{array} \]

**Lemma 63.4.5** In the context of the above definition, $\mathcal{L}(U_1, H)_0$ is dense in $\mathcal{L}_2(JQ^{1/2}U, H)$, the Hilbert Schmidt operators from $JQ^{1/2}U$ to $H$. That is, if $f \in \mathcal{L}_2(JQ^{1/2}U, H)$, there exists $g \in \mathcal{L}(U_1, H)_0$, $\|g - f\|_{\mathcal{L}_2(JQ^{1/2}U, H)} < \varepsilon$.

**Proof:** The operator $JJ^* \equiv Q_1 : U_1 \to U_1$ is self adjoint and nonnegative. It is also compact because $J$ is Hilbert Schmidt. Therefore, by Theorem 19.3.9 on Page 647, $Q_1 = \sum_{k=1}^{L} \lambda_k e_k \otimes e_k$

where the $\lambda_k$ are decreasing and positive, the $\{e_k\}$ are an orthonormal basis for $U_1$, and $\lambda_L$ is the last positive $\lambda_j$. (This is a lot like the singular value matrix in linear algebra.) Thus also

\[ Q_1 e_k = \lambda_k e_k \]

If the $\lambda_k$ are all positive, then $L \equiv \infty$. Then for $k \leq L$ if $L < \infty$, $k < \infty$ otherwise,

\[ \begin{pmatrix} J^* e_k & J^* e_j \\ \sqrt{\lambda_k} & \sqrt{\lambda_j} \end{pmatrix}_{Q^{1/2}(U)} = \begin{pmatrix} J J^* e_k & e_j \\ \sqrt{\lambda_k} & \sqrt{\lambda_j} \end{pmatrix}_{U_1} = \begin{pmatrix} \lambda_k e_k & e_j \\ \sqrt{\lambda_k} & \sqrt{\lambda_j} \end{pmatrix}_{U_1} = \sqrt{\lambda_k} \delta_{kj} = \delta_{kj} \]

Now in case $L < \infty$, $J(Q^{1/2}(U)) \subseteq \text{span}(e_1, \ldots, e_L)$. Here is why. First note that $Q_1$ is one to one on $\text{span}(e_1, \ldots, e_L)$ and maps this space onto itself because $Q_1$ maps $e_k$ to a nonzero multiple of $e_k$. Hence its restriction to this subspace has
an inverse which does the same. It also maps all of $U_1$ to span $(e_1, \cdots, e_L)$. This follows from the definition of $Q_1$ given in the above sum. For $x \in Q^{1/2}(U)$, $Jx \in U_1$ and so
\[ JJ^* Jx = Q_1(Jx) \in \text{span} (e_1, \cdots, e_L) \]
Hence $Jx \in Q_1^{-1} (\text{span} (e_1, \cdots, e_L)) \in \text{span} (e_1, \cdots, e_L)$. Recall that $J$ is one to one so there is only one element of $J^{-1}x$.

Then for $x \in Q^{1/2}U$,
\[
\sum_{j=1}^{L} \sqrt{\lambda_j} e_j \otimes Q^{1/2}U \frac{J^* e_j}{\sqrt{\lambda_j}} (x) = \sum_{j=1}^{L} \sqrt{\lambda_j} e_j \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, x \right)_{Q^{1/2}(U)}
\]
\[
= \sum_{j=1}^{L} \sqrt{\lambda_j} e_j \left( \frac{e_j}{\sqrt{\lambda_j}}, Jx \right)_{U_1} = \sum_{j=1}^{L} e_j (e_j, Jx)_{U_1}
\]
\[
= \sum_{j=1}^{\infty} e_j (e_j, Jx)_{U_1} = Jx. \quad \left( J \left( Q^{1/2}(U) \right) \subseteq \text{span} (e_1, \cdots, e_L) \text{ if } L < \infty \right)
\]
Thus,
\[
J = \sum_{j=1}^{L} \sqrt{\lambda_j} e_j \otimes Q^{1/2}U \frac{J^* e_j}{\sqrt{\lambda_j}}
\]

It follows that an orthonormal basis in $JQ^{1/2}U$ is $\left\{ \frac{J^* e_j}{\sqrt{\lambda_j}} \right\}_{j=1}^{L}$. This is because an orthonormal basis for $Q^{1/2}U$ is $\left\{ \frac{J^* e_k}{\sqrt{\lambda_k}} \right\}_{k=1}^{N}$. Since $J$ is one to one, it preserves norms between $Q^{1/2}U$ and $JQ^{1/2}U$. Let $\Phi \in L_2 \left( JQ^{1/2}U, H \right)$. Then by the discussion of Hilbert Schmidt operators given earlier, in particular the demonstration that these operators are compact,
\[
\Phi = \sum_{i,j}^{\infty} \phi_{ij} f_i \otimes JQ^{1/2}U \frac{J^* e_j}{\sqrt{\lambda_j}}
\]
where $\{f_i\}$ is an orthonormal basis for $H$. In fact, $\left\{ f_i \otimes \frac{J^* e_j}{\sqrt{\lambda_j}} \right\}_{i,j}$ is an orthonormal basis for $L_2 \left( JQ^{1/2}U, H \right)$ and $\sum_{i,j} \phi_{ij}^2 < \infty$, the $\phi_{ij}$ being the Fourier coefficients of $\Phi$. Then consider
\[
\Phi_n = \sum_{i,j}^{n} \phi_{ij} f_i \otimes JQ^{1/2}U \frac{J^* e_j}{\sqrt{\lambda_j}}
\]
(63.4.6)

Consider one of the finitely many operators in this sum. For $x \in JQ^{1/2}U$, since $J$ preserves norms,
\[
f_i \otimes JQ^{1/2}U \frac{J^* e_j}{\sqrt{\lambda_j}} (x) = f_i \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, x \right)_{JQ^{1/2}U} = f_i \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, J^{-1}x \right)_{JQ^{1/2}U}
\]
= f_i \left( \frac{e_j}{\sqrt{\lambda_j}}, JJ^{-1} x \right)_{U_1} = f_i \left( \frac{e_j}{\sqrt{\lambda_j}}, x \right)_{U_1} = \Lambda_{ij} \left( x \right)

Recall how, since \( J \) is one to one, it preserves norms and inner products. Now \( \Lambda_{ij} \) makes sense from the above formula for all \( x \in U_1 \) and is also a continuous linear map from \( U_1 \) to \( H \) because

\[
\left\| f_i \left( \frac{e_j}{\sqrt{\lambda_j}}, x \right)_{U_1} \right\|_H \leq \| f_i \|_H \frac{1}{\sqrt{\lambda_j}} \| x \|_{U_1}
\]

Thus each term in the finite sum of \( i = 1 \) is in \( L(U_1; H) \) and this proves the lemma.

It is interesting to note that \( Q_{1/2}^{1/2} U_1 = J Q_{1/2}^{1/2} (U) \).

\[
\sum_{j=1}^{L} \sqrt{\lambda_j} e_j \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, x \right)_{Q^{1/2}(U)} = Jx
\]

and \( \left\{ \frac{J^* e_j}{\sqrt{\lambda_j}} \right\} \) are an orthonormal set in \( Q^{1/2} (U) \). Therefore, the sum of the squares of \( \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, x \right)_{Q^{1/2}(U)} \) is finite. Hence you can define \( y \in U_1 \) by

\[
y = \sum_{j=1}^{L} \left( \frac{J^* e_j}{\sqrt{\lambda_j}}, x \right)_{Q^{1/2}(U)} e_j
\]

Also

\[
\sum_{i=1}^{L} \sqrt{\lambda_i} e_i \otimes e_i \left( y \right) = \sum_{i=1}^{L} \sqrt{\lambda_i} e_i \left( \frac{J^* e_i}{\sqrt{\lambda_i}}, x \right)_{Q^{1/2}(U)} = \sum_{i=1}^{L} e_i \left( e_i, Jx \right)_{U_1} = Jx
\]

Now you can show that \( Q_1^{1/2} = \sum_{i=1}^{L} \sqrt{\lambda_i} e_i \otimes e_i \). You do this by showing that it works and commutes with every operator which commutes with \( Q_1 \). Thus \( Jx = Q_1^{1/2} y \). This shows that \( J Q_{1/2}^{1/2} (U) \subseteq Q_1^{1/2} (U_1) \). However, you can also turn the inclusion around. Thus if you start with \( y \in U_1 \) and form

\[
Q_1^{1/2} y = \sum_{i=1}^{L} \sqrt{\lambda_i} e_i \otimes e_i \left( y \right) = \sum_{i=1}^{L} \sqrt{\lambda_i} e_i \left( y, e_i \right),
\]

then the \( \left( y, e_i \right)_{U_1}^2 \) has a finite sum because the \( \{ e_i \} \) are orthonormal. Thus you can form

\[
x \equiv \sum_{i=1}^{L} \left( y, e_i \right)_{U_1} \frac{J^* e_i}{\sqrt{\lambda_i}} \in Q^{1/2} (U)
\]
Then since the \( \{ J^*e_j / \sqrt{\lambda_j} \} \) are orthonormal,

\[
J(x) = \sum_{j=1}^{L} \sqrt{\lambda_j} e_j \left( J^*e_j, x \right)_{Q^{1/2}(U)} = \sum_{j=1}^{L} \sqrt{\lambda_j} e_j (y, e_j)_{U_1} = \sum_{j=1}^{L} \sqrt{\lambda_j} e_j \otimes e_j (y) = Q^{1/2}_{1}(y)
\]

It follows that \( Q^{1/2}_{1}(U_1) \subseteq J \left( Q^{1/2}(U) \right). \)

One can also show that \( W(t) = \sum_{k=1}^{L} \psi_k(t) Jg_k \) where the \( \psi_k(t) \) are the real Wiener processes described earlier and \( \{ g_k \} \) is an orthonormal basis for \( Q^{1/2}(U) \), is a \( Q_1 \) Wiener process. To see this, recall the above definition of a Wiener process in terms of Hilbert Schmidt operators, the convergence happening in \( U_1 \) in this case. Then by independence of the \( \psi_j, \)

\[
E \left( \left( \sum_{k=1}^{L} \psi_k(t-s) Jg_k \right) \left( \sum_{j=1}^{L} \psi_j(t-s) Jg_j \right) \right) = E \left( \sum_k (h,Jg_k)(l,Jg_j) \psi_k(t-s) \psi_j(t-s) \right) = \sum_k (h,Jg_k)(l,Jg_k) E(\psi_k^2(t-s)) = (t-s) \sum_k (h,Jg_k)(l,Jg_k) = (t-s) \sum_k (J^*h,g_k)_{Q^{1/2}(U)} (J^*l,g_k)_{Q^{1/2}(U)} = (t-s) (J^*h,J^*l)_{Q^{1/2}(U)} = (t-s)(Q_1h,l)_{U_1}
\]

### 63.5 The General Integral

It is time to generalize the integral. The following diagram illustrates the ingredients of the next lemma.

\[
\begin{array}{c}
W(t) \in U_1 \xrightarrow{\xi} Q^{1/2}U \xrightarrow{\Phi} H \\
U \downarrow Q^{1/2} \\
U_1 \supseteq Q^{1/2}U \xrightarrow{\xi_{1-1}} Q^{1/2}U \\
\Phi_n \quad \downarrow \Phi \\
\Phi \quad H
\end{array}
\]
Lemma 63.5.1 Let $\Phi \in L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(Q^{1/2}U, H\right)\right)$ and suppose also that $\Phi$ is progressively measurable with respect to the usual filtration associated with the Wiener process

$$W(t) = \sum_{k=1}^{L} \psi_k(t) Jg_k$$

which has values in $U_1$ for $U_1$ a separable real Hilbert space such that $J : Q^{1/2}U \to U_1$ is Hilbert Schmidt and one to one, $\{g_k\}$ an orthonormal basis in $Q^{1/2}U$. Then letting $J^{-1} : JQ^{1/2}U \to Q^{1/2}U$ be the map described in Definition 63.4.1, it follows that

$$\Phi \circ J^{-1} \in L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(JQ^{1/2}U, H\right)\right).$$

Also there exists a sequence of elementary functions $\{f_n\}$ having values in $L^2 \left(U_1, H; H\right)$ which converges to $\Phi \circ J^{-1}$ in $L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(JQ^{1/2}U, H\right)\right)$.

Proof: First, why is $\Phi \circ J^{-1} \in L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(JQ^{1/2}U, H\right)\right)$? This follows from the observation that $A$ is Hilbert Schmidt if and only if $A^*$ is Hilbert Schmidt. In fact, the Hilbert Schmidt norms of $A$ and $A^*$ are the same. Now since $\Phi$ is Hilbert Schmidt, it follows that $\Phi^*$ is and since $J^{-1}$ is continuous, it follows $(J^{-1})^* \Phi^* = (\Phi \circ J^{-1})^*$ is Hilbert Schmidt. Also letting $\mathcal{L}_2$ be the appropriate space of Hilbert Schmidt operators,

$$\left\|(J^{-1})^* \Phi^*\right\|_{\mathcal{L}_2} = \left\|(J^{-1})^*\right\|_{\mathcal{L}_2} \geq \left\|(\Phi \circ J^{-1})^*\right\|_{\mathcal{L}_2} = \left\|\Phi \circ J^{-1}\right\|_{\mathcal{L}_2}$$

Thus $\Phi \circ J^{-1}$ has values in $L^2 \left(JQ^{1/2}U, H\right)$. This also shows that

$$\Phi \circ J^{-1} \in L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(JQ^{1/2}U, H\right)\right).$$

Since $\Phi$ is given to be progressively measurable, so is $\Phi \circ J^{-1}$. Therefore, the existence of the desired sequence of elementary functions follows from Proposition 63.4.2 and Lemma 63.4.5.

Definition 63.5.2 Let $\Phi \in L^2 \left([a, T] \times \Omega; \mathcal{L}_2 \left(Q^{1/2}U, H\right)\right)$ and be progressively measurable where $Q$ is a self adjoint nonnegative operator defined on $U$. Let $J : Q^{1/2}U \to U_1$ be Hilbert Schmidt. Then the stochastic integral

$$\int_a^t \Phi dW$$

is defined as

$$\lim_{n \to \infty} \int_a^t \Phi_n dW$$

in $L^2 \left(\Omega; H\right)$

where $W(t)$ is a Wiener process

$$\sum_{k=1}^{\infty} \psi_k(t) Jg_k, \quad \{g_k\} \text{ orthonormal in } Q^{1/2}U,$$
and \( \Phi_n \) is an elementary function which has values in \( \mathcal{L}(U, H) \) and converges to \( \Phi \circ J^{-1} \) in
\[
L^2\left([a, T] \times \Omega; \mathcal{L}_2\left(JQ^{1/2}U, H\right)\right),
\]
such a sequence exists by Lemma \[63.4.3\] and Proposition \[63.3.2\].

It is necessary to show that this is well defined and does not depend on the choice of \( U_1 \) and \( J \).

**Theorem 63.5.3** The stochastic integral \[63.5.7\] is well defined. It also is a continuous martingale and does not depend on the choice of \( J \) and \( U_1 \). Furthermore,
\[
E\left(\left|\int_a^t \Phi(s) \, dW\right|^2_H\right) = \int_a^t E\left(||\Phi||^2_{\mathcal{L}_2(JQ^{1/2}U, H)}\right) \, ds
\]

**Proof:** First of all, it is obvious that it is well defined in the sense that the same stochastic process is obtained from two different sequences of elementary functions. This follows from the isometry of Proposition \[63.1.5\] with \( U_1 \) in place of \( U \) and \( Q^{1/2}U \) in place of \( U_0 \). Thus if \( \{\Psi_n\} \) and \( \{\Phi_n\} \) are two sequences of elementary functions converging to \( \Phi \circ J^{-1} \) in \( L^2\left([a, T] \times \Omega; \mathcal{L}_2\left(JQ^{1/2}U, H\right)\right) \),
\[
E\left(\left|\int_a^T (\Phi_n(s) - \Psi_n(s)) \, dW\right|^2_H\right) = \int_a^T E\left(||(\Phi_n - \Psi_n) \circ J||^2_{\mathcal{L}_2(JQ^{1/2}U, H)}\right) \, ds
\]
Now for \( \Phi \in \mathcal{L}_2(U, H) \) and \( \{g_k\} \) an orthonormal basis for \( Q^{1/2}U \),
\[
||\Phi \circ J||^2_{\mathcal{L}_2(JQ^{1/2}U, H)} = \sum_{k=1}^\infty |\Phi(J(g_k))|^2_H = ||\Phi||^2_{\mathcal{L}_2(JQ^{1/2}U, H)}
\]
because, by definition, \( \{Jg_k\} \) is an orthonormal basis in \( JQ^{1/2}U \). Hence \[63.5.8\] reduces to
\[
\int_a^T E\left(||(\Phi_n - \Psi_n)||^2_{\mathcal{L}_2(JQ^{1/2}U, H)}\right) \, ds
\]
which is given to converge to 0. This reasoning also shows that the sequence \( \left\{\int_a^t \Phi_n \, dW\right\} \) is indeed a Cauchy sequence in \( L^2(\Omega, H) \).
Why is \( \int_a^t \Phi dW \) a continuous martingale? The integrals \( \int_a^t \Phi_n dW \) are martingales and so, by the maximal estimate of Theorem 60.5.3,

\[
P \left( \sup_{t \in [a,T]} \left| \int_a^t \Phi_n dW - \int_a^t \Phi_m dW \right|_H \geq \lambda \right) \leq \frac{1}{\lambda^2} E \left( \int_a^T (\Phi_n - \Phi_m) dW \right)^2
\]

\[
= \frac{1}{\lambda^2} \int_a^T E \left( \| (\Phi_n - \Phi_m) \circ J \|_{\mathcal{L}_2(Q^{1/2}U,H)}^2 \right) ds
\]

which is given to converge to 0 as \( m, n \to \infty \). Therefore, there exists a subsequence \( \{n_k\} \) such that

\[
P \left( \sup_{t \in [a,T]} \left| \int_a^t \Phi_{n_k} dW - \int_a^t \Phi_{n_{k+1}} dW \right|_H \geq 2^{-k} \right) \leq 2^{-k}.
\]

Consequently, by the Borel Cantelli lemma, there is a set of measure zero \( N \) such that if \( \omega \notin N \), then the convergence of \( \int_a^t \Phi_{n_k} dW \) to \( \int_a^t \Phi dW \) is uniform on \( [a,T] \).

Hence \( t \to \int_a^t \Phi dW \) is continuous as claimed.

Why is it a martingale? Let \( s < t \) and \( A \in \mathcal{F}_s \). Then

\[
\int_A \left( \int_a^t \Phi dW \right) dP = \lim_{n \to \infty} \int_A \left( \int_a^t \Phi_n dW \right) dP = \lim_{n \to \infty} \int_A E \left( \left( \int_a^t \Phi_n dW \right) | \mathcal{F}_s \right) dP
\]

\[
= \lim_{n \to \infty} \int_A \left( \int_a^s \Phi_n dW \right) dP = \int_A \left( \int_a^s \Phi dW \right) dP
\]

Hence this is a martingale as claimed.

It remains to verify that the stochastic process does not depend on \( J \) and \( U_1 \). Let the approximating sequence of elementary functions be

\[
\Phi_n (t) = \sum_{j=0}^{m_n} f_j^n \chi_{(t_j^n, t_{j+1}^n]} (t)
\]

where \( f_j^n \) is \( \mathcal{F}_{t_j^n} \) measurable and has finitely many values in \( \mathcal{L}(U_1,H)_0 \), the restrictions of things in \( \mathcal{L}(U_1,H) \) to \( JQ^{1/2}U \). These are the elementary functions which converge to \( \Phi \circ J^{-1} \). Also let the partitions be such that

\[
\Phi^n \circ J^{-1} = \sum_{j=0}^{m_n} \Phi \left( t_j^n \right) \circ J^{-1} \chi_{(t_j^n, t_{j+1}^n]} \quad (63.5.10)
\]

converges to \( \Phi \circ J^{-1} \) in \( L^2 ([a,T] \times \Omega; \mathcal{L}_2 \left( JQ^{1/2}(U),H \right)) \). Then by definition,

\[
\int_a^t \Phi_n dW = \sum_{j=0}^{m_n} f_j^n \left( W (t \wedge t_{j+1}^n) - W (t \wedge t_j^n) \right)
\]
63.5. THE GENERAL INTEGRAL

\[
= \sum_{j=0}^{m_n} f_j^n \sum_{k=1}^{\infty} (\psi_k (t \wedge t_j^n + 1) - \psi_k (t \wedge t_j^n)) J g_k
\]

where \( \{g_k\} \) is an orthonormal basis for \( Q^{1/2} U \). The infinite sum converges in \( L^2 (\Omega; U) \) and \( f_j^n \) is continuous on \( U_1 \). Therefore, \( f_j^n \) can go inside the infinite sum, and this last expression equals

\[
= \sum_{j=0}^{m_n} \sum_{k=1}^{\infty} (\psi_k (t \wedge t_{k+1}) - \psi_k (t \wedge t_k)) f_j^n J g_k, \tag{63.5.11}
\]

the infinite sum converging in \( L^2 (\Omega, H) \).

Now consider the left sum 63.5.10. Since \( \Phi (t_j^n) \in L_2 (Q^{1/2} U, H) \), it follows that the sum

\[
\sum_{k=1}^{\infty} (\psi_k (t \wedge t_j^n + 1) - \psi_k (t \wedge t_j^n)) \Phi (t_j^n) g_k
\]

\[
= \sum_{k=1}^{\infty} (\psi_k (t \wedge t_{j+1}) - \psi_k (t \wedge t_j^n)) \Phi (t_j^n) \circ J^{-1} (J g_k) \tag{63.5.12}
\]

must converge in \( L^2 (\Omega, H) \). Let's review why this is.

**Diversion** The reason the series converges goes as follows. Estimate

\[
E \left( \sum_{k=p}^{q} (\psi_k (t \wedge t_{j+1}) - \psi_k (t \wedge t_j^n)) \Phi (t_j^n) g_k \right)^2_H
\]

First consider the mixed terms. Let \( \Delta \psi_k = \psi_k (t \wedge t_{j+1}) - \psi_k (t \wedge t_j^n) \). For \( l < k \),

\[
E \left( (\Delta \psi_k \Phi (t_j^n) g_k, \Delta \psi_l \Phi (t_j^n) g_l) \right) = E \left( \Delta \psi_k \Delta \psi_l \left( \Phi (t_j^n) g_k, \Phi (t_j^n) g_l \right) \right)
\]

Now by independence, this equals

\[
E (\Delta \psi_k) E (\Delta \psi_l) E \left( \left( \Phi (t_j^n) g_k, \Phi (t_j^n) g_l \right) \right) = 0
\]

Thus you only need to consider the non mixed terms, and the thing you want to estimate is of the form

\[
\sum_{k=p}^{q} E \left( \left( \psi_k (t \wedge t_{j+1}) - \psi_k (t \wedge t_j^n) \right) \Phi (t_j^n) g_k \right)^2
\]
Now by independence again, this equals
\[ \sum_{k=p}^{q} E \left( (\Delta \psi_k \Phi \left( t_j^n \right) g_k, \Delta \psi_k \Phi \left( t_j^n \right) g_k) \right) \]
\[ = \sum_{k=p}^{q} E \left( \Delta \psi_k^2 \left( \Phi \left( t_j^n \right) g_k, \Phi \left( t_j^n \right) g_k \right) \right) \]
\[ = \sum_{k=p}^{q} E \left( \Delta \psi_k^2 \right) E \left( \Phi \left( t_j^n \right) g_k, \Phi \left( t_j^n \right) g_k \right) \]
\[ = \left( (t \wedge t_{j+1}^n) - (t \wedge t_j^n) \right) \sum_{k=p}^{q} E \left( |\Phi \left( t_j^n \right) g_k|^2 \mathbf{H} \right) \]
and this sum is just a part of the convergent infinite sum for
\[ \int_{\Omega} \| \Phi \left( t_j^n \right) \|^2_{\mathcal{L}_2 (Q^{1/2} U; \mathbf{H})} \, dP < \infty \]
Therefore, this converges to 0 as \( p, q \to \infty \) and so the sum converges in \( L^2 (\Omega, H) \) as claimed.

**End of diversion**

The \( J \) and the \( J^{-1} \) cancel in \( \| \mathbf{B} \|_2 \) because \( J \) is one to one. It follows that
\[ \sum_{j=0}^{m_n} \sum_{k=1}^{\infty} (\psi_k \left( t \wedge t_{j+1}^n \right) - \psi_k \left( t \wedge t_j^n \right)) \Phi \left( t_j^n \right) g_k + \]
\[ \sum_{j=0}^{m_n} \sum_{k=1}^{\infty} (\psi_k \left( t \wedge t_{j+1}^n \right) - \psi_k \left( t \wedge t_j^n \right)) \left( (f_j^n - \Phi \left( t_j^n \right) \circ J^{-1} \right) (J g_k) \]
The first expression does not depend on \( J \) or \( U_1 \). I need only argue that the second expression converges to 0 as \( n \to \infty \). The infinite sum converges in \( L^2 (\Omega; H) \) and also, as in the above diversion, the independence of the \( \psi_k \) implies that
\[ E \left( \sum_{j=0}^{m_n} \sum_{k=1}^{\infty} (\psi_k \left( t \wedge t_{j+1}^n \right) - \psi_k \left( t \wedge t_j^n \right)) \left( (f_j^n - \Phi \left( t_j^n \right) \circ J^{-1} \right) (J g_k) \right)^2_{\mathbf{H}} \]
\[ = \sum_{j=0}^{m_n} (t \wedge t_{j+1}^n - t \wedge t_j^n) \sum_{k=1}^{\infty} E \left( \| f_j^n - \Phi \left( t_j^n \right) \circ J^{-1} \right) (J g_k) \right)^2_{\mathbf{H}} \]
\[ = \sum_{j=0}^{m_n} (t \wedge t_{j+1}^n - t \wedge t_j^n) E \left( \| f_j^n - \Phi \left( t_j^n \right) \circ J^{-1} \right)^2_{\mathcal{L}_2 (Q^{1/2} U; \mathbf{H})} \]
\[ = \int_{a}^{t} E \left( \| \Phi_n - \Phi_n \circ J^{-1} \right)^2_{\mathcal{L}_2 (Q^{1/2} U; \mathbf{H})} \right) \, ds \]
which is given to converge to 0 since both converge to \( \Phi \circ J^{-1} \). Consequently, the stochastic integral defined above does not depend on \( J \) or \( U_1 \).

It is interesting to note that in the above definition, the approximate problems do appear to depend on \( J \) and \( U_1 \) but the limiting stochastic process does not. Since it is the case that the stochastic integral is independent of \( U_1 \) and \( J \); it can only be dependent on \( Q_1 = 2U \) and \( U \); and so we refer to \( W(t) \) as a cylindrical process on \( U \).

By Lemma 63.4.3 you can take \( U_1 = U \) and so you can consider the finite sums defining the Wiener process to be in \( U \) itself. From the proof of this lemma, you can even have \( J \) being the identity on the span of the first \( n \) vectors in the orthonormal basis for \( Q_1 = 2U \). The case where \( Q \) is trace class follows in the next section. In this case, \( W \) is an actual \( Q \) Wiener process on \( U \).

The following corollary follows right away from the above theorem.

**Corollary 63.5.4** Let \( \Phi, \Psi \in L^2 \left([a,T] \times \Omega; \mathcal{L}_2 \left(Q^{1/2}U, H\right)\right) \) and suppose they are both progressively measurable. Then

\[
E \left( \left( \int_a^t \Phi dW, \int_a^t \Psi dW \right)_H \right) = E \left( \int_a^t (\Phi, \Psi)_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)} \, ds \right)
\]

Also if \( L \) is in \( L^\infty (\Omega, \mathcal{L}(H, H)) \) and is \( \mathcal{F}_a \) measurable, then

\[
L \int_a^t \Phi dW = \int_a^t L \Phi dW \tag{63.5.13}
\]

and

\[
E \left( \left( L \int_a^t \Phi dW, \int_a^t \Psi dW \right)_H \right) = E \left( \int_a^t (L\Phi, \Psi)_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)} \, ds \right). \tag{63.5.14}
\]

**Proof:** First note that

\[
\left( \int_a^t \Phi dW, \int_a^t \Psi dW \right)_H = \frac{1}{4} \left[ \left\| \int_a^t (\Phi + \Psi) \, dW \right\|_H^2 - \left\| \int_a^t (\Phi - \Psi) \, dW \right\|_H^2 \right]
\]

and so from the above theorem,

\[
E \left( \left( \int_a^t \Phi dW, \int_a^t \Psi dW \right)_H \right) =
E \left( \frac{1}{4} \left[ \left\| \int_a^t (\Phi + \Psi) \, dW \right\|_H^2 - \left\| \int_a^t (\Phi - \Psi) \, dW \right\|_H^2 \right] \right)
\]

\[
= \frac{1}{4} E \left( \int_a^t \|\Phi + \Psi\|_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)}^2 \, ds \right) + \frac{1}{4} E \left( \int_a^t \|\Phi - \Psi\|_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)}^2 \, ds \right)
\]

\[
= E \left( \int_a^t \frac{1}{4} \left[ \|\Phi + \Psi\|_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)}^2 + \|\Phi - \Psi\|_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)}^2 \right] \, ds \right)
\]

\[
= E \left( \int_a^t (\Phi, \Psi)_{\mathcal{L}_2 \left(Q^{1/2}U, H\right)} \, ds \right).
\]
Now consider the last claim. First suppose \( L = lX_A \) where \( A \in \mathcal{F}_a \), and \( l \in \mathcal{L}(H,H) \). Also suppose \( \Phi \) is an elementary function

\[
\Phi = \sum_{i=0}^{n} \psi_i X_{(s_i, s_{i+1}]}(t)
\]

Then

\[
L \int_a^t \Phi \, dW = lX_A \sum_{i=0}^{n} \psi_i (W(t \wedge s_{i+1}) - W(t \wedge s_i)) = \sum_{i=0}^{n} lX_A \psi_i (W(t \wedge s_{i+1}) - W(t \wedge s_i))
\]

Thus (3.13) also holds for \( L \) a simple function which is \( \mathcal{F}_a \) measurable. For general \( L \in L^\infty(\Omega, \mathcal{L}(H,H)) \), approximating with a sequence of such simple functions \( L_n \) yields

\[
L \int_a^t \Phi \, dW = \lim_{n \to \infty} L_n \int_a^t \Phi \, dW = \lim_{n \to \infty} \int_a^t L_n \Phi \, dW = \int_a^t L \Phi \, dW
\]

because \( L_n \Phi \to L \Phi \) in \( L^2([a,T] \times \Omega; \mathcal{L}_2(Q^{1/2}U,H)) \). Now what about general \( \Phi \)? Let \( \{ \Phi_n \} \) be elementary functions converging to \( \Phi \circ J^{-1} \) in \( L^2([a,T] \times \Omega; \mathcal{L}_2(JQ^{1/2}U,H)) \). Then by definition of the integral,

\[
L \int_a^t \Phi dW = \lim_{n \to \infty} L \int_a^t \Phi_n dW = \lim_{n \to \infty} \int_a^t L \Phi_n dW = \int_a^t L \Phi dW
\]

The remaining claim now follows from the first part of the proof. 

The above has discussed the integral of \( \Phi \in L^2([a,T] \times \Omega; \mathcal{L}_2(Q^{1/2}U,H)) \). An obvious case to consider is when

\[
\Phi = \sum_{k=0}^{n-1} \Phi_k X_{(t_k, t_{k+1}]}(t)
\]

and \( \Phi_k \in L^2(\Omega; \mathcal{L}_2(Q^{1/2}U,H)) \) with \( \Phi_k \) measurable with respect to \( \mathcal{F}_{t_k} \). What is \( \int_0^t \Phi \, dW \)? First note that \( \Phi_k \circ J^{-1} \in L^2(\Omega; \mathcal{L}_2(JQ^{1/2}U,H)) \). Let \( \lim_{m \to \infty} \Phi_k^m \to \Phi_k \circ J^{-1} \) in \( L^2(\Omega; \mathcal{L}_2(JQ^{1/2}U,H)) \) where \( \Phi_k^m \) is \( \mathcal{F}_{t_k} \) measurable and is a simple function having values in \( \mathcal{L}(U_1,H) \). Thus

\[
\Phi_m = \sum_{k=0}^{n-1} \Phi_k^m X_{(t_k, t_{k+1}]}(t)
\]

is an elementary function and it converges to \( \Phi \circ J^{-1} \) in \( L^2([a,T] \times \Omega; \mathcal{L}_2(JQ^{1/2}U,H)) \).
It follows that
\[
\int_a^t \Phi dW = \lim_{m \to \infty} \int_a^t \Phi_m dW = \lim_{m \to \infty} \sum_{k=0}^{n-1} \Phi_k^m (W(t \wedge t_{k+1}) - W(t \wedge t_k))
\]
\[= \sum_{k=0}^{n-1} \Phi_k \circ J^{-1} (W(t \wedge t_{k+1}) - W(t \wedge t_k)).\]

Note again how it appears to depend on $J$ but really doesn’t because there is a $J$ in the definition of $W$.

63.6 The Case That $Q$ Is Trace Class

In this special case, you have a $Q$ Wiener process with values in $U$ and still you have
\[
\Phi \in L^2 ([a, T] \times \Omega; \mathcal{L}_2 (Q^{1/2}U, H))
\]
with $\Phi$ progressively measurable. The difference here is that in fact, $Q$ is trace class.

\[
Q = \sum_{i=1}^{L} \lambda_i e_i \otimes e_i
\]
where $\lambda_i > 0$, $\sum_i \lambda_i < \infty$, and the $e_i$ form an orthonormal set of vectors. $L$ is either a positive integer or $\infty$. Then let $U_0 = Q^{1/2}U$. Then $Q^{1/2} = \sum_{i=1}^{L} \sqrt{\lambda_i} e_i \otimes e_i$ because this works, and the square root is unique. Hence $Q^{1/2}e_i = \sqrt{\lambda_i} e_i$ and so an orthonormal basis for $U_0 = Q^{1/2}U$ is $\{\sqrt{\lambda_i} e_i\}_{i=1}^{L}$. Now consider $J = \sum_{i=1}^{L} \sqrt{\lambda_i} (e_i \otimes \sqrt{\lambda_i} e_i)$, $J : U_0 \to U$, where the tensor product is defined in the usual way,
\[
u \otimes v (w) \equiv u(w, v)_{U_0}.
\]
Then $J^* = \sum_{i=1}^{L} \sqrt{\lambda_i} (\sqrt{\lambda_i} e_i \otimes e_i)$ and $JJ^* = \sum_{i=1}^{L} \lambda_i e_i \otimes e_i = Q$. Also, $J$ is a Hilbert Schmidt map into $U$ from $U_0$.

\[
\sum_{i=1}^{L} \left\| J \left( \sqrt{\lambda_i} e_i \right) \right\|_U^2 = \sum_{i=1}^{L} \left\| \sqrt{\lambda_i} e_i \right\|_U^2 = \sum_{i=1}^{L} \lambda_i < \infty
\]
and so $J$ is a Hilbert Schmidt mapping. In addition to this, from the construction, the span of $\{e_i\}_{i=1}^{L}$ is dense in $U_0$ and $Je_i = e_i$ because
\[
J e_k = \sum_{i=1}^{L} \sqrt{\lambda_i} (e_i \otimes \sqrt{\lambda_i} e_i) (e_k) = e_k \sqrt{\lambda_k} (\sqrt{\lambda_k} e_k)_{U_0} = e_k
\]
so in fact $J$ is just the injection map of $U_0$ into $U$. Hence $J^{-1}$ must also be the identity map. Now we can let $U_1 = \tilde{U}$ with $J$ the injection map. Thus, in this case, the elementary functions $\Phi_n$ simply converge to $\Phi$ in
\[
L^2 ([a, T] \times \Omega; \mathcal{L}_2 (JU_0, H))
\]
CHAPTER 63. STOCHASTIC INTEGRATION

Note that $\| J \sqrt{\lambda} \epsilon_i \|_U = \sqrt{\lambda}$ whereas $\| \sqrt{\lambda_i} \epsilon_i \|_{O^1(U)} = 1$, and so $J$ definitely does not preserve norms. That is, the norm in $U_0$ is not the same as the norm in $U$. Then everything else is the same. In particular

$$E \left( \int_a^t \Phi dW \right)_H = \int_a^t E \left( \| \Phi \|_{\mathcal{L}_2(U_0,H)}^2 \right) ds.$$  

63.7 A Short Comment On Measurability

It will also be important to consider the composition of functions. The following is the main result. With the explanation of progressively measurable given, it says the composition of progressively measurable functions is progressively measurable.

**Proposition 63.7.1** Let $A : [a;T] \times V \times \Omega \to U$ where $V, U$ are topological spaces and suppose $A$ satisfies its restriction to $[a,t] \times V \times \Omega$ is $\mathcal{B}([a,t]) \times \mathcal{B}(V) \times \mathcal{F}_t$ measurable. This will be referred to as $A$ is progressively measurable. Then if $X : [a;T] \times \Omega \to V$ is progressively measurable, then so is the map

$$(t, \omega) \to A(t, X(t, \omega), \omega)$$

**Proof:** Consider the restriction of this map to $[a,t_0] \times \Omega$. For such $(t, \omega)$, to say

$$A(t, X(t, \omega), \omega) \in O$$

for $O$ a Borel set in $U$ is to say that

$$X(t, \omega) \in \{ v : (t, v, \omega) \in A^{-1}(O), t \leq t_0 \} \equiv A^{-1}(O)_{t,\omega}$$

Consider the set

$$\{ (t, \omega) \in [a,t_0] \times \Omega : X(t, \omega) \in A^{-1}(O)_{t,\omega} \}$$

Is this in $\mathcal{B}([a,t_0]) \times \mathcal{F}_{t_0}$? This is what needs to be checked. Since $A$ is progressively measurable,

$$A^{-1}(O) \cap [a,t_0] \times V \times \Omega \in \mathcal{B}([a,t_0]) \times \mathcal{B}(V) \times \mathcal{F}_{t_0} \equiv \mathcal{P}_{t_0}$$

because $A^{-1}(O)$ is a progressively measurable set. So let

$$\mathcal{G} \equiv \{ S \in \mathcal{P}_{t_0} : \{ (t, \omega) \in [a,t_0] \times \Omega : X(t, \omega) \in S_{t,\omega} \} \in \mathcal{B}([a,t_0]) \times \mathcal{F}_{t_0} \}$$

It is clear that $\mathcal{G}$ contains the $\pi$ system composed of sets of the form $I \times B \times W$ where $I$ is an interval in $[a,t_0]$, $B$ is Borel, and $W \in \mathcal{F}_{t_0}$. This is because for $S$ of this form, $S_{t,\omega} = B$ or $\emptyset$. Thus if not empty,

$$\{ (t, \omega) \in [a,t_0] \times \Omega : X(t, \omega) \in S_{t,\omega} \} = X^{-1}(B) \cap [0,t_0] \times \Omega \in \mathcal{B}([a,t_0]) \times \mathcal{F}_{t_0}$$
because $X$ is given to be progressively measurable. Now if $S \in \mathcal{G}$, what about $S^C$?
You have $(S^C)_{t\omega} = (S_{t\omega})^C$ thus
\[
\{(t, \omega) \in [a, t_0] \times \Omega : X(t, \omega) \in (S^C)_{t\omega}\} = \{(t, \omega) \in [a, t_0] \times \Omega : X(t, \omega) \in (S_{t\omega})^C\}
\]
which is the complement with respect to $[a, t_0] \times \Omega$ of a set in $\mathcal{B}([a, t_0]) \times \mathcal{F}_{t_0}$.
Therefore, $\mathcal{G}$ is closed with respect to complements. It is clearly closed with respect to countable disjoint unions. It follows, $\mathcal{G} = \mathcal{P}_{t_0}$. Thus
\[
\{(t, \omega) \in [a, t_0] \times \Omega : X(t, \omega) \in S_{t\omega}\} \in \mathcal{B}([a, t_0]) \times \mathcal{F}_{t_0}
\]
where $S = A^{-1} (O) \cap [a, t_0] \times V \times \Omega$. In other words,
\[
\{(t, \omega), t \leq t_0 : A(t, X(t, \omega), \omega) \in O\} \in \mathcal{B}([0, t_0]) \times \mathcal{F}_{t_0}
\]
and so $(t, \omega) \rightarrow A(t, X(t, \omega), \omega)$ is progressively measurable. ■

63.8 Localization For Elementary Functions

It is desirable to extend everything to stochastically square integrable functions. This will involve localization using a suitable stopping time. First it is necessary to understand localization for elementary functions. As above, we are in the situation described by the following diagram.

\[
\begin{array}{ccc}
U_1 & \supseteq & JQ^{1/2}U \\
\downarrow & U & \downarrow \\
\Phi_n & \Phi & \downarrow \\
\Phi_n & \downarrow & H \\
\end{array}
\]

The elementary functions $\{\Phi_n\}$ have values in $\mathcal{L} (U_1, H)_0$ meaning they are restrictions of functions in $\mathcal{L} (U_1, H)$ to $JQ^{1/2}U$ and converge to $\Phi \circ J^{-1}$ in
\[
L^2 \left( [a, T] \times \Omega; \mathcal{L}_2 \left( JQ^{1/2}U, H \right) \right)
\]
where $\Phi \in L^2 \left( [a, T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right)$ is given. Let
\[
\Phi(t) = \sum_{k=0}^{n-1} \Phi(t_k) \mathcal{X}_{[t_k, t_{k+1}]}(t)
\]
be an elementary function. In particular, let $\Phi(t_k)$ be $\mathcal{F}_{t_k}$ measurable as a map into $\mathcal{L} (U_1, H)$, and has finitely many values. As just mentioned, the topic of interest
is the elementary functions \(\Phi_n\) in the above diagram. Thus \(\Phi\) will be one of these elementary functions.

Let \(\tau\) be a stopping time having values from the set of mesh points \(\{t_k\}\) for the elementary function. Then from the definition of the integral for elementary functions,

\[
\int_a^{t^{\land}\tau} \Phi dW \equiv \sum_{k=0}^{n-1} \Phi(t_k) \left( W(t^{\land}\tau \land t_{k+1}) - W(t^{\land}\tau \land t_k) \right)
\]

If \(\omega\) is such that \(\tau(\omega) = t_j\), then to get something nonzero, you must have \(t_j > t_k\) so \(k \leq j - 1\). Thus the above on the right reduces to

\[
\sum_{k=0}^{j-1} \Phi(t_k) \left( W(t^{\land}t_{k+1}) - W(t^{\land}t_k) \right)
\]

It clearly is 0 if \(j = 0\). Define \(\sum_{k=0}^{j-1} \equiv 0\). Thus the integral equals

\[
\sum_{j=0}^{n} \mathcal{X}_{[t^{\land}t_j]} \sum_{k=0}^{j-1} \Phi(t_k) \left( W(t^{\land}t_{k+1}) - W(t^{\land}t_k) \right)
\]

Interchanging the order of summation, \(k \leq j - 1\) so \(j \geq k + 1\) and this equals

\[
\sum_{k=0}^{n-1} \sum_{j=k+1}^{n} \mathcal{X}_{[t^{\land}t_j]} \Phi(t_k) \left( W(t^{\land}t_{k+1}) - W(t^{\land}t_k) \right)
\]

\[
= \sum_{k=0}^{n-1} \mathcal{X}_{[t^{\land}t_k]} \Phi(t_k) \left( W(t^{\land}t_{k+1}) - W(t^{\land}t_k) \right)
\]

Therefore

\[
\int_a^{t^{\land}\tau} \Phi dW = \int_a^t \sum_{k=0}^{n-1} \mathcal{X}_{[t^{\land}t_k]} \Phi(t_k) \mathcal{X}_{(t_k,t_{k+1})} dW \quad (63.8.15)
\]

Now observe

\[
\mathcal{X}_{[a,\tau]}(t) \Phi(t) = \sum_{k=0}^{n-1} \mathcal{X}_{[a,\tau]}(t) \Phi(t_k) \mathcal{X}_{(t_k,t_{k+1})}(t)
\]

\[
= \sum_{k=0}^{n-1} \mathcal{X}_{[t^{\land}t_k]} \Phi(t_k) \mathcal{X}_{(t_k,t_{k+1})}(t)
\]

\[
= \sum_{k=0}^{n-1} \mathcal{X}_{[t^{\land}t_k]} \Phi(t_k) \mathcal{X}_{(t_k,t_{k+1})}(t) \quad (63.8.16)
\]

The last step occurs because of the following reasoning. The \(k^{th}\) term of the sum in the middle expression above equals \(\Phi(t_k)\) if and only if \(t > t_k\) and \(\tau \geq t\). If the
two conditions do not hold, then the \( k \)th term equals 0. As to the third line, if \( \tau > t_k \) and \( t \in (t_k, t_{k+1}] \), then \( \tau \geq t_{k+1} \geq t \) which is the same as the situation in the second line. The term equals \( \Phi (t_k) \). Note that \( \chi_{[\tau > t_k]} (\omega) \) is \( \mathcal{F}_t \) measurable, because \( [\tau > t_k] \) is the complement of \( [\tau \leq t_k] \). Therefore, this is an elementary function. Thus, from Proposition 63.8.15, if you have two of these elementary functions

\[
\int_a^{t^\wedge \tau} \Phi dW = \int_a^t \sum_{k=0}^{n-1} \chi_{[\tau > t_k]} \Phi (t_k) \chi_{(t_k, t_{k+1}]} (t) \, dW = \int_a^t \chi_{[a, \tau]} (t) \Phi (t) \, dW
\]

From Proposition 63.8.15, if you have \( \Phi, \Psi \) two of these elementary functions

\[
E \left( \left\| \int_a^t \chi_{[a, \tau]} (t) \Phi (t) \, dW - \int_a^t \chi_{[a, \tau]} (t) \Psi (t) \, dW \right\|^2 \right) = \int_a^t \int_\Omega \chi_{[a, \tau]} (t) \left\| (\Phi (s) - \Psi (s)) \circ J \right\|^2_{L_2(Q^{1/2}U; H)} \, dPds
\]

\[
\leq \int_a^t \int_\Omega \left\| (\Phi (s) - \Psi (s)) \circ J \right\|^2_{L_2(Q^{1/2}U; H)} \, dPds
\]  

(63.8.17)

63.9 Localization In General

Next, what about the general case where \( \Phi \in L^2 ([a, T] \times \Omega; L_2(Q^{1/2}U, H)) \) and is progressively measurable? Is it the case that for an arbitrary stopping time \( \tau \),

\[
\int_a^{t^\wedge \tau} \Phi dW = \int_a^t \chi_{[a, \tau]} \Phi dW?
\]

This is the sort of thing which would be expected for an ordinary Stieltjes integral which of course this isn’t. Let

\[
L^2 ([a, T] \times \Omega; L_2(Q^{1/2}U, H)) = K
\]

From Doob’s result Proposition and Lemma there exists a sequence of elementary functions \( \{ \Phi_k \} \)

\[
\Phi_k (t) = \sum_{j=0}^{m_k - 1} \Phi (t_j^k) \chi_{(t_j^k, t_{j+1}^k]} (t)
\]

which converges to \( \Phi \circ J^{-1} \) in \( K \) where also the lengths of the sub intervals converge uniformly to 0 as \( k \to \infty \).

Now let \( \tau \) be an arbitrary stopping time. The partition points corresponding to \( \Phi_k \) are \( \{ t_j^k \}_{j=0}^{m_k} \). Let \( \tau_k = t_j^k + 1 \) on \( \tau^{-1}(t_j^k, t_{j+1}^k] \). Then \( \tau_k \) is a stopping time because

\[
[\tau_k \leq t] \in \mathcal{F}_t
\]
Here is why. If \( t \in (t_j^k, t_{j+1}^k) \), then if \( t = t_j^k \), it would follow that \( \tau_k(\omega) \leq t \) would be the same as saying \( \omega \in [\tau \leq t_{j+1}^k] = [\tau \leq t] \in \mathcal{F}_t \). On the other hand, if \( t < t_{j+1}^k \), then \( [\tau_k \leq t] = [\tau \leq t_j^k] \in \mathcal{F}_{t_j^k} \subseteq \mathcal{F}_t \) because \( \tau_k \) can only take the values \( t_j^k \).

Consider \( X_{[a,\tau_k]} \Phi_k \). It is given that \( \Phi_k \to \Phi \circ J^{-1} \) in \( K \). Does it follow that \( X_{[a,\tau_k]} \Phi_k \to X_{[a,\tau]} \Phi \circ J^{-1} \) in \( K \)? Consider first the indicator function. Let \( \tau(\omega) \in (t_j^k, t_{j+1}^k) \). Fixing \( t \), \( X_{[a,\tau]}(t) = 1 \), then also \( X_{[a,\tau_k]}(t) = 1 \) because \( \tau_k \geq \tau \). Therefore, in this case \( \lim_{k \to \infty} X_{[a,\tau_k]}(t) = X_{[a,\tau]}(t) \). Next suppose \( X_{[a,\tau]}(t) = 0 \) so that \( \tau(\omega) < t \). Since the intervals defined by the partition points have lengths which converge to 0, it follows that for all \( k \) large enough, \( \tau_k(\omega) < t \) also and so \( X_{[a,\tau_k]}(t) = 0 \). Therefore,

\[
\lim_{k \to \infty} X_{[a,\tau_k]}(\omega)(t) = X_{[a,\tau]}(\omega)(t).
\]

It follows that \( X_{[a,\tau_k]} \Phi_k \to X_{[a,\tau]} \Phi \circ J^{-1} \) in \( K \). From Theorem 33.3, the function \( X_{[a,\tau_k]} \Phi_k \) is progressively measurable. Therefore, the same is true of \( X_{[a,\tau]} \Phi \circ J^{-1} \).

From the proof of Theorem 33.3, the part depending on maximal estimates and the fact that \( \int_a^t X_{[a,\tau]} \Phi_k \, dW \) is a continuous martingale, there is a set of measure zero \( N \), such that off this set, a suitable subsequence satisfies

\[
\int_a^t X_{[a,\tau_k]} \Phi_k \, dW \to \int_a^t X_{[a,\tau]} \Phi \, dW
\]

uniformly on \([a, T]\). But also, since \( \Phi_k \to \Phi \circ J^{-1} \) in \( K \), a suitable subsequence satisfies,

\[
\int_a^t \Phi_k \, dW \to \int_a^t \Phi \, dW
\]

uniformly on \([a, T]\) a.e. \( \omega \). In particular, \( \int_a^{t \wedge \tau_k} \Phi_k \, dW \to \int_a^{t \wedge \tau} \Phi \, dW \). Therefore,

\[
\int_a^t X_{[a,\tau]} \Phi \, dW = \lim_{k \to \infty} \int_a^t X_{[a,\tau_k]} \Phi_k \, dW = \lim_{k \to \infty} \int_a^{t \wedge \tau_k} \Phi_k \, dW = \int_a^{t \wedge \tau} \Phi \, dW
\]

This has proved the following major localization lemma. This is a marvelous result. It says that the stochastic integral acts algebraically like an ordinary Stieltjes integral, one for each \( \omega \) off a set of measure zero.

**Lemma 63.9.1** Let \( \Phi \) be progressively measurable and in

\[
L^2 \left( [a, T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2} U, H \right) \right)
\]

Let \( W(t) \) be a cylindrical Wiener process as described above. Then for \( \tau \) a stopping time, \( X_{[a,\tau]} \Phi \) is progressively measurable, in \( K \), and

\[
\int_a^{t \wedge \tau} \Phi \, dW = \int_a^t X_{[a,\tau]} \Phi \, dW.
\]
63.10 The Stochastic Integral As A Local Martingale

With Lemma 63.9.1, it becomes possible to define the stochastic integral on functions which are only stochastically square integrable.

**Definition 63.10.1** \( \Phi \) is stochastically square integrable in \( L^2(Q^{1/2}U,H) \) if \( \Phi \) is progressively measurable and

\[
P \left( \left[ \int_a^T ||\Phi(s)||_{L^2(Q^{1/2}U,H)}^2 ds < \infty \right] \right) = 1
\]

Thus equivalently, there exists \( N \) such that \( P(N) = 0 \) and for \( \omega \notin N \),

\[
\int_a^T ||\Phi(s,\omega)||_{L^2(Q^{1/2}U,H)}^2 ds < \infty.
\]

**Lemma 63.10.2** Suppose \( \Phi \) is \( L^2(Q^{1/2}U,H) \) progressively measurable and

\[
P \left( \left[ \int_a^T ||\Phi||_{L^2(Q^{1/2}U,H)}^2 ds < \infty \right] \right) = 1.
\]

Define

\[
\tau_n(\omega) \equiv \inf \left\{ t \in [a,T]: \int_a^t ||\Phi||_{L^2(Q^{1/2}U,H)}^2 ds \geq n \right\},
\]

By convention, let \( \inf \emptyset = \infty \). Then \( \tau_n \) is a stopping time. Furthermore, \( \tau_n \) has the following properties.

1. \( \{\tau_n\} \) is an increasing sequence and for \( \omega \) outside a set of measure zero \( N \), for every \( t \in [a,T] \) there exists \( n \) such that \( \tau_n(\omega) > t \). (It is a localizing sequence of stopping times.)

2. For each \( n \), \( \chi_{[a,\tau_n]}\Phi \) is progressively measurable and

\[
E \left( \int_a^T ||\chi_{[a,\tau_n]}\Phi||_{L^2(Q^{1/2}U,H)}^2 dt \right) < \infty
\]

**Proof:** It follows from Proposition 63.10.2 that \( \tau_n \) is a stopping time because it is the first hitting time of a closed set by an adapted continuous process.

It remains to verify the two claims. There exists a set of measure 0, \( N \) such that for \( \omega \notin N \)

\[
\int_a^T ||\Phi||_{L^2(Q^{1/2}U,H)}^2 dt < \infty
\]
Therefore, for such \( \omega \), there exists \( n \) large enough that
\[
\int_a^t ||\Phi||^2_{L^2(Q^{1/2}U,H)} \, ds < n
\]
and so \( \tau_n(\omega) \geq t \). Now consider the second claim.
\[
E \left( \int_a^T ||\chi_{[a,\tau_n]}\Phi||^2_{L^2(Q^{1/2}U,H)} \, dt \right) = E \left( \int_a^{\tau_n(\omega)\land T} ||\Phi||^2_{L^2(Q^{1/2}U,H)} \, dt \right) \leq E(n) = n.
\]

With this lemma, it is possible to give the following definition.

**Definition 63.10.3** Suppose \( \Phi \) is \( L^2(Q^{1/2}U,H) \) progressively measurable and
\[
P \left( \int_a^T ||\Phi||^2_{L^2(Q^{1/2}U,H)} \, ds < \infty \right) = 1. \tag{63.10.18}
\]

More generally, suppose there exists a localizing sequence of stopping times \( \tau_n \) having the two properties of Lemma 63.10.2. Then for all \( \omega \) not in the exceptional set \( N \),
\[
\int_a^t \Phi dW = \lim_{n \to \infty} \int_a^t \chi_{[a,\tau_n]} \Phi dW
\]

**Lemma 63.10.4** The above definition is well defined. For all \( \omega \) not in a set of measure zero,
\[
\int_a^t \Phi dW (\omega) = \lim_{n \to \infty} \int_a^t \chi_{[a,\tau_n]} \Phi dW (\omega)
\]
the function on the right being constant for all \( n \) large enough for a given \( \omega \). The random variable \( \int_a^t \Phi dW \) is also \( \mathcal{F}_t \) adapted.

**Proof:** Let \( \{\tau_n\} \) be a sequence of stopping times as described in \( \Box \) and \( \Box \) of Lemma 63.10.2. Such a sequence exists by Lemma 63.10.2. It makes sense to define the random variable
\[
\int_a^t \chi_{[a,\tau_n]} \Phi dW
\]

Now what if both \( \tau_m \) and \( \tau_n \) are at least as large as \( t \) for some \( \omega \)? Do the two random variables coincide at that value of \( \omega \)? Say \( m > n \) so that \( \tau_m(\omega) \geq \tau_n(\omega) > t \). For the given \( \omega \),
\[
\int_a^t \chi_{[a,\tau_m]} \Phi dW = \int_a^{t \land \tau_m} \chi_{[a,\tau_m]} \Phi dW
\]
For the particular \( \omega \) of interest,
\[
= \int_a^{t \land \tau_n} \chi_{[a,\tau_m]} \Phi dW
\]
63.11. The Quadratic Variation of the Stochastic Integral

and this equals
\[ = \int_a^t X_{[a, \tau_n]} \Phi dW = \int_a^t X_{[a, \tau_m]} \Phi dW \]
for all \( \omega \), in particular for the given \( \omega \). Therefore, for the particular \( \omega \) of interest,
\[ \int_a^t X_{[a, \tau_n]} \Phi dW = \int_a^t X_{[a, \tau_m]} \Phi dW \]
Thus the limit exists because for all \( n \) large enough, the integral is eventually constant. Then \( \int_a^t \Phi dW \) is \( \mathcal{F}_t \) adapted because for \( U \) an open set in \( H \),
\[ \left( \int_a^t \Phi dW \right)^{-1} (U) = \cup_{n=1}^{\infty} \left( \left( \int_a^t X_{[a, \tau_n]} \Phi dW \right)^{-1} (U) \cap [\tau_n > t] \right) \in \mathcal{F}_t \]

The next lemma says that even when \( \int_a^t \Phi (s) dW (s) \) is only a local martingale relative to a suitable localizing sequence, it is still the case that
\[ \int_a^{t \wedge} \Phi dW = \int_a^t X_{[a, \sigma]} \Phi dW. \]

**Lemma 63.10.5** Let \( \Phi \) be progressively measurable and suppose there exists the localizing sequence described above. Then if \( \sigma \) is a stopping time,
\[ \int_a^{t \wedge} \Phi dW (s) = \int_a^t X_{[a, \sigma]} \Phi dW (s) \]

**Proof:** Let \( \{\tau_n\} \) be the localizing sequence described above for which, when the local martingale is stopped, it results in a martingale, (satisfying \( \mathbb{II} \) and \( \mathbb{II} \) on Page 2311). Then by definition,
\[ \int_a^{t \wedge} \Phi dW (s) = \lim_{n \to \infty} \int_a^{t \wedge \tau_n} \Phi dW (s) = \lim_{n \to \infty} \int_a^{t \wedge \tau_n} X_{[a, \sigma]} \Phi dW (s) = \int_a^t X_{[a, \sigma]} \Phi dW (s) \]

since \( t \wedge \tau_n = t \) for all \( n \) large enough. ■

63.11 The Quadratic Variation of the Stochastic Integral

An important corollary of Lemma 63.9.1 concerns the quadratic variation of \( \int_a^t \Phi dW \). It is convenient here to use the notation \( \int_a^t \Phi dW \equiv \Phi \cdot W (t) \). Recall this is a local submartingale \([\Phi \cdot W]\) such that
\[ ||\Phi \cdot W (t)||^2_H = [\Phi \cdot W] (t) + N (t) \]
CHAPTER 63. STOCHASTIC INTEGRATION

where \( N \) is a local martingale. Recall the quadratic variation is unique so that if it acts like the quadratic variation, then it is the quadratic variation. Recall also why this was so. If you have a local martingale equal to the difference of increasing adapted processes which equals 0 when \( t = 0 \), then the local martingale was equal to 0. Of course you can substitute a for 0.

**Corollary 63.11.1** Suppose \( \Phi \) is \( \mathcal{L}_2 \left( Q^{1/2}U, H \right) \) progressively measurable and has the localizing sequence with the two properties in Lemma 63.10.2. Then the quadratic variation, \( \langle \Phi \cdot W \rangle \) is given by the formula

\[
\langle \Phi \cdot W \rangle (t) = \int_a^t \| \Phi (s) \|^2_{\mathcal{L}_2 \left( Q^{1/2}U, H \right)} ds
\]

**Proof:** By the above discussion, \( \int_a^t \Phi dW \) is a local martingale. Let \( \{ \tau_n \} \) be a localizing sequence for which the stopped local martingale is a martingale and \( \Phi X_{[a, \tau_n]} \) is in \( L^2 \left( [a, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right) \). Also let \( \sigma \) be a stopping time with two values no larger than \( T \). Then from Lemma 63.10.5, the Ito isometry. There is also no change in letting \( \sigma = t \). You still get 0. It follows from Lemma 63.10.1, the lemma about recognizing a martingale when you see one, that

\[
t \to \left| \int_a^{t \wedge \tau_n} \Phi dW \right|^2_H - \int_a^{t \wedge \tau_n} \| \Phi (s) \|^2_{\mathcal{L}_2 \left( Q^{1/2}U, H \right)} ds
\]

is a martingale. Therefore,

\[
\left| \int_a^t \Phi dW \right|^2_H - \int_a^t \| \Phi (s) \|^2_{\mathcal{L}_2 \left( Q^{1/2}U, H \right)} ds
\]

is a local martingale and so, by uniqueness of the quadratic variation,

\[
\langle \Phi \cdot W \rangle (t) = \int_a^t \| \Phi (s) \|^2_{\mathcal{L}_2 \left( Q^{1/2}U, H \right)} ds
\]

Here is an interesting little lemma which seems to be true.
Lemma 63.11.2 Let $\Phi, \Phi_n$ all be in $L^2 ([0, T], L^2 (Q^{1/2} U, H))$ off some set of measure zero. These are all progressively measurable. Thus there are all stochastically square integrable.

$$P \left( \int_0^T \| \Phi \|^2 \, ds \right) = 1$$

Suppose also that for each $\omega \notin N$, the exceptional set,

$$\int_0^T \| \Phi_n - \Phi \|^2 \, dt \to 0$$

Then there exists a set of measure zero, still denoted as $N$ and a subsequence, still denoted as $n$ such that for each $\omega \notin N$,

$$\lim_{n \to \infty} \int_0^T \Phi_n \, dW = \int_0^T \Phi \, dW$$

Proof: Define stopping times

$$\tau_{np} \equiv \inf \left\{ t \in [0, T] : \int_0^t \| \Phi_n \|^2 \, ds > p \right\}$$

Let $\tau_p$ be similar but defined with reference to $\Phi$. Then by Ito isometry,

$$E \left( \left\| \int_0^T X_{[0, \tau_{np}]} \Phi_n \, dW - \int_0^T X_{[0, \tau_p]} \Phi \, dW \right\|^2 \right)$$

$$= E \left( \int_0^T \| X_{[0, \tau_{np}]} \Phi_n - X_{[0, \tau_p]} \Phi \|^2 \, dt \right)$$

(63.11.19)

The integrand in the right side is bounded by $2p^2$. Also this integrand converges to 0 for each $\omega$ as $n \to \infty$. This is shown next.

$$\int_0^T \| X_{[0, \tau_{np}]} \Phi_n - X_{[0, \tau_p]} \Phi \|^2 \, dt$$

$$\leq 2 \int_0^T \left( \| X_{[0, \tau_{np}]} \Phi_n - X_{[0, \tau_p]} \Phi \|^2 + \| X_{[0, \tau_p]} \Phi - X_{[0, \tau_p]} \Phi \|^2 \right) \, dt$$

$$\leq 2 \int_0^T \| \Phi_n - \Phi \|^2 \, dt + 2 \int_0^T \left| X_{[0, \tau_p]} (t) - X_{[0, \tau_p]} (t) \right|^2 \| \Phi \|^2 \, dt$$

The first converges to 0 by assumption. Problem is, it does not look like this second integral converges to 0. We do know that $\int_0^T \| \Phi_n \|^2 \, ds \to \int_0^T \| \Phi \|^2 \, ds$ uniformly so $\tau_{np} \to \tau_p$ is likely. However, this does not imply $X_{[0, \tau_{np}]} \to X_{[0, \tau_p]}$. However, it would converge in $L^2 (0, T)$ and so there is a subsequence such that convergence takes place a.e. $t$. Then restricting to this subsequence, the second integral converges.
CHAPTER 63. STOCHASTIC INTEGRATION

to 0. Actually, it may be easier than this. $X_{[0,\tau_p]}$ has a single point of discontinuity and convergence takes place at every other point. Thus it appears that the integrand in 63.11.19 converges to 0 for each $\omega$. Thus, by dominated convergence theorem the whole expectation converges to 0.

Now consider

$$P \left( \left| \int_0^T X_{[0,\tau_p]} \Phi_n dW - \int_0^T X_{[0,\tau_p]} \Phi dW \right|^2 > \lambda \right)$$

and so, there exists a subsequence, still denoted as $n$ such that

$$P \left( \left| \int_0^T X_{[0,\tau_p]} \Phi_n dW - \int_0^T X_{[0,\tau_p]} \Phi dW \right|^2 > \frac{1}{n} \right) < 2^{-k}$$

It follows that $N$ can be enlarged so that for $\omega \notin N_p$

$$\left| \int_0^T X_{[0,\tau_p]} \Phi_n dW - \int_0^T X_{[0,\tau_p]} \Phi dW \right|^2 \leq \frac{1}{n}$$

for all $n$ large enough. Now obtain a succession of subsequences for $p = 1, 2, \ldots$, each a subsequence of the preceding one such that the above convergence takes place and let $N$ include $\bigcup_p N_p$. Then for $\omega \notin N$, and letting $n$ denote the diagonal sequence, it follows that for all $p$,

$$\lim_{n \to \infty} \int_0^T X_{[0,\tau_p]} \Phi_n dW - \int_0^T X_{[0,\tau_p]} \Phi dW = 0$$

For $\omega \notin N$, there is a $p$ such that $\tau_p = \infty$. Then this means $\int_0^T \| \Phi \|^2 ds < p$. It follows that the same is true for $\Phi_n$ for all $n$ large enough. Hence $\tau_{np} = \infty$ also. Thus, for large enough $n$,

$$\left| \int_0^T \Phi_n dW - \int_0^T \Phi dW \right| = \left| \int_0^T X_{[0,\tau_p]} \Phi_n dW - \int_0^T X_{[0,\tau_p]} \Phi dW \right|$$

and the latter was just shown to converge to 0.

63.12 The Holder Continuity Of The Integral

Let $\Phi \in L^2 \left( [0,T] \times \Omega, L_2 \left( Q^{1/2} U, H \right) \right)$. Then you can consider the stochastic integral as described above and it yields a continuous function off a set of measure
zero. What if \( L_1(\Omega) \times L_2(Q^{1/2}U,H) \)? Can you say more? The short answer is yes. You obtain a Holder condition in addition to continuity. This is a consequence of the Burkholder Davis Gundy inequality and Corollary 63.11 above.

Let \( \alpha > 2 \). Let \( \| \Phi \|_\infty \) denote the norm in \( L_\infty([0,T] \times \Omega, L_2(\Omega)) \). By the Burkholder Davis Gundy inequality,

\[
\int_\Omega \left( \left\| \int_s^t \Phi dW \right\|^\alpha \right) dP \leq \int_\Omega \left( \sup_{\tau \in [s,t]} \left| \int_s^\tau \Phi dW \right| \right)^\alpha dP \leq C \int_\Omega \left( \int_s^t \| \Phi \|^2 d\tau \right)^{\alpha/2} dP \leq C \| \Phi \|_\infty^\alpha \int_\Omega \left( \int_s^t d\tau \right)^{\alpha/2} dP = C \| \Phi \|_\infty^\alpha |t-s|^{\alpha/2}
\]

By the Kolmogorov Čentsov theorem, Theorem 60.2.2, this shows that \( t \to \int_0^t \Phi dW \) is Holder continuous with exponent

\[
\gamma < \frac{\alpha/2 - 1}{\alpha} = \frac{1}{2} - \frac{1}{\alpha}
\]

Since \( \alpha > 2 \) is arbitrary, this shows that for any \( \gamma < 1/2 \), the stochastic integral is Holder continuous with exponent \( \gamma \). This is exactly the same kind of continuity possessed by the Wiener process.

**Theorem 63.12.1.** Suppose \( \Phi \in L_\infty([0,T] \times \Omega, L_2(Q^{1/2}U,H)) \) and is progressively measurable. Then if \( \gamma < 1/2 \), there exists a set of measure zero such that off this set,

\[
t \to \int_0^t \Phi dW
\]

is Holder continuous with exponent \( \gamma \).

### 63.13 Taking Out A Linear Transformation

When is

\[
L \int_a^T \Phi dW = \int_a^T L\Phi dW?
\]

It is assumed \( L \in \mathcal{L}(H,H_1) \) where \( H_1 \) is another separable real Hilbert space. First of all, here is a lemma which shows \( \int_a^T L\Phi dW \) at least makes sense.

**Proposition 63.13.1** Suppose \( \Phi \in L_2(Q^{1/2}U,H) \) progressively measurable and

\[
P \left( \left| \int_a^T \| \Phi \|^2_{L_2(Q^{1/2}U,H)} ds \right| < \infty \right) = 1.
\]
Then the same is true of \( L\Phi \). Furthermore, for each \( t \in [a, T] \)

\[
\int_a^t L\Phi dW = L \int_a^t \Phi dW
\]

**Proof:** First note that if \( \Phi \in \mathcal{L}_2 \left( Q^{1/2}U, H \right) \), then \( L\Phi \in \mathcal{L}_2 \left( Q^{1/2}U, H_1 \right) \) and that the map \( \Phi \to L\Phi \) is continuous. It follows \( L\Phi \) is \( \mathcal{L}_2 \left( Q^{1/2}U, H_1 \right) \) progressively measurable. All that remains is to check the appropriate integral.

\[
\int_a^T \|L\Phi\|^2_{\mathcal{L}_2(Q^{1/2}U,H_1)} dt \leq \int_a^T \|L\|^2 \|\Phi\|^2_{\mathcal{L}_2(Q^{1/2}U,H)} dt
\]

and so this proves \( L\Phi \) satisfies the same conditions as \( \Phi \), being stochastically square integrable.

It follows one can consider

\[
\int_a^T L\Phi dW.
\]

Assume to begin with that \( \Phi \in L^2 \left( [a,T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right) \). Next recall the situation in which the definition of the integral is considered.

\[
\begin{align*}
U & \supseteq JQ^{1/2}U \\
JQ^{1/2}U & \supseteq \bigcup_{1 \to 1} Q^{1/2}U \\
\Phi_n & \to \Phi
\end{align*}
\]

Letting \( \{\Phi_n\} \) be an approximating sequence of elementary functions satisfying

\[
E \left( \int_a^T \|\Phi_n - \Phi \circ J^{-1}\|^2_{\mathcal{L}_2(JQ^{1/2}U,H)} dt \right) \to 0,
\]

it is also the case that

\[
E \left( \int_a^T \|L\Phi_n - L\Phi \circ J^{-1}\|^2_{\mathcal{L}_2(JQ^{1/2}U,H_1)} dt \right) \to 0
\]

By the definition of the integral, for each \( t \)

\[
\int_a^t L\Phi dW = \lim_{n \to \infty} \int_a^t L\Phi_n dW = \lim_{n \to \infty} L \int_a^t \Phi_n dW
\]

\[
= L \lim_{n \to \infty} \int_a^t \Phi_n dW = L \int_a^t \Phi dW
\]

The second equality is obvious for elementary functions.
Now consider the case where $\Phi$ is only stochastically square integrable so that all is known is that

$$P \left( \int_a^T \|\Phi\|^2_{L^2(Q^{1/2}U,H)} \, dt < \infty \right) = 1.$$ 

Then define $\tau_n$ as above

$$\tau_n \equiv \inf \left\{ t : \int_a^t \|\Phi\|^2_{L^2(Q^{1/2}U,H)} \, dt \geq n \right\}$$

This sequence of stopping times works for $L\Phi$ also. Recall there were two conditions the sequence of stopping times needed to satisfy. The first is obvious. Here is why the second holds.

$$\int_a^T \|X_{[a,\tau_n]}L\Phi\|^2_{L^2(Q^{1/2}U,H)} \, dt \leq ||L||^2 \int_a^T \|X_{[a,\tau_n]}\Phi\|^2_{L^2(Q^{1/2}U,H)} \, dt$$

$$= ||L||^2 \int_a^{\tau_n} \|\Phi\|^2_{L^2(Q^{1/2}U,H)} \, dt \leq ||L||^2 n$$

Then let $t$ be given and pick $n$ such that $\tau_n(\omega) \geq t$. Then from the first part, for that $\omega$,

$$L \int_a^t \Phi \, dW \equiv L \int_a^t X_{[a,\tau_n]} \Phi \, dW$$

$$= \int_a^t L X_{[a,\tau_n]} \Phi \, dW$$

$$= \int_a^t X_{[a,\tau_n]} L \Phi \, dW \equiv \int_a^t L \Phi \, dW \blacksquare$$

### 63.14 A Technical Integration By Parts Result

Let $Z \in L^2([0,T] \times \Omega, L_2(Q^{1/2}U,H))$ where this has reference to the usual diagram

$$U \downarrow \Phi$$

$$U_1 \supseteq J Q^{1/2}U \quad \downarrow \quad Q^{1/2}U$$

Also suppose $X \in L^2([0,T] \times \Omega, H)$, both $X$ and $Z$ being progressively measurable. Let $\{t^n_j\}_{j=1}^{m_n}$ denote a sequence of partitions of the sort discussed earlier

$$X_n(t) \equiv \sum_{j=0}^{m_n-1} X(t^n_j) X_{[t^n_j, t^n_{j+1})}(t)$$
converges to $X$ in $L^2 \left( [0, T] \times \Omega, H \right)$. Thus $X_n(t)$ is right continuous. Let

$$\tau^n_p = \inf \{ t : |X_n(t)|_H > p \}.$$ 

This is the first hitting time of a right continuous adapted process so it is a stopping time. Also there exists a set of measure zero $N$ such that for $\omega \notin N$, then given $t$,

$$\tau^n_p \geq t$$

if $p$ is large enough because of the assumption on $X$. Here is why. There exists a set of measure 0 $N$ such that if $\omega \in 2N$, then given $t$, $n_p = \inf \{ t : X_n(t) < p \}$.

This is the first hitting time of a right continuous adapted process so it is a stopping time. Also there exists a set of measure zero $N$ such that for $\omega \notin N$, then given $t$,

$$\tau^n_p \geq t$$

This is the first hitting time of a right continuous adapted process so it is a stopping time. Also there exists a set of measure zero $N$ such that for $\omega \notin N$, then given $t$,

$$\tau^n_p \geq t$$

Next consider the expression

$$\sum_{j=0}^{m-1} \left( \int_{t^n_j}^{t^n_{j+1}} Z(u) \, dW, X(a) \right)_H$$

This expression is a function of $\omega$. I want to write this in the form of a stochastic integral. To begin with, consider one of the terms. For simplicity of notation, consider

$$\left( \int_a^b Z(u) \, dW, X(a) \right)_H$$

where $Z \in L^2 \left( [a, b] \times \Omega, \mathcal{L}_2 \left(Q^{1/2}U, H\right) \right)$ and $X(a) \in L^2 (\Omega, H)$. Also assume the function of $\omega$, $|X(a)|_H$, is bounded. There is an Itô integral involved in the above. Let $Z_n$ be a sequence of elementary functions defined on $[a, b]$ which converges to $Z \circ J^{-1}$ in $L^2 \left( [a, b] \times \Omega, \mathcal{L}_2 \left(JQ^{1/2}U, H\right) \right)$. Then by the definition of the integral,

$$\left\| \int_a^t Z(u) \, dW - \int_a^t Z_n(u) \, dW \right\|_{L^2(\Omega, H)} \to 0$$

Also, by the use of a maximal inequality and the fact that the two integrals above are martingales, there is a subsequence, still called $n$ and a set of measure zero $N$ such that for $\omega \notin N$, the convergence

$$\int_a^t Z_n(u) \, dW(\omega) \to \int_a^t Z(u) \, dW(\omega)$$

is uniform for $t \in [a, b]$. Therefore, for such $\omega$,

$$\left( \int_a^t Z(u) \, dW, X(a) \right)_H = \lim_{n \to \infty} \left( \int_a^t Z_n(u) \, dW, X(a) \right)_H$$
Say $Z_n(u) = \sum_{k=0}^{m_n-1} Z_k^n X_{[t_k^n, t_{k+1}^n)} (u)$ where $Z_k^n$ has finitely many values in $L(U_1, H)_0$, the restrictions of $L(U_1, H)$ to $JO^{1/2}U$. Then the inner product in the above formula on the right is of the form

$$\sum_{k=0}^{m_n-1} \left( Z_k^n \left( W (t \wedge t_{k+1}^n) - W (t \wedge t_k^n) \right), X(a) \right)_H$$

and

$$\sum_{k=0}^{m_n-1} \left( \left( W (t \wedge t_{k+1}^n) - W (t \wedge t_k^n) \right), (Z_k^n)^* X(a) \right)_{U_1}$$

$$= \sum_{k=0}^{m_n-1} \mathcal{R} \left( (Z_k^n)^* X(a) \right) \left( W (t \wedge t_{k+1}^n) - W (t \wedge t_k^n) \right)$$

$$= \int_a^t \mathcal{R} (Z_n^* X(a)) dW$$

where $\mathcal{R}$ is the Riesz map from $U_1$ to $U'_1$. Note that $\mathcal{R} (Z_n^* X(a))$ has values in $L(U_1, \mathbb{R})$. Now let $\{g_i\}$ be an orthonormal basis for $Q^{1/2}U$, so it follows that $\{Jg_i\}$ is an orthonormal basis for $JO^{1/2}U$. Then

$$\sum_i \left| \mathcal{R} \left( Z_n^* X(a) - (Z \circ J^{-1})^* X(a) \right) (Jg_i) \right|^2$$

and

$$\leq \sum_i |X(a)|^2 \left| \left( Z_n - Z \circ J^{-1} \right) Jg_i \right|^2_H = |X(a)|^2 \left\| Z_n - Z \circ J^{-1} \right\|_{L_2,copy}^2$$

When integrated over $[a, b] \times \Omega$, it is given that this converges to 0. This has shown that

$$\mathcal{R} (Z_n^* X(a)) \rightarrow \mathcal{R} \left( (Z \circ J^{-1})^* X(a) \right)$$

in $L_2 (JO^{1/2}U, \mathbb{R})$. In other words

$$\mathcal{R} (Z_n^* X(a)) \rightarrow \left( \mathcal{R} \left( (Z \circ J^{-1})^* X(a) \right) \circ J \right) \circ J^{-1}$$

It follows that

$$\left( \int_a^t Z(u) dW, X(a) \right)_H = \int_a^t \mathcal{R} \left( (Z \circ J^{-1})^* X(a) \right) \circ J dW$$
CHAPTER 63. STOCHASTIC INTEGRATION

From localization,

\[
\left( \int_{a \wedge \tau_p^n}^{b \wedge \tau_p^n} Z(u) \, dW, X(a) \right)_H = \left( \int_a^b X_{[0, \tau_p^n]} Z(u) \, dW, X(a) \right)_H
\]

\[
= \int_a^b X_{[0, \tau_p^n]} \mathcal{R} \left( (Z \circ J^{-1})^* X(a) \right) \circ JdW
\]

Then it follows that, using the stopping time,

\[
\sum_{j=0}^{m-1} \left( \int_{t_j^n \wedge \tau_p^n \wedge t}^{t_{j+1}^n \wedge \tau_p^n \wedge t} Z(u) \, dW, X(t_j^n) \right)_H = \sum_{j=0}^{m-1} \int_{t_j^n \wedge \tau_p^n \wedge t}^{t_{j+1}^n \wedge \tau_p^n \wedge t} \mathcal{R} \left( (Z \circ J^{-1})^* X_n(t_j^n) \right) \circ JdW
\]

\[
= \int_0^{t_{m-1}^n \wedge \tau_p^n \wedge t} \mathcal{R} \left( (Z \circ J^{-1})^* (X_n^t) \right) \circ JdW
\]

where \( X_n^t \) is the step function

\[
X_n^t(t) = \sum_{k=0}^{m_n-1} X(t_k^n) X_{[t_k^n, t_{k+1}^n)}(t)
\]

By localization, this is

\[
\int_0^t X_{[0, \tau_p^n]} \mathcal{R} \left( (Z \circ J^{-1})^* (X_n^t) \right) \circ JdW
\]

If \( \omega \) is not in a suitable set of measure zero, then \( \tau_p^n(\omega) \geq t \) provided \( p \) is large enough. Thus, for such \( \omega \), if \( p \) is large enough,

\[
\sum_{j=0}^{m_n-1} \left( \int_{t_j^n \wedge \tau_p^n \wedge t}^{t_{j+1}^n \wedge \tau_p^n \wedge t} Z(u) \, dW, X(t_j^n) \right)_H = \int_0^t X_{[0, \tau_p^n]} \mathcal{R} \left( (Z \circ J^{-1})^* (X_n^t) \right) \circ JdW
\]

\[
= \int_0^t \mathcal{R} \left( (Z \circ J^{-1})^* (X_n^t) \right) \circ JdW
\]

This shows that the expression is a local martingale. Also note that the expression on the left does not depend on \( J \) or \( U_1 \) so the same must be true of the expression on the right although it does not look that way. This has proved the following important theorem.

**Theorem 63.14.1.** Let \( Z \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, H \right) \right) \) and let \( X \in L^2 \left( [0, T] \times \Omega, H \right) \), both \( X, Z \) progressively measurable. Also let \( \{t_j^n\}_{j=1}^{m_n} \) be a sequence of partitions of \([0, T] \) such that each \( X(t_j^n) \) is in \( L^2(\Omega, H) \). Then

\[
\sum_{j=0}^{m-1} \left( \int_{t_j^n \wedge t}^{t_{j+1}^n \wedge t} Z(u) \, dW, X(t_j^n) \right)_H
\]

(63.14.21)
is a stochastic integral of the form

\[ \int_0^t R \left((Z \circ J^{-1})^* (X_n^l)\right) \circ JdW \]

where \( \{\tau_n^p\}_{p=1}^\infty \) is a localizing sequence used to define the above integral whose integrand is only stochastically square integrable. Here \( X_n^l \) is the step function defined by

\[ X_n^l (t) = \sum_{k=0}^{m_n-1} X(t_n^k) \mathcal{X}_{[t_n^k, t_{n+1}^k]}(t) \]

In particular, (63.14.22) is a local martingale.

Of course it would be very interesting to see what happens in the case where \( X_n^l \rightarrow X \) in \( L^2 ([0, T] \times \Omega, H) \). Is it the case that convergence to

\[ \int_0^t R \left((Z \circ J^{-1})^* (X)\right) \circ JdW \quad (63.14.22) \]

happens in some sense? Also, does the above stochastic integral even make sense? First of all, consider the question whether it makes sense. It would be nice to define a stopping time

\[ \tau_n \equiv \inf \{ t : |X(t)|_H > n \} \]

because then \( \mathcal{X}_{[0, \tau_n]} R \left((Z \circ J^{-1})^* (X)\right) \circ J \) would end up being integrable in the right way and you could define the stochastic integral provided \( \tau_n > t \) whenever \( n \) is large enough. However, this is problematic because \( t \rightarrow X(t) \) is not known to be continuous. Therefore, some other condition must be assumed.

**Lemma 63.14.2** Suppose \( t \rightarrow X(t) \) is weakly continuous into \( H \) for a.e. \( \omega \), and that \( X \) is adapted. Then the \( \tau_n \) described above is a stopping time.

**Proof:** Let \( B \equiv \{ x \in H : |x| > n \} \). Then the complement of \( B \) is a closed convex set. It follows that \( B^C \) is also weakly closed. Hence \( B \) must be weakly open. Now \( t \rightarrow X(t) \) is adapted as a function mapping into the topological space consisting of \( H \) with the weak topology because it is in fact adapted into the strong topology. Therefore, the above \( \tau_n \) is just the first hitting time of an open set by a continuous process so \( \tau_n \) is a stopping time by Proposition 60.7.4. Also, by the assumption that \( t \rightarrow X(t) \) is weakly continuous, it follows that \( X(t) \) for \( t \in [0, T] \) is weakly bounded. Hence, for each \( \omega \) off a set of measure zero, \( |X(t)| \) is bounded. Therefore, \( \tau_n = \infty \) for \( n \) large enough. \( \blacksquare \)

Hence the weak continuity of \( t \rightarrow X(t) \) suffices to define the stochastic integral in (63.14.22). It remains to verify some sort of convergence in the case that

\[ \lim_{n \rightarrow \infty} \max_{j \leq m_n-1} \left( t_{j+1}^n - t_j^n \right) = 0 \]
Lemma 63.14.3 Let $X (s) - X_k^l (s) \equiv \Delta_k (s)$. Here $Z \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, H \right) \right)$ and let $X \in L^2 ([0, T] \times \Omega, H)$ with both $X$ and $Z$ progressively measurable, $t \rightarrow X (t)$ being weakly continuous into $H$,

$$\lim_{k \to \infty} \|X - X_k^l\|_{L^2 ([0, T] \times \Omega, H)} = 0$$

Then the integral

$$\int_0^t \mathcal{R} \left( (Z \circ J^{-1})^* (X) \right) \circ JdW$$

exists as a local martingale and the following limit occurs for a suitable subsequence, still called $k$.

$$\lim_{k \to \infty} P \left( \sup_{t \in [0, T]} \left| \int_0^t \mathcal{R} \left( (Z \circ J^{-1})^* \Delta_k (s) \right) \circ JdW (s) \right| \geq \varepsilon \right) = 0. \quad (63.14.23)$$

That is,

$$\sup_{t \in [0, T]} \left| \int_0^t \mathcal{R} \left( (Z \circ J^{-1})^* (X (s) - X_k^l (s)) \right) \circ JdW (s) \right|$$

converges to 0 in probability.

**Proof:** Let $k$ denote a subsequence for which $X_k^l$ also converges pointwise to $X$.

The existence of the integral follows from Lemma 63.14.2. From the assumption of weak continuity, $\sup_{t \in [0, T]} |X (t)| \leq C \omega$ for a.e. $\omega$. For the first part of the argument, assume $C$ does not depend on $\omega$ off a set of measure zero. Let

$$M (t) \equiv \int_0^t ZdW$$

Let \{e_i\} be an orthonormal basis for $H$ and let $P_n$ be the orthogonal projection onto $\text{span} (e_1, \ldots, e_n)$. For each $e_i$

$$\lim_{k \to \infty} \left| (X (s) - X_k^l (s), e_i) \right| = 0$$

and so, by weak continuity,

$$\lim_{k \to \infty} P_n (X (s) - X_k^l (s)) = 0 \text{ for a.e. } \omega$$

Then

$$\lim_{k \to \infty} \int_0^T \int_0^T |P_n (X (s) - X_k^l (s))|^2 \|Z (s)\|_{\mathcal{L}_2}^2 dsdP = 0$$

because you can apply the dominated convergence theorem with respect to the measure $\|Z (s)\|_{\mathcal{L}_2}^2 dsdP$. 

Therefore,

\[
\lim_{k \to \infty} P \left( \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* P_n \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right) = 0
\]  
(63.14.24)

Here is why. By the Burkholder Davis Gundy theorem, Theorem 61.4.4 and Corollary 63.11.1 which describes the quadratic variation of the stochastic integral,

\[
\int_{\Omega} \left( \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* P_n \Delta_k(s) \right) dW(s) \right| \right)^{1/2} dP
\]

\[
\leq C \int_{\Omega} \left( \int_0^T \left| P_n \left( X(s) - X_k^{(l)}(s) \right) \right|^2 \|Z(s)\|^2 \Delta s \right)^{1/2} dP
\]

Consider the following two probabilities.

\[
P \left( \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* (I - P_n) X(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right)
\]

(63.14.25)

\[
P \left( \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* (I - P_n) X_k^{(l)}(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right)
\]

(63.14.26)

By Corollary 61.4.5 which depends on the Burkholder Davis Gundy inequality and Corollary 63.11.1 which describes the quadratic variation of the stochastic integral, (63.14.25) is dominated by

\[
\frac{C}{\varepsilon} E \left( \left( \int_0^T \|Z(s)\|^2 \left| (I - P_n) X(s) \right|^2 \Delta s \right)^{1/2} \wedge \delta \right)
\]

\[
+ P \left( \left( \int_0^T \|Z(s)\|^2 \left| (I - P_n) X(s) \right|^2 \Delta s \right)^{1/2} > \delta \right)
\]

\[
\leq \frac{C \delta}{\varepsilon} + P \left( \left( \int_0^T \|Z(s)\|^2 \left| (I - P_n) X(s) \right|^2 \Delta s \right)^{1/2} > \delta \right)
\]

(63.14.27)

Let \( \eta > 0 \) be given. Then let \( \delta \) be small enough that the first term is less than \( \eta \). Fix such a \( \delta \).

Consider the second of the above terms.

\[
P \left( \left( \int_0^T \|Z(s)\|^2 \left| (I - P_n) X(s) \right|^2 \Delta s \right)^{1/2} > \delta \right)
\]

\[
\leq \frac{1}{\delta} \left( E \left( \int_0^T \|Z(s)\|^2 \left| (I - P_n) X(s) \right|^2 \Delta s \right)^{1/2} \right)
\]
and this converges to 0 because \((I - P_n)X(s)\) is assumed to be bounded and converges to 0. Next consider \(X \in C([0,T])\). By similar reasoning, we end up with having to estimate
\[
\frac{1}{\delta} \left( E \left( \int_0^T \left| \frac{1}{ \eta} \left( |Z(s)|^2 - (I - P_n)X_k^l(s) \right)^2 ds \right| \right)^{1/2} .
\]
But this is dominated by
\[
\frac{2}{\delta} \left( E \left( \int_0^T \left| Z(s) \right|^2 \left| X_k^l(s) - X(s) \right|^2 ds \right) \right)^{1/2} + \frac{2}{\delta} \left( E \left( \int_0^T \left| Z(s) \right|^2 \left| (I - P_n)X(s) \right|^2 ds \right) \right)^{1/2} .
\]
The first term is no larger than \(\eta\) provided \(k\) is large enough, independent of \(n\) thanks to the pointwise convergence and the assumption that \(X\) is bounded. Thus, there exists \(K\) such that if \(k > K\), then the term in \(X \in C([0,T])\) is dominated by
\[
2\eta + \frac{2}{\delta} \left( E \left( \int_0^T \left| Z(s) \right|^2 \left| (I - P_n)X(s) \right|^2 ds \right) \right)^{1/2} .
\]
It follows that for \(k > K\), the sum of \(\text{innovative}\) and \(\text{innovative}\) is dominated by
\[
3\eta + \frac{3}{\delta} \left( E \left( \int_0^T \left| Z(s) \right|^2 \left| (I - P_n)X(s) \right|^2 ds \right) \right)^{1/2} .
\]
This is then no larger than \(4\eta\) provided \(n\) is large enough. Pick such an \(n\). Then for all \(k > K\), this has shown that
\[
P \left( \left\{ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( \left( Z(s) \circ J^{-1} \right)^* \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon \right\} \right) \leq P \left( \left\{ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( \left( Z(s) \circ J^{-1} \right)^* P_n \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right\} \right) + \frac{2}{\delta} \left( E \left( \int_0^T \left| Z(s) \right|^2 \left| (I - P_n)X(s) \right|^2 ds \right) \right)^{1/2}
\]
\[
P \left( \left\{ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( \left( Z(s) \circ J^{-1} \right)^* (I - P_n) \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right\} \right) \leq P \left( \left\{ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( \left( Z(s) \circ J^{-1} \right)^* P_n \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon/2 \right\} \right) + 4\eta
\]
63.14. A TECHNICAL INTEGRATION BY PARTS RESULT

By this whole thing is less than $5\eta$ provided $k$ is large enough. This has proved that under the assumption that $X$ is bounded uniformly off a set of measure zero,

$$\lim_{k \to \infty} P \left( \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon \right) = 0$$

This is what was desired to show. It remains to remove the extra assumption that $X$ is bounded.

Now to finish the argument, define the stopping time

$$\tau_m \equiv \inf \{ t > 0 : |X(t)|_H > m \}.$$ 

As observed in Lemma, this is a valid stopping time. Also define $\Delta^*_m \equiv X^{\tau_m} - (X^*_k)^{\tau_m}$. Using this stopping time on $X$ and $X^*_k$ does not affect the pointwise convergence to 0 as $k \to \infty$ of $\Delta^*_m$ on which the above argument depends.

Consider

$$A_{k\varepsilon} \equiv \left[ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* \Delta_k(s) \right) \circ JdW(s) \right| \geq \varepsilon \right]$$

Then

$$P(A_{k\varepsilon} \cap [\tau_m = \infty]) \leq P \left( \left[ \sup_{t \in [0,T]} \left| \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* \Delta^*_m(s) \right) \circ JdW(s) \right| \geq \varepsilon \right] \right)$$

which converges to 0 as $k \to \infty$ by the first part of the argument. This is because $|X^{\tau_m}|$ and $|(X^*_k)^{\tau_m}|$ are both bounded by $m$ and the same pointwise convergence condition still holds. Now

$$A_{k\varepsilon} = \bigcup_{m=1}^{\infty} A_{k\varepsilon} \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])$$

Thus

$$P(A_{k\varepsilon}) = \sum_{m=1}^{\infty} P(A_{k\varepsilon} \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])) \quad (63.14.28)$$

Also

$$P(A_{k\varepsilon} \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])) \leq P([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])$$

which is summable because these are disjoint sets. Hence one can apply the dominated convergence theorem in and conclude

$$\lim_{k \to \infty} P(A_{k\varepsilon}) = \sum_{m=1}^{\infty} \lim_{k \to \infty} P(A_{k\varepsilon} \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])) = 0$$
Chapter 64

The Integral \( \int_0^t (Y, dM)_H \)

First the integral is defined for elementary functions.

**Definition 64.0.1** Let an elementary function be one which is of the form

\[
\sum_{i=0}^{m-1} Y_i \mathcal{X}_{(t_i, t_{i+1}]} (t)
\]

where \( Y_i \) is \( \mathcal{F}_{t_i} \) measurable with values in \( H \) a separable real Hilbert space for \( 0 = t_0 < t_1 < \cdots < t_m = T \).

**Definition 64.0.2** Now let \( M \) be a \( H \)-valued continuous local martingale, \( M(0) = 0 \). Then for \( Y \) a simple function as above,

\[
\int_0^t (Y, dM) \equiv \sum_{i=0}^{m-1} (Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i))_H
\]

**Assumption 64.0.3** We will always assume that \( d[M] \) is absolutely continuous with respect to Lebesgue measure. Thus \( d[M] = k dt \) where \( k \geq 0 \) and is in \( L^1 ([0, T] \times \Omega) \). This is done to avoid technical questions related to whether \( t \rightarrow \int_0^t d[M] \) is continuous and also to make it easier to get examples of a certain class of functions.

This includes the usual stochastic integral \( M(t) = \int_0^t \Phi dW \) where \( [M](t) = \int_0^t \| \Phi \|_{L^2}^2 \, ds \) so \( d[M] = \| \Phi \|^2 \, dt \).

Next is to consider how this relates to stopping times which have values in the \( \{ t_i \} \). Let \( \tau \) be a stopping time which takes the values \( \{ t_i \}^{m}_{i=0} \). Then

\[
\int_0^{t \wedge \tau} (Y, dM) \equiv \sum_{i=0}^{m-1} (Y_i, M(t \wedge t_{i+1} \wedge \tau) - M(t \wedge t_i \wedge \tau))_H \quad (64.0.1)
\]
Now consider $\mathcal{X}_{[0,\tau]}Y$. Is it also an elementary function?

$$\mathcal{X}_{[0,\tau]}Y = \sum_{i=0}^{m-1} \mathcal{X}_{[0,\tau]}(t) Y_i \mathcal{X}_{(t_i,t_{i+1})}(t)$$

To get the $i^{th}$ term to be non-zero, you must have $\tau \geq t$ and $t \in (t_i, t_{i+1}]$. Thus it must be the case that $\tau > t_i$. Also, if $\tau > t_j$ and $t \in (t_i, t_{i+1}]$, then $\tau \geq t_{i+1}$ because $\tau$ has only the values $t_i$. Hence also $\tau \geq t$. Thus the above sum reduces to

$$\sum_{i=0}^{m-1} \mathcal{X}_{[\tau > t_i]}(\omega) Y_i \mathcal{X}_{(t_i,t_{i+1})}(t)$$

This shows that $\mathcal{X}_{[0,\tau]}Y$ is of the right sort, the sum of $\mathcal{F}_{t_i}$ measurable functions times $\mathcal{X}_{(t_i,t_{i+1})}(t)$. Thus from the definition of this funny integral,

$$\int_0^t (\mathcal{X}_{[0,\tau]}Y, dM) \equiv \sum_{i=0}^{m-1} \left( \mathcal{X}_{[\tau > t_i]}(\omega) Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i) \right)_H$$

(64.0.2)

Are the right sides of (64.0.1) and (64.0.2) equal?

Begin with the right side of (64.0.1) and consider $\tau = t_j$. Then to get something nonzero in the terms of the sum in (64.0.1), you would need to have $t_j \geq t_{i+1}$. Otherwise, $t_j \leq t_i$ and the difference involving $M$ would give 0. Hence, for such $\omega$ you would need to have the sum in (64.0.1) equal to

$$\sum_{i=0}^{j-1} (Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i))_H$$

Thus this sum in (64.0.1) equals

$$\sum_{j=0}^{m} \mathcal{X}_{[\tau = t_j]} \sum_{i=0}^{j-1} (Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i))_H$$

Of course when $j = 0$ the term in the sum in (64.0.1) equals 0 so there is no harm in defining $\sum_{i=0}^{-1} = 0$. Then from the sum, you have $i \leq j - 1$ and so when you interchange the order, you get that $\int_0^{t \wedge \tau} (Y, dM) =$

$$\sum_{i=0}^{m-1} \sum_{j=i+1}^{m} \mathcal{X}_{[\tau = t_j]} (Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i))_H$$

$$= \sum_{i=0}^{m-1} (\mathcal{X}_{[\tau > t_i]}(\omega) Y_i, M(t \wedge t_{i+1}) - M(t \wedge t_i))_H$$
Thus the right side of equals the right side of

\[
\int_0^t \left( \mathcal{X}_{[0,\tau]} Y, dM \right) = \sum_{i=0}^{m-1} \mathcal{X}_{[t_i, t_{i+1})}(\omega) Y_i, M\left( t \wedge t_{i+1} \right) - M\left( t \wedge t_i \right) = \int_0^{t \wedge \tau} (Y, dM)
\]

This has proved the first part of the following lemma.

**Lemma 64.0.4** For an elementary function \( Y \), and a stopping time \( \tau \) having values in the \( \{t_i\} \), the points of discontinuity of \( Y \), it follows that \( \mathcal{X}_{[0,\tau]} Y \) is also an elementary function and

\[
\int_0^{t \wedge \tau} (Y, dM) = \int_0^t \left( \mathcal{X}_{[0,\tau]} Y, dM \right) = \int_0^t (Y, dM^\tau)
\]

**Proof:** Consider the second equal sign. By definition,

\[
\int_0^{t \wedge \tau} (Y, dM) = \sum_{i=0}^{m-1} (Y_i, M\left( t \wedge t_{i+1} \right) - M\left( t \wedge t_i \right))_H
\]

\[
= \sum_{i=0}^{m-1} (Y_i, M^\tau(t \wedge t_{i+1}) - M^\tau(t \wedge t_i))_H \equiv \int_0^t (Y, dM^\tau)
\]

Next is another lemma about these integrals of elementary functions. First recall the following definition

\[
M^* \equiv \sup \{ ||M(t)|| : t \in [0,T] \}
\]

**Lemma 64.0.5** Let \( M \) be a local martingale on \( [0,T] \) where \( M(0) = 0 \) and \( M \) is continuous. Let \( 0 < r < s < T \) and consider \((Y, (M^{r^*} - M^{r^*}) (t))\) where \( Y(M^{r^*})^* \in L^2(\Omega) \) and \( Y \) is \( F_r \) measurable and \( \tau_p \) is a localizing sequence of stopping times for which \( M^{r^*} \) is a \( L^2 \) martingale. Then this is a martingale on \([0,T] \) which equals 0 at \( t = 0 \) and

\[
\left( [Y, (M^{r^*} - M^{r^*})] (t) \right) \leq ||Y||^2 [M^{r^*} - M^{r^*}] (t)
\]

\[
= ||Y||^2 ([M^{r^*}]^*(t) - [M^{r^*}]^*(t))
\]

\[
= ||Y||^2 ([M^{r^*}] (t \wedge s) - [M^{r^*}] (t \wedge r))
\]

It follows that for \( Y \) an elementary function where each \( Y_i (M^{r^*})^* \) is in \( L^2(\Omega) \),

\[
\int_0^t (Y, dM)
\]

is a local martingale.

**Proof:** To save notation, \( M \) is written in place of \( M^{r^*} \). It is clear that \((Y, (M^* - M^*) (t)) = 0 \) if \( t \leq r \). Is it a martingale?

\[
E \left( [Y, (M^* - M^*) (t)] \right) = E \left( E \left( [Y, (M^* - M^*) (t)] | F_r \right) \right)
\]

\[
= E \left( (Y, E \left( (M (s \wedge t) - M (r \wedge t)) | F_r \right)) \right) = 0
\]
because $M$ is a martingale. Now let $\sigma$ be a bounded stopping time with two values. Then using the optional sampling theorem where needed,

$$
E \left( (Y, (M^s - M^r)(\sigma)) \right) = E \left( E \left( (Y, (M^s - M^r)(\sigma)) | \mathcal{F}_r \right) \right) \\
= E \left( (Y, E \left( (M (s \wedge \sigma) - M (r \wedge \sigma)) | \mathcal{F}_r \right)) \right) \\
= E \left( (Y, M (s \wedge \sigma \wedge r) - M (r \wedge \sigma)) \right) \\
= E \left( (Y, M (\sigma \wedge r) - M (r \wedge \sigma)) \right) = 0
$$

It follows that this is indeed a martingale as claimed. By the definition of the quadratic variation,

$$
\left| (Y, (M^s - M^r) (t)) \right|^2 \leq \|Y\|^2 \|(M^s - M^r) (t)\|^2 \\
= \|Y\|^2 \left( (M^s - M^r) (t) + \|Y\|^2 \hat{N} (t) \right)
$$

where $\hat{N} (t)$ is a martingale. It equals 0 if $t \leq r$. By similar reasoning to the above, $\|Y\|^2 \hat{N} (t)$ is a martingale. To see this,

$$
E \left( \|Y\|^2 \hat{N} (\sigma) \right) = E \left( E \left( \|Y\|^2 \hat{N} (\sigma) | \mathcal{F}_r \right) \right) \\
= E \left( \|Y\|^2 E \left( \hat{N} (\sigma) | \mathcal{F}_r \right) \right) \\
= E \left( \|Y\|^2 N (\sigma \wedge r) \right) = 0
$$

One also sees that $E \left( \|Y\|^2 \hat{N} (t) \right) = 0$.

Now it follows from Corollary 61.3.3 that

$$
\left( (M^s - M^r) \right) (t) \leq \|Y\|^2 \left[ (M^s - M^r) (t) \right] = \|Y\|^2 \left( (M^s) (t) - (M^r) (t) \right)
$$

as claimed.

The last claim is easy. Let $\tau_p$ be a localizing sequence for which $M^{\tau_p}$ is a martingale. Then

$$
\int_0^{t \wedge \tau_p} (Y, dM) = \sum_{i=0}^{m-1} \left( Y_{i+1} M (t \wedge t_{i+1} \wedge \tau_p) - M (t \wedge t_i \wedge \tau_p) \right)_H \\
= \sum_{i=0}^{m-1} \left( Y_{i+1} M^{\tau_p} (t \wedge t_{i+1}) - M^{\tau_p} (t \wedge t_i) \right)_H
$$

a finite sum of martingales. \( \blacksquare \)

Note that this is just a definition and did not use the above localization lemma. In particular, $\tau_p$ is not restricted to having only the partition points as values.
Next one needs to generalize past the elementary functions. Continue writing $M$ in place of $M^T \rho$ in what follows. Consider an elementary function
\[
Y \equiv \sum_{k=0}^{m_n-1} Y_k \chi_{[t_k, t_{k+1}]}(t)
\]
where $Y_k M^* \in L^2(\Omega)$. Consider
\[
\int_0^t (Y, dM) \equiv \sum_{k=0}^{m_n-1} (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))
\] (64.0.3)
Then it is routine to verify that
\[
E \left( \left( \sum_{k=0}^{m_n-1} (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))^2 \right)^2 \right)
\]
\[
= \sum_{k=0}^{m_n-1} E \left( (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))^2 \right)^2
\] (64.0.4)
This is because the mixed terms all vanish. This follows from the following reasoning. Let $t_j < t_k$
\[
E \left( (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))^2 \right)^2
\]
\[
= E \left( E \left( (Y_k, \Delta_k M(t))^2 \right)^2 \right)
\]
\[
= E \left( (Y_j, \Delta_j M(t))^2 \right)^2
\]
\[
= E \left( (Y_j, \Delta_j M(t))^2 \right)^2
\]
\[
= E \left( (Y_j, \Delta_j M(t))^2 \right)^2
\]
\[
= 0
\]
Now
\[
\sum_{k=0}^{m_n-1} E \left( (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))^2 \right)^2
\]
\[
= \sum_{k=0}^{m_n-1} E \left( (Y_k, (M^{t_{k+1}} - M^{t_k})(t))^2 \right)^2
\]
It follows from (64.0.4)
\[
E \left( \left( \sum_{k=0}^{m_n-1} (Y_k, M(t \wedge t_{k+1}) - M(t \wedge t_k))^2 \right)^2 \right)
\]
\[
= \sum_{k=0}^{m_n-1} E \left( (Y_k, (M^{t_{k+1}} - M^{t_k})(t))^2 \right)^2
\]
\[
= \sum_{k=0}^{m_n-1} E \left( [(Y_k, (M^{t_{k+1}} - M^{t_k})(t))] + N_k(t) \right)
CHAPTER 64. THE INTEGRAL \( \int_0^T (Y, DM)_H \)

where \( N_k \) is a martingale equal to 0 for \( t \leq t_k \). Then this equals
\[
\sum_{k=0}^{m_n-1} E \left( \left[ (Y_k, (M^{t_{k+1}} - M^{t_k}) (t)) \right] \right)
\]

From Lemma 64.0.5
\[
\leq E \left( \sum_{k=0}^{m_n-1} \|Y_k\|^2_H \left( \left[ M \right]^{t_{k+1}} (t) - \left[ M \right]^{t_k} (t) \right) \right)
\]
\[
= E \left( \sum_{k=0}^{m_n-1} \|Y_k\|^2 \left( \left[ M \right] \left( t_{k+1}^n \wedge t \right) - \left[ M \right] \left( t_k^n \wedge t \right) \right) \right) \tag{64.0.5}
\]
\[
= E \left( \int_0^t \|Y\|^2_H d\left[ M^{\tau_p} \right] \right) = E \left( \int_0^t \|Y\|^2_H d\left[ M \right]^{\tau_p} \right)
\]

Note that everything makes sense because it is assumed that \( \|Y_k\| M^* \in L^2(\Omega) \). This proves the following lemma.

**Lemma 64.0.6** Let \( \|Y(t)\| (M^{\tau_p})^* \in L^2(\Omega) \) for each \( t \), where \( Y \) is an elementary function and let \( \tau_p \) be a stopping time for which \( M^{\tau_p} \) is a \( L^2 \) martingale. Then
\[
E \left( \left| \int_0^t (Y, dM^{\tau_p}) \right|^2 \right) \leq E \left( \int_0^t \|Y\|^2_H d\left[ M \right]^{\tau_p} \right)
\]

The condition that \( \|Y(t)\| (M^{\tau_p})^* \in L^2(\Omega) \) ensures that
\[
E \left( (Y_k, M^{\tau_p} (t \wedge t_{k+1}) - M^{\tau_p} (t \wedge t_{k+1}))^2_H \right)
\]
always is finite.

**Definition 64.0.7** Let \( \mathcal{G} \) denote those functions \( Y \) which are adapted and have the property that for each \( p \),
\[
\lim_{n \to \infty} E \left( \int_0^T \|Y - Y^n\|^2_H d\left[ M \right]^{\tau_p} \right) = 0
\]
for some sequence \( Y^n \) of elementary functions for which \( \|Y^n(t)\| M^* \in L^2(\Omega) \) for each \( t \). Here \( d\left[ M \right]^{\tau_p} \) signifies the Lebesgue Stieltjes measure determined by the increasing function \( t \mapsto \left[ M^{\tau_p} \right] (t) \). Let \( M^{\tau_p} \) be an \( L^2 \) martingale. Recall that \( \tau_p \) is just a localizing sequence for the local martingale \( M \).

It is not known whether this increasing function is absolutely continuous.

**Definition 64.0.8** Let \( Y \in \mathcal{G} \). Then
\[
\int_0^t (Y, dM^{\tau_p}) \equiv \lim_{n \to \infty} \int_0^t (Y^n, dM^{\tau_p}) \text{ in } L^2(\Omega)
\]
For example, suppose $Y$ is a bounded continuous process having values in $H$. Then you could look at the left step functions

$$Y^n(t) = \sum_{i=0}^{m_n-1} Y(t_i) \mathcal{X}_{[t_i, t_{i+1})}(t)$$

The $Y^n$ would converge to $Y$ pointwise on $[0, T]$ for each $\omega$ and these $Y^n$ are bounded. In fact, in this case, these converge uniformly to $Y$ on $[0, T]$. Thus this is an example of the situation in the above definition. In this case, the integrand would be bounded by $C$ for some $C$ and

$$E \left( \int_0^T C d[M]^\tau_p \right) = E(\|M\|^\tau_p(T)) = E\left(\|M\|^\tau_p(T)\|^2\right) < \infty$$

by assumption. Hence, by the dominated convergence theorem,

$$\lim_{n \to \infty} E\left( \int_0^T \|Y - Y^n\|^2_H d[M]^\tau_p \right) = 0.$$

What if $[M]^\tau_p$ were bounded and absolutely continuous with respect to Lebesgue measure? This could be the case if you had $\tau_p$ a stopping time of the form

$$\tau_p = \inf \{ t : [M](t) > p \}$$

Then if $Y \in L^2([0, T] \times \Omega, H)$, and progressively measurable there are left step functions which converge to $Y$ in $L^2([0, T] \times \Omega, H)$. Say $d[M]^\tau_p = k(t, \omega) dm$ where $k$ is bounded. Then

$$E \left( \int_0^T \|Y - Y^n\|^2_H d[M]^\tau_p \right) = E \left( \int_0^T \|Y - Y^n\|^2_H k dt \right) \to 0$$

**Lemma 64.0.9** The above definition is well defined. Also, $\int_0^t (Y, dM^\tau_p)$ is a continuous martingale. The inequality

$$E \left( \left| \int_0^t (Y, dM^\tau_p) \right|^2 \right) \leq E \left( \int_0^t \|Y\|^2_H d[M]^\tau_p \right)$$

is also valid. For any sequence of elementary functions $\{Y^n\}$, $\|Y^n(t)\| M^* \in L^2(\Omega)$,

$$\|Y^n - Y\|_{L^2(\Omega; L^2([0, T]; H, d[M]^\tau_p))} \to 0$$

there exists a subsequence, still denoted as $\{Y^n\}$ of elementary functions for which $\int_0^t (Y^n, dM^\tau_p)$ converges uniformly to $\int_0^t (Y, dM^\tau_p)$ on $[0, T]$ for $\omega$ off some set of measure zero.
**Proof:** First of all, why does the limit even exist? From Lemma

\[ E \left( \left\| \int_0^t (Y^n, dM^{\tau_p}) - \int_0^t (Y^m, dM^{\tau_p}) \right\|^2 \right) \leq E \left( \int_0^T \| Y^n - Y^m \|_H^2 d[M]^{\tau_p} \right) \]

which converges to 0 as \( n, m \to \infty \) by definition of \( Y \in G \). This also shows that the definition is well defined and that the same thing is obtained from any other sequence converging to \( Y \). \( \left\{ \int_0^t (Y^n, dM^{\tau_p}) \right\} \) is a Cauchy sequence in \( L^2(\Omega) \). Hence it converges to something \( N(t) \in L^2(\Omega) \). This is a martingale because if \( A \in F_s, s < t \)

\[ \int_A N(t) \, dP = \lim_{n \to \infty} \int_A \int_0^t (Y^n, dM^{\tau_p}) \, dP \]

\[ = \lim_{n \to \infty} \int_A \int_0^s (Y^n, dM^{\tau_p}) \, dP = \int_A N(s) \, dP \]

Since \( A \) is arbitrary, this shows that \( E(N(t) | F_s) = N(s) \). Then

\[ N(t) \equiv \int_0^t (Y^n, dM^{\tau_p}) \]

In fact, this has a continuous version off a set of measure zero.

These are martingales and so actually, by maximal theorems,

\[ P \left( \sup_{t \in [0,T]} \left\| \int_0^t (Y^n, dM^{\tau_p}) - \int_0^t (Y^m, dM^{\tau_p}) \right\|^2 > \lambda \right) \leq \frac{1}{\lambda} E \left( \left\| \int_0^T (Y^n, dM^{\tau_p}) - \int_0^T (Y^m, dM^{\tau_p}) \right\|^2 \right) \]

\[ \leq \frac{1}{\lambda} E \left( \int_0^T \| Y^n - Y^m \|_H^2 \, d[M]^{\tau_p} \right) \]

which converges to 0. Thus there is a subsequence still denoted with index \( k \) such that

\[ P \left( \sup_{t \in [0,T]} \left\| \int_0^t (Y^k, dM^{\tau_p}) - \int_0^t (Y^{k+1}, dM^{\tau_p}) \right\|^2 > 2^{-k} \right) < 2^{-k} \]

and so there exists a set of measure zero \( N \) such that for \( \omega \notin N \),

\[ \sup_{t \in [0,T]} \left\| \int_0^t (Y^k, dM^{\tau_p}) - \int_0^t (Y^{k+1}, dM^{\tau_p}) \right\|^2 \leq 2^{-k} \]

for all \( k \) large enough and so for this subsequence, the convergence is uniform. Hence \( t \to \int_0^t (Y^n, dM^{\tau_p}) \) has a continuous version obtained from the uniform limit of these.
Finally,

$$E \left( \left| \int_0^t (Y, dM^\tau) \right|^2 \right) = \lim_{n \to \infty} E \left( \left| \int_0^t (Y^n, dM^\tau) \right|^2 \right) \leq \lim_{n \to \infty} E \left( \int_0^t \|Y^n\|^2_H \, d[M]^\tau \right) = E \left( \int_0^t \|Y\|^2_H \, d[M]^\tau \right)$$

What is the quadratic variation of the martingale in the above lemma? I am not going to give it exactly but it is easy to give an estimate for it. Recall the following result. It is Theorem 61.6.4.

**Theorem 64.0.10** Let $H$ be a Hilbert space and suppose $(M, \mathcal{F}_t), t \in [0, T]$ is a uniformly bounded continuous martingale with values in $H$. Also let $\{t^n_k\}_{k=1}^m$ be a sequence of partitions satisfying

$$\lim_{n \to \infty} \max \{|t^n_i - t^n_{i+1}|, i = 0, \cdots, m_n\} = 0, \quad \{t^n_k\}_{k=1}^m \subseteq \{t^{n+1}_k\}_{k=1}^{m_{n+1}}.$$

Then

$$[M](t) = \lim_{n \to \infty} \sum_{k=0}^{m_n-1} \left| M(t \wedge t^n_k) - M(t \wedge t^n_{k+1}) \right|^2_H$$

the limit taking place in $L^2(\Omega)$. In case $M$ is just a continuous local martingale, the above limit happens in probability.

In the above Lemma, you would find the quadratic variation according to this theorem as follows.

$$\left[ \int_0^t (Y, dM^\tau) \right](t) = \lim_{n \to \infty} \sum_{k=0}^{m_n-1} \left| \int_{t \wedge t^n_k}^{t \wedge t^n_{k+1}} (Y, dM^\tau) \right|^2_H$$

where the limit is in probability. Thus

$$\lim_{n \to \infty} P \left( \left| \left[ \int_0^t (Y, dM^\tau) \right](t) - \sum_{k=0}^{m_n-1} \left| \int_{t \wedge t^n_k}^{t \wedge t^n_{k+1}} (Y, dM^\tau) \right|^2_H \right| \geq \varepsilon \right) = 0$$

Then you can obtain from this and the usual appeal to the Borel Cantelli lemma a set of measure zero $N_t$ and a subsequence still denoted with $n$ satisfying that for all $\omega \notin N_t$ and $n$ large enough,

$$\left| \int_0^t (Y, dM^\tau) \right| - \sum_{k=0}^{m_n-1} \left| \int_{t \wedge t^n_k}^{t \wedge t^n_{k+1}} (Y, dM^\tau) \right|^2_H \leq \frac{1}{n}$$

Hence

$$\left| \int_0^t (Y, dM^\tau) \right| \leq \frac{1}{n} + \sum_{k=0}^{m_n-1} \int_{t \wedge t^n_k}^{t \wedge t^n_{k+1}} \|Y\|^2_H \, d[M]^\tau$$
CHAPTER 64. THE INTEGRAL

\[ \int_0^T (Y, DM)_H = \frac{1}{n} + \int_0^t \|Y\|_H^2 d[M]^{T_p} \]

Then for that \( t \), you have on taking a limit as \( n \to \infty \),

\[ \left[ \int_0^t (Y, dM^{T_p}) \right] (t) \leq \int_0^t \|Y\|_H^2 d[M]^{T_p} \]

Now take the union of \( N_t \) for \( t \in \mathbb{Q} \cap [0, T] \). Denote this as \( N \). Then if \( \omega \notin N \), the above shows that for such \( t \),

\[ \left[ \int_0^t (Y, dM^{T_p}) \right] (t) \leq \int_0^t \|Y\|_H^2 d[M]^{T_p} \]

But both sides are continuous in \( t \) and so this inequality holds for all \( t \in [0, T] \).

Thus the following corollary is obtained.

**Corollary 64.0.11** Let \( M \) be a continuous local martingale and \( \tau_p \) a localizing sequence which makes \( M^{T_p} \) an \( L^2 \) martingale and assume that \( Y \in \mathcal{G} \). Then the quadratic variation of this martingale satisfies

\[ \left[ \int_0^t (Y, dM^{T_p}) \right] (t) \leq \int_0^t \|Y\|_H^2 d[M]^{T_p} \leq \int_0^t \|Y\|_H^2 d[M] \]

for \( \omega \) off a set of measure zero.

Does the localization stuff hold for an arbitrary stopping time? Let \( \{t^k_i\} \) denote the \( k^{th} \) partition of a sequence of nested partitions whose maximum length between successive points converges to 0. Let \( \tau \) be a stopping time and let \( \tau_k = t^k_{j+1} \) on \( \tau^{-1}(t^k_j, t^k_{j+1}) \). Then \( \tau_k \) is a stopping time because

\[ [\tau_k \leq t] \in \mathcal{F}_t \]

Here is why. If \( t \in (t^k_j, t^k_{j+1}) \), then if \( t = t^k_{j+1} \), it would follow that \( \tau_k (\omega) \leq t \) would be the same as saying \( \omega \in [\tau \leq t^k_{j+1}] = [\tau \leq t] \in \mathcal{F}_t \). On the other hand, if \( t < t^k_{j+1} \), then \( [\tau_k \leq t] = [\tau \leq t^k_j] \in \mathcal{F}_{t^k_j} = \mathcal{F}_t \) because \( \tau_k \) can only take the values \( t^k_j \).

Let \( Y \) be one of those elementary functions which is in \( \mathcal{G} \), \( \|Y (t)\| M^* \in L^2 (\Omega) \).

\[ Y (t) = \sum_{i=0}^{m_k-1} Y_i \mathcal{X}_{(t^k_i, t^k_{i+1})} (t) \]

and consider \( \mathcal{X}_{[0, \tau_k]} Y \). Here \( Y \) will be always the same for the different partitions. It is just that some of the \( Y_i \) will be repeated on smaller and smaller intervals. Does it follow that \( \mathcal{X}_{[0, \tau_k]} Y \to \mathcal{X}_{[0, \tau]} Y \) for each fixed \( \omega \)? This depends only on the indicator function. Let \( \tau (\omega) \in (t^k_j, t^k_{j+1}) \). Fixing \( t \), if \( \mathcal{X}_{[0, \tau]} (t) = 1 \), then also \( \mathcal{X}_{[0, \tau_k]} (t) = 1 \) because \( \tau_k \geq \tau \). Therefore, in this case \( \lim_{k \to \infty} \mathcal{X}_{[0, \tau_k]} (t) = \mathcal{X}_{[0, \tau]} (t) \). Next suppose
\(X_{[0, \tau]}(t) = 0\) so that \(\tau(\omega) < t\). Since the intervals defined by the partition points have lengths which converge to 0, it follows that for all \(k\) large enough, \(\tau_k(\omega) < t\) also and so \(X_{[0, \tau_k]}(t) = 0\). Therefore,

\[
\lim_{k \to \infty} X_{[0, \tau_k(\omega)]}(t) = X_{[0, \tau(\omega)]}(t).
\]

It follows that \(X_{[0, \tau_k]}Y \to X_{[0, \tau]}Y\). Also it is clear from the dominated convergence theorem,

\[
\|X_{[0, \tau_k]}Y - X_{[0, \tau]}Y\|_H^2 \leq 4\|Y\|_H^2,
\]

that

\[
\lim_{k \to \infty} \mathbb{E} \left( \int_0^T \|X_{[0, \tau_k]}Y - X_{[0, \tau]}Y\|_H^2 d[M^\tau] \right) = 0
\]

Thus \(X_{[0, \tau]}Y \in \mathcal{G}\). By Lemma 64.0.9, there is a subsequence, still denoted as \(X_{[0, \tau_k]}Y\) such that off a set of measure zero,

\[
\int_0^t (X_{[0, \tau_k]}Y, dM^\tau) \to \int_0^t (X_{[0, \tau]}Y, dM^\tau)
\]

uniformly on \([0, T]\). Therefore, from the localization for elementary functions and this uniform convergence,

\[
\int_0^t (X_{[0, \tau]}Y, dM^\tau) = \lim_{n \to \infty} \int_0^{t\wedge T_n} (X_{[0, \tau]}Y, dM^\tau) = \int_0^{t\wedge T} (Y, dM^\tau)
\]

This proves most of the following lemma.

**Lemma 64.0.12** Let \(Y\) be an elementary function. Then if \(\tau\) is any stopping time, then off a set of measure zero,

\[
\int_0^{t\wedge \tau} (Y, dM^\tau) = \int_0^{t\wedge T} (X_{[0, \tau]}Y, dM^\tau) = \int_0^t (Y, dM^{\tau\wedge \tau})
\]

**Proof:** It remains to prove the second equation.

\[
\int_0^{t\wedge \tau} (Y, dM^\tau) = \sum_{i=0}^{m-1} (Y_{t_i}, M^\tau) (t \wedge t_{i+1} \wedge \tau) - M^\tau (t \wedge t_i \wedge \tau)
\]

\[
= \sum_{i=0}^{m-1} (Y_{t_i}, M^{\tau \wedge \tau}) (t \wedge t_{i+1}) - M^\tau (t \wedge t_i)
\]

\[
= \int_0^t (Y, dM^{\tau \wedge \tau}) \quad \blacksquare
\]

**Lemma 64.0.13** Let \(Y \in \mathcal{G}\). Then for any stopping time \(\tau\),

\[
\int_0^{t\wedge \tau} (Y, dM^\tau) = \int_0^{t\wedge T} (X_{[0, \tau]}Y, dM^\tau) = \int_0^t (Y, dM^{\tau\wedge \tau})
\]

for \(\omega\) off some set of measure zero.
CHAPTER 64. THE INTEGRAL \( \int_0^T (Y, dM)_H \)

**Proof:** From Lemma 64.0.9, there exists a sequence of elementary functions \( Y^n \) such that \( t \to \int_0^t (Y^n, dM) \) converges uniformly to \( t \to \int_0^t (Y, dM^n) \) on \([0, T]\) for each \( \omega \notin N \), a set of measure zero. Then

\[
\int_0^{t^{\wedge} \tau} (Y, dM^n) = \lim_{n \to \infty} \int_0^{t^{\wedge} \tau} (Y^n, dM^n) = \lim_{n \to \infty} \int_0^t (X_{[\tau]} Y^n, dM^n) = \int_0^t (X_{[\tau]} Y, dM^n)
\]

The last claim needs a little clarification. As shown in the above discussion proving Lemma 64.0.12, while \( X_{[\tau]} Y^n \) is no longer obviously an elementary function due to the fact that \( \tau \) has values which are not partition points, it is still the limit of a sequence of elementary functions \( X_{[\tau]} Y^n \) and so the integral makes sense. Then from the inequality of Lemma 64.0.9,

\[
E \left( \int_0^T \left( X_{[\tau]} Y^n, dM^{\wedge} \tau \right)^2 \right) \leq E \left( \int_0^T \| Y^n - Y \|_H^2 \ d [M]^{\wedge} \tau \right)
\]

and so by the same Borel Cantelli argument of that lemma, there is a further subsequence for which the convergence is uniform off a set of measure zero as \( n \to \infty \). (Actually, the same subsequence as in the first part of the argument works.) Therefore, the conclusion follows.

What of the second equation? Let \( \{ Y^n \} \) be as above where uniform convergence takes place for the stochastic integrals. Then from Lemma 64.0.12

\[
\int_0^t (X_{[\tau]} Y^n, dM^{\wedge} \tau) = \int_0^t (Y^n, dM^{\wedge} \tau)
\]

Hence

\[
E \left( \int_0^T \left( Y^n, dM^{\wedge} \tau \right) - \int_0^t (X_{[\tau]} Y, dM^n) \right)^2 \leq E \left( \int_0^T \| Y^n - Y \|_H^2 \ d [M]^{\wedge} \tau \right)
\]

Now by the usual application of the Borel Canelli lemma, there is a subsequence and a set of measure zero off which \( \int_0^t (Y^n, dM^{\wedge} \tau) \) converges uniformly to \( \int_0^t (Y, dM^{\wedge} \tau) \) on \([0, T]\) and as \( n \to \infty \), and also

\[
\int_0^t (Y^n, dM^{\wedge} \tau) \to \int_0^t (X_{[\tau]} Y, dM^n)
\]

uniformly on \( t \in [0, T] \). Then from the above,

\[
\int_0^t (Y^n, dM^{\wedge} \tau) \to \int_0^t (X_{[\tau]} Y, dM^n) = \int_0^{t^{\wedge} \tau} (Y, dM^n)
\]

uniformly. Thus \( \int_0^t (Y, dM^{\wedge} \tau) = \int_0^{t^{\wedge} \tau} (Y, dM^n) \). \( \blacksquare \)
Definition 64.0.14 Let \( \tau_p \) be an increasing sequence of stopping times for which
\[
\lim_{p \to \infty} \tau_p = \infty \quad \text{and such that} \quad M^{\tau_p} \quad \text{is a } L^2 \quad \text{martingale and} \quad \mathcal{X}_{[0,\tau_p]}Y \in \mathcal{G}.
\]
Then the definition of \( \int_0^t (Y, dM) \) is as follows. For each \( \omega \),
\[
\int_0^t (Y, dM) = \lim_{p \to \infty} \int_0^t \left( \mathcal{X}_{[0,\tau_p]}Y, dM^{\tau_p} \right)
\]
In fact, this is well defined.

Theorem 64.0.15 The above definition is well defined. Also this makes \( \int_0^t (Y, dM) \) a local martingale. In particular,
\[
\int_0^{t \wedge \tau_p} (Y, dM) = \int_0^t \left( \mathcal{X}_{[0,\tau_p]}Y, dM^{\tau_p} \right)
\]
In addition to this, if \( \sigma \) is any stopping time,
\[
\int_0^{t \wedge \sigma} (Y, dM) = \int_0^t \left( \mathcal{X}_{[0,\sigma]}Y, dM \right)
\]
In this last formula, \( \mathcal{X}_{[0,\sigma]}\mathcal{X}_{[0,\tau_p]}Y \in \mathcal{G} \). In addition, the following estimate holds for the quadratic variation.
\[
\left[ \int_0^t (Y, dM) \right] (t) \leq \int_0^t \|Y\|^2 d[M]
\]

Proof: Suppose for some \( \omega, t < \tau_p < \tau_q \). Let \( \omega \) be such that both \( \tau_p, \tau_q \) are larger than \( t \). Then for all \( \omega \), and \( r \) a stopping time,
\[
\int_0^{t \wedge \tau} \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right) = \int_0^t \left( \mathcal{X}_{[0,\tau_q]}Y, d((M^{\tau_q})^\tau) \right)
\]
In particular, for the given \( \omega \),
\[
\int_0^t \left( \mathcal{X}_{[0,\tau_q]}Y, d((M^{\tau_q})^\tau) \right) = \int_0^t \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right) = \int_0^{t \wedge \tau_q} \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right) = \int_0^{t \wedge \tau_q} \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right)
\]
For the particular \( \omega \), this equals
\[
\int_0^{t \wedge \tau_p} \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right)
\]
Now for all \( \omega \) including the particular one, this equals
\[
\int_0^t \left( \mathcal{X}_{[0,\tau_q]}Y, d((M^{\tau_q})^\tau) \right) = \int_0^t \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right)
\]
For the \( \omega \) of interest, this is
\[
\int_0^{t \wedge \tau_p} \left( \mathcal{X}_{[0,\tau_q]}Y, dM^{\tau_q} \right)
\]
and for all \( \omega \), including the one of interest, the above equals
\[
\int_0^t (X_{[0,\tau_p]} X_{[0,\tau_q]} Y, dM^{\tau_p}) = \int_0^t (X_{[0,\tau_p]} Y, dM^{\tau_p})
\]
thus for this particular \( \omega \), you get the same for both \( p \) and \( q \). Thus the definition is well defined because for a given \( \omega \), \( \int_0^t (X_{[0,\tau_p]} Y, dM^{\tau_p}) \) is constant for all \( p \) large enough.

Next consider the claim about this process being a local martingale. Is \( \int_0^{t^\wedge_{\tau_p}} (Y, dM) \) a martingale? From the definition,
\[
\int_0^{t^\wedge_{\tau_p}} (Y, dM) = \lim_{q \to \infty} \int_0^{t^\wedge_{\tau_p}} (X_{[0,\tau_q]} Y, dM^{\tau_p})
\]
\[= \lim_{q \to \infty} \int_0^t (X_{[0,\tau_q]} Y, dM^{\tau_p}) = \lim_{q \to \infty} \int_0^{t^\wedge_{\tau_p}} (X_{[0,\tau_q]} Y, dM^{\tau_p})
\]
\[= \lim_{q \to \infty} \int_0^t (X_{[0,\tau_q]} Y, dM^{\tau_p}) = \int_0^t (X_{[0,\tau_p]} Y, dM^{\tau_p})
\]
which is known to be a martingale since \( X_{[0,\tau_p]} Y \in \mathcal{G} \). This is what it means to be a local martingale. You localize and get a martingale.

Next consider the claim about an arbitrary stopping time. Why is \( X_{[0,\tau_p]} Y \in \mathcal{G} \)? This is part of a more general question. Suppose \( \bar{Y} \in \mathcal{G} \). Then why is \( X_{[0,\tau]} \bar{Y} \in \mathcal{G} \). It suffices to show this. Let \( \{Y^n\} \) be the sequence of elementary functions which converge to \( \bar{Y} \) as in the definition. Also let \( \sigma_n \) be the stopping time with discreet values which equals \( t^n_{k+1} \) when \( \sigma \in (t^n_k, t^n_{k+1}) \), \( (t^n_k)_{k=0}^m \) being the partition associated with \( Y^n \). Then, as explained earlier, \( X_{[0,\sigma_n]} Y^n \) is an acceptable elementary function and also
\[
\left\{ E \left( \int_0^T \|X_{[0,\sigma]} Y^n - X_{[0,\sigma]} \bar{Y}\|^2 d[M] \right) \right\}^{1/2} \leq \left\{ E \left( \int_0^T \|X_{[0,\sigma]} Y^n - X_{[0,\sigma]} \bar{Y}\|^2 d[M] \right) \right\}^{1/2}
\]
\[+ \left\{ E \left( \int_0^T \|X_{[\sigma,\sigma_n]} \bar{Y}\|^2 d[M] \right) \right\}^{1/2}
\]
\[\leq \left\{ E \left( \int_0^T \|Y^n - \bar{Y}\|^2 d[M] \right) \right\}^{1/2} + \left\{ E \left( \int_0^T \|X_{[\sigma,\sigma_n]} \bar{Y}\|^2 d[M] \right) \right\}^{1/2}
\]
which converges to 0 from the definition of \( \bar{Y} \in \mathcal{G} \) and the dominated convergence theorem. Thus \( X_{[0,\sigma]} \bar{Y} \in \mathcal{G} \).
From the above definition, for each $\omega$ off a suitable set of measure zero, from Lemma 64.0.13,
\[ \int_0^{t \wedge \sigma} (Y, dM) \equiv \lim_{p \to \infty} \int_0^{t \wedge \sigma} (X_{[0, \tau_p]} Y, dM^{\tau_p}) = \lim_{p \to \infty} \int_0^t (X_{[0, \sigma]} Y, dM^{\tau_p}) = \int_0^t (X_{[0, \sigma]} Y, dM) \]
Finally, consider the claim about the quadratic variation. Using Lemma 64.0.6,
\[ \left[ \int_0^{(t)} (Y, dM) \right]^{\tau_p} (t) = \left[ \int_0^{(t)} (Y, dM) \right]^{\tau_p} (t) = \left[ \int_0^{(t)} (X_{[0, \tau_p]} Y, dM^{\tau_p}) \right] (t) \leq \int_0^t \|X_{[0, \tau_p]} Y\|^2 \, d[M]^{\tau_p} \leq \int_0^t \|Y\|^2 \, d[M] \]
Now letting $\tau_p \to \infty$,
\[ \left[ \int_0^{(t)} (Y, dM) \right] (t) \leq \int_0^t \|Y\|^2 \, d[M] \]
Next is the case in which $Y$ is continuous in $t$ but not necessarily bounded nor assumed to be in any kind of $L^2$ space either.

**Definition 64.0.16** Let $Y$ be continuous in $t$ and adapted. Let $M$ be a continuous local martingale $M(0) = 0$. Then the definition of a local martingale $\int_0^t (Y, dM)$ is as follows. Let $\tau_p$ be an increasing sequence of stopping times for which $[M]^{\tau_p}, \|M^{\tau_p}\|, \|X_{[0, \tau_p]} Y\|$ are all bounded by $p$. Then
\[ \int_0^t (Y, dM) \equiv \lim_{p \to \infty} \int_0^t (X_{[0, \tau_p]} Y, dM^{\tau_p}) \]
Then it is clear that $X_{[0, \tau_p]} Y \in \mathcal{G}$. Therefore, the above Theorem yields the following corollary.

**Corollary 64.0.17** The above definition is well defined. Also this makes $\int_0^t (Y, dM)$ a local martingale. In particular,
\[ \int_0^{t \wedge \sigma} (Y, dM) = \int_0^t (X_{[0, \tau_p]} Y, dM^{\tau_p}) \]
In addition to this, if $\sigma$ is any stopping time,
\[ \int_0^{t \wedge \sigma} (Y, dM) = \int_0^t (X_{[0, \sigma]} Y, dM) \]
In this last formula, $X_{[0, \sigma]} Y$ has the same properties as $Y$, being the pointwise limit on $[0, T]$ of a bounded sequence of elementary functions for each $\omega$. In addition to this, there is an estimate for the quadratic variation
\[ \left[ \int_0^{(t)} (Y, dM) \right] (t) \leq \int_0^t \|Y\|^2 \, d[M] \]
CHAPTER 64. THE INTEGRAL $\int_0^T (Y, DM)_H$

Of course there is no change in anything if $M$ has its values in a Hilbert space $W$ while $Y$ has its values in its dual space. Then one defines $\int_0^t (Y, dM)_{W',W}$ by analogy to the above for $Y$ an elementary function, step function which is adapted.

We use the following definition.

**Definition 64.0.18** Let $\tau_p$ be an increasing sequence of stopping times for which $M^{\tau_p}$ is a $L^2$ martingale. If $M$ is already an $L^2$ martingale, simply let $\tau_p \equiv \infty$. Let $\mathcal{G}$ denote those functions $Y$ which are adapted and for which there is a sequence of elementary functions $f$ satisfying $\|Y^n(t)\|_{W'} M^* \in L^2(\Omega)$ for each $t$ with

$$\lim_{n \to \infty} E \left( \int_0^T \|Y - Y^n\|^2_{W'}, d[M]^{\tau_p} \right) = 0$$

for each $\tau_p$.

Then exactly the same arguments given above yield the following simple generalizations.

**Definition 64.0.19** Let $Y \in \mathcal{G}$. Then

$$\int_0^t (Y, dM^{\tau_p})_{W',W} \equiv \lim_{n \to \infty} \int_0^t (Y^n, dM^{\tau_p})_{W',W} \text{ in } L^2(\Omega)$$

**Lemma 64.0.20** The above definition is well defined. Also, $\int_0^t (Y, dM^{\tau_p})_{W',W}$ is a continuous martingale. The inequality

$$E \left( \left\| \int_0^t (Y, dM^{\tau_p})_{W',W} \right\|^2 \right) \leq E \left( \int_0^t \|Y\|^2_{W'}, d[M]^{\tau_p} \right)$$

is also valid. For any sequence of elementary functions $\{Y^n\}$, $\|Y^n(t)\|_{W',M^*} \in L^2(\Omega)$,

$$\|Y^n - Y\|_{L^2(\Omega;L^2([0,T];W',d[M]^{\tau_p}))} \to 0$$

there exists a subsequence, still denoted as $\{Y^n\}$ of elementary functions for which $\int_0^t (Y^n, dM^{\tau_p})_{W',W}$ converges uniformly to $\int_0^t (Y, dM^{\tau_p})_{W',W}$ on $[0,T]$ for $\omega$ off some set of measure zero. In addition, the quadratic variation satisfies the following inequality.

$$\left[ \int_0^t (Y, dM^{\tau_p})_{W',W} \right](t) \leq \int_0^t \|Y\|^2_{W'}, d[M]^{\tau_p} \leq \int_0^t \|Y\|^2_{W'}, d[M]$$

As before, you can consider the case where you only know $X_{[0,\tau_p]} Y \in \mathcal{G}$. This yields a local martingale as before.
Definition 64.0.21 Let \( \tau_p \) be an increasing sequence of stopping times for which \( \lim_{p \to \infty} \tau_p = \infty \) and such that \( M^{\tau_p} \) is a martingale and \( X_{[0,\tau_p]} Y \in \mathcal{G} \). Then the definition of \( \int_0^t \langle Y, dM \rangle_{W',W} \) is as follows. For each \( \omega \) off a set of measure zero,

\[
\int_0^t \langle Y, dM \rangle_{W',W} = \lim_{p \to \infty} \int_0^t \langle X_{[0,\tau_p]} Y, dM^{\tau_p} \rangle_{W',W}
\]

where \( \int_0^t \langle X_{[0,\tau_p]} Y, dM^{\tau_p} \rangle_{W',W} \) is a martingale.

In fact, this is well defined.

Theorem 64.0.22 The above definition is well defined. Also this makes \( \int_0^t \langle Y, dM \rangle_{W',W} \) a local martingale. In particular,

\[
\int_0^{t \wedge \tau_p} \langle Y, dM \rangle_{W',W} = \int_0^t \langle X_{[0,\tau_p]} Y, dM^{\tau_p} \rangle_{W',W}
\]

In addition to this, if \( \sigma \) is any stopping time,

\[
\int_0^{t \wedge \sigma} \langle Y, dM \rangle_{W',W} = \int_0^t \langle X_{[0,\sigma]} Y, dM \rangle_{W',W}
\]

In this last formula, \( X_{[0,\sigma]} X_{[0,\tau_p]} Y \in \mathcal{G} \). In addition, the following estimate holds for the quadratic variation.

\[
\left[ \int_0^t \langle Y, dM \rangle_{W',W} \right](t) \leq \int_0^t \| Y \|_{W'}^2 \, d[M]
\]

Note that from Definition 64.0.21 it is also true that

\[
\int_0^t \langle Y, dM \rangle_{W',W} = \lim_{p \to \infty} \int_0^t \langle X_{[0,\tau_p]} Y, dM^{\tau_p} \rangle_{W',W}
\]

in probability. In addition, since \( \tau_p \to \infty \), it follows that for each \( \omega \), eventually \( \tau_p > T \). Therefore, \( t \to \int_0^t \langle Y, dM \rangle_{W',W} \) is continuous, being equal to \( \int_0^t \langle X_{[0,\tau_p]} Y, dM^{\tau_p} \rangle_{W',W} \) for that \( \omega \).
CHAPTER 64. THE INTEGRAL $\int_0^T \langle Y, DM \rangle_H$
Chapter 65

The Easy Ito Formula

First recall where it is shown that for every $\alpha$

$$E (|W (t) - W (s)|^\alpha) \leq C_{\alpha} |t - s|^{\alpha/2},$$

and so by Kolmogorov Censtsov continuity theorem

$$|W (t) - W (s)| \leq C_{\gamma} |t - s|^\gamma$$

(65.0.1)

for every $\gamma < 1/2$.

### 65.1 The Situation

The idea is as follows. You have a sufficiently smooth function $F : [0, T] \times H \to \mathbb{R}$ where $H$ is a separable Hilbert space. You also have the random variable

$$X (t) = X_0 + \int_0^t \phi (s) \, ds + \int_0^t \Phi \, dW$$

where $\Phi$ is progressively measurable and in $L^2 ([0, T] \times \Omega; L_2 (Q^{1/2}U, H))$ where $Q : U \to U$ is a positive self adjoint operator. Also assume $X_0$ is $\mathcal{F}_0$ measurable with values in $H$. Recall the descriptive diagram.

Here the Wiener process is in $U_1$ and the filtration with respect to which $\Phi$ is progressively measurable is the usual filtration determined by this Wiener process. Then the Ito formula is about writing the random variable $F (t, X (t))$ in terms of various integrals and derivatives of $F$. 

2347
CHAPTER 65. THE EASY ITO FORMULA

65.2 Assumptions And A Lemma

Assume $F : [0,T] \times H \times \Omega \rightarrow \mathbb{R}^1$ has continuous partial derivatives $F_t, F_X,$ and $F_{XX}$ which are uniformly continuous and bounded on bounded subsets of $[0,T] \times H$ independent of $\omega \in \Omega$. Also assume $F_{XX}$ is uniformly bounded and that $F_{XXX}$ exists.

Let $\phi : [0,T] \times \Omega \rightarrow H$ be progressively measurable and Bochner integrable for each $\omega$. Assume $\Phi$ is progressively measurable, and is in $L^2 \left([0,T] \times \Omega; L^2(Q^{1/2}U, H)\right)$.

Now here is the important lemma which makes the Ito formula possible.

**Lemma 65.2.1** Suppose $\eta_j$ are real random variables $E(\eta_j^2) < \infty$, such that $\eta_k$ is measurable with respect to $\mathcal{G}_j$ for all $j > k$ where $\{\mathcal{G}_k\}$ is increasing. Then

$$E \left( \sum_{k=0}^{m-1} \eta_k - \sum_{k=0}^{m-1} E(\eta_k|\mathcal{G}_k) \right)^2 \right)$$

(65.2.2)

$$= E \left( \sum_{k=0}^{m-1} \eta_k^2 - E(\eta_k|\mathcal{G}_k)^2 \right)$$

**Proof:** First consider a mixed term $i < k$.

$$E \left( (\eta_i - E(\eta_i|\mathcal{G}_i))(\eta_k - E(\eta_k|\mathcal{G}_k)) \right)$$

This equals

$$E(\eta_i,\eta_k) - E(\eta_i,E(\eta_k|\mathcal{G}_k)) - E(\eta_k,E(\eta_i|\mathcal{G}_i)) + E(\eta_i,E(\eta_k|\mathcal{G}_k)) E(\eta_k|\mathcal{G}_k)$$

$$= E(\eta_i,\eta_k) - E(\eta_i,E(\eta_k|\mathcal{G}_k)) - E(\eta_k,E(\eta_i|\mathcal{G}_i)) + E(\eta_k,E(\eta_i|\mathcal{G}_i)|\mathcal{G}_k)$$

$$= E(\eta_i,\eta_k) - E(\eta_i,E(\eta_k|\mathcal{G}_k)) - E(\eta_k,E(\eta_i|\mathcal{G}_i)) + E(\eta_i,E(\eta_k|\mathcal{G}_i))$$

$$= E(\eta_i,\eta_k) - E(\eta_i,\eta_k) - E(\eta_k,E(\eta_i|\mathcal{G}_i)) + E(\eta_k,E(\eta_i|\mathcal{G}_i)) = 0$$

Thus (65.2.2) equals

$$\sum_{k=0}^{m-1} E \left( (\eta_k - E(\eta_k|\mathcal{G}_k))^2 \right)$$
65.3. A SPECIAL CASE

which equals

\[ \sum_{k=0}^{m-1} E(\eta_k^2) - 2E(\eta_k E(\eta_k|\mathcal{G}_k)) + E\left(E(\eta_k |\mathcal{G}_k)^2\right) \]

\[ = \sum_{k=0}^{m-1} E(\eta_k^2) - 2E(\eta_k E(\eta_k|\mathcal{G}_k))|\mathcal{G}_k) + E\left(E(\eta_k |\mathcal{G}_k)^2\right) \]

\[ = \sum_{k=0}^{m-1} E(\eta_k^2) - 2E(\eta_k|\mathcal{G}_k) E(\eta_k|\mathcal{G}_k)) + E\left(E(\eta_k |\mathcal{G}_k)^2\right) \]

\[ = \sum_{k=0}^{m-1} E(\eta_k^2) - 2E\left(E(\eta_k|\mathcal{G}_k)^2\right) + E\left(E(\eta_k |\mathcal{G}_k)^2\right) \]

\[ = \sum_{k=0}^{m-1} E(\eta_k^2) - E\left(E(\eta_k |\mathcal{G}_k)^2\right) \]

\[ \square \]

65.3 A Special Case

To make it simpler, first consider the situation in which \( \Phi = \Phi_0 \) where \( \Phi_0 \) is \( \mathcal{F}_0 \) measurable and has finitely many values in \( \mathcal{L}(U_1, H) \), and \( \phi = \phi_0 \) where \( \phi_0 \) is \( \mathcal{F}_0 \) measurable and a simple function with values in \( H \). Thus

\[ X(t) = X_0 + \int_0^t \phi_0 ds + \int_0^t \Phi_0 dW \]

Now let \( \{t^n_k\}_{k=0}^m \) denote the \( n^{th} \) partition of \([0, T]\), referred to as \( \mathcal{P}_n \) such that

\[ \lim_{n \to \infty} \max \{ |t^n_k - t^n_{k-1}| , k = 0, 1, 2, \ldots, m_n \} = \lim_{n \to \infty} ||\mathcal{P}_n|| = 0. \]

The superscript \( n \) will be suppressed to save notation. Then

\[ F(T, X(T)) - F(0, X_0) = \sum_{k=0}^{m_n-1} (F(t_{k+1}, X(t_{k+1})) - F(t_k, X(t_k))) \]

\[ = \sum_{k=0}^{m_n-1} (F(t_{k+1}, X(t_{k+1})) - F(t_k, X(t_{k+1}))) \]

\[ + \sum_{k=0}^{m_n-1} (F(t_k, X(t_{k+1})) - F(t_k, X(t_k))) \]

This equals

\[ \sum_{k=0}^{m_n-1} F_l(t_k, X(t_{k+1}))(t_{k+1} - t_k) + o(|t_{k+1} - t_k|) \quad (65.3.3) \]
\[ + \sum_{k=0}^{m_n-1} F_X (t_k, X (t_k)) (X (t_{k+1}) - X (t_k)) \quad (65.3.4) \]

\[ + \frac{1}{2} \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) (X (t_{k+1}) - X (t_k)), (X (t_{k+1}) - X (t_k)))_H \quad (65.3.5) \]

\[ + \sum_{k=0}^{m_n-1} \mathcal{O} \left( |X (t_{k+1}) - X (t_k)|^3 \right) \quad (65.3.6) \]

Recall

\[ X (t) = X_0 + \int_0^t \Phi_0 ds + \int_0^t \Phi_0 dW \]

From the properties of the Wiener process in 65.0.1, the term in 65.3.6 converges to 0 as \( n \to \infty \) since these properties of the Wiener process imply \( X \) is H"older continuous with exponent 2/5.

Now consider the term of 65.3.5. All terms converge to 0 except

\[ \frac{1}{2} \sum_{k=0}^{m_n-1} \left( F_{XX} (t_k, X (t_k)) \int_{t_k}^{t_{k+1}} \Phi_0 dW, \int_{t_k}^{t_{k+1}} \Phi_0 dW \right)_H \quad (65.3.7) \]

Consider one of the terms in 65.3.7. Let \( A \in \mathcal{F}_{t_k} \). By Corollary 65.0.4,

\[ \int_A \frac{1}{2} \left( F_{XX} (t_k, X (t_k)) \int_{t_k}^{t_{k+1}} \Phi_0 dW, \int_{t_k}^{t_{k+1}} \Phi_0 dW \right)_H dP \]

\[ = \int_A \frac{1}{2} \left( \int_{t_k}^{t_{k+1}} F_{XX} (t_k, X (t_k)) \Phi_0 dW, \int_{t_k}^{t_{k+1}} \Phi_0 dW \right)_H dP \]

By independence,

\[ = P (A) \frac{1}{2} \int \Omega \left( \int_{t_k}^{t_{k+1}} F_{XX} (t_k, X (t_k)) \Phi_0 dW, \int_{t_k}^{t_{k+1}} \Phi_0 dW \right)_H dP \]

By the Ito isometry results presented earlier,

\[ = \int \Omega \mathcal{A} \frac{1}{2} \int_{t_k}^{t_{k+1}} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0)_{L^2} dsdP \] 

[\text{\mathcal{A} \text{ measurable}}]

\[ = \int_A \frac{1}{2} \int_{t_k}^{t_{k+1}} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0)_{L^2} dsdP \]

\[ = \int_A \frac{1}{2} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0)_{L^2} (t_{k+1} - t_k) dP \]
Since $A \in \mathcal{F}_{t_k}$ was arbitrary,

$$E\left(\frac{1}{2} \left( F_{XX} (t, X (t)) \int_{t_k}^{t_{k+1}} \Phi_0 dW; \int_{t_k}^{t_{k+1}} \Phi_0 dW \right) | \mathcal{F}_{t_k}\right)$$

$$= \frac{1}{2} \left( F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0 \right)_{L^2} (t_{k+1} - t_k).$$

From what was just shown, and Lemma 65.2.1,

$$E\left( \left[ \frac{1}{2} \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) \Phi_0 \Delta W (t_k), \Phi_0 \Delta W (t_k) )_H - \sum_{k=0}^{m_n-1} \frac{1}{2} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0 )_{L^2} (t_{k+1} - t_k) \right]^2 \right)$$

$$= \frac{1}{4} E\left( \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) \Phi_0 \Delta W (t_k), \Phi_0 \Delta W (t_k) )_H^2 - \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0 )_{L^2} (t_{k+1} - t_k)^2 \right)^2$$

Now $F_{XX}$ is bounded and so there exists a constant $M$ independent of $k$ and $n$,

$$M \geq ||\Phi_0 F_{XX} (t_k, X (t_k))\Phi_0||, ||(F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0 )_{L^2}||$$

Hence the above is dominated by

$$\leq \frac{1}{4} M^2 \sum_{k=0}^{m_n-1} E||\Delta W (t_k)||^4_{L^1} + \frac{1}{4} M^2 \sum_{k=0}^{m_n-1} (t_{k+1} - t_k)^2$$

$$\leq \frac{M^2}{4} \left( \sum_{k=0}^{m_n-1} (C_4 + 1) (t_{k+1} - t_k)^2 \right)$$

which converges to 0 as $n \to \infty$. Then from Lemma 65.2.1, and referring to Lemma 65.3.5,

$$\lim_{n \to \infty} \frac{1}{2} \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) (X (t_{k+1}) - X (t_k)), (X (t_{k+1}) - X (t_k)) )_H$$

$$= \lim_{n \to \infty} \frac{1}{2} \sum_{k=0}^{m_n-1} \left( F_{XX} (t_k, X (t_k)) \int_{t_k}^{t_{k+1}} \Phi_0 dW; \int_{t_k}^{t_{k+1}} \Phi_0 dW \right)_H$$

$$= \lim_{n \to \infty} \frac{1}{2} \sum_{k=0}^{m_n-1} (F_{XX} (t_k, X (t_k)) \Phi_0, \Phi_0 )_{L^2} (t_{k+1} - t_k)$$
if this last limit exists in $L^2(\Omega)$. However, since $F_{XX}$ is bounded, this limit certainly exists for a.e. $\omega$ and equals

$$\frac{1}{2} \int_0^T (F_{XX}(t, X(t)) \Phi_0, \Phi_0)_{\mathcal{L}_2} dt,$$

The limit also exists in $L^2(\Omega)$ obviously, since $F_{XX}$ is assumed bounded. Therefore, a subsequence of $\{F_{XX,n}\}$, still denoted as $F_{XX,n}$, must converge for a.e. $\omega$ to the above integral as $n \to \infty$.

Next consider $m_{n,1}$.

$$\sum_{k=0}^{m_{n-1}} F_X(t_k, X(t_k)) (X(t_{k+1}) - X(t_k)) = \sum_{k=0}^{m_{n-1}} F_X(t_k, X(t_k)) \left( \int_{t_k}^{t_{k+1}} \phi_0 ds \right)$$

$$+ \sum_{k=0}^{m_{n-1}} F_X(t_k, X(t_k)) \int_{t_k}^{t_{k+1}} \Phi_0 dW$$

(65.3.10)

Consider the second of these in $m_{n,1}$. From Corollary 65.3.4, it equals

$$\sum_{k=0}^{m_{n-1}} \int_{t_k}^{t_{k+1}} F_X(t_k, X(t_k)) \Phi_0 dW$$

$$= \int_0^T \left( \sum_{k=0}^{m_{n-1}} \mathcal{H}(t_k, t_{k+1}) (t) F_X(t_k, X(t_k)) \right) \Phi_0 dW$$

which converges as $n \to \infty$ to

$$\int_0^T F_X(t, X(t)) \Phi_0 dW$$

because

$$\lim_{n \to \infty} \left( \sum_{k=0}^{m_{n-1}} \mathcal{H}(t_k, t_{k+1}) (t) F_X(t_k, X(t_k)) \right) \Phi_0 = F_X(t, X(t)) \Phi_0$$

in $L^2([0, T] \times \Omega; \mathcal{L}_2(Q^{1/2}U, H))$. Next consider the first on the right in $m_{n,1}$. It equals

$$\sum_{k=0}^{m_{n-1}} (F_X(t_k, X(t_k)) \phi_0 (t_{k+1} - t_k))$$

and converges to

$$\int_0^T F_X(t, X(t)) \phi_0 dt.$$

Finally, it is obviously the case that $m_{n,1}$ converges to

$$\int_0^T F_i(t, X(t)) dt$$
This has shown
\[
F(T, X(T)) = F(0, X_0) + \int_0^T F_t(t, X(t)) + F_X(t, X(t)) \phi_0 dt \\
+ \int_0^T F_X(t, X(t)) \phi_0 dW + \frac{1}{2} \int_0^T (F_{XX}(t, X(t)) \Phi_0, \Phi_0)_{\mathcal{L}_2(Q^{1/2}, U, H)} dt
\]
when
\[
X(t) = X_0 + \int_0^t \phi_0 ds + \int_0^t \Phi_0 dW,
\]
\[\phi_0, \Phi_0, \mathcal{F}_0\] measurable as described above. This is the first version of the Ito formula.

### 65.4 The Case Of Elementary Functions

Of course there was nothing special about the interval $[0, T]$. It follows that for $[a, b] \subseteq [0, T], \Phi_a \in \mathcal{L}(U_1, U)$ and \mathcal{F}_a measurable, having finitely many values, \(\phi_a\) a simple function which is \(\mathcal{F}_a\) measurable,
\[
X(t) = X(a) + \int_a^t \phi_a dt + \int_a^t \Phi_a dW
\]
\[
F(b, X(b)) = F(a, X(a)) + \int_a^b (F_t(t, X(t)) + F_X(t, X(t)) \phi_a) dt \\
+ \int_a^b F_X(t, X(t)) \Phi_a dW + \frac{1}{2} \int_a^b (F_{XX}(t, X(t)) \Phi_a, \Phi_a)_{\mathcal{L}_2(Q^{1/2}, U, H)} dt.
\]
Therefore, if \(\Phi\) is any elementary function, being a sum of functions like \(\Phi_a \chi_{[a,b]}\), and \(\phi\) a similar sort of elementary function with
\[
X(t) = X_0 + \int_0^t \phi ds + \int_0^t \Phi dW,
\]
then
\[
F(T, X(T)) = F(0, X_0) + \int_0^T F_t(t, X(t)) + F_X(t, X(t)) \phi(t) dt \\
+ \int_0^T F_X(t, X(t)) \phi dW + \frac{1}{2} \int_0^T (F_{XX}(t, X(t)) \Phi, \Phi)_{\mathcal{L}_2(Q^{1/2}, U, H)} dt
\]
(65.4.11)
This has proved the following lemma.

**Lemma 65.4.1** Let \(\Phi, \phi\) be elementary functions as described and let
\[
X(t) = X_0 + \int_0^t \phi(s) ds + \int_0^t \Phi dW
\]
Then (65.4.11) holds.
65.5 The Integrable Case

Now let \( \Phi \in L^2 \left( [0,T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right) \), \( \phi \in L^1 \left( [0,T] \times \Omega; H \right) \) and be progressively measurable. Let \( \phi \) be as above, and let

\[
X(t) = X_0 + \int_0^t \phi(t) \, dt + \int_0^t \Phi \, dW \tag{65.5.12}
\]

Suppose also the additional condition that for some \( M \),

\[
|X(t,\omega)| < M \quad \text{for all} \quad (t,\omega) \in [0,T] \times N^C, \quad P(N) = 0.
\]

Does it follow that 65.4.11 holds?

There exists a sequence of elementary functions \( \{\Phi_n\} \) converging to \( \Phi \circ J^{-1} \) in \( L^2 \left( [0,T] \times \Omega; \mathcal{L}_2 \left( JQ^{1/2}U, H \right) \right) \). Similarly let \( \{\phi_n\} \) converge to \( \phi \) in \( L^1 \left( [0,T] \times \Omega; H \right) \) where \( \phi_n \) is also an elementary function, \( |\phi_n| \leq |\phi| \) at the mesh points. You could use that theorem about approximating with left and right step functions if desired, Lemma 63.3.1. Let

\[
X_n(t) = X_0 + \int_0^t \phi_n(s) \, ds + \int_0^t \Phi_n \, dW.
\]

Also let \( \tau_n \) be the stopping times

\[
\tau_n = \inf \{ t > 0 : |X_n(t)| > M \}.
\]

Since \( X_n \) is continuous, this is a well defined stopping time. Thus

\[
X_{\tau_n}^n(t) = X_0 + \int_0^{\tau_n} X_{[0,\tau_n]}(t) \, dt + \int_0^{\tau_n} X_{[0,\tau_n]} \Phi_n \, dW
\]

and as noted in the discussion of localization for elementary functions, \( X_{[0,\tau_n]} \Phi_n \) is an elementary function.

**Claim:** \( \lim_{n \to \infty} X_{[0,\tau_n]} = 1. \)

**Proof of claim:** From maximal estimates as in the construction of the stochastic integral and the Borel Cantelli lemma, it follows that there exists a subsequence still denoted by \( n \) and a set of measure zero \( N \) such that for \( \omega \notin N_1 \),

\[
\int_0^t \Phi_n \, dW \to \int_0^t \Phi \, dW
\]

uniformly on \( [0,T] \). Also one can show that off a set of measure zero, there is a subsequence still called \( n \) such that \( \int_0^t \phi_n(s) \, ds \to \int_0^t \phi(s) \, ds \) uniformly on \( [0,T] \).

Here is why.

\[
E \left( \left| \int_0^t \phi_n(s) \, ds - \int_0^t \phi(s) \, ds \right| \right) \leq \int_\Omega \int_0^T |\phi_n - \phi| \, dt \, dP
\]
which is given to converge to 0. Thus

\[
P\left( \max_{t \in [0,T]} \left| \int_0^t \phi_n (s) \, ds - \int_0^t \phi (s) \, ds \right| > \lambda \right) \leq P \left( \int_0^T |\phi_n (s) - \phi (s)| \, ds > \lambda \right)
\]

\[
\leq \frac{1}{\lambda} \int_0^T \int_0^T |\phi_n (s) - \phi (s)| \, dsdP
\]

\[
\leq \frac{1}{\lambda} \int_0^T \int_0^T |\phi_n (s) - \phi (s)| \, dsdP
\]

Thus

\[
P \left( \max_{t \in [0,T]} \left| \int_0^t \phi_n (s) \, ds - \int_0^t \phi (s) \, ds \right| > 2^{-k} \right) \leq 2^k \int_0^T \int_0^T |\phi_n (s) - \phi (s)| \, dsdP
\]

If \( n > n_k \), the right side is less than \( 2^{-k} \). Use \( \phi_{n_k} \). Then there exists a set of measure zero \( N_2 \) such that for \( \omega \notin N_2 \),

\[
\left| \int_0^t \phi_n (s) \, ds - \int_0^t \phi (s) \, ds \right| \to 0
\]

uniformly. Hence, you can take a couple of subsequences and assert that there exists a subsequence still called \( n \) and a set of measure zero \( N \) such that \( X_n (t) \to X (t) \) uniformly on \([0,T] \) for each \( \omega \notin N \). Since \( |X (t, \omega)| < M \), it follows that for each \( \omega \notin N \), when \( n \) is large enough, \( \tau_n = \infty \) and this proves the claim.

From the claim, it follows that \( H_{[0,\tau_n]} \Phi_n \to \Phi \circ J^{-1} \) in \( L^2 (\Omega) \) and \( H_{[0,\tau_n]} \phi_n \to \phi \) in \( L^1 (\Omega; H) \). Thus you can replace \( \Phi_n \) in the above with \( H_{[0,\tau_n]} \Phi_n \) and \( \phi_n \) with \( H_{[0,\tau_n]} \phi_n \). Thus there exists a subsequence, still called \( n \) and a set of measure zero \( N \) such that for \( \omega \notin N \),

\[
\int_0^t H_{[0,\tau_n]} \Phi_n dW \to \int_0^t \Phi dW
\]

uniformly and

\[
\int_0^t H_{[0,\tau_n]} \phi_n ds \to \int_0^t \phi ds
\]

uniformly. Hence also \( X_{\tau_n} (t) \to X (t) \) uniformly on \([0,T] \) whenever \( \omega \notin N \). Of course \( |X_{\tau_n} (t)|_H \) has the advantage of being bounded by \( M \).

From the above,

\[
F (T, X_{\tau_n} (T)) = F (0, X_0) + \int_0^T F_1 (t, X_{\tau_n} (t)) + F_X (t, X_{\tau_n} (t)) H_{[0,\tau_n]} \phi_n (t) \, dt
\]

\[
+ \int_0^T F_X (t, X_{\tau_n} (t)) \, H_{[0,\tau_n]} \Phi_n dW + \frac{1}{2} \int_0^T (F_{XX} (t, X_{\tau_n} (t)) H_{[0,\tau_n]} \phi_n, H_{[0,\tau_n]} \phi_n)_{L^2 (Q^{1/2} U, H)} \, dt
\]
Then it is obvious that one can pass to the limit in each of the non stochastic integrals in the above. It is necessary to consider the other one.

From the above claim, \( X_{[0,\tau_n]} \Phi_n \to \Phi \circ J^{-1} \) in \( L^2 \left( [0, T] \times \Omega; L_2 \left( JQ^{1/2}U, H \right) \right) \) and also, thanks to the stopping times \( \tau_n \), \( F_X(t, X_{\tau_n}^n(t)) \) is bounded and converges to \( F_X(t, X(t)) \). Hence the dominated convergence theorem applies, and letting \( n \to \infty \), the following is obtained for a.e. \( \omega \)

\[
F(T, X(T)) = F(0, X_0) + \int_0^T F_t(t, X(t)) + F_X(t, X(t)) \phi(t) \, dt \\
+ \int_0^T F_X(t, X(t)) \Phi_dW + \frac{1}{2} \int_0^T (F_{XX}(t, X(t)) \Phi, \Phi)_{L_2(Q^{1/2}U, H)} \, dt \tag{65.5.13}
\]

This is the Ito formula in case that \( \Phi \in L^2 \left( [0, T] \times \Omega; L_2 \left( Q^{1/2}U, H \right) \right) \) and \( |X| \) is bounded above by \( M \).

It is easy to remove this assumption on \( |X| \). Let \( X \) be given in 65.5.12. Let \( \tau_n \) be the stopping time

\[
\tau_n \equiv \inf \{ t > 0 : |X| > n \}
\]

Then 65.5.13 holds for the stopped process \( X^{\tau_n} \) and \( \Phi \) and \( \phi \) replaced with \( \Phi, X_{[0, \tau_n]} \) and \( \phi, X_{[0, \tau_n]} \) respectively. Then let \( n \to \infty \) in this expression, using the continuity of \( X \) and the fact that \( \tau_n \to \infty \) to recover 65.5.13 without the restriction on \( |X| \).

### 65.6 The General Stochastically Integrable Case

Now suppose that \( \Phi \) is only progressively measurable and stochastically integrable

\[
P \left( \left| \int_0^T ||\Phi||^2_{L_2(Q^{1/2}U, H)} \, dt < \infty \right| \right) = 1.
\]

Also \( \phi \) is only progressively measurable and Bochner integrable in \( t \). Define a stopping time

\[
\tau(\omega) = \inf \left\{ t \geq 0 : |X(t, \omega)|_H + \int_0^t ||\Phi||^2 ds + \int_0^t |\phi| ds > C \right\}
\]

This is just the first hitting time of an open set so it is a stopping time. For \( t \leq \tau \), all of the above quantities must be no larger than \( C \). In particular, \( X_{[0, \tau]} \Phi \in L^2 \left( [0, T] \times \Omega; L_2 \left( Q^{1/2}U, H \right) \right) \). Then

\[
X^{\tau}(t) = X_0 + \int_0^t X_{[0, \tau]} \phi ds + \int_0^t X_{[0, \tau]} \Phi dW
\]

and so 65.5.14 holds with \( X \to X^{\tau}, \Phi \to X_{[0, \tau]} \Phi \) and \( \phi \to X_{[0, \tau]} \phi \). Now simply let \( C \to \infty \) and exploit the continuity of \( X \) given by the formula 65.5.12 to obtain the validity of 65.5.14 without any reference to the stopping time. Of course arbitrary \( t \) can replace \( T \). This leads to the main result.
Theorem 65.6.1 Let $\Phi$ be a progressively measurable process having values in $L_2(Q^{1/2}U,H)$ which is stochastically integrable in $[0,T]$ because

$$P \left( \int_0^T ||\Phi||^2_{L_2(Q^{1/2}U,H)} dt < \infty \right) = 1$$

and let $\phi : [0,T] \times \Omega \rightarrow H$ be progressively measurable and Bochner integrable on $[0,T]$ for a.e. $\omega$, and let $X_0$ be $\mathcal{F}_0$ measurable and $H$ valued. Let

$$X(t) \equiv X_0 + \int_0^t \phi(s) ds + \int_0^t \Phi dW.$$

Let $F : [0,T] \times H \times \Omega \rightarrow \mathbb{R}^1$ be progressively measurable, have continuous partial derivatives $F_t, F_X, F_{XX}$ which are uniformly continuous on bounded subsets of $[0,T] \times H$ independent of $\omega \in \Omega$. Also assume $F_{XX}$ is bounded and let $F_{XXX}$ exist and be bounded. Then the following formula holds for a.e. $\omega$.

$$F(t,X(t)) = F(0,X_0) + \int_0^t F_t(s,X(s)) ds + \int_0^t \Phi dW + \int_0^t F_X(s,X(s)) \phi(s) ds + \frac{1}{2} \int_0^t (F_{XX}(s,X(s)) \Phi, \Phi)_{L_2(Q^{1/2}U,H)} ds$$

The dependence of $F$ on $\omega$ is suppressed.

That last term is interesting and can be written differently. Let $\{g_i\}$ be an orthonormal basis for $Q^{1/2}U$. Then this integrand equals

$$\sum_{i=1}^L (F_{XX}(s,X(s)) \Phi g_i, \Phi g_i)_H = \sum_{i=1}^L (\Phi^* F_{XX}(s,X(s)) \Phi g_i, g_i)_{Q^{1/2}H}$$

and we write this as

$$\text{trace} (\Phi^* (s) F_{XX}(s,X(s)) \Phi (s)).$$

A simple special case is where $Q = I$ and then $Q^{1/2}U = U$. Thus it is only required that $\Phi$ have values in $L_2(U,H)$.

65.7 Remembering The Formula

I find it almost impossible to remember this formula. Here is a way to do it. Recall that $|\Delta W|^2$ is like $\Delta t$. Therefore, in what follows, neglect all terms which are like $dWdt$, $dt^2$, but keep terms which are $dW dt, dW^2$. Then you start with $dX = \phi dt + \Phi dW$. Thus for $F(t,X)$,

$$dF = F_t dt + F_X dX + \frac{1}{2} (F_{XX} dX, dX)$$
other terms from Taylor’s formula are neglected because they involve \(dt dW\) or \(dt^2\).

Now the above equals

\[
dF = F_t dt + F_X (\phi dt + \Phi dW) + \frac{1}{2} (F_{XX} \Phi dW, \Phi dW)
\]

Since the \(dW\) occurs twice, in that inner product, you get a \(dt\) out of it. Hence you get

\[
dF = (F_t + F_X \phi) dt + \frac{1}{2} (F_{XX} \Phi, \Phi) dt + F_X \Phi dW
\]

Now place an \(\int_0^t\) in front of everything and you have the Ito formula.

### 65.8 An Interesting Formula

Suppose everything is real valued and \(\phi\) is progressively measurable and in

\[
L^2 ([0, T] \times \Omega).
\]

Let

\[
X(t) = \int_0^t \phi dW - \frac{1}{2} \int_0^t \phi^2 ds
\]

and consider \(F(X) = e^X\). Then from the Ito formula,

\[
dF = - \left( e^X \phi \frac{1}{2} \right) dt + \frac{1}{2} e^X \phi^2 dt + e^X \phi dW
\]

\[
dF = e^X \phi dW
\]

and then do an integral

\[
e^X(t) - 1 = \int_0^t e^X \phi dW
\]

Thus

\[
e^X(t) = 1 + \int_0^t e^X(s) \phi dW
\]

That expression on the right is obviously a local martingale and so the expression on the left is also. To see this, you can use a localizing sequence of stopping times which depend on the size of \(X(t)\). This will work fine because \(X(t)\) is continuous.

### 65.9 Some Representation Theorems

In this section is a very interesting representation theorem which comes from the Ito formula. In all of this, \(W\) will be a \(Q\) Wiener process having values in \(\mathbb{R}^n\) for which \(Q = I\). Recall that, letting

\[
\mathcal{G}_t = \sigma (W(s) : s \leq t)
\]
the normal filtration determined by the Wiener process is given by

\[ \mathcal{F}_t \equiv \cap_{s>t} \mathcal{G}_s \]

where \( \mathcal{G}_s \) is the completion of \( \mathcal{G}_t \). In this section, the theorems will all feature the smaller filtration \( \mathcal{G}_t \), not the filtration \( \mathcal{F}_t \). First here are some simple observations which tie this specialized material to what was presented earlier.

When you have an \( \mathcal{G}_t \) adapted function in \( L^2(\Omega; \mathbb{R}^n) \), you can consider \( f \) in the norm of \( Q^1/2\mathbb{R}^n \), as follows. Letting \( f \) be an orthonormal basis for the subspace \( Q^1/2\mathbb{R}^n \) in the norm of \( Q^1/2\mathbb{R}^n \),

\[ \| f \|^2_{L^2(Q^1/2\mathbb{R}^n, \mathbb{R})} = \sum_i (f_i g_i)^2 < \infty \]

For simplicity, let \( Q = I \). Then you have the simple situation that

\[ \| f^T \|_{L^2(Q^1/2\mathbb{R}^n, \mathbb{R})} = \| f \|^2_{\mathbb{R}^n} \]

In what follows \( W_t \) will be the \( Q \) Wiener process on \( \mathbb{R}^n \) where \( Q = I \). Then the Itô isometry is nothing more than the following lemma.

**Lemma 65.9.1** Let \( f \) be \( \mathcal{F}_t \) adapted in the sense that every component is \( \mathcal{F}_t \) adapted and \( f \in L^2(\Omega; \mathbb{R}^n) \). Here \( \mathcal{F}_t \) is the normal filtration coming from the Wiener process. Then

\[ \left\| \int_0^T f(s)^T dW_s \right\|_{L^2(\Omega)} = \| f \|_{L^2(\Omega \times [0,T], \mathbb{R}^n)} \cdot \]

**Lemma 65.9.2** Let \( X \geq 0 \) and measurable and integrable. Also define a finite measure \( \nu \) on \( \mathcal{B}(\mathbb{R}^p) \) by

\[ \nu(B) = \int_{\Omega} X \chi_B(Y) \, dP \]

Then

\[ \int_{\Omega} g(Y) XdP = \int_{\mathbb{R}^p} g(y) \, d\nu(y) \]

where here \( Y \) is a measurable function with values in \( \mathbb{R}^p \) and \( g \geq 0 \) is Borel measurable. Formally, \( XdP = d\nu \).

**Proof:** First say \( X = \chi_D \) and replace \( g(Y) \) with \( \chi_{Y^{-1}(B)} \). Let

\[ \mu(B) = \int_{\Omega} X_D \chi_B(Y) \, dP \]

Then

\[ \int_{\Omega} X_D \chi_{Y^{-1}(B)}dP = P(D \cap Y^{-1}(B)) \]
\[ \int_{\mathbb{R}^p} X_B(y) \, d\mu(y) = \mu(B) = \int_{\Omega} X_D X_B(Y) \, dP \]

\[ = \int_{\Omega} X_D X_{Y^{-1}(B)} \, dP = P(D \cap Y^{-1}(B)) \]

Thus

\[ \int_{\Omega} X_D X_{Y^{-1}(B)} \, dP = \int_{\Omega} X_D X_B(Y) \, dP = \int_{\mathbb{R}^p} X_B(Y) \, d\mu(y) \]

Now let \( s_n(y) \uparrow g(y) \), and let \( s_n(y) = \sum_{k=1}^m c_k X_{B_k}(y) \) where \( B_k \) is a Borel set. Then

\[ \int_{\mathbb{R}^p} s_n(y) \, d\mu(y) = \int_{\mathbb{R}^p} \sum_{k=1}^m c_k X_{B_k}(y) \, d\mu(y) = \sum_{k=1}^m c_k \int_{\mathbb{R}^p} X_{B_k}(y) \, d\mu(y) \]

\[ = \sum_{k=1}^m c_k P(D \cap Y^{-1}(B_k)) \]

\[ \int_{\Omega} s_n(Y) X_D \, dP = \sum_{k=1}^m c_k \int_{\Omega} X_D X_{B_k}(Y) \, dP = \sum_{k=1}^m c_k P(D \cap Y^{-1}(B_k)) \]

which is the same thing. Therefore,

\[ \int_{\Omega} s_n(Y) X_D \, dP = \int_{\mathbb{R}^p} s_n(y) \, d\mu(y) \]

Now pass to a limit using the monotone convergence theorem to obtain

\[ \int_{\Omega} g(Y) X_D \, dP = \int_{\mathbb{R}^p} g(y) \, d\mu(y) \]

Next replace \( X_D \) with \( \sum_{k=1}^m d_k X_{D_k}(\omega) \equiv s_n(\omega) \), a simple function. Then from what was just shown,

\[ \int_{\Omega} g(Y) \sum_{k=1}^m d_k X_{D_k} \, dP = \sum_{k=1}^m d_k \int_{\Omega} g(Y) X_{D_k} \, dP \]

\[ = \sum_{k=1}^m d_k \int_{\mathbb{R}^p} g(y) \, d\mu_k \]

where \( \mu_k(B) = \int_{\Omega} X_{D_k} X_B(Y) \, dP \). Now let

\[ \nu_n(B) = \int_{\Omega} \sum_{k=1}^m d_k X_{D_k} X_B(Y) \, dP = \int_{\Omega} s_n X_B(Y) \, dP \]

Then

\[ \nu_n(B) = \sum_{k=1}^m d_k \int_{\Omega} X_{D_k} X_B(Y) \, dP = \sum_{k=1}^m d_k \mu_k(B) \]
Hence
\[
\int_{\Omega} g(Y) s_n dP = \int_{\Omega} g(Y) \sum_{k=1}^{m} d_k X_{D_k} dP = \sum_{k=1}^{m} d_k \int_{\mathbb{R}^p} g(y) d\mu_k
\]
\[
= \int_{\mathbb{R}^p} g(y) \sum_{k=1}^{m} d_k d\mu_k = \int_{\mathbb{R}^p} g(y) d\nu_n
\]

Then let \( s_n(\omega) \uparrow X(\omega) \). Clearly \( \nu_n \ll \nu \) and so by the Radon Nikodym theorem \( d\nu_n = h_n d\nu \). Then by the monotone convergence theorem, for any \( B \) Borel in \( \mathbb{R}^p \),
\[
\int_{B} h_n d\nu = \nu_n(B) = \int_{\Omega} s_n(\omega) \chi_B(Y(\omega)) dP \uparrow \int_{\Omega} X(\omega) \chi_B(Y(\omega)) dP = \nu(B)
\]

Thus for each \( B \) Borel, \( 0 \leq h_n \leq 1 \) and
\[
\int_{B} h_n d\nu \to \nu(B)
\]

and so \( h_n \uparrow 1 \) a.e. Thus, from the above,
\[
\int_{\Omega} g(Y) s_n dP = \int_{\mathbb{R}^p} g(y) d\nu_n = \int_{\mathbb{R}^p} g(y) h_n(y) d\nu
\]

It follows from the monotone convergence theorem that one can pass to a limit in the above and obtain
\[
\int_{\Omega} g(Y) X dP = \int_{\mathbb{R}^p} g(y) d\nu \quad \blacksquare
\]

Note that the same conclusion will hold if the functions are suitably integrable without any restriction on the sign. In particular, this will hold if \( g(y) \) is bounded. One just considers positive and negative parts of real and imaginary parts of \( g \) and applies the above lemma.

Let
\[
\mathcal{G}_t \equiv \sigma(W(s) : s \leq t)
\]

thus the normal filtration for the Wiener process and the Ito integral and so forth is
\[
\mathcal{F}_t = \cap_{s \geq t} \mathcal{G}_s
\]

**Lemma 65.9.3** Let \( h \) be a deterministic step function of the form
\[
h = \sum_{i=0}^{m-1} a_i \chi_{[t_i, t_{i+1})}, \quad t_m = t
\]

Then for \( h \) of this form, linear combinations of functions of the form
\[
\exp \left( \int_{0}^{t} h^T dW - \frac{1}{2} \int_{0}^{t} h \cdot h d\tau \right)
\]

are dense in \( L^2(\Omega, \mathcal{G}_t, P) \) for each \( t \).
Proof: I will show in the process of the proof that functions of the form (65.9.14) are in $L^2(\Omega, P)$. Let $g \in L^2(\Omega, \mathcal{G}_t, P)$ be such that

$$
\int_{\Omega} g(\omega) \exp \left( \int_0^t h^T dW - \frac{1}{2} \int_0^t h \cdot h \, dt \right) \, dP = 0
$$

for all such $h$. It is required to show that whenever this happens for all such functions $\exp \left( \int_0^t h^T dW - \frac{1}{2} \int_0^t h \cdot h \, dt \right)$ then $g = 0$.

Letting $h$ be given as above, \( \int_0^t h^T dW \)

\[
= \sum_{i=0}^{m-1} a_i^T (W(t_{i+1}) - W(t_i)) \quad (65.9.15)
\]

\[
= \sum_{i=1}^m a_{i-1}^T W(t_i) - \sum_{i=0}^{m-1} a_i^T W(t_i)
\]

\[
= \sum_{i=1}^{m-1} (a_{i-1}^T - a_i^T) W(t_i) + a_0^T W(t_0) + a_{m-1}^T W(t_n). \quad (65.9.16)
\]

Also shows $\exp \left( \int_0^t h^T dW \right)$ is in $L^2(\Omega, P)$. To see this recall the $W(t_{i+1}) - W(t_i)$ are independent and the density of $W(t_{i+1}) - W(t_i)$ is

$$
C(n, \Delta t_i) \exp \left( -\frac{1}{2} \frac{|x|^2}{(t_{i+1} - t_i)} \right), \; \Delta t_i \equiv t_{i+1} - t_i,
$$

so

$$
\int_{\Omega} \left( \exp \left( \int_0^t h^T dW \right) \right)^2 \, dP = \int_{\Omega} \exp \left( 2 \int_0^t h^T dW \right) \, dP
$$

\[
= \int_{\Omega} \exp \left( \sum_{i=0}^{m-1} 2a_i^T (W(t_{i+1}) - W(t_i)) \right) \, dP
\]

\[
= \prod_{i=0}^{m-1} \exp (2a_i^T (W(t_{i+1}) - W(t_i))) \, dP
\]

\[
= \prod_{i=0}^{m-1} \int_{\Omega} \exp (2a_i^T (W(t_{i+1}) - W(t_i))) \, dP
\]

\[
= \prod_{i=0}^{m-1} \int_{\mathbb{R}^n} C(n, \Delta t_i) \exp (2a_i^T x) \exp \left( -\frac{1}{2} \frac{|x|^2}{\Delta t_i} \right) \, dx < \infty
\]
Choosing the $a_i$ appropriately in $65.9.16$, the formula in $65.9.16$ is of the form
\[ \sum_{i=0}^{m} y_i^T W_{t_i} \]
where $y_i$ is an arbitrary vector in $\mathbb{R}^n$. It follows that for all choices of $y_j \in \mathbb{R}^n$,
\[ \int_{\Omega} g(\omega) \exp \left( \sum_{j=0}^{m} y_j^T W_{t_j}(\omega) \right) dP = 0. \]

Now the mapping
\[ y = (y_0, \cdots, y_m) \rightarrow \int_{\Omega} g(\omega) \exp \left( \sum_{j=0}^{m} y_j^T W_{t_j}(\omega) \right) dP \]
is analytic on $\mathbb{C}^{(m+1)n}$ and equals zero on $\mathbb{R}^{(m+1)n}$ so from standard complex variable theory, this analytic function must equal zero on $\mathbb{C}^{(m+1)n}$, not just on $\mathbb{R}^{(m+1)n}$. In particular, for all $y = (y_0, \cdots, y_m) \in \mathbb{R}^{(m+1)n}$,
\[ \int_{\Omega} g(\omega) \exp \left( \sum_{j=0}^{m} i y_j^T W_{t_j}(\omega) \right) dP = 0. \quad (65.9.17) \]

This left side equals
\[ \int_{\Omega} g_+(\omega) \exp \left( \sum_{j=0}^{m} i y_j^T W_{t_j}(\omega) \right) dP - \int_{\Omega} g_-(\omega) \exp \left( \sum_{j=0}^{m} i y_j^T W_{t_j}(\omega) \right) dP \]
where $g_+$ and $g_-$ are the positive and negative parts of $g$. By the Lemma and the observation at the end, this equals
\[ \int_{\mathbb{R}^{nm}} \exp \left( \sum_{j=0}^{m} i y_j^T x_j \right) d\nu_+ - \int_{\mathbb{R}^{nm}} \exp \left( \sum_{j=0}^{m} i y_j^T x_j \right) d\nu_- \]
where $\nu_+(B) \equiv \int_{\Omega} g_+(\omega) \mathcal{X}_B(W_{t_1}(\omega), \cdots, W_{t_m}(\omega)) dP$ and $\nu_-$ is defined similarly. Then letting $\nu$ be the measure $\nu_+ - \nu_-$, it follows that
\[ 0 = \int_{\mathbb{R}^{nm}} \exp \left( \sum_{j=0}^{m} i y_j^T x_j \right) d\nu(y) \]
and this just says that the inverse Fourier transform of $\nu$ is 0. It follows that $\nu = 0$. Thus
\[ \int_{\Omega} g(\omega) X_B(W_{t_1}(\omega), \cdots, W_{t_m}(\omega)) dP = \int_{\Omega} g(\omega) X_{W_m^{-1}(B)}(\omega) dP = 0 \]
for every $B$ Borel in $\mathbb{R}^m$ where

$$W_m(\omega) \equiv (W_{t_1}(\omega), \cdots, W_{t_m}(\omega))$$

Let $\mathcal{K}$ be the $\pi$ system defined as $W_m^{-1}(B)$ for $B$ of the form $\prod_{i=1}^m U_i$ where $U_i$ is open in $\mathbb{R}^n$, this for some $m$ a positive integer. This is indeed a $\pi$ system because it includes $W_1^{-1}(\mathbb{R}^n) = \Omega$ and the empty set. Also it is closed with respect to intersections because, in the situation where each $s_i$ is larger than every $t_i$,

$$\left(\prod_{i=1}^m U_i\right) \cap \left(\prod_{i=1}^2 V_i\right) = \left(\prod_{i=1}^m U_i \times \prod_{k=1}^n \mathbb{R}^n\right) \cap \left(\prod_{i=1}^2 V_i\right) = \left(\prod_{i=1}^m U_i \times \prod_{k=1}^n V_k\right)$$

In general, you would just make the obvious modification where you insert a copy of $\mathbb{R}^n$ in the appropriate position after rearranging so that the indices are increasing.

It was just shown that $K \subseteq G$ where

$$G \equiv \left\{ U \in \mathcal{G}_t : \int \Omega g \chi_U dP = 0 \right\}.$$

Now it is clear that $G$ is closed with respect to countable disjoint unions and complements. The case of complements goes as follows. $\Omega \in \mathcal{K}$ and so if $U \in G$,

$$\int \Omega g \chi_U dP + \int \Omega g \chi_{U^c} dP = \int \Omega g dP$$

The last on the left and the integral on the right are both 0 so it follows that $\int \Omega g \chi_{U^c} dP = 0$ also. It follows from Dynkin’s lemma that $G \supseteq \sigma(\mathcal{K})$. Now $\sigma(\mathcal{K})$ is $\sigma(W(u) : u \leq t) \equiv \mathcal{G}_t$. Hence, $G = \mathcal{G}_t$ and so $g$ is in $L^2(\Omega, \mathcal{G}_t)$ and for every $U \in \mathcal{G}_t$,

$$\int \Omega g \chi_U dP = 0$$

which requires $g = 0$. Thus functions of the above form are indeed dense in $L^2(\Omega, \mathcal{G}_t)$. £

Note that this involves $g$ being $\mathcal{G}_t$ measurable, not $\mathcal{F}_t$ measurable. It is not clear to me whether it suffices to assume only that $g$ is $\mathcal{F}_t$ measurable. If true, this above has not proved it. The problem is the argument at the end using Dynkin’s lemma to conclude that $g = 0$. 

Why such a funny lemma? It is because of the following computation which depends on Itô’s formula. Let

\[ X = \int_0^t h^T dW - \frac{1}{2} \int_0^t h \cdot h \, dt \]

and \( g(x) = e^x \) and consider \( g(X) = Y \). Recall the Ito formula. Formally,

\[ dY = g'(X) dX + \frac{1}{2} g''(X) (dX)^2 \]

\[
\begin{align*}
\quad dY &= g(X) \left( h^T dW - \frac{1}{2} |h|^2 \, dt \right) \\
&+ \frac{1}{2} g(X) \left( h^T dW - \frac{1}{2} |h|^2 \, dt \right) \left( h^T dW - \frac{1}{2} |h|^2 \, dt \right) \\
&= Y \left( h^T dW - \frac{1}{2} |h|^2 \, dt \right) + \frac{1}{2} Y \left[ (h^T dW) (h^T dW) - h^T dW |h|^2 \, dt + \frac{1}{4} |h|^2 \, dt^2 \right]
\end{align*}
\]

Then neglecting the terms of the form \( dW \, dt, dt^2 \) and so forth,

\[
\begin{align*}
\quad dY &= Y h^T dW - \frac{1}{2} Y |h|^2 \, dt + \frac{1}{2} Y (h^T dW) (h^T dW) \\
\end{align*}
\]

Now the \( dW \) occurs twice in the last term so it leads to a \( dt \) and you get

\[
\begin{align*}
\quad dY &= Y h^T dW - \frac{1}{2} Y |h|^2 \, dt + \frac{1}{2} (Y h^T, h^T) \, dt \\
\quad dY &= Y h^T dW - \frac{1}{2} Y |h|^2 \, dt + \frac{1}{2} Y |h|^2 \, dt \\
\quad dY &= Y h^T dW \\
\end{align*}
\]

Note that \( \|h^T\|_{L_2(\mathbb{R}^n, \mathbb{R})} = \sum_{k=1}^n (h^T e_k)^2 = |h|^2_{\mathbb{R}^n} \). Place an \( f_0^t \) in place of both sides to obtain

\[
\begin{align*}
Y(t) - Y(0) &= \int_0^t Y h^T dW \\
Y(t) &= 1 + \int_0^t Y h^T dW \\
(65.9.18)
\end{align*}
\]

Now here is the interesting part of this formula.

\[
E \left( \int_0^t Y h^T dW \right) = 0
\]

because the stochastic integral is a martingale and equals 0 at \( t = 0 \).

\[
E \left( \int_0^t Y h^T dW \right) = E \left( E \left( \int_0^t Y h^T dW | \mathcal{F}_0 \right) \right) = 0
\]
Thus
\[ E(Y(t)) = 1 \]
and for \( Y \) one obtains
\[
Y(t) = E(Y(t)) + \int_0^t Yh^T dW
\]
where \( f^T \) is adapted and square integrable. It is just \( Yh^T \) where \( h \) does not depend on \( \omega \) and \( Y \) is a function of an adapted function.

Does such a function \( f \) exist for all \( F \in L^2(\Omega, \mathcal{G}_t, P) \)? The answer is yes and this is the content of the next theorem which is called the It\( \bar{\text{o}} \) representation theorem.

**Theorem 65.9.4** Let \( F \in L^2(\Omega, \mathcal{G}_t, P) \). Then there exists a unique \( \mathcal{G}_t \) adapted \( f \in L^2(\Omega \times [0,t]; \mathbb{R}^n) \) such that
\[
F = E(F) + \int_0^t f(s, \omega)^T dW.
\]

**Proof:** By Lemma 65.9.3, the span of functions of the form
\[
\exp \left( \int_0^t h^T dW - \frac{1}{2} \int_0^t h \cdot h dt \right)
\]
where \( h \) is a vector valued deterministic step function of the sort described in this lemma, are dense in \( L^2(\Omega, \mathcal{G}_t, P) \). Given \( F \in L^2(\Omega, \mathcal{G}_t, P) \), \( \{G_k\}_{k=1}^{\infty} \) be functions in the subspace of linear combinations of the above functions which converge to \( F \) in \( L^2(\Omega, \mathcal{G}_t, P) \). For each of these functions there exists \( f_k \) an adapted step function such that
\[
G_k = E(G_k) + \int_0^t f_k(s, \omega)^T dW.
\]
Then from the It\( \bar{\text{o}} \) isometry, and the observation that \( E(G_k - G_l)^2 \to 0 \) as \( k, l \to \infty \) by the above definition of \( G_k \) in which the \( G_k \) converge to \( F \) in \( L^2(\Omega) \),
\[
0 = \lim_{k,l \to \infty} E \left( (G_k - G_l)^2 \right)
= \lim_{k,l \to \infty} E \left( \left( E(G_k) + \int_0^t f_k(s, \omega)^T dW - \left( E(G_l) + \int_0^t f_l(s, \omega)^T dW \right) \right)^2 \right)
= \lim_{k,l \to \infty} \left\{ E(G_k - G_l)^2 + 2E(G_k - G_l) \int_{\Omega} \int_0^t (f_k - f_l)^T dW dP \right. \\
+ \int_{\Omega} \left( \int_0^t (f_k - f_l)^T dW \right)^2 dP \right\}
65.9. SOME REPRESENTATION THEOREMS

\[ \lim_{k, l \to \infty} \left\{ E(G_k - G_l)^2 + \int_{\Omega} \left( \int_0^t (f_k - f_l)^T dW \right)^2 dP \right\} = \]

\[ \lim_{k, l \to \infty} \int_{\Omega} \left( \int_0^t (f_k - f_l)^T dW \right)^2 dP = \lim_{k, l \to \infty} ||f_k - f_l||_{L^2(\Omega \times [0, T]; \mathbb{R}^n)} \]  

(65.9.19)

Going from the third to the fourth equations, is justified because

\[ \int_{\Omega} \int_0^t (f_k - f_l)^T dW dP = 0 \]

thanks to the fact that the Ito integral is a martingale which equals 0 at \( t = 0 \).

This shows \( \{f_k\}_{k=1}^{\infty} \) is a Cauchy sequence in \( L^2(\Omega \times [0, t]; \mathbb{R}^n, \mathcal{P}) \), where \( \mathcal{P} \) denotes the progressively measurable sets. It follows there exists a subsequence and \( f \in L^2(\Omega \times [0, t]; \mathbb{R}^n) \) such that \( f_k \) converges to \( f \) in \( L^2(\Omega \times [0, t]; \mathbb{R}^n, \mathcal{P}) \) with \( f \) being progressively measurable. Then by the Itô isometry and the equation

\[ G_k = E(G_k) + \int_0^t f_k(s, \omega)^T dW \]

you can pass to the limit as \( k \to \infty \) and obtain

\[ F = E(F) + \int_0^t f(s, \omega)^T dW \]

Now \( E(G_k) \to E(F) \). Consider the stochastic integrals. By the maximal estimate, Theorem 65.3.4, and the Ito isometry,

\[ P \left( \sup_{s \in [0, t]} \left| \int_0^s f_k(\cdot, \omega)^T dW - \int_0^s f(\cdot, \omega)^T dW \right| > \delta \right) \]

\[ \leq \frac{E \left( \int_0^t f_k(\cdot, \omega)^T dW - \int_0^t f(\cdot, \omega)^T dW \right)^2}{\delta^2} \]

\[ = \frac{E \left( \int_0^t ||f_k - f||_{\mathbb{R}^n}^2 ds \right)}{\delta^2} \]

From the above convergence result and an application of the Borel Cantelli lemma, there is a set of measure zero \( N \) and a subsequence, still denoted as \( f_k \) such that for \( \omega \notin N \), the convergence of the stochastic integrals for this subsequence is uniform. Thus for \( \omega \notin N \),

\[ F = E(F) + \int_0^t f(s, \omega)^T dW \]

This proves the existence part of this theorem.
It remains to consider the uniqueness. Suppose then that
\[
F = E(F) + \int_0^T f(t, \omega)^T dW = E(F) + \int_0^T f_1(t, \omega)^T dW.
\]
Then
\[
\int_0^T f(t, \omega)^T dW = \int_0^T f_1(t, \omega)^T dW
\]
and so
\[
\int_0^T \left( f(t, \omega)^T - f_1(t, \omega)^T \right) dW = 0
\]
and by the Itô isometry,
\[
0 = \int_0^T \left( f(t, \omega)^T - f_1(t, \omega)^T \right) dW = ||f - f_1||_{L^2(\Omega \times [0,T]; \mathbb{R}^n)}
\]
which proves uniqueness.

With the above major result, here is another interesting representation theorem. Recall that if you have an \(F_t\) adapted function \(f\) and \(f \in L^2(\Omega \times [0,T]; \mathbb{R}^n)\), then \(\int_0^T f^T dW\) is a martingale. The next theorem is sort of a converse. It starts with a \(G_t\) martingale and represents it as an Itô integral. In this theorem, \(G_t\) continues to be the filtration determined by \(n\) dimensional Wiener process.

**Theorem 65.9.5** Let \(M\) be an \(G_t\) martingale and suppose \(M(t) \in L^2(\Omega)\) for all \(t \geq 0\). Then there exists a unique stochastic process, \(g(s, \omega)\) such that \(g\) is \(G_t\) adapted and in \(L^2(\Omega \times [0,t])\) for each \(t > 0\), and for all \(t \geq 0\),
\[
M(t) = E(M(0)) + \int_0^t g^T dW
\]

**Proof:** First suppose \(f\) is an adapted function of the sort that \(g\) is. Then the following claim is the first step in the proof.

**Claim:** Let \(t_1 < t_2\). Then
\[
E \left( \int_{t_1}^{t_2} f^T dW | G_{t_1} \right) = 0
\]

**Proof of claim:** This follows from the fact that the Itô integral is a martingale adapted to \(G_t\). Hence the above reduces to
\[
E \left( \int_0^{t_2} f^T dW - \int_0^{t_1} f^T dW | G_{t_1} \right) = \int_0^{t_1} f^T dW - \int_0^{t_1} f^T dW = 0.
\]

Now to prove the theorem, it follows from Theorem 65.9.4 and the assumption that \(M\) is a martingale that for \(t > 0\) there exists \(f^t \in L^2(\Omega \times [0,T]; \mathbb{R}^n)\) such that
\[
M(t) = E(M(0)) + \int_0^t f^t(s, \omega)^T dW = E(M(0)) + \int_0^t f^t(s, \omega)^T dW.
\]
Now let \( t_1 < t_2 \). Then since \( M \) is a martingale and so is the Ito integral,

\[
M (t_1) = E (M (t_2) | \mathcal{G}_{t_1}) = E \left( E (M (0)) + \int_{0}^{t_2} f^t (s, \cdot)^T dW | \mathcal{G}_{t_1} \right)
\]

\[
= E (M (0)) + E \left( \int_{0}^{t_1} f^t (s, \cdot)^T dW \right)
\]

Thus

\[
M (t_1) = E (M (0)) + \int_{0}^{t_1} f^t (s, \cdot)^T dW = E (M (0)) + \int_{0}^{t_1} f^t (s, \cdot)^T dW
\]

and so

\[
0 = \int_{0}^{t_1} f^t (s, \cdot)^T dW - \int_{0}^{t_1} f^t (s, \cdot)^T dW
\]

and so by the Itô isometry,

\[
\| f^{t_1} - f^{t_2} \|_{L^2 (\Omega \times [0, t_1]; \mathbb{R}^n)} = 0.
\]

Letting \( N \in \mathbb{N} \), it follows that

\[
M (t) = E (M (0)) + \int_{0}^{t} f^N (s, \cdot)^T dW
\]

for all \( t \leq N \). Let \( g = f^N \) for \( t \in [0, N]. \) Then aside from a set of measure zero, this is well defined and for all \( t \geq 0 \)

\[
M (t) = E (M (0)) + \int_{0}^{t} g (s, \cdot)^T dW \quad \blacksquare
\]

Surely this is an incredible theorem. Note that it implies all the martingales adapted to \( \mathcal{G}_t \) which are in \( L^2 \) for each \( t \) must be continuous a.e. and are obtained from an Ito integral. Also, any such martingale satisfies \( M (0) = E (M (0)) \). Isn’t that amazing? Also note that this featured \( \mathbb{R}^n \) as where \( W \) has its values and \( n \) was arbitrary. One could have \( n = 1 \) if desired.

The above theorems can also be obtained from another approach. It involves showing that random variables of the form

\[
\phi (W (t_1), \cdots, W (t_k))
\]

are dense in \( L^2 (\Omega, \mathcal{G}_T) \). This theorem is interesting for its own sake and it involves interesting results discussed earlier. Recall the Doob Dynkin lemma, Lemma 57.3.6 on Page 1911 which is listed here.

**Lemma 65.9.6** Suppose \( X, Y_1, Y_2, \cdots, Y_k \) are random vectors, \( X \) having values in \( \mathbb{R}^n \) and \( Y_j \) having values in \( \mathbb{R}^{p_j} \) and

\[
X, Y_j \in L^1 (\Omega).
\]
Suppose \( X \) is \( \sigma(Y_1, \ldots, Y_k) \) measurable. Thus

\[
\{X^{-1}(E) : E \text{ Borel} \} \subseteq \left\{ (Y_1, \ldots, Y_k)^{-1}(F) : F \text{ is Borel in } \prod_{j=1}^{k} \mathbb{R}^{p_j} \right\}
\]

Then there exists a Borel function, \( g : \prod_{j=1}^{k} \mathbb{R}^{p_j} \to \mathbb{R}^n \) such that

\[
X = g(Y).
\]

Recall also the submartingale convergence theorem.

**Theorem 65.9.7 (submartingale convergence theorem)** Let

\[
\{(X_i, S_i)\}_{i=1}^{\infty}
\]

be a submartingale with \( K \equiv \sup E (|X_n|) < \infty \). Then there exists a random variable \( X \), such that \( E (|X|) \leq K \) and

\[
\lim_{n \to \infty} X_n(\omega) = X(\omega) \text{ a.e.}
\]

Recall

\[
\mathcal{G}_t \equiv \sigma(W(u) - W(r) : 0 \leq r < u \leq t)
\]

It suffices to consider only \( t \) and \( u, r \) in a countable dense subset of \( \mathbb{R} \) denoted as \( D \). This follows from continuity of the Wiener process. To see this, let \( 0 \leq r < u \leq t \) be open and \( U_n \uparrow U \) where each \( U_n \) is open and \( \overline{U_n} \subseteq U_{n+1}, \cup_n U_n = U \). Then letting \( u_n \uparrow u \) and \( r_n \uparrow r \), \( u_n r_n \) being in the countable dense set,

\[
(W(u) - W(r))^{-1}(U_n) \subseteq \bigcup_{k=1}^{\infty} \cap_{j \geq k} (W(u_j) - W(r_j))^{-1}(U_n)
\]

and so

\[
(W(u) - W(r))^{-1}(U) = \bigcup_{n=1}^{\infty} (W(u) - W(r))^{-1}(U_n)
\]

Now the set in the middle which has two countable unions and a countable intersection is in

\[
\sigma(W(u) - W(r) : 0 \leq r < u \leq t, r, u \in D)
\]

Thus in particular, one would get the same filtration from

\[
\mathcal{G}_t = \sigma(W(u) - W(r) : 0 \leq r < u \leq t, r, u \in D)
\]

Since \( W(0) = 0 \), this is the same as

\[
\mathcal{G}_t = \sigma(W(u) : 0 \leq u \leq t, u \in D)
\]
Lemma 65.9.8 \textit{Random variables of the form}

\[ \phi(W(t_1), \ldots, W(t_k)), \phi \in C_c^\infty(\mathbb{R}^k) \]

\textit{are dense in} \(L^2(\Omega, \mathcal{G}_T, P)\) \textit{where} \(t_1 < t_2 < \cdots < t_k\) \textit{is a finite increasing sequence of} \((Q \cup \{T\}) \cap [0, T] \).

\textbf{Proof:} Let \(g \in L^2(\Omega, \mathcal{G}_T, P)\). Also let \(\{t_j\}_{j=1}^\infty\) be the points of \((Q \cup \{T\}) \cap [0, T]\). Let

\[ \mathcal{G}_m = \sigma(W(t_k) : k \leq m) \]

Thus the \(\mathcal{G}_m\) are increasing but each is generated by finitely many \(W(t_k)\). Also as explained above,

\[ \mathcal{G}_T = \sigma(W(u) : 0 \leq u \leq T, u \in (Q \cup \{T\}) \cap [0, T]) = \sigma(\mathcal{G}_m, m < \infty). \]

Now consider the martingale,

\[ \{E(g_M|\mathcal{G}_m)\}_{m=1}^\infty \]

where here

\[ g_M(\omega) = \begin{cases} g(\omega) & \text{if } g(\omega) \leq M \\ M & \text{if } g(\omega) > M \\ -M & \text{if } g(\omega) < -M \end{cases} \]

and \(M\) is chosen large enough that

\[ ||g - g_M||_{L^2(\Omega)} < \varepsilon/4. \quad (65.9.20) \]

Now the terms of this martingale are uniformly bounded by \(M\) because

\[ |E(g_M|\mathcal{G}_m)| \leq E(||g_M|||\mathcal{G}_m) \leq E(M|\mathcal{G}_m) = M. \]

It follows the martingale is certainly bounded in \(L^1\) and so the martingale convergence theorem stated above can be applied, and so there exists \(f\) measurable in \(\sigma(\mathcal{G}_m, m < \infty)\) such that \(\lim_{m \to \infty} E(g_M|\mathcal{G}_m)(\omega) = f(\omega)\) a.e. Also \(|f(\omega)| \leq M\) a.e. Since all functions are bounded, it follows that this convergence is also in \(L^2(\Omega)\).

Now letting \(A \in \sigma(\mathcal{G}_m, m < \infty)\), it follows from the dominated convergence theorem that

\[ \int_A f dP = \lim_{m \to \infty} \int_A E(g_M|\mathcal{G}_m) dP = \int_A g_M dP \]

Now \(\mathcal{G}_T = \sigma(W(t_k), t_k \leq T) = \sigma(\mathcal{G}_m, m \geq 1)\) and so the above equation implies that \(f = g_M\) a.e.

By the Doob Dynkin lemma listed above, there exists a Borel measurable \(h : \mathbb{R}^{nm} \to \mathbb{R}\) such that

\[ E(g_M|\mathcal{G}_m) = h(W_{t_1}, \ldots, W_{t_m}) \text{ a.e.} \]
CHAPTER 65. THE EASY ITO FORMULA

Of course $h$ is not in $C_c^\infty(\mathbb{R}^{nm})$. Let $m$ be large enough that

$$
\|g_M - E(g_M \mid \mathcal{G}_m)\|_{L^2} = \|f - E(g_M \mid \mathcal{G}_m)\|_{L^2} < \frac{\varepsilon}{4}.
$$

(65.9.21)

Let $\lambda(W_{t_1}, \ldots, W_{t_m})$ be the distribution measure of the random vector $(W_{t_1}, \ldots, W_{t_m})$. Thus $\lambda(W_{t_1}, \ldots, W_{t_m})$ is a Radon measure and so there exists $\phi \in C_c(\mathbb{R}^{nm})$ such that

$$
\left( \int_\Omega |E(g_M \mid \mathcal{G}_m) - \phi(W_{t_1}, \ldots, W_{t_m})|^2 \, dP \right)^{1/2}
= \left( \int_\Omega |h(W_{t_1}, \ldots, W_{t_m}) - \phi(W_{t_1}, \ldots, W_{t_m})|^2 \, dP \right)^{1/2}
= \left( \int_{\mathbb{R}^{nm}} |h(x_1, \ldots, x_m) - \phi(x_1, \ldots, x_m)|^2 \, d\lambda(W_{t_1}, \ldots, W_{t_m}) \right)^{1/2} < \varepsilon/4.
$$

By convolving with a mollifier, one can assume that $\phi \in C_c^\infty(\mathbb{R}^{nm})$ also. It follows from (65.9.21) and (65.9.24) that

$$
\|g - \phi(W_{t_1}, \ldots, W_{t_m})\|_{L^2}
\leq \|g - g_M\|_{L^2} + \|g_M - E(g_M \mid \mathcal{G}_m)\|_{L^2}
+ \|E(g_M \mid \mathcal{G}_m) - \phi(W_{t_1}, \ldots, W_{t_m})\|_{L^2}
\leq 3\left(\frac{\varepsilon}{4}\right) < \varepsilon
$$
Chapter 66

A Different Kind Of
Stochastic Integration

For more on this material, see [X] which is what this is based on. Recall the following corollary. It is Corollary 57.20.3 on Page 1982.

**Corollary 66.0.1** Let $H$ be a real Hilbert space. Then there exist random variables $W(h)$ for $h \in H$ such that each is normally distributed with mean 0 and for every $h, g, (W(h), W(g))$ is normally distributed and

$$E(W(h)W(g)) = (h, g)_H$$

Furthermore, if $\{e_i\}$ is an orthogonal set of vectors of $H$, then $\{W(e_i)\}$ are independent random variables. Also for any finite set $\{f_1, f_2, \cdots, f_n\}$,

$$(W(f_1), W(f_2), \cdots, W(f_n))$$

is normally distributed.

Here are some simple examples.

**Example 66.0.2** Let $H = L^2([0, T])$. For $f \in H$, let

$$W(f) = \int_0^T f(u) dW$$

where $W(t)$ is the one dimensional Wiener process.

First of all, note that the integrand is adapted to the usual filtration determined by the Wiener process. This is because $f$ does not depend on $\omega$. That $W(f)$ is normally distributed can be seen from the approximation of the Ito integral with the integral of elementary functions. These are clearly normally distributed because they are just linear combinations of increments of the Wiener process. Recall these
You could let the above Ito integral. It follows that which comes from having to define the Wiener process. Thus which from the above equals. Then let Example 66.0.3 One can verify this by considering.

$E(W(f)W(g)) = \int_0^T f(u)g(u)\,du = (f,g)_H$

One can verify this by considering $E\left(W(f + g)^2\right), E\left(W(f - g)^2\right)$.

This example is called the isonormal Gaussian process. There is a measure space $(\Omega, \mathcal{F}, P)$ where $\sigma(W(s) : s \leq T) = \mathcal{F}$. There must be an underlying measure space which comes from having to define the Wiener process.

**Example 66.0.3** You could let $H = \mathbb{R}$ and let $\xi$ be normally distributed density with mean 0 and variance 1. Then let $W(a) \equiv \xi a$. Does it work?

$E(ab\xi^2) = abE(\xi^2) = ab$

Is $W(a)$ normally distributed? $E(e^{ia\xi^2}) = \int e^{iaxt}\,dx = e^{-(1/2)a^2t^2}$ which is the characteristic function of a normally distributed random variable having mean 0 and variance $a^2$. It is clear that any linear combination of $a_2\xi$ is normally distributed and so the vector $(a_1\xi, \ldots, a_n\xi)$ is normally distributed. This is by Theorem 27.16.3.

The above implies $W$ is actually linear.

$$E\left((W(f + g) - (W(f) + W(g)))^2\right) = E\left((W(f + g))^2 + (W(f))^2 + (W(g))^2 + 2W(f)W(g)\right)$$

$$-2(W(f + g)W(f) + W(f + g)W(g)) = E\left((W(f + g))^2\right) + E\left(W(f)^2\right) + E\left(W(g)^2\right) + E(W(f)W(g))$$

which from the above equals

$$|f + g|^2 + |f|^2 + |g|^2 + 2(f,g) - 2[(f + g,f) + (f + g),g]$$

$$= 2|f|^2 + 2|g|^2 + 4(f,g) - 2(|f|^2 + |g|^2 + 2(f,g)) = 0$$

Thus $W(f + g) - (W(f) + W(g)) = 0$. Is it true that $W(af) = aW(f)$?
This is easier to show.

\[ E \left( (W(af) - aW(f))^2 \right) = E \left( W(af)^2 - 2W(af) aW(f) + a^2 W(f)^2 \right) \]

\[ = |af|^2 - 2aE(W(af)W(f)) + a^2 E(W(f)^2) \]

\[ = a^2 |f|^2 - 2a^2 |f|^2 + a^2 |f|^2 = 0 \]

Thus \( W \) is indeed linear.

### 66.1 Hermite Polynomials

Consider

\[ \exp \left( tx - \frac{t^2}{2} \right) = \exp \left( \frac{x^2}{2} - \frac{1}{2} (x - t)^2 \right) \]

Now the Hermite polynomials are the coefficients of the power series of this function expanded in powers of \( t \). Thus the \( n^{th} \) one of these is

\[ H_n(x) = \exp \left( \frac{x^2}{2} \right) \frac{1}{n!} \frac{d^n}{dt^n} \left( \exp \left( -\frac{1}{2} (x - t)^2 \right) \right) \bigg|_{t=0} \quad (66.1.1) \]

and

\[ \exp \left( tx - \frac{t^2}{2} \right) = \sum_{n=0}^{\infty} H_n(x) t^n \quad (66.1.2) \]

Note that \( H_0(x) = 1, \)

\[ H_1(x) = \exp \left( \frac{x^2}{2} \right) \frac{d}{dt} \left( \exp \left( -\frac{1}{2} (x - t)^2 \right) \right) \bigg|_{t=0} \]

\[ = -e^{-\frac{1}{2} (t-x)^2} e^{\frac{1}{2} x^2} (t-x) \bigg|_{t=0} = x \]

From \(66.1.2\), differentiating both sides formally with respect to \( x \),

\[ t \exp \left( tx - \frac{t^2}{2} \right) = \sum_{n=1}^{\infty} H'_n(x) t^n \]

and so

\[ \sum_{n=0}^{\infty} H_n(x) t^n = t \exp \left( tx - \frac{t^2}{2} \right) = \sum_{n=1}^{\infty} H'_n(x) t^{n-1} = \sum_{n=0}^{\infty} H'_{n+1}(x) t^n \]

showing that

\[ H'_n(x) = H_{n-1}(x), \quad n \geq 1, \quad H_0(x) = 0, H_1(x) = x \]
which could have been obtained with more work from \[66.1.1\]. Also, differentiating both sides of \[66.1.2\] with respect to \(t;\)

\[
\exp\left(tx - \frac{t^2}{2}\right) (t - x) = \sum_{n=0}^{\infty} nH_n (x) t^{n-1}
\]

Thus

\[
(x - t) \sum_{n=0}^{\infty} H_n (x) t^n = \sum_{n=0}^{\infty} nH_n (x) t^{n-1} = \sum_{n=0}^{\infty} (n + 1) H_{n+1} (x) t^n
\]

and so

\[
\sum_{n=0}^{\infty} xH_n (x) t^n - \sum_{n=0}^{\infty} H_n (x) t^{n+1} = \sum_{n=0}^{\infty} (n + 1) H_{n+1} (x) t^n
\]

and so

\[
\sum_{n=0}^{\infty} xH_n (x) t^n - \sum_{n=1}^{\infty} H_{n-1} (x) t^n = \sum_{n=0}^{\infty} (n + 1) H_{n+1} (x) t^n
\]

Thus for \(n \geq 1,\)

\[
xH_n (x) - H_{n-1} (x) = (n + 1) H_{n+1} (x)
\]

Now also

\[
\exp\left(t (-x) - \frac{t^2}{2}\right) = \sum_{n=0}^{\infty} H_n (-x) t^n
\]

and taking successive derivatives with respect to \(t\) of the left side and evaluating at \(t = 0\) yields

\[
H_n (-x) = (-1)^n H_n (x).
\]

Summarizing these as in \[93\],

\[
H'_n (x) = H_{n-1} (x), n \geq 1, \quad H_0 (x) = 0, \quad H_1 (x) = x
\]

\[
xH_n (x) - H_{n-1} (x) = (n + 1) H_{n+1} (x), \quad n \geq 1
\]

\[
H_n (-x) = (-1)^n H_n (x)
\]

Clearly, these relations show that all of these \(H_n\) are polynomials. Also the degree of \(H_n (x)\) is \(n\) and the coefficient of \(x^n\) is \(1/n!\).

**Definition 66.1.1** You can also consider Hermite polynomials which depend on \(\lambda.\) These are defined as follows:

\[
H_n (x, \lambda) \equiv \frac{(-\lambda)^n}{n!} e^{\frac{\lambda x^2}{1}} \frac{\partial^n}{\partial x^n} \left(e^{-\frac{\lambda x^2}{2}}\right)
\]

You can see clearly that these are polynomials in \(x.\) For example, let \(n = 2.\) Then you would have from the above definition.

\[
H_0 (x, \lambda) = 1, \quad H_1 (x, \lambda) = \frac{(-\lambda)^1}{1!} e^{\frac{\lambda x^2}{1}} \frac{\partial}{\partial x} \left(e^{-\frac{\lambda x^2}{2}}\right) = x
\]
66.1. HERMITE POLYNOMIALS

\[ H_2(x, \lambda) = \frac{(-\lambda)^2}{2!} e^{\frac{x^2}{4\lambda}} \frac{\partial^2}{\partial x^2} \left(e^{-\frac{x^2}{4\lambda}}\right) = \frac{1}{2} x^2 - \frac{1}{2} \lambda \]

The idea is you end up with polynomials of degree \( n \) times \( e^{-x^2/2\lambda} \) in the derivative part and then this cancels with \( e^{x^2/2\lambda} \) to leave you with a polynomial of degree \( n \). Also the leading term will always be \( \frac{x^n}{n!} \) which is easily seen from the above. Then there are some relationships satisfied by these.

Say \( n > 1 \) in what follows.

\[ \frac{\partial}{\partial x} H_n(x, \lambda) = \frac{x (-\lambda)^n}{\lambda} \frac{1}{n!} \frac{n!}{\partial x^n} \left(e^{-\frac{x^2}{2\lambda}}\right) + \frac{(-\lambda)^n}{n!} e^{\frac{x^2}{4\lambda}} \frac{\partial^n}{\partial x^n} \left( \frac{\partial}{\partial x} e^{-\frac{x^2}{4\lambda}} \right) \]

\[ = \frac{x (-\lambda)^n}{\lambda} \frac{1}{n!} \frac{n!}{\partial x^n} \left(e^{-\frac{x^2}{2\lambda}}\right) + \frac{(-\lambda)^n}{n!} e^{\frac{x^2}{4\lambda}} \frac{\partial^n}{\partial x^n} \left( -\frac{x}{\lambda} e^{-\frac{x^2}{2\lambda}} \right) \]

Now since \( n > 1 \), that last term reduces to

\[ \frac{(-\lambda)^n}{n!} e^{\frac{x^2}{4\lambda}} \left[ -\frac{x}{\lambda} \frac{\partial^n}{\partial x^n} \left(e^{-\frac{x^2}{2\lambda}}\right) + n \frac{\partial}{\partial x} \left( -\frac{x}{\lambda} \frac{\partial^{n-1}}{\partial x^{n-1}} \left(e^{-\frac{x^2}{2\lambda}}\right) \right) \right] \]

, this by Leibniz formula. Thus this cancels with the first term to give

\[ \frac{\partial}{\partial x} H_n(x, \lambda) = \frac{(-\lambda)^n}{n!} \frac{1}{n!} \frac{n!}{\partial x^n} \left(e^{-\frac{x^2}{2\lambda}}\right) \]

\[ = \frac{(-\lambda)^{n-1}}{(n-1)!} \frac{n!}{\partial x^{n-1}} \left(e^{-\frac{x^2}{2\lambda}}\right) \equiv H_{n-1}(x, \lambda) \]

In case of \( n = 1 \), this appears to also work. \( \frac{\partial}{\partial x} H_1(x, \lambda) = 1 = H_0(x, \lambda) \) from the above computations. This shows that

\[ \frac{\partial}{\partial x} H_n(x, \lambda) = H_{n-1}(x, \lambda) \]

Next, is the claim that

\( (n + 1) H_{n+1}(x, \lambda) = x H_n(x, \lambda) - \lambda H_{n-1}(x, \lambda) \)

If \( n = 1 \), this says that

\[ 2H_2(x, \lambda) = xH_1(x, \lambda) - \lambda H_0(x, \lambda) = x^2 - \lambda \]

and so the formula does indeed give the correct description of \( H_2(x, \lambda) \) when \( n = 1 \). Thus assume \( n > 1 \) in what follows. The left side equals

\[ \frac{(-\lambda)^{n+1}}{n!} e^{\frac{x^2}{4\lambda}} \frac{\partial^{n+1}}{\partial x^{n+1}} \left(e^{-\frac{x^2}{4\lambda}}\right) \]
CHAPTER 66. A DIFFERENT KIND OF STOCHASTIC INTEGRATION

This equals

$$\left( -\frac{\lambda}{\lambda} \right)^{n+1} e^{\frac{x^2}{2\lambda}} \frac{\partial^n}{\partial x^n} \left( -\frac{x}{\lambda} e^{-\frac{x^2}{2\lambda}} \right)$$

Now by Liebniz formula,

$$\frac{(-\lambda)^{n+1}}{n!} e^{\frac{x^2}{2\lambda}} \left[ \frac{-x}{\lambda} \frac{\partial^n}{\partial x^n} e^{-\frac{x^2}{2\lambda}} + n \left( -\frac{1}{\lambda} \right) \frac{\partial^{n-1}}{\partial x^{n-1}} \left( e^{-\frac{x^2}{2\lambda}} \right) \right]$$

$$\frac{(-\lambda)^{n+1}}{n!} e^{\frac{x^2}{2\lambda}} \left( \frac{-x}{\lambda} \frac{\partial^n}{\partial x^n} e^{-\frac{x^2}{2\lambda}} \right) + \frac{(-\lambda)^{n+1}}{n!} e^{\frac{x^2}{2\lambda}} \frac{\partial^{n-1}}{\partial x^{n-1}} \left( e^{-\frac{x^2}{2\lambda}} \right)$$

$$= x \frac{(-\lambda)^n}{n!} e^{\frac{x^2}{2\lambda}} \frac{\partial^n}{\partial x^n} e^{-\frac{x^2}{2\lambda}} + \frac{(-\lambda)^n}{(n-1)!} e^{\frac{x^2}{2\lambda}} \frac{\partial^{n-1}}{\partial x^{n-1}} \left( e^{-\frac{x^2}{2\lambda}} \right)$$

which shows the formula is valid for all \( n \geq 1 \).

Next is the claim that

$$H_n (-x, \lambda) = (-1)^n H_n (x, \lambda)$$

This is easy to see from the observation that

$$\frac{\partial}{\partial x} = \frac{\partial}{\partial (-x)} (-1)$$

Thus if it involves \( n \) derivatives, you end up multiplying by \((-1)^n\).

Finally is the claim that

$$\frac{\partial}{\partial \lambda} H_n (x, \lambda) = -\frac{1}{2} \frac{\partial^2}{\partial x^2} H_n (x, \lambda)$$

It is certainly true for \( n = 0, 1, 2 \). So suppose it is true for all \( k \leq n \). Then from earlier claims and induction,

\[
(n + 1) H_{(n+1)\lambda} (x, \lambda) = x H_{n\lambda} (x, \lambda) - H_{(n-1)\lambda} (x, \lambda) - \lambda H_{(n-1)\lambda} (x, \lambda)
\]

\[
= x \left( \frac{-1}{2} \right) H_{n xx} - H_{n - 1} + \frac{1}{2} H_{(n-1)xx} = x \left( \frac{-1}{2} \right) H_{n - 2} - H_{n - 1} + \frac{1}{2} H_{(n-3)}
\]

\[
= -\frac{1}{2} (x H_{n - 2} - \lambda H_{n - 3} + 2 H_{n - 1}) = -\frac{1}{2} ((n - 1) H_{n - 1} + 2 H_{n - 1}) = -\frac{1}{2} ((n + 1) H_{n - 1})
\]

comparing the ends,

$$H_{(n+1)\lambda} = -\frac{1}{2} H_{n - 1} = -\frac{1}{2} H_{(n+1)xx}$$

This proves the following theorem.
Theorem 66.1.2 Let \( H_n(x, \lambda) \) be defined by
\[
H_n(x, \lambda) = \frac{(-\lambda)^n}{n!} e^{\frac{1}{2} \pi^2 x^2} \frac{\partial^n}{\partial x^n} \left( e^{-\frac{1}{2} \pi x^2} \right)
\]
for \( \lambda > 0 \). Then the following properties are valid.
\[
\frac{\partial}{\partial x} H_n(x, \lambda) = H_{n-1}(x, \lambda) \tag{66.1.4}
\]
\[
(n + 1) H_{n+1}(x, \lambda) = x H_n(x, \lambda) - \lambda H_{n-1}(x, \lambda) \tag{66.1.5}
\]
\[
H_n(-x, \lambda) = (-1)^n H_n(x, \lambda) \tag{66.1.6}
\]
\[
\frac{\partial}{\partial \lambda} H_n(x, \lambda) = -\frac{1}{2} \frac{\partial^2}{\partial x^2} H_n(x, \lambda) \tag{66.1.7}
\]

With this theorem, one can also prove the following.

Theorem 66.1.3 The Hermite polynomials are the coefficients of a certain power series. Specifically,
\[
\exp \left( tx - \frac{1}{2} t^2 \lambda \right) = \sum_{n=0}^{\infty} H_n(x, \lambda) t^n
\]

**Proof:** Replace \( H_n \) with \( K_n \) which really are the coefficients of the power series and then show \( K_n = H_n \). Thus
\[
\exp \left( tx - \frac{1}{2} t^2 \lambda \right) = \sum_{n=0}^{\infty} K_n(x, \lambda) t^n
\]
Then \( K_0 = 1 = H_0(x) \). Also \( K_1(x) = x = H_1(x) \).
\[
\frac{\partial}{\partial t} \left( \exp \left( tx - \frac{1}{2} t^2 \lambda \right) \right) = \exp \left( tx - \frac{1}{2} t^2 \lambda \right) (x - t\lambda)
\]
\[
= \sum_{n=0}^{\infty} xK_n(x, \lambda) t^n - \sum_{n=0}^{\infty} \lambda K_n(x, \lambda) t^{n+1} = \sum_{n=0}^{\infty} xK_n(x, \lambda) t^n - \sum_{n=1}^{\infty} \lambda K_{n-1}(x, \lambda) t^n
\]
Also,
\[
\frac{\partial}{\partial t} \left( \exp \left( tx - \frac{1}{2} t^2 \lambda \right) \right) = \sum_{n=1}^{\infty} nK_n(x, \lambda) t^{n-1} = \sum_{n=0}^{\infty} (n + 1) K_{n+1}(x, \lambda) t^n
\]
It follows that for \( n \geq 1 \),
\[
(n + 1) K_{n+1}(x, \lambda) = xK_n(x, \lambda) - \lambda K_{n-1}(x, \lambda)
\]
Thus the first two $K_0, K_1$ coincide with $H_0$ and $H_1$ respectively. Then since both
$K_n$ and $H_n$ satisfy the recursion relation (66.2), it follows that $K_n = H_n$ for all $n$.

The first version is just letting $\lambda = 1$ in the second version.

There is something very interesting about these Hermite polynomials $H_n(x, \lambda)$.
Let $W$ be the real Wiener process. Consider the stochastic process
$H_n(W(t), t), n \geq 1$. This ends up being a martingale. Using Ito’s formula, the easy to remember ver-
sion of it presented above, and the above properties of the Hermite polynomials,
\[
dH_n = H_n(W(t), t) dW + H_n(W(t), t) dt + \frac{1}{2} H_{nxx}(W(t), t) dW^2
\]
\[
= H_{n-1}(W(t), t) dW - \frac{1}{2} H_{nxx}(W(t), t) dt + \frac{1}{2} H_{nxx}(W(t), t) dt
\]
Note that if $n < 2$, both of the last two terms are 0. In general, they cancel and so
\[
dH_n = H_{n-1}(W(t), t) dW
\]
and so
\[
H_n(W(t), t) = H_n(W(0), 0) + \int_0^t H_{n-1}(W(t), t) dW
\]
now the constant term in the above equation is $\mathcal{F}_0$ measurable and the stochastic
integral is a martingale. Thus this is indeed a martingale assuming everything is
suitably integrable. However, this is not hard to see because these $H_n$ are just
polynomials. It was shown in Theorem (62.1.3) that $W(t) \in L^q(\Omega)$ for all $q$. Hence
there is no integrability issue in doing these things. Actually, $H_n(W(0), 0) = 0$ To
see this, note that $E(W(0)^2) = (0, 0)_H = 0$ and so $W(0) = 0$. Now it is not hard
to see that $H_n(0, 0) = 0$. Indeed,
\[
\exp\left(tx - \frac{1}{2}t^2\lambda\right) = \sum_{n=0}^{\infty} H_n(x, \lambda) t^n
\]
Thus $H_n(x, 0) = \sum_{n=0}^{\infty} H_n(x, 0) t^n = \exp(tx) = \sum_{n=0}^{\infty} \frac{(tx)^n}{n!} = \sum_{n=0}^{\infty} \frac{x^n t^n}{n!}$ and
so for all $n \geq 1, H_n(0, 0) = 0$. Thus in fact, for $n \geq 1$, $t \rightarrow H_n(W(t), t)$ is a
martingale which equals 0 when $t = 0$.

66.2 A Remarkable Theorem Involving The Her-
mite Polynomials

Lemma 66.2.1 Say $(X, Y)$ is generalized normally distributed and $E(X) = E(Y) = 0, E(X^2) = E(Y^2) = 1$. Then for $m, n \geq 0$,
\[
E(H_n(X) H_m(Y)) = \begin{cases} 0 & \text{if } n \neq m \\ \frac{1}{m!} (E(XY))^n & \text{if } n = m \end{cases}
\]
6.2. A REMARKABLE THEOREM INVOLVING THE HERMITE POLYNOMIALS

Proof: By assumption, \( sX + tY \) is normal distributed with mean 0. This follows from Theorem 5.16. Also

\[ \sigma^2 \equiv E \left( (sX + tY)^2 \right) = s^2 + t^2 + 2E(XY)st \]

and so its characteristic function is

\[ E \left( \exp \left( i \lambda (sX + tY) \right) \right) = \phi_{sX+tY}(\lambda) = e^{-\frac{1}{2}\sigma^2\lambda^2} = e^{-\frac{1}{2}(s^2+t^2)\lambda^2} e^{-E(XY)st\lambda^2} \]

So let \( \lambda = -i \). You can do this because both sides are analytic in \( \lambda \in \mathbb{C} \) and they are equal for real \( \lambda \), a set with a limit point. This leads to

\[ E \left( \exp (sX + tY) \right) = e^{\frac{1}{2}(s^2+t^2)} e^{E(XY)st} \]

Hence, multiplying both sides by \( e^{-\frac{1}{2}(s^2+t^2)} \),

\[ e^{-\frac{1}{2}(s^2+t^2)} E \left( \exp (sX + tY) \right) = E \left( \exp \left( sX - \frac{s^2}{2} \right) \exp \left( tY - \frac{t^2}{2} \right) \right) = \exp (stE(XY)) \]

Now take \( \frac{\partial^{n+m}}{\partial^n \partial^m t} \) of both sides. Recall the description of the Hermite polynomials given above

\[ n!H_n(x) = \frac{d^n}{dt^n} \exp \left( tx - \frac{t^2}{2} \right) \bigg|_{t=0} \]

Thus

\[ E \left( n!H_n(X) m!H_m(Y) \right) = \frac{\partial^{n+m}}{\partial^n \partial^m t} \exp (stE(XY)) \bigg|_{s=t=0} \]

Consider \( m < n \)

\[ \frac{\partial^{n+m}}{\partial^n \partial^m t} \exp (stE(XY)) = \frac{\partial^n}{\partial t^n} \left( (tE(XY))^n \exp (stE(XY)) \right) \]

You have something like

\[ \frac{\partial^n}{\partial t^n} \left[ t^n ((E(XY))^n \exp (stE(XY)) \right] \]

and \( m < n \) so when you take partial derivatives with respect to \( t \), \( m \) times and set \( s, t = 0 \), you must have 0. Hence, if \( n > m \),

\[ E \left( n!H_n(X) m!H_m(Y) \right) = 0 \]

Similarly this equals 0 if \( m > n \). So assume \( m = n \). Then you will go through the same process just described but this time at the end you will have something of the form

\[ n!E(XY)^n + \text{terms multiplied by } s \text{ or } t \]
Hence, in this case,
\[
E (n! H_n (X) n! H_n (Y)) = n! E (XY)^n
\]
and so
\[
E (H_n (X) H_n (Y)) = \frac{1}{n!} E (XY)^n \quad \blacksquare
\]

Let \( W \) be the function defined above, \( W (h) \) is normally distributed with mean 0 and variance \( |h|^2 \) and \( E (W (h) W (g)) = (h, g)_H \). Then from Lemma 66.2.4,
\[
E (H_n (W (h)) H_m (W (g))) = \begin{cases} 0 & \text{if } n \neq m \\ \frac{1}{n!} (E (W (h) W (g)))^n & \text{if } n = m \end{cases}
\]

This is a really neat result. From definition of \( W \),
\[
E \left( (W (h) W (g))^1 \right) = (h, g)_H
\]

Note this is a special case of the above result because \( H_1 (x) = x \). However, we don’t know that \( E ((W (h) W (g))^n) \) is equal to something times \( (h, g)_H^n \) but we know that this is true of some \( n^{th} \) degree polynomials in \( W (h) \) and \( W (g) \).

**Definition 66.2.2** Let \( \mathcal{H}_n \equiv \text{span} \{ H_n (W (h)) : h \in H, |h|_H = 1 \} \).

Thus \( \mathcal{H}_n \) is a closed subspace of \( L^2 (\Omega, \mathcal{F}) \). Recall \( \mathcal{F} \equiv \sigma (W (h) : h \in H) \). This subspace \( \mathcal{H}_n \) is called the Wiener chaos of order \( n \).

**Theorem 66.2.3** \( L^2 (\Omega, \mathcal{F}, P) = \bigoplus_{n=0}^{\infty} \mathcal{H}_n \). The symbol denotes the infinite orthogonal sum of the closed subspaces \( \mathcal{H}_n \). That is, if \( f \in L^2 (\Omega) \), there exists \( f_n \in \mathcal{H}_n \) and constants such that \( f = \sum_n c_n f_n \) and if \( f \in \mathcal{H}_n, g \in \mathcal{H}_m \), then \( (f, g)_{L^2 (\Omega)} = 0 \).

**Proof:** Clearly each \( \mathcal{H}_n \) is a closed subspace. Also, if \( f \in \mathcal{H}_n \) and \( g \in \mathcal{H}_m \) for \( n \neq m \), what about \( (f, g)_{L^2 (\Omega)} ? \)

\[
(f, g)_{L^2 (\Omega)} = \lim_{l \to \infty} E \left( \sum_{k=1}^{M_l} a_k^l H_n (W (h_k^l)) \cdot \sum_{j=1}^{M_p} a_j^l H_m (W (h_j^l)) \right)
\]

\[
= \lim_{l \to \infty} \sum_{k,j} a_k^l a_j^l E \left( H_n (W (h_k^l)) H_m (W (h_j^l)) \right) = 0
\]

Thus these are orthogonal subspaces. Clearly \( L^2 (\Omega) \supseteq \bigoplus \mathcal{H}_n \). Suppose \( X \) is orthogonal to each \( \mathcal{H}_n \). Is \( X = 0? \) Each \( x^n \) can be obtained as a linear combination of the \( H_k (x) \) for \( k \leq n \). This is clear because the space of polynomials of degree \( n \) is of dimension \( n + 1 \) and \( \{ H_0 (x), H_1 (x), \ldots, H_n (x) \} \) is independent on \( \mathbb{R} \).
66.2. A REMARKABLE THEOREM INVOLVING THE HERMITE POLYNOMIALS

This is easily seen as follows. Suppose

\[ \sum_{k=0}^{n} c_k H_k(x) = 0 \]

and that not all \( c_k = 0 \). Let \( m \) be the smallest index such that

\[ \sum_{k=0}^{m} c_k H_k(x) = 0 \]

with \( c_m \neq 0 \). Then just differentiate both sides and obtain

\[ \sum_{k=1}^{m} c_k H_{k-1}(x) = 0 \]

contradicting the choice of \( m \).

Therefore, each \( x^n \) is really a unique linear combination of the \( H_k \) as claimed. Say

\[ x^n = \sum_{k=0}^{n} c_k H_k(x) \]

Then for \( |h| = 1 \),

\[ W(h)^n = \sum_{k=0}^{n} c_k H_k(W(h)) \in \mathcal{H}_n \]

Hence \((X, W(h)^n)_{L^2(\Omega)} = 0\) whenever \(|h| = 1\). It follows that for \( h \in H \) arbitrary, and the fact that \( W \) is linear,

\[ (X, W(h)^n)_{L^2} = \left( X, \left( |h| W \left( \frac{h}{|h|} \right) \right)^n \right) = |h|^n \left( X, W \left( \frac{h}{|h|} \right)^n \right) = 0 \]

Therefore, \( X \) is perpendicular to \( e^{W(h)} \) for every \( h \in H \) and so from Lemma 66.2.5, \( X = 0 \). Thus \( \oplus \mathcal{H}_n \) is dense in \( L^2(\Omega) \).

Note that from Lemma 66.2.3, every polynomial in \( W(h) \) is in \( L^p(\Omega) \) for all \( p > 1 \). Now what is next is really tricky.

**Corollary 66.2.4** Let \( P^0_n \) denote all polynomials of the form

\[ p(W(h_1), \ldots, W(h_k)), \text{ degree of } p \leq n, \text{ some } h_1, \ldots, h_k \]

Also let \( P_n \) denote the closure in \( L^2(\Omega, \mathcal{F}, P) \) of \( P^0_n \). Then

\[ P_n = \oplus_{i=0}^{n} \mathcal{H}_i \]

**Proof:** It is obvious that \( P_n \supseteq \oplus_{i=0}^{n} \mathcal{H}_i \) because the thing on the right is just the closure of a set of polynomials of degree no more than \( n \), a possibly smaller set than the polynomials used to determine \( P^0_n \) and hence \( P_n \). If \( P_n \) is orthogonal to \( \mathcal{H}_m \) for
all $m > n$, then from the above Theorem you must have $\mathcal{P}_n \subseteq \oplus_{i=0}^n H_i$. So consider $H_m (W (h))$. Recall that $H_m$ is the closure of the span of things like this for $|h|_H = 1$. Thus we need to consider

$$E (p (W (h_1), \cdots, W (h_k)) H_m (W (h))), \ |h|_H = 1,$$

and show that this is 0. Now here is the tricky part. Let $\{e_1, \cdots, e_s, h\}$ be an orthonormal basis for

$$\text{span} (h_1, \cdots, h_k, h).$$

Then since $W$ is linear, there is a polynomial $q$ of degree no more than $n$ such that

$$p (W (h_1), \cdots, W (h_k)) = q (W (e_1), \cdots, W (e_s), W (h))$$

Then consider a term of $q (W (e_1), \cdots, W (e_s), W (h)) H_m (W (h))$

$$aW (e_1)^{r_1} \cdots W (e_s)^{r_s} W (h)^r H_m (W (h))$$

Now from Corollary these random variables $\{W (e_1), \cdots, W (e_s), W (h)\}$ are independent due to the fact that the vector $(W (e_1), \cdots, W (e_s), W (h))$ is multivariate normally distributed and the covariance is diagonal. Therefore,

$$E (aW (e_1)^{r_1} \cdots W (e_s)^{r_s} W (h)^r H_m (W (h)))$$

$$= aE (W (e_1)^{r_1}) \cdots E (W (e_s)^{r_s}) E (W (h)^r H_m (W (h)))$$

Now since $r \leq n$, $W (h)^r = \sum_{k=1}^r c_k H_k (W (h))$ for some choice of scalars $c_k$. By Lemma this last term,

$$E (W (h)^r H_m (W (h))) = \sum_k c_k E (H_k (W (h)) H_m (W (h))) = 0$$

since each $k < m$.

Note how remarkable this is. $\mathcal{P}_n^0$ includes all polynomials in $W (h_1), \cdots, W (h_k)$ some $h_1, \cdots, h_k$, of degree no more than $n$, including those which have mixed terms but a typical thing in $\oplus_{i=0}^n H_i$ is a sum of Hermite polynomials in $W (h_k)$. It is not the case that you would have terms like $W (h_1) W (h_2)$ as could happen in the case of $\mathcal{P}_n$.

Obviously it would be a good idea to obtain an orthonormal basis for $L^2 (\Omega, \mathcal{F}, P)$. This is done next. Let $\Lambda$ be the multiindices, $(a_1, a_2, \cdots)$ each $a_k$ a nonnegative integer. Also in the description of $\Lambda$ assume that $a_k = 0$ for all $k$ large enough. For such a multiindex $a \in \Lambda$, 

$$a! \equiv \prod_{i=1}^\infty a_i!, \ |a| \equiv \sum_i a_i$$

Also for $a \in \Lambda$, define

$$H_n (x) \equiv \prod_{j=1}^\infty H_{a_j} (x)$$
66.2. A REMARKABLE THEOREM INVOLVING THE HERMITE POLYNOMIALS

This is well defined because $H_0(x) = 1$ and all but finitely many terms of this infinite product are therefore equal to 1. Now let $\{e_i\}$ be an orthonormal basis for $H$. For $a \in \Lambda$,

$$\Phi_a = \sqrt{a!} \prod_{i=1}^{\infty} H_{a_i}(W(e_i)) \in L^2(\Omega)$$

Suppose $a, b \in \Lambda$.

$$\int_{\Omega} \Phi_a \Phi_b dP = \sqrt{a!} \sqrt{b!} \prod_{i=1}^{\infty} H_{a_i}(W(e_i)) H_{b_i}(W(e_i)) dP$$

Now recall from Corollary 62.6.1 the random variables $\{W(e_i)\}$ are independent. Therefore, the above equals

$$\sqrt{a!} \sqrt{b!} \prod_{i=1}^{\infty} H_{a_i}(W(e_i)) H_{b_i}(W(e_i)) dP = \begin{cases} 1 & \text{if } a = b \\ 0 & \text{if } a \neq b \end{cases}$$

Thus $\{\Phi_a : a \in \Lambda\}$ is an orthonormal set in $L^2(\Omega)$.

**Lemma 66.2.5** If $s_k \to h$, then for $n \in \mathbb{N}$, there is a subsequence, still called $s_k$ for which $W(s_k)^n \to W(h)^n$ in $L^2(\Omega)$.

**Proof:** If $s_k \to h$, does $W(s_k)^n \to W(h)^n$ in $L^2(\Omega)$ for some subsequence? First of all,

$$\|W(h) - W(s_k)\|_{L^2(\Omega)}^2 = |s_k - h|^2 \to 0$$

and so there is a subsequence, still called $k$ such that $W(s_k)(\omega) \to W(h)(\omega)$ for a.e. $\omega$. Consider

$$\int_{\Omega} |W(h)^n - W(s_k)^n|^2 dP$$

(66.2.8)

Does this converge to 0? The integrand is bounded by $2 \left( W(h)^{2n} + W(s_k)^{2n} \right)$. Since $W(h), W(s_k)$ are symmetric,

$$\int_{\Omega} \left( 2 \left( W(h)^{2n} + W(s_k)^{2n} \right) \right)^2 dP \leq 8 \int_{\Omega} \left( W(h)^{4n} + W(s_k)^{4n} \right) dP$$

$$= 16 \int_{\Omega \cap \{W(h) \geq 0\}} e^{4nW(h)} dP + 16 \int_{\Omega \cap \{W(s_k) \geq 0\}} e^{4nW(s_k)} dP$$

$$\leq 16 \int_{\Omega} e^{4nW(h)} dP + 16 \int_{\Omega} e^{4nW(s_k)} dP$$

$$\leq 16e^{\frac{1}{2} |4nh|} + 16e^{\frac{1}{2} |4n|s_k|}$$

which is bounded independent of $k$, the last step following from Lemma 62.6.4. Therefore, the Vitali convergence theorem applies in 66.2.8. ■
CHAPTER 66. A DIFFERENT KIND OF STOCHASTIC INTEGRATION

Given an $h \in H$, let $s_k = \sum_{j=1}^{k} (h, e_j) e_j$, the $k^{th}$ partial sum in the Fourier series for $h$.

$$W(s_k)^m = \left( \sum_{j=1}^{k} (h, e_j) W(e_j) \right)^m = p(W(e_1), \cdots, W(e_k))$$

where $p$ is a homogeneous polynomial of degree $m$. Now this equals

$$q(H_0(W(e_1)), \cdots, H_0(W(e_k)) \cdots H_m(W(e_1)), \cdots, H_m(W(e_k)))$$

where $q$ is a polynomial. This is because each $W(e_j)^r$ is a linear combination of $H_s(W(e_j))$ for $s \leq r$. Now you look at terms of this polynomial. They are all of the form $c\Phi_n$ for some constant $c$ and $a \in \Lambda$. Therefore, if $X \in L^2(\Omega)$, there is a subsequence, still denoted as $\{s_k\}$ such that

$$E(W(h)^n X) = \lim_{k \to \infty} E(W(s_k)^n X)$$

Now if $X$ is orthogonal to each $\Phi_n$, then for any $h$ and $n$, there is a subsequence still denoted with $k$ such that

$$E(W(h)^n X) = \lim_{k \to \infty} E(W(s_k)^n X) = 0$$

It follows from Lemma the part about the convergence of the partial sums to $e^{W(h)}$ that $X$ is orthogonal to $e^{W(h)}$ for any $h$. Here are the details. From the lemma, for large $n,$

$$\left| E\left(e^{W(h)}X\right) - E\left(\sum_{j=0}^{n} \frac{W(h)^j}{j!} X\right) \right| < \varepsilon,$$

Also for large $k,$

$$\left| E\left(\sum_{j=0}^{n} \frac{W(s_k)^j}{j!} X\right) - E\left(\sum_{j=0}^{n} \frac{W(h)^j}{j!} X\right) \right| = \left| E\left(\sum_{j=0}^{n} \frac{W(h)^j}{j!} X\right) \right| < \varepsilon$$

Therefore,

$$\left| E\left(e^{W(h)}X\right) \right| < 2\varepsilon$$

Since $\varepsilon$ is arbitrary, this proves the desired result. By Lemma, $X = 0$ and this shows that $\{\Phi_n : a \in \Lambda\}$ is complete.

**Proposition 66.2.6** $\{\Phi_n : a \in \Lambda\}$ is a complete orthonormal set for $L^2(\Omega, \mathcal{F}, P)$. 

66.3 A Multiple Integral

Consider trying to find
\[ \int_0^1 \int_0^1 dB_s dB_t \]

Here \( B_t \) is just one dimensional Wiener process. You would want it to equal
\[ 2 \int_0^1 \int_0^t dB_s dB_t = 2 \int_0^1 B_t dB_t \]

So what should this equal? Let \( F(x) = x^2 \) so \( F'(x) = 2x, F''(x) = 2 \). Consider \( F(B_t) \). Then using the formalism for the Ito formula,
\[ dF(B_t) = d(B_t^2) = 2B_t dB_t + \frac{1}{2} (2) (dB_t)^2 = 2B_t dB_t + dt \]

Therefore,
\[ B_t^2 = 2 \int_0^t B_s dB_s + t \]

and letting \( t = 1 \),
\[ \frac{1}{2} B_1^2 - \frac{1}{2} = \int_0^1 B_s dB_s = \int_0^1 \int_0^s dB_r dB_s \]

and so we would want to have
\[ B_1^2 - 1 = 2 \int_0^1 \int_0^s dB_r dB_s \]

and we want this to equal \( \int_0^1 \int_0^t dB_s dB_t \) so we need to be defining this in a way such that this will result. Of course, this is just the simplest example of an iterated integral with respect to these one dimensional Wiener processes.

Now partition \([0,1]\) as \( 0 = t_0 < t_1 < \cdots < t_n = 1 \). Then sum over all \([t_{i-1}, t_i] \times [t_{j-1}, t_j]\) but leave out those which are on the “diagonal”. These would be of the form \([t_{i-1}, t_i] \times [t_{i-1}, t_i]\). Here you would have in the sum products of the form \((B_{t_i} - B_{t_{i-1}})(B_{t_j} - B_{t_{j-1}})\). Thus you would have
\[
\sum_{i,j} (B_{t_i} - B_{t_{i-1}}) (B_{t_j} - B_{t_{j-1}}) = \sum_{i=1}^n (B_{t_i} - B_{t_{i-1}})^2
\]
\[
= \left( \sum_{i=1}^n B_{t_i} - B_{t_{i-1}} \right)^2 - \sum_{i=1}^n (B_{t_i} - B_{t_{i-1}})^2
\]
\[
= (B_1 - B_0)^2 - \sum_{i=1}^n (B_{t_i} - B_{t_{i-1}})^2
\]
Then of course you take a limit as the norm of the partition goes to 0. This yields in the limit

\[ B^2_1 - 1 \]

which is the thing which is wanted. Thus the idea is to consider only functions which are equal to 0 on the “diagonal” and define an integral for these. Then hopefully these will be dense in \( L^2([0,T]^n) \) and the multiple integral can then be defined as some sort of limit.

Now in the above construction, from now on, unless indicated otherwise, \( H = L^2(T) \) where the measure is ordinary Lebesgue measure on \( T = [0,T] \) or \( [0,\infty) \) or some other interval of time. However, it could be more general, but for the sake of simplicity let it be Lebesgue measure. Generalities appear to be nothing but identifying that which works in the case of Lebesgue measure. If \( \mu \ll m \) everything would work also. A careful description of what kind of measures work is in [93].

Also, for \( A \) a Borel set having finite Lebesgue measure,

\[ W(A) \equiv W(\mathcal{X}_A). \]

This is a random variable, and as explained earlier, since any finite set of these is normally distributed, if all the sets are pairwise disjoint, the random variables are independent because the covariance is a diagonal matrix.

**Definition 66.3.1** Let \( D \equiv \{(t_1, \cdots, t_m) : t_i = t_j \text{ for some } i \neq j\} \). This is called the diagonal set. Here \( D \subseteq T^m \) where \( T \) is an interval \([0,T]\). Assume \( T < \infty \) here. Let

\[ 0 = \tau_0 < \tau_1 < \cdots < \tau_k = T \]

Then this can be used to partition \( T^m \) into sets of the form

\[ [\tau_{i_1-1}, \tau_{i_1}) \times \cdots \times [\tau_{i_m-1}, \tau_{i_m}) \]

such that \( T^m \) is the disjoint union of these. An off diagonal step function \( f \) is one which is of the form

\[ f(t_1, \cdots, t_m) = \sum_{t_{i_1} \cdots, t_{i_m}} a_{i_1, \cdots, i_m} \mathcal{X}_{[\tau_{i_1-1}, \tau_{i_1}) \times \cdots \times [\tau_{i_m-1}, \tau_{i_m})} (t_1, \cdots, t_m) \]

where \( a_{i_1, \cdots, i_m} = 0 \) if \( i_p = i_q \). This would correspond to a diagonal term because it would result in a repeated half open interval. Thus we assume all these are equal to 0. The collection of all such off diagonal step functions will be denoted as \( \mathcal{E}_m \). The \( m \) corresponds to the dimension.

**Definition 66.3.2** Let \( I_m : \mathcal{E}_m \to L^2(\Omega) \) be defined in the obvious way.

\[ I_m \left( \sum_{t_{i_1} \cdots, t_{i_m}} a_{i_1, \cdots, i_m} \mathcal{X}_{[\tau_{i_1-1}, \tau_{i_1}) \times \cdots \times [\tau_{i_m-1}, \tau_{i_m})} (t_1, \cdots, t_m) \right) \]
\[ \equiv \sum_{i_1, \ldots, i_m} a_{i_1, \ldots, i_m} \prod_{p=1}^{m} (B_{\tau_p} - B_{\tau_{p-1}}) \]

Then \( I_m \) is linear. If you had two different partitions, you could take the union of them both and by letting coefficients be repeated on the smaller boxes, one can assume that a single partition is being used. This is why it is clear that \( I_m \) is linear.

**Definition 66.3.3** Let \( f \in L^2(T^m) \). The symetrization of \( f \) is given by

\[ \tilde{f}(t_1, \cdots, t_m) = \frac{1}{m!} \sum_{\sigma \in S_m} f(t_{\sigma_1}, \cdots, t_{\sigma_m}) \]

**Lemma 66.3.4** The following holds for \( f \in E_m \)

\[ \|\tilde{f}\|_{L^2(T^m)} \leq \|f\|_{L^2(T^m)} \]

also

\[ I_m(f) = I_m(\tilde{f}) \]

**Proof:** This follows because, thanks to the properties of Lebesgue measure,

\[ \int_{T^m} |f(t_1, \cdots, t_m)|^2 dt_1 \cdots dt_m = \int_{T^m} |f(t_{\sigma_1}, \cdots, t_{\sigma_m})|^2 dt_1 \cdots dt_m \]

\[ = \int_{T^m} |f_{\sigma}|^2 dt_1 \cdots dt_m \]

therefore,

\[ \|\tilde{f}\|_{L^2(T^m)} \leq \frac{1}{m!} \sum_{\sigma \in S_m} \|f_{\sigma}\|_{L^2(T^m)} = \frac{1}{m!} \sum_{\sigma \in S_m} \|f\|_{L^2(T^m)} = \|f\|_{L^2(T^m)} \]

The next claim follows because on the right, the terms making up the sum just happen in a different order for each \( \sigma \).

More generally, here is a lemma about off diagonal things. It uses sets \( A_i \) rather than intervals \([a, b]\).

**Lemma 66.3.5** Let \( \{A_1, \cdots, A_m\} \) be pairwise disjoint sets in \( \mathcal{B}(T) \) each having finite measure. Then the products \( A_{i_1} \times \cdots \times A_{i_m} \) are pairwise disjoint. Also to say that the function

\[ (t_1, \cdots, t_m) \rightarrow \sum_{i} c_i \chi_{A_{i_1} \times \cdots \times A_{i_m}}(t_1, \cdots, t_n) \]

equals 0 whenever some \( t_j = t_i, i \neq j \) is to say that \( c_i = 0 \) whenever there is a repeated index in \( i \).
Proof: Suppose the condition that the $A_k$ are pairwise disjoint holds and consider two of these products, $A_{i_1} \times \cdots \times A_{i_n}$ and $A_{j_1} \times \cdots \times A_{j_n}$. If the two ordered lists $(i_1, \ldots, i_n), (j_1, \ldots, j_n)$ are different, then since the $A_k$ are disjoint the two products have empty intersection because they differ in some position.

Now suppose that $c_{1} = 0$ whenever there is a repeated index. Then the sum is taken over all permutations of $n$ things taken from $\{1, \ldots, m\}$ and so if some $t_r = t_s$ for $r \neq s$, all terms of the sum equal zero because $\mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \neq 0$ only if $t \in A_{i_1} \times \cdots \times A_{i_n}$ and since $t_r = t_s$ and the sets $\{A_k\}$ are disjoint, there must be the same set in positions $r$ and $s$ so $c_1 = 0$. Hence the function equals 0.

Conversely, suppose the sum $\sum c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}}$ equals zero whenever some $t_r = t_s$ for $s \neq r$. Does it follow that $c_1 = 0$ whenever some $t_r = t_s$? The value of this function at $t \in A_{i_1} \times \cdots \times A_{i_n}$ is $c_1$ because for any other ordered list of indices, the resulting product has empty intersection with $A_{i_1} \times \cdots \times A_{i_n}$. Thus, since $t_r = t_s$, it is given that this function equals 0 which equals $c_1$. $\blacksquare$

This says that when you consider such a function $\sum c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}}$ with the $A_k$ pairwise disjoint, then to say that it equals 0 whenever some $t_i = t_j$ is to say that it is really a sum over all permutations of $n$ indices taken from $\{1, \ldots, m\}$. Thus there are $\binom{m}{n} n! = P(m, n)$ possible non zero terms in this sum.

Lemma 66.3.6 Consider the set of all ordered lists of $n$ indices from $\{1, 2, \ldots, m\}$. Thus two lists are the same if they consist of the same numbers in the same positions. We denote by $i$ or $j$ such an index, $i$ from $\{1, \ldots, m\}$ and $j$ from $\{1, \ldots, q\}$. Also let $\{A_1, \ldots, A_m\}, \{B_1, \ldots, B_q\}$ are two lists of pairwise disjoint Borel sets from $T$ having finite Lebesgue measure. Also suppose

$$\sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} = \sum_j d_j \mathcal{X}_{B_{j_1} \times \cdots \times B_{j_n}}$$

Then

$$\sum_i c_i \prod_{k=1}^{n} W(A_{i_k}) = \sum_j d_j \prod_{k=1}^{n} W(B_{j_k})$$

Proof: Suppose that $n = 1$ first. Then you have

$$\sum_i c_i \mathcal{X}_{A_i} = \sum_j d_j \mathcal{X}_{B_j} \quad (66.3.9)$$

where the sets $\{A_i\}$ and $\{B_j\}$ are disjoint. Clearly

$$A_i \supseteq \bigcup_j A_i \cap B_j \quad (66.3.10)$$

Consider

$$c_i \mathcal{X}_{A_i}, \sum_j c_i \mathcal{X}_{A_i \cap B_j} \quad (66.3.11)$$

If strict inequality holds in (66.3.10), then you must have a point in $A_i \setminus \bigcup_j A_i \cap B_j$ where the left side of $\sum_i c_i \mathcal{X}_{A_i}$ equals $c_i$ but the right side would equal 0. Hence
$c_i = 0$ and so $\sum_j c_i \chi_{A_i \cap B_j} = 0$ which shows that the two expressions in 66.3.11 are equal. If $A_i = \bigcup_j A_i \cap B_j$, it is also true that the two expressions in 66.3.11 are equal. Thus

$$\sum_i c_i \chi_{A_i} = \sum_i \sum_j c_i \chi_{A_i \cap B_j}$$

Similar considerations apply to the right side. Thus

$$\sum_i \sum_j c_i \chi_{A_i \cap B_j} = \sum_j \sum_i d_j \chi_{A_i \cap B_j}$$

$$\sum_{i,j} (c_i - d_j) \chi_{A_i \cap B_j} = 0$$

hence if $W(A_i \cap B_j) \neq 0$, then, since these sets are disjoint, $c_i - d_j = 0$. It follows that

$$\sum_{i,j} (c_i - d_j) W(A_i \cap B_j) = 0$$

and so

$$\sum_i c_i W(A_i) = \sum_i \sum_j c_i W(A_i \cap B_j) = \sum_j \sum_i d_j W(A_i \cap B_j) = \sum_j d_j W(B_j)$$

This proves the theorem if $n = 1$. Consider the general case. Let $\mathbf{i}'$ be

$$(i_1, \ldots, i_{n-1}), i_k \leq m$$

$$\sum_{i_{n-1}=1}^{m} \sum_{i'=(i_1, \ldots, i_{n-1})} c_{i'(i_{n})} \chi_{A_{i_{n}}(t_{n})} \chi_{A_{i_1} \times \cdots \times A_{i_{n-1}}} = \sum_i c_i \chi_{A_{i_1} \times \cdots \times A_{i_{n-1}}}$$

$$= \sum_j d_j \chi_{B_{j_1} \times \cdots \times B_{j_{n-1}}} = \sum_{j_{n-1}=1}^{m} \sum_{j'=(j_1, \ldots, j_{n-1})} d_{j'(j_{n})} \chi_{B_{j_{n}}(t_{n})} \chi_{B_{j_1} \times \cdots \times B_{j_{n-1}}}$$

Now pick $(t_1, \ldots, t_{n-1})$. The above is then

$$\sum_{i_{n-1}=1}^{m} \left( \sum_{i'} c_{i'(i_{n})} \chi_{A_{i_1} \times \cdots \times A_{i_{n-1}}} (t_1, \ldots, t_{n-1}) \right) \chi_{A_{i_{n}}(t_{n})}$$

$$= \sum_{j_{n-1}=1}^{m} \left( \sum_{j'} d_{j'(j_{n})} \chi_{B_{j_1} \times \cdots \times B_{j_{n-1}}} (t_1, \ldots, t_{n-1}) \right) \chi_{B_{j_{n}}(t_{n})}$$

and by what was just shown for $n = 1$, for each such choice,

$$\sum_{i_{n}} \left( \sum_{i'} c_{i'(i_{n})} \chi_{A_{i_1} \times \cdots \times A_{i_{n-1}}} \right) W(A_{i_{n}})$$

$$= \sum_{j_{n}} \left( \sum_{j'} d_{j'(j_{n})} \chi_{B_{j_1} \times \cdots \times B_{j_{n-1}}} \right) W(B_{j_{n}})$$
Then

\[ \sum_{i} \left( \sum_{i_n} W(A_{i_n}) c(\omega_0, i_n) \right) X_{A_{i_1} \times \cdots \times A_{i_{n-1}}} = \]

\[ \sum_{j'} \left( \sum_{j_n} W(B_{j_n}) d(\omega_0, j_n) \right) X_{B_{j_1} \times \cdots \times B_{j_{n-1}}} \]

Pick \( \omega = \omega_0 \). Then by induction,

\[ \sum_{i} \left( \sum_{i_n} W(A_{i_n}) (\omega_0) c(i', i_n) \right) W(A_{i_1}) \cdots W(A_{i_{n-1}}) \]

\[ = \sum_{j'} \left( \sum_{j_n} W(B_{j_n}) (\omega_0) d(j', j_n) \right) W(B_{j_1}) \cdots W(B_{j_{n-1}}) \]

and this reduces to what was to be shown because \( \omega_0 \) was arbitrary.

In what follows it will be assumed \( c_i = 0 \) if any two of the \( i_k \) are equal. That is

\[ \sum_{i} c_i X_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \cdots, t_n) = 0 \]

if any \( t_i = t_j \).

**Definition 66.3.7** Let \( E_n \) be functions of the form

\[ f(t_1, \cdots, t_n) = \sum_{i} c_i X_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \cdots, t_n) \]

where the \( A_k \) come from some list of the form \( \{A_1, A_2, \cdots, A_m\} \) where this list of sets is pairwise disjoint, each \( A_k \neq \emptyset \) and \( c_i = 0 \) whenever two indices are equal. By Lemma 66.3.5 this is the same as saying that \( f = 0 \) if \( t_i = t_j \) for some \( i \neq j \). A function of \( n \) variables \( f \) is symmetric means that for \( \sigma \) a permutation,

\[ f(t_1, \cdots, t_n) = f(t_{\sigma(1)}, \cdots, t_{\sigma(n)}) \]

**Lemma 66.3.8** Let \( f(t_1, \cdots, t_n) = \sum_{i} c_i X_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \cdots, t_n) \). Then \( f \) is symmetric if and only if for all \( \{c_{i_1}, \cdots, i_n\} \)

\[ c_{i_1, \cdots, i_n} = c_{i_{\sigma(1)}, \cdots, i_{\sigma(n)}} \]

**Proof:** First of all, every \( c_i = 0 \) if there are repeated indices so it suffices to consider only the case where all indices are distinct.

Consider all the terms associated with a particular set of indices \( \{i_1, \cdots, i_n\} \). Then, since these sets \( A_{i_k} \) are disjoint, the function \( f \) is symmetric if and only if the part of the sum in the definition of \( f \) associated with each such set of indices is
symmetric. To save on notation, denote such a list by \( \{1, 2, \ldots, n\} \). It suffices then to show that

\[
f(t_1, \ldots, t_n) = \sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_1, \ldots, t_n)
\]

is symmetric if and only if for all \( \sigma, c_{\sigma(1)\ldots\sigma(n)} = c_{1\ldots n} \). Suppose then that \( f \) is symmetric. Then

\[
f(t_{\beta(1)}, \ldots, t_{\beta(n)}) = \sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_{\beta(1)}, \ldots, t_{\beta(n)})
\]

\[
= \sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_1, \ldots, t_n) = f(t_1, \ldots, t_n)
\]

However,

\[
\sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_{\beta(1)}, \ldots, t_{\beta(n)})
\]

\[
= \sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\beta^{-1}\sigma(1)} \times \cdots \times A_{\beta^{-1}\sigma(n)}} (t_1, \ldots, t_n) \quad (66.3.12)
\]

It is supposed to equal

\[
\sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_1, \ldots, t_n)
\]

\[
= \sum_{\sigma \in S_n} c_{\beta^{-1}\sigma(1)\ldots\beta^{-1}\sigma(n)} \mathcal{X}_{A_{\beta^{-1}\sigma(1)} \times \cdots \times A_{\beta^{-1}\sigma(n)}} (t_1, \ldots, t_n) \quad (66.3.13)
\]

Thus

\[
\sum_{\sigma \in S_n} c_{\sigma(1)\ldots\sigma(n)} \mathcal{X}_{A_{\beta^{-1}\sigma(1)} \times \cdots \times A_{\beta^{-1}\sigma(n)}} (t_1, \ldots, t_n)
\]

\[
= \sum_{\sigma \in S_n} c_{\beta^{-1}\sigma(1)\ldots\beta^{-1}\sigma(n)} \mathcal{X}_{A_{\beta^{-1}\sigma(1)} \times \cdots \times A_{\beta^{-1}\sigma(n)}} (t_1, \ldots, t_n) \quad (66.3.14)
\]

Since the sets \( A_k \) are distinct, as explained above, this requires that

\[
\mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} \neq \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}}
\]

if \( \alpha \neq \sigma \). Therefore, (66.3.12) requires that for all \( \beta \) and each \( \sigma \),

\[
c_{\sigma(1)\ldots\sigma(n)} = c_{\beta^{-1}\sigma(1)\ldots\beta^{-1}\sigma(n)}
\]

In particular, this is true if \( \beta = \sigma \) and so \( c_{\sigma(1)\ldots\sigma(n)} = c_{1\ldots n} \).
The converse of this is also clear. If \( c_{\sigma(1)\cdots\sigma(n)} = c_1 \cdots c_n \) for each \( \sigma \), then

\[
f (t_{\beta(1)}, \ldots, t_{\beta(n)}) = \sum_{\sigma \in S_n} c_{\sigma(1)\cdots\sigma(n)} \mathcal{X}_{A_{\sigma(1)} \times \cdots \times A_{\sigma(n)}} (t_{\beta(1)}, \ldots, t_{\beta(n)})
\]

\[
= \sum_{\sigma \in S_n} c_{\sigma(1)\cdots\sigma(n)} \mathcal{X}_{A_{\beta^{-1}(1)} \times \cdots \times A_{\beta^{-1}(n)}} (t_1, \ldots, t_n)
\]

\[
= \sum_{\sigma \in S_n} c_{1\cdots n} \mathcal{X}_{A_{\beta^{-1}(1)} \times \cdots \times A_{\beta^{-1}(n)}} (t_1, \ldots, t_n)
\]

\[
= \sum_{\sigma \in S_n} c_{\alpha(1)\cdots\alpha(n)} \mathcal{X}_{A_{\alpha(1)} \times \cdots \times A_{\alpha(n)}} (t_1, \ldots, t_n)
\]

\[
= f (t_1, \ldots, t_n) \quad \blacksquare
\]

Observe that \( \mathcal{E}_n \) is a vector space because if you have two such functions

\[
\sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \ldots, t_n), \sum_i d_i \mathcal{X}_{B_{i_1} \times \cdots \times B_{i_n}} (t_1, \ldots, t_n)
\]

where the \( A_{i_k} \) are from \( \{A_1, A_2, \ldots, A_m\} \) and the \( B_{i_k} \) are from \( \{B_1, B_2, \ldots, B_q\} \).

Then consider the single list consisting of the sets of the form \( A_k \cap B_j \). You could write each of these functions in terms of indicator functions of products of these disjoint sets. Thus the sum of the two functions can be written in the desired form. Since each are equal to 0 when some \( t_j = t_k \), the same is true of their sum. Thus \( \mathcal{E}_n \) is closed with respect to sums. It is obviously closed with respect to scalar multiplication. Hence it is a subspace of the vector space of all functions and it is therefore, a vector space.

Following [62], for \( f \) one of these elementary functions,

\[
f (t_1, \ldots, t_n) \equiv \sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \ldots, t_n)
\]

where if any two indices are repeated, then \( c_i = 0 \), and the \( A_k \) are all disjoint,

\[
I_n (f) \equiv \sum_i c_i W (A_{i_1}) \cdots W (A_{i_n})
\]

**Lemma 66.3.9** \( I_n \) is linear on \( \mathcal{E}_n \). If \( f \in \mathcal{E}_n \) and \( \sigma \) is a permutation of \( (1, \ldots, n) \) and

\[
f_{\sigma} (t_1, \ldots, t_n) \equiv f (t_{\sigma(1)}, \ldots, t_{\sigma(n)})
\]

and \( f \) is symmetric, then

\[
I_n (f_{\sigma}) = I_n (f)
\]

For \( f = \sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \), one can conclude that

\[
I_n (f) = n! \sum_{i_1 < i_2 < \cdots < i_n} c_{i_1, \ldots, i_n} \prod W (A_{i_n}) \tag{66.3.15}
\]
Also, the following holds for the expectation. For \( f, g \in \mathcal{E}_n, \mathcal{E}_m \) respectively,

\[
E (I_n (f) I_m (g)) = \begin{cases} 
0 & \text{if } n \neq m \\
 n! \left( \tilde{f}, \tilde{g} \right)_{L^2 (\mathbb{T}^n)} & \text{if } n = m
\end{cases}
\]

where \( \tilde{f} \) denotes the symetrization of \( f \) given by

\[
\tilde{f} (t_1, \cdots, t_n) \equiv \frac{1}{n!} \sum_{\sigma \in S_n} f (t_{\sigma(1)}, \cdots, t_{\sigma(n)})
\]

**Proof:** It is clear from the definition being well defined that \( I_n \) is linear. In particular, consider

\[
I_n \left( a \sum_i c_i \chi_{A_{i_1} \times \cdots \times A_{i_n}} + b \sum_j d_j \chi_{B_{j_1} \times \cdots \times B_{j_n}} \right).
\]

As explained above in the observation that \( \mathcal{E}_n \) is a vector space, it can be assumed that the \( A_{i_k} \) and \( B_{j_k} \) are all from a single set of disjoint Borel sets of \( \mathbb{T} \). Then the above is of the form

\[
= a \sum_i c_i \prod_k W (A_{i_k}) + b \sum_j d_j \prod_k W (B_{j_k})
\]

Next consider for \( i = (i_1 \cdots i_n) \),

\[
f_\sigma (t_1, \cdots, t_n) = \sum_i c_i \chi_{A_{i_1} \times \cdots \times A_{i_n}} (t_{\sigma(1)}, \cdots, t_{\sigma(n)})
\]

\[
= \sum_i c_i \prod_{j=1}^n \chi_{A_{i_j}} (t_{\sigma(j)}) = \sum_i c_i \prod_{j=1}^n \chi_{A_{i_{\sigma^{-1}(j)}}} (t_j)
\]

\[
= \sum_i c_i \chi_{A_{i_{\sigma^{-1}(1)}} \times \cdots \times A_{i_{\sigma^{-1}(n)}}} (t_1, \cdots, t_n)
\]

Thus, it appears that \( f_\sigma \neq f \). However,

\[
I_n (f_\sigma) = \sum_i c_i \prod_{k=1}^n W (A_{i_{\sigma^{-1}(k)}}) = I_n (f)
\]

(66.3.16)

because one just considers the factors in a different order than the other. The permutation acts on \( (i_1 \cdots i_n) \). Define the symetrization of \( f \) by \( \tilde{f} \) given by

\[
\tilde{f} (t_1, \cdots, t_n) \equiv \frac{1}{n!} \sum_\sigma f_\sigma (t_1, \cdots, t_n)
\]
CHAPTER 66. A DIFFERENT KIND OF STOCHASTIC INTEGRATION

Then \( I_n (\tilde{f}) = I_n (f) \) and \( \tilde{f} (t_{\sigma(1)}, \cdots, t_{\sigma(n)}) = \tilde{f} (t_1, \cdots, t_n) \). If \( f (t_{\sigma(1)}, \cdots, t_{\sigma(n)}) = f (t_1, \cdots, t_n) \) for all \( \sigma \) then \( \tilde{f} = f \). From the above, \( \tilde{f} \) equals

\[
\frac{1}{n!} \sum_{\sigma} \sum_{i} c_i \mathcal{X}_{A_{i_{\sigma(1)}}, \cdots, A_{i_{\sigma(n)}}} (t_1, \cdots, t_n)
\]

Note that 66.3.16 implies that \( I_n (f) = I_n (\tilde{f}) = n! \sum_{i_1 < i_2 < \cdots < i_n} c_{i_1, \cdots, i_n} \prod_k W (A_{i_k}) \) (66.3.17)

Now consider

\[
\tilde{f} = \sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \text{ and } \tilde{g} = \sum_i d_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}}
\]

where without loss of generality, these sets \( A_k \) come from a single list of disjoint sets. As above, \( I_n (f) = I_n (\tilde{f}) \) and so it follows that

\[
E (I_n (f) I_n (g)) = E (I_n (\tilde{f}) I_n (\tilde{g}))
\]

From the above, \( E (I_n (\tilde{f}) I_n (\tilde{g})) = \)

\[
E \left( \left( n! \right)^2 \sum_{i_1 < \cdots < i_n} \sum_{j_1 < \cdots < j_n} c_{i_1, \cdots, i_n} d_{j_1, \cdots, j_n} \prod_k W (A_{i_k}) \prod_l W (A_{j_l}) \right)
\]

\[
= (n!)^2 \sum_{i_1 < \cdots < i_n} \sum_{j_1 < \cdots < j_n} c_{i_1, \cdots, i_n} d_{j_1, \cdots, j_n} E \left( \prod_k W (A_{i_k}) \prod_l W (A_{j_l}) \right)
\]

\[
= (n!)^2 \sum_{i_1 < \cdots < i_n} \sum_{j_1 < \cdots < j_n} c_{i_1, \cdots, i_n} d_{j_1, \cdots, j_n} E \left( \prod_k W (A_{i_k}) W (A_{j_k}) \right) \text{(66.3.18)}
\]

That product is of independent random variables. Recall any collection of the \( W (A_k) \) are normally distributed and also the covariance is diagonal and so these will all be independent random variables. If any one of them is not repeated, say \( W (A_{i_1}) \), then

\[
E \left( \prod_k W (A_{i_k}) W (A_{j_k}) \right) = E (W (A_{i_k})) \text{(stuff)} = 0
\]

It follows that to get something nonzero out of this, all \( A_{i_k} \) are repeated. That is,
66.3. A MULTIPLE INTEGRAL

you must have \( j = i \) and \( \text{Lemma 66.3.8} \) reduces to

\[
E \left( \prod_k W(A_{i_k})^2 \right) = \left( n! \right)^2 \sum_{i_1 < \cdots < i_n} c_{i_1} \cdots c_{i_n} d_{i_1} \cdots d_{i_n} \prod_k E \left( W(A_{i_k})^2 \right)
\]

\[
= \left( n! \right)^2 \sum_{i_1 < \cdots < i_n} c_{i_1} \cdots c_{i_n} d_{i_1} \cdots d_{i_n} \prod_k m(A_{i_k}) \quad (66.3.19)
\]

By Lemma 66.3.8 used at the end of the following string of equalities, and the observation that

\[
\mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \mathcal{X}_{A_{j_1} \times \cdots \times A_{j_m}} = 0
\]

to eliminate mixed terms,

\[
\left( \hat{f}, \hat{g} \right)_{L^2(T^n)} = 
\]

\[
= \int_0^\infty \cdots \int_0^\infty \left( \sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \right) \left( \sum_i d_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \right) dt \cdots dt
\]

\[
= \int_0^\infty \cdots \int_0^\infty \left( \sum_i c_i d_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} \right) dt \cdots dt
\]

\[
= \sum_i c_i d_i \prod_k m(A_{i_k}) = n! \sum_{i_1 < \cdots < i_n} c_{i_1} \cdots c_{i_n} d_{i_1} \cdots d_{i_n} \prod_k m(A_{i_k})
\]

Now it follows from this and \( \text{Lemma 66.3.8} \) that

\[
E \left( I_n \left( f \right) I_n \left( g \right) \right) = n! \left( \hat{f}, \hat{g} \right)_{L^2(T^n)}.
\]

What happens if you consider \( E \left( I_n \left( f \right) I_m \left( g \right) \right) \) where \( m < n \)? You would still get

\[
E \left( I_n \left( f \right) I_m \left( g \right) \right) = E \left( I_n \left( \hat{f} \right) I_m \left( \hat{g} \right) \right)
\]

\[
= E \left( \left( n! \right) \left( m! \right) \sum_{i_1 < i_2 < \cdots < i_n} \sum_{j_1 < \cdots < j_m} c_{i_1} \cdots c_{i_n} d_{j_1} \cdots d_{j_m} W(A_{i_1}) \cdots W(A_{i_n}) W(A_{j_1}) \cdots W(A_{j_m}) \right)
\]

Then at least one of the \( W(A_{i_k}) \) is not repeated. This is because \( n > m \). That product is a product of independent random variables at least one of which is of the form \( W(A_{i_k}) \). Hence when you take the expectation of the product it is of the form \( E \left( W(A_{i_k}) \right) \) (Other terms) = 0. Thus if \( n \neq m \), the result is 0 as claimed. ■

An integral has now been defined on the functions of the form

\[
f (t_1, \cdots, t_n) = \sum_i c_i \mathcal{X}_{A_{i_1} \times \cdots \times A_{i_n}} (t_1, \cdots, t_n)
\]
where \( f = 0 \) if any \( t_i = t_j \) for \( i \neq j \). This integral defined on these elementary functions is interesting because for such functions \( f, g \)

\[
E (I_n (f) I_m (g)) = \begin{cases} 
0 & \text{if } n \neq m \\
1 & \text{if } n = m 
\end{cases}
\]

where \( \hat{f} \) is the symmetrization of \( f \). It is desired to extend this integral to \( L^2 (T^n) \).

Simple functions are always dense in \( L^2 (T^n) \): Also, there is an easy lemma which can be concluded for \( L^2 (T^n) \).

**Lemma 66.3.10** Let \( B^0 (T) \) be the Borel sets having finite measure. Linear combinations of functions of the form

\[
\mathcal{X}_{A_1 \times \cdots \times A_n}
\]

where \( A_i \in B^0 (T) \) are dense in \( L^2 (T, B^n) \) where of course \( B^n \) refers to the product \( \sigma \) algebra.

**Proof:** If you have \( U = A_1 \times \cdots \times A_n \) in \( T^n \) one can approximate \( \mathcal{X}_{U \cap R_p} \) for \( R_p = (-p, p)^n \) in \( L^2 \) with linear combinations of sets of the desired form. In fact, you just consider \( \mathcal{X}_{A_1 \cap (-p, p) \times \cdots \times A_n (-p, p)} \) and you get equality. Now let \( K \) denote the \( \pi \) system of sets of this sort. Let \( \mathcal{G} \) denote those Borel sets \( G \) such that there exists a sequence of linear combinations of sets of the form \( \mathcal{X}_{A, A} = A_1 \times \cdots \times A_n \) which converges to \( \mathcal{X}_{G \cap R_p} \) in \( L^2 (T^n) \). Thus \( \mathcal{G} \supseteq K \).

Let \( \{ G_k \} \) be a disjoint sequence of sets of \( \mathcal{G} \). Is \( G \equiv \cup_k G_k \in \mathcal{G} \)? By monotone convergence theorem,

\[
\left\| \mathcal{X}_{G \cap R_p} - \sum_{k=1}^m \mathcal{X}_{G_k \cap R_p} \right\|_{L^2 (T^n)} < \varepsilon
\]

provided \( m \) is large enough. Now by definition of \( \mathcal{G} \) there exists \( L_k \) a linear combination of these special sets such that

\[
\left\| \mathcal{X}_{G_k \cap R_p} - L_k \right\|_{L^2 (T^n)} < \frac{\varepsilon}{m}
\]

It follows that

\[
\left\| \mathcal{X}_{G \cap R_p} - \sum_{k=1}^m L_k \right\|_{L^2} \leq \left\| \mathcal{X}_{G \cap R_p} - \sum_{k=1}^m \mathcal{X}_{G_k \cap R_p} \right\|_{L^2} + \left\| \sum_{k=1}^m \mathcal{X}_{G_k \cap R_p} - \sum_{k=1}^m L_k \right\|_{L^2} < \varepsilon + \varepsilon
\]

and so, it follows that \( G \in \mathcal{G} \). If \( G \in \mathcal{G} \), does it follow that \( G^c \) is also?

\[
\mathcal{X}_{R_p} = \mathcal{X}_{R_p \cap G} + \mathcal{X}_{R_p \cap G^c}
\]
Hence

\[ \mathcal{X}_{R_p} - \mathcal{X}_{R_p \cap \mathcal{G}} = \mathcal{X}_{R_p \cap \mathcal{G}^c} \]

Both of the functions on the left can be approximated in \( L^2 \) by the desired kind of functions and so the one on the right can also. It follows from Dynkin’s lemma that \( \mathcal{G} \equiv \sigma(\mathcal{K}) \) which is the product measurable sets. Thus if \( U \) is any set in \( \mathcal{B}_n \), it follows that \( \mathcal{X}_U \) can be approximated in \( L^2(T^n) \) with linear combinations of sets like \( \mathcal{X}_{A_1 \times \cdots \times A_n} \).

Of course nothing is known about whether the sets \( A_i \) are disjoint. Also it is not known whether these linear combinations of these functions equals 0 if \( t_i = t_j \).

Thus there is something which needs to be proved.

**Lemma 66.3.11** The functions in \( \mathcal{E}_n \) mentioned above are dense in \( L^2(T^n) \).

**Proof:** From Lemma 66.3.10, it suffices to show that \( \mathcal{X}_{A_1 \times \cdots \times A_n} \) can be approximated in \( L^2(T^n) \) with functions in \( \mathcal{E}_n \). This is where it will be important that the measure is sufficiently like Lebesgue measure. Let \( \{B_k^i\}_{k=1}^m \) be a partition of \( A_i \) such that \( m(B_k^i) \leq \frac{2m(A_i)}{m} \). Let \( \{B_k\}_{k=1}^p \) denote all these sets so \( p = mn \). They are not necessarily disjoint because it is not known that the \( A_i \) are disjoint. However, one can say that it is possible to choose \( e_i \) equal to either 0 or 1 such that

\[ \mathcal{X}_{A_1 \times \cdots \times A_n} = \sum_i e_i \mathcal{X}_{B_1^i \times \cdots \times B_{i n}} \]

where we can have \( B_{i k} \subsetneq A_k \). Let \( J \) be those indices \( i \) which involve a repeated set. That is some \( B_{i j} = B_{i k} \) for some \( j \neq k \). How many possibilities are there? There are no more than \( C(n, 2) m \) because there are \( C(n, 2) \) possibilities for duplicates among the \( A_k \) and then there are \( m \) sets in the partition of \( A_k \).

\[
\int_T \cdots \int_T \left( \sum_{i \in J} e_i \mathcal{X}_{B_1^i \times \cdots \times B_{i n}} \right)^2 dt \cdots dt
= \int_T \cdots \int_T C(n, 2) m \mathcal{X}_{B_1^i \times \cdots \times B_{i n}} dt \cdots dt
\leq C(n, 2) m \prod_{k=1}^n m(B_{i k})
\]

The mixed terms are 0 because for a fixed \( k \); \( \{B_{i k}\}_{i=1}^m \) are disjoint. Now from the description of these, \( m(B_{i k}) m < m(A_k) \) and so

\[
\int_T \cdots \int_T \left( \sum_{i \in J} e_i \mathcal{X}_{B_1^i \times \cdots \times B_{i n}} \right)^2 dt \cdots dt
\leq C(n, 2) m \prod_{k=1}^n \frac{2m(A_k)}{m} = \frac{C(n, 2) m}{m^n} \prod_{k=1}^n m(A_k)
\]
which clearly converges to 0 as \( m \to \infty \) provided that \( n \geq 2 \). In case \( n = 1 \), all you have to do is approximate \( \mathcal{X}_A \) from something in \( \mathcal{E}_1 \) and of course you just use \( \mathcal{X}_A \).

Let \( f, g \in \mathcal{E}_n \). Then from Lemma 66.3.11,

\[
E \left( (I_n (f - g))^2 \right) = n! \left\| f - g \right\|_{L^2(T^n)}^2
\]

\[
\left\| \hat{f} \right\|_{L^2(T^n)} = \left( \int_T \cdots \int_T \left| \hat{f}(t) \right|^2 \, dt \right)^{1/2} = \left( \int_T \cdots \int_T \left| \frac{1}{n!} \sum_{\sigma} f(t_{\sigma(1)}, \cdots, t_{\sigma(n)}) \right|^2 \, dt \right)^{1/2}
\]

\[
\leq \frac{1}{n!} \sum_{\sigma} \left( \int_T \cdots \int_T \left| f(t_{\sigma(1)}, \cdots, t_{\sigma(n)}) \right|^2 \, dt \right)^{1/2} = \frac{1}{n!} \sum_{\sigma} \left\| f \right\|_{L^2(T^n)} = \left\| f \right\|_{L^2(T^n)}
\]

Therefore,

\[
E \left( (I_n (f - g))^2 \right) = n! \left\| f - g \right\|_{L^2(T^n)}^2 \leq n! \left\| f - g \right\|_{L^2(T^n)}^2.
\] (66.3.20)

The following theorem comes right away from this and Lemma 66.3.11.

**Theorem 66.3.12** The integral \( I_n \) defined on \( \mathcal{E}_n \) extends uniquely to an integral \( I_n \) defined on \( L^2(T^n) \). This integral satisfies

\[ I_n (f) \in L^2(\Omega) \]

Also

\[ E (I_n (f) I_n (g)) = n! \left( \hat{f}, \hat{g} \right)_{L^2(T^n)} \]

**Proof:** This follows right away from the density of \( \mathcal{E}_n \) in \( L^2(T^n) \) and the inequality (66.3.20).

Obviously one wonders whether linear combinations \( \sum_n c_n I_n (f_n) \) are dense in \( L^2(\Omega) \). It looks like the important thing to notice is that for \( f \in \mathcal{E}_n \), \( I_n (f) \) is a polynomial in \( W(A_{h_k}) \equiv W \left( \mathcal{X}_{A_{h_k}} \right) \). Recall the corollary above, Corollary 66.2.3.

**Corollary 66.3.13** Let \( \mathcal{P}_n^0 \) denote all polynomials of the form

\[ p(W(h_1), \cdots, W(h_k)), \text{ degree of } p \leq n, \text{ some } h_1, \cdots, h_k \]

Also let \( \mathcal{P}_n \) denote the closure in \( L^2(\Omega, \mathcal{F}, \mathbb{P}) \) of \( \mathcal{P}_n^0 \). Then

\[ \mathcal{P}_n = \bigoplus_{i=0}^n H_i \]
66.3. A MULTIPLE INTEGRAL

Consider \( \bigcup_{p \leq n} \{ I_p(f) : f \in \mathcal{E}_p \} \). This is a subset of \( \mathcal{P}_n \) and so it is a subset of \( \oplus_{i=0}^n \mathcal{H}_i \). Now for \( h \in L^2(T^n) \), it was shown above that there exists a sequence \( g_k \to h \) in \( L^2(T^n) \) where each \( h_k \in \mathcal{E}_n \). Then \( I_n(g_k) \to I_n(h) \). In particular, if \( h \in L^2(T) \equiv H \), then there is a sequence \( g_k \in \mathcal{E}_1 \) such that \( g_k \to h \) in \( L^2(T) \). Then clearly

\[
E \left( \left| W(g_k) - W(h) \right|^2 \right) = E \left( \left| W(g_k - h) \right|^2 \right) = \| g_k - h \|_{L^2(T)}^2 \to 0
\]

and so each polynomial \( p(W(h_1), \ldots, W(h_k)) \) can be approximated in \( L^2(\Omega) \) by one which is of the form \( p(W(g_1), \ldots, W(g_k)) \) where each \( g_j \in \mathcal{E}_1 \). Corresponding to each \( g_j \), there is a list of disjoint sets. Now consider the union of all the sets just described and let \( \{ A_k \} \) be a partition of this union such that the \( A_k \) are pairwise disjoint and for each \( j \), every set corresponding to \( g_j \) is partitioned by a subset of the \( \{ A_k \} \). Thus

\[
g_j = \sum_i c_i x_{B_i} = \sum_i c_i \sum_{s=1}^{m_i} x_{A_{i_j}^s}
\]

where \( B_i \) is partitioned by the \( A_{i_j}^s \). Then consider \( p(g_1, \ldots, g_k) \). Then the terms of degree \( m \) are of the form

\[
p_m \equiv \sum_i c_i x_{A_{i_1} \times \cdots \times A_{i_m}} \tag{66.3.21}
\]

where the \( A_{i_k} \) come from the list of disjoint sets \( \{ A_k \} \). The terms of degree \( m \) in \( p(W(g_1), \ldots, W(g_k)) \) are also of the form

\[
p_m(W(g_1), \ldots, W(g_k)) \equiv \sum_i c_i \prod_k W(A_{i_k})
\]

The problem is that \( \{ A_k \} \) is not in \( \mathcal{E}_m \) because it is not known whether \( c_i = 0 \) if two indices are repeated. However, as explained in the proof of Lemma 66.3.11 there is a further partition such that the contribution of those terms corresponding to \( i \) in which two indices are repeated can be made as small as desired. Therefore, the terms of order \( m \) are approximated in \( L^2(T^m) \) by \( g_m \in \mathcal{E}_m \). Assume this approximation is good enough that, from the estimates given above in Lemma 66.3.11,

\[
E \left( \left| I_m(g_m) - p_m(W(g_1), \ldots, W(g_k)) \right|^2 \right)^{1/2} < \frac{\varepsilon}{n + 1}
\]

Thus, taking a succession of partitions if necessary,

\[
E \left( \left| p(W(g_1), \ldots, W(g_k)) - \sum_{m=0}^n I_m(g_m) \right|^2 \right)^{1/2} \leq \sum_{m=1}^n E \left( \left| I_m(g_m) - p_m(W(g_1), \ldots, W(g_k)) \right|^2 \right)^{1/2} < \sum_{m=1}^n \frac{\varepsilon}{n + 1} < \varepsilon.
\]

This has proved the following lemma.
Lemma 66.3.14 Let \( n \) be given. Then \( \cup_{p \leq n} \{ I_p (f) : f \in \mathcal{E}_p \} \) is dense in \( \mathcal{P}_n = \oplus_{i=0}^n \mathcal{H}_i \). Consequently, every \( f \in L^2 (\Omega, \mathcal{F}) \) may be written as an infinite sum

\[
f = \sum_{k=1}^{\infty} c_k I_k (g_k)
\]

where \( g_k \in \mathcal{E}_k \) and it can also be assumed that \( g_k \) is symmetric.

**Proof:** It only remains to verify that \( g_k \) can be symmetric. However, this is obvious because if \( g_k \) is replaced with \( \tilde{g}_k \) the integral \( I_k \) is unchanged. ■

### 66.4 The Skorokhod Integral

This integral allows for one to obtain a stochastic integral of functions which are not adapted. It is a generalization of the Ito integral. There is also a strange sort of derivative which can be defined and the two are related in a natural way.

#### 66.4.1 The Derivative

Let \( F : \mathbb{R}^n \to \mathbb{R} \) be smooth and have polynomial growth. Then consider

\[
F (W (h_1), \cdots, W (h_n))
\]

where \( W \) is defined above. Recall that \( h \in H \) a separable real Hilbert space and \( W (h) \in L^2 (\Omega, \mathcal{F}, \mathbb{P}) \) where \( \mathcal{F} = \sigma (W (h), h \in H) \). Also \( (W (h_1), \cdots, W (h_n)) \) is multivariate normal and \( E (W (g) W (h)) = (h, g)_H \).

**Definition 66.4.1** In the above situation,

\[
DF = \sum_{k=1}^n D_k F (W (h_1), \cdots, W (h_n)) h_k
\]

Thus from Lemma 62.6.4, \( F, D_k F \) are in \( L^p (\Omega) \) and so \( DF \) is in \( L^p (\Omega; H) \) for every \( p \).

First it is good to consider whether \( DF \) is well defined.

**Lemma 66.4.2** The derivative is well defined. Also, if \( F (W (h_1), \cdots, W (h_n)) = 0 \) for \( \{ h_1, \cdots, h_n \} \) independent, then for all \( x, F (x) = 0 \).

**Proof:** Suppose \( F (W (h_1), \cdots, W (h_n)) = 0 \).

Is it true that \( DF = 0 \)? Let \( \lambda \) be the distribution measure of \( (W (h_1), \cdots, W (h_n)) \equiv W (h) \). Then the above requires that for any ball \( B \) in \( \mathbb{R}^n \),

\[
E (\chi_B (W (h)) F^2 (W (h))) = \int_B F^2 (x) d\lambda (x) = 0
\]
66.4. THE SKOROKHOD INTEGRAL

If \( \{h_1, \ldots, h_n\} \) is independent, then \( \lambda \) has a normal density function and \( \lambda \ll m_n \) and so \( F^2(x) = 0 \) for a.e. \( x \). Since \( F \) is smooth, this means that \( F = 0 \) everywhere. Hence \( D_k F = 0 \) and so \( DF = 0 \). Thus the case where the \( h_i \) are independent is easy.

Next suppose without loss of generality that a basis for \( \text{span}(h_1, \ldots, h_n) \) is

\[ \{h_1, \ldots, h_r\} \]

where \( r < n \). Say \( h_k = \sum_{i=1}^{r} c_i^k h_i \) for \( k > r \). Then

\[
0 = F \left( W(h_1), \ldots, W(h_r), W\left( \sum_{i=1}^{r} c_i^{r+1} h_i \right), \ldots, W\left( \sum_{i=1}^{r} c_i^n h_i \right) \right)
\]

\[
= F \left( W(h_1), \ldots, W(h_r), \sum_{j=1}^{r} c_j^{r+1} W(h_j), \ldots, \sum_{j=1}^{r} c_j^n W(h_j) \right)
\]

and so in terms of \( \{h_1, \ldots, h_r\}, \)

\[
DF = \sum_{i=1}^{r} (D_i F) h_i + \sum_{i=r+1}^{n} (D_i F) \sum_{j=1}^{r} c_j^i h_j
\]

\[
= \sum_{j=1}^{r} (D_j F) h_j + \sum_{j=1}^{r} \sum_{i=r+1}^{n} (D_i F) c_j^i h_j
\]

\[
= \sum_{j=1}^{r} \left( D_j F + \sum_{i=r+1}^{n} (D_i F) c_j^i \right) h_j
\]

Now it was just shown that \( G(x) \) is identically 0 and so \( D_j G = 0, \ j \leq r \). So what is \( D_j G? \) From the above, it equals

\[
D_j F + \sum_{i=r+1}^{n} (D_i F) c_j^i = 0
\]

Hence \( DF = 0 \). Now if \( F(W(h_1), \ldots, W(h_n)) = G(W(k_1), \ldots, W(k_m)) \), then \( F - G = 0 \) and so from what was just shown, \( D(F - G) = DF - DG = 0 \). Thus the derivative is well defined. \( \blacksquare \)

**Lemma 66.4.3** Let \( \mathcal{P} \) denote the set of all polynomials in \( W(h) \) for \( h \in H \). Then \( \mathcal{P} \) is dense in \( L^p(\Omega) \).
Proof: Let \( g \in L^p'(\Omega) \) and suppose that for every \( f \in D, \int_{\Omega} g f dP = 0 \). Does it follow that \( g = 0 \)? If so, then by the Riesz representation theorem, \( \mathcal{P} \) is dense in \( L^p(\Omega) \). From Lemma \ref{lem:66.6.4} for a given \( h \), there is a sequence of functions of \( \mathcal{P}, \{f_n\} \) which converges to \( e^{W(h)} \) in \( L^p(\Omega) \). It follows that

\[
\int_{\Omega} g e^{W(h)} dP = \lim_{n \to \infty} \int_{\Omega} g f_n dP = 0
\]

Hence by Lemma \ref{lem:66.6.5} it follows that \( g = 0 \). Hence \( \mathcal{P} \) is dense in \( L^p(\Omega) \).

Let \( D^{1,p} \) denote the closure in \( L^p(\Omega) \) of functions in \( \mathcal{P} \) with respect to the seminorm

\[
\|f\|_{1,p} = \left( \|f\|_{L^p(\Omega)}^p + \|Df\|_{L^p(\Omega,H)}^p \right)^{1/p}
\]

By this we mean the following. The above \( \|f\|_{1,p} \) makes perfect sense for every \( f \in \mathcal{P} \) and is algebraically like a norm. Thus it makes \( \mathcal{P} \) into a normed linear space. \( D^{1,p} \) is just the completion of this normed linear space. Then for \( f \in D^{1,p} \), we define \( Df \equiv \lim_{n \to \infty} Df_n \) in \( L^p(\Omega,H) \) where \( f_n \in \mathcal{P} \).

66.4.2 The Integral

The derivative has been defined above. Now here is the definition of the integral defined on functions in \( L^p'(\Omega,H) \), possibly not all of them.

**Definition 66.4.4** We say a random variable \( F \) is “smooth” if it is of the form \( F(\omega) = F(W(h_1), \cdots W(h_r)) \) where \( x \to F(x) \) is a smooth function of the real variables \( x_i \). It has polynomial growth if

\[
\frac{|F(x)|}{(1 + |x|^2)^m}
\]

is bounded for some positive integer \( m \). Let \( u \in L^p'(\Omega,H) \). Then \( u \in D(\delta) \) if for all \( F \) smooth having polynomial growth in the \( W(h) \),

\[
|E\langle DF, u \rangle| \leq C(u) \|F\|_{L^p(\Omega)}
\]

Then \( \delta u \in L^p'(\Omega) \) is defined by

\[
E\langle DF, u \rangle = E(F\delta u)
\]

Thus you have \( \delta \) is the adjoint of \( D \).

\[
\begin{array}{ccl}
L^p'(\Omega) & \overset{\delta}{\longrightarrow} & L^p'(\Omega,H) \\
L^p(\Omega) & \overset{D}{\supseteq} & D(D) & \overset{D}{\longrightarrow} & L^p(\Omega,H)
\end{array}
\]
66.4. THE SKOROKHOD INTEGRAL

Next it is shown that there are functions in $D(\delta)$ by giving examples of them. It turns out that functions of the form $\sum_i F_i h_i$ where $F_i$ is smooth with polynomial growth are in $D(\delta)$. Consider

$$E \langle DG, F(W(h_1), \cdots, W(h_n)) h \rangle$$

where $G = G(W(k_1), \cdots, W(k_p))$ and for simplicity, $\|h\|_H = 1$.

Consider the vectors $\{h, h_1, \cdots, h_n, k_1, \cdots, k_p\}$. Starting with the left and moving toward the right, delete vectors which are dependent on the preceding vectors, obtaining a linearly independent set of vectors which includes $h$. Then let $\{h, e_1, \cdots, e_q\}$ be an orthonormal basis having the same span as the original vectors $\{h, h_1, \cdots, h_n, k_1, \cdots, k_p\}$. Then from the fact that $W$ is linear, there are smooth functions having polynomial growth $\hat{G}, \hat{F}$ such that

$$G(W(k_1), \cdots, W(k_p)) = \hat{G}(W(h), W(e_1), \cdots, W(e_q))$$
$$F(W(h_1), \cdots, W(h_n)) = \hat{F}(W(h), W(e_1), \cdots, W(e_q))$$

Note that $h_i = \sum_{j=1}^q (h_i, e_j) e_j + (h_i, h) h$. Thus

$$F(W(h_1), \cdots, W(h_n)) =$$

$$F\left(W\left(\sum_{j=1}^q (h_1, e_j) e_j + (h_1, h) h\right), \cdots, W\left(\sum_{j=1}^q (h_n, e_j) e_j + (h_n, h) h\right)\right)$$

$$= F\left(\sum_{j=1}^q (h_1, e_j) W(e_j) + (h_1, h) W(h), \cdots, \sum_{j=1}^q (h_n, e_j) W(e_j) + (h_n, h) W(h)\right)$$

and so, $D_1 \hat{F}$ is given by

$$D_1 \hat{F} = \sum_{i=1}^n D_i \left(F(W(h_1), \cdots, W(h_n))\right)(h_i, h)$$

Then by Lemma 66.4.2

$$E \langle DG, F(W(h_1), \cdots, W(h_n)) h \rangle = E \langle D\hat{G}, \hat{F} h \rangle$$

$$= E \left(D_1 \left(\hat{G}\right) h + \sum_{k=1}^q D_k \left(\hat{G}\right) e_k, \hat{F} h \right) = E \left(D_1 \left(\hat{G}\right) \hat{F} \right)$$

$$= \frac{1}{(\sqrt{2\pi})^{q+1}} \int_{\mathbb{R}^q} \int_{\mathbb{R}} D_1 \hat{G}(x) \hat{F}(x) e^{-\frac{1}{2} |x|^2} dx_1 d\mathbf{x}_1$$

$$= \frac{-1}{(\sqrt{2\pi})^{q+1}} \int_{\mathbb{R}^q} \hat{G}(x) D_1 \left(\hat{F}(x) e^{-\frac{1}{2} |x|^2}\right) dx_1 d\mathbf{x}_1$$
that polynomial

Functions of the form\( W \) functions

Thus

CHAPTER 66. A DIFFERENT KIND OF STOCHASTIC INTEGRATION

\[
\delta (Fh) = FW (h) - \sum_{i=1}^{n} D_i (F) (h_i, h) \]

Since \( \delta \) is an adjoint map, it is clearly linear. Hence, if \( h \) is arbitrary, \( h \neq 0 \) of course,

\[
\delta (Fh) = \| h \| \delta \left( F \frac{W (h)}{\| h \|} \right) = \| h \| F \frac{W (h)}{\| h \|} - \| h \| \sum_{i=1}^{n} D_i (F) \left( h_i, \frac{h}{\| h \|} \right) \]

\[
= FW (h) - \sum_{i=1}^{n} D_i (F) (h_i, h) = FW (h) - \langle DF, h \rangle \quad (66.4.22)
\]

Note how this looks just like integration by parts. More generally,

\[
\delta \left( \sum_{j=1}^{m} F_j h_j \right) = \sum_{j=1}^{m} \delta (F_j h_j) = \sum_{j=1}^{m} F_j W (h_j) - \langle DF_j, h_j \rangle
\]

Are functions like \( \sum_{j=1}^{m} F_j h_j \) where \( F_j \) is a polynomial in variables of the form \( W (h) \) dense in \( L^p (\Omega, H) \)? It was shown earlier in Lemma 66.4.3X that polynomial functions \( F \) in the \( W (h) \) are dense in \( L^p (\Omega) \) for any \( p \). Let \( s (\omega) = \sum_{k=1}^{n} h_k X_{E_k} \) be a simple function. Then \( X_{E_k} \) is clearly in \( L^p (\Omega) \) and so there exists \( F_k \) a polynomial in the \( W (h) \) which is as close as desired to \( X_{E_k} \) in \( L^p \). Hence \( \sum_{k=1}^{n} h_k F_k \) is close to \( s \) in \( L^p (\Omega, H) \) and so since these simple functions are dense, it follows that these kinds of functions are indeed dense in \( L^p (\Omega, H) \), this for any \( p > 1 \). The above discussion is summarized in the following lemma.

**Lemma 66.4.5** Functions of the form \( \sum_{k=1}^{n} F_k h_k \) where \( F_k \) is a polynomial in the \( W (h) \) (\( F_j \in \mathcal{P}) \) are dense in \( L^p (\Omega, H) \) for any \( p > 1 \). Also each function of this form is in \( D \delta \) and

\[
\delta \left( \sum_{j=1}^{m} F_j h_j \right) = \sum_{j=1}^{m} \delta (F_j h_j) = \sum_{j=1}^{m} F_j W (h_j) - \langle DF_j, h_j \rangle
\]

What does \( D \) do to \( \delta (Fh) \)? It is shown above that \( \delta (Fh) = FW (h) - \langle DF, h \rangle \). Say \( F = F (W (h_1), \cdots , W (h_n)) \). Then when you do \( D \) to \( \delta (Fh) \), you would get

\[
Fh + \sum_{k=1}^{n} D_k (F) W (h) h_k - \sum_{k=1}^{n} \sum_{j=1}^{n} D_j (D_k (F)) h_j (h_k, h)
\]
In other words,

\[ Fh + W(h)D(F) = D\langle DF, h \rangle \]

Recall that \( DG \) is well defined. This means that we can replace \( \{h_1, \ldots, h_n, h\} \) with an orthonormal basis \( \{e_1, \ldots, e_p, h\} \) as in

\[ G(W(h_1), \ldots, W(h_n), W(h)) = \hat{G}(W(e_1), \ldots, W(e_p), W(h)) \]

where we assume \( \|h\| = 1 \) for simplicity. Thus the above equals

\[ D\langle \delta(F) \rangle = D\left(\delta\left(\hat{F}\right)\right) = \hat{F}h + W(h)D\left(\hat{F}\right) - D\langle D\hat{F}, h \rangle \]

Now consider \( E\left(\delta(Fh)^2\right) = E\langle D\langle \delta(Fh)\rangle, Fh \rangle \). Thus the following must be considered.

\[ E\left(\hat{F}h + W(h)D\left(\hat{F}\right) - D\langle D\hat{F}, h \rangle, \hat{F}h\right) \quad (66.4.23) \]

Consider the terms involved. The first term is just

\[ E\left(\left\|\hat{F}h\right\|^2_H\right) = E\left(\left\|Fh\right\|^2_H\right) \]

Now consider the third term. It equals

\[ -E\left(D\left(D_{p+1}\hat{F}\right), \hat{F}h\right) = -E\left(D_{p+1}^2\left(\hat{F}\right)\right) \]

\[ = \frac{-1}{(\sqrt{2\pi})^{p+1}} \int_{\mathbb{R}^p} \int_{\mathbb{R}} D_{p+1}^2\left(\hat{F}(x)\right) \hat{F}(x) e^{-\frac{1}{2}|x|^2} dx_{p+1} d\xi_{p+1} \]

\[ = \frac{1}{(\sqrt{2\pi})^{p+1}} \int_{\mathbb{R}^p} \int_{\mathbb{R}} D_{p+1}\left(\hat{F}(x)\right) D_{p+1}\left(\hat{F}(x)\right) e^{-\frac{1}{2}|x|^2} dx_{p+1} d\xi_{p+1} \]

\[ - \frac{1}{(\sqrt{2\pi})^{p+1}} \int_{\mathbb{R}^p} \int_{\mathbb{R}} D_{p+1}\left(\hat{F}(x)\right) \left(x_{p+1}\hat{F}(x)\right) e^{-\frac{1}{2}|x|^2} dx_{p+1} d\xi_{p+1} \]

\[ = E\left(D_{p+1}\hat{F}\right)^2 - E\left(W(h)D_{p+1}\left(\hat{F}\right)\hat{F}\right) \]

\[ = E\left(D_{p+1}\hat{F}\right)^2 - E\left(W(h)D\left(\hat{F}\right), \hat{F}h\right) \]

Hence \( 66.4.23 \) reduces to

\[ E\left(\left\|\hat{F}h\right\|^2\right) + E\left(D_{p+1}\hat{F}\right)^2 = E\left(\left\|\hat{F}h\right\|^2\right) + E\left(D\left(\hat{F}\right), h\right)^2 \]

\[ = E\left(\left\|Fh\right\|^2\right) + E\left(D\left(F\right), h\right)^2 \]
This assumed that \( \|h\| = 1 \). For arbitrary nonzero \( h \),

\[
E \left( \delta (Fh)^2 \right) = \|h\|^2 E \left( \delta \left( F \frac{h}{\|h\|} \right)^2 \right)
\]

\[
= \|h\|^2 \left( E \left( \left\| F \frac{h}{\|h\|} \right\|^2 \right) + E \left( \langle D (F), \frac{h}{\|h\|} \rangle^2 \right) \right)
\]

\[
= E \left( \|Fh\|^2 \right) + E \left( \langle D (F), h \rangle^2 \right)
\]

Next consider a generalization, \( u = \sum_{j=1}^{m} F_j h_j \) where the \( \{h_j\} \) is an orthonormal set of vectors. Say \( F_j = F_j (W (k_1), \ldots, W (k_n)) \). Let \( \{h_1, \ldots, h_m, e_1, \ldots, e_p\} = \{g_i\}_{i=1}^{m+p} \) be an orthonormal basis for the span of all the \( h_j \) and \( k_i \). Thus \( g_i = h_i \) for \( i \leq m \). Then let

\[
F_j (W (k_1), \ldots, W (k_n)) = \hat{F}_j (W (h_1), \ldots, W (h_m), W (e_1), \ldots, W (e_p))
\]

The computations will be done with respect to this orthonormal set because it will be simpler. Also, the above argument using the density function for the normal distribution will be used without explicitly repeating it.

It is desired to consider \( E \left( \delta (u)^2 \right) \). Recall that

\[
D (\delta (Fh)) = Fh + W (h) D (F) - D (DF, h).
\]

Thus \( E \left( \delta (u)^2 \right) = \sum_{j,k=1}^{m} E \left( \delta (\hat{F}_j h_j) \delta (\hat{F}_k h_k) \right) = \sum_{j,k=1}^{m} E \left( \langle D (\delta (\hat{F}_j h_j)), (\hat{F}_k h_k) \rangle \right) \)

\[
= \sum_{j,k=1}^{m} E \left( \langle \hat{F}_j h_j + W (h_j) D (\hat{F}_j) - D (\hat{F}_j, h_j), (\hat{F}_k h_k) \rangle \right)
\]

Separating out the first term this is

\[
= E \left( \sum_{k=1}^{m} \|\hat{F}_k\|^2 \right) + \sum_{k,k} E \left( \langle W (h_j) D (\hat{F}_j), \hat{F}_k h_k \rangle \right)
\]

\[
- \sum_{j,k} E \left( D_k (D_j \hat{F}_j) F_k \right)
\]

\[
= E \left( \sum_{k=1}^{m} \|\hat{F}_k\|^2 \right) + \sum_{k,k} E \left( \langle W (h_j) D (\hat{F}_j), \hat{F}_k h_k \rangle \right)
\]

\[
- \sum_{j,k} E \left( D_k (D_j \hat{F}_j) \hat{F}_k \right)
\]
66.4. THE SKOROKHOD INTEGRAL

\[ E \left( \sum_{k=1}^{m} \left\| \hat{F}_k \right\|^2 \right) + \sum_{k,k} E \left( W(h_j) D_k \left( \hat{F}_j \right) \hat{F}_k \right) \]

\[ - \sum_{j,k} E \left( D_k \left( D_j \hat{F}_j \right) \hat{F}_k \right) \]

(66.4.24)

By equality of mixed partial derivatives, the third term equals

\[ - \sum_{j,k} E \left( D_j \left( D_k \hat{F}_j \right) \hat{F}_k \right) = \sum_{j,k} E \left( \left( D_k \hat{F}_j \right) \left( D_j \hat{F}_k \right) \right) - \sum_{j,k} E \left( D_k \left( \hat{F}_j \right) \hat{F}_k W(h_j) \right) \]

Therefore, (66.4.24) reduces to

\[ E \left( \delta \left( \sum_{j=1}^{m} F_j h_j \right)^2 \right) = E \left( \sum_{k=1}^{m} \left\| \hat{F}_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left( D_k \hat{F}_j \right) \left( D_j \hat{F}_k \right) \right) \]

\[ = E \left( \sum_{k=1}^{m} \left\| \hat{F}_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left\langle D \hat{F}_j, h_k \right\rangle \left\langle D \hat{F}_k, h_j \right\rangle \right) \]

\[ = E \left( \sum_{k=1}^{m} \left\| F_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left\langle D F_j, h_k \right\rangle \left\langle D F_k, h_j \right\rangle \right) \]

because the derivative is well defined. All of this assumes the \( h_k \) form an orthonormal set. Suppose these are just orthogonal but nonzero. Then

\[ E \left( \delta \left( \sum_{j=1}^{m} F_j h_j \right)^2 \right) = E \left( \sum_{j,k=1}^{m} E \left( \delta \left( F_j h_j \right) \delta \left( F_k h_k \right) \right) \right) \]

\[ = E \left( \sum_{j,k} \left\langle h_j \right\rangle \left\langle h_k \right\rangle \delta \left( F_j h_j / \left\| h_j \right\| \right) \delta \left( F_k h_k / \left\| h_k \right\| \right) \right) \]

and doing exactly the same steps but keeping the factor \( \left\| h_j \right\| \left\| h_k \right\| \) throughout, this yields

\[ E \left( \sum_{k=1}^{m} \left\| h_k \right\|^2 \left\| F_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left\langle h_j \right\rangle \left\langle h_k \right\rangle \left\langle D F_j, h_k / \left\| h_k \right\| \right\rangle \left\langle D F_k, h_j / \left\| h_j \right\| \right\rangle \right) \]

\[ = E \left( \sum_{k=1}^{m} \left\| F_k h_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left\langle D F_j, h_k \right\rangle \left\langle D F_k, h_j \right\rangle \right) \]

\[ = E \left( \sum_{k=1}^{m} \left\| F_k h_k \right\|^2_H \right) + \sum_{j,k=1}^{m} E \left( \left\langle D F_j, h_k \right\rangle \left\langle D F_k, h_j \right\rangle \right) \]
It appears from the computations to be correct, but it does not look right. This is because the second term is not clearly nonnegative. It is the expectation of the trace of $A^2$ where $A$ is the matrix whose $jk^{th}$ entry is $\langle DF, h_k \rangle$. One wonders whether the end result is nonnegative.

### 66.4.3 The Ito And Skorokhod Integrals

If you let $H = L^2(0, \infty; U)$ where $U$ is a separable Hilbert space, and if $f \in D(\delta)$, it is very natural to ask whether $fX_{(0,t)} \in D(\delta)$. This is not so. There is a counter example given in [93]. However, this is true if you change the definition of the integral such that in the definition of $\delta$, it is only necessary for $j\langle DF, G \rangle j \leq C \|F\|_{L^p(\Omega)}$ where $F$ is in $\mathcal{P}$. When you see why this is so, it will be clear why it is not so for the definition given above.

**Lemma 66.4.6** Suppose the definition of the Skorokhod integral is changed so that it is only necessary to have

$$\|\langle DF, G \rangle\| \leq C \|F\|_{L^p(\Omega)}$$

for all $F$ in $\mathcal{P}$. Then let $H \equiv L^2(0, \infty; U)$ or $L^2([0,T]; U)$ where $U$ is a separable real Hilbert space. For this modified definition of the integral, if $f \in D(\delta)$, it follows that $fX_{(0,t)}$. This is not so. There is a counter example given in [93]. However, this is true if you change the definition of the integral such that in the definition of $\delta$, it is only necessary for $j\langle DF, G \rangle j \leq C \|F\|_{L^p(\Omega)}$ where $F$ is in $\mathcal{P}$. When you see why this is so, it will be clear why it is not so for the definition given above.

**Proof:** The case $L^2(0, \infty; U)$ is considered here. The other case is similar. $\delta$ will be defined on some things in $L^2(\Omega, L^2(0, \infty; U), \mathcal{F})$ where, as discussed earlier,

$$\mathcal{F} = \sigma(W(h) : h \in H)$$

Then if you have $f \in D(\delta)$ so $f \in L^2(\Omega, L^2(0, \infty; U))$, does it follow that $fX_{(0,t)} \in D(\delta)$ also? Let $F$ be one of those polynomial functions of some $W(h)$. Assume first that $a_0$, the constant term is 0 and consider

$$E\left\langle DF, fX_{[0,t]} \right\rangle \equiv E\left(\sum_k D_k(F) h_k, fX_{[0,t]} \right)$$

Since $h_k \in H = L^2(0, \infty; U)$, so is $h_kX_{[0,t]}$. Thus the above reduces to

$$= \sum_k E\left\langle D_k(F) h_k, fX_{[0,t]} \right\rangle = \sum_k E\left(\int_0^\infty D_k(F(W(h_1) , \cdots W(h_n))) h_k X_{[0,t]} f dt \right)$$

Since $F$ is just a polynomial and $W$ is linear and $X_{[0,t]}^q = X_{[0,t]}$, this equals

$$\sum_k E\left(\int_0^\infty D_k(F(W(h_1) , \cdots W(h_{n})) h_k X_{[0,t]} f dt \right)$$
Let \( F_t = F(\mathcal{X}_{[0,t]} h_1) \) and so the above is nothing more than
\[
E \langle DF, f \mathcal{X}_{[0,t]} \rangle = E \langle DF_t, f \rangle
\]
and since \( f \in D(\delta) \),
\[
|E \langle DF, f \mathcal{X}_{[0,t]} \rangle| = |E \langle DF_t, f \rangle| \leq C(f) \| F_t \|_{L^2(\Omega)}
\]
Also
\[
\| F_t \|_{L^2(\Omega)}^2 = \int_\Omega F(\mathcal{X}_{[0,t]} h_1) \cdots W(\mathcal{X}_{[0,t]} h_n))^2 dP
\]
\[
\quad = \int_\Omega \mathcal{X}_{[0,t]} F(W(h_1) \cdots W(h_n))^2 dP
\]
\[
\quad \leq \int_\Omega F(W(h_1) \cdots W(h_n))^2 dP
\]
Thus for such \( F \) which have zero constant term,
\[
|E \langle DF, f \mathcal{X}_{[0,t]} \rangle| \leq C \| F \|_{L^2(\Omega)}
\]
Now what if \( F \) is a constant \( a \)? In this case, \( DF = Da = 0 \)
\[
|E \langle Da, f \mathcal{X}_{[0,t]} \rangle| = 0 \leq \| a \|_{L^2(\Omega)}
\]
It follows that \( \mathcal{X}_{[0,t]} f \in D(\delta) \) whenever \( f \) is.

Note how it was essential in this argument to have \( F \) be a polynomial or perhaps more generally an analytic function. However, in the definition of the Skorokhod integral, one must test with functions \( F \) which are smooth and have polynomial growth. In particular, this would include functions which are infinitely differentiable with compact support, none of which have valid power series.

How does the Skorokhod integral relate to the Ito integral? What about elementary functions and so forth? Let \( 0 = t_0 < t_1 < \cdots < t_n = T \). Consider
\[
\sum_{k=0}^{n-1} F_k \mathcal{X}_{(t_k, t_{k+1})}
\]
As shown above, this is one of the things in \( D(\delta) \).
\[
\delta \left( \mathcal{X}_{(0,t)} \sum_{k=0}^{n-1} F_k \mathcal{X}_{(t_k, t_{k+1})} \right) = \delta \left( \sum_{k=0}^{n-1} F_k \mathcal{X}_{[t_k, t \wedge t_{k+1}]} \right)
\]
\[
= \sum_{k=0}^{n-1} F_k W(\mathcal{X}_{[t_k, t \wedge t_{k+1}]}) - \langle DF_k, \mathcal{X}_{[t_k, t \wedge t_{k+1}]} \rangle
\]
\[
= \sum_{k=0}^{n-1} F_k \left( W(\mathcal{X}_{(0,t \wedge t_{k+1})}) - W(\mathcal{X}_{(0,t \wedge t_k)}) \right) - \langle DF_k, \mathcal{X}_{[t_k, t \wedge t_{k+1}]} \rangle
\]
In terms of the Wiener process, this is of the form

\[ \sum_{k=0}^{n-1} F_k (W (t \land t_{k+1}) - W (t \land t_k)) = \langle DF_k, \mathcal{X}_{[0, t \land t_{k+1}]} - \mathcal{X}_{[0, t \land t_k]} \rangle_H \]

What if

\[ F_k = F_k (W (\mathcal{X}_{[0, t_k]} h_1), \ldots, W (\mathcal{X}_{[0, t_k]} h_n)) ? \]

Let \( F_k \equiv \sigma (W (\mathcal{X}_{[0, t]} h) : h \in H) \). Then this is clearly a filtration. If \( F_k \) is as just described, then \( F_k \) is \( \mathcal{F}_{t_k} \) adapted.

\[ \langle DF_k, \mathcal{X}_{[0, t \land t_{k+1}]} - \mathcal{X}_{[0, t \land t_k]} \rangle = \int_0^\infty \sum_s D_s (F_k) \mathcal{X}_{(0, t_k)} h_s \mathcal{X}_{(t_{t \land t}, t \land t_{k+1})} = 0 \]

because the intervals are disjoint. In this case, the troublesome term at the end vanishes and you are left with

\[ \sum_{k=0}^{n-1} F_k (W (t \land t_{k+1}) - W (t \land t_k)) \]

which is similar to the usual definition for the Ito integral.

What if \( F \in L^2 (\Omega \times [0, T]) \) and is progressively measurable. Does it have a Skorokhod integral, and if so, is it the same as the Ito integral? Recall the following useful lemma. It is Lemma 63.3.1 on Page 2288.

**Lemma 66.4.7** Let \( \Phi : [0, T] \times \Omega \to E \), be \( \mathcal{B} ([0, T]) \times \mathcal{F} \) measurable and suppose

\( \Phi \in K \equiv L^p ([0, T] \times \Omega; E), p \geq 1 \)

Then there exists a sequence of nested partitions, \( \mathcal{P}_k \subseteq \mathcal{P}_{k+1}, \)

\[ \mathcal{P}_k \equiv \{t^k_0, \ldots, t^k_{m_k}\} \]

such that the step functions given by

\[ \Phi^k_0 (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_j) \mathcal{X}_{[t^k_{j-1}, t^k_j)} (t) \]

\[ \Phi^k_0 (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_j) \mathcal{X}_{[t^k_{j-1}, t^k_j)} (t) \]

both converge to \( \Phi \) in \( K \) as \( k \to \infty \) and

\[ \lim_{k \to \infty} \max \{|t^k_j - t^k_{j+1}| : j \in \{0, \cdots, m_k\}\} = 0. \]
Also, each \( \Phi \left( t_j^k \right), \Phi \left( t_{j-1}^k \right) \) is in \( L^p (\Omega; E) \). One can also assume that \( \Phi (0) = 0 \). The mesh points \( \{ t_j^k \}_{j=0}^{m_k} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that

\[
|t_j^k - t_{j-1}^k| = 2^{-n_k}
\]

except for the case where \( j = 1 \) or \( j = m_k \) when this is so, you could have \( |t_j^k - t_{j-1}^k| < 2^{-n_k} \).

**Theorem 66.4.8** Let \( F \in L^2 (\Omega \times [0, T]) \) and is progressively measurable. Then it has a Skorokhod integral which coincides with the Ito integral.

**Proof:** From Lemma 66.4.3 there is a sequence of left step functions denoted here as \( \{ F_k \}_{k=1}^\infty \) which converges to \( F \) in \( L^2 (\Omega \times [0, T]) \) where \( F_k (t_j^k) = F (t_j^k) \).

We can take a subsequence if necessary and assume

\[
\| F_k^j - F \|_{L^2([0,T] \times \Omega)} < 2^{-k}
\]

Here the \( \{ t_j^k \} \) are mesh points corresponding to the \( k^{th} \) partition described above. Thus each \( F_k^j (t_j^k) \) is in \( L^2 (\Omega) \). By Lemma 66.4.3 there exists a random variable \( G_k^j (t_j^k) \) which is a polynomial function of some \( W (h) \) for \( h \in L^2 (0, t_j^k) \) which can approximate \( F_k^j (t_j^k) \) as closely as desired in \( L^2 (\Omega) \). Then choosing these sufficiently close, it can be assumed that the step functions

\[
G_k^j \equiv \sum_{j=0}^{m_k-1} G_k^j (t_j^k) \chi_{(j, j+1) t_k}
\]

also converge in \( L^2 (\Omega \times [0, T]) \) to \( F \). Of course, each of these last step functions are in \( D (\delta) \).

The idea is to show that \( \delta (G_k^j) \) is Cauchy in \( L^2 (\Omega) \) as \( k \to \infty \) and then use the fact that, since \( \delta \) is an adjoint, it must be a closed operator. This will show that \( F \in L^2 (\Omega \times [0, T]) \), considered as a subspace of \( L^2 (\Omega; L^2 (0, \infty, \mathbb{R})) \), is in \( D (\delta) \) and \( \delta (F) \) is equal to the above limit. Using 66.4.3 which comes from the fact that the functions are adapted to the given filtration,

\[
\| \delta \left( \chi_{[0,T]} G_k^j \right) - \delta \left( \chi_{[0,T]} G_{k+1}^j \right) \|_{L^2(\Omega)}^2
= E \left( \sum_{j=0}^{m_k-1} (G_k^j (t_j^{k+1}) - G_{k+1}^j (t_j^{k+1})) (W (t_j^{k+1}) - W (t_j^{k+1})) \right)^2
\]

Consider a mixed term. To save on space, let \( \Delta_j = G_k^j (t_j^{k+1}) - G_{k+1}^j (t_j^{k+1}) \) and say \( i < j \). Then

\[
E \left( (\Delta_j, (\Delta_i) (W (t_j^{k+1} - W (t_j^{k+1})) (W (t_i^{k+1}) - W (t_i^{k+1})))
\]

CHAPTER 66. A DIFFERENT KIND OF STOCHASTIC INTEGRATION

By independence of the increments for $W$, this is

$$E \left( W \left( t_{j+1}^k \right) - W \left( t_{j}^k \right) \right) E \left( (\Delta_j) (\Delta_i) (W \left( t_{i+1}^{k+1} \right) - W \left( t_{i}^{k+1} \right)) \right) = 0$$

and so the above reduces to

$$\sum_{j=0}^{m_{k+1}-1} E \left( \Delta_j^2 \left( W \left( t_{j+1}^k \right) - W \left( t_{j}^k \right) \right)^2 \right)$$

$$= \sum_{j=0}^{m_{k+1}-1} E \left( (G_k^l \left( t_{j+1}^k \right) - G_{k+1}^l \left( t_{j}^k \right))^2 \right) (t_{j+1}^k - t_j^k)$$

$$= E \left( \int_0^T \left( G_k^l - G_{k+1}^l \right)^2 dt \right) \leq 2 \left( E \int_0^T (G_k^l - F)^2 dt + E \int_0^T (F - G_{k+1}^l)^2 dt \right)$$

which is given to converge to 0 as $k \to \infty$. It follows that $\mathcal{X}_{[0,T]} G_k \to \mathcal{X}_{[0,T]} F$ in $L^2 (\Omega, L^2 (0, \infty; \mathbb{R}))$ by construction and $\delta (\mathcal{X}_{[0,T]} G_k^l)$ is a Cauchy sequence in $L^2 (\Omega)$. Therefore, it converges to something in $L^2 (\Omega)$ and since $\delta$ is a closed operator, that which it converges to is $\delta (F)$.

However, by the definition of the Ito integral, $\delta (\mathcal{X}_{[0,T]} G_k^l)$ also converges to the Ito integral $\int_0^T F dW$. $\blacksquare$

It follows that the Skorokhod integral is more general than the Ito integral but it gives the Ito integral in the special case where the function is adapted. This also shows that the progressively measurable functions in $L^2 ([0, T] \times \Omega)$ are in $D (\delta)$, but as shown above, there are many other functions which are not progressively measurable but which are still in $D (\delta)$. Just consider, for example $\sum_{k=1}^n F h_k$ where $F$ is just a polynomial in $W (h)$ for $h \in L^2 (0, \infty; \mathbb{R})$. 
Chapter 67

Gelfand Triples

Let $H$ be a separable real Hilbert space and let $V \subseteq H$ be a separable Banach space which is embedded continuously into $H$ and which is also dense in $H$. Then identifying $H$ and $H'$ you can write

$$V \subseteq H = H' \subseteq V'.$$

This is called a Gelfand triple. If $V$ is reflexive, you could conclude separability of $V$ from the separability of $H$. However, if $V$ is not reflexive, this might not happen. For example, you could take $V = L^1(0,1)$ and $H = L^2(0,1)$.

**Proposition 67.0.1** Suppose $V$ is reflexive and a subset of $H$ a separable Hilbert space with the inclusion map continuous. Suppose also that $V$ is dense in $H$. Then identifying $H$ and $H'$, it follows that $H$ is dense in $V'$ and $V$ is separable.

**Proof:** If $H$ is not dense in $V'$, then by the Hahn Banach theorem, there exists $\phi^{**} \in V''$ such that $\phi^{**}(H) = 0$ but $\phi^{**}(\phi^*) \neq 0$ for some $\phi^* \in V' \setminus \overline{H}$. Since $V$ is reflexive there exists $v \in V$ such that $\phi^{**} = Jv$ for $J$ the standard mapping from $V$ to $V''$. Thus

$$\phi^{**}(h) \equiv \langle h, v \rangle \equiv (v, h)_H = 0$$

for all $h \in H$. Therefore, $v = 0$ and so $Jv = 0 = \phi^{**}$ which contradicts $\phi^{**}(\phi^*) \neq 0$. Therefore, $H$ is dense in $V'$. Now by Theorem [1] which says separability of the dual space implies separability of the space, it follows $V$ is separable as claimed. This proves the proposition.

From now on, it is assumed $V$ and $V'$ are both separable and that $H$ is dense in $V'$. This is summarized in the following definition.

**Definition 67.0.2** $V, H, V'$ will be called a Gelfand triple if $V, V'$ are separable, $V \subseteq H$ with the inclusion map continuous, $H = H'$, and $H = H'$ is dense in $V'$.

What about the Borel sets on $V$ and $H'$?
**Proposition 67.0.3** Denote by $\mathcal{B}(X)$ the Borel sets of $X$ where $X$ is any separable Banach space. Then

$$\mathcal{B}(X) = \sigma(X').$$

Here $\sigma(X')$ is the smallest $\sigma$ algebra such that each $\phi \in X'$ is measurable. Also in the context of the above definition, $\mathcal{B}(V) = \sigma(i^*H')$ because $H'$ is dense in $V'$.

Here $i^*$ is the restriction to $V$ so that $i^*h(v) \equiv h(v) \equiv (h,v)_H$ for all $v \in V$ and $\sigma(i^*H')$ denotes the smallest $\sigma$ algebra such that $i^*h$ is measurable for each $h \in H'$.

**Proof:** By Lemma [9.1.3] there exists a countable subset of the unit ball in $X'$

$$\{\phi_n\}_{n=1}^\infty = D'$$

such that

$$||v||_X = \sup \{|\phi(v)| : \phi \in D'|.$$

Consider a closed ball $\overline{B}(v_0,r)$ in $X$. This equals

$$\left\{ v \in X : \sup_n |\phi_n(v) - \phi_n(v_0)| \leq r \right\} = \cap_{n=1}^\infty \phi_n^{-1}(\overline{B}(\phi_n(v_0),r))$$

and this last set is in $\sigma(D')$. Therefore, every closed ball is in $\sigma(D')$ which implies every open ball is also in $\sigma(D')$ since open balls are the countable union of closed balls. Since $X$ is separable, it follows every open set is the countable union of balls and so every open set is in $\sigma(D')$. It follows $\mathcal{B}(X) \subseteq \sigma(D') \subseteq \sigma(X')$. On the other hand, every $\phi \in X'$ is continuous and so it is Borel measurable. Hence $\sigma(X') \subseteq \mathcal{B}(X)$.

Now consider the last claim. From Lemma [9.1.4] and density of $H' = H$ in $V'$, it can be assumed $D' \subseteq H = H'$. Therefore, from the first part of the argument

$$\mathcal{B}(V) \subseteq \sigma(D') \subseteq \sigma(i^*H')$$

Also each $i^*h$ is continuous on $V$ so in fact, equality holds in the above because $\sigma(i^*H') \subseteq \mathcal{B}(V)$. This proves the proposition.

Next I want to verify that $V$ is in $\mathcal{B}(H)$. This will be true if $V$ is reflexive. More generally, here is an interesting result.

**Proposition 67.0.4** Let $X \subseteq Y$, $X$ dense in $Y$ and suppose $X$, $Y$ are Banach spaces and that $X$ is reflexive. Then $X \in \mathcal{B}(Y)$.

**Proof:** Define the functional

$$\phi(x) \equiv \begin{cases} ||x||_X & \text{if } x \in X \\ \infty & \text{if } x \in Y \setminus X \end{cases}$$

Then $\phi$ is lower semicontinuous on $Y$. Here is why. Suppose $(x,a) \notin \text{epi}(\phi)$ so that $a < \phi(x)$. I need to verify this situation persists for $(x,b)$ near $(x,a)$. If this is not so, there exists $x_n \to x$ and $a_n \to a$ such that $a_n \geq \phi(x_n)$. If $\lim \inf_{n \to \infty} \phi(x_n) < \infty$, then there exists a subsequence still denoted by $n$ such that $||x_n||_X$ is bounded.
Then by the Eberlein Smulian theorem, there exists a further subsequence such that \( x_n \) converges weakly in \( X \) to some \( z \). Now since \( X \) is dense in \( Y \) it follows \( Y' \) can be considered a subspace of \( X' \) and so for \( f \in Y' \)

\[
f(x_n) \to f(z), \quad f(x_n) \to f(x)
\]

and so \( f(z - x) = 0 \) for all \( f \in Y' \) which requires \( z = x \). Now \( x \to \|x\|_X \) is convex and lower semicontinuous on \( X \) so it follows from Corollary [16.7.12]

\[
a = \lim \inf_{n \to \infty} a_n \geq \lim \inf_{n \to \infty} \phi(x_n) \geq \phi(x) > a
\]

which is a contradiction. If \( \lim \inf_{n \to \infty} \phi(x_n) = \infty \), then

\[
\infty > a = \lim \inf_{n \to \infty} a_n = \infty
\]

another contradiction. Therefore, \( \text{epi} (\phi) \) is closed and so \( \phi \) is lower semicontinuous as claimed. Therefore,

\[
X = Y \setminus \left( \cap_{n=1}^{\infty} \phi^{-1}((n, \infty)) \right)
\]

and since \( \phi \) is lower semicontinuous, each \( \phi^{-1}((n, \infty)) \) is open. Hence \( X \) is a Borel subset of \( Y \). This proves the proposition.

## 67.1 An Unnatural Example

Recall Gelfand triples are of the form

\[
V \subseteq H \subseteq V'
\]

where \( H \) is a Hilbert space and \( V \) is a Banach space contained in \( H \) and each of the above inclusions is continuous and each space is dense in the next one. The standard example of a Gelfand triple is \( H^1_0(D) \subseteq L^2(D) \subseteq (H^1_0(D))' \) with the convention that \( L^2(D) \) is identified with its dual space. Thus for \( f \in L^2(D) \), \( f \) is considered as something in \( (H^1_0(D))' \) according to the rule

\[
\langle f, \phi \rangle \equiv \langle f, \phi \rangle_{L^2(D)}
\]

This is a very pleasant thing to contemplate and it is natural and transparent. However, there are other ways to come up with a Gelfand triple which are much more perverse. The following is an example of such a thing along with an application. See [MS] and references given there.

First consider the following situation.

\[
X \overset{\theta}{\to} Y
\]

where \( \theta \) is continuous, linear and one to one and \( X \) is a Banach space. Then \( \theta(X) \subseteq Y \) and you could define

\[
\|\theta x\|_{\theta(X)} \equiv \|x\|_X.
\]
Then $\theta(X)$ can be considered the same thing as $X$ because $\theta$ preserves distances and all algebraic properties. Thus people write $X \subseteq Y$ to save space. In the above simple example, it is obvious what $\theta$ is. This is because the things in $H^0$ and things in $L^2$ are both functions defined on $D$ and we can simply take $\theta$ to be the identity map. However, you might have $H$ be the dual space of something. Thus it consists of bounded linear transformations defined on some Banach space. Then it becomes necessary to specify the manner in which vectors in $V$ can be considered as vectors of $H$.

Let $\infty > p \geq 2$. Then letting $D$ be a bounded open set, $H^1_0(D)$ embeds continuously into $L^p(D)$. That is

$$||\phi||_{L^p} \leq C ||\phi||_{H^1_0}. \quad (67.1.1)$$

Here $\frac{1}{p} + \frac{1}{\infty} = 1$. Also note that an equivalent inner product on $H^1_0(D)$ is

$$(f,g)_{H^1_0} = \int_D \nabla f \cdot \nabla g dx$$

Then with respect to this inner product, the Riesz map is given by $-\Delta$.

$$-\Delta : H^1_0(D) \rightarrow (H^1_0(D))'$$

Thus a typical vector of $(H^1_0(D))'$ is of the form $-\Delta \phi$ where $\phi \in H^1_0(D)$ and the following hold.

$$(\phi,\psi)_{H^1_0} \equiv (-\Delta \phi,\psi), \quad (-\Delta \phi,-\Delta \psi)_{H^1_0} \equiv (\phi,\psi)_{H^1_0} = \langle -\Delta \psi,\phi \rangle$$

The following is about the Gelfand triple

$$V = L^p(D) \subseteq (H^1_0)' \subseteq (L^p(D))'$$

**Lemma 67.1.1** It is possible to consider $L^p(D) \equiv V$ as a dense subspace of $(H^1_0)' \equiv H$ as follows. For $f \in L^p(D)$ and $\phi \in H^1_0(D)$,

$$\langle f,\phi \rangle \equiv \int_D f(x) \phi(x) dx$$

One can also consider $H \equiv (H^1_0)'$ as a dense subspace of $(L^p(D))' \equiv V'$ as follows. For $-\Delta \phi \in H$ and $f \in L^p(D)$,

$$\langle -\Delta \phi,f \rangle \equiv (-\Delta \phi,f)_H \equiv \langle f,\phi \rangle$$

$-\Delta$ maps $H^1_0(D)$ to $H \equiv (H^1_0)' \subseteq V'$. $-\Delta$ can be extended to yield a map $-\Delta_1$ from $L^p(D)$ to $V'$.

$$H^1_0(D) \xrightarrow{-\Delta} (H^1_0)'$$

$$L^p(D) = V \xrightarrow{-\Delta_1} V'$$
Proof: First of all, note that by
\[ |\langle f, \phi \rangle| \leq \|f\|_{L^p} \|\phi\|_{L^{p'}} \leq C \|f\|_{L^p} \|\phi\|_{H_0^1} \]
and so it is certainly possible to consider \( L^p \subseteq H \equiv (H_0^1)' \) as just claimed. Now why can \( L^p (D) \) be considered dense in \( H \equiv (H_0^1)' \)? If it isn’t dense, then there exists \( \psi \in H^1_0(D), \psi \neq 0 \) such that
\[ (-\Delta \psi, f)_H = 0 \]
for all \( f \in L^p (D) \). However, the above would say that for all \( f \in L^p \),
\[ (-\Delta \psi, f)_H \equiv \langle f, \psi \rangle \equiv \int_D f \psi = 0 \]
But \( \psi \in L^p (D) \) because \( H^1_0(D) \) embeds continuously into \( L^p (D) \) and so the above holding for all \( f \in L^p (D) \) implies by the usual Riesz representation theorem that \( \psi = 0 \) contrary to the way \( \psi \) was chosen.

Now consider the next claim. For \(-\Delta \phi \in H \equiv (H_0^1)' \) and \( f \in L^p (D) \) and from the first part
\[ |\langle -\Delta \phi, f \rangle| \equiv |(-\Delta \phi, f)_H| \equiv |\langle f, \phi \rangle| \leq C \|f\|_{L^p} \|\phi\|_{H_0^1(D)} \]
Thus \(-\Delta \phi \in H \) can be considered in \( (L^p (D))' \). Why should \( H \) be dense in \( (L^p (D))' \)? If it is not dense, then there exists \( g^* \in (L^p (D))' \) which is not the limit of vectors of \( H \). Then since \( L^p (D) \) is reflexive, an application of the Hahn Banach theorem shows there exists \( f \in L^p (D) \) such that
\[ \langle g^*, f \rangle_{(L^p(D))'} = 0, \quad (-\Delta \phi, f)_{(L^p(D))'} = 0 \] (67.1.2)
for all \(-\Delta \phi \in H \). However, it was just shown \( H \) could be considered a subset of \( (L^p (D))' \) in the manner described above. Therefore, the last equation in the above is of the form
\[ 0 = (-\Delta \phi, f)_H = \langle f, \phi \rangle = \int_D f \phi dx \]
and since this holds for all \( \phi \in H^1_0(D) \), it follows by density of \( H^1_0(D) \) in \( L^{p'}(D) \), that \( f = 0 \) and now this contradicts the inequality in (67.1.2).

Now \( \Delta \) is defined on \( H^1_0(D) \) and it delivers something in \( (H^1_0)' \equiv H \). Of course \( H^1_0(D) \) is dense in \( L^{p'}(D) \). Can \( \Delta \) be extended to all of \( L^{p'}(D) \)? The answer is yes and it is more of the same given above. For \( \phi \in H^1_0(D), -\Delta \phi \in H \subseteq (L^p(D))' \).

Then by the above, for \( \phi \in H^1_0(D) \) and \( f \in L^p (D) \),
\[ \langle -\Delta \phi, f \rangle \equiv \langle f, \phi \rangle = \int_D f \phi dx \]
\[ |\langle -\Delta \phi, f \rangle| \equiv |\langle f, \phi \rangle| \equiv \left| \int_D f \phi ds \right| \leq \|\phi\|_{L^{p'}(D)} \|f\|_{L^p(D)} \]
and so $-\Delta$ is a continuous linear mapping defined on a dense subspace $H_0^1(D)$ of $L^{p'}(D)$ and so this does indeed extend to a continuous linear map defined on all of $L^{p'}(D)$ given by the formula

$$\langle -\Delta g, f \rangle = \int_D fg \, dx$$

This proves the lemma.

Thus letting $V \equiv L^p(D)$, and $H \equiv (H_0^1(D))'$, it follows $V \subseteq H \subseteq V'$ is a Gelfand triple with the understanding of what it means for one space to be included in another described above. To emphasize the above, for $-\Delta \phi \in H, f \in L^p$,

$$\langle -\Delta \phi, f \rangle_H \equiv \langle f, \phi \rangle_H = \int_D f \phi \, dx$$

More generally, for $g \in L^{p'}(D), -\Delta g \in (L^p(D))'$ according to the rule

$$\langle -\Delta g, f \rangle = \int_D fg \, dx.$$

With this example of a Gelfand triple, one can define a “porous medium operator” $A : V \to V'$. Let $\Psi$ be a real valued function defined on $\mathbb{R}$ which satisfies

1. $\Psi$ is continuous
2. $(t - s) (\Psi(t) - \Psi(s)) \geq 0$
3. There exists $p \geq 2, p < \infty$ and $\alpha \in (0, \infty)$ such that for all $s \in \mathbb{R}$
   $$s \Psi(s) \geq \alpha |s|^p - c$$
4. There exist $c_3, c_4 \in (0, \infty)$ such that for all $s \in \mathbb{R}$
   $$|\Psi(s)| \leq c_4 + c_3 |s|^{p-1}$$

Note that (67.1.4) implies that if $v \in L^p(D)$, then

$$\int_D |\Psi(v)|^p \, dx \leq C \int_D \left(1 + |v|^{p(p-1)}\right) \, dx = C \int_D (1 + |v|^p) \, dx < \infty.$$ 

Thus for $v \in L^p(D), \Psi(v)$ is something you can do $\Delta$ to and obtain something in $V'$. The porous medium operator $A : V \to V'$ is given as follows.

$$\langle Av, w \rangle_{V', V} \equiv \langle \Delta \Psi(v), w \rangle_{V', V} \equiv - \int_D \Psi(v) \, w \, dx$$

What are the properties of $A$?

$$\langle A(u + \lambda v), w \rangle \equiv - \int_D \Psi(u + \lambda v) \, w \, dx$$
and this is easily seen to be a continuous function of \( \lambda \) Thus \( A \) is Hemicontinuous.

\[
\langle A(u) - A(v), u - v \rangle = - \int_D \Psi(u)(u - v) \, dx + \int_D \Psi(v)(u - v) \, dx \leq 0
\]

Thus \(-A\) is monotone. Also there is a coercivity estimate which is routine.

\[
\langle A(v), v \rangle = - \int_D \Psi(v)(u - v) \, dx \leq \int_D c - \alpha |v|^p \, dx = C - \alpha \|v\|^p
\]

This operator also has a boundedness estimate.

\[
\|A(v)\|_{V'} \equiv \sup_{\|w\|_V \leq 1} |\langle A(v), w \rangle| \equiv \sup_{\|w\|_V \leq 1} \int_D \Psi(v) \, w \, dx
\]

\[
\leq \sup_{\|w\|_V \leq 1} \left( \int_D \left( c_4 + c_3 |v|^{p-1} \right) w \, dx \right)
\]

\[
\leq \left( \int_D C \left( 1 + |v|^p \right) \, dx \right)^{1/p'} \leq C + C \left( \int_D |v|^p \, dx \right)^{1/p'}
\]

\[
= C + C \|v\|_{V'}^{p/p'} = C + C \|v\|_{V'}^{p-1}.
\]

Since \( \Psi \) is continuous, it will also follow that \( A \) is \( B(V) \) measurable. Consider

\[
u \to \langle Au, w \rangle \equiv - \int_D \Psi(u) \, w \, dx
\]

for fixed \( w \in V \). Suppose \( u_n \to u \) in \( V \) and fix \( w \in L^\infty(D) \subseteq V \). Then it follows from an easy argument using the Vitali convergence theorem and the fact that from the estimates above

\[
\Psi(u_n) \, w
\]

is uniformly integrable that

\[
u \to - \int_D \Psi(u) \, w \, dx
\]

is continuous. For general \( w \in L^p(D) \), let \( w_n \to w \) in \( L^p(D) \) where each \( w_n \) is in \( L^\infty(D) \). Then the function

\[
u \to - \int_D \Psi(u) \, w_n \, dx \equiv \langle Au, w \rangle
\]

(67.1.7)

is the limit of the continuous functions

\[
u \to - \int_D \Psi(u) \, w_n \, dx
\]

and so the function \( \text{(67.1.7)} \) is Borel measurable. Now by the Pettis theorem this shows \( A : V \to V' \) is \( B(V) \) measurable. This shows \( A \) is an example of an operator which satisfies some conditions which will be considered later.
67.2 Standard Techniques In Evolution Equations

In this section, several significant theorems are presented. Unless indicated otherwise, the measure will be Lebesgue measure. First here is a lemma.

**Lemma 67.2.1** Suppose \( g \in L^1 ([a, b]; X) \) where \( X \) is a Banach space. Then if \( \int_a^b g(t) \phi(t) \, dt = 0 \) for all \( \phi \in C_c^\infty (a, b) \), then \( g(t) = 0 \) a.e.

**Proof:** Let \( E \) be a measurable subset of \((a, b)\) and let \( K \subseteq E \subseteq V \subseteq (a, b)\) where \( K \) is compact, \( V \) is open and \( m (V \setminus K) < \varepsilon \). Let \( K < h < V \) as in the proof of the Riesz representation theorem for positive linear functionals. Enlarging \( K \) slightly and convolving with a mollifier, it can be assumed \( h \in C_c^\infty (a, b) \). Then

\[
\left| \int_a^b \mathcal{X}_E (t) g(t) \, dt \right| = \left| \int_a^b (\mathcal{X}_E (t) - h(t)) g(t) \, dt \right| \\
\leq \int_a^b |\mathcal{X}_E (t) - h(t)| ||g(t)|| \, dt \\
\leq \int_{V \setminus K} ||g(t)|| \, dt.
\]

Now let \( K_n \subseteq E \subseteq V_n \) with \( m (V_n \setminus K_n) < 2^{-n} \). Then from the above,

\[
\left| \int_a^b \mathcal{X}_E (t) g(t) \, dt \right| \leq \int_a^b \mathcal{X}_{V_n \setminus K_n} (t) ||g(t)|| \, dt
\]

and the integrand of the last integral converges to 0 a.e. as \( n \to \infty \) because \( \sum_n m (V_n \setminus K_n) < \infty \). By the dominated convergence theorem, this last integral converges to 0. Therefore, whenever \( E \subseteq (a, b) \),

\[
\int_a^b \mathcal{X}_E (t) g(t) \, dt = 0.
\]

Since the endpoints have measure zero, it also follows that for any measurable \( E \), the above equation holds.

Now \( g \in L^1 ([a, b]; X) \) and so it is measurable. Therefore, \( g ([a, b]) \) is separable. Let \( D \) be a countable dense subset and let \( E \) denote the set of linear combinations of the form \( \sum a_i d_i \) where \( a_i \) is a rational point of \( \mathbb{F} \) and \( d_i \in D \). Thus \( E \) is countable. Denote by \( Y \) the closure of \( E \) in \( X \). Thus \( Y \) is a separable closed subspace of \( X \) which contains all the values of \( g \).

Now let \( S_n \equiv g^{-1} (B (y_n, ||y_n|| / 2)) \) where \( E = \{ y_n \}_{n=1}^\infty \). Therefore, \( \cup_n S_n = g^{-1} (X \setminus \{ 0 \}) \). This follows because if \( x \in Y \) and \( x \neq 0 \), then in \( B \left( x, ||x|| \right) \) there is a point of \( E, y_n \). Therefore, \( ||y_n|| > \frac{3}{4} ||x|| \) and so \( \frac{||y_n||}{2} > \frac{3}{8} ||x|| > ||x|| \) so \( x \in B (y_n, ||y_n|| / 2) \). It follows that if each \( S_n \) has measure zero, then \( g(t) = 0 \) for a.e.
67.2. STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

$t$. Suppose then that for some $n$, the set, $S_n$, has positive measure. Then from what was shown above,

$$\|y_n\| = \left\| \frac{1}{m(S_n)} \int_{S_n} g(t) dt - y_n \right\| = \left\| \frac{1}{m(S_n)} \int_{S_n} g(t) dt - y_n dt \right\|$$

$$\leq \frac{1}{m(S_n)} \int_{S_n} \|g(t) - y_n\| dt \leq \frac{1}{m(S_n)} \int_{S_n} \|y_n\| dt = \|y_n\| / 2$$

and so $y_n = 0$ which implies $S_n = \emptyset$, a contradiction to $m(S_n) > 0$. This contradiction shows each $S_n$ has measure zero and so as just explained, $g(t) = 0$ a.e.

\[ \Box \]

**Definition 67.2.2** For $f \in L^1(a,b;X)$, define an extension, $\overline{f}$ defined on

$$[2a - b, 2b - a] = [a - (b - a), b + (b - a)]$$

as follows.

$$\overline{f}(t) \equiv \begin{cases} f(t) & \text{if } t \in [a, b] \\ f(2a - t) & \text{if } t \in [2a - b, a] \\ f(2b - t) & \text{if } t \in [b, 2b - a] \end{cases}$$

**Definition 67.2.3** Also if $f \in L^p(a,b;X)$ and $h > 0$, define for $t \in [a, b]$, $f_h(t) \equiv \overline{f}(t - h)$ for all $h < b - a$. Thus the map $f \to f_h$ is continuous and linear on $L^p(a,b;X)$. It is continuous because

$$\int_a^b \|f_h(t)\|^p dt = \int_a^{a+h} \|f(2a-t+h)\|^p dt + \int_a^{b-h} \|f(t)\|^p dt$$

$$= \int_a^{a+h} \|f(t)\|^p dt + \int_a^{b-h} \|f(t)\|^p dt \leq 2\|f\|^p_p.$$.

The following lemma is on continuity of translation in $L^p(a,b;X)$.

**Lemma 67.2.4** Let $\overline{f}$ be as defined in Definition 67.2.3. Then for $f \in L^p(a,b;X)$ for $p \in [1, \infty)$,

$$\lim_{\delta \to 0} \int_a^b \|\overline{f}(t - \delta) - f(t)\|^p_X dt = 0.$$

**Proof:** Regarding the measure space as $(a,b)$ with Lebesgue measure, by regularity of the measure, there exists $g \in C_c(a,b;X)$ such that $\|f - g\|_p < \varepsilon$. Here the norm is the norm in $L^p(a,b;X)$. Therefore,

$$\|f_h - f\|_p \leq \|f_h - gh\|_p + \|gh - g\|_p + \|g - f\|_p$$

$$\leq (2^{1/p} + 1) \|f - g\|_p + \|gh - g\|_p$$

$$< (2^{1/p} + 1) \varepsilon + \varepsilon$$

whenever $h$ is sufficiently small. This is because of the uniform continuity of $g$. Therefore, since $\varepsilon > 0$ is arbitrary, this proves the lemma. \[ \Box \]
Definition 67.2.5 Let \( f \in L^1(a,b; X) \). Then the distributional derivative in the sense of \( X \) valued distributions is given by
\[
f'(\phi) \equiv - \int_a^b f(t) \phi'(t) \, dt
\]
Then \( f' \in L^1(a,b; X) \) if there exists \( h \in L^1(a,b; X) \) such that for all \( \phi \in C_c^\infty(a,b) \),
\[
f'(\phi) = \int_a^b h(t) \phi(t) \, dt.
\]
Then \( f' \) is defined to equal \( h \). Here \( f \) and \( f' \) are considered as vector valued distributions in the same way as was done for scalar valued functions.

Lemma 67.2.6 The above definition is well defined.

Proof: Suppose both \( h \) and \( g \) work in the definition. Then for all \( \phi \in C_c^\infty(a,b) \),
\[
\int_a^b (h(t) - g(t)) \phi(t) \, dt = 0.
\]
Therefore, by Lemma 67.2.1, \( h(t) - g(t) = 0 \) a.e. \( \blacksquare \)

The other thing to notice about this is the following lemma. It follows immediately from the definition.

Lemma 67.2.7 Suppose \( f, f' \in L^1(a,b; X) \). Then if \( [c,d] \subseteq [a,b] \), it follows that \( (f|_{[c,d]})' = f'|_{[c,d]} \). This notation means the restriction to \( [c,d] \).

Recall that in the case of scalar valued functions, if you had both \( f \) and its weak derivative, \( f' \) in \( L^1(a,b) \), then you were able to conclude that \( f \) is almost everywhere equal to a continuous function, still denoted by \( f \) and
\[
f(t) = f(a) + \int_a^t f'(s) \, ds.
\]
In particular, you can define \( f(a) \) to be the initial value of this continuous function. It turns out that an identical theorem holds in this case. To begin with here is the same sort of lemma which was used earlier for the case of scalar valued functions. It says that if \( f' = 0 \) where the derivative is taken in the sense of \( X \) valued distributions, then \( f \) equals a constant.

Lemma 67.2.8 Suppose \( f \in L^1(a,b; X) \) and for all \( \phi \in C_c^\infty(a,b) \),
\[
\int_a^b f(t) \phi'(t) \, dt = 0.
\]
Then there exists a constant, \( a \in X \) such that \( f(t) = a \) a.e.
Proof: Let \( \phi_0 \in C_c^\infty (a, b) \), \( \int_a^b \phi_0 (x) \, dx = 1 \) and define for \( \phi \in C_c^\infty (a, b) \)

\[
\psi_\phi (x) = \int_a^x [\phi (t) - \left( \int_a^b \phi (y) \, dy \right) \phi_0 (t)] \, dt
\]

Then \( \psi_\phi \in C_c^\infty (a, b) \) and \( \psi_\phi' = \phi - \left( \int_a^b \phi (y) \, dy \right) \phi_0 \). Then

\[
\int_a^b f (t) (\phi (t)) \, dt = \int_a^b f (t) \left( \psi_\phi' (t) + \left( \int_a^b \phi (y) \, dy \right) \phi_0 (t) \right) \, dt
\]

\[
= \int_a^b f (t) \psi_\phi' (t) \, dt + \left( \int_a^b \phi (y) \, dy \right) \int_a^b f (t) \phi_0 (t) \, dt
\]

\[
= \left( \int_a^b \left( \int_a^b f (t) \phi_0 (t) \, dt \right) \phi (y) \, dy \right).
\]

It follows that for all \( \phi \in C_c^\infty (a, b) \),

\[
\int_a^b \left( f (y) - \left( \int_a^b f (t) \phi_0 (t) \, dt \right) \right) \phi (y) \, dy = 0
\]

and so by Lemma 67.2.3.

\[
f (y) - \left( \int_a^b f (t) \phi_0 (t) \, dt \right) = 0 \text{ a.e. } y
\]

**Theorem 67.2.9** Suppose \( f, f' \) both are in \( L^1 (a, b; X) \) where the derivative is taken in the sense of \( X \) valued distributions. Then there exists a unique point of \( X \), denoted by \( f (a) \) such that the following formula holds a.e. \( t \).

\[
f (t) = f (a) + \int_a^t f' (s) \, ds
\]

Proof:

\[
\int_a^b \left( f (t) - \int_a^t f' (s) \, ds \right) \phi' (t) \, dt = \int_a^b f (t) \phi' (t) \, dt - \int_a^b \int_a^t f' (s) \phi' (t) \, ds \, dt.
\]

Now consider \( \int_a^b \int_a^t f' (s) \phi' (t) \, ds \, dt \). Let \( \Lambda \in X' \). Then it is routine from approximating \( f' \) with simple functions to verify

\[
\Lambda \left( \int_a^b \int_a^t f' (s) \phi' (t) \, ds \, dt \right) = \int_a^b \int_a^t \Lambda (f' (s)) \phi' (t) \, ds \, dt.
\]
Now the ordinary Fubini theorem can be applied to obtain

$$= \int_a^b \int_s^b \Delta (f'(s)) \phi'(t) \, dt \, ds = \Delta \left( \int_a^b \int_s^b f'(s) \phi'(t) \, dt \, ds \right).$$

Since $X'$ separates the points of $X$, it follows

$$\int_a^b \int_s^t f'(s) \phi'(t) \, ds \, dt = \int_a^b \int_s^b f'(s) \phi'(t) \, dt \, ds.$$

Therefore,

$$\int_a^b \left( f(t) - \int_s^t f'(s) \, ds \right) \phi'(t) \, dt$$

$$= \int_a^b f(t) \phi'(t) \, dt - \int_a^b \int_s^b f'(s) \phi'(t) \, dt \, ds$$

$$= \int_a^b f(t) \phi'(t) \, dt - \int_a^b f'(s) \int_s^b \phi'(t) \, dt \, ds$$

$$= \int_a^b f(t) \phi'(t) \, dt + \int_a^b f'(s) \phi(s) \, ds = 0.$$

Therefore, by Lemma 67.2.8, there exists a constant, denoted as $f(a)$ such that

$$f(t) - \int_a^t f'(s) \, ds = f(a).$$

The integration by parts formula is also important.

**Corollary 67.2.10** Suppose $f, f' \in L^1(a, b; X)$ and suppose $\phi \in C^1([a, b])$. Then the following integration by parts formula holds.

$$\int_a^b f(t) \phi'(t) \, dt = f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(t) \phi(t) \, dt.$$
67.2. STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

Proof: From Theorem 67.2.9

\[
\int_a^b f(t) \phi'(t) \, dt = \int_a^b \left( f(a) + \int_t^b f'(s) \, ds \right) \phi'(t) \, dt
\]

\[
= f(a) \left( \phi(b) - \phi(a) \right) + \int_a^b \int_t^b f'(s) \, ds \phi'(t) \, dt
\]

\[
= f(a) \left( \phi(b) - \phi(a) \right) + \int_a^b f'(s) \int_s^b \phi'(t) \, dt \, ds
\]

\[
= f(a) \left( \phi(b) - \phi(a) \right) + \int_a^b f'(s) \left( \phi(b) - \phi(s) \right) \, ds
\]

\[
= f(a) \left( \phi(b) - \phi(a) \right) - \int_a^b f'(s) \phi(s) \, ds + (f(b) - f(a)) \phi(b)
\]

\[
= f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(s) \phi(s) \, ds.
\]

The interchange in order of integration is justified as in the proof of Theorem 67.2.9.

With this integration by parts formula, the following interesting lemma is obtained. This lemma shows why it was appropriate to define \( \overline{f} \) as in Definition 67.2.2.

Lemma 67.2.11 Let \( \overline{f} \) be given in Definition 67.2.2 and suppose \( f, f' \in L^1(a,b;X) \). Then \( \overline{f}, \overline{f}' \in L^1(2a-b,2b-a;X) \) also and

\[
\overline{f}'(t) \equiv \begin{cases} 
  f'(t) & \text{if } t \in [a,b] \\
  -f'(2a-t) & \text{if } t \in [2a-b,a] \\
  -f'(2b-t) & \text{if } t \in [b,2b-a]
\end{cases}
\]

(67.2.8)

Proof: It is clear from the definition of \( \overline{f} \) that \( \overline{f} \in L^1(2a-b,2b-a;X) \) and that in fact

\[
\| \overline{f} \|_{L^1(2a-b,2b-a;X)} \leq 3 \| f \|_{L^1(a,b;X)}.
\]

(67.2.9)
Let $\phi \in C_c^\infty(2a - b, 2b - a)$. Then from the integration by parts formula,
\[
\int_{2a-b}^{2b-a} f(t) \phi'(t) \, dt = \int_a^b f(t) \phi'(t) \, dt + \int_a^{2b-a} f(2b - t) \phi'(t) \, dt + \int_{2a-b}^a f(2a - t) \phi'(t) \, dt
\]
\[
= \int_a^b f(t) \phi'(t) \, dt + \int_a^b f(u) \phi'(2b - u) \, du + \int_a^{2b-a} f(u) \phi'(2a - u) \, du
\]
\[
= f(b) \phi(b) - f(a) \phi(a) - \int_a^b f'(t) \phi(t) \, dt - f(b) \phi(b) + f(a) \phi(2b - a) + \int_a^b f'(u) \phi(2b - u) \, du - f(b) \phi(2b - a) + f(a) \phi(a) + \int_a^b f'(u) \phi(2a - u) \, du
\]
\[
= \int_a^b f'(t) \phi(t) \, dt + \int_a^b f'(u) \phi(2b - u) \, du + \int_a^b f'(u) \phi(2a - u) \, du
\]
\[
= \int_a^b f'(t) \phi(t) \, dt - \int_b^{2b-a} -f'(2b - t) \phi(t) \, dt - \int_{2a-b}^a -f'(2a - t) \phi(t) \, dt
\]
\[
= \int_{2a-b}^{2b-a} f'(t) \phi(t) \, dt
\]
where $f'(t)$ is given in Definition 67.2.12. \hfill \square

**Definition 67.2.12** Let $V$ be a Banach space and let $H$ be a Hilbert space. (Typically $H = L^2(\Omega)$) Suppose $V \subseteq H$ is dense in $H$ meaning that the closure in $H$ of $V$ gives $H$. Then it is often the case that $H$ is identified with its dual space, and then because of the density of $V$ in $H$, it is possible to write
\[
V \subseteq H = H' \subseteq V'
\]
When this is done, $H$ is called a pivot space. Another notation which is often used is $\langle f, g \rangle$ to denote $f(g)$ for $f \in V'$ and $g \in V$. This may also be written as $\langle f, g \rangle_{V', V}$. Another term is that $V \subseteq H = H' \subseteq V'$ is called a Gelfand triple.

The next theorem is an example of a trace theorem. In this theorem, $f \in L^p(0, T; V)$ while $f' \in L^p(0, T; V')$. It makes no sense to consider the initial values of $f$ in $V$ because it is not even continuous with values in $V$. However, because of the derivative of $f$ it will turn out that $f$ is continuous with values in a larger space and so it makes sense to consider initial values of $f$ in this other space. This other space is called a trace space.

**Theorem 67.2.13** Let $V$ and $H$ be a Banach space and Hilbert space as described in Definition 67.2.12. Suppose $f \in L^p(0, T; V)$ and $f' \in L^p(0, T; V')$. Then $f$ is
67.2. STANDARD TECHNIQUES IN EVOLUTION EQUATIONS

a.e. equal to a continuous function mapping \([0, T]\) to \(H\). Furthermore, there exists \(f(0) \in H\) such that

\[
\frac{1}{2} |f(t)|_H^2 - \frac{1}{2} |f(0)|_H^2 = \int_0^t \langle f'(s), f(s) \rangle \, ds,
\]

(67.2.10)

and for all \(t \in [0, T]\),

\[
\int_0^t f'(s) \, ds \in H,
\]

(67.2.11)

and for a.e. \(t \in [0, T]\),

\[
f(t) = f(0) + \int_0^t f'(s) \, ds \text{ in } H,
\]

(67.2.12)

Here \(f'\) is being taken in the sense of \(V'\) valued distributions and \(\frac{1}{p} + \frac{1}{p'} = 1\) and \(p \geq 2\).

**Proof:** Let \(\Psi \in C^\infty_c (\mathbb{R}, 2T)\) satisfy \(\Psi(t) = 1\) if \(t \in [-T/2, 3T/2]\) and \(\Psi(t) \geq 0\). For \(t \in \mathbb{R}\), define

\[
\tilde{\Psi}(t) = \begin{cases} \Psi(t) & \text{if } t \in [-T, 2T] \\ 0 & \text{if } t \notin [-T, 2T] \end{cases}
\]

and

\[
f_n(t) = \int_{-1/n}^{1/n} \tilde{\Psi}(t-s) \phi_n(s) \, ds
\]

(67.2.13)

where \(\phi_n\) is a mollifier having support in \((-1/n, 1/n)\). Then by Minkowski’s inequality

\[
\left\| f_n - \tilde{f} \right\|_{L^p(\mathbb{R}; V)} = \left( \int_{\mathbb{R}} \left\| \tilde{\Psi}(t) - \int_{-1/n}^{1/n} \tilde{\Psi}(t-s) \phi_n(s) \, ds \right\|_V^p \, dt \right)^{1/p} \\
\leq \left( \int_{\mathbb{R}} \left( \int_{-1/n}^{1/n} \left\| \tilde{\Psi}(t) - \tilde{\Psi}(t-s) \right\|_V \phi_n(s) \, ds \right)^p \, dt \right)^{1/p} \\
\leq \int_{-1/n}^{1/n} \phi_n(s) \left( \int_{\mathbb{R}} \left\| \tilde{\Psi}(t) - \tilde{\Psi}(t-s) \right\|_V^p \, dt \right)^{1/p} \, ds \\
\leq \int_{-1/n}^{1/n} \phi_n(s) \varepsilon \, ds = \varepsilon
\]

provided \(n\) is large enough. This follows from continuity of translation in \(L^p\) with Lebesgue measure. Since \(\varepsilon > 0\) is arbitrary, it follows \(f_n \to \tilde{f}\) in \(L^p(\mathbb{R}; V)\). Similarly,
$f_n \to f$ in $L^2(\mathbb{R}; H)$. This follows because $p \geq 2$ and the norm in $V$ and norm in $H$ are related by $|x|_H \leq C||x||_V$ for some constant, $C$. Now

$$\hat{f}(t) = \begin{cases} 
\Psi(t) f(t) & \text{if } t \in [0, T], \\
\Psi(t) f(2T - t) & \text{if } t \in [T, 2T], \\
\Psi(t) f(-t) & \text{if } t \in [0, T], \\
0 & \text{if } t \notin [-T, 2T].
\end{cases}$$

An easy modification of the argument of Lemma 67.2.14 yields

$$\hat{f}'(t) = \begin{cases} 
\Psi'(t) f(t) + \Psi(y) f'(t) & \text{if } t \in [0, T], \\
\Psi'(t) f(2T - t) - \Psi(t) f'(2T - t) & \text{if } t \in [T, 2T], \\
\Psi'(t) f(-t) - \Psi(t) f'(-t) & \text{if } t \in [-T, 0], \\
0 & \text{if } t \notin [-T, 2T].
\end{cases}$$

Recall

$$f_n(t) = \int_{-1/n}^{1/n} \hat{f}(t-s) \phi_n(s) \, ds = \int_{\mathbb{R}} \hat{f}(t-s) \phi_n(s) \, ds$$

$$= \int_{\mathbb{R}} \hat{f}(s) \phi_n(t-s) \, ds.$$ 

Therefore,

$$f'_n(t) = \int_{\mathbb{R}} \hat{f}'(s) \phi'_n(t-s) \, ds = \int_{-1/n}^{2T+1/n} \hat{f}'(s) \phi'_n(t-s) \, ds$$

$$= \int_{-T-1/2}^{2T+1/2} \hat{f}'(s) \phi_n(t-s) \, ds = \int_{\mathbb{R}} \hat{f}'(s) \phi_n(t-s) \, ds$$

$$= \int_{\mathbb{R}} \hat{f}'(t-s) \phi_n(s) \, ds = \int_{-1/n}^{1/n} \hat{f}'(t-s) \phi_n(s) \, ds$$

and it follows from the first line above that $f'_n$ is continuous with values in $V$ for all $t \in \mathbb{R}$. Also note that both $f'_n$ and $f_n$ equal zero if $t \notin [-T, 2T]$ whenever $n$ is large enough. Exactly similar reasoning to the above shows that $f'_n \to f'$ in $L^{p'}(\mathbb{R}; V')$.

Now let $\phi \in C_c^\infty(0, T)$.

$$\int_{\mathbb{R}} |f_n(t)|_H^2 \phi'(t) \, dt = \int_{\mathbb{R}} (f_n(t), f_n(t))_H \phi'(t) \, dt \quad (67.2.14)$$

$$= -\int_{\mathbb{R}} 2 (f'_n(t), f_n(t)) \phi(t) \, dt = -\int_{\mathbb{R}} 2 (f'_n(t), f_n(t)) \phi(t) \, dt$$

Now

$$\left| \int_{\mathbb{R}} (f'_n(t), f_n(t)) \phi(t) \, dt - \int_{\mathbb{R}} (f'(t), f(t)) \phi(t) \, dt \right|$$

$$\leq \int_{\mathbb{R}} |(f'_n(t) - f'(t), f_n(t)) + (f'(t), f_n(t) - f(t))| \phi(t) \, dt.$$
From the first part of this proof which showed that \( f_n \to \hat{f} \) in \( L^p (\mathbb{R}; V) \) and \( f'_n \to \hat{f}' \) in \( L^{p'} (\mathbb{R}; V') \), an application of Holder’s inequality shows the above converges to 0 as \( n \to \infty \). Therefore, passing to the limit as \( n \to \infty \) in the

\[
\int_{\mathbb{R}} |\hat{f} (t)|^2_H \phi' (t) dt = - \int_{\mathbb{R}} 2 \left< \hat{f}' (t), \hat{f} (t) \right> \phi (t) dt
\]

which shows \( t \to |\hat{f} (t)|^2_H \) equals a continuous function a.e. and it also has a weak derivative equal to \( 2 \left< \hat{f}', \hat{f} \right> \).

It remains to verify that \( \hat{f} \) is continuous on \([0, T]\). Of course \( \hat{f} = f \) on this interval. Let \( N \) be large enough that \( f_n (-T) = 0 \) for all \( n > N \). Then for \( m, n > N \) and \( t \in [-T, 2T] \)

\[
|f_n (t) - f_m (t)|^2_H = 2 \int_{-T}^{t} (f'_n (s) - f'_m (s), f_n (s) - f_m (s)) ds
\]

\[
= 2 \int_{-T}^{t} \langle f'_n (s) - f'_m (s), f_n (s) - f_m (s) \rangle_{V', V} ds
\]

\[
\leq 2 \int_{-T}^{t} ||f'_n (s) - f'_m (s)||_{V'} ||f_n (s) - f_m (s)||_V ds
\]

\[
\leq 2 ||f_n - f_m||_{L^p (\mathbb{R}; V')} ||f_n - f_m||_{L^p (\mathbb{R}; V)}
\]

which shows from the above that \( \{f_n\} \) is uniformly Cauchy on \([-T, 2T]\) with values in \( H \). Therefore, there exists \( g \) a continuous function defined on \([-T, 2T]\) having values in \( H \) such that

\[
\lim_{n \to \infty} \max \{|f_n (t) - g (t)|_H ; t \in [-T, 2T]\} = 0.
\]

However, \( g = \hat{f} \) a.e. because \( f_n \) converges to \( f \) in \( L^p (0, T; V) \). Therefore, taking a subsequence, the convergence is a.e. It follows from the fact that \( V \subseteq H = H' \subseteq V' \) and Theorem 67.2.9, there exists \( f (0) \in V' \) such that for a.e. \( t \),

\[
f (t) = f (0) + \int_{0}^{t} f' (s) ds \text{ in } V'
\]

Now \( g = f \) a.e. and \( g \) is continuous with values in \( H \) hence continuous with values in \( V' \) and so

\[
g (t) = f (0) + \int_{0}^{t} f' (s) ds \text{ in } V'
\]

for all \( t \). Since \( g \) is continuous with values in \( H \) it is continuous with values in \( V' \). Taking the limit as \( t \downarrow 0 \) in the above, \( g (a) = \lim_{t \to 0^+} g (t) = f (0) \), showing that \( f (0) \in H \). Therefore, for a.e. \( t \),

\[
f (t) = f (0) + \int_{0}^{t} f' (s) ds \text{ in } H, \int_{0}^{t} f' (s) ds \in H.\]
Note that if \( f \in L^p (0, T; V) \) and \( f' \in L^{p'} (0, T; V') \), then you can consider the initial value of \( f \) and it will be in \( H \). What if you start with something in \( H \)? Is it an initial condition for a function \( f \in L^p (0, T; V) \) such that \( f' \in L^{p'} (0, T; V') \)? This is worth thinking about. If it is not so, what is the space of initial values? How can you give this space a norm? What are its properties? It turns out that if \( V \) is a closed subspace of the Sobolev space, \( W^{1,p}_0 (\Omega) \) which contains \( W^{1,p}_0 (\Omega) \) for \( p \geq 2 \) and \( H = L^2 (\Omega) \) the answer to the above question is yes. Not surprisingly, there are many generalizations of the above ideas.

### 67.3 An Important Formula

It is not necessary to have \( p > 2 \) in order to do the sort of thing just described. Here is a major result which will have a much more difficult stochastic version presented later. First is an approximation theorem of Doob. See Lemma 63.3.1.

**Lemma 67.3.1** Let \( Y : [0, T] \to E \), be \( \mathcal{B} ([0, T]) \) measurable and suppose

\[
Y \in L^p (0, T; E) \equiv K, \ p \geq 1
\]

Then there exists a sequence of nested partitions, \( \mathcal{P}_k \subseteq \mathcal{P}_{k+1} \),

\[
\mathcal{P}_k \equiv \{ t_0^k, \ldots, t_m^k \}
\]

such that the step functions given by

\[
\begin{align*}
Y_k^r (t) & = \sum_{j=1}^{m_k} Y (t_j^k) \chi_{[t_{j-1}^k, t_j^k]} (t) \\
Y_k^l (t) & = \sum_{j=1}^{m_k} Y (t_{j-1}^k) \chi_{(t_{j-1}^k, t_j^k]} (t)
\end{align*}
\]

both converge to \( Y \) in \( K \) as \( k \to \infty \) and

\[
\lim_{k \to \infty} \max \{ |t_j^k - t_{j+1}^k| : j \in \{0, \ldots, m_k\} \} = 0.
\]

Also, each \( Y (t_j^k), Y (t_{j-1}^k) \) is in \( E \). One can also assume that \( Y (0) = 0 \). The mesh points \( \{ t_j^k \}_{j=0}^{m_k} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that

\[
|t_j^k - t_{j-1}^k| = 2^{-n_k}
\]

except for the case where \( j = 1 \) or \( j = m_k \) when this might not be so. In the case of the last subinterval defined by the partition, we can assume

\[
|t_m^k - t_{m-1}^k| = |T - t_m^k| \geq 2^{-(n_k+1)}
\]
Theorem 67.3.2 Let $V \subseteq H = H' \subseteq V'$ be a Gelfand triple and suppose $Y \in L^p(0, T; V') \equiv K$ and

$$X(t) = X_0 + \int_0^t Y(s) \, ds \text{ in } V'$$  \hspace{1cm} (67.3.15)$$

where $X_0 \in H$, and it is known that $X \in L^p(0, T, V) \equiv K$ for $p > 1$. Then $t \to X(t)$ is in $C([0, T], H)$ and also

$$\frac{1}{2} \|X(t)\|^2_H = \frac{1}{2} \|X_0\|^2_H + \int_0^t \langle Y(s), X(s) \rangle \, ds$$

Proof: By Lemma 67.3.1, there exists a sequence of uniform partitions $\{t^n_k\}_{k=0}^{m_n} = \mathcal{P}_n, \mathcal{P}_n \subseteq \mathcal{P}_{n+1}$, of $[0, T]$ such that the step functions

$$\sum_{k=0}^{m_n-1} X(t^n_k) \mathcal{X}_{(t^n_k, t^n_{k+1})}(t) = X^l(t)$$

$$\sum_{k=0}^{m_n-1} X(t^n_{k+1}) \mathcal{X}_{(t^n_k, t^n_{k+1})}(t) = X^r(t)$$

converge to $X$ in $K$ and in $L^2([0, T], H)$.

Lemma 67.3.3 Let $s < t$. Then for $X, Y$ satisfying (67.3.15)

$$|X(t)|^2 = |X(s)|^2 + 2 \int_s^t \langle Y(u), X(t) \rangle \, du - |X(t) - X(s)|^2$$  \hspace{1cm} (67.3.16)$$

Proof: It follows from the following computations

$$X(t) - X(s) = \int_s^t Y(u) \, du$$

$$- |X(t) - X(s)|^2 = - |X(t)|^2 + 2 \langle X(t), X(s) \rangle - |X(s)|^2$$

$$= - |X(t)|^2 + 2 \left( X(t) - \int_s^t Y(u) \, du \right) - |X(s)|^2$$

$$= - |X(t)|^2 + 2 |X(t)|^2 - 2 \left( \int_s^t Y(u) \, du, X(t) \right) - |X(s)|^2$$

Hence

$$|X(t)|^2 = |X(s)|^2 + 2 \int_s^t \langle Y(u), X(t) \rangle \, du - |X(t) - X(s)|^2$$

Lemma 67.3.4 In the above situation,

$$\sup_{t \in [0, T]} |X(t)|_H \leq C \left( \|Y\|_{K'}, \|X\|_K \right)$$

Also, $t \to X(t)$ is weakly continuous with values in $H$. 

**Proof:** From the above formula applied to the $k^{th}$ partition of $[0,T]$ described above,

$$|X(t_m)|^2 - |X_0|^2 = \sum_{j=0}^{m-1} |X(t_{j+1})|^2 - |X(t_j)|^2$$

$$= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} (Y(u), X(t_{j+1})) \, du - |X(t_{j+1}) - X(t_j)|_H^2$$

$$= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} (Y(u), X_k^r(u)) \, du - |X(t_{j+1}) - X(t_j)|_H^2$$

Thus, discarding the negative terms and denoting by $P_k$ the $k^{th}$ of these partitions,

$$\sup_{t_j \in P_k} |X(t_j)|_H^2 \leq |X_0|^2 + 2 \int_0^T \langle Y(u), X_k^r(u) \rangle \, du$$

$$\leq |X_0|^2 + 2 \left( \int_0^T \|Y(u)\|_{V'}, \|X_k^r(u)\|_{V'} \, du \right)$$

because these partitions are chosen such that

$$\lim_{k \to \infty} \left( \int_0^T \|X_k^r(u)\|_{V'}^p \right)^{1/p} = \left( \int_0^T \|X(u)\|_{V'}^p \right)^{1/p}$$

and so these are bounded. This has shown that for the dense subset of $[0,T], D = \cup_k P_k,$

$$\sup_{t \in D} |X(t)| < C (\|Y\|_{K'}, \|X\|_K)$$

Now let $\{g_k\}_{k=1}^\infty$ be linearly independent vectors of $V$ whose span is dense in $V$. This is possible because $V$ is separable. Then let $\{e_j\}_{j=1}^\infty$ be an orthonormal basis for $H$ such that $e_k \in \text{span}(g_1, \ldots, g_k)$ and each $g_k \in \text{span}(e_1, \ldots, e_k)$ This is done with the Gram Schmidt process. Then it follows that span $\{\{e_k\}_{k=1}^\infty\}$ is dense in $V$. I claim

$$|y|_H^2 = \sum_{j=1}^\infty |\langle y, e_j \rangle|^2.$$ 

This is certainly true if $y \in H$ because

$$\langle y, e_j \rangle = (y, e_j)_H$$
If \( y \notin H \), then the series must diverge since otherwise, you could consider the infinite sum
\[
\sum_{j=1}^{\infty} \langle y, e_j \rangle e_j \in H
\]
because
\[
\left| \sum_{j=p}^{q} \langle y, e_j \rangle e_j \right| = \sum_{j=p}^{q} |\langle y, e_j \rangle|^2 \to 0 \text{ as } p, q \to \infty.
\]
Letting \( z = \sum_{j=1}^{\infty} \langle y, e_j \rangle e_j \), it follows that \( \langle y, e_j \rangle \) is the \( j^{th} \) Fourier coefficient of \( z \) and that
\[
\langle z - y, v \rangle = 0
\]
for all \( v \in \text{span} (\{e_k\}_{k=1}^{\infty}) \) which is dense in \( V \). Therefore, \( z = y \in V' \) and so \( y \in H \).

It follows
\[
|X(t)|^2 = \sup_{n} \sum_{j=1}^{n} |\langle X(t), e_j \rangle|^2
\]
which is just the sup of continuous functions of \( t \). Therefore, \( t \to |X(t)|^2 \) is lower semicontinuous. It follows that for any \( t \), letting \( t_j \to t \) for \( t_j \in D \),
\[
|X(t)|^2 \leq \liminf_{j \to \infty} |X(t_j)|^2 \leq C (\|Y\|_{K'}, \|X\|_{K})
\]
This proves the first claim of the lemma.

Consider now the claim that \( t \to X(t) \) is weakly continuous. Letting \( v \in V \),
\[
\lim_{t \to s} \langle X(t), v \rangle = \langle X(s), v \rangle = \langle X(s), v \rangle
\]
Since it was shown that \( |X(t)| \) is bounded independent of \( t \), and since \( V \) is dense in \( H \), the claim follows. \( \blacksquare \)

Now
\[
- \sum_{j=0}^{m-1} |X(t_{j+1}) - X(t_j)|^2_H = |X(t_m)|^2 - |X_0|^2 - \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y(u), X_k^*(u) \rangle \, du
\]
\[
= |X(t_m)|^2 - |X_0|^2 - 2 \int_{0}^{t_m} \langle Y(u), X_k^*(u) \rangle \, du
\]
Thus, since the partitions are nested, eventually \( |X(t_m)|^2 \) is constant for all \( k \) large enough and the integral term converges to
\[
\int_{0}^{t_m} \langle Y(u), X(u) \rangle \, du
\]
It follows that the term on the left does converge to something. It just remains to consider what it does converge to. However, from the equation solved by \( X \),
\[
X(t_{j+1}) - X(t_j) = \int_{t_j}^{t_{j+1}} Y(u) \, du
\]
Therefore, this term is dominated by an expression of the form

\[
\sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) - X(t_j) \rangle \, du
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) \rangle - \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_j) \rangle
\]

\[
= \int_0^T \langle Y(u), X^r(u) \rangle \, du - \int_0^T \langle Y(u), X^l(u) \rangle \, du
\]

However, both \(X^r\) and \(X^l\) converge to \(X\) in \(K = L^p(0, T; V)\). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \(t \in D\), the desired formula holds. Thus, for such \(t\),

\[
|X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(u), X(u) \rangle \, du
\]

It remains to verify that this holds for all \(t\). Let \(t \notin D\) and let \(t(k) \in P_k\) be the largest point of \(P_k\) which is less than \(t\). Suppose \(t(m) \leq t(k)\) so that \(m \leq k\). Then

\[
X(t(m)) = X_0 + \int_0^{t(m)} Y(s) \, ds,
\]

a similar formula for \(X(t(k))\). Thus for \(t > t(m)\),

\[
X(t) - X(t(m)) = \int_{t(m)}^t Y(s) \, ds
\]

which is the same sort of thing already looked at except that it starts at \(t(m)\) rather than at 0 and \(X_0 = 0\). Therefore,

\[
|X(t(k)) - X(t(m))|^2 = 2 \int_{t(m)}^{t(k)} \langle Y(s), X(s) - X(t(m)) \rangle \, ds
\]

Thus, for \(m \leq k\)

\[
\lim_{m,k \to \infty} |X(t(k)) - X(t(m))|^2 = 0
\]

Hence \(\{X(t(k))\}_{k=1}^\infty\) is a convergent sequence in \(H\). Does it converge to \(X(t)\)? Let \(\xi(t) \in H\) be what it does converge to. Let \(v \in V\). Then

\[
(\xi(t), v) = \lim_{k \to \infty} (X(t(k)), v) = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \langle X(t), v \rangle = (X(t), v)
\]
because it is known that \( t \to X(t) \) is continuous into \( V' \) and it is also known that \( X(t) \in H \) and that the \( X(t) \) for \( t \in [0,T] \) are uniformly bounded. Therefore, since \( V \) is dense in \( H \), it follows that \( \xi(t) = X(t) \).

Now for every \( t \in D \), it was shown above that

\[
|X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds
\]

Thus, using what was just shown, if \( t \notin D \) and \( t_k \to t \),

\[
|X(t)|^2 = \lim_{k \to \infty} |X(t_k)|^2 = \lim_{k \to \infty} \left( |X_0|^2 + 2 \int_0^{t_k} \langle Y(s), X(s) \rangle \, ds \right)
\]

\[
= |X_0|^2 + 2 \int_0^t \langle Y(s), X(s) \rangle \, ds
\]

which proves the desired formula. From this it follows right away that \( t \to X(t) \) is continuous into \( H \) because it was just shown that \( t \to |X(t)| \) is continuous and \( t \to X(t) \) is weakly continuous. Since Hilbert space is uniformly convex, this implies the \( t \to X(t) \) is continuous. To see this in the special case of Hilbert space,

\[
|X(t) - X(s)|^2 = |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2
\]

Then \( \lim_{t \to s} \left( |X(t)|^2 - 2 \langle X(s), X(t) \rangle + |X(s)|^2 \right) = 0 \) by weak convergence of \( X(t) \) to \( X(s) \) and the convergence of \( |X(t)|^2 \) to \( |X(s)|^2 \).

### 67.4 The Implicit Case

The above theorem can be generalized to the case where the formula is of the form

\[
BX(t) = BX_0 + \int_0^t Y(s) \, ds
\]

This involves an operator \( B \in \mathcal{L}(W,W') \) and \( B \) satisfies

\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle
\]

for

\[
V \subseteq W, W' \subseteq V'
\]

Where \( V \) is dense in the Hilbert space \( W \). Before giving the theorem, here is a technical lemma.

**Lemma 67.4.1** Suppose \( V, W \) are separable Banach spaces, \( W \) also a Hilbert space such that \( V \) is dense in \( W \) and \( B \in \mathcal{L}(W,W') \) satisfies

\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle, \quad B \neq 0.
\]
Then there exists a countable set \( \{e_i\} \) of vectors in \( V \) such that
\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]
and for each \( x \in W \),
\[
\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,
\]
and also
\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i,
\]
the series converging in \( W' \).

**Proof:** Let \( \{g_k\}_{k=1}^{\infty} \) be linearly independent vectors of \( V \) whose span is dense in \( V \). This is possible because \( V \) is separable. Thus, their span is also dense in \( W \). Let \( n_1 \) be the first index such that \( \langle Bg_{n_1}, g_{n_1} \rangle \neq 0 \).

**Claim:** If there is no such index, then \( B = 0 \).

**Proof of claim:** First note that if there is no such first index, then if \( x = \sum_{i=1}^{k} a_i g_i \)
\[
|\langle Bx, y \rangle| = \left| \sum_{i \neq j} a_i a_j \langle Bg_i, g_j \rangle \right| \leq \sum_{i \neq j} |a_i| |a_j| |\langle Bg_i, g_j \rangle| \leq \sum_{i \neq j} |a_i| |a_j| |\langle Bg_i, g_j \rangle|^{1/2} (\langle Bg_j, g_j \rangle)^{1/2} = 0
\]
Therefore, if \( x \) is given, you could take \( x_k \) in the span of \( \{g_1, \ldots, g_k\} \) such that \( \|x_k - x\|_W \to 0 \). Then
\[
|\langle Bx, y \rangle| = \lim_{k \to \infty} |\langle Bx_k, y \rangle| \leq \lim_{k \to \infty} \langle Bx_k, x_k \rangle^{1/2} (\langle By, y \rangle)^{1/2} = 0
\]
because \( \langle Bx_k, x_k \rangle \) is zero by what was just shown.

Thus assume there is such a first index. Let
\[
e_1 = \frac{g_{n_1}}{\langle Bg_{n_1}, g_{n_1} \rangle^{1/2}}
\]
Then \( \langle Be_1, e_1 \rangle = 1 \). Now if you have constructed \( e_j \) for \( j \leq k \),
\[
e_j \in \text{span}(g_{n_1}, \ldots, g_{n_k}), \quad \langle Be_i, e_j \rangle = \delta_{ij},
\]
g_{n_{j+1}} being the first for which
\[
\left( Bg_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j+1}}, e_i \rangle Be_i, g_{n_{j+1}} - \sum_{i=1}^{j} \langle Bg_{n_{j}}, e_i \rangle e_i \right) \neq 0,
\]
and

\[ \text{span}(g_{n_1}, \cdots, g_{n_k}) = \text{span}(e_1, \cdots, e_k), \]

let \( g_{n+1} \) be such that \( g_{n+1} \) is the first in the list \( \{g_n\} \) such that

\[ \left\langle Bg_{n+1} - \sum_{i=1}^{k} \langle Bg_{n+1}, e_i \rangle Be_i, g_{n+1} - \sum_{i=1}^{k} \langle Bg_{n+1}, e_i \rangle e_i \right\rangle \neq 0 \]

Note the difference between this and the Gram Schmidt process. Here you don’t necessarily use all of the \( g_k \) due to the possible degeneracy of \( B \).

**Claim:** If there is no such first \( g_{n+1} \), then \( B(\text{span}(e_1, \cdots, e_k)) = BW \) so in this case, \( \{Be_i\}_{i=1}^{k} \) is actually a basis for \( BW \).

**Proof:** Let \( x \in W \). Let \( x_r \in \text{span}(g_1, \cdots, g_r), r > n_k \) such that \( \lim_{r \to \infty} x_r = x \) in \( W \). Then

\[ x_r = \sum_{i=1}^{k} c^*_i e_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^{r} d^*_i g_i = y_r + z, \quad (67.4.17) \]

If \( l \notin \{n_1, \cdots, n_k\} \), then by the construction and the above assumption, for some \( j \leq k \)

\[ \left\langle Bg_l - \sum_{i=1}^{j} \langle Bg_l, e_i \rangle Be_i, g_l - \sum_{i=1}^{j} \langle Bg_l, e_i \rangle e_i \right\rangle = 0 \quad (67.4.18) \]

If \( l < n_k \), this follows from the construction. If the above is nonzero all \( j \leq k \), then \( l \) would have been chosen but it wasn’t. Thus

\[ Bg_l = \sum_{i=1}^{j} \langle Bg_l, e_i \rangle Be_i \]

If \( l > n_k \), then by assumption, \text{[Reference]} holds for \( j = k \). Thus, in any case, it follows that for each \( l \notin \{n_1, \cdots, n_k\} \),

\[ Bg_l \in B(\text{span}(e_1, \cdots, e_k)) \]

Now it follows from \text{[Reference]} that

\[ Bx_r = \sum_{i=1}^{k} c^*_i Be_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^{r} d^*_i Bg_i \]

\[ = \sum_{i=1}^{k} c^*_i Be_i + \sum_{i \notin \{n_1, \cdots, n_k\}}^{r} d^*_i \sum_{j=1}^{k} c^*_j Be_j \]

and so \( Bx_r \in B(\text{span}(e_1, \cdots, e_k)) \). Then \( Bx = \lim_{r \to \infty} Bx_r = \lim_{r \to \infty} By_r \) where \( y_r \in \text{span}(e_1, \cdots, e_k) \). Say

\[ Bx_r = \sum_{i=1}^{k} a^*_i Be_i \]
It follows easily that \( \langle Bx_r, e_j \rangle = a_r^j \). (Act on \( e_j \) by both sides and use \( \langle Be_i, e_j \rangle = \delta_{ij} \).) Now since \( x_r \) is bounded, it follows that these \( a_r^j \) are also bounded. Hence, defining \( y_r = \sum_{i=1}^k a_r^i e_i \), it follows that \( y_r \) is bounded in \( \operatorname{span} \{ e_i, \ldots, e_k \} \) and so, there exists a subsequence, still denoted by \( r \) such that \( y_r \to y \in \operatorname{span} \{ e_i, \ldots, e_k \} \). Therefore, \( Bx = \lim_{r \to \infty} By_r = By \). In other words, \( BW = B \left( \operatorname{span} \{ e_i, \ldots, e_k \} \right) \) as claimed. This proves the claim.

If this happens, the process being described stops. You have found what is desired which has only finitely many vectors involved.

As long as the process does not stop, let

\[
e_{k+1} = \frac{g_{n_{k+1}} - \sum_{i=1}^k \langle Bg_{n_{k+1}}, e_i \rangle e_i}{\sqrt{\left\langle B \left( g_{n_{k+1}} - \sum_{i=1}^k \langle Bg_{n_{k+1}}, e_i \rangle e_i \right), g_{n_{k+1}} - \sum_{i=1}^k \langle Bg_{n_{k+1}}, e_i \rangle e_i \right\rangle}}
\]

Thus, as in the usual argument for the Gram Schmidt process, \( \langle Be_i, e_j \rangle = \delta_{ij} \) for \( i, j \leq k + 1 \). This is already known for \( i, j \leq k \). Letting \( l \leq k \), and using the orthogonality already shown,

\[
\langle Be_{k+1}, e_l \rangle = C \left\langle B \left( g_{n_{k+1}} - \sum_{i=1}^k \langle Bg_{n_{k+1}}, e_i \rangle e_i \right), e_l \right\rangle
= C \left( \langle Bg_{k+1}, e_l \rangle - \langle Bg_{n_{k+1}}, e_l \rangle \right) = 0
\]

Consider

\[
\left\langle Bg_p - B \left( \sum_{i=1}^k \langle Bg_p, e_i \rangle e_i \right), g_p - \sum_{i=1}^k \langle Bg_p, e_i \rangle e_i \right\rangle
\]

Either this equals 0 because \( p \) is never one of the \( n_k \) or eventually it equals 0 for some \( k \) because \( g_p = g_{n_k} \) for some \( n_k \) and so, from the construction, \( g_{n_k} = g_p \in \operatorname{span} \{ e_1, \ldots, e_k \} \) and therefore,

\[
g_p = \sum_{j=1}^k a_j e_j
\]

which requires easily that

\[
Bg_p = \sum_{i=1}^k \langle Bg_p, e_i \rangle Be_i,
\]

the above holding for all \( k \) large enough. It follows that for any \( x \in \operatorname{span} \{ g_k \}_{k=1}^\infty \),

(\text{finite linear combination of vectors in } \{ g_k \}_{k=1}^\infty)

\[
Bx = \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i
\]  \hspace{1cm} (67.4.19)
because for all $k$ large enough,

$$Bx = \sum_{i=1}^{k} \langle Bx, e_i \rangle Be_i$$

Also note that for such $x \in \text{span}(\{g_k\}_{k=1}^{\infty})$,

$$\langle Bx, x \rangle = \left\langle \sum_{i=1}^{k} \langle Bx, e_i \rangle Be_i, x \right\rangle = \sum_{i=1}^{k} \langle Bx, e_i \rangle \langle Bx, e_i \rangle$$

$$= \sum_{i=1}^{k} |\langle Bx, e_i \rangle|^2 = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2$$

Now for $x$ arbitrary, let $x_k \to x$ in $W$ where $x_k \in \text{span}(\{g_k\}_{k=1}^{\infty})$. Then by Fatou’s lemma,

$$\sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2 \leq \liminf_{k \to \infty} \sum_{i=1}^{\infty} |\langle Bx_k, e_i \rangle|^2$$

$$= \liminf_{k \to \infty} \langle Bx_k, x_k \rangle = \langle Bx, x \rangle \quad (67.4.20)$$

Thus the series on the left converges. Then also, from the above inequality,

$$\left| \sum_{i=p}^{q} \langle Bx, e_i \rangle Be_i, y \right| \leq \sum_{i=p}^{q} \langle Bx, e_i \rangle |\langle Be_i, y \rangle|$$

$$\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=p}^{q} |\langle By, e_i \rangle|^2 \right)^{1/2}$$

$$\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=1}^{\infty} |\langle By, e_i \rangle|^2 \right)^{1/2}$$

By [10.4.20]

$$\leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left( \|B\| \|y\|_W^2 \right)^{1/2} \leq \left( \sum_{i=p}^{q} |\langle Bx, e_i \rangle|^2 \right)^{1/2} \|B\|^{1/2} \|y\|_W$$

It follows that

$$\sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i \quad (67.4.21)$$
converges in $W'$ because it was just shown that
\[ \left\| \sum_{i=p}^q \langle Bx, e_i \rangle Be_i \right\|_{W'} \leq \left( \sum_{i=p}^q |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left\| B \right\|_{W'}^{1/2} \]
and it was shown above that $\sum_{i=1}^\infty |\langle Bx, e_i \rangle|^2 < \infty$, so the partial sums of the series are a Cauchy sequence in $W'$. Also, the above estimate shows that for $\|y\| = 1$,
\[ \left\| \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i, y \right\| \leq \left( \sum_{i=1}^\infty |\langle By, e_i \rangle|^2 \right)^{1/2} \left( \sum_{i=1}^\infty |\langle Bx, e_i \rangle|^2 \right)^{1/2} \]
and so
\[ \left\| \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i \right\|_{W'} \leq \left( \sum_{i=1}^\infty |\langle Bx, e_i \rangle|^2 \right)^{1/2} \left\| B \right\|_{W'}^{1/2} \quad (67.4.22) \]

Now for $x$ arbitrary, let $x_k \in \text{span} \left( \{g_j\}_{j=1}^\infty \right)$ and $x_k \to x$ in $W$. Then for a fixed $k$ large enough,
\[ \left\| Bx - \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i \right\| \leq \| Bx - Bx_k \| + \left\| Bx_k - \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i \right\| + \left\| \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i - \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i \right\| \leq \varepsilon + \left\| \sum_{i=1}^\infty \langle B(x_k - x), e_i \rangle Be_i \right\|, \]
the term
\[ \left\| Bx_k - \sum_{i=1}^\infty \langle Bx_k, e_i \rangle Be_i \right\| \]
equaling 0 by $|\langle Bx, e_i \rangle|^2 < \infty$. From $67.4.14$ and $67.4.15$,
\[ \leq \varepsilon + \| B \|^{1/2} \left( \sum_{i=1}^\infty |\langle B(x_k - x), e_i \rangle|^2 \right)^{1/2} \leq \varepsilon + \| B \|^{1/2} \langle B(x_k - x), x_k - x \rangle^{1/2} < 2\varepsilon \]
whenever $k$ is large enough. Therefore,
\[ Bx = \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i \]
in $W'$. It follows that
\[
(Bx, x) = \lim_{k \to \infty} \left( \sum_{i=1}^{k} (Bx, e_i) Be_i, x \right) = \lim_{k \to \infty} \sum_{i=1}^{k} |(Bx, e_i)|^2 \equiv \sum_{i=1}^{\infty} |(Bx, e_i)|^2 \quad \blacksquare
\]

**Theorem 67.4.2** Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, $W$ a separable Hilbert space, and let $Y \in L^p((0, T); V') \equiv K'$ and
\[
BX(t) = BX_0 + \int_0^t Y(s) \, ds \quad \text{in} \quad V'
\]  
(67.4.23)
where $X_0 \in W$, and it is known that $X \in L^p((0, T); V) \equiv K$ for $p > 1$. Then $t \to BX(t)$ is in $C([0, T], W')$ and also
\[
\frac{1}{2} \langle BX(t), X(t) \rangle = \frac{1}{2} \langle BX_0, X_0 \rangle + \int_0^t \langle Y(s), X(s) \rangle \, ds
\]

**Proof:** By Lemma 63.3.1 there exists a sequence of uniform partitions \( \{t^n_k\}_{k=0}^{m_n} = \mathcal{P}_n, \mathcal{P}_n \subseteq \mathcal{P}_{n+1}, \) of $[0, T]$ such that the step functions
\[
\sum_{k=0}^{m_n-1} X(t^n_k) \mathcal{X}(t^n_k, t^n_{k+1}) (t) = X^l(t)
\]
\[
\sum_{k=0}^{m_n-1} X(t^n_{k+1}) \mathcal{X}(t^n_k, t^n_{k+1}) (t) = X^r(t)
\]
converge to $X$ in $K$ and also $BX^l, BX^r \to BX$ in $L^2([0, T], W')$.

**Lemma 67.4.3** Let $s < t$. Then for $X, Y$ satisfying 67.4.23
\[
\langle BX(t), X(t) \rangle = \langle BX(s), X(s) \rangle + 2 \int_s^t \langle Y(u), X(t) \rangle \, du - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]  
(67.4.24)

**Proof:** It follows from the following computations
\[
B(X(t) - X(s)) = \int_s^t Y(u) \, du
\]
and so
\[
2 \int_s^t \langle Y(u), X(t) \rangle \, du - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]
\[
= 2 \langle B(X(t) - X(s)), X(t) \rangle - \langle B(X(t) - X(s)), (X(t) - X(s)) \rangle
\]
\[
= 2 \langle BX(t), X(t) \rangle - 2 \langle BX(s), X(t) \rangle - \langle BX(t), X(t) \rangle
\]
\[
+ 2 \langle BX(s), X(t) \rangle - \langle BX(s), X(s) \rangle
\]
= \langle BX (t), X (t) \rangle - \langle BX (s), X (s) \rangle

Thus
\langle BX (t), X (t) \rangle - \langle BX (s), X (s) \rangle
= 2 \int_s^t \langle Y (u), X (t) \rangle \, du - \langle B (X (t) - X (s)), (X (t) - X (s)) \rangle

Lemma 67.4.4 In the above situation,

\sup_{t \in [0, T]} \langle BX (t), X (t) \rangle \leq C \left( \|Y\|_{K'}, \|X\|_K \right)

Also, \( t \to BX (t) \) is weakly continuous with values in \( W' \).

Proof: From the above formula applied to the \( k^{th} \) partition of \([0, T]\) described above,

\langle BX (t_m), X (t_m) \rangle - \langle BX_0, X_0 \rangle = \sum_{j=0}^{m-1} \langle BX (t_{j+1}), X (t_{j+1}) \rangle - \langle BX (t_j), X (t_j) \rangle

= \sum_{j=0}^{m-1} 2 \int_{t_j}^{t_{j+1}} \langle Y (u), X (t_{j+1}) \rangle \, du - \langle B (X (t_{j+1}) - X (t_j)), X (t_{j+1}) - X (t_j) \rangle

= \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y (u), X_k^r (u) \rangle \, du - \langle B (X (t_{j+1}) - X (t_j)), X (t_{j+1}) - X (t_j) \rangle

Thus, discarding the negative terms and denoting by \( P_k \) the \( k^{th} \) of these partitions,

\sup_{t_j \in P_k} \langle BX (t_j), X (t_j) \rangle \leq \langle BX_0, X_0 \rangle + 2 \int_0^T \langle Y (u), X_k^r (u) \rangle \, du

\leq \langle BX_0, X_0 \rangle + 2 \int_0^T \|Y (u)\|_{V'}, \|X_k^r (u)\|_V \, du

\leq \langle BX_0, X_0 \rangle + 2 \left( \int_0^T \|Y (u)\|_{V'}^{p'} \, du \right)^{1/p'} \left( \int_0^T \|X_k^r (u)\|_V^p \, du \right)^{1/p} \leq C \left( \|Y\|_{K'}, \|X\|_K \right)

because these partitions are chosen such that

\lim_{k \to \infty} \left( \int_0^T \|X_k^r (u)\|_V^p \right)^{1/p} = \left( \int_0^T \|X (u)\|_V^p \right)^{1/p}

and so these are bounded. This has shown that for the dense subset of \([0, T]\),

\sup_{t \in D} \langle BX (t), X (t) \rangle < C \left( \|Y\|_{K'}, \|X\|_K \right)
67.4. THE IMPLICIT CASE

From Lemma 67.4.1 above, there exists \( \{e_i\} \subseteq V \) such that \( \langle Be_i, e_j \rangle = \delta_{ij} \) and
\[
\langle BX (t), X (t) \rangle = \sum_{k=1}^{\infty} |\langle BX (t), e_i \rangle|^2 = \sup \sum_{m=1}^{m} |\langle BX (t), e_i \rangle|^2
\]
Since each \( e_i \in V \), and since \( t \rightarrow BX (t) \) is continuous into \( V' \) thanks to the formula 67.4.23, it follows that \( t \rightarrow \sum_{k=1}^{m} |\langle BX (t), e_i \rangle| \) is continuous and so \( t \rightarrow \langle BX (t), X (t) \rangle \) is the sup of continuous functions. Therefore, this function of \( t \) is lower semicontinuous. Since \( D \) is dense in \([0, T]\), it follows that for all \( t \),
\[
\langle BX (t), X (t) \rangle \leq C (\|Y\|_{K'}, \|X\|_K)
\]
It only remains to verify the claim about weak continuity.
Consider now the claim that \( t \rightarrow BX (t) \) is weakly continuous. Letting \( v \in V \),
\[
\lim_{t \rightarrow s} \langle BX (t), v \rangle = \langle BX (s), v \rangle = \langle BX (s), v \rangle
\]
The limit follows from the formula 67.4.25 which implies \( t \rightarrow BX (t) \) is continuous into \( V' \). Now
\[
\|BX (t)\| = \sup_{\|v\| \leq 1} |\langle BX (t), v \rangle| \leq \langle Bv, v \rangle^{1/2} \langle BX (t), X (t) \rangle^{1/2}
\]
which was shown to be bounded for \( t \in [0, T] \). Now let \( w \in W \). Then
\[
|\langle BX (t), w \rangle - \langle BX (s), w \rangle| \leq |\langle BX (t) - BX (s), w - v \rangle| + |\langle BX (t) - BX (s), v \rangle|
\]
Then the first term is less than \( \varepsilon \) if \( v \) is close enough to \( w \) and the second converges to 0 so 67.4.22 holds for all \( v \in W \) and so this shows the weak continuity. 

Now pick \( t \in D \), the union of all the mesh points. Then for all \( k \) large enough, \( t \in P_k \). Say \( t = t_m \). From Lemma 67.4.3,
\[
-\sum_{j=0}^{m-1} \langle B (X (t_{j+1}) - X (t_j)), (X (t_{j+1}) - X (t_j)) \rangle = \langle BX (t_m), X (t_m) \rangle - \langle BX_0, X_0 \rangle - 2 \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y (u), X (u) \rangle \, du
\]
Thus, \( \langle BX (t_m), X (t_m) \rangle \) is constant for all \( k \) large enough and the integral term converges to
\[
\int_{0}^{t_m} \langle Y (u), X (u) \rangle \, du
\]
It follows that the term on the left does converge to something as \( k \rightarrow \infty \). It just remains to consider what it does converge to. However, from the equation solved by \( X \),
\[
BX (t_{j+1}) - BX (t_j) = \int_{t_j}^{t_{j+1}} Y (u) \, du
\]
Therefore, this term is dominated by an expression of the form

\[
\sum_{j=0}^{m_k-1} \left( \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right)
\]

\[
= \sum_{j=0}^{m_k-1} \left\langle \int_{t_j}^{t_{j+1}} Y(u) \, du, X(t_{j+1}) - X(t_j) \right\rangle
\]

\[
= \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X(t_{j+1}) - X(t_j) \rangle \, du
\]

However, both \(X_r\) and \(X_l\) converge to \(X\) in \(K = L^p(0,T;V)\). Therefore, this term must converge to 0. Passing to a limit, it follows that for all \(t \in D\), the desired formula holds. Thus, for such \(t \in D\),

\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(u) \rangle \, du
\]

It remains to verify that this holds for all \(t\). Let \(t \notin D\) and let \(t(k) \in P_k\) be the largest point of \(P_k\) which is less than \(t\). Suppose \(t(m) \leq t(k)\) so that \(m \leq k\). Then

\[
BX(t(m)) = BX_0 + \int_0^{t(m)} Y(s) \, ds,
\]

a similar formula for \(X(t(k))\). Thus for \(t > t(m)\),

\[
BX(t) - BX(t(m)) = \int_{t(m)}^t Y(s) \, ds
\]

which is the same sort of thing already looked at except that it starts at \(t(m)\) rather than at 0 and \(X_0 = 0\). Therefore,

\[
\langle B(X(t(k)) - X(t(m))), X(t(k)) - X(t(m)) \rangle = 2 \int_{t(m)}^{t(k)} \langle Y(s), X(s) - X(t(m)) \rangle \, ds
\]

Thus, for \(m \leq k\)

\[
\lim_{m,k \to \infty} \langle B(X(t(k)) - X(t(m))), X(t(k)) - X(t(m)) \rangle = 0 \quad (67.4.26)
\]
Hence \( \{BX(t(k))\}_{k=1}^{\infty} \) is a convergent sequence in \( W' \) because

\[
\left| \langle B(X(t(k)) - X(t(m)), y \rangle \right| \\
\leq \langle B(X(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle^{1/2} \langle By, y \rangle^{1/2} \\
\leq \langle B(X(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle^{1/2} ||B||^{1/2} ||y||_W
\]

Does it converge to \( BX(t) \)? Let \( \xi(t) \in W' \) be what it does converge to. Let \( v \in V \).

Then

\[
\langle \xi(t), v \rangle = \lim_{k \to \infty} \langle BX(t(k)), v \rangle = \lim_{k \to \infty} \langle BX(t(k)), v \rangle = \langle BX(t), v \rangle
\]

because it is known that \( t \to BX(t) \) is continuous into \( V' \). It is also known that \( BX(t) \in W' \subseteq V' \) and that the \( BX(t) \) for \( t \in [0,T] \) are uniformly bounded in \( W' \). Therefore, since \( V \) is dense in \( W \), it follows that \( \xi(t) = BX(t) \).

Now for every \( t \in D \), it was shown above that

\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(u) \rangle du
\]

Also it was just shown that \( BX(t(k)) \to BX(t) \). Then

\[
\left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right| \\
\leq \left| \langle BX(t(k)), X(t(k)) - X(t) \rangle \right| + \left| \langle BX(t(k)) - BX(t), X(t) \rangle \right|
\]

Then the second term converges to 0. The first equals

\[
\left| \langle BX(t(k)) - BX(t), X(t(k)) \rangle \right| \\
\leq \langle B(X(t(k)) - X(t)), X(t(k)) - X(t) \rangle^{1/2} \langle BX(t(k)), X(t(k)) \rangle^{1/2}
\]

From the above, this is dominated by an expression of the form

\[
\langle B(X(t(k)) - X(t)), X(t(k)) - X(t) \rangle^{1/2} C
\]

Then using the lower semicontinuity of \( t \to \langle B(X(t(k)) - X(t)), X(t(k)) - X(t) \rangle \) which follows from the above, this is no longer than

\[
\lim_{m \to \infty} \inf \langle B(X(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle^{1/2} C < \varepsilon
\]

provided \( k \) is large enough. This follows from \( \text{[7.3.20]} \). Since \( \varepsilon \) is arbitrary, it follows that

\[
\lim_{k \to \infty} \left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right| = 0
\]

Then from the formula,

\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(u) \rangle du
\]
valid for \( t \in D \), it follows that the same formula holds for all \( t \). This formula implies \( t \rightarrow \langle BX(t), X(t) \rangle \) is continuous. Also recall that \( t \rightarrow BX(t) \) was shown to be weakly continuous into \( W' \). Then
\[
\langle B(X(t) - X(s)), X(t) - X(s) \rangle = \langle BX(t), X(t) \rangle - 2\langle BX(t), X(s) \rangle + \langle BX(s), X(s) \rangle
\]
From this, it follows that \( t \rightarrow BX(t) \) is continuous into \( W' \) because \( \lim_{t \to s} \) of the right side gives 0 and so the same is true of the left. Hence,
\[
\|B(X(t) - X(s)), y)\| \leq \langle By, y \rangle^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \leq \|B\|^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \|y\|
\]
so
\[
\|B(X(t) - X(s))\|_{W'} \leq \|B\|^{1/2} \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2}
\]
which converges to 0 as \( t \to s \).

### 67.5 Some Imbedding Theorems

The next theorem is very useful in getting estimates in partial differential equations. It is called Erling’s lemma.

**Definition 67.5.1** Let \( E, W \) be Banach spaces such that \( E \subseteq W \) and the injection map from \( E \) into \( W \) is continuous. The injection map is said to be compact if every bounded set in \( E \) has compact closure in \( W \). In other words, if a sequence is bounded in \( E \) it has a convergent subsequence converging in \( W \). This is also referred to by saying that bounded sets in \( E \) are precompact in \( W \).

**Theorem 67.5.2** Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Then for every \( \varepsilon > 0 \) there exists a constant, \( C_\varepsilon \) such that for all \( u \in E \),
\[
\|u\|_W \leq \varepsilon \|u\|_E + C_\varepsilon \|u\|_X
\]

**Proof:** Suppose not. Then there exists \( \varepsilon > 0 \) and for each \( n \in \mathbb{N} \), \( u_n \) such that
\[
\|u_n\|_W > \varepsilon \|u_n\|_E + n\|u_n\|_X
\]
Now let \( v_n = u_n/\|u_n\|_E \). Therefore, \( \|v_n\|_E = 1 \) and
\[
\|v_n\|_W > \varepsilon + n\|v_n\|_X
\]
It follows there exists a subsequence, still denoted by \( v_n \) such that \( v_n \) converges to \( v \) in \( W \). However, the above inequality shows that \( \|v_n\|_X \to 0 \). Therefore, \( v = 0 \). But then the above inequality would imply that \( \|v_n\| > \varepsilon \) and passing to the limit yields \( 0 > \varepsilon \), a contradiction.
Define $C ([a, b]; X)$ the space of functions continuous at every point of $[a, b]$ having values in $X$.

You should verify that this is a Banach space with norm

$$
||u||_{\infty, X} = \max \{ ||u_{n_k}(t) - u(t)||_X : t \in [a, b] \} .
$$

The following theorem is an infinite dimensional version of the Ascoli Arzela theorem. It is like a well known result due to Simon. It is the appropriate generalization to stochastic problems in which you do not have weak derivatives. See Theorem 63.12.1 on the Holder continuity of the stochastic integral.

**Theorem 67.5.4** Let $q > 1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$
\{ u \text{ such that } ||u(t)||_E \leq R \text{ for all } t \in [a, b], \text{ and } ||u(s) - u(t)||_X \leq R|t - s|^{1/q} \} .
$$

Thus $S$ is bounded in $L^\infty (0, T, E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C ([a, b]; W)$ and if $\{ u_n \} \subseteq S$, there exists a subsequence, $\{ u_{n_k} \}$ which converges to a function $u \in C ([a, b]; W)$ in the following way.

$$
\lim_{k \to \infty} ||u_{n_k} - u||_{\infty, W} = 0 .
$$

**Proof:** First consider the issue of $S$ being a subset of $C ([a, b]; W)$. Let $\varepsilon > 0$ be given. Then by Theorem 67.5.4 there exists a constant, $C_\varepsilon$ such that for all $u \in W$

$$
||u||_W \leq \frac{\varepsilon}{4R} ||u||_E + C_\varepsilon ||u||_X .
$$

Therefore, for all $u \in S$,

$$
||u(t) - u(s)||_W \leq \frac{\varepsilon}{6R} ||u(t) - u(s)||_E + C_\varepsilon ||u(t) - u(s)||_X
$$

$$
\leq \frac{\varepsilon}{6R} (||u(t)||_E + ||u(s)||_E) + C_\varepsilon ||u(t) - u(s)||_X
$$

$$
\leq \frac{\varepsilon}{3} + C_\varepsilon R|t - s|^{1/q} .
$$

(67.5.27)

Since $\varepsilon$ is arbitrary, it follows $u \in C ([a, b]; W)$.

Let $D = \mathbb{Q} \cap [a, b]$ so $D$ is a countable dense subset of $[a, b]$. Let $D = \{ t_n \}_{n=1}^\infty$. By compactness of the embedding of $E$ into $W$, there exists a subsequence $u_{(n,1)}$ such that as $n \to \infty$, $u_{(n,1)} (t_1)$ converges to a point in $W$. Now take a subsequence of this, called $(n, 2)$ such that as $n \to \infty$, $u_{(n,2)} (t_2)$ converges to a point in $W$. It follows that $u_{(n,2)} (t_1)$ also converges to a point of $W$. Continue this way. Now consider the diagonal sequence, $u_k \equiv u_{(k,k)}$. This sequence is a subsequence of $u_{(n,t)}$ whenever $k > l$. Therefore, $u_k (t_j)$ converges for all $t_j \in D$.

**Claim:** Let $\{ u_k \}$ be as just defined, converging at every point of $D = [a, b] \cap \mathbb{Q}$. Then $\{ u_k \}$ converges at every point of $[a, b]$. 
Proof of claim: Let \( \varepsilon > 0 \) be given. Let \( t \in [a,b] \). Pick \( t_m \in D \cap [a,b] \) such that in \( 67.5.27 \) \( C \varepsilon R |t - t_m| < \varepsilon / 3 \). Then there exists \( N \) such that if \( l, n > N \), then \( \|u_l(t_m) - u_n(t_m)\|_X < \varepsilon / 3 \). It follows that for \( l, n > N \),
\[
\begin{align*}
\|u_l(t) - u_n(t)\|_W &\leq \|u_l(t) - u_l(t_m)\|_W + \|u_l(t_m) - u_n(t_m)\|_W + \|u_n(t_m) - u_n(t)\|_W \\
&\leq \frac{2\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} < 2\varepsilon
\end{align*}
\]
Since \( \varepsilon \) was arbitrary, this shows \( \{u_k(t)\}_{k=1}^\infty \) is a Cauchy sequence. Since \( W \) is complete, this shows this sequence converges.

Now let \( s \neq t \). Then
\[
\|u_n(s) - u_m(s)\|_W \leq \|u_n(s) - u_n(t)\|_W + \|u_n(t) - u_m(t)\|_W + \|u_m(t) - u_m(s)\|_W
\]
From \( 67.5.27 \)
\[
\|u_n(s) - u_m(s)\|_W \leq 2 \left( \frac{\varepsilon}{3} + C \varepsilon R |t - s|^{1/2} \right) + \|u_n(t) - u_m(t)\|_W
\]
and so it follows that if \( \delta \) is sufficiently small and \( s \in B(t, \delta) \), then when \( n, m > N \),
\[
\|u_n(s) - u_m(s)\| < \varepsilon.
\]
Since \( [a,b] \) is compact, there are finitely many of these balls, \( \{B(t_i, \delta)\}_{i=1}^p \), such that for \( s \in B(t_i, \delta) \) and \( n, m > N_i \), the above inequality holds. Let \( N > \max \{N_i, \cdots , N_p\} \). Then if \( m, n > N \) and \( s \in [a,b] \) is arbitrary, it follows the above inequality must hold. Therefore, this has shown the following claim.

Claim: Let \( \varepsilon > 0 \) be given. Then there exists \( N \) such that if \( m, n > N \), then
\[
\|u_n - u_m\|_{\infty, W} < \varepsilon.
\]
Now let \( u(t) = \lim_{k \to \infty} u_k(t) \).
\[
\|u(t) - u(s)\|_W \leq \|u(t) - u_n(t)\|_W + \|u_n(t) - u_n(s)\|_W + \|u_n(s) - u(s)\|_W
\]
(67.5.28)
Let \( N \) be in the above claim and fix \( n > N \). Then
\[
\|u(t) - u_n(t)\|_W = \lim_{m \to \infty} \|u_m(t) - u_n(t)\|_W \leq \varepsilon
\]
and similarly, \( \|u_n(s) - u(s)\|_W \leq \varepsilon \). Then if \( |t - s| \) is small enough, \( 67.5.27 \) shows the middle term in (67.5.28) is also smaller than \( \varepsilon \). Therefore, if \( |t - s| \) is small enough,
\[
\|u(t) - u(s)\|_W < 3\varepsilon.
\]
Thus \( u \) is continuous. Finally, let \( N \) be as in the above claim. Then letting \( m, n > N \), it follows that for all \( t \in [a,b] \),
\[
\|u_m(t) - u_n(t)\|_W < \varepsilon.
\]
Therefore, letting \( m \to \infty \), it follows that for all \( t \in [a, b] \),

\[
\|u(t) - u_n(t)\|_W \leq \varepsilon.
\]

and so \( \|u - u_n\|_{\infty, W} \leq \varepsilon \). \( \blacksquare \)

Here is an interesting corollary. Recall that for \( E \) a Banach space \( C^{0, \alpha}([0, T], E) \) is the space of continuous functions \( u \) from \([0, T]\) to \( E \) such that

\[
\|u\|_{\alpha, E} \equiv \|u\|_{\infty, E} + \rho_{\alpha, E}(u) < \infty
\]

where here

\[
\rho_{\alpha, E}(u) \equiv \sup_{t \neq s} \frac{|u(t) - u(s)|_E}{|t - s|^{\alpha}}
\]

**Corollary 67.5.5** Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Then if \( \gamma > \alpha \), the embedding of \( C^{0, \gamma}([0, T], E) \) into \( C^{0, \alpha}([0, T], X) \) is compact.

**Proof:** Let \( \phi \in C^{0, \gamma}([0, T], E) \)

\[
\frac{\|\phi(t) - \phi(s)\|_X}{|t - s|^\alpha} \leq \left( \frac{\|\phi(t) - \phi(s)\|_W}{|t - s|^{\gamma}} \right)^{\alpha/\gamma} \frac{\|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)}}{\|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)}} \leq \rho_{\gamma, E}(\phi) \|\phi(t) - \phi(s)\|_W^{1-(\alpha/\gamma)}
\]

Now suppose \( \{u_n\} \) is a bounded sequence in \( C^{0, \gamma}([0, T], E) \). By Theorem 67.5.2 above, there is a subsequence still called \( \{u_n\} \) which converges in \( C^0([0, T], W) \). Thus from the above inequality

\[
\frac{\|u_n(t) - u_m(t) - (u_n(s) - u_m(s))\|_X}{|t - s|^\alpha} \leq \rho_{\gamma, E}(u_n - u_m) \|u_n(t) - u_m(t) - (u_n(s) - u_m(s))\|_W^{1-(\alpha/\gamma)} \leq C(\{u_n\}) \left(\frac{2\|u_n - u_m\|_{\infty, W}}{|t - s|}\right)^{1-(\alpha/\gamma)}
\]

which converges to 0 as \( n, m \to \infty \). Thus

\[
\rho_{\alpha, X}(u_n - u_m) \to 0 \text{ as } n, m \to \infty
\]

Also \( \|u_n - u_m\|_{\infty, X} \to 0 \text{ as } n, m \to \infty \) so this is a Cauchy sequence in \( C^{0, \alpha}([0, T], X) \). \( \blacksquare \)

The next theorem is a well known result probably due to Lions.

**Theorem 67.5.6** Let \( E \subseteq W \subseteq X \) where the injection map is continuous from \( W \) to \( X \) and compact from \( E \) to \( W \). Let \( p \geq 1 \), let \( q > 1 \), and define

\[
S \equiv \{u \in L^p([a, b]; E) : \text{ for some } C, \|u(t) - u(s)\|_X \leq C|t - s|^{1/q}\}
\]
and \( \|u\|_{L^p([a,b]; E)} \leq R \). 

Thus \( S \) is bounded in \( L^p([a,b]; E) \) and Holder continuous into \( X \). Then \( S \) is pre-compact in \( L^p([a,b]; W) \). This means that if \( \{u_n\}_{n=1}^\infty \subseteq S \), it has a subsequence \( \{u_{n_k}\} \) which converges in \( L^p([a,b]; W) \).

**Proof:** By Proposition 6.2.5 on Page 446 it suffices to show \( S \) has an \( \eta \) net in \( L^p([a,b]; W) \) for each \( \eta > 0 \).

If not, there exists \( \eta > 0 \) and a sequence \( \{u_n\} \subseteq S \), such that

\[
\|u_n - u_m\| \geq \eta \quad (67.5.29)
\]

for all \( n \neq m \) and the norm refers to \( L^p([a,b]; W) \). Let \( a = t_0 < t_1 < \cdots < t_k = b \), \( t_i - t_{i-1} = (b - a)/k \).

Now define

\[
\pi_n(t) = \sum_{i=1}^k \pi_n \chi_{[t_{i-1}, t_i]}(t), \quad \pi_n \equiv \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n(s) \, ds.
\]

The idea is to show that \( \pi_n \) approximates \( u_n \) well and then to argue that a subsequence of the \( \{\pi_n\} \) is a Cauchy sequence yielding a contradiction to \( 67.5.29 \).

Therefore,

\[
u_n(t) - \pi_n(t) = \sum_{i=1}^k u_n(t) \chi_{[t_{i-1}, t_i]}(t) - \sum_{i=1}^k \pi_n \chi_{[t_{i-1}, t_i]}(t) \]

\[
= \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n(t) \, ds \chi_{[t_{i-1}, t_i]}(t) - \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} u_n(s) \, ds \chi_{[t_{i-1}, t_i]}(t) \]

\[
= \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} (u_n(t) - u_n(s)) \, ds \chi_{[t_{i-1}, t_i]}(t) .
\]

It follows from Jensen’s inequality that

\[
\|u_n(t) - \pi_n(t)\|_W^p \leq \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \|u_n(t) - u_n(s)\|_W^p \, ds \chi_{[t_{i-1}, t_i]}(t) \]

\[
\leq \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \|u_n(t) - u_n(s)\|_W^p \, ds \chi_{[t_{i-1}, t_i]}(t) .
\]
and so
\[ \int_a^b \| (u_n(t) - \bar{u}_n(s)) \|^p_W \, ds \]
\[ \leq \int_a^b \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \| u_n(t) - u_n(s) \|^p_W \, ds \chi_{[t_{i-1}, t_i)}(t) \, dt \]
\[ = \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} \| u_n(t) - u_n(s) \|^p_W \, ds \, dt. \]  
(67.5.30)

From Theorem 67.5.2 if \( \varepsilon > 0 \), there exists \( C_\varepsilon \) such that
\[ \| u_n(t) - u_n(s) \|^p_W \leq \varepsilon \| u_n(t) - u_n(s) \|^p_E + C_\varepsilon \| u_n(t) - u_n(s) \|^p_X \]
\[ \leq 2^{p-1} \varepsilon (\| u_n(t) \|^p + \| u_n(s) \|^p) + C_\varepsilon |t - s|^{p/q} \]
This is substituted in to 67.5.30 to obtain
\[ \int_a^b \| (u_n(t) - \bar{u}_n(s)) \|^p_W \, ds \leq \]
\[ \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} \left( 2^{p-1} \varepsilon (\| u_n(t) \|^p + \| u_n(s) \|^p) + C_\varepsilon |t - s|^{p/q} \right) \, ds \, dt \]
\[ = \sum_{i=1}^k 2^p \varepsilon \int_{t_{i-1}}^{t_i} \| u_n(t) \|^p \, dt + \frac{C_\varepsilon}{t_i - t_{i-1}} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} |t - s|^{p/q} \, ds \, dt \]
\[ \leq 2^p \varepsilon \int_a^b \| u_n(t) \|^p \, dt + C_\varepsilon \sum_{i=1}^k \frac{1}{t_i - t_{i-1}} (t_i - t_{i-1})^{p/q} \int_{t_{i-1}}^{t_i} \int_{t_{i-1}}^{t_i} \, ds \, dt \]
\[ = 2^p \varepsilon \int_a^b \| u_n(t) \|^p \, dt + C_\varepsilon \sum_{i=1}^k \frac{1}{(t_i - t_{i-1})^2} (t_i - t_{i-1})^{p/q} (t_i - t_{i-1})^2 \]
\[ \leq 2^p \varepsilon R^p + C_\varepsilon \sum_{i=1}^k (t_i - t_{i-1})^{1+p/q} = 2^p \varepsilon R^p + C_\varepsilon k \left( \frac{b-a}{k} \right)^{1+p/q}. \]

Taking \( \varepsilon \) so small that \( 2^p \varepsilon R^p < \eta p^8/8^p \) and then choosing \( k \) sufficiently large, it follows
\[ \| u_n - \bar{u}_n \|_{L^p([a,b];W)} < \frac{\eta}{4}. \]

Thus \( k \) is fixed and \( \bar{u}_n \) at a step function with \( k \) steps having values in \( E \). Now use compactness of the embedding of \( E \) into \( W \) to obtain a subsequence such that \( \{ \bar{u}_n \} \) is Cauchy in \( L^p(a,b; W) \) and use this to contradict 67.5.3. The details follow.

Suppose \( \bar{u}_n(t) = \sum_{i=1}^k u_i^n \chi_{[t_{i-1}, t_i)}(t) \). Thus
\[ \| \bar{u}_n(t) \|_E = \sum_{i=1}^k |u_i^n|_E \chi_{[t_{i-1}, t_i)}(t) \]
and so
\[ R \geq \int_a^b \| u_n(t) \|_E dt = \frac{T}{k} \sum_{i=1}^k \| u_n^i \|_E \]

Therefore, the \( \{ u_n^i \} \) are all bounded. It follows that after taking subsequences
\( k \) times there exists a subsequence \( \{ u_{n_k} \} \) such that \( u_{n_k} \) is a Cauchy sequence in
\( L^p(a,b;W) \). You simply get a subsequence such that \( u_{n_k}^i \) is a Cauchy sequence in
\( W \) for each \( i \). Then denoting this subsequence by \( n \),
\[
\| u_n - u_m \|_{L^p(a,b,W)} \leq \| u_n - \overline{u}_n \|_{L^p(a,b,W)} + \| \overline{u}_n - \overline{u}_m \|_{L^p(a,b,W)} + \| \overline{u}_m - u_m \|_{L^p(a,b,W)} \\
\leq \frac{\eta}{4} + \| \overline{u}_n - \overline{u}_m \|_{L^p(a,b,W)} + \frac{\eta}{4} < \eta
\]

provided \( m, n \) are large enough, contradicting \( 67.5.29 \).
Chapter 68

Measurability Without Uniqueness

With the Ito formula which holds for a single space, it is time to consider stochastic ordinary differential equations. First is a general theory which allows one to consider measurable solutions to stochastic equations in which there is no uniqueness available. Unfortunately, it does not include obtaining adapted solutions. Instead, it includes measurability of functions with respect to a single \(\sigma\) algebra. Then when path uniqueness is available, one can include the concept of adapted solutions rather easily and this will be done for ordinary differential equations. First is a general result about multifunctions.

68.1 Multifunctions And Their Measurability

Let \(X\) be a separable complete metric space and let \((\Omega, \mathcal{C}, \mu)\) be a set, a \(\sigma\) algebra of subsets of \(\Omega\), and a measure \(\mu\) such that this is a complete \(\sigma\) finite measure space. Also let \(\Gamma : \Omega \to \mathcal{P}_F(X)\), the closed subsets of \(X\).

Definition 68.1.1 We define \(\Gamma^- (S) \equiv \{\omega \in \Omega : \Gamma(\omega) \cap S \neq \emptyset\}\)

We will consider a theory of measurability of set valued functions. The following theorem is the main result in the subject. In this theorem the third condition is what we will refer to as measurable. The second condition is called strongly measurable. More can be said than what we will prove here.

Theorem 68.1.2 In the following, 1. \(\Rightarrow\) 2. \(\Rightarrow\) 3. \(\Rightarrow\) 4.

1. For all \(B\) a Borel set in \(X, \Gamma^- (B) \in \mathcal{C}\).
2. For all \(F\) closed in \(X, \Gamma^- (F) \in \mathcal{C}\)
3. For all \(U\) open in \(X, \Gamma^- (U) \in \mathcal{C}\)

2455
4. There exists a sequence, \( \{ \sigma_n \} \) of measurable functions satisfying \( \sigma_n (\omega) \in \Gamma (\omega) \) such that for all \( \omega \in \Omega \),

\[
\Gamma (\omega) = \{ \sigma_n (\omega) : n \in \mathbb{N} \}
\]

These functions are called measurable selections.

Also 4. \( \Rightarrow \) 3. If \( \Gamma (\omega) \) is compact for each \( \omega \), then also 3. \( \Rightarrow \) 2.

**Proof:** It is obvious that 1.) \( \Rightarrow \) 2.). To see that 2.) \( \Rightarrow \) 3.) note that \( \Gamma^{-} (\bigcup_{i=1}^{\infty} F_{i}) = \bigcup_{i=1}^{\infty} \Gamma^{-} (F_{i}) \). Since any open set in \( X \) can be obtained as a countable union of closed sets, this implies 2.) \( \Rightarrow \) 3.).

Now we verify that 3.) \( \Rightarrow \) 4.). Let \( \{ x_{n} \}_{n=1}^{\infty} \) be a countable dense subset of \( X \). For \( \omega \in \Omega \), let \( \psi_{1} (\omega) = x_{n} \) where \( n \) is the smallest integer such that \( \Gamma (\omega) \cap B (x_{n}, 1) \neq \emptyset \). Therefore, \( \psi_{1} (\omega) \) has countably many values, \( x_{n_{1}}, x_{n_{2}}, \ldots \) where \( n_{1} < n_{2} < \cdots \).

Now

\[
\{ \omega : \psi_{1} = x_{n} \} = \\
\{ \omega : \Gamma (\omega) \cap B (x_{n}, 1) \neq \emptyset \} \cap [\Omega \setminus \bigcup_{k<n} \{ \omega : \Gamma (\omega) \cap B (x_{k}, 1) \neq \emptyset \}] \in \mathcal{C}.
\]

Thus we see that \( \psi_{1} \) is measurable and \( \text{dist} (\psi_{1} (\omega), \Gamma (\omega)) < 1 \). Let

\[
\Omega_{n} \equiv \{ \omega \in \Omega : \psi_{1} (\omega) = x_{n} \}.
\]

Then \( \Omega_{n} \in \mathcal{C} \) and \( \Omega_{n} \cap \Omega_{m} = \emptyset \) for \( n \neq m \) and \( \bigcup_{n=1}^{\infty} \Omega_{n} = \Omega \). Let \( D_{n} \equiv \{ x_{k} : x_{k} \in B (x_{n}, 1) \} \). Now for each \( n \), and \( \omega \in \Omega_{n} \), let \( \psi_{2} (\omega) = x_{k} \) where \( k \) is the smallest index such that \( x_{k} \in D_{n} \) and \( B (x_{k}, \frac{1}{2}) \cap \Gamma (\omega) \neq \emptyset \). Thus \( \text{dist} (\psi_{2} (\omega), \Gamma (\omega)) < \frac{1}{2} \) and \( \text{dist} (\psi_{2} (\omega), \psi_{1} (\omega)) < 1 \). Continue this way obtaining \( \psi_{k} \) a measurable function such that

\[
\text{dist} (\psi_{k} (\omega), \Gamma (\omega)) < \frac{1}{2^{k-1}}, \text{ dist} (\psi_{k} (\omega), \psi_{k+1} (\omega)) < \frac{1}{2^{k-2}}.
\]

Then for each \( \omega, \{ \psi_{k} (\omega) \} \) is a Cauchy sequence converging to a point, \( \sigma (\omega) \in \Gamma (\omega) \).

This has shown that if \( \Gamma \) is measurable there exists a measurable selection, \( \sigma (\omega) \in \Gamma (\omega) \). It remains to show there exists a sequence of these measurable selections, \( \sigma_{n} \) such that the conclusion of 4.) holds. To do this we define

\[
\Gamma_{n_{i}} (\omega) \equiv \begin{cases} 
\Gamma (\omega) \cap B (x_{n}, 2^{-i}) & \text{if } \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \neq \emptyset \\
\Gamma (\omega) & \text{otherwise}.
\end{cases}
\]

First we show that \( \Gamma_{n_{i}} \) is measurable. Let \( U \) be open. Then

\[
\{ \omega : \Gamma_{n_{i}} (\omega) \cap U \neq \emptyset \} = \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \cap U \neq \emptyset \} \cup \\
[\{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) = \emptyset \} \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}] \\
= \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \cap U \neq \emptyset \} \cup \\
[\Omega \setminus \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \neq \emptyset \}] \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \},
\]

\[
\text{dist} (\psi_{k} (\omega), \Gamma (\omega)) < \frac{1}{2^{k-1}}, \text{ dist} (\psi_{k} (\omega), \psi_{k+1} (\omega)) < \frac{1}{2^{k-2}}.
\]

Then for each \( \omega, \{ \psi_{k} (\omega) \} \) is a Cauchy sequence converging to a point, \( \sigma (\omega) \in \Gamma (\omega) \).

This has shown that if \( \Gamma \) is measurable there exists a measurable selection, \( \sigma (\omega) \in \Gamma (\omega) \). It remains to show there exists a sequence of these measurable selections, \( \sigma_{n} \) such that the conclusion of 4.) holds. To do this we define

\[
\Gamma_{n_{i}} (\omega) \equiv \begin{cases} 
\Gamma (\omega) \cap B (x_{n}, 2^{-i}) & \text{if } \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \neq \emptyset \\
\Gamma (\omega) & \text{otherwise}.
\end{cases}
\]

First we show that \( \Gamma_{n_{i}} \) is measurable. Let \( U \) be open. Then

\[
\{ \omega : \Gamma_{n_{i}} (\omega) \cap U \neq \emptyset \} = \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \cap U \neq \emptyset \} \cup \\
[\{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) = \emptyset \} \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \}] \\
= \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \cap U \neq \emptyset \} \cup \\
[\Omega \setminus \{ \omega : \Gamma (\omega) \cap B (x_{n}, 2^{-i}) \neq \emptyset \}] \cap \{ \omega : \Gamma (\omega) \cap U \neq \emptyset \},
\]
a measurable set. By what was just shown there exists \( \sigma_{n_1} \), a measurable function such that \( \sigma_{n_1}(\omega) \in \Gamma_{n_1}(\omega) \subseteq \Gamma(\omega) \) for all \( \omega \in \Omega \). If \( x \in \Gamma(\omega) \), then \( x \in B(x_n, 2^{-i}) \) whenever \( x_n \) is close enough to \( x \). Therefore, \( |\sigma_{n_1}(\omega) - x| < 2^{-i} \). And it follows that condition 4.) holds.

Now we verify that 4.) \( \Rightarrow \) 3.). Suppose there exist measurable selections \( \sigma_n(\omega) \in \Gamma(\omega) \) satisfying condition 4.). Let \( U \) be open. Then

\[
\{ \omega : \Gamma(\omega) \cap U \neq \emptyset \} = \bigcup_{n=1}^{\infty} \sigma_n^{-1}(U) \in \mathcal{C}.
\]

Now suppose \( \Gamma(\omega) \) is compact for every \( \omega \) and that \( \Gamma^{-1}(U) \in \mathcal{C} \) for every \( U \) open. Then let \( F \) be a closed set and let \( \{U_n\} \) be a decreasing sequence of open sets whose intersection equals \( F \) such that also, for all \( n \), \( U_n \supseteq \overline{U_{n+1}} \). Then

\[
\Gamma(\omega) \cap F = \cap_n \Gamma(\omega) \cap U_n = \cap_n \Gamma(\omega) \cap \overline{U_n}.
\]

Now because of compactness, the set on the left is nonempty if and only if each set on the right is also nonempty. Thus \( \Gamma^{-1}(F) = \cap_n \Gamma^{-1}(U_n) \in \mathcal{C} \).

Actually these are all equivalent in the case of complete measure spaces but we do not need this and it is much harder to show.

### 68.2 A Measurable Selection

This section deals with the problem of getting product measurable functions in a context of no uniqueness. The following is the main result. It is stated in great generality because it has fairly wide application although it will be used first in finite dimensions.

**Theorem 68.2.1** Let \( V \) be a reflexive separable Banach space and \( V' \) its dual and \( \frac{1}{p} + \frac{1}{p'} = 1 \) where \( p > 1 \) as usual. For \( n \in \mathbb{N} \) let the functions \( t \to u_n(t, \omega) \) be in \( L^p ([0, T]; V') \) and \( (t, \omega) \to u_n(t, \omega) \) be \( B([0, T]) \times F \equiv \mathcal{P} \) measurable into \( V' \). Suppose there is a set of measure zero \( N \) such that if \( \omega \notin N \), then for all \( n \),

\[
\sup_{t \in [0, T]} \| u_n(t, \omega) \|_{V'} \leq C(\omega).
\]

Also suppose for each \( \omega \notin N \), each subsequence of \( \{u_n\} \) has a further subsequence which converges weakly in \( L^p ([0, T]; V') \) to \( u(\cdot, \omega) \in L^p ([0, T]; V') \) such that \( t \to u(t, \omega) \) is weakly continuous into \( V' \). Then there exists \( u \) product measurable, with \( t \to u(t, \omega) \) being weakly continuous into \( V' \). Moreover, there exists, for each \( \omega \notin N \), a subsequence \( u_{n(\omega)} \) such that \( u_{n(\omega)}(\cdot, \omega) \to u(\cdot, \omega) \) weakly in \( L^p ([0, T]; V') \).

Note that the exceptional set is given. It could be the empty set with no change in the conclusion of the theorem.

Let \( X = \prod_{k=1}^{\infty} C([0, T]) \) with the product topology. One can consider this as a metric space using the metric

\[
d(f, g) = \sum_{k=1}^{\infty} 2^{-k} \frac{\|f_k - g_k\|}{1 + \|f_k - g_k\|},
\]
where the norm is the maximum norm in $C([0, T])$. With this metric, $X$ is complete and separable.

**Lemma 68.2.2** Let $\{f_n\}$ be a sequence in $X$ and suppose that the $k^{th}$ components $f_{nk}$ are bounded in $C^{0,1}([0, T])$. (This refers to the Hölder space with $\gamma = 1$.) Then there exists a subsequence converging to some $f \in X$. Thus if $\{f_n\}$ has each component bounded in $C^{0,1}([0, T])$, then $\{f_n\}$ is pre-compact in $X$.

**Proof:** By the Ascoli–Arzelà theorem, there exists a subsequence $n_1$ such that the first component $f_{n_1,1}$ converges in $C([0, T])$. Then taking a subsequence, one can obtain $n_2$ a subsequence of $n_1$ such that both the first and second components of $f_{n_2}$ converge. Continuing this way one obtains a sequence of subsequences, each a subsequence of the previous one such that $f_{n_j}$ has the first $j$ components converging to functions in $C([0, T])$. Therefore, the diagonal subsequence has the property that it has every component converging to a function in $C([0, T])$. The resulting function in $\prod_k C([0, T])$ is $f$. \[\Box\]

Now for $m \in \mathbb{N}$ and $\phi \in V'$, define $l_m(t) \equiv \max(0, t - (1/m))$ and $\psi_{m,\phi} : L^p([0, T]; V') \to C([0, T])$ as follows

$$\psi_{m,\phi} u(t) = \int_0^T \langle m\phi \chi_{[l_m(t), t]}(s), u(s) \rangle_{V;V}, ds = m \int_{l_m(t)}^t \langle \phi, u(s) \rangle_{V;V}, ds.$$ 

Let $D = \{\phi_r\}_{r=1}^\infty$ denote a countable dense subset of $V$. Then the pairs $(\phi, m)$ for $\phi \in D$ and $m \in \mathbb{N}$ yield a countable set. Let $(m_k, \phi_{r_k})$ denote an enumeration of these pairs $(m, \phi) \in \mathbb{N} \times D$. To save notation, we denote

$$f_k(u)(t) \equiv \psi_{m_k,\phi_{r_k}} u(t) = m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u(s) \rangle_{V;V}, ds.$$ 

For fixed $\omega \notin N$ and $k$, the functions $\{t \mapsto f_k(u_j(\cdot, \omega))(t)\}_j$ are uniformly bounded and equicontinuous because they are in $C^{0,1}([0, T])$. Indeed,

$$|f_k(u_j(\cdot, \omega))(t)| = \left| m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_{V;V}, ds \right| \leq C(\omega) \|\phi_{r_k}\|_{V'}.$$ 

and for $t \leq t'$

$$|f_k(u_j(\cdot, \omega))(t) - f_k(u_j(\cdot, \omega))(t')|$$

$$\leq \left| m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_{V;V}, ds - m_k \int_{l_{m_k}(t')}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_{V;V}, ds \right|$$

$$\leq 2m_k |t' - t| \|\phi_{r_k}\|_{V'}, C(\omega).$$

By Lemma 68.2.2, the set of functions $\{f(u_j(\cdot, \omega))\}_{j=n}^\infty$ is pre-compact in $X = \prod_k C([0, T])$. Then define a set valued map $\Gamma^n : \Omega \to X$ as follows.

$$\Gamma^n(\omega) = \bigcup_{j \geq n} \{f(u_j(\cdot, \omega))\},$$
where the closure is taken in $X$. Then $\Gamma^n(\omega)$ is the closure of a pre-compact set in $\prod_k C([0, T])$ and so $\Gamma^n(\omega)$ is compact in $\prod_k C([0, T])$. From the definition, a function $f$ is in $\Gamma^n(\omega)$ if and only if $d(f, f(w_l)) \to 0$ as $l \to \infty$, where each $w_l$ is one of the $u_j(\cdot, \omega)$ for $j \geq n$. From the topology on $X$ this happens if and only if for every $k$,

$$f_k(t) = \lim_{l \to \infty} m_k \int_{m_k(t)}^t \langle \phi_{\rho_k}, w_l(s, \omega) \rangle_{V, V}, ds,$$

where the limit is the uniform limit in $t$.

Note that in the case of a filtration, instead of a single $\sigma$-algebra $\mathcal{F}$ where each $u_j$ is progressively measurable, if the sequence $w_l$ does not have the index $l$ dependent on $\omega$, then if such a limit holds for each $\omega$, it follows that $(t, \omega) \to f_k(t, \omega)$ will inherit progressive measurability from the $w_l$. This situation will be typical when dealing with stochastic equations with path uniqueness known. Thus this is a reasonable way to attempt to consider measurability and the more difficult question of whether a process is adapted.

**Lemma 68.2.3** $\omega \to \Gamma^n(\omega)$ is a $\mathcal{F}$ measurable set valued map with values in $X$. If $\sigma$ is a measurable selection, $(\sigma(\omega) \in \Gamma^n(\omega)$ so $\sigma = \sigma(\cdot, \omega)$ a continuous function. To have this measurable would mean that $\sigma_k^{-1}(\text{open}) \in \mathcal{F}$ where the open set is in $C([0, T])$. Then for each $t$, $\omega \to \sigma(t, \omega)$ is $\mathcal{F}$ measurable and $(t, \omega) \to \sigma(t, \omega)$ is $B([0, T]) \times \mathcal{F} \equiv \mathcal{P}$ measurable.

**Proof:** Let $O$ be a basic open set in $X$. Thus $O = \prod_{k=1}^\infty O_k$ where $O_k$ is a proper open set of $C([0, T])$ only for $k \in \{k_1, \ldots, k_r\}$. We need to consider whether

$$\Gamma^n(O) \equiv \{\omega : \Gamma^n(\omega) \cap O \neq \emptyset\} \in \mathcal{F}. $$

Now $\Gamma^n(O)$ equals

$$\bigcap_{k=1}^n \{\omega : \Gamma^n(\omega)_{k_i} \cap O_{k_i} \neq \emptyset\} \cap \{\omega : \Gamma^n(\omega)_{k_j} \cap O_{k_j} \neq \emptyset\} \cap \{\omega : \Gamma^n(\omega)_{k_l} \cap O_{k_l} \neq \emptyset\} \cap \ldots \cap \{\omega : \Gamma^n(\omega)_{k_r} \cap O_{k_r} \neq \emptyset\} \in \mathcal{F}$$

(68.2.1)

From the definition of $\Gamma^n(\omega)$, this is equivalent to the condition that for some $j \geq n$,

$$f_{k_i}(u_j(\cdot, \omega)) = (f(u_j(\cdot, \omega)))_{k_i} \in O_{k_i}$$

and so the above set in (68.2.1) is of the form

$$\bigcup_{j=n}^\infty \{\omega : (f(u_j(\cdot, \omega)))_{k_i} \in O_{k_i}\}$$

Now $\omega \to (f(u_j(\cdot, \omega)))_{k_i}$ is $\mathcal{F}$ measurable into $C([0, T])$ and so the above set in $\mathcal{F}$. To see this, let $g \in C([0, T])$ and consider the inverse image of the ball $B(g, r)$,

$$\left\{\omega : \|f(u_j(\cdot, \omega)))_{k_i} - g\|_{C([0, T])} < r\right\}.$$
By continuity considerations,
\[
\left\| \left( f(u_j(\cdot, \omega)) \right)_{k_i} - g \right\|_{C([0, T])} = \sup_{t \in \mathbb{Q} \cap [0, T]} \left| \left( f(u_j(t, \omega)) \right)_{k_i} - g(t) \right|
\]
which is the sup of countably many \( F \) measurable functions. Thus it is \( F \) measurable. Since every open set is the countable union of such balls, it follows that the claim about \( F \) measurability is valid. Thus \( \Gamma^{n-}(O) \) is \( F \) measurable whenever \( O \) is a basic open set.

Now \( X \) is a separable metric space and so every open set is a countable union of these basic sets. Let \( U \) be an open set in \( X \) and let \( U = \bigcup_{i=1}^{\infty} O^i \) where \( O^i \) is a basic open set as above. Then
\[
\Gamma^{n-}(U) = \bigcup_{i=1}^{\infty} \Gamma^{n-}(O^i) \in \mathcal{F}.
\]
That there exists a measurable selection follows from the standard theory of measurable multi-functions [1], [3]. This is proved in Theorem 68.1.2 above. For one of these measurable selections, the evaluation at \( t \) is \( F \) measurable. Thus \( \omega \rightarrow \Gamma(t, \omega) \) is continuous, and so it follows that in fact \( \sigma \) is product measurable as claimed.

**Definition 68.2.4** Let \( \Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma^{n}(\omega) \).

**Lemma 68.2.5** \( \Gamma \) is a nonempty \( F \) measurable set valued function having values in the compact sub-sets of \( X \). There exists a measurable selection \( \gamma \). For \( \gamma \) a \( F \) measurable selection, \( (t, \omega) \rightarrow \gamma(t, \omega) \) is \( P \) measurable. Also, for each \( \omega \), there exists a subsequence, \( u_{n(\omega)}(\cdot, \omega) \) such that for each \( k \),
\[
\gamma_k(t, \omega) = \lim_{n(\omega) \to \infty} f(u_{n(\omega)}(t, \omega)) = \lim_{n(\omega) \to \infty} m_k \int_{m_k(t)}^{t} \phi_{r_k}, u_{n(\omega)}(s, \omega) \rangle_{V, V'} ds
\]

**Proof:** Consider \( \Gamma(\omega) = \cap_{n=1}^{\infty} \Gamma^{n}(\omega) \). Then \( \omega \rightarrow \Gamma(\omega) \) is a compact set valued map in \( X \). It is nonempty because each \( \Gamma^n(\omega) \) is nonempty and compact, and these sets are nested. Is it \( F \) measurable? Each \( \Gamma^n \) is compact valued and \( F \) measurable. Hence if \( F \) is closed,
\[
\Gamma(\omega) \cap F = \cap_{n=1}^{\infty} \Gamma^{n}(\omega) \cap F
\]
and the left is non empty if and only if each \( \Gamma^n(\omega) \cap F \neq \emptyset \). Hence for \( F \) closed,
\[
\{ \omega : \Gamma(\omega) \cap F \neq \emptyset \} = \cap_{n} \{ \omega : \Gamma^{n}(\omega) \cap F \neq \emptyset \}
\]
and so
\[
\Gamma^{-}(F) = \cap_{n} \Gamma^{n-}(F) \in \mathcal{F}
\]
The last claim follows from the theory of multi-functions Theorem 68.1.2, [3], [5]. Since \( \Gamma^n(\omega) \) is compact, the measurability of \( \Gamma^n \), that \( \Gamma^{n-}(U) \in \mathcal{F} \) for \( U \) open implies the strong measurability of \( \Gamma^n \), that \( \Gamma^{n-}(F) \in \mathcal{F} \). Thus \( \omega \rightarrow \Gamma(\omega) \) is non empty compact valued in \( X \) and \( F \) measurable.
68.2. A MEASURABLE SELECTION

From standard theory of measurable multi-functions, Theorem 68.2.1, there exists a $\mathcal{F}$ measurable selection $\omega \to \gamma (\omega)$ with $\gamma (\omega) \in \Gamma (\omega)$ for each $\omega$. Now it follows that $t \to \gamma_k (t, \omega)$ is continuous. This is what it means for $\gamma (\omega) \in X$. What of the product measurability of $\gamma_k$? We know that $\omega \to \gamma_k (t, \omega)$ is $\mathcal{F}$ measurable into $C([0, T])$ and so since pointwise evaluation is continuous, $\omega \to \gamma_k (t, \omega)$ is $\mathcal{F}$ measurable. Then since $t \to \gamma_k (t, \omega)$ is continuous, it follows that $\gamma_k$ is a $\mathcal{P}$ measurable real valued function and that $\gamma$ is a $\mathcal{P}$ measurable $\mathbb{R}^\infty$ valued function.

Since $\gamma (\omega) \in \Gamma (\omega)$, it follows that for each $n, \gamma (\omega) \in \Gamma^n (\omega)$. Therefore, there exists $j_n \geq n$ such that for each $\omega$,

$$d \left( f (u_{j_n} (\cdot, \omega)), \gamma (\omega) \right) < 2^{-n}$$

It follows that, taking a suitable subsequence, denoted as $\{ u_{n(\omega)} (\cdot, \omega) \}$,

$$\gamma (\omega) = \lim_{n(\omega) \to \infty} f \left( u_{n(\omega)} (\cdot, \omega) \right)$$

for each $\omega$. In particular, for each $k$

$$\gamma_k (t, \omega) = \lim_{n(\omega) \to \infty} f \left( u_{n(\omega)} (t, \omega) \right)_k = \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k} (t)}^{t} \langle \phi_{r_k}, u_{n(\omega)} (s, \omega) \rangle_{V, V}, ds$$

(68.2.2)

for each $t$. ■

Note that it is not clear that $(t, \omega) \to f \left( u_{n(\omega)} (t, \omega) \right)$ is $\mathcal{P}$ measurable although $(t, \omega) \to \gamma (t, \omega)$ is $\mathcal{P}$ measurable.

**Proof of the theorem:** By assumption, there exists a further subsequence still denoted by $n (\omega)$ such that, in addition to 68.2.1 above, the weak limit

$$\lim_{n(\omega) \to \infty} u_{n(\omega)} (\cdot, \omega) = u (\cdot, \omega)$$

exists in $L^{p'} ([0, T]; V')$ such that $t \to u (t, \omega)$ is weakly continuous into $V'$. Then the above equation 68.2.2 continues to hold for this further subsequence and in addition to this,

$$m_k \int_{l_{m_k} (t)}^{t} \langle \phi_{r_k}, u (s, \omega) \rangle_{V, V}, ds = \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k} (t)}^{t} \langle \phi_{r_k}, u_{n(\omega)} (s, \omega) \rangle_{V, V}, ds = \gamma_k (t, \omega)$$

Letting $\phi \in \mathcal{D}$ given, there exists a sub-sequence denoted by $k$ such that $m_k \to \infty$ and $\phi_{r_k} = \phi$ for all $k$. Then passing to a limit and using the assumed continuity of $s \to u (s, \omega)$, the left side of this equation converges to $\langle \phi, u (t, \omega) \rangle_{V, V}$, and so the right side, $\gamma_k (t, \omega)$ must also converge, this for each $\omega$. Since the right side is a product measurable function of $(t, \omega)$, it follows that the pointwise limit is also product measurable. Hence $(t, \omega) \to \langle \phi, u (t, \omega) \rangle_{V, V}$, is product measurable, this for each $\phi \in \mathcal{D}$. Since $\mathcal{D}$ is a dense set, it follows that $(t, \omega) \to \langle \phi, u (t, \omega) \rangle_{V, V}$, is $\mathcal{P}$ measurable for all $\phi \in V$ and so by the Pettis theorem, 68.2.1, $(t, \omega) \to u (t, \omega)$ is $\mathcal{P}$ measurable into $V'$. ■

One can say more about the measurability of the approximating sequence. In fact, we can obtain one for which $\omega \to u_{n(\omega)} (t, \omega)$ is also $\mathcal{F}$ measurable.
Lemma 68.2.6 Suppose, \( u_n(\omega) \to u \) weakly in \( L^p([0,T];V') \) where \( u \) is product measurable measurable and \( \{u_n(\omega)\} \) is a subsequence of \( \{u_n\} \) where

\[
\sup_{t \in [0,T]} \|u_n(t,\omega)\|_V < C(\omega), \text{ for } \omega \notin N \text{ a set of measure zero},
\]

Then for each \( \omega \notin N \), there exists a subsequence of \( \{u_n\} \) denoted as \( \{u_{k(\omega)}\} \) such that \( u_{k(\omega)} \to u \) weakly in \( L^p([0,T];V') \), \( \omega \to k(\omega) \) is \( F \) measurable, and \( \omega \to u_{k(\omega)}(t,\omega) \) is also \( F \) measurable, the last assertions holding for all \( \omega \notin N \).

**Proof:** For \( f,g \in L^p([0,T];V') = V' \), \( L^p([0,T];V) \equiv V \), let \( \{\phi_k\} \) be a countable dense subset of \( L^p([0,T];V) \) with the weak topology can be considered a complete metric space using the following metric.

\[
d(f,g) = \sum_{j=1}^{\infty} 2^{-j} \frac{|\langle \phi_k,f-g\rangle_{V',V}|}{1 + |\langle \phi_k,f-g\rangle_{V',V}|}
\]

Now let \( k(\omega) \) be the first index from the indices of \( \{u_n\} \) at least as large as \( k \) such that

\[
d(u_{k(\omega)},u) \leq 2^{-k}
\]

Such an index exists because there exists a convergent sequence \( u_{n(\omega)} \) which does converge weakly to \( u \). This is just picking another one which happens to also retain measurability. In fact,

\[
\{\omega : k(\omega) = l\} = \{\omega : d(u_l,u) \leq 2^{-k}\} \cap \cap_{j=k}^{k-1} \{\omega : d(u_j,u) > 2^{-k}\}
\]

Since \( u \) is product measurable and each \( u_l \) is also product measurable, these are all measurable sets with respect to \( F \) and so \( \omega \to k(\omega) \) is \( F \) measurable. Now we have \( u_{k(\omega)} \to u \) weakly in \( L^p([0,T];V') \) for each \( \omega \) with each function being \( F \) measurable because

\[
u_{k(\omega)}(t,\omega) = \sum_{j=1}^{\infty} \mathcal{X}_{k(\omega)=j} u_j(t,\omega)
\]

and every term in the sum is \( F \) measurable. ■

The following obvious corollary shows the significance of this lemma.

**Corollary 68.2.7** Let \( V \) be a reflexive separable Banach space and \( V' \) its dual and \( \frac{1}{p} + \frac{1}{p'} = 1 \) where \( p > 1 \) as usual. Let the functions \( t \to u_{n(\omega)}(t,\omega) \) be in \( L^p([0,T];V') \) and \( (t,\omega) \to u_{n(\omega)}(t,\omega) \) be \( B([0,T]) \times F \equiv \mathcal{P} \) measurable into \( V' \). Here \( \{u_{n(\omega)}\}_{n=1}^{\infty} \) is a sequence, one for each \( \omega \). Suppose there is a set of measure zero \( N \) such that if \( \omega \notin N \), then for all \( n \),

\[
\sup_{t \in [0,T]} \|u_{n(\omega)}(t,\omega)\|_{V'} \leq C(\omega).
\]

Also suppose for each \( \omega \notin N \), each subsequence of \( \{u_{n(\omega)}\} \) has a further subsequence which converges weakly in \( L^p([0,T];V') \) to \( u(\cdot,\omega) \in L^p([0,T];V') \) such that \( t \to \)
68.3. MEASURABILITY IN FINITE DIMENSIONAL PROBLEMS

Suppose \( u(t, \omega) \) is weakly continuous into \( V' \). Then there exists \( u \) product measurable, with \( t \to u(t, \omega) \) being weakly continuous into \( V' \). Moreover, there exists, for each \( \omega \notin N \), a subsequence \( u_{n(\omega)} \) such that \( u_{n(\omega)}(\cdot, \omega) \to u(\cdot, \omega) \) weakly in \( L^p([0,T]; V') \).

**Proof:** It suffices to consider the functions \( u_n(t, \omega) \equiv u_{n(\omega)}(t, \omega) \) and use the result of Theorem 68.2.4.

Of course when you have all functions having values in \( H \) a separable Hilbert space, there is no change in the argument to obtain the following theorem.

**Theorem 68.2.8** Let \( H \) be a real separable Hilbert space. For \( n \in \mathbb{N} \) let the functions \( t \to u_n(t, \omega) \) be in \( L^2([0,T]; H) \) and \( (t, \omega) \to u_n(t, \omega) \) be \( \mathcal{B}([0,T]) \times \mathcal{F} \equiv \mathcal{P} \) measurable into \( H \). Suppose there is a set of measure zero \( N \) such that if \( \omega \notin N \), then for all \( n \),

\[
\sup_{t \in [0,T]} |u_n(t, \omega)|_H \leq C(\omega).
\]

Also suppose for each \( \omega \notin N \), each subsequence of \( \{u_n\} \) has a further subsequence which converges weakly in \( L^2([0,T]; H) \) to \( u(\cdot, \omega) \in L^2([0,T]; H) \) such that \( t \to u(t, \omega) \) is weakly continuous into \( H \). Then there exists \( u \) product measurable, with \( t \to u(t, \omega) \) being weakly continuous into \( H \). Moreover, there exists, for each \( \omega \notin N \), a subsequence \( u_{n(\omega)} \) such that \( u_{n(\omega)}(\cdot, \omega) \to u(\cdot, \omega) \) weakly in \( L^2([0,T]; H) \).

### 68.3 Measurability In Finite Dimensional Problems

What follows is like the Peano existence theorem from ordinary differential equations except that it provides a solution which retains product measurability. It is a nice example of the above theory. It will be used in the next section in the Galerkin method.

**Lemma 68.3.1** Suppose \( \mathbf{N}(t, u, v, w, \omega) \in \mathbb{R}^d \) for \( u, v, w \in \mathbb{R}^d, t \in [0,T] \) and \( (t, u, v, w, \omega) \to \mathbf{N}(t, u, v, w, \omega) \) is progressively measurable relative to the filtration consisting of the single \( \sigma \) algebra \( \mathcal{F} \). Also suppose \( (t, u, v, w, \omega) \to \mathbf{N}(t, u, v, w, \omega) \) is continuous and that \( \mathbf{N}(t, u, v, w, \omega) \) is uniformly bounded in \( (t, u, v, w) \) by \( M(\omega) \).

Let \( \mathbf{f} \) be \( \mathcal{P} \) measurable and \( \mathbf{f}(\cdot, \omega) \in L^2([0,T]; \mathbb{R}^d) \). Then for \( h > 0 \), there exists a \( \mathcal{P} \) measurable solution \( u \) to the integral equation

\[
u(t, \omega) - u_0(\omega) + \int_0^t \mathbf{N}(s, u(s, \omega), u(s - h, \omega), w(s, \omega) \omega) ds = \int_0^t \mathbf{f}(s, \omega) ds.
\]

Here \( u_0 \) has values in \( \mathbb{R}^d \) and is \( \mathcal{F} \) measurable, \( u(s - h, \omega) \equiv u_0(\omega) \) if \( s - h < 0 \) and for \( w_0 \) a given \( \mathcal{F} \) measurable function,

\[
w(t, \omega) \equiv w_0(\omega) + \int_0^t u(s, \omega) ds.
\]
Proof: Let $u_n$ be the solution to the following equation:

$$u_n(t, \omega) - u_0(\omega) + \int_0^t N(s, \tau_{1/n} u_n(s, \omega), u_n(s - h, \omega), \tau_{1/n} w_n(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds.$$  

where here $\tau_{1/n}$ is defined as follows. For $\delta > 0$,

$$\tau_{\delta} u(s) \equiv \begin{cases} u(s - \delta) & \text{if } s > \delta \\ 0 & \text{if } s - \delta \leq 0 \end{cases}$$

It follows that $(t, \omega) \mapsto u_n(t, \omega)$ is $\mathcal{P}$ measurable. From the assumptions on $N$, it follows that for fixed $\omega$, $\{u_n(\cdot, \omega)\}$ is uniformly bounded:

$$\sup_{t \in [0,T]} |u_n(t, \omega)| \leq |u_0(\omega)| + \int_0^T M(\omega) \, ds + \int_0^T |f(s, \omega)| \, ds =: C(\omega),$$

and is also equicontinuous because for $s < t$,

$$|u_n(t, \omega) - u_n(s, \omega)| \leq \int_s^t |N(r, \tau_{1/n} u_n(r, \omega), u_n(r - h, \omega), \tau_{1/n} w_n(r, \omega), \omega)| \, dr$$

$$+ \int_s^t |f(r, \omega)| \, dr \leq C(\omega, f) |t - s|^{1/2}.$$ 

Therefore, by the Ascoli–Arzelà theorem, for each $\omega$, there exists a subsequence $\tilde{n}(\omega)$ depending on $\omega$ and a function $\tilde{u}(t, \omega)$ such that

$$u_{\tilde{n}(\omega)}(t, \omega) \to \tilde{u}(t, \omega) \text{ uniformly in } C\left([0,T]; \mathbb{R}^d\right).$$

This verifies the assumptions of Theorem 65.22.

It follows that there exists $\tilde{u}$ product measurable and a subsequence $\{u_{n(\omega)}\}$ for each $\omega$ such that

$$\lim_{n(\omega) \to \infty} u_{n(\omega)}(\cdot, \omega) = \tilde{u}(\cdot, \omega) \text{ weakly in } L^2\left([0,T]; \mathbb{R}^d\right)$$

and that $t \to \tilde{u}(t, \omega)$ is continuous. (Note that weak continuity is the same as continuity in $\mathbb{R}^d$.) The same argument given above applied to the $u_{n(\omega)}$ for a fixed $\omega$ yields a further subsequence, denoted as $\{u_{\tilde{n}(\omega)}(\cdot, \omega)\}$ which converges uniformly to a function $u(\cdot, \omega)$ on $[0,T]$. So $\tilde{u}(t, \omega) = u(t, \omega)$ in $L^2\left([0,T]; \mathbb{R}^d\right)$. Since both of these functions are continuous in $t$, they must be equal for all $t$. Hence, $(t, \omega) \mapsto u(t, \omega)$ is product measurable. Passing to the limit in the equation solved by $\{u_{n(\omega)}(\cdot, \omega)\}$ using the dominated convergence theorem, we obtain

$$u(t, \omega) - u_0(\omega) + \int_0^t \left( N(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) \right) \, ds = \int_0^t f(s, \omega) \, ds.$$
Thus $t \to u(t, \omega)$ is a product measurable solution to the integral equation. □

This lemma gives the existence of the approximate solutions in the following theorem in which the assumption that the integrand is bounded is replaced with an estimate. The following elementary consideration will be used whenever convenient. Note that it holds for all $\omega$.

**Remark 68.3.2** When $w(t) \equiv w_0(\omega) + \int_0^t u(s, \omega) \, ds$,

$$v(t) = \begin{cases} u(t-h) & \text{if } t \geq h \\ u_0 & \text{if } t < h \end{cases}$$

and when the estimate

$$(N(t, u, v, w, \omega), u) \geq -C(t, \omega) - \mu \left( |u|^2 + |v|^2 + |w|^2 \right)$$

holds, it follows that

$$\int_0^t (N(t, u, v, w, \omega), u) \, ds \geq -C \left( C(\omega) + \int_0^t |u|^2 \, ds \right)$$

for some constant $C$ depending on the initial data but not on $u$.

To see this,

$$\int_0^t |u(s-h)|^2 \, ds = \int_0^h |u_0|^2 \, ds + \int_h^t |u(s-h)|^2 \, ds$$

$$= |u_0|^2 h + \int_{t-h}^t |u(s)|^2 \, ds \leq |u_0|^2 h + \int_0^t |u(s)|^2 \, ds$$

if $t \geq h$ and if $s < h$, this is dominated by

$$|u_0|^2 t \leq |u_0|^2 h \leq |u_0|^2 h + \int_0^t |u(s)|^2 \, ds$$

As to the terms from $w$,

$$\int_0^t |w(s)|^2 \, ds$$

$$\leq \int_0^t \left( \int_0^s \left| u(r) \, dr \right| \right)^2 \, ds \leq \int_0^t \left( \left| \int_0^s u(r) \, dr \right| + \left| \int_0^s u(r) \, dr \right| \right)^2 \, ds$$

$$\leq \int_0^t \left( |w_0|^2 + 2 |w_0| \left| \int_0^s u(r) \, dr \right| + \left| \int_0^s u(r) \, dr \right| \right)^2 \, ds$$

$$\leq T |w_0|^2 + T |w_0|^2 + \int_0^t \left( \int_0^s |u(r)| \, dr \right)^2 \, ds + \int_0^t \left( \int_0^s |u(r)| \, dr \right)^2 \, ds$$

$$\leq 2T |w_0|^2 + 2 \int_0^t \left( \int_0^s |u(r)| \, dr \right)^2 \, ds \leq 2T |w_0|^2 + 2 \int_0^t \int_0^s |u(r)|^2 \, dr \, ds$$

$$\leq 2T |w_0|^2 + 2T \int_0^t \int_0^s |u(r)|^2 \, dr \, ds$$
From this, the claimed result follows.

**Theorem 68.3.3** Suppose \( N(t, u, v, w, \omega) \in \mathbb{R}^d \) for \( u, v, w \in \mathbb{R}^d, t \in [0, T] \) and \( (t, u, v, w, \omega) \to N(t, u, v, w, \omega) \) is progressively measurable with respect to a constant filtration \( \mathcal{F}_t = \mathcal{F} \). Also suppose \( (t, u, v, w) \to N(t, u, v, w, \omega) \) is continuous and satisfies the following conditions for \( C(\cdot, \omega) \geq 0 \) in \( L^1([0, T]) \) and some \( \mu > 0 \):

\[
(N(t, u, v, w, \omega), u) \geq -C(t, \omega) - \mu \left( |u|^2 + |v|^2 + |w|^2 \right).
\]

Also let \( f \) be product measurable and \( f(\cdot, \omega) \in L^2([0, T]; \mathbb{R}^d) \). Then for \( h > 0 \), there exists a product measurable solution \( u \) to the integral equation

\[
u(t, \omega) - u_0(\omega) + \int_0^t N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds,
\]

where \( u_0 \) has values in \( \mathbb{R}^d \) and is \( \mathcal{F} \) measurable. Here \( u(s-h, \omega) \equiv u_0(\omega) \) for all \( s-h \leq 0 \) and for \( w_0 \) a given \( \mathcal{F} \) measurable function,

\[
w(t, \omega) \equiv w_0(\omega) + \int_0^t u(s, \omega) \, ds
\]

**Proof:** Let \( P_m \) denote the projection onto the closed ball \( B(0, 9^m) \). Then from the above lemma, there exists a product measurable solution \( u_m \) to the integral equation

\[
u_m(t, \omega) - u_0(\omega) + \int_0^t N(s, P_m u_m(s, \omega), P_m u_m(s-h, \omega), P_m w_m(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds.
\]

Define a stopping time

\[
\tau_m(\omega) \equiv \inf \left\{ t \in [0, T] : |u_m(t, \omega)|^2 + |w_m(t, \omega)|^2 > 2^m \right\},
\]

where \( \inf \emptyset \equiv T \). Localizing with the stopping time,

\[
u_m^{\tau_m}(t, \omega) - u_0(\omega) + \int_0^t \mathcal{A}_{[0, \tau_m]} N(s, u_m^{\tau_m}(s, \omega), u_m^{\tau_m}(s-h, \omega), w_m^{\tau_m}(s, \omega), \omega) \, ds = \int_0^t \mathcal{A}_{[0, \tau_m]} f(s, \omega) \, ds.
\]

Note how the stopping time allowed the elimination of the projection map in the equation. Then we get

\[
\frac{1}{2} |u_m^{\tau_m}(t, \omega)|^2 - \frac{1}{2} |u_0(\omega)|^2 + \int_0^t \mathcal{A}_{[0, \tau_m]} N(s, u_m^{\tau_m}(s, \omega), u_m^{\tau_m}(s-h, \omega), w_m^{\tau_m}(s, \omega), \omega) \, ds = \int_0^t \mathcal{A}_{[0, \tau_m]} f(s, \omega, u_m^{\tau_m}(s, \omega)) \, ds.
\]
From the estimate,
\[
\frac{1}{2} |u^m_n(t, \omega)|^2 + \frac{1}{2} |u_0(\omega)|^2 \leq \int_0^t \left( \mu \left( |u^m_n(s, \omega)|^2 + |u^m_n(s - h, \omega)|^2 + |w^m_n(s, \omega)|^2 \right) \\
+ C(s, \omega) + \frac{1}{2} |f(s, \omega)|^2 \right) ds + \frac{1}{2} \int_0^t |u^m_n(s, \omega)|^2 ds.
\]
Note that
\[
|u_0| + \int_0^t |u^m_n(s)|^2 ds \geq \int_0^t |u^m_n(s - h, \omega)|^2 ds
\]
and
\[
\int_0^t |w^m_n(s, \omega)|^2 ds = \int_0^t |w_0 + \int_0^s X_{[0, \tau_n]} u_n(r) dr|^2 ds
\]
\[
\leq C(w_0(\omega)) + CT \int_0^t |u^m_n|^2 ds.
\]
By Gronwall’s inequality,
\[
|u^m_n(t, \omega)|^2 \leq C(u_0(\omega), w_0(\omega), \mu, \|C(\cdot, \omega)\|_{L^1([0, T]; \mathbb{R}^d)}, T, \|f(\cdot, \omega)\|_{L^2([0, T]; \mathbb{R}^d)})
\]
\[
\equiv C(\omega).
\]
Thus, for a.e. $\omega, \tau_m = T$ for all $m$ large enough, say for $m \geq M(\omega)$ where
\[
C(\omega) \leq 2^{M(\omega)}.
\]
Then define the functions
\[
y_n(t, \omega) \equiv u^m_n(t, \omega).
\]
These are product measurable and
\[
y_n(t, \omega) - u_0(\omega) + \\
\int_0^t X_{[0, \tau_n]} N(s, y_n(s, \omega), y_n(s - h, \omega), w_0(\omega) + \int_0^s y_n(r, \omega) dr, \omega) ds
\]
\[
= \int_0^t X_{[0, \tau_n]} f(s, \omega) ds.
\]
So each is continuous in $t$. For large enough $n, \tau_n = T$ and hence
\[
y_n(t, \omega) - u_0(\omega) + \int_0^t N(s, y_n(s, \omega), y_n(s - h, \omega), w_0(\omega) + \int_0^s y_n(r, \omega) dr, \omega) ds
\]
\[
= \int_0^t f(s, \omega) ds.
Also these satisfy the inequality
\[
\sup_{t \in [0, T]} |y_n(t, \omega)|^2 \leq C(\omega) \leq 2^M(\omega) < 9^M(\omega),
\]
the constant on the right not depending on \(n\). Thus for fixed \(\omega\), we can regard \(N\) as bounded and the same reasoning used in the above lemma involving the Ascoli–Arzelà theorem implies that every subsequence has a further subsequence which converges to a solution to the integral equation for that \(\omega\). Thus it is continuous into \(\mathbb{R}^d\). It follows from the measurable selection theorem above that there exists \(u\) product measurable and continuous in \(t\) such that \(u(\cdot, \omega) = \lim_{n \to \infty} y_n(\cdot, \omega)\) in \(L^2([0, T]; \mathbb{R}^d)\). By the reasoning of the above lemma, there is a further subsequence, denoted the same way, for which \(\lim_{n \to \infty} y_n(\cdot, \omega)\) in \(C([0, T]; \mathbb{R}^d)\) solves the integral equation for a fixed \(\omega\). Thus \(u\) is a product measurable solution to the integral equation as claimed. \(\square\)

We made use of an estimate in order to get the conclusion of this theorem. However, all that is really needed is the following.

Corollary 68.3.4 Suppose \(N(t, u, v, w, \omega) \in \mathbb{R}^d\) for \(u, v, w \in \mathbb{R}^d\), \(t \in [0, T]\) and \((t, u, v, w, \omega) \to N(t, u, v, w, \omega)\) is progressively measurable with respect to a constant filtration \(F_t = \mathcal{F}\). Also suppose \((t, u, v, w) \to N(t, u, v, w, \omega)\) is continuous. Suppose for each \(\omega\), there exists an estimate for any solution \(u(\cdot, \omega)\) to the integral equation
\[
\int_0^t N(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) ds = \int_0^t f(s, \omega) ds,
\]
which is of the form
\[
\sup_{t \in [0, T]} |u(t, \omega)| \leq C(\omega) < \infty
\]
Also let \(f\) be product measurable and \(f(\cdot, \omega) \in L^1([0, T]; \mathbb{R}^d)\). Here \(u_0\) has values in \(\mathbb{R}^d\) and is \(\mathcal{F}\) measurable and \(u(s - h, \omega) \equiv u_0(\omega)\) whenever \(s - h \leq 0\) and
\[
w(t, \omega) \equiv w_0(\omega) + \int_0^t u(s, \omega) ds
\]
where \(w_0\) is a given \(\mathcal{F}\) measurable function. Then for \(h > 0\), there exists a product measurable solution \(u\) to the integral equation.

Of course the same conclusions apply when there is no dependence in the integral equation on \(u(s - h, \omega)\) or the integral \(w(t, \omega)\). Note that these theorems hold for all \(\omega\).

68.4 The Navier–Stokes Equations

In this section, we study the stochastic Navier–Stokes equations of arbitrary dimension. We prove there exists a global solution which is product measurable. The
68.4. THE NAVIER–STOKES EQUATIONS

The main result is Theorem 68.4.6. We use the Galerkin method and Theorem 68.3.3 to get product measurable approximate solutions. Then we take weak limits and get path solutions. After this, we apply Theorem 68.2.8 to get product measurable global solutions.

As in [14], an important part of our argument is the theorem in Lions [82] which follows. See Theorem 67.5.6.

**Theorem 68.4.1** Let \( W, H, \) and \( V' \) be separable Banach spaces. Suppose \( W \subseteq H \subseteq V' \) where the injection map is continuous from \( H \) to \( V' \) and compact from \( W \) to \( H \). Let \( q_1 \geq 1, q_2 > 1 \), and define

\[
S = \{ u \in L^{q_1}([a,b]; W) : u' \in L^{q_2}([a,b]; V') \}
\]

and \( \|u\|_{L^{q_1}([a,b]; W)} + \|u'\|_{L^{q_2}([a,b]; V')} \leq R \). Then \( S \) is pre-compact in \( L^{q_1}([a,b]; H) \). This means that if \( \{u_n\}_{n=1}^{\infty} \subseteq S \), it has a subsequence \( \{u_{n_k}\} \) which converges in \( L^{q_1}([a,b]; H) \).

A proof of a generalization of this theorem is found on Page 2451. Let \( U \) be a bounded open set in \( \mathbb{R}^d \) and let \( S \) denote the functions which are infinitely differentiable having zero divergence and also having compact support in \( U \). We have in mind \( d = 3 \), but the approach is not limited by dimension. We use the same Galerkin method found in [14], the details being included in slightly abbreviated form for convenience of the reader. The difference is that we switch the roles of \( V \) and \( W \) along with a few other minor modifications. This is the part of the argument which gives a solution for each \( \omega \) and it is standard material. Define

\[
V \equiv \overline{S} \text{ in } \left( H^{d*} (U) \right)^d, \quad W \equiv \overline{S} \text{ in } \left( H^1 (U) \right)^d, \quad \text{and } H \equiv \overline{S} \text{ in } \left( L^2 (U) \right)^d,
\]

where \( d^* \) is such that for \( w \in \left( H^{d^*} (U) \right)^d \) then \( \|Dw\|_{L^\infty (U)} < \infty \). For example, you could take \( d^* = 3 \) for \( d = 3 \). In [14], they take \( d^* = 8 \) which is large enough to work for all dimensions of interest.

Let \( A : W \to W' \) and \( N : W \to V' \) be defined by

\[
\langle Au, v \rangle = \int_U \nabla u \cdot \nabla v dx, \quad \langle Nu, v \rangle = -\int_U u_i u_j v_{ij} dx.
\]

Then \( N \) is a continuous function. Indeed, pick \( v \in V \) and suppose \( u_n \to u \) in \( W \), then

\[
|\langle Nu - Nu_n, v \rangle| \leq \int_U \sum_{i,j} (u_{ni} u_{nj} - u_i u_j) v_{ij} dx \leq C \|v\|_V \int_U (|u_n| + |u|)(|u_n - u|) dx
\]

\[
\leq C \|v\|_V \left( \int_U |u_n|^2 + |u|^2 dx \right)^{1/2} \left( \int_U u_n - u^2 dx \right)^{1/2},
\]

where \( d \) is such that for \( w \in \left( H^d (U) \right)^d \) then \( \|Dw\|_{L^\infty (U)} < \infty \). For example, you could take \( d = 3 \) for \( d = 3 \). In [14], they take \( d = 8 \) which is large enough to work for all dimensions of interest.
where what multiplies $\|v\|_V$ clearly converges to 0.

An abstract form for the incompressible Navier–Stokes equations is

$$u' + \nuAu + Nu = f, \quad u(0) = u_0,$$

where $f \in L^2([0, T]; W')$, for some fixed $T > 0$. As in [14], we will let $\nu = 1$ to simplify the presentation. A stochastic version of this would be the integral equation

$$u(t, \omega) - u_0(\omega) + \int_0^t A(u(s, \omega)) \, ds + \int_0^t N(u(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds + q(t, \omega),$$

where $q(\cdot, \omega)$ will be continuous into $V$, $(t, \omega) \mapsto q(t, \omega)$ will be product measurable having values in $V$, and $q(0, \omega) = 0$. So $q$ here is a fixed stochastic process, which serves as the random source. Also $(t, \omega) \mapsto f(t, \omega)$ will be product measurable into $W'$ as well as having $t \mapsto f(t, \omega)$ in $L^2([0, T]; W')$. Our problem is to show the existence of a product measurable solution.

Let $T$ be any fixed positive number and let $q$ be any fixed process satisfying the above.

**Definition 68.4.2** A global solution to the above integral equation is a process $u(t, \omega)$, for which $\omega \mapsto u(t, \omega)$ is $F$ measurable and satisfies for each $\omega$ outside a set of measure zero and all $t \in [0, T]$,

$$u(t, \omega) - u_0(\omega) + \int_0^t A(u(s, \omega)) \, ds + \int_0^t N(u(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds + q(t, \omega).$$

In order to apply the earlier result, let $w(t, \omega) = u(t, \omega) - q(t, \omega)$ and write the equation in terms of $w$,

$$w(t, \omega) - u_0(\omega) + \int_0^t A(w(s, \omega) + q(s, \omega)) \, ds + \int_0^t N(w(s, \omega) + q(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds.$$

It turns out that it is convenient to define

$$\langle B(u, v), w \rangle \equiv -\int_U u_i v_j w_{j,i} \, dx,$$

and write the equation in the following form:

$$w(t, \omega) - u_0(\omega) + \int_0^t A(w(s, \omega)) \, ds + \int_0^t N(w(s, \omega)) \, ds = \int_0^t \hat{f}(s, \omega) \, ds,$$

where

$$\hat{N}(w(t, \omega)) \equiv N(w(t, \omega)) + B(w(t, \omega), q(t, \omega)) + B(q(t, \omega), w(t, \omega)),$$

$$\hat{f}(t, \omega) \equiv f(t, \omega) - A(q(t, \omega)) - N(q(t, \omega)).$$

This is an equation in $V'$. Moreover, we have the following:
Lemma 68.4.3  For fixed $\omega \in \Omega$, $\hat{f} \in L^2 ([0, T]; W')$, and
\[
(t, w) \rightarrow B (w, q(t, \omega)), \quad (t, w) \rightarrow B (q(t, \omega), w)
\]
are continuous functions having values in $W'$. For fixed $w \in W$,
\[
(t, \omega) \rightarrow B (w, q(t, \omega)), \quad (t, \omega) \rightarrow B (q(t, \omega), w)
\]
are product measurable. In addition to this, if $z \in W$,
\[
|\langle B (w, q(t, \omega)), z \rangle| \leq C \|q(t, \omega)\|_V \|w\|_H \|z\|_H,
\]
\[
|\langle B (q(t, \omega), w), z \rangle| \leq C \|q(t, \omega)\|_V \|w\|_H \|z\|_H.
\]

Proof: The first claim is straightforward to prove from the definition of $A$ and $N$. Consider the next claim about continuity. Let $z \in W$ be given. Then from the fact that all the functions are divergence free,
\[
|\langle B (w, q(t)) - B (\hat{w}, q(s)), z \rangle| = \left| \int_U (w_i q_j (t) - \hat{w}_i q_j (s)) z_{j,i} dx \right| \leq C \left( \|q(t)\|_V \int_U |w - \hat{w}| |z| dx + \|q(t) - q(s)\|_V \int_U |\hat{w}| |z| dx \right)
\]
where we have suppressed the dependence of $q$ on $\omega$ to simplify the notation. The other function is similar.

As to the claim about product measurability, this follows from the above definition and assumptions about $q$ being product measurable. For the estimates,
\[
|\langle B (w, q), z \rangle| = \left| \int_U w_i q_j z_{j,i} \right| = \left| \int_U w_i q_j z \right| \leq C \|q\|_V \int_U |w| |z| dx,
\]
and apply Hölder’s inequality. The other estimate is similar. 

This has shown that it suffices to verify that there exists a global solution $u$ to the equation
\[
u (t, \omega) - u_0 (\omega) + \int_0^t A (u(s, \omega)) ds + \int_0^t \hat{N} (u(s, \omega)) ds = \int_0^t f (s, \omega) ds,
\]
where $f (\cdot, \omega) \in L^2 ([0, T]; W')$ for each $\omega \in \Omega$.

Let $R$ be the Riesz map from $V$ to $V'$, so $\langle R v_1, v_2 \rangle_{V', V} = \langle v_1, v_2 \rangle_V$ for any $v_1, v_2 \in V$. The compactness of the embeddings imply that $R^{-1}$ is a compact self adjoint operator on $H$ and so there is a complete orthonormal basis $\{w_k\}$ for $H$ such that $R^{-1} w_k = \mu_k w_k$, where $\{\mu_k\}$ is a decreasing sequence of positive numbers
which converges to 0. Thus \( Rw_k = \lambda_k w_k \), where \( \lim_{k \to \infty} \lambda_k = \infty \). \( \{w_k\} \) is a special basis. It is orthonormal in \( H \) and orthogonal in \( V \), since \( (w_k, w_j)_V = (Rw_k, w_j)_H = (\lambda_k w_k, w_j)_H \).

To use the Galerkin method, let \( V_n = \text{span} \{w_1, \ldots, w_n\} \). Clearly \( \cup_n V_n \) is dense in \( H \). This is also dense in \( V \). If not, then there exists \( \phi \in V \) such that \( \phi \neq 0 \) but \( \cup_n V_n \subseteq \ker \phi \). Then \( \phi = Ry \). Hence for \( z \in \cup_n M = \bigcup_{n=1}^{M} V_n \)

\[
0 = \langle Ry, z \rangle = \langle Rz, y \rangle = \langle Rz, y \rangle_H .
\]

But \( Rz \in \text{span} \{w_1, \ldots, w_M\} \) and in fact, \( R \) maps \( V_n \) onto \( V_n \) and so this shows that \( y \) is perpendicular to \( \text{span} \{w_1, \ldots, w_M\} \) for each \( M \) so \( y = 0 \) and \( \phi = 0 \) after all. Thus \( \cup_n V_n \) is also dense in \( V \) and hence it is also dense in \( W \).

Let \( u_n(t, \omega) = \sum_{k=1}^{n} x_k(t, \omega) w_k \), where \( x(t, \omega) = (x_1(t, \omega), \ldots, x_n(t, \omega))^T \in \mathbb{R}^n \). We consider the problem of finding \( x(t, \omega) \) such that for all \( w_k, k \leq n \),

\[
(u_n(t, \omega), w_k)_H - (u_{0n}(\omega), w_k)_H + \int_0^t \langle A(u_n(s, \omega)), w_k \rangle ds
\]

\[
+ \int_0^t \langle \bar{N}(u_n(s, \omega)), w_k \rangle ds = \int_0^t \langle f(s, \omega), w_k \rangle ds , \quad (68.4.6)
\]

where \( u_{0n} \) is the orthogonal projection of \( u_0 \) onto \( V_n \).

By the continuity of the operators described above, and the orthonormality of the \( w_k \), this is nothing but an ordinary differential equation for the vector \( x(t, \omega) \).

By Theorem 6.7.1, there exists a product measurable solution \( x \) and therefore, \( u_n(t, \omega) \) is also product measurable in \( H \).

Take the derivative, multiply by \( x_k(t, \omega) \), add, and integrate again in the usual way to obtain

\[
\frac{1}{2} |u_n(t, \omega)|_H^2 - \frac{1}{2} |u_{0n}(\omega)|_H^2
\]

\[
= - \int_0^t \langle A(u_n(s, \omega)), u_n(s, \omega) \rangle ds - \int_0^t \langle \bar{N}(u_n(s, \omega)), u_n(s, \omega) \rangle ds
\]

\[
+ \int_0^t \langle f(s, \omega), u_n(s, \omega) \rangle ds .
\]

Recall that \( \bar{N}(u(t, \omega)) = N(u(t, \omega)) + B(u(t, \omega), q(s, \omega)) + B(q(t, \omega), u(t, \omega)) \).

From the above lemma and that all functions are divergence free, we obtain

\[
\int_0^t \langle B(q(s, \omega), u_n(s, \omega)), u_n(s, \omega) \rangle ds = 0,
\]

and

\[
\left| \int_0^t \langle B(u_n(s, \omega), q(s, \omega)), u_n(s, \omega) \rangle ds \right| \leq C \int_0^t \|q(s, \omega)\|_V |u_n(s, \omega)|_H^2 ds .
\]
Then one can obtain an inequality of the following form

\[
\frac{1}{2} \|u_n (t, \omega)\|^2_H + \int_0^t \|u_n(s, \omega)\|^2_W \, ds \\
\leq \frac{1}{2} \|u_{0n} (\omega)\|^2_H + C \int_0^t \|q(s, \omega)\|_V \|u_n(s, \omega)\|^2_H \, ds \\
+ C \int_0^t \|f(s, \omega)\|^2_W \, ds + \frac{1}{2} \int_0^t \|u_n(s, \omega)\|^2_W \, ds.
\]

Since \( t \to \|q(t, \omega)\|_V \) is continuous, it follows from Gronwall's inequality that there is an estimate of the form

\[
\|u_n(t, \omega)\|^2_H + \int_0^t \|u_n(s, \omega)\|^2_W \, ds \leq C (u_0, f, q, T, \omega).
\]

(68.4.7)

The next task is to estimate \( \|u'_n(\omega)\|_{L^2([0,T];V')} \) for each fixed \( \omega \in \Omega \). We will suppress the dependence on \( \omega \) of all functions whenever it is appropriate. With \( u \), the fundamental theorem of calculus implies that for each \( w \in V_n \),

\[
\langle u_n'(t), w \rangle_{V',V} + \langle A(u_n(t)), w \rangle_{V',V} + \langle \tilde{N}(u_n(t)), w \rangle = \langle f(t), w \rangle.
\]

In terms of inner products in \( V \),

\[
\left( R^{-1}u'_n(t) + R^{-1}A(u_n(t)) + R^{-1}\tilde{N}(u_n(t)) - R^{-1}f(t), w \right)_V = 0
\]

for all \( w \in V_n \). This is equivalent to saying that for \( P_n \) the orthogonal projection in \( V \) onto \( V_n \),

\[
\left( R^{-1}u'_n(t) + R^{-1}A(u_n(t)) + R^{-1}\tilde{N}(u_n(t)) - R^{-1}f(t), P_n w \right)_V = 0
\]

for all \( w \in V \). This is to say that

\[
R^{-1}u'_n(t) + P_nR^{-1}A(u_n(t)) + P_nR^{-1}\tilde{N}(u_n(t)) = P_nR^{-1}f(t).
\]

Now the projection map decreases norms and \( R^{-1} \) preserves norms. Hence

\[
\|u'_n(t)\|_{V'} = \|R^{-1}u'_n(t)\|_V \leq \|A(u_n(t))\|_{V'} + \|\tilde{N}(u_n(t))\|_{V'} + \|f(t)\|_{V'},
\]

from which it follows that \( u'_n \) is bounded in \( L^2([0,T];V') \). Indeed, this is the case because \( A(u_n) \) and \( \tilde{N}(u_n) \) are both bounded in \( L^2([0,T];V') \). The term \( \|\tilde{N}(u_n(t))\|_{V'} \) can be split further into terms involving \( \|N(u_n)\|, \|B(u_n, q)\| \), and \( \|B(q, u_n)\| \). For example, consider \( N(u_n) \) which is the least obvious. Let \( w \in L^2([0,T];V) \). From the definitions,

\[
\left| \langle N(u_n), w \rangle_{L^2([0,T];V)} \right| = \left| \int_0^T \int_U u_{ni}u_{nj}w_{ji} \, dx \, dt \right|.
\]
There is a subsequence, still denoted as \( n \) and a function \( u(t, \omega) \) such that

\[
\begin{align*}
    u_n \to u & \quad \text{weakly in } L^\infty([0,T]; H), \\
u'_n \to u' & \quad \text{weakly in } L^2([0,T]; V'), \\
u_n \to u & \quad \text{weakly in } L^2([0,T]; W), \\
u_n \to u & \quad \text{strongly in } L^2([0,T]; H).
\end{align*}
\] (68.4.10)

This last convergence follows from Theorem 68.3.1. The sequence is bounded in \( L^2([0,T]; W) \) and the derivative is bounded in \( L^2([0,T]; V') \) so such a strongly convergent subsequence exists. Since \( A \) is linear, we can also assume that

\[
Au_n \to Au \quad \text{weakly in } L^2([0,T]; W').
\] (68.4.11)

What happens with the nonlinear operator \( \tilde{N} \)? Let \( w \in L^\infty([0,T]; V) \). A computation shows then that

\[
\begin{align*}
    &\left| \int_0^T \langle N u_n(t) - Nu(t), w(t) \rangle \, dt \right| \\
    &= \left| \int_0^T \int_U (u_n(t) u_{nj}(t) - u(t) u_{nj}(t)) w_{ji} \, dx dt \right| \\
    &\leq \|w\|_{L^\infty([0,T], V)} \int_0^T \int_U \left( |u_n(t)| + |u(t)| \right) \left( |u(t) - u_n(t)| \right) \, dx dt \\
    &\leq \|w\|_{L^\infty([0,T], V)} \left( \int_0^T \int_U (|u_n| + |u|)^2 \, dx dt \right)^{1/2} \left( \int_0^T \int_U (|u - u_n|)^2 \, dx dt \right)^{1/2}.
\end{align*}
\]

This converges to 0 thanks to the estimates and the strong convergence. Similar convergence holds for the other nonlinear terms \( B(u_n(t), q), B(q, u_n(t)) \).

We have shown that for any \( n \geq m \), and \( w \in V_m \),

\[
\begin{align*}
    &\langle u'_n(t), w \rangle_{V', V} + \langle A(u_n(t)), w \rangle_{V', V} + \langle \tilde{N}(u_n(t)), w \rangle = \langle f(t), w \rangle.
\end{align*}
\] (68.4.12)
Let \( \zeta \in C^\infty ([0,T]) \) be such that \( \zeta (T) = 0 \). Then
\[
\langle u'_n (t), w \zeta (t) \rangle_{V',V} + \langle A(u_n(t)), w \zeta (t) \rangle_{V',V} + \langle \tilde{N}(u_n(t)), w \zeta (t) \rangle = \langle f(t), w \zeta (t) \rangle.
\]
Integrating this equation from 0 to \( T \) we obtain
\[
- \langle u_{0n} (\omega), w \zeta (0) \rangle_H - \int_0^T \zeta' (s) \langle u_n(s, \omega), w \rangle_H \, ds
= - \int_0^T \langle A(u_n(s, \omega)), w \zeta (s) \rangle \, ds - \int_0^T \langle \tilde{N}(u_n(s, \omega)), w \zeta (s) \rangle \, ds
+ \int_0^T \langle f(s, \omega), w \zeta (s) \rangle \, ds.
\]
Now letting \( n \to \infty \), from the above list of convergent sequences,
\[
- \langle u_0 (\omega), w \zeta (0) \rangle_H - \int_0^T \zeta' (s) \langle u(s, \omega), w \rangle_H \, ds
= - \int_0^T \langle A(u(s, \omega)), w \zeta (s) \rangle \, ds - \int_0^T \langle \tilde{N}(u(s, \omega)), w \zeta (s) \rangle \, ds
+ \int_0^T \langle f(s, \omega), w \zeta (s) \rangle \, ds.
\]
It follows that in the sense of \( V' \) valued distributions,
\[
u'(\omega) + A(u(\omega)) + \tilde{N}(u(\omega)) = f(\omega)
\] (68.4.13)
along with the initial condition
\[
u(0) = u_0.
\] (68.4.14)
This has proved most of the following lemma:

**Lemma 68.4.4** Let \( u_0 \) have values in \( H \) and be \( F \) measurable, and let \( u_n \) be a solution to (68.4.1). Then for each \( \omega \), the estimate (68.4.1) holds. Also there is a subsequence, still called \( u_n \), such that the convergence for (68.4.12) - (68.4.14) are valid. For all \( \omega \), the function \( u(\cdot, \omega) \) is a solution to (68.4.12) - (68.4.14) and satisfies
\[
u(\cdot, \omega) \in L^\infty ([0, T]; H) \cap L^2 ([0, T]; W), u'(\cdot) \in L^2 ([0, T]; V').
\] This solution is also weakly continuous into \( H \) for each \( \omega \).

**Proof:** All that remains to show is the last claim about weak continuity into \( H \). The equation (68.4.13) shows that \( u(\cdot, \omega) \) is continuous into \( V' \). However, the weak convergence and the estimate (68.4.14) show that \( u(\cdot, \omega) \) is bounded in \( H \). It follows from density of \( V \) in \( H \) that \( t \to u(t, \omega) \) is weakly continuous into \( H \).

From (68.4.13) - (68.4.14), the following integral equation for a path solution holds:
\[
u(t, \omega) - u_0(\omega) + \int_0^t A(u(s, \omega)) \, ds + \int_0^t \tilde{N}(u(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds.
\]
We apply Theorem (68.4.15) to prove the above solution could be taken product measurable.
Theorem 68.4.5 Let \( f(t, \omega), q(t, \omega) \) be product measurable and \( u_0 \) be measurable, such that for each \( \omega \in \Omega \), \( f(\cdot, \omega) \in L^2([0, T]; W') \), \( q(\cdot, \omega) \in C([0, T]; V) \) with \( q(0) = 0 \), and \( u_0(\omega) \in H \). Then there exists a global solution to the integral equation

\[
\begin{align*}
  u(t, \omega) - u_0(\omega) + \int_0^t A(u(s, \omega)) \, ds + \int_0^t N(u(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds.
\end{align*}
\]

**Proof:** Letting \( u_n \) be a solution to (68.4.8) for \( u_0 \), we verify the conditions of Theorem 68.4.6 for \( u_n \).

The assumption in this theorem that the \( u_n \) are bounded follows from the above estimate (68.4.5). Then it was shown in the above lemma that whenever a sequence satisfies the estimate (68.4.6) it has a subsequence which converges as in (68.4.3) to a weakly continuous \( u(\cdot, \omega) \). Therefore, by Theorem 68.4.5 there is a subsequence \( u_n(\cdot, \omega) \) converging weakly to \( u(\cdot, \omega) \), such that \( (t, \omega) \rightarrow u(t, \omega) \) is a product measurable function into \( H \). Then a further subsequence converges to a path solution to the above integral equation, which must be the same function because when a sequence converges, all subsequences converge to the same thing. In addition to this, \( u \) is also product measurable into \( W \). This follows from the above estimate 68.4.6. For \( \phi \in H \), \( (t, \omega) \rightarrow (\phi, u(t, \omega)) \) is product measurable. However, \( H \) is dense in \( W \) and so if \( \psi \in W \), there is a sequence \( \{\phi_n\} \) in \( H \) such that \( \phi_n \rightarrow \psi \). Then

\[
\langle \psi, u \rangle = \lim_{n \rightarrow \infty} \langle \phi_n, u \rangle,
\]

so by the Pettis theorem (68.4.8), \( u \) is product measurable into \( W \) also.

This shows much of the following theorem which is the main result.

Theorem 68.4.6 Let \( f(t, \omega), q(t, \omega) \) be product measurable and \( u_0 \) be measurable, such that for each \( \omega \in \Omega \), \( f(\cdot, \omega) \in L^2([0, T]; W') \), \( q(\cdot, \omega) \in C([0, T]; V) \) with \( q(0) = 0 \), and \( u_0(\omega) \in H \). Then there exists a global solution to the integral equation

\[
\begin{align*}
  u(t, \omega) - u_0(\omega) + \int_0^t A(u(s, \omega)) \, ds + \int_0^t N(u(s, \omega)) \, ds = \int_0^t f(s, \omega) \, ds + q(t, \omega).
\end{align*}
\]

In addition to this, \( t \rightarrow u(t, \omega) \) is continuous into \( H \) and satisfies

\[
\begin{align*}
  u(\cdot, \omega) \in L^\infty([0, T]; H) \cap L^2([0, T]; W).
\end{align*}
\]

If, in addition to the above, \( u_0 \in L^2(\Omega; H) \) and \( f \in L^2([0, T] \times \Omega; W') \) and \( q \in L^2([0, T] \times \Omega; V) \), then the solution \( u \) is in \( L^2([0, T] \times \Omega; H) \cap L^2([0, T] \times \Omega; W) \).

**Proof:** The last claim follows from the estimates used in the Galerkin method, taking expectations and passing to a limit. To verify the continuity into \( H \), one can observe that from the integral equation, \( u \) is continuous into \( V' \). One has

\[
|u(t)|_H^2 = \sum_{k=1}^\infty (u(t), w_k)^2 = \sum_{k=1}^\infty (u(t), w_k)^2,
\]
and so $t \to |u(t)|_H^2$ is lower semi-continuous. Since it is in $L^\infty$, this implies this function is bounded. Hence the continuity into $V'$ and density of $V$ in $H$ implies that $u(t)$ is weakly continuous into $H$. Then one can use the formulation in Theorem 68.4.5 to verify $t \to |u(t)|_H$ is continuous and apply uniform convexity of the Hilbert space $H$.  

One can replace $q(t, \omega)$ with $q(t, \omega, u)$ and $f(t, \omega)$ with $f(t, \omega, u)$ in the above with no change in the argument, provided it is assumed that $(t, \omega, u)$ are product measurable, continuous in $(t, u)$ and bounded.

### 68.5 A Friction contact problem

In this section we will consider a friction contact problem which has a coefficient of friction which is dependent on the slip speed.

\[
\ddot{u}_i = \sigma_{ij,j}(u, \dot{u}) + f_i \quad \text{for} \quad (t, x) \in (0, T) \times U, \quad (68.5.15) \\
u(0, x) = u_0(x), \quad (68.5.16) \\
\dot{u}(0, x) = v_0(x), \quad (68.5.17)
\]

where $U$ is a bounded open subset of $\mathbb{R}^3$ having Lipschitz boundary, along with some boundary conditions which pertain to a part of the boundary of $U$, $\Gamma_C$. For $x \in \Gamma_C$,

\[
\sigma_n = -p((u_n - g)_+) C_n, \quad (68.5.18)
\]

This is the normal compliance boundary condition.

\[
|\sigma_T| \leq F((u_n - g)_+) \mu \left( |\dot{u}_T - \dot{U}_T| \right), \quad (68.5.19) \\
|\sigma_T| < F((u_n - g)_+) \mu \left( |\dot{u}_T - \dot{U}_T| \right) \quad \text{implies} \quad \dot{u}_T - \dot{U}_T = 0, \quad (68.5.20) \\
|\sigma_T| = F((u_n - g)_+) \mu \left( |\dot{u}_T - \dot{U}_T| \right) \quad \text{implies} \quad \dot{u}_T - \dot{U}_T = -\lambda \sigma_T(u, \dot{u}). \quad (68.5.21)
\]

Here $C_n$ is a positive function in $L^\infty(\Gamma_C)$, which we take equal to 1 to simplify notation, $\dot{U}_T$ is the velocity of the foundation, $\lambda$ is non negative, and $\mu$ is a bounded positive function having a bounded continuous derivative. We could also let $\mu$ depend on $x \in \Gamma_C$ to model the roughness of the contact surface but we will suppress this dependence in the interest of simpler notation. Also, $n$ is the unit outward normal to $\partial U$ and $u_n, u_T, \sigma_T$, and $\sigma_n$ are defined by the following.

\[
u_n = u \cdot n \\
u_T = u - (u \cdot n)n \\
\sigma_n = \sigma_{ij} n_j n_i
\]
CHAPTER 68. MEASURABILITY WITHOUT UNIQUENESS

\[
\sigma_{Ti} = \sigma_{ij}n_j - \sigma_{in_i},
\]

written more simply,

\[
\sigma_T = \sigma_n - \sigma_n n
\]

Systems like the above model dynamic friction contact problems \[34\], \[35\], \[36\]. The function \( g \) represents the gap between the contact surface of \( U \), \( \Gamma_C \), and a foundation which is sliding tangent to \( \Gamma_C \) with tangential velocity \( \dot{U}_T \).

The new ingredient in this paper is that we allow \( g = g(t, x, \omega) \), where \( \omega \in (\Omega, \mathcal{F}) \) and we assume \( (t, x, \omega) \rightarrow g(x, \omega) \) is \( B([0, T] \times \Gamma_C) \times \mathcal{F} \) measurable. Also, we make the reasonable assumption that

\[
0 \leq g(t, x, \omega) \leq t < \infty
\]

for all \( (t, x, \omega) \). We also assume that the given motion of the foundation \( \dot{U}_T \) is a stochastic process

\[
\dot{U}_T = \dot{U}_T (t, x, \omega)
\]

and is \( B([0, T] \times \Gamma_C) \times \mathcal{F} \) measurable. Here \( B([0, T] \times \Gamma_C) \) denotes the Borel sets of \([0, T] \times \Gamma_C \). We make the reasonable assumption that \( \dot{U}_T (t, x, \omega) \) is uniformly bounded. In the interest of notation, we will often suppress the dependence on \( t, x, \) and \( \omega \).

The condition \( 68.5.18 \) is the contact condition. It says the normal component of the traction force density is dependent on the normal penetration of the body into the foundation surface. Conditions \( 68.5.19 \) - \( 68.5.21 \) model friction. They say that the tangential part of the traction force density is bounded by a function determined by the normal force or penetration. No sliding takes place until \( |\sigma_T| \) reaches this bound, \( F((u_n - g)_+\mu(0), 68.5.20 \). When this occurs, the tangential force density has a direction opposite the relative tangential velocity \( 68.5.21 \). The dependence of the friction coefficient on the magnitude of the slip velocity, \( \dot{u}_T - \dot{U}_T \), may be experimentally verified and so it has been included. The new feature in this model is the assumption that the gap is a random variable for each \( x \in \Gamma_C \) and we want to consider measurability of the solutions. Thus for a fixed \( \omega \), we have a standard friction problem and it is the measurability which is of interest here.

In this paper, we assume the following on \( p \) and \( F \). The functions \( p \) and \( F \) are increasing and

\[
\delta^2r - K \leq p(r) \leq K(1 + r), \quad r \geq 0, \quad (68.5.22)
\]

\[
p(r) = 0, \quad r < 0,
\]

\[
F(r) \leq K(1 + r) \quad r \geq 0, \quad (68.5.23)
\]

\[
F(r) = 0 \text{ if } r < 0,
\]

\[
|\mu(r_1) - \mu(r_2)| \leq \text{Lip} (\mu)|r_1 - r_2|, \quad ||\mu||_\infty \leq C, \quad (68.5.24)
\]
A FRICTION CONTACT PROBLEM

and for \( a = F, p, \) and \( r_1, r_2 \geq 0, \)

\[
|a(r_1) - a(r_2)| \leq K|r_1 - r_2|. \tag{68.5.25}
\]

One can consider more general growth conditions than this, but we are keeping this part simple to emphasize the new stochastic considerations.

It will be assumed that

\[
\sigma_{ij} = A_{ijkl} u_k + C_{ijkl} \gamma_{i l}, \tag{68.5.26}
\]

where \( A \) and \( C \) are in \( L^1(U) \) and for \( B = A \) or \( C \), we have the following symmetries.

\[
B_{ijkl} = B_{ijlk}, B_{jikl} = B_{ijkl}, B_{ijkl} = B_{klij}, \tag{68.5.27}
\]

and we also assume for \( B = A \) or \( C \) that

\[
B_{ijkl} - H_{ij} H_{kl} \geq \varepsilon H_{rs} H_{rs}, \tag{68.5.28}
\]

for all symmetric \( H \).

Throughout the paper, \( V \) will be a closed subspace of \( (H^1(U))^3 \) containing the test functions \( (C^0_0(U))^3 \), \( \rightharpoonup \) will denote weak or weak * convergence while \( \rightarrow \) will mean strong convergence. \( \gamma \) will denote the trace map from \( W^{12}(U) \) into \( L^2(\partial U) \). \( H \) will denote \( (L^2(U))^3 \) and we will always identify \( H \) and \( H' \) to write

\[
V \subseteq H = H' \subseteq V'.
\]

We define

\[
V = L^2(0,T;V), \mathcal{H} = L^2(0,T,H), V' = L^2(0,T;V')
\]

68.5.1 The Abstract Problem

We shall use two theorems found in Lions \[82\], and Simon \[106\] respectively. These theorems apply for fixed \( \omega \). Proofs of generalizations of these theorems begin on Page 2449.

**Theorem 68.5.1** If \( p \geq 1, q > 1, \) and \( W \subseteq U \subseteq Y \) where the inclusion map of \( W \) into \( U \) is compact and the inclusion map of \( U \) into \( Y \) is continuous, let

\[
S = \{ u \in L^p(0,T;W) : u' \in L^q(0,T;Y) \text{ and} \}
\]

\[
\|u\|_{L^p(0,T;W)} + \|u'\|_{L^q(0,T;Y)} < R \}
\]

Then \( S \) is pre compact in \( L^p(0,T;U) \).

**Theorem 68.5.2** Let \( W, U, \) and \( Y \) be as in Theorem 68.5.1 and let

\[
S = \{ u : \|u(t)\|_W + \|u'(t)\|_{L^q(0,T;Y)} \leq R \text{ for } t \in [0,T] \}
\]

for \( q > 1 \). Then \( S \) is pre compact in \( C(0,T;U) \).
CHAPTER 68. MEASURABILITY WITHOUT UNIQUENESS

Now we give an abstract formulation of the problem described roughly in 68.5.15 - 68.5.21. We begin by defining several operators. Let $M, A : V \to V'$ be given by

$$\langle M u, v \rangle = \int_U C_{ijkl} u_{k,l} v_{i,j} dx,$$

$$(68.5.29)$$

$$\langle A u, v \rangle = \int_U A_{ijkl} u_{k,l} v_{i,j} dx.$$  

$$(68.5.30)$$

Also let the operator $v \to P(u)$ map $V$ to $V'$ be given by

$$\langle P(u), w \rangle = \int_0^T \int_{\Gamma_C} p((u_n - g)_+) w_n d\sigma dt,$$

$$(68.5.31)$$

where

$$u(t) = u_0 + \int_0^t v(s) ds,$$

$$(68.5.32)$$

for $u_0 \in V_q$. (Technically, $P$ depends on $u_0$ but we suppress this in favor of simpler notation.) Let $\gamma_T : L^2 (0, T; L^2 (\Gamma_C)^3) \to V'$ is defined as

$$\langle \gamma_T^* \xi, w \rangle = \int_0^T \int_{\Gamma_C} \xi \cdot w_T d\sigma dt.$$

Now the abstract form of the problem, denoted by $P$, is the following.

$$v' + M v + A u + P u + \gamma_T^* \xi = f \text{ in } V',$$

$$(68.5.33)$$

$$v(0) = v_0 \in H,$$

$$(68.5.34)$$

where

$$u(t) = u_0 + \int_0^t v(s) ds, \quad u_0 \in V_h,$$

$$(68.5.35)$$

and for all $w \in V$,

$$\langle \gamma_T^* \xi, w \rangle \leq \int_0^T \int_{\Gamma_C} F((u_n - g)_+) \mu \left( |v_T - \dot{U}_T| + |v_T - \dot{U}_T + w_T| - |v_T - \dot{U}_T| \right) d\sigma dt.$$  

$$(68.5.36)$$

Also $f \in L^2(0, T; V')$ so $f$ can include the body force as well as traction forces on various parts of $\partial U$. If $v$ solves the above abstract problem, then $u$ can be considered a weak solution to 68.5.26 - 68.5.28 along with other variational and stable boundary conditions depending on the choice of $W$ and $f \in L^2(0, T; V')$.

In order to carry out our existence and uniqueness proofs, we assume $M$ and $A$ satisfy the following for some $\delta > 0, \lambda \geq 0$.

$$\langle Bu, u \rangle \geq \delta^2 ||u||^2_W - \lambda ||u||^2_H, \quad \langle Bu, u \rangle \geq 0, \quad \langle Bu, v \rangle = \langle B v, u \rangle,$$

$$(68.5.37)$$

for $B = M$ or $A$. This is the assumption that we use, and we note that 68.5.37 is a consequence of 68.5.26 - 68.5.28 and Korn’s inequality 19.
68.5.  A FRICTION CONTACT PROBLEM

68.5.2 An Approximate Problem

We will use the Galerkin method. To do this, we will first regularize that subgradient material. Let

$$\psi_\varepsilon (r) = \sqrt{|r|^2 + \varepsilon}$$

Then this is a convex, Lipschitz continuous function having bounded derivative which converges uniformly to $\psi (r) = |r|$ on $\mathbb{R}$. Also

$$|\psi_\varepsilon (x) - \psi_\varepsilon (y)| \leq |x - y|, \quad |\psi_\varepsilon' (t)| \leq 1$$

And finally, $\psi_\varepsilon'$ is Lipschitz continuous with a Lipschitz constant $C/\sqrt{\varepsilon}$. Here $\psi_\varepsilon'$ denotes the gradient or Frechet derivative of the scalar valued function.

Our approximate problem for which we will apply the Galerkin method will be $P_{\varepsilon}$ given by

$$v' + Mv + Au + u\gamma_T^* F \left((u_n - g)_+\right) \mu \left(\left|v_T - \hat{U}_T\right|\right) \psi_\varepsilon' \left(v_T - \hat{U}_T\right) = f \text{ in } V',$$

$$v(0) = v_0 \in H,$$  \hspace{1cm} (68.5.38)

where

$$u(t) = u_0 + \int_0^t v(s) ds, \quad u_0 \in V,$$ \hspace{1cm} (68.5.39)

Here the long operator on the left is defined in the following manner.

$$\left< \gamma_T^* F \left((u_n - g)_+\right) \mu \left(\left|v_T - \hat{U}_T\right|\right) \psi_\varepsilon' \left(v_T - \hat{U}_T\right), w \right>$$

$$= \int_{\Gamma_C} F \left((u_n - g)_+\right) \mu \left(\left|v_T - \hat{U}_T\right|\right) \psi_\varepsilon' \left(v_T - \hat{U}_T\right) \cdot w_T ds$$

Let $R$ denote the Riesz map from $V$ to $V'$ defined by $\langle Ru, v \rangle = (u, v)_V$. Then $R^{-1} : H \to V$ is a compact self adjoint operator and so there exists a complete orthonormal basis for $H$, $\{e_k\} \subseteq V$ such that

$$Re_k = \lambda_k e_k$$

where $\lambda_k \to \infty$. Let $V_n = \text{span} (e_1, \ldots, e_n)$. Thus $\cup_n V_n$ is dense in $H$. In addition $\cup_n V_n$ is dense in $V$ and $\{e_k\}$ is also orthogonal in $V$. To see first that $\{e_k\}$ is orthogonal in $V$,

$$0 = (e_k, e_l)_H = \frac{1}{\lambda_k} \langle Re_k, e_l \rangle_H = \frac{1}{\lambda_k} \langle Re_k, e_l \rangle = \frac{1}{\lambda_k} (e_k, e_k)_V$$

Next consider why $\cup_n V_n$ is dense in $V$. If this is not so, then there exists $f \in V'$, $f \neq 0$ such that $\cup_n V_n$ is in $\ker (f)$. But $f = Ru$ and so

$$0 = \langle Ru, e_k \rangle = \langle Re_k, u \rangle = \lambda_k (e_k, u)_H$$
for all $e_k$ and so $u = 0$ by density of $\cup_n V_n$ in $H$. Hence $Ru = 0 = f$ after all, a contradiction. Hence $\cup_n V_n$ is dense in $V$ as claimed.

Now we set up the Galerkin method for Problem $P_\varepsilon$. Let

$$v_k(t, \omega) = \sum_{j=1}^{k} x_j(t, \omega) e_j, \quad u_k(t) = u_0 + \int_0^t v_k(s)ds$$

and let $v_k$ be the solution to the following integral equation for each $\omega$ and $j \leq k$.

The dependence on $\omega$ is suppressed in most terms in order to save space.

$$\langle v_k(t) - v_{0k}, f_j \rangle = \int_0^T \mu \left( \left| v_{kT} - \hat{U}_T \right| \right) \psi'_{\varepsilon} \left( v_{kT} - \hat{U}_T \right) \cdot v_k \cdot dS$$

(68.5.41)

Here $v_{0k} \to v_0 \in H$ and the equation holds for each $e_j$ for each $j \leq k$. Then this integral equation reduces to a system of ordinary differential equations for the vector $x(t, \omega)$ whose $j^{th}$ component is $x_j(t, \omega)$ mentioned above. Differentiate, multiply by $x_j$ and add. Then integrate. This will yield some terms which need to be estimated. Here is the one which comes from the long term.

$$\int_0^t \int_{\Gamma_C} F \left( (u_{kn} - g(\omega))_+ \right) \mu \left( \left| v_{kT} - \hat{U}_T \right| \right) \psi'_{\varepsilon} \left( v_{kT} - \hat{U}_T \right) \cdot v_{kT} ds \cdot dS$$

$$= \int_0^t \int_{\Gamma_C} F \left( (u_{kn} - g(\omega))_+ \right) \mu \left( \left| v_{kT} - \hat{U}_T \right| \right) \psi'_{\varepsilon} \left( v_{kT} - \hat{U}_T \right) \cdot v_{kT} ds \cdot dS$$

The first of these is nonnegative and the second is bounded below by an expression of the form

$$-C \int_0^t \int_{\Gamma_C} (1 + |u_{kn}|) \left| \hat{U}_T \right| ds \cdot dS \geq -C \int_0^t \| u_k \|_W \left| \hat{U}_T \right|_{L^2(\Gamma_C)^3} ds - C$$

$$\geq -C \int_0^t \| u_k \|_W - C$$

Where $W$ embeds compactly into $V$ and the trace map from $W$ to $L^2(\Gamma_C)^3$ is continuous. In the above, $C$ is independent of $\varepsilon, \omega$, and $k$. To estimate the term from $P$ one exploits the linear growth condition of $P$ in [85, 22] to obtain a suitable estimate.
It follows from equivalence of norms in finite dimensional spaces, the assumed estimates on \( M, A, \) and \( P \) and standard manipulations depending on compact embeddings that there exists an estimate suitable to apply Theorem 68.3.3 to obtain the existence of a solution such that \( (t, \omega) \to x(t, \omega) \) is measurable into \( \mathbb{R}^k \) which implies that \( (t, \omega) \to v_k(t, \omega) \) is product measurable into \( V \) and \( H \). This yields the measurable Galerkin approximation.

Also, the estimates and compact embedding results for Sobolev spaces imply an inequality of the form

\[
|v_k(t)|_H^2 + \int_0^T \|v_k\|^2_V \, ds + \|u_k(t)\|^2_V \leq C \tag{68.5.42}
\]

where in fact \( C \) does not depend on \( \varepsilon, \omega \) or \( k \). Everything would work if \( C \) depended on \( \varepsilon \) but because of our simplifying assumptions, we can get a single \( C \) as above.

Next we need to estimate the time derivative in \( V' \). The integral equation implies that for all \( w \in V_k \),

\[
(v'_k(t), w)_{V', V} + \left( \frac{Mv_k + Au_k + Pu_k + \gamma_T^*F((u_{kn} - g(\omega))_+)}{\mu(v_k - \dot{U}_T)} \psi'_\varepsilon(v_k - \dot{U}_T), w \right)_{V', V} = (f, w) \tag{68.5.43}
\]

where the dependence on \( t \) and \( \omega \) is suppressed in most terms. In terms of inner products in \( V \) this reduces to

\[
(R^{-1}v'_k(t), w)_V + \left( R^{-1} \left( \frac{Mv_k + Au_k + Pu_k + \gamma_T^*F((u_{kn} - g(\omega))_+)}{\mu(v_k - \dot{U}_T)} \psi'_\varepsilon(v_k - \dot{U}_T) \right), w \right)_V = (R^{-1}f, w)_V
\]

In terms of \( P_k \) the orthogonal projection in \( V \) onto \( V_k \), this takes the form

\[
(R^{-1}v'_k(t), P_k w)_V + \left( R^{-1} \left( \frac{Mv_k + Au_k + Pu_k + \gamma_T^*F((u_{kn} - g(\omega))_+)}{\mu(v_k - \dot{U}_T)} \psi'_\varepsilon(v_k - \dot{U}_T) \right), P_k w \right)_V = (R^{-1}f, P_k w)_V
\]

for all \( w \in V \). Now \( v'_k(t) \in V_k \) and so the first term can be simplified and we can write

\[
(R^{-1}v'_k(t), w)_V + \left( R^{-1} \left( \frac{Mv_k + Au_k + Pu_k + \gamma_T^*F((u_{kn} - g(\omega))_+)}{\mu(v_k - \dot{U}_T)} \psi'_\varepsilon(v_k - \dot{U}_T) \right), P_k w \right)_V = (R^{-1}f, P_k w)_V
\]
for all $w \in V$. Then it follows that for all $w \in V$,

$$\left( R^{-1}v'_k(t), w \right)_V +$$

$$\left( P_k R^{-1} \left( Mv_k + Au_k + Pu_k + \gamma^*_T F \left( (u_n - g(\omega))_+ \right) \cdot \mu \left( |v_{kT} - \hat{U}_T| \right) \psi'_\varepsilon \left( v_{kT} - \hat{U}_T \right) \right), w \right)_V$$

$$= \left( P_k R^{-1}f, w \right)_V$$

Thus in $V$ we have

$$R^{-1}v'_k(t) + P_k R^{-1} \left( Mv_k + Au_k + Pu_k + \gamma^*_T F \left( (u_n - g(\omega))_+ \right) \cdot \mu \left( |v_{kT} - \hat{U}_T| \right) \psi'_\varepsilon \left( v_{kT} - \hat{U}_T \right) \right) = P_k R^{-1}f$$

and $R^{-1}$ preserves norms while $P_k$ decreases them. Hence the estimate 68.5.42 implies that $\|v'_k\|_V$ is also bounded independent of $\varepsilon, \omega$ and $k$. Then summarizing this yields

$$|v_k(t, \omega)|_H + \|v_k(\cdot, \omega)\|_V + \|v'_k(\cdot, \omega)\|_V + \|u_k(t, \omega)\|_V \leq C(\omega) \quad (68.5.44)$$

where $C$ is some constant which does not depend on $\varepsilon, \omega$, and $k$. Also, integrating 68.5.43, it follows that

$$i^*_k \left( v_k(t) - v_0 \right) + \int_0^t Mv_k ds + \int_0^t Au_k ds + \int_0^t Pu_k ds +$$

$$\int_0^t \gamma^*_T F \left( (u_{kn} - g(\omega))_+ \right) \mu \left( |v_{kT} - \hat{U}_T| \right) \psi'_\varepsilon \left( v_{kT} - \hat{U}_T \right) ds = i^*_k \int_0^t f ds \quad (68.5.45)$$

Where $i^*_k$ is the dual map to the inclusion map $i_k : V_k \rightarrow V$.

Let

$$V \subseteq W, \ V \text{ dense in } W,$$

where the embedding is compact and the trace map onto the boundary of $U$ is continuous. Using Theorem 68.5.2 and 68.5.4, it follows that for a fixed $\omega$, there exist the following convergences valid for a suitable subsequence, still denoted as $\{v_k\}$ which may depend on $\omega$.

$$v_k \rightarrow v \text{ in } V \quad (68.5.46)$$

$$v'_k \rightarrow v' \text{ in } V' \quad (68.5.47)$$

$$v_k \rightarrow v \text{ strongly in } C(\{0, T\}, W') \quad (68.5.48)$$

$$v_k \rightarrow v \text{ strongly in } L^2(\{0, T\}; W) \quad (68.5.49)$$

$$v_k(t) \rightarrow v(t) \text{ in } W \text{ for a.e. } t \quad (68.5.50)$$

$$u_k \rightarrow u \text{ strongly in } C(\{0, T\}; W') \quad (68.5.51)$$
\[ Au_k \to Au \text{ in } \mathcal{V}' \quad (68.5.52) \]
\[ Mv_k \to Mv \text{ in } \mathcal{V}' \quad (68.5.53) \]

Now from these convergences and the density of \( \bigcup_n V_n \), it follows on passing to a limit and using dominated convergence theorem and the strong convergences above in the nonlinear terms, we obtain the following equation which holds in \( \mathcal{V}' \).

\[
\begin{align*}
\mathbf{v} (t) - \mathbf{v}_0 + \int_0^t M \mathbf{v} ds + \int_0^t A \mathbf{u} ds + \int_0^t P \mathbf{u} ds + \\
\int_0^t \gamma_T^* F \left( (u_{n_k} - g (\omega))_+ \right) \mu \left( \left| \mathbf{v}_T - \mathbf{U}_T \right| \right) \psi_{t/k} \left( \mathbf{v}_T - \mathbf{U}_T \right) ds = \int_0^t \mathbf{f} ds
\end{align*}
\]  

(68.5.54)

Thus \( t \to \mathbf{v} (t, \omega) \) is continuous into \( \mathcal{V}' \). This along with the estimate \[ \| \mathbf{v} \| \leq C \| \mathbf{f} \| \] implies that the conditions of Theorem \[ \text{68.5.5.6} \] are satisfied. It follows that there is a function \( \bar{v} \) which is product measurable into \( \mathcal{V}' \) and weakly continuous in \( t \) and for each \( \omega \), a subsequence \( v_{k(\omega)} \) such that \( v_{k(\omega)} (\cdot, \omega) \to \bar{v} (\cdot, \omega) \) in \( \mathcal{V}' \). Then by a repeat of the above argument, for each \( \omega \), there exists a further subsequence still denoted as \( v_{k(\omega)} \) which converges in \( \mathcal{V}' \) to \( v (\cdot, \omega) \) which is a solution to the above integral equation which is continuous into \( \mathcal{V}' \). Hence, \( \bar{v} (\cdot, \omega) = v (\cdot, \omega) \) and since these are both weakly continuous into \( \mathcal{V}' \) they must be the same function. Hence, there is a product measurable solution \( \mathbf{v} \).

Next we pass to a limit as \( \varepsilon \to 0 \). Denoting the product measurable solution to the above integral equation as \( \mathbf{v}_k \), where \( \varepsilon = 1/k \). The estimate \[ \| \mathbf{v}_k \| \leq C \| \mathbf{f} \| \] is obtained as before. Then we get a subsequence, still denoted as \( v_k \) which has the same convergences as in \[ \text{68.5.5.6} \] - \[ \text{68.5.5.7} \]. Thus we obtain these convergences along with the fact that \( v_k \) is product measurable and for each \( \omega \), it is a solution of

\[
\begin{align*}
\mathbf{v}_k (t) - \mathbf{v}_0 + \int_0^t M \mathbf{v}_k ds + \int_0^t A \mathbf{u}_k ds + \int_0^t P \mathbf{u}_k ds + \\
\int_0^t \gamma_T^* F \left( (u_{kn} - g (\omega))_+ \right) \mu \left( \left| \mathbf{v}_{kT} - \mathbf{U}_T \right| \right) \psi_{t/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T \right) ds = \int_0^t \mathbf{f} ds
\end{align*}
\]  

(68.5.55)

Now in addition to these convergences, we can also obtain

\[
\psi_{t/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T \right) \to \xi \text{ in } L^\infty \left( [0, T]; L^\infty (\Gamma_C) \right)
\]

We have also

\[
\psi_{1/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T \right) \cdot \mathbf{w}_T \leq \psi_{1/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T + \mathbf{w}_T \right) - \psi_{1/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T \right)
\]

and so, passing to a limit, using the strong convergence of \( \mathbf{v}_{kT} \) to \( \mathbf{v}_T \) in \( L^2 \left( [0, T]; W \right) \), uniform convergence of \( \psi_{1/k} \) to \( \| \cdot \| \), and pointwise convergence in \( W \), we obtain using the dominated convergence theorem that for \( \mathbf{w} \in \mathcal{V} \),

\[
\int_0^t \int_{\Gamma_C} F \left( (u_{kn} - g (\omega))_+ \right) \mu \left( \left| \mathbf{v}_{kT} - \mathbf{U}_T \right| \right) \psi_{t/k} \left( \mathbf{v}_{kT} - \mathbf{U}_T \right) \cdot \mathbf{w}_T dx ds
\]

\[
\to \int_0^t \int_{\Gamma_C} F \left( (u_n - g (\omega))_+ \right) \mu \left( \left| \mathbf{v}_T - \mathbf{U}_T \right| \right) \xi \cdot \mathbf{w}_T dx ds
\]
where

$$
\int_0^t \int_{\Gamma_C} \xi \cdot w_T \, ds \leq \int_0^t \int_{\Gamma_C} \left| v_{kT} - \dot{U}_T + w_T \right| \, ds
$$

(68.5.56)

Then passing to the limit in the integral equation (68.5.55), we obtain that $v$ is a solution for each $\omega$ to the integral equation

$$
v(t) - v_0 + \int_0^t M v \, ds + \int_0^t A u \, ds + \int_0^t P u \, ds +
\int_0^t \gamma_0^+ F \left( (u_n - g(\omega))^+ \right) \mu \left( \left| v_{T} - \dot{U}_T \right| \right) \xi \, ds = \int_0^t f \, ds
$$

(68.5.57)

where $\xi$ satisfies the inequality (68.5.56). In particular, $v$ is continuous into $V'$ and now, the conclusion of the measurable selection theorem applies and yields the existence of a measurable solution to the integral equation just displayed for each $\omega$. Taking a weak derivative, it follows that we have obtained a measurable solution to the system (68.5.33) - (68.5.36).

In this case of Lipschitz $\mu$ one can show that the solution for each $\omega$ to the above integral equation is unique although this it is not an obvious theorem. This follows standard procedures involving Gronwall's inequality and estimates. Therefore, it is possible to obtain the measurability using more elementary methods. In addition, it becomes possible to include a stochastic integral of the form $\int_0^t \Phi \, dW$. In this case one must consider a filtration and obtain solutions which are adapted to the filtration. In the next section we consider the case of discontinuous friction coefficient and in this case it is not clear whether there is uniqueness but we have still obtained a measurable solution.

### 68.5.3 Discontinuous coefficient of friction

In this section we consider the case where the coefficient of friction is a discontinuous function of the slip speed. This is the case described in elementary physics courses which state that the coefficient of sliding friction is less than the coefficient of static friction. Specifically, we assume the function $\mu$, has a jump discontinuity at 0, becoming smaller when the speed is positive.
We assume the function $\mu_\epsilon$ of the picture is Lipschitz continuous and decreasing just as shown. The new function $\nu$ is extended for $r < 0$ as shown and is just $\mu_\epsilon (r) + \eta$ for $r > 0$.

Let

$$h_\epsilon (r) = (\eta^2 r^2 + \epsilon)^{1/2}$$

$$\mu_\epsilon (r) = \nu (r) - h_\epsilon ' (r)$$

Thus $\mu_\epsilon$ is bounded, Lipschitz continuous and as $\epsilon \to 0$, $\mu_\epsilon (r) \to \mu (r)$ for $r > 0$. Thus, for each $\epsilon = 1/k$, there exists a measurable solution to the integral equation

$$v_k (t) - v_0 + \int_0^t M v_k ds + \int_0^t A u_k ds + \int_0^t P u_k ds +$$

$$\int_0^t \gamma_1^2 F \left( (u_{kn} - g (\omega))_+ \right) \mu_{1/k} \left( \left| v_{kT} - \bar{U}_T \right| \right) \xi_k ds = \int_0^t f ds$$

(68.5.58)

where

$$\int_0^t \int_{\Gamma_C} \xi_k \cdot w_T dxdos \leq \int_0^t \int_{\Gamma_C} \left| v_{kT} - \bar{U}_T + w_T \right| \left| v_{kT} - \bar{U}_T \right| dxdos$$

(68.5.59)

Now for a given $\omega$, the same estimate obtained earlier is available. Thus

$$|v_k (t)|^2_H + \int_0^T \| v_k \|^2_V ds + \| u_k (t) \|^2_V \leq C$$

where $C$ is not dependent on $k$. Recall also that $\xi_k$ is bounded. Hence from the estimate, it also follows that $v'_k$ is bounded in $V'$. Thus

$$|v_k (t)|^2_H + \int_0^T \| v_k \|^2_V ds + \| u_k (t) \|^2_V + \| v'_k \|^2_{V'} \leq C$$

As earlier, we can take $C$ independent of $k$ and $\omega$ although we do not need this constant to be independent of $\omega$. Now for fixed $\omega$, there exists a subsequence, still denoted as $\{ v_k \}$ such that the convergences obtained earlier all hold, that is, $v_{1/k}$ converges to $v$ in $L^\infty ([0,T], L^\infty (\Gamma_C))$. Taking a further subsequence, we may assume also that

$$\psi - h_{1/k} \left( \left| v_{kT} - \bar{U}_T \right| \right) \to 0 \text{ in } L^\infty ([0,T], L^\infty (\Gamma_C)),$$

$$\xi_k \to \xi \text{ weak * in } L^\infty \left( [0,T], L^\infty (\Gamma_C)^3 \right).$$

That is, $h_{1/k} \left( \left| v_{(1/k)T} - \bar{U}_T \right| \right)$ converges weak * in $L^\infty ([0,T], L^\infty (\Gamma_C))$ to some $\psi$. This is because

$$h_\epsilon ' (r) = \frac{\eta^2 r}{r^2 \eta^2 + \epsilon}$$
and this is bounded. Letting \( w \in L^1 \left( [0, T]; L^1(\Gamma_C) \right) \),

\[
\int_0^T \int_{\Gamma_C} h'_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| \right) w \, dt \\
\leq \int_0^T \int_{\Gamma_C} h_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| + w \right) - h_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| \right) w \, dt
\]

Thanks to the strong convergences and the uniform convergence of \( h_{(1/k)} (r) \) to \(|\eta|\),

\[
\int_0^T \int_{\Gamma_C} \psi w \, dt \leq \int_0^T \int_{\Gamma_C} \eta \left( \left| v_{T} - \hat{U}_T \right| + w \right) - \eta \left| v_{T} - \hat{U}_T \right| \, dt
\]

Therefore, for a.e.t, \( \psi(t, x, \omega) \) is in the subgradient of the function \( \phi_{t} (r) = |\eta| \) for a.e.x \( \in \Gamma_C \) at the point \( r = \left| v_{kT} - \hat{U}_T \right| \). In particular, \( \psi \in [-\eta, \eta] \) so that \( \nu \left( \left| v_{kT} - \hat{U}_T \right| \right) - \psi \) is between \( \mu_0 (0) \) and \( \mu_0 \) if \( \left| v_{kT} - \hat{U}_T \right| = 0 \). If this quantity is positive, then \( \psi = \eta \) and \( \nu \left( \left| v_{kT} - \hat{U}_T \right| \right) - \psi \) reduces to \( \mu_0 \left( \left| v_{kT} - \hat{U}_T \right| \right) \). Thus

\[
\left( \left| v_{kT} - \hat{U}_T \right|, \nu \left( \left| v_{kT} - \hat{U}_T \right| \right) - \psi \right)
\]

is in the graph of \( \mu \) a.e. Similar reasoning based on strong convergence and \ref{68.5.58} implies that for a.e.t, \( \xi \in \partial \gamma \) where \( \gamma(y) = |y| \) at the point \( v_{kT} - \hat{U}_T \) for a.e. \( x \in \Gamma_C \).

Consider the friction terms in \ref{68.5.58}. Letting \( w \in \mathcal{V} \) and recalling that \( \mu_{(1/k)} (r) = \nu (r) - h'_{(1/k)} (r) \),

\[
\int_0^T \int_{\Gamma_C} \mathcal{F} \left( (u_n - g)_+ \right) \mu_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| \right) \xi_k \cdot w \, dt \\
= \int_0^T \int_{\Gamma_C} \mathcal{F} \left( (u_n - g)_+ \right) \left( \nu \left( \left| v_{kT} - \hat{U}_T \right| \right) - h'_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| \right) \right) \xi_k \cdot w \, dt
\]

\[
+ \int_0^T \int_{\Gamma_C} \mathcal{F} \left( (u_n - g)_+ \right) \left( \psi - h'_{(1/k)} \left( \left| v_{kT} - \hat{U}_T \right| \right) \right) \xi_k \cdot w \, dt
\]

Now consider the first integral. The strong convergence yields that this integral in \ref{68.5.60} converges to

\[
\int_0^T \int_{\Gamma_C} \mathcal{F} \left( (u_n - g)_+ \right) \psi \left( \left| v_{T} - \hat{U}_T \right| \right) - \psi \xi_k \cdot w \, dt
\]

where \( \nu \left( \left| v_{T} - \hat{U}_T \right| \right) - \psi \) is in the graph of \( \mu \) a.e.
Consider the second integral in (68.5.61)

\[ \int_0^T \int_{\Gamma_C} \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \right) \xi_k \cdot w_T \, \text{d}t \, \text{d}a \]

\[ \leq \int_0^T \int_{\Gamma_C} \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \right) \cdot \left( \left[ v_{kT} - \dot{U}_T + w_T \right] - \left[ v_{kT} - \dot{U}_T \right] \right) \, \text{d}a \, \text{d}t \]

Similarly,

\[ - \int_0^T \int_{\Gamma_C} \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \right) \xi_k \cdot w_T \, \text{d}t \, \text{d}a \]

\[ \leq \int_0^T \int_{\Gamma_C} \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \right) \cdot \left( \left[ v_{kT} - \dot{U}_T - w_T \right] - \left[ v_{kT} - \dot{U}_T \right] \right) \, \text{d}a \, \text{d}t \]

Each of these integrals on the right side converge to 0 because, from the strong convergence results,

\[ \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \left[ v_{kT} - \dot{U}_T \pm w_T \right] - \left[ v_{kT} - \dot{U}_T \right] \right) \]

converges in \( L^1 \left( [0, T], L^1 (\Gamma_C) \right) \) and so the weak * convergence to 0 of

\[ \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \]

implies that these integrals converge to 0. Thus the integral in (68.5.61)

\[ \int_0^T \int_{\Gamma_C} \mathcal{F} \left( \left( u_{kn} - g \right)_+ \right) \left( \psi - h'_T \left[ v_{kT} - \dot{U}_T \right] \right) \xi_k \cdot w_T \, \text{d}t \, \text{d}a \]

is between two sequences each of which converges to 0 so it also converges to 0.

To save space, denote by

\[ \tilde{\mu} = \nu \left( \left| v_T - \dot{U}_T \right| \right) - \psi \]

Then passing to the limit in this subsequence, we obtain for fixed \( \omega \) the existence of a solution to the following integral equation.

\[
\mathbf{v} \left( t \right) - \mathbf{v}_o + \int_0^t M \mathbf{v} \, \text{d}s + \int_0^t A \mathbf{u} \, \text{d}s + \int_0^t P \mathbf{u} \, \text{d}s + \int_0^t \gamma_T^* \mathcal{F} \left( \left( u_n - g \right)_+ \right) \tilde{\mu} \xi \, \text{d}s = \int_0^t \mathbf{f} \, \text{d}s
\]  

(68.5.62)
where
\[
u(t) = u_0 + \int_0^t v(s) \, ds
\] (68.5.63)
and \(\left| v_{kT} - \hat{U}_T \right| \) is contained in the graph of \(\mu\) a.e. Also for each \(w \in V\),
\[
\int_0^T \int_{\Gamma_C} \xi \cdot w_T \, d\alpha \leq \int_0^T \int_{\Gamma_C} \left| v_{kT} - \hat{U}_T + w_T \right| - \left| v_{kT} - \hat{U}_T \right| \, d\alpha \quad (68.5.64)
\]

The remaining issue concerns the existence of a measurable solution. However, this follows in the same way as before from the measurable selection theorem, Theorem 68.2.1. From the above reasoning, for fixed \(\omega\) any sequence has a subsequence which leads to a solution to the integral equation 68.5.62 - 68.5.64 which is continuous into \(V'\). There is also an estimate of the right sort for all of the \(v_k\). Therefore, from this theorem, there is a function \(v(\cdot, \omega)\) in \(V'\) which is weakly continuous into \(V'\) and a sequence \(v_{k(\omega)}(\cdot, \omega)\) converging to \(v(\cdot, \omega)\). Then from the above argument, a subsequence converges to a solution to the integral equation and since both are weakly continuous into \(V'\), it follows that the solution to the integral equation equals this measurable function for all \(t\), this for each \(\omega\). Thus there is a measurable solution to the stochastic friction problem. The result is stated in the following theorem.

**Theorem 68.5.3** For each \(\omega\) let \(u_0(\omega) \in V, v_0(\omega) \in H\). Let \(f \in V'\). Also assume the gap \(g\) and sliding velocity \(\hat{U}_T\) are \(\mathcal{F}\) measurable. Then there exists a solution \(v\), to the problem summarized in 68.5.62 - 68.5.64 for each \(\omega\). This solution \((t, \omega) \mapsto v(t, \omega)\) is measurable into \(V', H'\) and \(V'\).

It only remains to check the last claim about measurability into the other spaces. By density of \(V\) into \(H\), it follows that \(H'\) is dense in \(V'\) and so a simple Pettis theorem argument implies right away that \(\omega \mapsto v(t, \omega)\) is \(\mathcal{F}\) measurable into both \(V\) and \(H\).
Chapter 69

Stochastic O.D.E. One Space

69.1 Adapted Solutions With Uniqueness

Instead of a single \(\sigma\) algebra \(\mathcal{F}\), one can generalize to the case of a normal filtration \(\mathcal{F}_t\) and obtain adapted solutions to finite dimensional theorems, provided one also knows path uniqueness of the solutions. Recall that a filtration is normal includes the following condition which is what we will use.

\[
\mathcal{F}_t = \bigcap_{s > t} \mathcal{F}_s \quad (69.1.1)
\]

Theorem 69.1.1 Suppose \(N(t, u, v, w, \omega) \in \mathbb{R}^d\) for \(u, v, w \in \mathbb{R}^d, t \in [0, T]\) and \((t, u, v, w, \omega) \to N(t, u, v, w, \omega)\) is progressively measurable with respect to a normal filtration or more generally one which satisfies (69.1.1). Also suppose \((t, u, v, w) \to N(t, u, v, w, \omega)\) is continuous. Suppose for each \(\omega\), there exists an estimate for any solution \(u(\cdot, \omega)\) to the integral equation

\[
u(t, \omega) - u_0(\omega) + \int_0^t N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds,
\]

which is of the form

\[
\sup_{t \in [0, T]} |u(t, \omega)| \leq C(\omega) < \infty
\]

Also let \(f\) be progressively measurable and \(f(\cdot, \omega) \in L^1([0, T]; \mathbb{R}^d)\). Here \(u_0\) has values in \(\mathbb{R}^d\) and is \(\mathcal{F}_0\) measurable and \(u(s-h, \omega) = u_0(\omega)\) whenever \(s-h \leq 0\) and

\[
w(t, \omega) = w_0(\omega) + \int_0^t u(s, \omega) \, ds
\]

where \(w_0\) is a given \(\mathcal{F}_0\) measurable function. Also assume that for each \(\omega\) there is at most one solution to the integral equation (69.1.1). Then for \(h > 0\), there exists a progressively measurable solution \(u\) to the integral equation (69.1.2).
Proof: Let \(0 = t_0 < t_1 < \cdots < t_n = T\). From Theorem 68.3.3, there exists a solution to the integral equation \(u\) which has the property that \(u(t \wedge t_j)\) is \(\mathcal{F}_{t_j}\) measurable. One simply applies this theorem to the succession of intervals determined by the given partition. Now suppose \(\mathcal{P}^n\) consists of the points \(k2^{-n}T = t_j^n\) so that these satisfy \(\mathcal{P}^n \subseteq \mathcal{P}^{n+1}\) and the lengths of the sub-intervals decreases to 0 with increasing \(n\). Let \(u_n\) denote the solution just described corresponding to \(\mathcal{P}^n\) such that \(u_n(t \wedge t_j^n)\) is \(\mathcal{F}_{t_j^n}\) measurable. As before, using the estimate, these \(u_n(\cdot, \omega)\) for a fixed \(\omega\) are uniformly bounded and equicontinuous. This is because it is a solution to the integral equation for each \(\omega\) and so by assumption, there is an estimate. Therefore, for fixed \(\omega\), there exists \(u(\cdot, \omega)\) and a subsequence, denoted as \(u_{n_k}(\cdot, \omega)\) which converges uniformly to \(u(\cdot, \omega)\) on \([0, T]\). Therefore, \(u(\cdot, \omega)\) will be a solution to the integral equation for that \(\omega\). It follows from the uniqueness assumption, that it is not necessary to take a subsequence. Thus

\[
u(t, \omega) = \lim_{n \to \infty} u_n(t, \omega)
\]

For \(t \in (t_j^{n-1}, t_j^n]\), it follows that \(\omega \to u(t, \omega)\) is \(\mathcal{F}_{t_j^n}\) measurable. Since this is true for each \(n\) and the filtration is assumed to be a normal filtration, we conclude that \(\omega \to u(t, \omega)\) is \(\mathcal{F}_t\) measurable. \(\blacksquare\)

Why can’t this be generalized to the situation where no uniqueness is known? We have been unable to do this. It appears that the difficulty is related to the need to use theorems about measurable selections and these theorems pertain to a single \(\sigma\) algebra. Attempts to use the \(\sigma\)-algebra of progressively measurable sets have not been successful either.

69.2 Including Stochastic Integrals

It is not surprising that Theorem 69.1.1 is sufficient to allow the inclusion of a stochastic integral. Thus, with the same descriptions of the symbols used in that theorem, one could consider the following integral equation.

\[
u(t, \omega) - \nu_0(\omega) + \int_0^t N(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) \, ds
\]

\[
= \int_0^t f(s, \omega) \, ds + \int_0^t \Phi dW
\]

where, as usual \(\Phi \in L^2([0, T] \times \Omega; L_2(Q^{1/2}U, \mathbb{R}^d))\) where \(U\) is a Hilbert space. It could be \(\mathbb{R}^d\) of course. To include a stochastic integral, you define a new variable.

\[
\hat{u}(t) = u(t) - \int_0^t \Phi dW
\]

Then in terms of this new variable, the integral equation is

\[
\hat{u}(t, \omega) - \hat{u}_0(\omega) + \int_0^t N(s, \hat{u}(s, \omega) + \int_0^s \Phi dW, \hat{u}(s - h, \omega) + \int_0^{s-h} \Phi dW, \omega)
\]
69.2. INCLUDING STOCHASTIC INTEGRALS

\[ \int_0^s \left( \dot{u}(r) + \int_0^r \Phi \, dW \right) \, dr, \omega \, ds = \int_0^t f(s, \omega) \, ds \]

This is in the situation of Theorem 69.1 provided \( N \) is progressively measurable with respect to the normal filtration \( \mathcal{F}_t \) determined by the Wiener process and there exists an estimate of the sort in this theorem and for a given \( \omega \) there is at most one solution \( t \to \dot{u}(t, \omega) \) to the above integral equation.

**Theorem 69.2.1** Suppose \( N(t, u, v, w, \omega) \in \mathbb{R}^d \) for \( u, v, w \in \mathbb{R}^d, t \in [0, T] \) and \( (t, u, v, w, \omega) \to N(t, u, v, w, \omega) \) is progressively measurable with respect to the normal filtration \( \mathcal{F}_t \) determined by a given Wiener process \( W(t) \). Also suppose

\[ (t, u, v, w) \to N(t, u, v, w, \omega) \]

is continuous and satisfies the following conditions for \( C(\cdot, \omega) \geq 0 \) in \( L^1([0, T]) \) and some \( \mu > 0 \):

\[ (N(t, u, v, w, \omega), u) \geq -C(t, \omega) - \mu \left( |u|^2 + |v|^2 + |w|^2 \right). \]  

(69.2.3)

Also let \( f \) be progressively measurable and \( f(\cdot, \omega) \in L^2([0, T]; \mathbb{R}^d) \). Let

\[ \Phi \in L^2 \left( [0, T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2} U, \mathbb{R}^d \right) \right) \]

where \( U \) is some Hilbert space, \( \mathbb{R}^d \), for example. Also suppose path uniqueness. That is, for each \( \omega \), there is at most one solution to the integral equation

\[ u(t, \omega) - u_0(\omega) + \int_0^t N(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) \, ds \]

\[ = \int_0^t f(s, \omega) \, ds + \int_0^t \Phi \, dW, \]  

(69.2.4)

Then for \( h > 0 \), there exists a unique progressively measurable solution \( u \) to the integral equation 69.2.4 where \( u_0 \) has values in \( \mathbb{R}^d \) and is \( \mathcal{F}_0 \) measurable. Here \( u(s - h, \omega) \equiv u_0(\omega) \) for all \( s - h \leq 0 \) and for \( w_0 \) a given \( \mathcal{F}_0 \) measurable function,

\[ w(t, \omega) \equiv w_0(\omega) + \int_0^t u(s, \omega) \, ds \]

**Proof:** The only thing left is to observe that the given estimate is sufficient to obtain an estimate for the solutions to the integral equation for \( \dot{u} \) defined above. Then from Theorem 69.1 there exists a unique progressively measurable solution for \( \dot{u} \) and hence for \( u \). Note that the integral equation holds for all \( t \) for each \( \omega \). There is no exceptional set of measure zero which might depend on the initial condition needed.

What is a sufficient condition for path uniqueness? Suppose the following weak monotonicity condition for \( \mu = \mu(\omega) \),

\[ (N(t, u_1, v_1, w_1, \omega) - N(t, u_2, v_2, w_2, \omega), u_1 - u_2) \]

\[ \geq -\mu \left( |u_1 - u_2|^2 + |v_1 - v_2|^2 + |w_1 - w_2|^2 \right) \]  

(69.2.5)
Then path uniqueness will hold. This follows from subtracting the two integral equations, one for \( u_1 \) and one for \( u_2 \), using the estimate and then applying Gronwall’s inequality.

Recall the Ito formula

\[
 u(t) - u_0 + \int_0^t N(s)ds = \int_0^t f(s)ds + \int_0^t \Phi dW
\]

where \( u(t) \in H \) a Hilbert space. Consider \( F(u) = \frac{1}{2} |u|^2 \). Also let \( R \) denote the Riesz map from \( H \to H' \) such that \( \langle Rx, y \rangle = \langle x, y \rangle_H \). Then proceeding formally, to see what the Ito formula says,

\[
dF = DF(u)du + \frac{1}{2} D^2 F(u)(du, du) + O(du^3)
\]

Recall then that \( du = -Ndt + fdt + \Phi dW \) and so recalling \( (dW, dW) = dt \),

\[
 R(u)(-Ndt + fdt + \Phi dW) + \frac{1}{2} \|\Phi\|^2 dt
\]

Hence

\[
 \frac{1}{2} |u(t)|^2_H - \frac{1}{2} |u_0|^2_H + \int_0^t \langle N, u \rangle_H ds - \frac{1}{2} \int_0^t \|\Phi\|_{L_2}^2 ds = \int_0^t (f, u) ds + \int_0^t R(u)(\Phi) dW
\]

The last term is a martingale or local martingale \( M \) whose quadratic variation is given by

\[
 [M](t) = \int_0^t \|\Phi\|_{L_2}^2 |u|^2 ds
\]

This is all that is of importance in what follows. Therefore, this martingale may be simply denoted as \( M(t) \) in what follows.

Under the assumption \( 69.2.5 \) you can include instead of the term \( \int_0^t \Phi dW \), the more general term \( \int_0^t \sigma(s, u, \omega) dW \). This will be shown by doing the argument and indicating what extra assumptions are needed as this is done. Let \( z \) be progressively measurable and in \( L^2(\Omega; C([0, T]; \mathbb{R}^n)) \). Also assume that \( \sigma \) has linear growth. That is

\[
 \|\sigma(s, u, \omega)\|_{L_2} \leq a + b |u|_{\mathbb{R}^n}
\]

Then from the above theorem, there exists a unique progressively measurable solution \( u \) to

\[
 u(t, \omega) - u_0(\omega) + \int_0^t N(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) ds
\]

\[
 = \int_0^t f(s, \omega) ds + \int_0^t \sigma(s, z) dW; \tag{69.2.7}
\]

This holds for all \( \omega \). There is no exceptional set needed. Now assume

\[
 u_0 \in L^2(\Omega) \tag{69.2.8}
\]
and also a Lipschitz condition
\[ \| \sigma (s, u, \omega) - \sigma (s, \tilde{u}, \omega) \|_{\mathcal{L}_2} \leq K |u - \tilde{u}| \]  
(69.2.9)

Then let \( u \) coincide with \( z \) and \( \tilde{u} \) come from \( \tilde{z} \). Then applying the Ito formula, one can obtain the following for a constant \( C \) which does not depend on \( u, \tilde{u} \).

\[
\frac{1}{2} |u(t) - \tilde{u}(t)|^2 - C \int_0^t |u(s) - \tilde{u}(s)|^2 ds - K \int_0^t |u(s) - \tilde{u}(s)|^2 ds = M(t)
\]

where \( M(t) \) is a local martingale whose quadratic variation satisfies

\[
[M](t) = \int_0^t \| \sigma (s, z, \omega) - \sigma (s, \tilde{z}, \omega) \|_{\mathcal{L}_2}^2 |u - \tilde{u}|^2 ds
\]

Thus, simplifying the constants,

\[
\sup_{s \in [0, t]} |u(s) - \tilde{u}(s)|^2 \leq C \int_0^t |u(s) - \tilde{u}(s)|^2 ds + M^*(t)
\]

where \( M^*(t) = \sup_{s \in [0, t]} |M(s)| \). Then by Gronwall’s inequality,

\[
\sup_{s \in [0, t]} |u(s) - \tilde{u}(s)|^2 \leq CM^*(t)
\]

Then take the expectation of both sides. Using the Burkholder Davis Gundy inequality,

\[
E \left( \sup_{s \in [0, t]} |u(s) - \tilde{u}(s)|^2 \right) \leq CE \left( \int_0^t K |z - \tilde{z}|^2 |u - \tilde{u}|^2 ds \right)^{1/2}
\]

Then adjusting the constant again,

\[
\leq \frac{1}{2} E \left( \sup_{s \in [0, t]} |u(s) - \tilde{u}(s)|^2 \right) + CE \left( \int_0^t K |z - \tilde{z}|^2 ds \right)^{1/2}
\]

and so,

\[
E \left( \sup_{s \in [0, t]} |u(s) - \tilde{u}(s)|^2 \right) \leq C \int_0^t E \left( \sup_{r \in [0, s]} |z(s) - \tilde{z}(s)|^2 \right) ds
\]

Letting \( Tz = u \) where \( u \) is defined from \( z \) in the integral equation 69.2.7, the above inequality implies that

\[
E \left( \sup_{s \in [0, t]} |T^n z_1(s) - T^n z_2(s)|_H^2 \right) \leq C \int_0^t E \left( \sup_{r \in [0, s]} |T^{n-1} z_1(r) - T^{n-1} z_2(r)|_H^2 \right) ds
\]
Suppose the weak monotonicity condition and the growth condition

\[ \leq C^2 \int_0^t \int_s^0 E \left( \sup_{r_1 \in [0,r]} |T^u z_1(r_1) - T^u z_2(r_1)|^2 \right) dr ds \]

One can iterate this, eventually finding that

\[ E \left( \sup_{s \in [0,t]} |T^n z_1(s) - T^n z_2(s)|^2 \right) \]

\[ \leq C^n \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} dt_{n-1} \cdots dt E \left( \sup_{s \in [0,t]} |z_1(s) - z_2(s)|^2 \right) \]

\[ = \frac{C^n T^n}{(n!)} E \left( \sup_{s \in [0,t]} |z_1(s) - z_2(s)|^2 \right) \]

In particular, this holds for \( t = T \) and so, letting \( z \in L^2(\Omega, C([0,T], \mathbb{R}^n)) \), \( \{T^n z\} \) is a Cauchy sequence in this space because a high enough power is a contraction map, so it converges to a unique fixed point \( u \). Each \( T^n z \) is progressively measurable and so the fixed point is also. In \( L^2(\Omega, C([0,T], \mathbb{R}^n)) \), you get the integral equation

\[ u(t, \omega) - u_0(\omega) + \int_0^t \mathbf{N}(s, u(s, \omega), u(s - h, \omega), w(s, \omega), \omega) ds \]

\[ = \int_0^t f(s, \omega) ds + \int_0^t \sigma(s, u) dW, \]

Thus off a set of measure zero, the equation holds for all \( t \) and \( u \) is progressively measurable. The place where \( u_0 \in L^2(\Omega) \) is needed is in having \( Tz \in L^2(\Omega, C([0,T]; \mathbb{R}^n)) \). One uses a similar procedure involving the Ito formula, the growth condition

\[ \mathbf{N}(t, u, v, w, \omega, u) \geq -C(t, \omega) - \mu \left( |u|^2 + |v|^2 + |w|^2 \right) \]

and the Burkholder Davis Gundy inequality to verify this. Since \( T \) depends on \( u_0 \), it appears that the set of measure zero, off which the integral equation holds, will also depend on \( u_0 \). It appears that this ultimately results from the need to take an expectation in order to deal with the stochastic integral. If this integral could be generalized in such a way that it made sense for each \( \omega \) as in the usual Riemann Stieltjes integral, then likely this restriction could be removed. It is a problem because the Wiener process is not of bounded variation.

**Theorem 69.2.2** Suppose the weak monotonicity condition and the growth estimate. Also assume \( \mathbf{N}(t, u, v, w, \omega) \in \mathbb{R}^d \) for \( u, v, w \in \mathbb{R}^d, t \in [0,T] \) and \( (t, u, v, w, \omega) \to \mathbf{N}(t, u, v, w, \omega) \) is progressively measurable with respect to the normal filtration \( \mathcal{F}_t \) determined by a given Wiener process \( W(t) \). Also suppose \( (t, u, v, w) \to \mathbf{N}(t, u, v, w, \omega) \) is continuous. Let \( f \in L^2(\Omega, C([0,T], \mathbb{R}^n)) \) and
69.3. STOCHASTIC DIFFERENTIAL EQUATIONS IN A HILBERT SPACE

$(t, u, \omega) \rightarrow \sigma (t, u, \omega)$ is progressively measurable and satisfies the linear growth condition \([69.2.7]\) and the Lipschitz condition \([69.2.9]\). Also suppose $u_0$ is $\mathcal{F}_0$ measurable and in $L^2 (\Omega, \mathbb{R}^n)$. Then there exists a progressively measurable solution $u$ to \([69.2.10]\). If $\hat{u}$ is another such solution, then there is a set of measure zero $N$ such that for $\omega \notin N, \hat{u}(t) = u(t)$ for all $t$.

Proof: It only remains to verify the uniqueness assertion. This happens because the fixed point is unique in $L^2 (\Omega, C([0, T], \mathbb{R}^n))$. Therefore, off a set of measure zero the two solutions are equal for all $t$. ■

69.3 Stochastic Differential Equations In A Hilbert Space

In this section, ordinary differential equations in Hilbert space which are of the form

$$du + N(u) dt = f dt + \sigma(u) dW$$

are considered under Lipschitz assumptions on $N$ and $\sigma$. A very satisfactory theorem can be proved.

The assumptions made are as follows.

$$\|\sigma(t, u, \omega) - \sigma(t, \hat{u}, \omega)\|_{\mathcal{L}_2(\Omega)} \leq K |u - \hat{u}|_H,$$

$$|N(t, u_1, v_1, w_1, \omega) - N(t, u_2, v_2, w_2, \omega)| \leq K (|u_1 - u_2| + |v_1 - v_2| + |w_1 - w_2|)$$

where the norms $|\cdot|$ refer here to the Hilbert space $H$. Assume $N, \sigma$ are both progressively measurable. From the Lipschitz condition given above,

$$|N(t, u, v, w, \omega) - N(t, 0, 0, 0, \omega)| \leq K (|u| + |v| + |w|)$$

and it is assumed that

$$t \rightarrow N(t, 0, 0, 0, \omega)$$

is in $L^2 (\Omega, C([0, T]; H))$. Also consider the growth condition which is implied by the above condition and the Lipschitz assumption.

$$(N(t, u, v, w, \omega), u) \geq -C(t, \omega) - \mu \left(|u|^2 + |v|^2 + |w|^2\right)$$

where $C \in L^1 ([0, T] \times \Omega)$ and the linear growth condition for $\sigma$,

$$\|\sigma(t, u, \omega)\| \leq a + b |u|_H$$
CHAPTER 69. STOCHASTIC O.D.E. ONE SPACE

69.3.1 The Lipschitz Case

Theorem 69.3.1 Suppose \( w(t) = w_0 + \int_0^t u(s) \, ds, \ w_0 \in L^2(\Omega), \ w_0 \) is \( \mathcal{F}_0 \) measurable.

Then there exists a unique progressively measurable solution \( u \) to the integral equation

\[
\begin{align*}
    u(t, \omega) - u_0(\omega) + \int_0^t &N(s, u(s, \omega), u(s-h, \omega), w(s, \omega), \omega) \, ds \\
    = &\int_0^t f(s, \omega) \, ds + \int_0^t \sigma(s, u, \omega) \, dW. \tag{69.3.16}
\end{align*}
\]

where \( u \in L^2(\Omega; C([0, T]; H)), u_0 \in L^2(\Omega) \), \( u_0 \) is \( \mathcal{F}_0 \) measurable, \( f \) is progressively measurable and in \( L^2([0, T] \times \Omega; H) \). Here there is a set of measure zero such that if \( \omega \) is not in this set, then \( u(\cdot, \omega) \) solves the above integral equation \( \text{PDE} \) and furthermore, if \( \bar{u}(\cdot, \omega) \) is another solution to it, then \( u(t, \omega) = \bar{u}(t, \omega) \) for all \( t \) if \( \omega \) is off some set of measure zero.

Proof: Let \( v \in L^2(\Omega; C([0, T]; H))) \) where \( v \) is also progressively measurable. Then let \( u \) be given by

\[
\begin{align*}
    u(t, \omega) - u_0(\omega) + \int_0^t &N(s, v(s, \omega), v(s-h, \omega), w(s, \omega), \omega) \, ds \\
    = &\int_0^t f(s, \omega) \, ds + \int_0^t \sigma(s, v, \omega) \, dW. \tag{69.3.17}
\end{align*}
\]

The Lipschitz condition \( \text{PDE} \), the assumption \( \text{PDE} \) and the linear growth assertion \( \text{PDE} \) implies that \( u \) is also in \( L^2(\Omega; C([0, T]; H))) \). The proof of this involves the same arguments about to be given in order to show that this determines a mapping which has a sufficiently high power a contraction map. They are also the same arguments to be used in the following theorem to establish estimates which imply a stopping time is eventually infinity.

Let \( v_1, v_2 \) be two given functions of this sort and let the corresponding \( u \) be denoted by \( u_1, u_2 \) respectively. Then

\[
\begin{align*}
    u_1(t) - u_2(t) + \int_0^t &N(s, v_1(s), v_1(s-h), w_1(s)) - N(s, v_2(s), v_2(s-h), w_2(s)) \, ds \\
    = &\int_0^t \sigma(s, v_1, \omega) - \sigma(s, v_2, \omega) \, dW
\end{align*}
\]

Use the Ito formula and the Lipschitz condition on \( N \) to obtain an expression of the form

\[
\frac{1}{2} |u_1(t) - u_2(t)|^2 - C \int_0^t |v_1 - v_2|^2 \, ds - C \int_0^t |u_1 - u_2|^2 \, ds
\]
69.3. STOCHASTIC DIFFERENTIAL EQUATIONS IN A HILBERT SPACE

\[ \frac{1}{2} \int_0^t \| \sigma(s,v_1,\omega) - \sigma(s,v_2,\omega) \|^2 \, ds \leq |M(t)| \]

where \( M(t) \) is a martingale whose quadratic variation is dominated by

\[ C \int_0^t \| \sigma(s,v_1,\omega) - \sigma(s,v_2,\omega) \|^2 \, |u_1 - u_2|^2 \, ds \]

Therefore, using the Lipschitz condition on \( \sigma \) and the Burkholder-Davis-Gundy inequality, the above implies

\[
\begin{align*}
E \left( \sup_{s \in [0,t]} |u_1(s) - u_2(s)|^2 \right) & \leq CE \int_0^t \sup_{r \in [0,s]} |v_1(r) - v_2(r)|^2 \, ds \\
& + CE \int_0^t \sup_{r \in [0,s]} |v_1(r) - v_2(r)|^2 \, ds \\
& + CE \left( \left( \int_0^t \| \sigma(s,v_1,\omega) - \sigma(s,v_2,\omega) \|^2 \, |u_1 - u_2|^2 \, ds \right)^{1/2} \right)
\end{align*}
\]

Then a use of Gronwall’s inequality allows this to be simplified to an expression of the form

\[
\begin{align*}
E \left( \sup_{s \in [0,t]} |u_1(s) - u_2(s)|^2 \right) & \leq CE \int_0^t \sup_{r \in [0,s]} |v_1(r) - v_2(r)|^2 \, ds \\
& + CE \left( \left( \int_0^t \| \sigma(s,v_1,\omega) - \sigma(s,v_2,\omega) \|^2 \, |u_1 - u_2|^2 \, ds \right)^{1/2} \right)
\end{align*}
\]

\[
\leq C \int_0^t E \left( \sup_{r \in [0,s]} |v_1(r) - v_2(r)|^2 \right) \, ds + \frac{1}{2} \int_0^t E \left( \sup_{s \in [0,t]} |u_1(s) - u_2(s)|^2 \right) \, ds \\
+ CE \left( \int_0^t \| \sigma(s,v_1,\omega) - \sigma(s,v_2,\omega) \|^2 \, ds \right)
\]

Now using the Lipschitz condition on \( \sigma \), this simplifies further to give an inequality of the form

\[
E \left( \sup_{s \in [0,t]} |u_1(s) - u_2(s)|^2 \right) \leq C \int_0^t E \left( \sup_{r \in [0,s]} |v_1(r) - v_2(r)|^2 \right) \, ds
\]

Letting \( T^v = u \) where \( u \) is defined from \( v \) in the integral equation 69.3.17, the above inequality implies that

\[
E \left( \sup_{s \in [0,t]} |T^n v_1(s) - T^n v_2(s)|^2 \right) \leq C \int_0^t E \left( \sup_{r \in [0,s]} |T^{n-1} v_1(r) - T^{n-1} v_2(r)|^2 \right) \, ds
\]
\[
\leq C^2 \int_0^t \int_0^s E \left( \sup_{r_1 \in [0, r]} \left| T^{n-2} v_1 (r_1) - T^{n-2} v_2 (r_1) \right|^2 \right) \, dr \, ds
\]

One can iterate this, eventually finding that

\[
E \left( \sup_{s \in [0, t]} \left| T^n v_1 (s) - T^n v_2 (s) \right|^2 \right)
\leq C^n \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} dt_{n-1} \cdots dt E \left( \sup_{s \in [0, t]} \left| v_1 (s) - v_2 (s) \right|^2 \right)
= \frac{C^n T^n}{(n!)} E \left( \sup_{s \in [0, t]} \left| v_1 (s) - v_2 (s) \right|^2 \right)
\]

In particular, one could take \( t = T \). This shows that for all \( n \) large enough, \( T^n \) is a contraction map on \( L^2 (\Omega, C ([0, T]; H)) \). Therefore, picking \( v \in L^2 (\Omega, C ([0, T]; H)) \), such that \( v \) is also progressively measurable, \( \{ T^k v \}_{k=1}^\infty \) converges in \( L^2 (\Omega, C ([0, T]; H)) \) to the unique fixed point of \( T \) denoted as \( u \). Thus \( Tu = u \) in \( L^2 (\Omega; C ([0, T]; H)) \).

That is,
\[
\int_{\Omega} \sup_t |Tu - u|^2 \, dP = 0
\]

It follows that there is a set of measure zero such that for \( \omega \) not in this set,

\[
u (t, \omega) - u_0 (\omega) + \int_0^t N (s, u(s, \omega), u (s - h, \omega), w (s, \omega), \omega) \, ds
\leq \int_0^t f (s, \omega) \, ds + \int_0^t \sigma (s, u, \omega) \, dW.
\] 

(69.3.18)

The function \( u \) is progressively measurable because each \( T^n v \) is progressively measurable and there exists a subsequence still indexed with \( n \) such that for \( \omega \) off a set of measure zero, \( T^n v (\cdot, \omega) \rightarrow u (\cdot, \omega) \) in \( C ([0, T]; H) \).

Note that the fixed point of \( T \) is unique in the space \( L^2 (\Omega; C ([0, T]; H)) \) and so any solution to the integral equation in this space must equal this one. Hence, there exists a set of measure zero such that for \( \omega \) off this set, the two solutions are equal for all \( t \).

### 69.3.2 The Locally Lipschitz Case

Now replace the Lipschitz assumption with the locally Lipschitz assumption which says that if \( \max \left( |u|, |v|, |w| \right) < R \), then there is a constant \( K_R \) such that

\[
|N (t, u_1, v_1, w_1, \omega) - N (t, u_2, v_2, w_2, \omega)| \leq K (R) (|u_1 - u_2| + |v_1 - v_2| + |w_1 - w_2|)
\]

(69.3.19)

Also assume the growth condition

\[
(N (t, u, v, w, \omega), u) \geq -C (t, \omega) - \mu \left( |u|^2 + |v|^2 + |w|^2 \right)
\]

(69.3.20)
and the linear growth condition on $\sigma$

$$\|\sigma(t, u, \omega)\| \leq a + b \|u\|_H$$

and the Lipschitz condition on $\sigma$. This can likely be relaxed as in the case of the Lipschitz condition for $N$ but for simplicity, we keep it.

**Theorem 69.3.2** Suppose $u_0$, $u$, $w_0$, $f$ are measurable, $f$ is progressively measurable and in $L^2([0, T] \times \Omega; H)$. Then there exists a unique progressively measurable solution $u$ to the integral equation

$$u(t, \omega) = u_0(\omega) + \int_0^t N(s, u(s, \omega), u(s - h, \omega), w(s, \omega, \omega)) \, ds$$

$$= \int_0^t f(s, \omega) \, ds + \int_0^t \sigma(s, u, \omega) \, dW.$$  \hfill (69.3.21)

where $u \in L^2(\Omega, C([0, T]; H))$, $u_0 \in L^2(\Omega, H)$, $u_0$ is $F_0$ measurable, $f$ is progressively measurable and in $L^2([0, T] \times \Omega; H)$. Here there is a set of measure zero such that if $\omega$ is not in this set, then $u(\cdot, \omega)$ solves the above integral equation and furthermore, if $\hat{u}(\cdot, \omega)$ is another solution to it, then $u(t, \omega) = \hat{u}(t, \omega)$ for all $t$ if $\omega$ is off some set of measure zero.

**Proof:** Let $u_n$ be the unique solution to the integral equation

$$u_n(t, \omega) = u_0(\omega) + \int_0^t N(s, P_n u_n(s, \omega), P_n u_n(s - h, \omega), P_n w_n(s, \omega, \omega)) \, ds$$

$$= \int_0^t f(s, \omega) \, ds + \int_0^t \sigma(s, u_n, \omega) \, dW.$$ \hfill (69.3.22)

where $P_n$ is the projection onto $B(0, 2^n)$. Thus the modified problem is in the situation of Theorem 69.3.1 so there exists such a solution. Then let

$$\tau_n = \inf \{ t : |u_n(t)| + |w_n(t)| > 2^n \}$$

Then stopping the equation with this stopping time, we can write

$$u_n^{\tau_n}(t, \omega) = u_0(\omega) + \int_0^{\tau_n} N(s, u_n^{\tau_n}(s, \omega), u_n^{\tau_n}(s - h, \omega), w_n^{\tau_n}(s, \omega, \omega)) \, ds$$

$$= \int_0^{\tau_n} f(s, \omega) \, ds + \int_0^{\tau_n} \sigma(s, u_n^{\tau_n}, \omega) \, dW.$$ \hfill (69.3.23)

Then using the growth condition and the Ito formula,

$$\frac{1}{2} \|u_n^{\tau_n}(t)\|_H^2 \leq C(u_0, w_0, f) + C \int_0^{\tau_n} \|u_n^{\tau_n}\|_H^2 \, ds + \sup_{s \in [0, t]} |M(t)|$$
where \( M(t) \) is a martingale whose quadratic variation is dominated by

\[
\int_0^t \|\sigma(s, u_n^\tau(s))\|^2 |u_n^\tau(s)|^2 \, ds
\]

Then it follows by the Burkholder-Davis-Gundy inequality

\[
E \left( \sup_{s \in [0,t]} |u_n^\tau(s)|_H^2 \right) \leq E \left( C(u_0, w_0, f) \right) + C \int_0^t E \left( \sup_{r \in [0,s]} |u_n^\tau(r)|^2 \, dr \right) \, ds
\]

\[
+ CE \left( \left( \int_0^t \|\sigma(s, u_n^\tau(s))\|^2 |u_n^\tau(s)|^2 \, ds \right)^{1/2} \right)
\]

Now apply Gronwall’s inequality and modify the constants so that

\[
E \left( \sup_{s \in [0,t]} |u_n^\tau(s)|_H^2 \right) \leq E \left( C(u_0, w_0, f) \right) + CE \left( \left( \int_0^t \|\sigma(s, u_n^\tau(s))\|^2 |u_n^\tau(s)|^2 \, ds \right)^{1/2} \right)
\]

\[
E \left( \sup_{s \in [0,t]} |u_n^\tau(s)|_H^2 \right) \leq E \left( C(u_0, w_0, f) \right) + \frac{1}{2} E \left( \sup_{s \in [0,t]} |u_n^\tau(s)|_H^2 \right) + CE \left( \int_0^t \|\sigma(s, u_n^\tau(s))\|^2 |u_n^\tau(s)|^2 \, ds \right)
\]

Then, using the linear growth condition on \( \sigma \), it follows on modification of the constants again that

\[
E \left( \sup_{s \in [0,t]} |u_n^\tau(s)|_H^2 \right) \leq E \left( C(u_0, w_0, f) \right) + CE \left( \int_0^t |u_n^\tau(s)|^2 \, ds \right)
\]

\[
\leq E \left( C(u_0, w_0, f) \right) + CE \left( \int_0^t \sup_{r \in [0,s]} |u_n^\tau(r)|^2 \, dr \right)
\]

and so, another application of Gronwall’s inequality implies that

\[
E \left( \sup_{s \in [0,T]} |u_n^\tau(s)|_H^2 \right) \leq E \left( C(u_0, w_0, f) \right) < \infty
\]

Then

\[
P \left( \sup_{s \in [0,T]} |u_n^\tau(s)|_H^2 > \left( \frac{3}{2} \right)^n \right) \leq E \left( C(u_0, w_0, f) \right) \left( \frac{2}{3} \right)^n
\]

Now an application of the Borel Cantelli lemma shows that there exists a set of measure zero \( \tilde{N} \) such that for \( \omega \notin \tilde{N} \), it follows that for all \( n \) large enough,

\[
\sup_{s \in [0,T]} |u_n^\tau(s)|_H^2 < (3/2)^n
\]

and so \( \tau_n = \infty \) for all \( n \) large enough.
Claim: For \( m < n \), there is a set of measure zero \( N_{mn} \) such that if \( \omega \notin N_{mn} \), then \( u^n_m(s) = u^m_m(s) \) on \([0, T \wedge \tau_m]\).

Proof of the claim: Note that \( m < n \). Therefore, these are both progressively measurable solutions to the integral equation

\[
\begin{align*}
    u(t \wedge \tau_m, \omega) - u_0(\omega) + \int_0^t X_{[0, \tau_m]}(s, u(s, \omega), u(s - h, \omega), w_u(s, \omega), \omega) \, ds \\
    = \int_0^t X_{[0, \tau_m]} f(s, \omega) \, ds + \int_0^t X_{[0, \tau_m]} \sigma(s, u, \omega) \, dW. \tag{69.3.24}
\end{align*}
\]

where

\[
    w_u(t) = w_0 + \int_0^t u(s) \, ds.
\]

To save notation, refer to these functions as \( u, v \) and let \( \tau_m = \tau \). Subtract and use the Ito formula to obtain

\[
    \frac{1}{2} \left| u(t \wedge \tau) - v(t \wedge \tau) \right|_H^2 \leq \int_0^t X_{[0, \tau]} \| \sigma(s, u, \omega) - \sigma(s, v, \omega) \|^2 |u - v|^2 \, ds
\]

Then from the assumption that \( N \) is locally Lipschitz and routine manipulations,

\[
    \frac{1}{2} \left| u(t \wedge \tau) - v(t \wedge \tau) \right|_H^2 \leq C_m \int_0^t X_{[0, \tau]} |u - v|^2 \, ds + \sup_{s \in [0, t]} |M(s)|
\]

and so, adjusting the constants yields

\[
    \sup_{s \in [0, t]} |u(s \wedge \tau) - v(s \wedge \tau)|_H^2 \leq C_m \int_0^t X_{[0, \tau]} \sup_{r \in [0, s]} |u(r \wedge \tau) - v(r \wedge \tau)|^2 \, ds + \sup_{s \in [0, t]} |M(s)|
\]

and so, by Gronwall’s inequality followed by the Burkholder-Davis-Gundy inequality,

\[
    E \left( \sup_{s \in [0, t]} |u(s \wedge \tau) - v(s \wedge \tau)|_H^2 \right) \leq \ldots
\]
and so, adjusting the constant again,
\[
E \left( \sup_{s \in [0,t]} |u(s) - v(s)|^2 \right)
\]
\[
\leq \frac{1}{2} E \left( \sup_{s \in [0,t]} |u(s) - v(s)|^2 \right) + CE \left( \int_0^t X_{[0,\tau]} \left( \left\| \sigma(s, u) - \sigma(s, v) \right\|^2 \right) \, ds \right)
\]
and so, Gronwall’s inequality shows that for every \( t \),
\[
E \left( \sup_{s \in [0,t]} |u(s) - v(s)|^2 \right) = 0
\]
In particular, for \( t = T \) this holds. Hence
\[
E \left( \sup_{s \in [0,T]} |u(s) - v(s)|^2 \right) = 0
\]
It follows that
\[
E \left( \sup_{s \in [0,\tau \wedge T]} |u(s) - v(s)|^2 \right) = 0
\]
so that off a set of measure zero, \( u(s) = v(s) \) for all \( s \in [0, \tau] \). This proves the claim.

Now let the set of measure zero \( N \) be given by \( N = \cup_{m<\tau} N \cup \hat{N} \) where \( \hat{N} \) is the set of measure zero off which \( \tau_m = \infty \) for all \( m \) large enough. Then for \( \omega \notin N \), it follows that \( u_m^\tau(s) = u_m^\tau(s) \) on \( [0, \tau_m \wedge T] \) and, for all \( m \) large enough, \( \tau_m = \infty \). Hence for all \( m \) large enough, and such \( \omega \), \( u_m(s, \omega) = u_m(s, \omega) \) for all \( s \in [0, T] \). Thus, for \( \omega \) off \( N \), it follows that \( \lim_{m \to \infty} u_m^\tau(s, \omega) = u(s, \omega) \) exists, this for each \( s \in [0, T] \) and \( \omega \) off a fixed set of measure zero. In fact, this convergence is uniform on \( [0, T] \) because for all \( n \) sufficiently large and for such a fixed \( \omega \notin N \), there is no change in increasing \( m \). Hence, \( u \) is progressively measurable and satisfies the integral equation (69.3.21).
It remains to verify uniqueness. Suppose there are two solutions $u, v$ each progressively measurable solutions of the given integral equation. Then let $\tau_n$ be a stopping time

$$\tau_n = \inf \{ t : |u(t)| + |v(t)| > 2^n \}$$

Then a repeat of the arguments given in the above claim shows that on $[0, \tau_n \wedge T]$ the two functions $u^{\tau_n}, v^{\tau_n}$ are equal on $[0, \tau_n \wedge T]$ off a set of measure zero $N_n$. Let $N$ be the union of the exceptional sets. Then for $\omega \notin N$, $u(t, \omega) = v(t, \omega)$ for all $t \in [0, \tau_n \wedge T]$. However, $\tau_n(\omega) = \infty$ for all $n$ large enough because each of these functions is continuous. Hence, the two functions are equal on $[0, T]$ for such $\omega$. This shows uniqueness. \(\blacksquare\)
Chapter 70

The Hard Ito Formula

Recall the following definition of stochastically continuous.

$X$ is stochastically continuous at $t_0 \in I$ means: for all $\varepsilon > 0$ and $\delta > 0$ there exists $\rho > 0$ such that

$$P \left( \| X(t) - X(t_0) \| \geq \varepsilon \right) \leq \delta \text{ whenever } |t - t_0| < \rho, t \in I.$$ 

Note the above condition says that for each $\varepsilon > 0$,

$$\lim_{t \to t_0} P \left( \| X(t) - X(t_0) \| \geq \varepsilon \right) = 0.$$ 

70.1 Predictable And Stochastic Continuity

Definition 70.1.1 Let $\mathcal{F}_t$ be a filtration. The predictable sets consists of those sets which are in the smallest $\sigma$ algebra which contains the sets $E \times \{0\}$ for $E \in \mathcal{F}_0$ and $E \times (a, b]$ where $E \in \mathcal{F}_a$. Thus every predictable set is a progressively measurable set.

First of all, here is an important observation.

Proposition 70.1.2 Let $X(t)$ be a stochastic process having values in $E$ a complete metric space and let it be $\mathcal{F}_t$ adapted and left continuous where $\mathcal{F}_t$ is a normal filtration. Then it is predictable. If $t \to X(t, \omega)$ is continuous for all $\omega \in \mathcal{N}, P(N) = 0$, then $(t, \omega) \to X(t, \omega) \chi_{\mathcal{N}C}(\omega)$ is predictable. Also, if $X(t)$ is stochastically continuous and adapted on $[0, T]$, then it has a predictable version. If $X \in C([0, T]; L^p(\Omega; F)), p \geq 1$ for $F$ a Banach space, then $X$ is stochastically continuous.

Proof: First suppose $X$ is continuous for all $\omega \in \Omega$. Define

$$I_{m,k} \equiv ((k - 1)2^{-m}T, k2^{-m}T]$$

2507
if \( k \geq 1 \) and \( I_{m,0} = \{0\} \) if \( k = 1 \). Then define

\[
X_m(t) \equiv \sum_{k=1}^{2^m} X\left(T\left(k-1\right)2^{-m}\right)X_{((k-1)2^{-m}T,k2^{-m}T]}(t) \\
+X(0)X_{[0,0]}(t)
\]

Here the sum means that \( X_m(t) \) has value \( X\left(T\left(k-1\right)2^{-m}\right) \) on the interval \((k-1)2^{-m}T,k2^{-m}T]\). Thus \( X_m \) is predictable because each term in the formal sum is. Thus

\[
X_1m(U) = \bigcup_{k=1}^{2^m} \left( X\left(T\left(k-1\right)2^{-m}\right)X_{((k-1)2^{-m}T,k2^{-m}T]} \right)^{-1}(U)
\]

a finite union of predictable sets. Since \( X \) is left continuous,

\[
X(t,\omega) = \lim_{m \to \infty} X_m(t,\omega)
\]

and so \( X \) is predictable.

Now suppose that for \( \omega \notin N \), \( P(N) = 0 \), \( t \to X(t,\omega) \) is continuous. Then applying the above argument to \( X(t)X_{N^c} \) it follows \( X(t)X_{N^c} \) is predictable by completeness of \( \mathcal{F}_t \), \( X(t)X_{N^c} \) is \( \mathcal{F}_t \) measurable.

Next consider the other claim. Since \( X \) is stochastically continuous on \([0,T]\) it is uniformly stochastically continuous on this interval by Lemma 60.1.1. Therefore, there exists a sequence of partitions of \([0,T]\), the \( m^{th} \) being

\[
0 = t_{m,0} < t_{m,1} < \cdots < t_{m,n(m)} = T
\]

such that for \( X_m \) defined as above, then for each \( t \)

\[
P\left(\left[d\left(X_m(t),X(t)\right) \geq 2^{-m}\right]\right) \leq 2^{-m} \tag{70.1.1}
\]

Then as above, \( X_m \) is predictable. Let \( A \) denote those points of \( \mathcal{P}_T \) at which \( X_m(t,\omega) \) converges. Thus \( A \) is a predictable set because it is just the set where \( X_m(t,\omega) \) is a Cauchy sequence. Now define the predictable function \( Y \)

\[
Y(t,\omega) \equiv \left\{ \begin{array}{ll} & \lim_{m \to \infty} X_m(t,\omega) \text{ if } (t,\omega) \in A \\
& 0 \text{ if } (t,\omega) \notin A \end{array} \right.
\]

From 70.1.1 it follows from the Borel Cantelli lemma that for fixed \( t \), the set of \( \omega \) which are in infinitely many of the sets,

\[
[d\left(X_m(t),X(t)\right) \geq 2^{-m}]
\]

has measure zero. Therefore, for each \( t \), there exists a set of measure zero, \( N(t) \) such that for \( \omega \notin N(t) \) and all \( m \) large enough

\[
[d\left(X_m(t,\omega),X(t,\omega)\right) < 2^{-m}]
\]
70.2. APPROXIMATING WITH STEP FUNCTIONS

Hence for $\omega \notin N(t), (t, \omega) \in A$ and so $X_m(t, \omega) \rightarrow Y(t, \omega)$ which shows

$$d(Y(t, \omega), X(t, \omega)) = 0$$  if $\omega \notin N(t).$

The predictable version of $X(t)$ is $Y(t)$.

Finally consider the claim about the specific example where $X_{2N}(t; \omega)$ and so $X_{m}(t; \omega)$ which shows

$$d(Y(t; \omega), X(t; \omega)) = 0$$  if $\omega \notin N(t):$

The predictable version of $X(t)$ is $Y(t)$.

Finally consider the claim about the specific example where $X_{2N}(t; \omega)$ and so $X_{m}(t; \omega)$ which shows

$$d(Y(t; \omega), X(t; \omega)) = 0$$  if $\omega \notin N(t):$

70.2 Approximating With Step Functions

This Ito formula seems to be the fundamental idea which allows one to obtain solutions to stochastic partial differential equations using a variational point of view. I am following the treatment found in [72]. The following lemma is fundamental to the presentation. It approximates a function with a sequence of two step functions $X_r^k; X_l^k$ where $X_r^k$ has the value of $X$ at the right end of each interval and $X_l^k$ gives the value $X$ at the left end of the interval. The lemma is very interesting for its own sake. You can obviously do this sort of thing for a continuous function but here the function is not continuous and in addition, it is a stochastic process depending on $\omega$ also. This lemma was proved earlier Lemma 63.3.1.

**Lemma 70.2.1** Let $\Phi : [0, T] \times \Omega \rightarrow V$, be $B([0, T]) \times F$ measurable and suppose

$$\Phi \in K \equiv L^p([0, T] \times \Omega; E), \ p \geq 1$$

Then there exists a sequence of nested partitions, $\mathcal{P}_k \subseteq \mathcal{P}_{k+1},$

$$\mathcal{P}_k = \{t_{0}^{k}, \ldots, t_{m_k}^{k}\}$$

such that the step functions given by

$$\Phi^r_k(t) = \sum_{j=1}^{m_k} \Phi(t_j^k) X_{r(t_{j-1}^k, t_j^k)}(t)$$

$$\Phi^l_k(t) = \sum_{j=1}^{m_k} \Phi(t_{j-1}^k) X_{l(t_{j-1}^k, t_j^k)}(t)$$

both converge to $\Phi$ in $K$ as $k \rightarrow \infty$ and

$$\lim_{k \rightarrow \infty} \max \{ |t_j^k - t_{j+1}^k| : j \in \{0, \ldots, m_k\} \} = 0.$$
Also, each \( \Phi \left( t^k_j \right), \Phi \left( t^k_{j-1} \right) \) is in \( L^p(\Omega;E) \). One can also assume that \( \Phi(0) = 0 \).

The mesh points \( \left\{ t^k_j \right\}_{j=0}^{m_k} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that

\[
|t^k_j - t^k_{j-1}| = 2^{-n_k}
\]

except for the case where \( j = 1 \) or \( j = m_n \) when this might not be so. In the case of the last subinterval defined by the partition, we can assume

\[
|t^k_m - t^k_{m-1}| = |T - t^k_{m-1}| \geq 2^{-(n_k+1)}
\]

The following lemma is convenient.

**Lemma 70.2.2** Let \( f_n \to f \) in \( L^p \left( [0,T] \times \Omega, E \right) \). Then there exists a subsequence \( n_k \) and a set of measure zero \( N \) such that if \( \omega \notin N \), then

\[
f_{n_k}(\cdot, \omega) \to f(\cdot, \omega)
\]

in \( L^p \left( [0,T], E \right) \) and for a.e. \( t \).

**Proof:** We have

\[
P \left( \left\| f_n - f \right\|_{L^p([0,T],E)} > \lambda \right) \leq \frac{1}{\lambda} \int_{\Omega} \left\| f_n - f \right\|_{L^p([0,T],E)} dP \leq \frac{1}{\lambda} \left\| f_n - f \right\|_{L^p([0,T] \times \Omega, E)}
\]

Hence there exists a subsequence \( n_k \) such that

\[
P \left( \left\| f_{n_k} - f \right\|_{L^p([0,T],E)} > 2^{-k} \right) \leq 2^{-k}
\]

Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero \( N \) such that for all \( k \) large enough and \( \omega \notin N \),

\[
\left\| f_{n_k} - f \right\|_{L^p([0,T],E)} \leq 2^{-k}
\]

Because of this lemma, it can also be assumed that for a.e. \( \omega \) pointwise convergence is obtained on \( [0,T] \) as well as convergence in \( L^p \left( [0,T] \right) \). This kind of assumption will be tacitly made whenever convenient in the context of the above lemma.

Also recall the diagram for the definition of the integral.

\[
\begin{array}{c}
U \\
\downarrow \\
JQ^{1/2}U \quad \xi \quad Q^{1/2}U \\
\Phi_n \quad \Phi \\
\downarrow \\
H
\end{array}
\]

The idea was to get \( \int_0^t \Phi dW \) where \( \Phi \in L^2 \left( [0,T] \times \Omega; L_2 \left( Q^{1/2}U, H \right) \right) \). Here \( W(t) \) was a cylindrical Wiener process. This meant that it was a \( Q_1 \) Wiener process on \( U_1 \) for \( Q_1 = JJ^* \) and \( J \) was a Hilbert Schmidt operator mapping \( Q^{1/2}U \) to \( U_1 \).
70.3. THE SITUATION

Now consider the following situation.

**Situation 70.3.1** Let $X$ satisfy the following.

\[ X(t) = X_0 + \int_0^t Y(s) \, ds + \int_0^t Z(s) \, dW(s), \]  

(70.3.2)

$X_0 \in L^2(\Omega; H)$ and is $\mathcal{F}_0$ measurable, where $Z$ is $\mathcal{L}_2(Q^{1/2}U; H)$ progressively measurable and

\[ \int_0^T \int_\Omega ||Z(s)||^2_{L^2(Q^{1/2}U, H)} \, dP \, dt < \infty \]

so that the stochastic integral makes sense. Also $X$ has a measurable representative $\tilde{X}$ which has values in $V$. (For a.e. $t$, $\tilde{X}(t) = X(t)$ for $P$ a.e. $\omega$). This representative satisfies

$\tilde{X} \in L^2([0,T] \times \Omega, \mathcal{B}([0,T] \times \mathcal{F}, H)) \cap L^p([0,T] \times \Omega, \mathcal{B}([0,T] \times \mathcal{F}, V)$

Assume $Y(s)$ satisfies

$Y \in K' = L^{p'}([0,T] \times \Omega; V')$

where $1/p' + 1/p = 1$ and $Y$ is $V'$ progressively measurable. The situation in which the equation holds is as follows. For a.e. $\omega$, the equation holds for all $t \in [0,T]$ in $V'$. Thus it follows that $X(t)$ is automatically progressively measurable into $V'$ from Proposition 70.1.2. Also $W(t)$ is a Wiener process on $U_1$ in the above diagram. Thus $X$ is continuous into $V'$ off a set of measure zero, and it is also $V'$ predictable.

The goal is to prove the following Ito formula.

\[ |X(t)|^2 = |X_0|^2 + \int_0^t \left( 2 \langle Y(s), \tilde{X}(s) \rangle + ||Z(s)||^2_{L^2(Q^{1/2}U, H)} \right) \, ds \]

\[ + 2 \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* \tilde{X}(s) \right) \circ J dW(s) \]  

(70.3.3)

where $\mathcal{R}$ is the Riesz map which takes $U_1$ to $U_1'$. The main thing is that the last term above be a local martingale.

In all that follows, the mesh points $t_j$ will be points where $\tilde{X}(t_j) = X(t_j)$ a.e. $\omega$.

**Lemma 70.3.2** Let $X$ be as in Situation 70.3.1 and let $X_k^j$ be as in Lemma 70.2.4, corresponding to $\tilde{X}$ above. Say

\[ X_k^j(t) = \sum_{j=0}^{m_k} \tilde{X}(t_j) X_{[t_j, t_{j+1})} (t), \quad X_k^j(0) \equiv 0. \]

Then each term in the above sum for which $t_j > 0$ is predictable into $H$. As mentioned earlier, we can take $X(0) \equiv 0$ in the definition of the “left step function”. Since, at the mesh points, $\tilde{X} = X$ a.e., it makes no difference off a set of measure zero whether we use $\tilde{X}(t_j)$ or $X(t_j)$ at the left end point.
**Proof:** This is a step function and a typical term is of the form $X(a) \mathcal{X}_{[a,b]}(t)$. I will try and show this is predictable. Let $a_n$ be an increasing sequence converging to $a$ and let $b_n$ be an increasing sequence converging to $b$. Then for a.e. $\omega$,

$$X(a_n) \mathcal{X}_{[a_n,b_n]}(t) \to X(a) \mathcal{X}_{[a,b]}(t)$$

in $V'$ due to the fact that $t \to X(t)$ is continuous into $V'$ for a.e. $\omega$. Therefore, letting $v \in V$ be given, it follows that for a.e. $\omega$

$$\langle X(a_n) \mathcal{X}_{[a_n,b_n]}(t), v \rangle \to \langle X(a) \mathcal{X}_{[a,b]}(t), v \rangle,$$

and since the filtration is a normal filtration in which all sets of measure zero from $\mathcal{F}_t$ are in $\mathcal{F}_0$, this shows

$$(t, \omega) \to \langle X(a) \mathcal{X}_{[a,b]}(t), v \rangle$$

is real predictable because it is the pointwise limit of real predictable functions, those in the sequence being real predictable because of the continuity of $X(t)$ into $V'$ and Proposition 70.3.2. Now since $H \subseteq V'$ it follows that for all $v \in V$,

$$(t, \omega) \to \langle X(a) \mathcal{X}_{[a,b]}(t), v \rangle$$

is real predictable. This holds for $h \in H$ replacing $v$ in the above because $V$ is dense in $H$. By the Pettis theorem, this proves the lemma. $lacksquare$

**Lemma 70.3.3** In Situation 70.3.2, the following formula holds for a.e. $\omega$ for $0 < s \leq t$ where $M(t) \equiv \int_0^t Z(u) dW(u)$. Here and elsewhere, $|\cdot|$ denotes the norm in $H$ and $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $V, V'$. Also $X = \bar{X}$ for a.e. $\omega$ at $t, s$ so that it makes no difference off a set of measure zero whether we write $\langle Y(u), X(t) \rangle$ or $\langle Y(u), \bar{X}(t) \rangle$

$$|X(t)|^2 = |X(s)|^2 + 2 \int_s^t \langle Y(u), X(t) \rangle du + 2 \langle X(s), M(t) - M(s) \rangle$$

$$+ |M(t) - M(s)|^2 - |X(t) - X(s) - (M(t) - M(s))|^2 \quad (70.3.4)$$

Also for $t > 0$

$$|X(t)|^2 = |X_0|^2 + 2 \int_0^t \langle Y(u), X(t) \rangle du + 2 \langle X_0, M(t) \rangle$$

$$+ |M(t)|^2 - |X(t) - X_0 - M(t)|^2 \quad (70.3.5)$$

**Proof:** The formula is a straightforward computation which holds a.e. $\omega$.

$$|M(t) - M(s)|^2 - |X(t) - X(s) - (M(t) - M(s))|^2 + 2 \langle X(s), M(t) - M(s) \rangle$$

$$= |M(t) - M(s)|^2 - |X(t) - X(s)|^2 - |M(t) - M(s)|^2$$

$$+ 2 \langle X(t) - X(s), M(t) - M(s) + 2 \langle X(s), M(t) - M(s) \rangle$$
Comparing the ends of this string of equations,

\[
|X(t)|^2 = |X(s)|^2 + 2 \int_s^t \langle Y(u), X(t) \rangle \, du + 2 \int_s^t \langle Y(u), X(t) \rangle \, du
\]

which is what was to be shown.

Noting that \(X(0) = X_0 \in L^2(\Omega, H)\) and is \(\mathcal{F}_0\) measurable, the first formula works in both cases.

70.4 The Main Estimate

The following phenomenal estimate holds and it is this estimate which is the main idea in proving the Ito formula. The last assertion about continuity is like the well known result that if \(y \in L^p(0, T; V)\) and \(y' \in L^p(0, T; V')\), then \(y\) is actually continuous with values in \(H\). Later, this continuity result is strengthened further to give strong continuity.
Lemma 70.4.1 In the Situation [70.3.3],

\[
E \left( \sup_{t \in [0,T]} |X(t)|^2 \right) < C \left( \|Y\|_{K'}, \|X\|_K, \|Z\|_{J'}, \|X_0\|_{L^2(\Omega,H)} \right) < \infty,
\]

where

\[
J = L^2 \left( [0,T] \times \Omega; L_2 \left( Q^{1/2} U; H \right) \right), K = L^p \left( [0,T] \times \Omega; V \right),
\]

\[
K' = L^{p'} \left( [0,T] \times \Omega; V' \right).
\]

Also, \( C \) is a continuous function of its arguments and \( C(0,0,0,0) = 0 \). Thus for a.e. \( \omega \),

\[
\sup_{t \in [0,T]} |X(t,\omega)|_H \leq C(\omega) < \infty.
\]

Also for a.e. \( \omega, t \to X(t,\omega) \) is weakly continuous with values in \( H \).

**Proof:** Consider the formula in Lemma [0.3.2]

\[
|X(t)|^2 = |X(s)|^2 + 2 \int_s^t \langle Y(u), X(t) \rangle \, du + 2 \langle X(s), M(t) - M(s) \rangle
\]

\[
+ |M(t) - M(s)|^2 - |X(t) - X(s) - (M(t) - M(s))|^2
\]

(70.4.6)

Now let \( t_j \) denote a point of \( \mathcal{P}_k \) from Lemma [0.2.1]. Then for \( t_j > 0 \), \( X(t_k) \) is just the value of \( X \) at \( t_k \) but when \( t = 0 \), the definition of \( X(0) \) in this step function is \( X(0) \equiv 0 \). Thus

\[
|X(t_m)|^2 - |X_0|^2 = \sum_{j=1}^{m-1} |X(t_{j+1})|^2 - |X(t_j)|^2 + |X(t_1)|^2 - |X_0|^2
\]

Using the formula in Lemma [0.3.3] for \( t = t_m \) this yields

\[
|X(t_m)|^2 - |X_0|^2 = 2 \sum_{j=1}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y(u), X_k(u) \rangle \, du +
\]

\[
+ 2 \sum_{j=1}^{m-1} \int_{t_j}^{t_{j+1}} Z(u) \, dW_t \cdot X(t_j) \bigg|_H - \sum_{j=1}^{m-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2
\]

\[
+ 2 \int_0^{t_1} \langle Y(u), X(t_1) \rangle \, du + 2 \left( X_0, \int_0^{t_1} Z(u) \, dW \right) + |M(t_1)|^2
\]

\[
- |X(t_1) - X_0 - M(t_1)|^2
\]

(70.4.7)
Of course
\[ 2 \int_0^{t_1} \langle Y(u), X(t_1) \rangle \, du + 2 \left( X_0, \int_0^{t_1} Z(u) \, dW \right) + |M(t_1)|^2 \]
converges to 0 for a.e. \( \omega \) as \( k \to \infty \) because the norms of the partitions converge to 0 and the stochastic integral is continuous off a set of measure zero. Actually this is not completely clear for the first of the above terms. This term is dominated by
\[
\left( \int_0^{t_1} \| Y(u) \|^{p'} \, du \right)^{1/p} \left( \int_0^{t_1} \| X_k(u) \|_p \, du \right)^{1/p}
\leq C(\omega) \left( \int_0^{t_1} \| Y(u) \|^{p'} \, du \right)^{1/p}
\]
Hence this converges to 0 for a.e. \( \omega \). At this time, not much is known about the last term in 70.4.7, but it is negative and is about to be neglected anyway. The Ito isometry implies the other two terms converge to 0 in \( L^1(\Omega) \) also, in addition to converging for a.e. \( \omega \). At this time, not much is known about the last term in 70.4.7, but it is negative and is about to be neglected anyway.

The term involving the stochastic integral equals
\[
2 \sum_{j=1}^{m-1} \left( \int_{t_j}^{t_{j+1}} Z(u) \, dW, X(t_j) \right)_H
\]
By Theorem 63.14.1, this equals
\[
t \to \int_0^t \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^j(u) \right) \circ JdW;
\]
\( t \to \int_0^t \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^j(u) \right) \circ JdW \) being a local martingale. Therefore, 70.4.7 equals
\[
|X(t_m)|^2 - |X_0|^2 = 2 \int_0^{t_m} \langle Y(u), X_k^j(u) \rangle \, du + e(k)
\]
\[
2 \int_{t_1}^{t_m} \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^j(u) \right) \circ JdW + \sum_{j=1}^{m-1} |M(t_{j+1}) - M(t_j)|^2
- \sum_{j=1}^{m-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2 - |X(t_1) - X_0 - M(t_1)|^2
\]
where \( e(k) \) converges to 0 in \( L^1(\Omega) \) and for a.e. \( \omega \). Note that \( X_k^j(u) = 0 \) on \([0, t_1)\) and so that stochastic integral equals
\[
\int_0^{t_m} \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^j(u) \right) \circ JdW.
\]
Therefore, from the above,

\[
|X(t_m)|^2 - |X_0|^2 = 2 \int_0^{t_m} \langle Y(u), X^r_k(u) \rangle \, du + e(k)
\]

\[
2 \int_0^{t_m} R \left( (Z(u) \circ J^{-1})^* X^l_k(u) \right) \circ JdW + \sum_{j=0}^{m-1} |M(t_{j+1}) - M(t_j)|^2 - |M(t_1)|^2
\]

\[
- \sum_{j=1}^{m-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2 - |X(t_1) - X_0 - M(t_1)|^2
\]

Then since \(|M(t_1)|^2\) converges to 0 in \(L^1(\Omega)\) and for a.e. \(\omega\), as discussed above,

\[
|X(t_m)|^2 - |X_0|^2 = 2 \int_0^{t_m} \langle Y(u), X^r_k(u) \rangle \, du + e(k)
\]

\[
+ 2 \int_0^{t_m} R \left( (Z(u) \circ J^{-1})^* X^l_k(u) \right) \circ JdW + \sum_{j=0}^{m-1} |M(t_{j+1}) - M(t_j)|^2
\]

\[
- |X(t_1) - X_0 - M(t_1)|^2
\]

\[
- \sum_{j=1}^{m-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2
\]

(70.4.8)

where \(e(k) \to 0\) for a.e. \(\omega\) and also in \(L^1(\Omega)\).

Now it follows on discarding the negative terms,

\[
\sup_{t_j \in \mathcal{P}_k} |X(t_j)|^2 \leq |X_0|^2 + 2 \int_0^T |\langle Y(u), X^r_k(u) \rangle| \, du
\]

\[
+ 2 \sup_{t \in [0,T]} \left| \int_0^t R \left( (Z(u) \circ J^{-1})^* X^l_k(u) \right) \circ JdW \right| + \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} Z(u) \, dW \right|^2
\]

where there are \(m_k + 1\) points in \(\mathcal{P}_k\).

Do \(\int_{\Omega}\) to both sides. Using the Ito isometry, this yields

\[
\int_{\Omega} \left( \sup_{t_j \in \mathcal{P}_k} |X(t_j)|^2 \right) \, dP \leq E \left( |X_0|^2 \right) + 2 \|Y\|_{K'} \|X^r_k\|_K
\]

\[
+ \sum_{j=0}^{m_k-1} \int_{t_j}^{t_{j+1}} \int_{\Omega} |Z(u)|^2 \, dP \, du
\]

\[
+ 2 \int_{\Omega} \left( \sup_{t \in [0,T]} \left| \int_0^T R \left( (Z(u) \circ J^{-1})^* X^l_k(u) \right) \circ JdW \right| \right) \, dP + E (|e(k)|)
\]
70.4. THE MAIN ESTIMATE

\[ \leq C + \int_0^T \int_\Omega \|Z(u)\|^2 dP du + \]
\[ + 2 \int_\Omega \left( \sup_{t \in [0,T]} \left( \int_0^T \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^l(u) \right) \circ J dW \right) \right) dP \]
\[ \leq C + 2 \int_\Omega \left( \sup_{t \in [0,T]} \left( \int_0^T \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^l(u) \right) \circ J dW \right) \right) dP \]

where the result of Lemma 70.2.1 that \( X_k^l \) converges to \( \tilde{X} \) in \( K \) shows the term \( 2 \|Y\|_{K'} \|X_k^l\|_K \) is bounded. Note that the constant \( C \) is a continuous function of \( \|X_k\|_{L^2(\Omega, H)} \) which equals zero when all are equal to zero. The term involving the stochastic integral is next.

Applying the Burkholder Davis Gundy inequality, Theorem 61.4.4 for \( F(r) = r \) along with the description of the quadratic variation of the Ito integral found in Corollary 63.11.1

\[ \int_\Omega \sup_{t_j \in \mathcal{P}_k} \left| X(t_j) \right|^2 dP \]
\[ \leq C + C \int_\Omega \left( \int_0^T \left\| \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k^l(u) \right) \circ J \right\|^2 du \right)^{1/2} dP \]
\[ \leq C + C \int_\Omega \left( \int_0^T \left\| X_k^l(u) \right\|^2 \left\| X_k^l(u) \right\|^2 \right)^{1/2} dP \]

Now for each \( \omega \), there are only finitely many values of \( X_k^l(u) \) and they equal \( X(t_j) \) for \( t_j \in \mathcal{P}_k \) with the convention that \( X(0) = 0 \). Therefore, the above is dominated by

\[ C + C \int_\Omega \left( \sup_{t_j \in \mathcal{P}_k} \left| X(t_j) \right|^2 \right)^{1/2} \left( \int_0^T \left\| Z(u) \right\|^2 du \right)^{1/2} dP \]
\[ \leq C + \frac{1}{2} \int_\Omega \sup_{t_j \in \mathcal{P}_k} \left| X(t_j) \right|^2 + C \int_\Omega \int_0^T \left\| Z(u) \right\|^2 dZ(t) \right) dudP \]

and so

\[ \frac{1}{2} \int_\Omega \sup_{t_j \in \mathcal{P}_k} \left| X(t_k) \right|^2 dP \leq C \]

for some constant \( C \) independent of \( \mathcal{P}_k \) dependent on \( \int_\Omega \int_0^T \left\| Z(u) \right\|^2 dZ(t) \right) dudP \).

This constant is dependent on \( \|Y\|_{K'}, \|X_k\|_{K'}, \|X_0\|_{L^2(\Omega, H)} \) and equals zero when all of these quantities equal 0.
Let \( D \) denote the union of all the \( \mathcal{P}_k \). Thus \( D \) is a dense subset of \([0, T]\) and it has just been shown that for a constant \( C \) independent of \( \mathcal{P}_k \),

\[
E \left( \sup_{t \in D} |X(t)|^2 \right) \leq C.
\]

Let \( \{e_j\} \) be an orthonormal basis for \( H \) which is also contained in \( V \) and has the property that \( \text{span} \left( \{e_k\}_{k=1}^\infty \right) \) is dense in \( V \). I claim that for \( y \in V' \)

\[
|y|^2_H = \sup_n \sum_{j=1}^n |\langle y, e_j \rangle|^2
\]

This is certainly true if \( y \in H \) because in this case

\[
\langle y, e_j \rangle = \langle y, e_j \rangle
\]

If \( y \notin H \), then the series must diverge. If not, you could consider the infinite sum

\[
z = \sum_{j=1}^\infty \langle y, e_j \rangle e_j \in H
\]

and argue that \( \langle z - y, v \rangle = 0 \) for all \( v \in \text{span} \left( \{e_k\}_{k=1}^\infty \right) \) which would also imply that this is true for all \( v \in V \). Then since \( z = y \) in \( V' \), it follows that \( y \in H \) contrary to the assumption that \( y \notin H \).

It follows

\[
|X(t)|^2 = \sup_n \sum_{j=1}^n |\langle X(t), e_j \rangle|^2
\]

and for a.e. \( \omega \), this is just the sup of continuous functions of \( t \). Therefore, for given \( \omega \) off a set of measure zero,

\[
t \to |X(t)|^2
\]

is lower semicontinuous. Hence letting \( t \in [0, T] \) and \( t_j \to t \) where \( t_j \in D \),

\[
|X(t)|^2 \leq \liminf_{j \to \infty} |X(t_j)|^2
\]

so it follows for a.e. \( \omega \)

\[
\sup_{t \in [0, T]} |X(t)|^2 \leq \sup_{t \in D} |X(t)|^2 \leq \sup_{t \in [0, T]} |X(t)|^2
\]

Hence

\[
E \left( \sup_{t \in [0, T]} |X(t)|^2 \right) \leq C \left( \|Y\|_{K'}, \|X\|_{K'}, \|Z\|_J, \|X_0\|_{L^2(\Omega, H)} \right). \tag{70.4.9}
\]
Note the above shows that for a.e. $\omega$, $\sup_{t \in [0,T]} |X(t)|_H < \infty$ so that for such $\omega$, $X(t)$ has values in $H$. Note that we began by assuming it had a representative with values in $H$ although the equation only held in $V'$. Say

$$|X(t, \omega)| \leq C(\omega).$$

Hence if $v \in V$, then for a.e. $\omega$

$$\lim_{t \to s} (X(t), v) = \lim_{t \to s} (X(s), v) = (X(s), v)$$

Therefore, since for such $\omega$, $|X(t, \omega)|$ is bounded, the above holds for all $h \in H$ in place of $v$ as well. Therefore, for a.e. $\omega, t \to X(t, \omega)$ is weakly continuous with values in $H$. $lacksquare$

Eventually, it is shown that in fact, the function $t \to X(t, \omega)$ is continuous with values in $H$.

This lemma also provides a way to simplify one of the formulas derived earlier in the case that $X_0 \in L^p(\Omega, V)$. Refer to \[\text{[4.1.2]}\]. One term there is $|X(t_1) - X_0 - M(t_1)|^2$.

$$|X(t_1) - X_0 - M(t_1)|^2 \leq 2 |X(t_1) - X_0|^2 + 2 |M(t_1)|^2$$

It was shown above that $2 |M(t_1)|^2 \to 0$ a.e. and also in $L^1(\Omega)$ as $k \to \infty$. Apply the above lemma to $|X(t) - X_0|^2$ using $[0, t_1]$ instead of $[0, T]$ . The new $X_0$ equals 0. Then from the estimate \[\text{[4.1.2]}\], it follows that

$$E\left( |X(t_1) - X_0|^2 \right) \to 0$$

as $k \to \infty$. Taking a subsequence, we could also assume that $|X(t_1) - X_0|^2 \to 0$ a.e. $\omega$ as $k \to \infty$. Then, using this subsequence, it would follow from \[\text{[4.1.2]}\]

$$|X(t_m)|^2 \to |X_0|^2 = 2 \int_0^{t_m} \langle Y(u), X_k(u) \rangle \, du + e(k)$$

$$+ 2 \int_0^{t_m} \mathcal{R} \left( (Z(u) \circ J^{-1})^* X_k(u) \right) \circ JdW + \sum_{j=0}^{m-1} |M(t_{j+1}) - M(t_j)|^2$$

$$- \sum_{j=1}^{m-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2$$

where $e(k) \to 0$ in $L^1(\Omega)$ and a.e. $\omega$.

Can you obtain something similar even in case $X_0$ is not assumed to be in $L^p(\Omega, V)$? Let $Z_{0k} \in L^p(\Omega, V) \cap L^2(\Omega, H), Z_{0k} \to X_0$ in $L^2(\Omega, H)$. Then

$$|X(t_1) - X_0| \leq |X(t_1) - Z_{0k}| + |Z_{0k} - X_0|$$
Also, restoring the superscript to identify the partition,

\[ X \left( t^{k} \right) - Z_{0k} = X_{0} - Z_{0k} + \int_{0}^{t^{k}_{1}} Y \left( s \right) ds + \int_{0}^{t^{k}_{1}} Z \left( s \right) dW. \]

Of course \( \| \bar{X} - Z_{0k} \|_{K} \) is not bounded but for each \( k \) it is at least finite. There is a sequence of partitions \( \mathcal{P}_{k}, \| \mathcal{P}_{k} \| \to 0 \) such that all the above holds. In the definitions of \( K, K', J \) replace \([0, T]\) with \([0, t]\) and let the resulting spaces be denoted by \( K_{t}, K'_{t}, J_{t} \). Let \( n_{k} \) denote a subsequence of \( \{ k \} \) such that

\[ \| \bar{X} - Z_{0k} \|_{K'_{t^{n_{k}}_{1}}} < 1/k. \]

Then from the above lemma,

\[
E \left( \sup_{t \in [0, t^{n_{k}}_{1}]} |X \left( t^{n_{k}}_{1} \right) - Z_{0k}|_{H}^{2} \right) \\
\leq C \left( \| Y \|_{K'_{t^{n_{k}}_{1}}}, \| \bar{X} - Z_{0k} \|_{K'_{t^{n_{k}}_{1}}}, \| Z \|_{J_{t^{n_{k}}_{1}}}, \| X_{0} - Z_{0k} \|_{L^{2}(\Omega, H)} \right) \\
\leq C \left( \| Y \|_{K'_{t^{n_{k}}_{1}}}, \frac{1}{k}, \| Z \|_{J_{t^{n_{k}}_{1}}}, \| X_{0} - Z_{0k} \|_{L^{2}(\Omega, H)} \right)
\]

Hence

\[
E \left( |X \left( t^{n_{k}}_{1} \right) - X_{0}|^{2} \right) \leq 2E \left( |X \left( t^{n_{k}}_{1} \right) - Z_{0k}|_{H}^{2} \right) + 2E \left( |Z_{0k} - X_{0}|_{H}^{2} \right) \\
\leq 2C \left( \| Y \|_{K'_{t^{n_{k}}_{1}}}, \frac{1}{k}, \| Z \|_{J_{t^{n_{k}}_{1}}}, \| X_{0} - Z_{0k} \|_{L^{2}(\Omega, H)} \right) + 2 \| Z_{0k} - X_{0} \|^{2}
\]

which converges to 0 as \( k \to \infty \). It follows that there exists a suitable subsequence such that \( \text{Lemma 70.4.10} \) holds even in the case that \( X_{0} \) is only known to be in \( L^{2}(\Omega, H) \). From now on, assume this subsequence for the partitions \( \mathcal{P}_{k} \). Thus \( k \) will really be \( n_{k} \).

### 70.5 Converging In Probability

I am working toward the Ito formula \( \text{Lemma 70.3.3} \). In order to get this, there is a technical result which will be needed.

**Lemma 70.5.1** Let \( X \left( s \right) - X^{k}_{t} \left( s \right) \equiv \Delta_{k} \left( s \right) \). Then the following limit occurs.

\[
\lim_{k \to \infty} P \left( \left\| \sup_{t \in [0, T]} \left| \int_{0}^{t} \mathcal{R} \left( \left( Z \circ J^{-1} \right)^{*} \Delta_{k} \left( s \right) \circ JdW \left( s \right) \right) \right| \geq \varepsilon \right\} = 0. \tag{70.5.11}
\]

That is,

\[
\sup_{t \in [0, T]} \left| \int_{0}^{t} \mathcal{R} \left( \left( Z \circ J^{-1} \right)^{*} \left( X \left( s \right) - X^{k}_{t} \left( s \right) \right) \right) \circ JdW \left( s \right) \right|
\]
converges to 0 in probability. Also the stochastic integral makes sense because \( X \) is \( H \) predictable.

**Proof:** First note that from Lemma 70.4.1 for a.e. \( \omega \), \( X (t) \) has values in \( H \) for \( t \in [0, T] \) and so it makes sense to consider it in the stochastic integral provided it is \( H \) progressively measurable. However, as noted in Situation 70.3.1, this function is automatically \( V' \) predictable. Therefore, 
\[
\langle X (t), v \rangle = (X (t), v)
\]
is real predictable for every \( v \in V \). Now if \( h \in H \), let \( v_n \to h \) in \( H \) and so for each \( \omega \),
\[
(X (t, \omega), v_n) \to (X (t, \omega), h)
\]
By the Pettis theorem, \( X \) is \( H \) predictable, hence progressively measurable. Also it was shown above that \( t \to X (t) \) is weakly continuous into \( H \). Therefore, the desired result follows from Lemma 63.14.3 on Page 2324.

### 70.6 The Ito Formula

Now at long last, here is the first version of the Ito formula.

**Lemma 70.6.1** In Situation 70.3.1, let \( D \) be as above, the union of all the positive mesh points for all the \( P_k \). Also assume \( X_0 \in L^2 (\Omega; H) \). Then for every \( t \in D \),
\[
|X (t)|^2 = |X_0|^2 + \int_0^t \left( 2 \langle Y (s), \dot{X} (s) \rangle + ||Z (s)||_{L^2 (Q^{1/2} U, H)}^2 \right) ds
+ 2 \int_0^t \mathcal{R} \left((Z (s) \circ J^{-1})^* X (s)\right) \circ JdW (s)
\]
(70.6.12)

Note that it was shown above that \( X (t, \omega) \) has values in \( H \) for a.e. \( \omega \).

**Proof:** Let \( t \in D \). Then \( t \in P_k \) for all \( k \) large enough. Consider \( X_k \) for all \( k \).
\[
|X (t)|^2 - |X_0|^2 = 2 \int_0^t \langle Y (u), X_k (u) \rangle \ du
+ 2 \int_0^t \mathcal{R} \left((Z (u) \circ J^{-1})^* X_k (u)\right) \circ JdW + \sum_{j=0}^{q_k-1} |M (t_{j+1}) - M (t_j)|^2
- \sum_{j=1}^{q_k-1} |X (t_{j+1}) - X (t_j) - (M (t_{j+1}) - M (t_j))|^2 + o (k)
\]
(70.6.13)

where \( t_{q_k} = t \). By Lemma 70.5.1 the second term on the right, the stochastic integral, converges to
\[
2 \int_0^t \mathcal{R} \left((Z (u) \circ J^{-1})^* X (u)\right) \circ JdW
\]
in probability. The first term on the right converges to
\[ 2 \int_0^t \langle Y(u), \tilde{X}(u) \rangle \, du \]
in \( L^1(\Omega) \) because \( X^r_k \to X \) in \( K \). Therefore, this also happens in probability. Consider the next term.

\[ E \left( \sum_{j=0}^{q_k-1} |M(t_{j+1}) - M(t_j)|^2 \right). \]

It is known from the theory of the quadratic variation that this term converges in probability to 
\[ [M](t) = \int_0^t \|Z(s)\|^2 \, ds. \]
See Theorem 61.6.4 on Page 2198 and the description of the quadratic variation in Corollary 63.11.1.

Thus all the terms in 70.6.13 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

\[ |X(t)|^2 - |X_0|^2 = 2 \int_0^t \langle Y(u), \tilde{X}(u) \rangle \, du \]

\[ + 2 \int_0^t \mathcal{R} \left( (Z(u) \circ J^{-1})^* X(u) \right) \circ JdW + \int_0^t \|Z(s)\|^2 \, ds - a \]

where \( a \) is the limit in probability of the term

\[ \sum_{j=1}^{q_k-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2 \]

Let \( P_n \) be the projection onto \( \text{span}(e_1, \cdots, e_n) \) as before where \( \{e_k\} \) is an orthonormal basis for \( H \) with each \( e_k \in V \). Then using

\[ X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j)) = \int_{t_j}^{t_{j+1}} Y(s) \, ds \]

the troublesome term above is of the form

\[ \sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X(t_{j+1}) - X(t_j) - P_n (M(t_{j+1}) - M(t_j)) \rangle \, ds \] \hspace{1cm} (70.6.14)

\[ - \sum_{j=1}^{q_k-1} (X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j)), (I - P_n)(M(t_{j+1}) - M(t_j))) \] \hspace{1cm} (70.6.15)

The sum in (70.6.14) is dominated by

\[ \left( \sum_{j=1}^{q_k-1} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2 \right)^{1/2}. \]
Now it is known that \( \sum_{j=1}^{q_k} |X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))|^2 \) converges in probability to \( a \). If you take the expectation of the other factor it is

\[
E \left( \sum_{j=1}^{q_k} \left( I - P_n \right) \int_{t_j}^{t_{j+1}} Z(s) \, dW(s) \right) \]

\[
= \sum_{j=1}^{q_k} E \left( \int_{t_j}^{t_{j+1}} \left( I - P_n \right) Z(s) \, dW(s) \right)^2 \]

\[
= \sum_{j=1}^{q_k} E \left( \int_{t_j}^{t_{j+1}} \left( I - P_n \right) Z(s) \, dW(s) \right)^2 \|Z(\Omega^{1/2} U,H)\|^2 \, ds \]

\[
\leq E \left( \int_0^T \|\left( I - P_n \right) Z(s) \|_{\mathcal{L}^2(\Omega^{1/2} U,H)}^2 \right) \, ds \]

\[
= \int_{\Omega} \int_0^T \sum_{i=n+1}^{\infty} (Z(s), e_i)^2 \, ds \, dP \]

The integrand converges to 0 as \( n \to \infty \) and is dominated by \( \sum_{i=1}^{\infty} \|Z(s), e_i\|^2 \) which is given to be in \( L^1([0,T] \times \Omega) \). Therefore, it converges to 0.

Thus the expression in 70.6.16 is of the form \( f_k g_{nk} \) where \( f_k \) converges in probability to \( a \) as \( k \to \infty \) and \( g_{nk} \) converges in probability to 0 as \( n \to \infty \) independently of \( k \). Now this implies \( f_k g_{nk} \) converges in probability to 0. Here is why.

\[
P(\|f_k g_{nk}| > \varepsilon) \leq P(2\delta |f_k| > \varepsilon) + P(2C \delta |g_{nk}| > \varepsilon) \leq P(2\delta |f_k - a| + 2\delta |a| > \varepsilon) + P(2C \delta |g_{nk}| > \varepsilon) \]

where \( \delta |f_k| + C \delta |g_{nk}| > |f_k g_{nk}| \) and \( \lim_{\delta \to 0} C \delta = \infty \). Pick \( \delta \) small enough that \( \varepsilon - 2\delta |a| > \varepsilon/2 \). Then this is dominated by

\[
\leq P(2\delta |f_k - a| > \varepsilon/2) + P(2C \delta |g_{nk}| > \varepsilon) \]

Fix \( n \) large enough that the second term is less than \( \eta \). Now taking \( k \) large enough, the above is less than \( \eta \). It follows the expression in 70.6.16 and consequently in 70.6.15 converges to 0 in probability.

Now consider the other term, 70.6.15 using the \( n \) just determined. This term is of the form

\[
\sum_{j=1}^{q_k} \int_{t_j}^{t_{j+1}} \langle Y(s), X_k^r(s) - X_k^l(s) - P_n (M_k^r(s) - M_k^l(s)) \rangle \, ds \]

\[
= \int_{t_1}^t \langle Y(s), X_k^r(s) - X_k^l(s) - P_n (M_k^r(s) - M_k^l(s)) \rangle \, ds \]
where $M^r_k$ denotes the step function

$$M^r_k (t) = \sum_{i=0}^{m_k-1} M (t_{i+1}) \mathcal{X}_{(t_i, t_{i+1})} (t)$$

and $M^l_k$ is defined similarly. The term

$$\int_{t_1}^t \langle Y (s), P_n (M^r_k (s) - M^l_k (s)) \rangle ds$$

converges to 0 for a.e. $\omega$ as $k \to \infty$. This is because the integrand converges to 0 thanks to the continuity of $M (t)$ and also since this is a projection onto a finite dimensional subspace of $V$. Therefore, for each $\omega$ off a set of measure zero,

$$\int_{t_1}^t \| Y (s) \|_V \| P_n (M^r_k (s) - M^l_k (s)) \|_V ds$$

and this last integral converges to 0 as $k \to \infty$ because $P_n (M (s))$ is uniformly bounded in $V$ so there is no problem getting a dominating function for the dominated convergence theorem. Let

$$A_k = \left[ \left( \int_{t_1}^t \| Y (s) \|_V \| P_n (M^r_k (s) - M^l_k (s)) \|_V ds \right) > \varepsilon \right]$$

Then since the partitions are increasing, these sets are decreasing as $k$ increases and their intersection has measure zero. Hence $P (A_k) \to 0$. It follows that

$$\lim_{k \to \infty} P \left( \left( \int_{t_1}^t \langle Y (s), P_n (M^r_k (s) - M^l_k (s)) \rangle ds \right) > \varepsilon \right) \leq 0$$

Now consider

$$\int_{t_1}^t \langle Y (s), X^r_k (s) - X^l_k (s) \rangle ds$$

This converges to 0 in $L^1 (\Omega)$ because it is of the form

$$\int_{t_1}^t \langle Y (s), X^r_k (s) \rangle ds - \int_{t_1}^t \langle Y (s), X^l_k (s) \rangle ds$$

and both $X^l_k$ and $X^r_k$ converge to $X$ in $K$. Therefore, the expression

$$\sum_{j=1}^{q_k-1} |X (t_{j+1}) - X (t_j) - (M (t_{j+1}) - M (t_j))^2$$

converges to 0 in probability. □

In fact, the formula (70.6.12) is valid for all $t \in [0, T]$. 

CHAPTER 70. THE HARD ITO FORMULA
70.6. THE ITO FORMULA

**Theorem 70.6.2** In Situation 70.3.4, off a set of measure zero, for every \( t \in [0, T] \),

\[
|X(t)|^2 = |X_0|^2 + \int_0^t \left( 2 \langle Y(s), \dot{X}(s) \rangle + ||Z(s)||^2_{L^2(Q^{1/2} U, H)} \right) ds
+ 2 \int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* X(s) \right) \circ JdW(s)
\]

Furthermore, for \( t \in [0, T] \), \( t \rightarrow X(t) \) is continuous as a map into \( H \) for a.e. \( \omega \).

In addition to this,

\[
E \left( |X(t)|^2 \right) = E \left( |X_0|^2 \right) + E \left( \int_0^t \left( 2 \langle Y(s), \dot{X}(s) \rangle + ||Z(s)||^2_{L^2(Q^{1/2} U, H)} \right) ds \right)
\]

**Proof:** Let \( t \notin D \). For \( t > 0 \), let \( t(k) \) denote the largest point of \( P_k \) which is less than \( t \). Suppose \( t(m) < t(k) \). Hence \( m \leq k \). Then

\[
X(t(m)) = X_0 + \int_0^{t(m)} Y(s) ds + \int_0^{t(m)} Z(s) dW(s),
\]

a similar formula holding for \( X(t(k)) \). Thus for \( t > t(m) \),

\[
X(t) - X(t(m)) = \int_{t(m)}^t Y(s) ds + \int_{t(m)}^t Z(s) dW(s)
\]

which is the same sort of thing studied so far except that it starts at \( t(m) \) rather than at 0 and \( X_0 = 0 \). Therefore, from Lemma 70.3.3 it follows

\[
|X(t(k)) - X(t(m))|^2 = \int_{t(m)}^{t(k)} \left( 2 \langle Y(s), X(s) - X(t(m)) \rangle + ||Z(s)||^2 \right) ds
+ 2 \int_{t(m)}^{t(k)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X(t(m))) \right) \circ JdW(s)
\]

Consider that last term. It equals

\[
2 \int_{t(m)}^{t(k)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X_m^l(s)) \right) \circ JdW(s)
\]

This is dominated by

\[
2 \int_0^{t(k)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X_m^l(s)) \right) \circ JdW(s)
- 2 \int_0^{t(m)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X_m^l(s)) \right) \circ JdW(s)
\]
\[
\int_{0}^{t(k)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X^I_{m}(s)) \right) \circ JdW(s) \\
+ 2 \int_{0}^{t(m)} \mathcal{R} \left( (Z(s) \circ J^{-1})^* (X(s) - X^I_{m}(s)) \right) \circ JdW(s) \\
\leq 4 \sup_{t \in [0,T]} \left| \int_{0}^{t} \langle Y(s), X(s) - X^I_{m}(s) \rangle \right| ds
\]

In Lemma 70.5.1 the above expression was shown to converge to 0 in probability. Therefore, by the usual appeal to the Borel Cantelli lemma, there is a subsequence still referred to as \( \{m\} \), such that it converges to 0 pointwise in \( \omega \) for all \( \omega \) off some set of measure 0 as \( m \to \infty \). It follows there is a set of measure 0 such that for \( \omega \) not in that set, 70.6.20 converges to 0 in \( \mathbb{R} \). Note that \( t > 0 \) is arbitrary. Similar reasoning shows the first term in the non stochastic integral of 70.6.19 is dominated by an expression of the form

\[
4 \int_{0}^{T} \left| \langle Y(s), \bar{X}(s) - X^I_{m}(s) \rangle \right| ds
\]

which clearly converges to 0 for \( \omega \) not in some set of measure zero because \( X^I_{m} \) converges in \( K \) to \( \bar{X} \). Finally, it is obvious that

\[
\lim_{m \to \infty} \int_{0}^{t(k)} \|Z(s)\|^2 ds = 0 \text{ for a.e. } \omega
\]

due to the assumptions on \( Z \).

This shows that for \( \omega \) off a set of measure 0

\[
\lim_{m,k \to \infty} |X(t(k)) - X(t(m))|^2 = 0
\]

and so \( \{X(t(k))\}_{k=1}^{\infty} \) is a convergent sequence in \( H \). Does it converge to \( X(t) \)? Let \( \xi(t) \in H \) be what it converges to. Let \( v \in V \) then

\[
\langle \xi(t), v \rangle = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \lim_{k \to \infty} \langle X(t(k)), v \rangle = \langle X(t), v \rangle = \langle X(t), v \rangle
\]

and now, since \( V \) is dense in \( H \), this implies \( \xi(t) = X(t) \).

Now for every \( t \in D \),

\[
|X(t)|^2 = |X_0|^2 + \int_{0}^{t} \left( 2 \langle Y(s), \bar{X}(s) \rangle + \|Z(s)\|^2_{L^2(\Omega^1; \mathbb{H})} \right) ds
\]

and so, using what was just shown along with the obvious continuity of the functions of \( t \) on the right of the equal sign, it follows the above holds for all \( t \in [0,T] \) off a set of measure zero.
It only remains to verify that 
\( t \to X(t) \) is continuous with values in \( H \). However, the above shows that \( t \to |X(t)|^2 \) is continuous and it was shown in Lemma 70.4.1 that 
\( t \to X(t) \) is weakly continuous into \( H \). Therefore, from the uniform convexity of the norm in \( H \) it follows that \( t \to X(t) \) is continuous. This is very easy to see in Hilbert space. Say \( a_n \to a \) and \( |a_n| \to |a| \). From the parallelogram identity,

\[
|a_n - a|^2 + |a_n + a|^2 = 2|a_n|^2 + 2|a|^2
\]

so

\[
|a_n - a|^2 = 2|a_n|^2 + 2|a|^2 - \left( |a_n|^2 + 2(a_n, a) + |a|^2 \right)
\]

Then taking \( \limsup \) both sides,

\[
0 \leq \limsup_{n \to \infty} |a_n - a|^2 \leq 2|a|^2 + 2|a|^2 - \left( |a|^2 + 2(a, a) + |a|^2 \right) = 0.
\]

Of course this fact also holds in any uniformly convex Banach space.

Now consider the last claim. If the last term in (70.6.17) were a martingale, then there would be nothing to prove. This is because if \( M(t) \) is a martingale which equals 0 when \( t = 0 \), then

\[
E(M(t)) = E(E(M(t)|\mathcal{F}_0)) = E(M(0)) = 0.
\]

However, that last term is unfortunately only a local martingale. One can obtain a localizing sequence as follows.

\[
\tau_n(\omega) = \inf \{ t : |X(t, \omega)| > n \}
\]

where as usual \( \inf(\emptyset) \equiv \infty \). This is all right because it was shown above that \( t \to X(t, \omega) \) is continuous into \( H \) for a.e. \( \omega \). Then stopping both processes on the two sides of (70.6.17) with \( \tau_n \),

\[
|X(t \wedge \tau_n)|^2 = |X_0|^2 + \int_0^{t \wedge \tau_n} \left( 2(Y(s), X(s)) + \|Z(s)\|^2_{L^2(Q^{1/2};U,H)} \right) ds
\]

\[
+ 2\int_0^{t \wedge \tau_n} \mathcal{R} \left( (Z(s) \circ J^{-1})^* X(s) \right) \circ JdW(s)
\]

Now from Lemma 70.1.4,

\[
|X(t \wedge \tau_n)|^2 = |X_0|^2 + \int_0^t \mathcal{X}_{[0, \tau_n]}(s) \left( 2(Y(s), X(s)) + \|Z(s)\|^2_{L^2(Q^{1/2};U,H)} \right) ds
\]

\[
+ 2\int_0^t \mathcal{X}_{[0, \tau_n]}(s) \mathcal{R} \left( (Z(s) \circ J^{-1})^* X(s) \right) \circ JdW(s)
\]

That last term is now a martingale and so you can take the expectation of both sides. This gives

\[
E\left(|X(t \wedge \tau_n)|^2\right) = E\left(|X_0|^2\right)
\]
+E \left( \int_0^t \mathcal{X}_{[0,\tau_n]}(s) \left( 2 \langle Y(s), \tilde{X}(s) \rangle + \|Z(s)\|_{L_2(Q^{1/2}_{U,H})}^2 \right) ds \right)

Letting \( n \to \infty \) and using the dominated convergence theorem and \( \tau_n \to \infty \) yields the desired result.

**Notation 70.6.3** The stochastic integrals are unpleasant to look at.

\[
\int_0^t \mathcal{R} \left( (Z(s) \circ J^{-1})^* X(s) \right) \circ JdW(s) \equiv \int_0^t \langle X(s), Z(s) dW(s) \rangle .
\]
Chapter 71

The Hard Ito Formula, Implicit Case

71.1 Approximating With Step Functions

This Ito formula seems to be the fundamental idea which allows one to obtain solutions to stochastic partial differential equations using a variational point of view. I am following the treatment found in [13]. The following lemma is fundamental to the presentation. It approximates a function with a sequence of two step functions $X^r_k, X^l_k$ where $X^r_k$ has the value of $X$ at the right end of each interval and $X^l_k$ gives the value $X$ at the left end of the interval. The lemma is very interesting for its own sake. You can obviously do this sort of thing for a continuous function but here the function is not continuous and in addition, it is a stochastic process depending on $\omega$ also. This lemma was proved earlier, Lemma 63.3.1.

Lemma 71.1.1 Let $\Phi : [0, T] \times \Omega \to V$, be $B([0, T]) \times F$ measurable and suppose

$$
\Phi \in K \equiv L^p ([0, T] \times \Omega; E),\ p \geq 1
$$

Then there exists a sequence of nested partitions, $\mathcal{P}_k \subseteq \mathcal{P}_{k+1}$,

$$
\mathcal{P}_k \equiv \{ t^k_0, \cdots, t^k_{m_k} \}
$$

such that the step functions given by

$$
\Phi^r_k (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_j) X(t^k_{j-1}, t^k_j) (t)
$$

$$
\Phi^l_k (t) \equiv \sum_{j=1}^{m_k} \Phi (t^k_{j-1}) X(t^k_{j-1}, t^k_j) (t)
$$

both converge to $\Phi$ in $K$ as $k \to \infty$ and

$$
\lim_{k \to \infty} \max \{ |t^k_j - t^k_{j+1}| : j \in \{0, \cdots, m_k\} \} = 0.
$$
Also, each \( \Phi \left( t_j^k \right) \), \( \Phi \left( t_{j-1}^k \right) \) is in \( L^p(\Omega; E) \). One can also assume that \( \Phi(0) = 0 \).

The mesh points \( \{ t_j^k \}_{j=0}^{m_k} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that
\[
|t_j^k - t_{j-1}^k| = 2^{-nk}
\]
except for the case where \( j = 1 \) or \( j = m_n \) when this might not be so. In the case of the last subinterval defined by the partition, we can assume
\[
|t_m^k - t_{m-1}^k| = |T - t_{m-1}^k| \geq 2^{-(nk+1)}
\]

The following lemma is convenient.

**Lemma 71.1.2** Let \( f_n \to f \) in \( L^p([0,T] \times \Omega, E) \). Then there exists a subsequence \( n_k \) and a set of measure zero \( N \) such that if \( \omega \notin N \), then
\[
f_{n_k}(\cdot, \omega) \to f(\cdot, \omega)
\]
in \( L^p([0,T], E) \) and for a.e. \( t \).

**Proof:** We have
\[
P \left( \left[ \| f_n - f \|_{L^p([0,T], E)} > \lambda \right] \right) \leq \frac{1}{\lambda} \int_\Omega \| f_n - f \|_{L^p([0,T], E)} dP \leq \frac{1}{\lambda} \| f_n - f \|_{L^p([0,T] \times \Omega, E)}
\]
Hence there exists a subsequence \( n_k \) such that
\[
P \left( \left[ \| f_{n_k} - f \|_{L^p([0,T], E)} > 2^{-k} \right] \right) \leq 2^{-k}
\]
Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero \( N \) such that for all \( k \) large enough and \( \omega \notin N \),
\[
\| f_{n_k} - f \|_{L^p([0,T], E)} \leq 2^{-k}
\]
Now by the usual arguments used in proving completeness, \( f_{n_k}(t) \to f(t) \) for a.e.t.

Because of this lemma, it can also be assumed that for a.e. \( \omega \), pointwise convergence is obtained on \([0,T]\) as well as convergence in \( L^p([0,T]) \). This kind of assumption will be tacitly made whenever convenient.

Also recall the diagram for the definition of the integral which has values in a Hilbert space \( W \).
The idea was to get \( \int_0^t ZdW \) where \( Z \in L^2 \left( [0, T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2}U, W \right) \right) \). Here \( W(t) \) was a cylindrical Wiener process. This meant that it was a \( Q_1 \) Wiener process on \( U_1 \) for \( Q_1 = JJ^* \) and \( J \) was a Hilbert Schmidt operator mapping \( Q^{1/2}U \) to \( U_1 \).

To get \( \int_0^t ZdW \), \( Z \circ J^{-1} \) was approximated by a sequence of elementary functions having values in \( \mathcal{L} \left( U_1, W \right) \). Then

\[
\int_0^t ZdW = \lim_{n \to \infty} \int_0^t Z_n dW
\]

and this limit existed in \( L^2 \left( \Omega, W \right) \).

### 71.2 The Situation

Now consider the following situation. There are real separable Banach spaces \( V, W \) such that \( W \) is a Hilbert space and

\[
V \subseteq W, \quad W' \subseteq V'
\]

where \( V \) is dense in \( W \). Also let \( B \in \mathcal{L} \left( W, W' \right) \) satisfy

\[
\langle Bw, w \rangle \geq 0, \quad \langle Bu, v \rangle = \langle Bv, u \rangle
\]

Note that \( B \) does not need to be one to one. Also allowed is the case where \( B \) is the Riesz map. It could also happen that \( V = W \).

**Situation 71.2.1** Let \( X \) have values in \( V \) and satisfy the following

\[
BX(t) = BX_0 + \int_0^t Y(s) ds + B \int_0^t Z(s) dW(s), \quad (71.2.1)
\]

\( X_0 \in L^2 \left( \Omega; W \right) \) and is \( F_0 \) measurable, where \( Z \) is \( \mathcal{L}_2 \left( Q^{1/2}U, W \right) \) progressively measurable and

\[
\|Z\|_{L^2 \left( [0, T] \times \Omega; \mathcal{L}_2 \left( Q^{1/2}U, W \right) \right)} < \infty.
\]

This is what is needed to define the stochastic integral in the above formula.

Assume \( X, Y \) satisfy

\[
BX, Y \in K' \equiv L^p' \left( [0, T] \times \Omega; V' \right),
\]

the \( \sigma \) algebra of measurable sets defining \( K' \) will be the progressively measurable sets. Here \( 1/p' + 1/p = 1, \ p > 1 \).

Also the sense in which the equation holds is as follows. For a.e. \( \omega \), the equation holds in \( V' \) for all \( t \in [0, T] \). Thus we are considering a particular representative \( X \) of \( K \) for which this happens. **Also it is only assumed that \( BX(t) = B(X(t)) \) for a.e. \( t \). Thus \( BX \) is the name of a function having values in \( V' \) for which \( BX(t) = B(X(t)) \) for a.e. \( t \).** Assume that \( X \) is progressively measurable also and

\[
X \in L^p \left( [0, T] \times \Omega, V \right)
\]
Also \( W(t) \) is a \( JJ^* \) Wiener process on \( U_1 \) in the above diagram.

The goal is to prove the following Ito formula valid for a.e. \( t \) for each \( \omega \) off a set of measure zero.

\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t \left( 2 \langle Y(s), X(s) \rangle + \langle BZ, Z \rangle \right) ds + \int_0^t \langle Z \circ J^{-1} \rangle^* BX \circ J dW
\]

(71.2.2)

The most significant feature of the last term is that it is a local martingale. The term \( \langle BZ, Z \rangle \) will be discussed later, as will the meaning of the stochastic integral.

The idea is that \( (Z \circ J^{-1})^* BX \circ J \) has values in \( L^2(Q^{1/2}U, R) \) and so it makes sense to consider this stochastic integral. To see this, \( BX \) and \( (Z \circ J^{-1})^* BX \) have values in \( L^2(\mathbb{Q}^{1/2}U, R) = (Q^{1/2}U)^* \) and so

\[
(Z \circ J^{-1})^* BX \in \left( JQ^{1/2}U \right)^*
\]

and so \( (Z \circ J^{-1})^* BX \circ J \in L^2(Q^{1/2}U, R) = (Q^{1/2}U)^* \). Note that in general \( H' = L^2(H, R) \) because if you have \( \{e_i\} \) an orthonormal basis in \( H \), then for \( f \in H' \),

\[
\sum_i |(R^{-1} f, e_i)|^2 \leq \sum_i |(f, e_i)|^2 = \|f\|^2_{H'}.
\]

The main item of interest relative to this stochastic integral will be a statement about its quadratic variation. It appears to depend on \( J \) but this is not the case because the other terms in the formula do not.

### 71.3 Preliminary Results

Here are discussed some preliminary results which will be needed. From the integral equation, if \( \phi \in L^q(\Omega; V) \) and \( \psi \in C^\infty_c(0, T) \) for \( q = \max(p, 2) \),

\[
\int_0^T \int_0^t \left( (BX)(t) - B \int_0^t Z(s) dW(s) - BX_0 \right) \psi'(t) dtdP
\]

\[
= \int_0^T \int_0^t Y(s) \psi'(t) dsd\phi(\omega) dP
\]

Then the term on the right equals

\[
\int_0^T \int_s^T Y(s) \psi'(t) dt dsd\phi(\omega) dP = \int_0^T \left( - \int_0^T Y(s) \psi(s) ds \right) \phi(\omega) dP
\]

It follows that, since \( \phi \) is arbitrary,

\[
\int_0^T \left( (BX)(t) - B \int_0^t Z(s) dW(s) - BX_0 \right) \psi'(t) dt = - \int_0^T Y(s) \psi(s) ds
\]

71.3. PRELIMINARY RESULTS

! =
equation, for each of these

This will be important in what follows. In addition to this, from the integral

\mathcal{C}(0, T) \times \Omega; V) to X

and such that each \{t_k^n\}_{k=1}^{m_n} has empty intersection with the set of measure zero \(N\) where, in \(L^q(\Omega; V')\), \((BX)(t) \neq B(X(t))\) in \(L^q(\Omega; V')\). Thus for \(t_k\) a generic partition point,

\(BX(t_k) = B(X(t_k))\) in \(L^q(\Omega; V')\)

Hence there is an exceptional set of measure zero, \(N(t_k) \subseteq \Omega\) such that for \(\omega \notin N(t_k), BX(t_k)(\omega) = B(X(t_k, \omega))\). We define an exceptional set \(N \subseteq \Omega\) to be the union of all these \(N(t_k)\). There are countably many and so \(N\) is also a set of measure zero. Then for \(\omega \notin N\), and \(t_k\) any mesh point at all, \(BX(t_k)(\omega) = B(X(t_k, \omega))\).

This will be important in what follows. In addition to this, from the integral equation, for each of these \(\omega \notin N\), \(BX(t)(\omega) = B(X(t, \omega))\) for all \(t \notin N_\omega \subseteq [0, T]\) where \(N_\omega\) is a set of Lebesgue measure zero. Thus the \(t_k\) from the various partitions are always in \(N_\omega\). By Lemma 71.4.1, there exists a countable set \(\{e_i\}\) of vectors in \(V\) such that

\(\langle Be_i, e_j \rangle = \delta_{ij}\)

and for each \(x \in W,\)

\(\langle Bx, x \rangle = \sum_{i=0}^{\infty} |\langle Bx, e_i \rangle|^2, Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i\)

Thus the conclusion of the above discussion is that at the mesh points, it is valid to write

\(\langle (BX)(t_k), X(t_k) \rangle = \langle B(X(t_k)), X(t_k) \rangle \)

\(= \sum_i \langle (BX)(t_k), e_i \rangle^2 = \sum_i \langle B(X(t_k)), e_i \rangle^2\)
just as would be the case if \((BX)(t) = B(X(t))\) for every \(t\). In all which follows, the mesh points will be like this and an appropriate set of measure zero which may be replaced with a larger set of measure zero finitely many times is being neglected. Obviously, one can take a subsequence of the sequence of partitions described above without disturbing the above observations. We will denote these partitions as \(P_k\).

As a case of this, we obtain the following interesting lemma.

**Lemma 71.3.1** In the above situation, there exists a set of measure zero \(N \subseteq \Omega\) and a dense subset of \([0,T]\), \(D\) such that for \(\omega \notin N\), \(BX(t,\omega) = B(X(t,\omega))\) for all \(t \in D\).

**Theorem 71.3.2** Let \(Z\) be progressively measurable and in

\[
L^2 \left( [0,T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2}U, W \right) \right).
\]

Also suppose \(X\) is progressively measurable and in \(L^2 ([0,T] \times \Omega, W)\). Let \(\{t^n_j\}_{j=0}^{m_n}\) be a sequence of partitions of the sort in Lemma 71.1.1 such that if

\[
X_n(t) \equiv \sum_{j=0}^{m_n-1} X(t^n_j) X \left( [t^n_j, t^n_{j+1}) \right)(t) \equiv X^n_1(t)
\]

then \(X_n \to X\) in \(L^p ([0,T] \times \Omega, W)\). Also, it can be assumed that none of these mesh points are in the exceptional set off which \(BX(t) = B(X(t))\). (Thus it will make no difference whether we write \(BX(t)\) or \(B(X(t))\) in what follows for all \(t\) one of these mesh points.) Then the expression

\[
\sum_{j=0}^{m_n-1} \left< B \int_{t^n_j \wedge t}^{t^n_{j+1} \wedge t} ZdW, X(t^n_j) \right> = \sum_{j=0}^{m_n-1} \left< BX(t^n_j), \int_{t^n_j \wedge t}^{t^n_{j+1} \wedge t} ZdW \right> \tag{71.3.3}
\]

is a local martingale which can be written in the form

\[
\int_0^t (Z \circ J^{-1})^* BX^n_1 \circ JdW
\]

where

\[
X^n_1(t) = \sum_{k=0}^{m_n-1} X(t^n_k) X \left( [t^n_k, t^n_{k+1}) \right)(t)
\]

**Proof:** First suppose that \((BX(t^n_k), X(t^n_k)) \in L^\infty ([0,T] \times \Omega, W')\). Then

\[
\left< BX(t^n_j), \int_{t^n_j \wedge t}^{t^n_{j+1} \wedge t} ZdW \right>
\]

is in \(L^1(\Omega)\) for each \(t\) since both entries are in \(L^2(\Omega)\). Why is this a martingale?

\[
E \left( \left< BX(t^n_j), \int_{t^n_j \wedge t}^{t^n_{j+1} \wedge t} ZdW \right> \right) = E \left( E \left( \left< BX(t^n_j), \int_{t^n_j \wedge t}^{t^n_{j+1} \wedge t} ZdW \right> \mid \mathcal{F}_{t^n_k} \right) \right)
\]
71.3. PRELIMINARY RESULTS

\[ E \left( \left\{ BX \left( t^n_j \right), \int_{t^n_j}^{t^n_{j+1} \wedge \sigma} ZdW \right\} \right) = E \left( \left\{ BX \left( t^n_j \right), \int_{t^n_j}^{t^n_{j+1} \wedge \sigma} ZdW \mid \mathcal{F}_{t^n_j} \right\} \right) \]

because the stochastic integral is a martingale. Now let \( \sigma \) be a bounded stopping time.

\[ E \left( \left\{ BX \left( t^n_j \right), \int_{t^n_j}^{t^n_{j+1} \wedge \sigma} ZdW \right\} \right) = E \left( E \left( \left\{ BX \left( t^n_j \right), \int_{t^n_j}^{t^n_{j+1} \wedge \sigma} ZdW \right\} \mid \mathcal{F}_{t^n_j} \right) \right) \]

\[ = E \left( \left\{ BX \left( t^n_j \right), E \left( \int_{t^n_j}^{t^n_{j+1} \wedge \sigma} ZdW \right) \right\} \right) \]

\[ = E \left( \left\{ BX \left( t^n_j \right), E \left( \int_{0}^{t^n_{j+1} \wedge \sigma} ZdW - \int_{0}^{t^n_{j} \wedge \sigma} ZdW \right) \right\} \right) \]

\[ = E \left( \left\{ BX \left( t^n_j \right), 0 \right\} \right) = 0 \]

and so this is a martingale. I want to write the formula in (71.3.3) as a stochastic integral. First note that \( W \) has values in \( U_1 \).

Consider one of the terms of the sum more simply as

\[ \left\{ B \int_{a}^{b} ZdW, X \left( a \right) \right\}, \quad a = t^n_k \wedge \tau, \quad b = t^n_{k+1} \wedge \tau. \]

Then from the definition of the integral, let \( Z_n \) be a sequence of elementary functions converging to \( Z \circ J^{-1} \) in \( L^2 \left( [a, b] \times \Omega, \mathcal{L}_2 \left( JQ^{1/2}U, W \right) \right) \) and

\[ \left\| \int_{a}^{t} ZdW - \int_{a}^{t} Z_n dW \right\|_{L^2(\Omega, W)} \to 0 \]

Using a maximal inequality and the fact that the two integrals are martingales along with the Borel Cantelli lemma, there exists a set of measure 0 \( N \) such that for \( \omega \notin N \), the convergence of a suitable subsequence of these integrals, still denoted by \( n \), is uniform for \( t \in [a, b] \). It follows that for such \( \omega \),

\[ \left\{ B \int_{a}^{b} ZdW, X \left( a \right) \right\} = \lim_{n \to \infty} \left\{ B \int_{a}^{b} Z_n dW, X \left( a \right) \right\}. \] (71.3.4)

Say

\[ Z_n \left( u \right) = \sum_{k=0}^{m_n-1} Z^n_k X_{[t^n_k, t^n_{k+1}]} \left( u \right) \]

where \( Z^n_k \) has finitely many values in \( L \left( U_1, W \right)_b \), the restrictions of maps in \( L \left( U_1, W \right) \) to \( JQ^{1/2}U \), and the \( t^n_k \) refer to a partition of \( [a, b] \). Then the product on the right in (71.3.4) is of the form

\[ \sum_{k=0}^{m_n-1} \left\{ BZ^n_k \left( W \left( t \wedge t^n_{k+1} \right) - W \left( t \wedge t^n_k \right) \right), X \left( a \right) \right\} \mid W', W \]
Note that it makes sense because $Z^n_k$ is the restriction to $J(Q^{1/2}U)$ of a map from $U_1$ to $W$ and so $BZ^n_k$ is a map from $U_1$ to $W'$. Then the Wiener process has values in $U_1$ so when you apply $BZ^n_k$ to $W(t \wedge t^n_k) - W(t \wedge t^n_k)$, you get something in $W'$ and so the duality pairing is between $W'$ and $W$ as shown. Also, $Z^n_k(W(t \wedge t^n_k) - W(t \wedge t^n_k))$ gives something in $W$ because the Wiener process has values in $U_1$ and $Z^n_k$ acts on these things to give something in $W$. Thus the above equals

\[
\sum_{k=0}^{m_n-1} \langle BX(a), Z^n_k(W(t \wedge t^n_k) - W(t \wedge t^n_k)) \rangle_{W', W}
\]

\[
= \sum_{k=0}^{m_n-1} \langle (Z^n_k)^* BX(a), (W(t \wedge t^n_k) - W(t \wedge t^n_k)) \rangle_{U'_i, U_i}
\]

\[
= \sum_{k=0}^{m_n-1} (Z^n_k)^* BX(a)(W(t \wedge t^n_k) - W(t \wedge t^n_k))
\]

\[
= \int_a^t Z^n_k BX(a) dW
\]

Note that the restriction of $(Z_n)^* BX(a)$ is in

\[
\mathcal{L}(U_1, \mathbb{R})_0 \subseteq \mathcal{L}_2(JQ^{1/2}U, \mathbb{R}).
\]

Recall also that the space on the left is dense in the one on the right. Now let $\{g_i\}$ be an orthonormal basis for $Q^{1/2}U$, so that $\{Jg_i\}$ is an orthonormal basis for $JQ^{1/2}U$. Then

\[
\sum_{i=1}^{\infty} \left| \langle (Z_n)^* BX(a) - (Z \circ J^{-1})^* BX(a) \rangle (Jg_i) \right|^2
\]

\[
= \sum_{i=1}^{\infty} \left| \langle BX(a), (Z_n - Z \circ J^{-1}) (Jg_i) \rangle \right|^2
\]

\[
\leq \langle BX(a), X(a) \rangle \sum_{i=1}^{\infty} \langle B(Z_n - Z \circ J^{-1}) (Jg_i), (Z_n - Z \circ J^{-1}) (Jg_i) \rangle
\]

\[
\leq \langle BX(a), X(a) \rangle \| B \| \sum_{i=1}^{\infty} \| (Z_n - Z \circ J^{-1}) (Jg_i) \|_W^2
\]

\[
= \langle BX(a), X(a) \rangle \| B \| \| Z_n - Z \circ J^{-1} \|^2_{\mathcal{L}_2(JQ^{1/2}U, W)}
\]

When integrated over $[a, b] \times \Omega$, it is given that this converges to 0, assuming that $\langle BX(a), X(a) \rangle \in L^\infty(\Omega)$, which is assumed for now.
71.3. PRELIMINARY RESULTS

It follows that, with this assumption,

\[ Z_n^* BX (a) \rightarrow (Z \circ J^{-1})^* BX (a) \]

in \( L^2 ([a, b] \times \Omega, \mathcal{L}_2 \left( JQ^{1/2} U, \mathbb{R} \right) ) \). Writing this differently, it says

\[ Z_n^* BX (a) \rightarrow \left( (Z \circ J^{-1})^* BX (a) \circ J \right) \circ J^{-1} \text{ in } L^2 ([a, b] \times \Omega, \mathcal{L}_2 \left( JQ^{1/2} U, \mathbb{R} \right) ) \]

It follows from the definition of the integral that the Ito integrals converge. Therefore,

\[ \langle B \int_a^t ZdW, X (a) \rangle = \int_a^t (Z \circ J^{-1})^* BX (a) \circ JdW \]

The term on the right is a martingale because the one on the left is.

Next it is necessary to drop the assumption that \( \langle BX (a), X (a) \rangle \in L^\infty (\Omega) \).

Note that \( X_n^l \) is right continuous and \( BX_n^l \) progressively measurable. Thus,

\[ \langle BX_n^l (t), X_n^l (t) \rangle = \sum_i \langle BX_i^l (t), \epsilon_i \rangle^2 \]

where \( \{ \epsilon_i \} \) is the set defined in Lemma 7.2.1 each in \( V \). Thus \( \langle BX_n^l, X_n^l \rangle \) is also progressively measurable and right continuous, and one can define the stopping time

\[ \sigma_q^n \equiv \inf \{ t : \langle BX_n^l (t), X_n^l (t) \rangle > q \} \]

the first hitting time of an open set. Also, for each \( \omega \), there are only finitely many values for \( \langle BX_n^l (t), X_n^l (t) \rangle \) and so \( \sigma_q^n = \infty \) for all \( q \) large enough.

From localization,

\[ \langle B \int_{a \wedge \sigma_q^n}^{t \wedge \sigma_q^n} ZdW, X (a) \rangle = \langle B \int_{a}^{t} X_{[0, \sigma_q^n]} ZdW, X (a) \rangle \]

\[ = \int_a^t \left( X_{[0, \sigma_q^n]} \circ J \right)^* BX (a) \circ JdW \]

\[ = \int_{a \wedge \sigma_q^n}^{t \wedge \sigma_q^n} (Z \circ J^{-1})^* BX (a) \circ JdW \]

Then it follows that, using the stopping time,

\[ \sum_{j=0}^{m_n-1} \left\langle B \int_{t_{j+1}^n \wedge t \wedge \sigma_q^n}^{t_j^n} ZdW, X (t_j^n) \right\rangle = \int_0^{t \wedge \sigma_q^n} (Z \circ J^{-1})^* BX_n^l \circ JdW \]

where \( X_n^l \) is the step function

\[ X_n^l (t) = \sum_{k=0}^{m_n-1} X (t_k^n) \Delta X_{[t_k^n, t_{k+1}^n]} (t) \].
Thus the given sum equals the local martingale
\[
\int_0^t (Z \circ J^{-1})^* BX_n^l \circ JdW.
\]
Note that the sum does not depend on J or on \(U_1\) so the same must be true of what it equals although it does not look that way. The question of convergence as \(n \to \infty\) is considered later.

What follows is the main estimate and discrete formulas.

### 71.4 The Main Estimate

The argument will be based on a formula which follows in the next lemma.

**Lemma 71.4.1** In Situation 71.2.1 the following formula holds for a.e. \(\omega\) for \(0 < s < t\) where \(\mathcal{M} (t) = \int_0^t Z(u) dW(u)\) which has values in \(W\). In the following, \(\langle \cdot, \cdot \rangle\) denotes the duality pairing between \(V, V'\).

\[
\langle BX (t), X (t) \rangle = \langle BX (s), X (s) \rangle + 2 \int_s^t \langle Y(u), X(t) \rangle du + \langle B(M(t) - M(s)), M(t) - M(s) \rangle
\]

\[
- \langle BX (t) - BX (s), (M(t) - M(s)), X(t) - X(s), (M(t) - M(s)) \rangle
\]

\[
+ 2 \langle BX (s), M(t) - M(s) \rangle
\]  

(71.4.6)

Also for \(t > 0\)

\[
\langle BX (t), X (t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(t) \rangle du + 2 \langle BX_0, M(t) \rangle + \langle BM (t), M (t) \rangle - \langle BX (t) - BX_0 - BM (t), X (t) - X_0 - M (t) \rangle
\]

(71.4.7)

**Proof:** From the formula which is assumed to hold,

\[
BX (t) = BX_0 + \int_0^t Y(u) du + BM (t)
\]

\[
BX (s) = BX_0 + \int_0^s Y(u) du + BM (s)
\]

Then

\[
BM (t) - BM (s) + \int_s^t Y(u) du = BX (t) - BX (s)
\]

It follows that

\[
\langle B(M(t) - M(s)), M(t) - M(s) \rangle - \langle BX (t) - BX (s), (M(t) - M(s)), X(t) - X(s), (M(t) - M(s)) \rangle
\]
continuity result is strengthened further to give strong continuity. In all of this, \( X \) actually continuous a.e. with values in \( X \) and the well known result that if \( y \) is similar.

The case with \( X \) is similar. \( \blacksquare \)

The following phenomenal estimate holds and it is this estimate which is the main idea in proving the Ito formula. The last assertion about continuity is like the well known result that if \( y \in L^p (0,T;V) \) and \( y' \in L^p (0,T;V') \), then \( y \) is actually continuous a.e. with values in \( H \), for \( V,H,V' \) a Gelfand triple. Later, this continuity result is strengthened further to give strong continuity. In all of this, \( X_k \) and \( X_k' \) are as described above, converging in \( K \) to \( X \).

\[
+ 2 \langle BX(s), M(t) - M(s) \rangle 
\]

\[
= \langle B(M(t) - M(s)), M(t) - M(s) \rangle - \langle BX(t) - BX(s), X(t) - X(s) \rangle + 2 \langle BX(t) - BX(s), M(t) - M(s) \rangle 
\]

\[
= \langle B(M(t) - M(s)), M(t) - M(s) \rangle - 2 \langle BX(s), X(t) - X(s) \rangle + 2 \langle B(M(t) - M(s)), X(t) \rangle 
\]

Some terms cancel and this yields

\[
= - \langle BX(t) - BX(s), X(t) - X(s) \rangle + 2 \langle BX(t), M(t) - M(s) \rangle 
\]

\[
= - \langle BX(t) - BX(s), X(t) - X(s) \rangle + 2 \langle B(M(t) - M(s)), X(t) \rangle 
\]

\[
= - \langle BX(t), X(t) \rangle - \langle BX(s), X(s) \rangle + 2 \langle BX(t), X(s) \rangle + 2 \langle BX(t), X(t) \rangle 
\]

\[
- 2 \langle BX(s), X(t) \rangle - 2 \int_s^t \langle Y(u), X(t) \rangle \] \] 

\[
= \langle BX(t), X(t) \rangle - \langle BX(s), X(s) \rangle - 2 \int_s^t \langle Y(u), X(t) \rangle \] 

Therefore,

\[
\langle BX(t), X(t) \rangle - \langle BX(s), X(s) \rangle 
\]

\[
= 2 \int_s^t \langle Y(u), X(t) \rangle \] \] 

\[
- \langle BX(t) - BX(s) - (M(t) - M(s)), X(t) - X(s) - (M(t) - M(s)) \rangle 
\]

\[
+ 2 \langle BX(s), M(t) - M(s) \rangle 
\]

The case with \( X_0 \) is similar. \( \blacksquare \)
Lemma 71.4.2 In the Situation \cite{[??]}, the following holds. For a.e. \( t \)
\[
E \left( \langle BX (t) , X (t) \rangle \right) < C \left( \| Y \|_{K'} , \| X \|_K , \| Z \|_J , \| \langle BX_0 , X_0 \rangle \|_{L^1 (\Omega)} \right) < \infty. \tag{71.4.8}
\]
where \( K , K' \) were defined earlier and
\[
J = L^2 \left( [0,T] \times \Omega ; L_2 \left( Q^{1/2} U; W \right) \right)
\]
In fact,
\[
E \left( \sup \sum \langle BX (t) , x_i \rangle^2 \right) \leq C \left( \| Y \|_{K'} , \| X \|_K , \| Z \|_J , \| \langle BX_0 , X_0 \rangle \|_{L^1 (\Omega)} \right)
\]
Also, \( C \) is a continuous function of its arguments, increasing in each one, and \( C (0,0,0,0) = 0 \). Thus for a.e. \( \omega \),
\[
\sup \langle BX (t, \omega) , X (t, \omega) \rangle \leq C (\omega) < \infty.
\]
Also for \( \omega \) off a set of measure zero described earlier, \( t \to BX (t) (\omega) \) is weakly continuous with values in \( W' \) on \( [0,T] \). Also \( t \to \langle BX (t) , X (t) \rangle \) is lower semi-continuous on \( N^C \).

**Proof:** Consider the formula in Lemma \cite{[??]}
\[
\langle BX (t) , X (t) \rangle = \langle BX (s) , X (s) \rangle
\]
\[
+ 2 \int_s^t \langle Y (u) , X (t) \rangle du + \langle B (M (t) - M (s)) , M (t) - M (s) \rangle
\]
\[
- \langle B (X (t) - X (s) - (M (t) - M (s))) , X (t) - X (s) - (M (t) - M (s)) \rangle
\]
\[
+ 2 \langle BX (s) , M (t) - M (s) \rangle \tag{71.4.9}
\]
Now let \( t_j \) denote a point of \( P_k \) from Lemma \cite{[??]} Then for \( t_j > 0, X (t_j) \) is just the value of \( X \) at \( t_j \) but when \( t = 0 \), the definition of \( X (0) \) in this step function is \( X (0) \equiv 0 \). Thus
\[
\sum_{j=1}^{m-1} \langle BX (t_{j+1}) , X (t_{j+1}) \rangle - \langle BX (t_j) , X (t_j) \rangle
\]
\[
+ \langle BX (t_1) , X (t_1) \rangle - \langle BX_0 , X_0 \rangle
\]
\[
= \langle BX (t_m) , X (t_m) \rangle - \langle BX_0 , X_0 \rangle
\]
Using the formula in Lemma \cite{[??]} for \( t = t_m \) this yields
\[
\langle BX (t_m) , X (t_m) \rangle - \langle BX_0 , X_0 \rangle = 2 \sum_{j=1}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y (u) , X_k (u) \rangle du + \]
71.4. THE MAIN ESTIMATE

\[ +2 \sum_{j=1}^{m-1} \left\langle B \int_{t_j}^{t_{j+1}} Z(u) \, dW, X(t_j) \right\rangle \]
\[ + \sum_{j=1}^{m-1} \langle B (M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle \]
\[ - \sum_{j=1}^{m-1} \langle B (X(t_{j+1}) - X(t_j)), (M(t_{j+1}) - M(t_j)) \rangle, \]
\[ X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j)) \]
\[ +2 \int_0^{t_1} \langle Y(u), X(t_1) \rangle \, du + 2 \left\langle BX_0, \int_0^{t_1} Z(u) \, dW \right\rangle + \langle BM(t_1), M(t_1) \rangle \]
\[ - \langle B (X(t_1) - X_0 - M(t_1)), X(t_1) - X_0 - M(t_1) \rangle \]

(71.4.10)

First consider

\[ 2 \int_0^{t_1} \langle Y(u), X(t_1) \rangle \, du + 2 \left\langle BX_0, \int_0^{t_1} Z(u) \, dW \right\rangle + \langle BM(t_1), M(t_1) \rangle. \]

Each term of the above converges to 0 for a.e. \( \omega \) as \( k \to \infty \) and in \( L^1(\Omega) \). This follows right away for the second two terms from the Ito isometry and continuity properties of the stochastic integral. Consider the first term. This term is dominated by

\[ \left( \int_0^{t_1} \|Y(u)\|^{p'} \, du \right)^{1/p'} \left( \int_0^T \|X_k^r(u)\|^p \, du \right)^{1/p} \]
\[ \leq C(\omega) \left( \int_0^{t_1} \|Y(u)\|^{p'} \, du \right)^{1/p'} \leq \left( \int_\Omega C(\omega)^p \, dP \right)^{1/p} < \infty \]

Hence this converges to 0 for a.e. \( \omega \) and also converges to 0 in \( L^1(\Omega) \).

At this time, not much is known about the last term in (71.4.10), but it is negative and is about to be neglected anyway.

The term involving the stochastic integral equals

\[ 2 \sum_{j=1}^{m-1} \left\langle B \int_{t_j}^{t_{j+1}} Z(u) \, dW, X(t_j) \right\rangle \]

By Theorem 71.3.2 this equals

\[ 2 \int_{t_1}^{t_m} (Z \circ J^{-1})^* BX^*_k \circ JdW \]
CHAPTER 71. THE HARD ITO FORMULA, IMPLICIT CASE

Also note that since \( \langle BM(t_1), M(t_1) \rangle \) converges to 0 in \( L^1(\Omega) \) and for a.e. \( \omega \), the sum involving

\[
\langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

can be started at 0 rather than 1 at the expense of adding in a term which converges
to 0 a.e. and in \( L^1(\Omega) \). Thus (71.4.10) is of the form

\[
\langle BX(t_m), X(t_m) \rangle - \langle BX_0, X_0 \rangle = e(k) + 2 \int_0^{t_m} \langle Y(u), X_k(u) \rangle du +
\]

\[
+2 \int_0^{t_m} (Z \circ J^{-1})^* BX_k^l \circ JdW + \sum_{j=0}^{m-1} \langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

\[
- \sum_{j=1}^{m-1} \langle B(X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))), X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j)) \rangle
\]

\[
- \langle B(X(t_1) - X_0 - M(t_1)), X(t_1) - X_0 - M(t_1) \rangle
\]

(71.4.11)

where \( e(k) \to 0 \) for a.e. \( \omega \) and also in \( L^1(\Omega) \).

By definition, \( M(t_{j+1}) - M(t_j) = \int_{t_j}^{t_{j+1}} ZdW \). Now it follows, on discarding the
negative terms,

\[
\langle BX(t_m), X(t_m) \rangle - \langle BX_0, X_0 \rangle \leq e(k) + 2 \int_0^{t_m} \langle Y(u), X_k^l(u) \rangle du +
\]

\[
+2 \int_0^{t_m} (Z \circ J^{-1})^* BX_k^l \circ JdW + \sum_{j=0}^{m-1} \left\langle B \left( \int_{t_j}^{t_{j+1}} ZdW, \int_{t_j}^{t_{j+1}} ZdW \right) \right\rangle
\]

Therefore,

\[
\sup_{t_m \in \mathcal{P}_k} \langle BX(t_m), X(t_m) \rangle \leq \langle BX_0, X_0 \rangle + e(k) + 2 \int_0^{T} |\langle Y(u), X_k^l(u) \rangle| du +
\]

\[
+2 \sup_{t_m \in \mathcal{P}_k} \left| \int_0^{t_m} (Z \circ J^{-1})^* BX_k^l \circ JdW \right|
\]

\[
+ \sum_{j=0}^{m_k-1} \left\langle B \left( \int_{t_j}^{t_{j+1}} Z(u) dW, \int_{t_j}^{t_{j+1}} Z(u) dW \right) \right\rangle
\]

where there are \( m_k + 1 \) points in \( \mathcal{P}_k \).
71.4. THE MAIN ESTIMATE

The next task is to somehow take the expectation of both sides. However, this is problematic because the stochastic integral is only a local martingale. Let

\[ \tau_p = \inf \{ t : \langle B X^l_k (t), X^l_k (t) \rangle > p \} \]

By right continuity this is a well defined stopping time. Then you obtain the above inequality for \( (X^l_k)^{\tau_p} \) in place of \( X^l_k \). Take the expectation and use the Ito isometry to obtain

\[
\int_{\Omega} \left( \sup_{t \in \mathcal{P}_k} \mathbb{E} \left[ \left( B \left( X^l_k \right)^{\tau_p} (t), X^l_k (t) \right) \right] \right) dP \\
\leq E \left( \langle BX_0, X_0 \rangle \right) + 2 \|Y\|_{K'} \|X^l_k\|_K + 2 \left\| B \right\| \sum_{j=0}^{m-1} \int_{t_j}^{t_{j+1}} \mathbb{E} \left[ \|Z(u)\|^2 \right] dP du \\
+ 2 \int_{\Omega} \left( \sup_{t \in [0,T]} \mathbb{E} \left[ \left( Z \circ J^{-1} \right)^* B \left( X^l_k \right)^{\tau_p} \circ J dW \right] \right) dP
\]

where the convergence of \( X^l_k \) to \( X \) in \( K \) shows the term \( 2 \|Y\|_{K'} \|X^l_k\|_K \) is bounded. Thus the constant \( C \) can be assumed to be a continuous function of \( \|Z\|_J, \|X\|_K, \|Y\|_{K'} \) which equals zero when all are equal to zero and is increasing in each. The term involving the stochastic integral is next.

Let \( \mathcal{M} (t) = \int_0^t \left( Z \circ J^{-1} \right)^* B \left( X^l_k \right)^{\tau_p} \circ J dW \). Then thanks to Corollary 63.11.1

\[
d[\mathcal{M}] = \left\| \left( Z \circ J^{-1} \right)^* B \left( X^l_k \right)^{\tau_p} \circ J \right\|^2 ds
\]

Applying the Burkholder Davis Gundy inequality, Theorem 61.4.4 for \( F (r) = r \) in that stochastic integral,

\[
2 \int_{\Omega} \left( \sup_{t \in [0,T]} \mathbb{E} \left[ \left( Z \circ J^{-1} \right)^* B \left( X^l_k \right)^{\tau_p} \circ J dW \right] \right) dP
\]
\[ \int_\Omega \left( \int_0^T \left\| (Z \circ J^{-1})^* B \left( X_k^l \right)^{\tau_p} \circ J \right\|^2_{L^2(Q^{1/2}U,R)} \, ds \right)^{1/2} \, dP \]  

(71.4.13)

So let \( \{g_i\} \) be an orthonormal basis for \( Q^{1/2}U \) and consider the integrand in the above. It equals

\[ \sum_{i=1}^\infty \left( \left( (Z \circ J^{-1})^* B \left( X_k^l \right)^{\tau_p} \right) (J (g_i)) \right)^2 = \sum_{i=1}^\infty \left\langle B \left( X_k^l \right)^{\tau_p}, Z (g_i) \right\rangle \]

\[ \leq \sum_{i=1}^\infty \left\langle B \left( X_k^l \right)^{\tau_p}, (X_k^l)^{\tau_p} \right\rangle \left\langle BZ, Z(g_i) \right\rangle \]

\[ \leq \left( \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle \right) \|B\| \|Z\|_{L^2}^2 \]

It follows that the integral in (71.4.13) is dominated by

\[ C \int \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle^{1/2} \|B\|^{1/2} \left( \int_0^T \|Z\|_{L^2}^2 \, ds \right)^{1/2} \, dP \]

Now return to (71.4.12). From what was just shown,

\[ E \left( \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle \right) \]

\[ \leq C + E (|e(k)|) + 2 \int_\Omega \left( \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \left( X_k^l \right)^{\tau_p} \circ JdW \right| \right) \, dP \]

\[ \leq C + C \int \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle^{1/2} \|B\|^{1/2} \left( \int_0^T \|Z\|_{L^2}^2 \, ds \right)^{1/2} \, dP + E (|e(k)|) \]

\[ \leq C + \frac{1}{2} E \left( \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle \right) + C \|Z\|_{L^2([0,T] \times \Omega, L^2)}^2 + E (|e(k)|). \]

It follows that

\[ \frac{1}{2} E \left( \sup_{t_m \in P_k} \left\langle B \left( X_k^l \right)^{\tau_p} (t_m), (X_k^l)^{\tau_p} (t_m) \right\rangle \right) \leq C + E (|e(k)|) \]
71.4. THE MAIN ESTIMATE

Now let $p \to \infty$ and use the monotone convergence theorem to obtain

$$
E \left( \sup_{t \in \mathcal{P}_k} \langle BX_k^l (t_m), X_k^l (t_m) \rangle \right) = E \left( \sup_{t \in \mathcal{P}_k} \langle BX (t_m), X (t_m) \rangle \right) \leq C + E(\|e (k)\|)
$$

(71.4.14)

As mentioned above, this constant $C$ is a continuous function of

$$
\|Y\|_{K'}, \|X\|_{K}, \|Z\|_{J}, \|\langle BX_0, X_0 \rangle\|_{L^1(\Omega, H)}
$$

and equals zero when all of these quantities equal 0 and is increasing with respect to each of the above quantities. Also, for each $\varepsilon > 0$,

$$
E \left( \sup_{t \in \mathcal{P}_k} \langle BX (t_m), X (t_m) \rangle \right) \leq C + \varepsilon
$$

whenever $k$ is large enough.

Let $D$ denote the union of all the $\mathcal{P}_k$. Thus $D$ is a dense subset of $[0, T]$ and it has just been shown, since the $\mathcal{P}_k$ are nested, that for a constant $C$ dependent only on the above quantities which is independent of $\mathcal{P}_k$,

$$
E \left( \sup_{t \in D} \langle BX (t), X (t) \rangle \right) \leq C + \varepsilon.
$$

Since $\varepsilon > 0$ is arbitrary,

$$
E \left( \sup_{t \in D} \langle BX (t), X (t) \rangle \right) \leq C
$$

(71.4.15)

Thus, enlarging $N$, for $\omega \notin N$,

$$
\sup_{t \in D} \langle BX (t), X (t) \rangle = C (\omega) < \infty
$$

(71.4.16)

where $\int_{\Omega} C (\omega) dP < \infty$. By Lemma [71.4.11], there exists a countable set $\{e_i\}$ of vectors in $V$ such that

$$
\langle Be_i, e_j \rangle = \delta_{ij}
$$

and for each $x \in W$,

$$
\langle Bx, x \rangle = \sum_{i=0}^{\infty} \langle Bx, e_i \rangle^2, \quad Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i
$$

Thus for $t$ not in a set of measure zero off which $BX (t) = B (X (t))$,

$$
\langle BX (t), X (t) \rangle = \sum_{i=0}^{\infty} \langle BX (t), e_i \rangle^2 = \sup_m \sum_{k=1}^{m} \langle BX (t), e_i \rangle^2
$$
Now from the formula for $BX(t)$, it follows that $BX$ is continuous into $V'$. For any $t \notin \tilde{N}$ so that $(BX)(t) = B(X(t))$ in $L^d(\Omega; V')$ and letting $t_k \to t$ where $t_k \in D$, Fatou’s lemma implies

$$E(\langle BX(t), X(t) \rangle) = \sum_i E(\langle BX(t), e_i \rangle^2) = \sum_i \lim_{k \to \infty} E(\langle BX(t_k), e_i \rangle^2)$$

$$\leq \lim_{k \to \infty} \inf \sum_i E(\langle BX(t_k), e_i \rangle^2) = \lim_{k \to \infty} E(\langle BX(t_k), X(t_k) \rangle)$$

$$\leq C\left( \|Y\|_{K'}, \|X\|_K, \|Z\|_J, \|BX_0, X_0\|_{L^1(\Omega)} \right)$$

In addition to this, for arbitrary $t \in [0,T]$, and $t_k \to t$ from $D$,

$$\sum_i \langle BX(t), e_i \rangle^2 \leq \lim_{k \to \infty} \sum_i \langle BX(t_k), e_i \rangle^2 \leq \sup_{s \in D} \langle BX(s), X(s) \rangle$$

Hence

$$\sup_{t \in [0,T]} \sum_i \langle BX(t), e_i \rangle^2 \leq \sup_{s \in D} \langle BX(s), X(s) \rangle = \sup_{s \in D} \sum_i \langle BX(s), e_i \rangle^2 \leq \sup_{t \in [0,T]} \sum_i \langle BX(t), e_i \rangle^2$$

It follows that $\sup_{t \in [0,T]} \sum_i \langle BX(t), e_i \rangle^2$ is measurable and

$$E\left( \sup_{t \in [0,T]} \sum_i \langle BX(t), e_i \rangle^2 \right) \leq E\left( \sup_{s \in D} \langle BX(s), X(s) \rangle \right)$$

$$\leq C\left( \|Y\|_{K'}, \|X\|_K, \|Z\|_J, \|BX_0, X_0\|_{L^1(\Omega)} \right)$$

And so, for $\omega$ off a set of measure zero, $\sup_{t \in [0,T]} \sum_i \langle BX(t), e_i \rangle^2$ is bounded above.

Also for $t \notin N_\omega$ and a given $\omega \notin N$, letting $t_k \to t$ for $t_k \in D$,

$$\langle BX(t), X(t) \rangle = \sum_i \langle BX(t), e_i \rangle^2 \leq \lim_{k \to \infty} \inf \sum_i \langle BX(t_k), e_i \rangle^2$$

$$= \lim_{k \to \infty} \langle BX(t_k), X(t_k) \rangle \leq \sup_{t \in D} \langle BX(t), X(t) \rangle$$

and so

$$\sup_{t \in N_\omega} \langle BX(t), X(t) \rangle \leq \sup_{t \in D} \langle BX(t), X(t) \rangle \leq \sup_{t \notin N_\omega} \langle BX(t), X(t) \rangle$$

From

$$\sup_{t \notin N_\omega} \langle BX(t), X(t) \rangle = C(\omega) \text{ a.e. } \omega$$
This shows that also, \[ \lim_{t \to s} \langle BX(t), v \rangle = \langle BX(s), v \rangle, \quad t, s \]

Therefore, since for such \( \omega \), \( \|BX(t)\|_{W'} \) is bounded for \( t \notin N_\omega \), the above holds for all \( v \in W \) also. Therefore, for a.e. \( \omega \), \( t \to BX(t, \omega) \) is weakly continuous with values in \( W' \) for \( t \notin N_\omega \).

Note also that

\[
\int_0^T \int_{\Omega} \|BX(t)\|^2 \, dt \, dP \leq \int_0^T \int_{\Omega} \|B\|^{1/2} \langle BX(t), X(t) \rangle \, dt \, dP
\]

\[
\leq C \left( \|Y\|_{L^2}, \|X\|_{L^2}, \|Z\|_{L^2}, \|\langle BX_0, X_0 \rangle\|_{L^1(\Omega)} \right) \|B\|^{1/2} T \tag{71.4.17}
\]

Eventually, it is shown that in fact, the function \( t \to BX(t, \omega) \) is continuous with values in \( W' \). The above shows that \( BX \in L^2([0, T] \times \Omega, W') \).

Finally consider the claim of weak continuity of \( BX \) into \( W' \). From the integral equation, \( BX \) is continuous into \( V' \). Also \( BX \) is bounded on \( N_\omega^C \). Let \( s \in [0, T] \) be arbitrary. I claim that if \( t_n \to s, t_n \in D \), it follows that \( BX(t_n) \to BX(s) \) weakly in \( W' \). If not, then there is a subsequence, still denoted as \( t_n \) such that \( BX(t_n) \to Y \) weakly in \( W' \) but \( Y \neq BX(s) \). However, the continuity into \( V' \) means that for all \( v \in V \),

\[
\langle Y, v \rangle = \lim_{n \to \infty} \langle BX(t_n), v \rangle = \langle BX(s), v \rangle
\]

which is a contradiction since \( V \) is dense in \( W \). This establishes the claim. Also this shows that \( BX(s) \) is bounded in \( W' \).

\[
|\langle BX(s), w \rangle| = \lim_{n \to \infty} |\langle BX(t_n), w \rangle| \leq \liminf_{n \to \infty} \|BX(t_n)\|_{W'}, \|w\|_{W'} \leq C(\omega) \|w\|_{W'}
\]

Now a repeat of the above argument shows that \( s \to BX(s) \) is weakly continuous into \( W' \). □

### 71.5 A Simplification Of The Formula

This lemma also provides a way to simplify one of the formulas derived earlier in the case that \( X_0 \in L^p(\Omega, V) \) so that \( X - X_0 \in L^p([0, T] \times \Omega, V) \). Refer to [71.4.11].

One term there is

\[
\langle B(X(t_1) - X_0 - M(t_1)), X(t_1) - X_0 - M(t_1) \rangle
\]

Also,

\[
\langle B(X(t_1) - X_0 - M(t_1)), X(t_1) - X_0 - M(t_1) \rangle
\]
It was observed above that $2 \langle BM (t_1), M (t_1) \rangle \to 0$ a.e. and also in $L^1 (\Omega)$ as $k \to \infty$. Apply the above lemma to $\langle B (X (t_1) - X_0), X (t_1) - X_0 \rangle$ using $[0, t_1]$ instead of $[0, T]$. The new $X_0$ equals 0. Then from the estimate (14.11), it follows that
\[ E (\langle B (X (t_1) - X_0), X (t_1) - X_0 \rangle) \to 0 \]
as $k \to \infty$. Taking a subsequence, we could also assume that
\[ \langle B (X (t_1) - X_0), X (t_1) - X_0 \rangle \to 0 \]
a.e. $\omega$ as $k \to \infty$. Then, using this subsequence, it would follow from (14.11),
\[ \langle BX (t_m), X (t_m) \rangle - \langle BX_0, X_0 \rangle = e (k) + 2 \int_0^{t_m} \langle Y (u), X^k_1 (u) \rangle du + 2 \int_0^{t_m} (Z \circ J^{-1})^* BX^1_k \circ J dW \]
\[ + \sum_{j=0}^{m-1} \langle B (M (t_{j+1}) - M (t_j)), M (t_{j+1}) - M (t_j) \rangle \]
\[ - \sum_{j=1}^{m-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), \Delta X (t_j) - \Delta M (t_j) \rangle \quad (71.5.18) \]
where $e (k) \to 0$ in $L^1 (\Omega)$ and a.e. $\omega$ and
\[ \Delta X (t_j) \equiv X (t_{j+1}) - X (t_j) \]
$\Delta M (t_j)$ being defined similarly. Note how this eliminated the need to consider the term
\[ \langle B (X (t_1) - X_0 - M (t_1)), X (t_1) - X_0 - M (t_1) \rangle \]
in passing to a limit. This is a very desirable thing to be able to conclude.

Can you obtain something similar even in case $X_0$ is not assumed to be in $L^p (\Omega, V)$? Let $Z_{0k} \in L^p (\Omega, V) \cap L^2 (\Omega, W)$, $Z_{0k} \to X_0$ in $L^2 (\Omega, W)$. Then from the usual arguments involving the Cauchy Schwarz inequality,
\[ \langle B (X (t_1) - X_0), X (t_1) - X_0 \rangle^{1/2} \leq \langle B (X (t_1) - Z_{0k}), X (t_1) - Z_{0k} \rangle^{1/2} + \langle B (Z_{0k} - X_0), Z_{0k} - X_0 \rangle^{1/2} \]

Also, restoring the superscript to identify the partition,
\[ B (X (t_1^k) - Z_{0k}) = B (X_0 - Z_{0k}) + \int_0^{t_1^k} Y (s) ds + B \int_0^{t_1^k} Z (s) dW. \]

Of course $\|X - Z_{0k}\|_K$ is not bounded, but for each $k$ it is finite. There is a sequence of partitions $\mathcal{P}_k$, $\|\mathcal{P}_k\| \to 0$ such that all the above holds. In the definitions
of $K,K',J$ replace $[0,T]$ with $[0,t]$ and let the resulting spaces be denoted by $K_t,K_{t'},J_t$. Let $n_k$ denote a subsequence of $\{k\}$ such that

$$\|X - Z_{0k}\|_{K_{t_k}^{t_k}} < 1/k.$$ 

Then from the above lemma,

$$E \left( \langle B (X (t_k^n) - Z_{0k}) , X (t_1^n) - Z_{0k} \rangle \right)$$

$$\leq C \left( \|Y\|_{K_{t_k}^{t_k}}, \|X - Z_{0k}\|_{K_{t_k}^{t_k}}, \|Z\|_{J_{t_k}^{t_k}}, \langle B (X_0 - Z_{0k}) , X_0 - Z_{0k} \rangle_{L^1(\Omega)} \right)$$

$$\leq C \left( \|Y\|_{K_{t_k}^{t_k}}, \frac{1}{k}, \|Z\|_{J_{t_k}^{t_k}}, \langle B (X_0 - Z_{0k}) , X_0 - Z_{0k} \rangle_{L^1(\Omega)} \right).$$

Hence

$$E \left( \langle B (X (t_k^n) - X_0) , X (t_1^n) - X_0 \rangle \right)$$

$$\leq 2E \left( \langle B (X (t_k^n) - Z_{0k}) , X (t_1^n) - Z_{0k} \rangle \right) + 2E \left( \langle B (Z_{0k} - X_0) , Z_{0k} - X_0 \rangle \right)$$

$$\leq 2C \left( \|Y\|_{K_{t_k}^{t_k}}, \frac{1}{k}, \|Z\|_{J_{t_k}^{t_k}}, \langle B (X_0 - Z_{0k}) , X_0 - Z_{0k} \rangle_{L^1(\Omega)} \right)$$

$$+ 2\|B\| \|Z_{0k} - X_0\|^2_{L^2(\Omega,W)}$$

which converges to 0 as $k \to \infty$. It follows that there exists a suitable subsequence such that (18.5.18) holds even in the case that $X_0$ is only known to be in $L^2(\Omega,W)$. From now on, assume this subsequence for the partitions $P_k$. Thus $k$ will really be $n_k$ and it suffices to consider the limit as $k \to \infty$ of the equation of (18.5.18). To emphasize this point again, the reason for the above observations is to argue that, even when $X_0$ is only in $L^2(\Omega,W)$, one can neglect

$$\langle B (X (t_1) - X_0 - M (t_1)) , X (t_1) - X_0 - M (t_1) \rangle$$

in passing to the limit as $k \to \infty$ provided a suitable subsequence is used.

### 71.6 Convergence

The question is whether the above stochastic integral $\int_0^t (Z \circ J^{-1})^*BX_n \circ JdW$ converges as $n \to \infty$ in some sense to

$$\int_0^t (Z \circ J^{-1})^*BX \circ JdW \quad (71.6.19)$$

and whether the above is also a local martingale. Maybe it is well to pause and consider the integral and and what it means. $Z \circ J^{-1}$ maps $Q^{1/2}U$ to $W$ and so $(Z \circ J^{-1})^*$ maps $W'$ to $(Q^{1/2}U)'$. Thus

$$(Z \circ J^{-1})^*BX \in \left( Q^{1/2}U \right)' \quad \text{so} \quad (Z \circ J^{-1})^*BX \circ J \in Q^{1/2}(U)' = L_2 \left( Q^{1/2}U, \mathbb{R} \right)$$
Thus it has the right values.

Does the stochastic integral just written even make sense? The integrand is Hilbert Schmidt and has values in \( \mathbb{R} \) so it seems like we ought to be able to define an integral. The problem is that the integrand is not in \( L^2(\Omega; L^2([0,T], \mathbb{R})) \).

By assumption, \( t \to BX(t) \) is continuous into \( V' \) thanks to the integral equation solved, and also \( BX(t) = B(X(t)) \) for \( t \notin N_\omega \) a set of measure zero. For such \( t \), it follows from Lemma 67.4.1,

\[
\langle BX(t), X(t) \rangle = \sum_i \langle BX(t), e_i \rangle^2_{V',V} \quad \text{a.e.} \omega
\]

and so \( t \to \sum_i \langle BX(t), e_i \rangle^2 \) is lower semicontinuous and as just explained, it equals \( \langle BX(t), X(t) \rangle \) for a.e. \( t \), this for each \( \omega \notin N \), a single set of measure zero. Also, \( t \to \sum_i \langle BX(t), e_i \rangle^2_{V',V} \) is progressively measurable and lower semicontinuous in \( t \) so by Proposition 60.7.3, one can define a stopping time

\[
\tau_p = \inf \left\{ t : \sum_i \langle BX(t), e_i \rangle^2_{V',V} > p \right\}, \tau_0 \equiv 0 \quad (71.6.20)
\]

Instead of referring to this Proposition, you could consider

\[
\tau_p^m = \inf \left\{ t : \sum_{i=1}^m \langle BX(t), e_i \rangle^2_{V',V} > p \right\}
\]

which is clearly a stopping time because \( t \to \sum_{i=1}^m \langle BX(t), e_i \rangle^2_{V',V} \) is a continuous process. Then observe that \( \tau_p = \sup_m \tau_p^m \). Then

\[
[F_t] = \bigcup_m \left[ \tau_p^m \leq t \right] \in \mathcal{F}_t.
\]

Is it the case that \( \tau_p = \infty \) for all \( p \) large enough? Yes, this follows from Lemma 64.6.4.

**Lemma 71.6.1** Suppose \( \tau_p = \infty \) for all \( p \) large enough off a set of measure zero, then

\[
P\left( \int_0^T \left| (Z \circ J^{-1})^* BX \circ J \right|^2 dt < \infty \right) = 1
\]

Also \( \int_0^T (Z \circ J^{-1})^* BX \circ J dW \) can be defined as a local martingale.

**Proof:** Let

\[
A \equiv \left\{ \omega : \int_0^T \left| (Z \circ J^{-1})^* BX \circ J \right|^2 dt = \infty \right\}
\]

Then from the assumption that \( \tau_p = \infty \) for all \( p \) large enough, it follows that

\[
A = \bigcup_{m=1}^\infty A \cap (\tau_m = \infty) \setminus (\tau_{m-1} < \infty)
\]
71.6. CONVERGENCE

Now

\[ P(A \cap [\tau_m = \infty]) \leq P \left( \omega : \int_0^T \chi_{[0,\tau_m]} \left| (Z \circ J^{-1})^* BX \circ J \right|^2 dt = \infty \right) \]  \hspace{1cm} (71.6.21)

Look at the integrand. What is the meaning of \[ (Z \circ J^{-1})^* BX \circ J \] ? You have \( (Z \circ J^{-1})^* \in L_2 \left( W', J (Q^{1/2}U)' \right) \) while \( BX \in W' \) and so \( (Z \circ J^{-1})^* BX \in L_2 \left( J (Q^{1/2}U)', \mathbb{R} \right) \) which is just \( J (Q^{1/2}U)' \). Thus \( (Z \circ J^{-1})^* BX \circ J \) would be in \( (Q^{1/2}U)' \) and to get the \( L_2 \) norm, you would take an orthonormal basis in \( Q^{1/2}U \) denoted as \( \{g_i\} \) and the square of this norm is just

\[
\sum_i \left[ (Z \circ J^{-1})^* BX \circ J (g_i) \right]^2 = \sum_i \left[ (Z \circ J^{-1})^* BX (Jg_i) \right]^2 = \sum_i [BX (Zg_i)]^2 \leq \sum_i \|BX\|^2 \|Zg_i\|^2_W
\]

Now incorporating the stopping time, you know that for a.e. \( t, \langle BX, X(t) \rangle = \langle BX(t), X(t) \rangle \leq m \) and so \( \|BX(t)\| \) can be estimated in terms of \( m \) as follows.

\[
|\langle BX(t), w \rangle| \leq \langle BX(t), X(t) \rangle^{1/2} \|B\|^{1/2} \|w\|_W = \left( \sum_i \langle BX(t), e_i \rangle_{V', V}^2 \right)^{1/2} \|B\|^{1/2} \|w\|_W \leq \sqrt{m} \|B\|^{1/2} \|w\|_W, \text{ so } \|BX(t)\| \leq m \|B\|^{1/2}
\]

Thus the integrand satisfies for a.e. \( t \)

\[ \chi_{[0,\tau_m]} \left| (Z \circ J^{-1})^* BX \circ J \right|^2 \leq m \|B\| \|Z\|_{L_2}^2 \]

Hence, from (71.6.21), \( P(A \cap [\tau_m = \infty]) \)

\[
\leq P \left( \omega : \int_0^T \|Z\|_{L_2}^2 m \|B\| dt = \infty \right)
\]

However,

\[
\int_{\Omega} \int_0^T \|Z\|_{L_2}^2 m \|B\| dtdP < \infty
\]
by the assumptions on $Z$. Therefore, $P \left(A \cap [\tau_m = \infty]\right) = 0$. It follows that

$$P(A) = \sum_m P(A \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])) = \sum_m 0 = 0$$

It follows that $P\left(\int_0^T \left| (Z \circ J^{-1})^* BX \circ J \right|^2 dt < \infty\right) = 1$ and so from Definition

Convergence will be shown for a subsequence and from now on every sequence will be a subsequence of this one. As part of Lemma 71.6.2, see Section 71.1.1.1, it was shown that $BX \in L^2([0, T] \times \Omega, W')$. Therefore, there exist partitions of $[0, T]$ like the above such that

$$BX_k^l, BX_k^r \rightarrow BX$$
in addition to the convergence of $X_k^l, X_k^r$ to $X$ in $K$. From now on, the argument will involve a subsequence of these.

Lemma 71.6.2 There exists a subsequence still denoted with the subscript $k$ and an enlarged set of measure zero $N$ including the earlier one such that $BX_k^l(t), BX_k^r(t)$ also converges pointwise a.e. to $BX(t)$ in $W'$ and $X_k^l(t), X_k^r(t)$ converge pointwise a.e. in $V$ to $X(t)$ for $\omega \notin N$ as well as having convergence of $X_k^l(\cdot, \omega)$ to $X(\cdot, \omega)$ in $L^p([0, T]; V)$ and $BX_k^l(\cdot, \omega)$ to $BX(\cdot, \omega)$ in $L^2([0, T]; W)$.

Proof: To see that such a sequence exists, let $n_k$ be such that

$$\int_\Omega \int_0^T \left\| BX_{n_k}^l(t) - BX(t) \right\|^2_{W'} dt dP + \int_\Omega \int_0^T \left\| X_{n_k}^r(t) - X(t) \right\|^p_V dt dP +$$

$$\int_\Omega \int_0^T \left\| BX_{n_k}^r(t) - BX(t) \right\|^2_{W'} dt dP + \int_\Omega \int_0^T \left\| X_{n_k}^l(t) - X(t) \right\|^p_V dt dP < 4^{-k}.$$  

Then

$$P\left(\int_0^T \left\| BX_{n_k}^l(t) - BX(t) \right\|^2_{W'} dt + \int_0^T \left\| X_{n_k}^r(t) - X(t) \right\|^p_V dt > 2^{-k}\right)$$

$$\leq 2^k \left(4^{-k}\right) = 2^{-k}$$

and so by Borel Cantelli lemma, there is a set of measure zero $N$ such that if $\omega \notin N$,

$$\int_0^T \left\| BX_{n_k}^l(t) - BX(t) \right\|^2_{W'} dt + \int_0^T \left\| X_{n_k}^r(t) - X(t) \right\|^p_V dt +$$

$$\int_0^T \left\| BX_{n_k}^r(t) - BX(t) \right\|^2_{W'} dt + \int_0^T \left\| X_{n_k}^l(t) - X(t) \right\|^p_V dt \leq 2^{-k}$$
for all \( k \) large enough. By the usual proof of completeness of \( L^p \), it follows that \( X_{n_k}^t (t) \to X(t) \) for a.e. \( t \), this for each \( \omega \notin N \), a similar assertion holding for \( X_{n_k}^t \).

We denote these subsequences as \( \{X_k^t\}_{k=1}^\infty \), \( \{X_k^l\}_{k=1}^\infty \).

Now with this preparation, it is possible to show the desired convergence.

**Lemma 71.6.3** In the above context, let \( X(s) - X_k^l(s) \equiv \Delta_k(s) \). Then the integral

\[
\int_0^t (Z \circ J^{-1})^* BX \circ JdW
\]

exists as a local martingale and the following limit is valid for the subsequence of Lemma 71.6.2

\[
\lim_{k \to \infty} P \left( \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \Delta_k \circ JdW \right| \geq \varepsilon \right) = 0.
\]

That is,

\[
\sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \Delta_k \circ JdW \right|
\]

converges to 0 in probability.

**Proof:** In the argument \( \tau_m \) will be defined in [71.6.20]. Let

\[
A_k \equiv \left\{ \omega : \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \Delta_k \circ JdW \right| \geq \varepsilon \right\}
\]

then

\[
A_k \cap \{ \omega : \tau_m = \infty \} \subseteq \left\{ \omega : \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \Delta_k \circ JdW \right| \geq \varepsilon \right\}
\]

By Burkholder Davis Gundy inequality,

\[
P \left( A_k \cap \{ \omega : \tau_m = \infty \} \right) \leq \frac{C}{\varepsilon} \int \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B \Delta_k \circ JdW \right| dP
\]

\[
\leq \frac{C}{\varepsilon} \int \left( \int_0^T \|Z\|_{L^2}^2 \|B \Delta_k \|^2 \|dt \right)^{1/2} dP
\]

\[
\leq \frac{C}{\varepsilon} \left( \int \int_0^T \|Z\|_{L^2}^2 \|B \Delta_k \|^2 dtdP \right)^{1/2}
\]

Recall that if \( \langle Bx, x \rangle \leq m \), then \( \|Bx\|_{W^*} \leq m^{1/2} \|B\|^{1/2} \). Then the integrand is bounded for a.e. \( t \) by \( \|Z\|_{L^2}^2 4m \|B\| \). Next use the result of Lemma [71.6.2] and
the dominated convergence theorem to conclude that the above converges to 0 as \( k \to \infty \). Then from the assumption that \( \tau_m = \infty \) for all \( m \) large enough,

\[
P(A_k) = \sum_{m=1}^{\infty} P(A_k \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty]))
\]

Now \( \sum_m P([\tau_m = \infty] \setminus [\tau_{m-1} < \infty]) = 1 \) and so, one can apply the dominated convergence theorem to conclude that

\[
\lim_{k \to \infty} P(A_k) = \sum_{m=1}^{\infty} \lim_{k \to \infty} P(A_k \cap ([\tau_m = \infty] \setminus [\tau_{m-1} < \infty])) = 0 \]

Lemma 71.6.4 Let \( X \) be as in Situation [71.2.2] and let \( X^l_k \) be as in Lemma [71.1.1] corresponding to \( X \) above. Let \( X^l_k \) and \( X^r_k \) both converge to \( X \) in \( K \) and also

\[
BX^l_k, BX^r_k \to BX \text{ in } L^2([0, T] \times \Omega, W')
\]

Say

\[
X^l_k(t) = \sum_{j=0}^{m_k} X(t_j) X_{[t_j, t_{j+1})}(t), \quad (71.6.22)
\]

\[
BX^l_k(t) = \sum_{j=0}^{m_k} BX(t_j) X_{[t_j, t_{j+1})}(t) \quad (71.6.23)
\]

Then the sum in [71.6.23] is progressively measurable into \( W' \). As mentioned earlier, we can take \( X(0) \equiv 0 \) in the definition of the “left step function”.

Proof: This follows right away from the definition of progressively measurable.

One can take a further subsequence such that uniform convergence is obtained.

Lemma 71.6.5 Let \( X(s) - X^l_k(s) \equiv \Delta_k(s) \). Then the following limit occurs.

\[
\lim_{k \to \infty} P \left( \sup_{t \in [0, T]} \left| \int_0^t (Z \circ J^{-1})^* B\Delta_k \circ JdW \right| \geq \varepsilon \right) = 0
\]

The stochastic integral

\[
\int_0^t (Z \circ J^{-1})^* BX_k \circ JdW
\]

makes sense because \( BX \) is \( W' \) progressively measurable and is in \( L^2([0, T] \times \Omega, W') \). Also, there exists a further subsequence, still denoted as \( k \) such that

\[
\int_0^t (Z \circ J^{-1})^* BX_k \circ JdW \to \int_0^t (Z \circ J^{-1})^* BX \circ JdW
\]

uniformly on \([0, T]\) for a.e. \( \omega \).
71.7. THE ITO FORMULA

Proof: This follows from Lemma 71.6.3. The last conclusion follows from the usual use of the Borel Cantelli lemma. There exists a further subsequence, still denoted with subscript $k$ such that

$$P \left( \sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B\Delta_k \circ JdW \right| \geq \frac{1}{k} \right) < 2^{-k}$$

Then by the Borel Cantelli lemma, one can enlarge the set of measure zero such that for $\omega \notin N$,

$$\sup_{t \in [0,T]} \left| \int_0^t (Z \circ J^{-1})^* B\Delta_k \circ JdW \right| < \frac{1}{k}$$

for all $k$ large enough. That is, the claimed uniform convergence holds. ■

From now on, the sequence will either be this subsequence or a further subsequence.

71.7 The Ito Formula

Now at long last, here is the first version of the Ito formula valid on the partition points.

Lemma 71.7.1 In Situation 71.2.1, let $D$ be as above, the union of all the positive mesh points for all the $P_k$. Also assume $X_0 \in L^2(\Omega;W)$. Then for $\omega \notin N$ the exceptional set of measure zero in $\Omega$ and every $t \in D$,

$$\langle BX(t) , X(t) \rangle = \langle BX_0 , X_0 \rangle + \int_0^t (2 \langle Y(s) , X(s) \rangle + \langle BZ , Z \rangle_{L^2}) \, ds$$

$$+ 2 \int_0^t (Z \circ J^{-1})^* BX \circ JdW$$

(71.7.24)

where, in the above formula,

$$\langle BZ , Z \rangle_{L^2} = (R^{-1}BZ , Z)_{L^2(Q^{1/2}U,W)}$$

for $R$ the Riesz map from $W$ to $W'$.

Note first that for $\{g_i\}$ an orthonormal basis for $Q^{1/2}(U)$,

$$(R^{-1}BZ , Z)_{L^2} = \sum_i (R^{-1}BZ(g_i), Z(g_i))_W = \sum_i \langle BZ(g_i) , Z(g_i) \rangle_{W,W} \geq 0$$

Proof: Let $t \in D$. Then $t \in P_k$ for all $k$ large enough. Consider $\{B_k\}$.

$$\langle BX(t) , X(t) \rangle - \langle BX_0 , X_0 \rangle = e(k) + 2 \int_0^t \langle Y(u) , X_k^r(u) \rangle \, du$$
+2 \int_0^t (Z \circ J^{-1})^* BX_k \circ J \, dW + \sum_{j=0}^{q_k-1} \langle B (M (t_{j+1}) - M (t_j)), M (t_{j+1}) - M (t_j) \rangle

- \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), \Delta X (t_j) - \Delta M (t_j) \rangle

(71.7.25)

where \( t_{q_k} = t \), \( \Delta X (t_j) = X (t_{j+1}) - X (t_j) \) and \( \varepsilon (k) \to 0 \) in probability. By Lemma 71.6.5, the stochastic integral on the right converges uniformly for \( t \in [0, T] \) to

\[
2 \int_0^t (Z \circ J^{-1})^* BX \circ J \, dW
\]

for \( \omega \) off a set of measure zero. The deterministic integral on the right converges uniformly for \( t \in [0, T] \) to

\[
2 \int_0^t \langle Y (u), X (u) \rangle \, du
\]

thanks to Lemma 71.6.4.

\[
\left| \int_0^t \langle Y (u), X (u) \rangle \, du - \int_0^t \langle Y (u), X_k^* (u) \rangle \, du \right| \leq \int_0^T \| Y (u) \|_{L^2} \| X (u) - X_k^* (u) \|_{L^2}
\]

\[
\leq \| Y \|_{L^2 ([0, T])} \cdot 2^{-k}
\]

for all \( k \) large enough. Consider the fourth term. It equals

\[
\sum_{j=0}^{q_k-1} \left( R^{-1} B (M (t_{j+1}) - M (t_j)), M (t_{j+1}) - M (t_j) \right)_W
\]

(71.7.26)

where \( R^{-1} \) is the Riesz map from \( W \) to \( W' \). This equals

\[
\frac{1}{4} \left( \sum_{j=0}^{q_k-1} \left( R^{-1} BM (t_{j+1}) + M (t_{j+1}) - (R^{-1} BM (t_j) + M (t_j)) \right)^2 - \sum_{j=0}^{q_k-1} \left( R^{-1} BM (t_{j+1}) - M (t_{j+1}) - (R^{-1} BM (t_j) - M (t_j)) \right)^2 \right)
\]

From Theorem 71.6.4, as \( k \to \infty \), the above converges in probability to \( (t_{q_k} = t) \)

\[
\frac{1}{4} \left( \left[ R^{-1} BM + M \right] (t) - \left[ R^{-1} BM - M \right] (t) \right)
\]

However, from the description of the quadratic variation of \( M \), the above equals

\[
\frac{1}{4} \left( \int_0^t \| R^{-1} BZ + Z \|_{L^2}^2 \, ds - \int_0^t \| R^{-1} BZ - Z \|_{L^2}^2 \, ds \right)
\]
71.7. THE ITO FORMULA

which equals

\[ \int_0^t (R^{-1}BZ, Z)_{L^2} \, ds \equiv \int_0^t \langle BZ, Z \rangle_{L^2} \, ds \]

This is what was desired.

Note that in the case of a Gelfand triple, when \( W = H = H' \), the term \( \langle BZ, Z \rangle_{L^2} \) will end up reducing to nothing more than \( \|Z\|_{L^2}^2 \).

Thus all the terms in 71.7.25 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

\[
\langle BX(t), X(t) \rangle - \langle BX_0, X_0 \rangle = 2 \int_0^t \langle Y(u), X(u) \rangle \, du \\
+2 \int_0^t (Z \circ J^{-1})^* BX \circ JdW + \int_0^t \langle BZ, Z \rangle_{L^2} \, ds - a
\]

where \( a \) is the limit in probability of the term

\[
\sum_{j=1}^{q_n-1} \langle B(\Delta X(t_j) - \Delta M(t_j)), \Delta X(t_j) - \Delta M(t_j) \rangle \tag{71.7.27}
\]

Let \( P_n \) be the projection onto \( \text{span} (e_1, \cdots, e_n) \) where \( \{e_k\} \) is an orthonormal basis for \( W \) with each \( e_k \in V \). Then using

\[
BX(t_{j+1}) - BX(t_j) - (BM(t_{j+1}) - BM(t_j)) = \int_{t_j}^{t_{j+1}} Y(s) \, ds
\]

the troublesome term of 71.7.26 above is of the form

\[
\sum_{j=1}^{q_n-1} \int_{t_j}^{t_{j+1}} \langle Y(s), \Delta X(t_j) - \Delta M(t_j) \rangle \, ds
\]

\[
= \sum_{j=1}^{q_n-1} \int_{t_j}^{t_{j+1}} \langle Y(s), \Delta X(t_j) - P_n \Delta M(t_j) \rangle \, ds \\
+ \sum_{j=1}^{q_n-1} \int_{t_j}^{t_{j+1}} \langle Y(s), -(I - P_n) \Delta M(t_j) \rangle \, ds
\]

which equals

\[
\sum_{j=1}^{q_n-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X(t_{j+1}) - X(t_j) - P_n (M(t_{j+1}) - M(t_j)) \rangle \, ds \tag{71.7.28}
\]
\[ + \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), -(I - P_n)(M (t_{j+1}) - M (t_j)) \rangle \]  
(71.7.29)

The reason for the \( P_n \) is to get \( P_n (M (t_{j+1}) - M (t_j)) \) in \( V \). The sum in \( 71.7.29 \) is dominated by

\[
\left( \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), (\Delta X (t_j) - \Delta M (t_j)) \rangle \right)^{1/2} \]  
\[ = \left( \sum_{j=1}^{q_k-1} \left| \langle B (I - P_n) \Delta M (t_j), (I - P_n) \Delta M (t_j) \rangle \right|^2 \right)^{1/2} \]  
(71.7.30)

Now it is known from the above that \( \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), (\Delta X (t_j) - \Delta M (t_j)) \rangle \) converges in probability to \( a \geq 0 \). If you take the expectation of the square of the other factor, it is no larger than

\[
\|B\| E \left( \sum_{j=1}^{q_k-1} \left\| (I - P_n) \Delta M (t_j) \right\|_W^2 \right)
\]

\[
= \|B\| E \left( \sum_{j=1}^{q_k-1} \left\| (I - P_n) \int_{t_j}^{t_{j+1}} Z (s) dW (s) \right\|_W^2 \right)
\]

\[
= \|B\| \sum_{j=1}^{q_k-1} E \left( \int_{t_j}^{t_{j+1}} \left\| (I - P_n) Z (s) dW (s) \right\|_W^2 \right)
\]

\[
= \|B\| \sum_{j=1}^{q_k-1} E \left( \int_{t_j}^{t_{j+1}} \| (I - P_n) Z (s) \|^2_{L_2(Q^{1/2};W)} ds \right)
\]

\[
\leq \|B\| E \left( \int_0^T \| (I - P_n) Z (s) \|^2_{L_2(Q^{1/2};H)} ds \right)
\]

Now letting \( \{g_i\} \) be an orthonormal basis for \( Q^{1/2} U \),

\[
= \|B\| \int_0^T \sum_{i=1}^\infty \| (I - P_n) Z (s) (g_i) \|^2_W ds dP \]  
(71.7.31)

The integrand \( \sum_{i=1}^\infty \| (I - P_n) Z (s) (g_i) \|^2_W \) converges to 0. Also, it is dominated by

\[
\sum_{i=1}^\infty \|Z (s) (g_i)\|^2_W = \|Z\|^2_{L_2(Q^{1/2};W)}
\]
which is given to be in \( L^1 ([0, T] \times \Omega) \). Therefore, from the dominated convergence theorem, the expression in (71.7.31) converges to 0 as \( n \to \infty \).

Thus the expression in (71.7.30) is of the form \( f_k g_{nk} \) where \( f_k \) converges in probability to \( a^{1/2} \) as \( k \to \infty \) and \( g_{nk} \) converges in probability to 0 as \( n \to \infty \) independently of \( k \). Now this implies \( f_k g_{nk} \) converges in probability to 0. Here is why.

\[
P ([|f_k g_{nk}| > \varepsilon]) \leq P (2\delta |f_k| > \varepsilon) + P (2C_\delta |g_{nk}| > \varepsilon)
\leq P (2\delta |f_k - a^{1/2}| + 2\delta |a^{1/2}| > \varepsilon) + P (2C_\delta |g_{nk}| > \varepsilon)
\]

where \( \delta |f_k| + C_\delta |g_{nk}| > |f_k g_{nk}| \) and \( \lim_{\delta \to 0} C_\delta = \infty \). Pick \( \delta \) small enough that \( \varepsilon - 2\delta a^{1/2} > \varepsilon / 2 \). Then this is dominated by

\[
P (2\delta |f_k - a^{1/2}| > \varepsilon / 2) + P (2C_\delta |g_{nk}| > \varepsilon)
\]

Fix \( n \) large enough that the second term is less than \( \eta \) for all \( k \). Now taking \( k \) large enough, the above is less than \( \eta \). It follows the expression in (71.7.30) and consequently in (71.7.29) converges to 0 in probability.

Now consider the other term (71.7.28) using the \( n \) just determined. This term is of the form

\[
\sum_{j=1}^{n} \int_{t_j}^{t_{j+1}} \langle Y (s), X (t_{j+1}) - X (t_j) - P_n (M (t_{j+1}) - M (t_j)) \rangle ds =
\]

\[
\sum_{j=1}^{n} \int_{t_j}^{t_{j+1}} \langle Y (s), X^r_k (s) - X^l_k (s) - P_n (M^r_k (s) - M^l_k (s)) \rangle ds
\]

where \( M^r_k \) denotes the step function

\[
M^r_k (t) = \sum_{i=0}^{m_k - 1} M (t_{i+1}) X_{(t_i, t_{i+1})} (t)
\]

and \( M^l_k \) is defined similarly. The term

\[
\int_{t_1}^{t} \langle Y (s), P_n (M^r_k (s) - M^l_k (s)) \rangle ds
\]

converges to 0 for a.e. \( \omega \) as \( k \to \infty \) thanks to continuity of \( t \to M (t) \). However, more is needed than this. Define the stopping time

\[
\tau_p = \inf \{ t > 0 : \| M (t) \|_W > p \}.
\]
Then \( \tau_p = \infty \) for all \( p \) large enough, this for \( a.e. \, \omega \). Let

\[
A_k = \left[ \left| \int_{t_1}^{t} \langle Y(s), P_n(M_r^k(s) - M_l^k(s)) \rangle \, ds \right| > \varepsilon \right]
\]

\[
P(A_k) = \sum_{p=0}^{\infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) \tag{71.7.32}
\]

Now

\[
P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) \leq P \left( \left| \int_{t_1}^{t} \langle Y(s), P_n \left( (M_r^\tau)^k(s) - (M_l^\tau)^k(s) \right) \rangle \, ds \right| > \varepsilon \right)
\]

This is so because if \( \tau_p = \infty \), then it has no effect but also it could happen that the defining inequality may hold even if \( \tau_p < \infty \) hence the inequality. This is no larger than an expression of the form

\[
\frac{C_n}{\varepsilon} \int_{\Omega} \int_{0}^{T} \|Y(s)\|_{V'} \left\| (M_r^\tau)^k(s) - (M_l^\tau)^k(s) \right\|_{W} \, ds \, dP \tag{71.7.33}
\]

The inside integral converges to 0 by continuity of \( M \). Also, thanks to the stopping time, the inside integral is dominated by an expression of the form

\[
\int_{0}^{T} \|Y(s)\|_{V'}, 2pds
\]

and this is a function in \( L^1(\Omega) \) by assumption on \( Y \). It follows that the integral in \( \text{71.7.33} \) converges to 0 as \( k \to \infty \) by the dominated convergence theorem. Hence

\[
\lim_{k \to \infty} P(A_k \cap ([\tau_p = \infty])) = 0.
\]

Since the sets \([\tau_p = \infty] \setminus [\tau_{p-1} < \infty]\) are disjoint, the sum of their probabilities is finite. Hence there is a dominating function in \( \text{71.7.32} \) and so, by the dominated convergence theorem applied to the sum,

\[
\lim_{k \to \infty} P(A_k) = \sum_{p=0}^{\infty} \lim_{k \to \infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) = 0
\]

Thus \( \int_{t_1}^{t} \langle Y(s), P_n(M_r^k(s) - M_l^k(s)) \rangle \, ds \) converges to 0 in probability as \( k \to \infty \).

Now consider

\[
\left| \int_{t_1}^{t} \langle Y(s), X_r^k(s) - X_l^k(s) \rangle \, ds \right| \leq \int_{0}^{T} |\langle Y(s), X_r^k(s) - X(s) \rangle| \, ds
\]

\[
+ \int_{0}^{T} |\langle Y(s), X_l^k(s) - X(s) \rangle| \, ds
\]
\[ \leq 2 \| Y (\cdot, \omega) \|_{L^p (0, T)} 2^{-k} \]

for all \( k \) large enough, this by Lemma 71.6.2. Therefore,

\[ \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), \Delta X (t_j) - \Delta M (t_j) \rangle \]

converges to 0 in probability. This establishes the desired formula for \( t \in D \). \( \blacksquare \)

In fact, the formula 71.7.24 is valid for all \( t \in N^C \).

**Theorem 71.7.2** In Situation 71.2.1, for \( \omega \) off a set of measure zero, for every \( t \not\in N_\omega \),

\[
\langle BX (t), X (t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t \left( 2 \langle Y (s), X (s) \rangle + \langle BZ, Z \rangle_{L_2} \right) ds \\
+ 2 \int_0^t (Z \circ J^{-1})^* BX \circ J dW \tag{71.7.34}
\]

Also, there exists a unique continuous, progressively measurable function denoted as \( \langle BX;X \rangle \) such that it equals \( \langle BX (t), X (t) \rangle \) for a.e. \( t \) and \( \langle BX, X \rangle (t) \) equals the right side of the above for all \( t \). In addition to this,

\[
E \langle \langle BX, X \rangle (t) \rangle = E \langle \langle BX_0, X_0 \rangle \rangle + E \left( \int_0^t \left( 2 \langle Y (s), X (s) \rangle + \langle BZ, Z \rangle_{L_2} \right) ds \right) \tag{71.7.35}
\]

Also the quadratic variation of the stochastic integral in 71.7.34 is dominated by

\[
C \int_0^t \| Z \|^2_{L_2} \| BX \|^2_{W'} ds \tag{71.7.36}
\]

for a suitable constant \( C \). Also \( t \to BX (t) \) is continuous with values in \( W' \) for \( t \in N^C_\omega \).

**Proof:** Let \( t \in N^C_\omega \setminus D \). For \( t > 0 \), let \( t (k) \) denote the largest point of \( P_k \) which is less than \( t \). Suppose \( t (m) < t (k) \). Hence \( m \leq k \). Then

\[
BX (t (m)) = BX_0 + \int_0^{t (m)} Y (s) ds + B \int_0^{t (m)} Z (s) dW (s),
\]

a similar formula holding for \( X (t (k)) \). Thus for \( t > t (m), t \not\in N_\omega \),

\[
B (X (t) - X (t (m))) = \int_{t (m)}^t Y (s) ds + B \int_{t (m)}^t Z (s) dW (s)
\]
which is the same sort of thing studied so far except that it starts at \( t(m) \) rather than at 0 and \( BX_0 = 0 \). Therefore, from Lemma \[71.7.1\] it follows

\[
\langle B \left( X(t(k)) - X(t(m)) \right), X(t(k)) - X(t(m)) \rangle
\]

\[
= \int_{t(m)}^{t(k)} \left( 2 \langle Y(s), X(s) - X(t(m)) \rangle + \langle BZ, Z \rangle_{L^2} \right) ds
\]

\[
+ 2 \int_{t(m)}^{t(k)} (Z \circ J^{-1})^* B \left( X(s) - X(t(m)) \right) \circ JdW
\]

\[\text{(71.7.37)}\]

Consider that last term. It equals

\[
2 \int_{t(m)}^{t(k)} (Z \circ J^{-1})^* B \left( X(s) - X_m^i(s) \right) \circ JdW
\]

\[\text{(71.7.38)}\]

This is dominated by

\[
2 \left| \int_{t(m)}^{t(k)} (Z \circ J^{-1})^* B \left( X(s) - X_m^i(s) \right) \circ JdW \right|
\]

\[
- \int_{t(m)}^{t(k)} (Z \circ J^{-1})^* B \left( X(s) - X_m^i(s) \right) \circ JdW
\]

\[
\leq 4 \sup_{t \in [0,T]} \left| \int_{0}^{t} (Z \circ J^{-1})^* B \left( X(s) - X_m^i(s) \right) \circ JdW \right|
\]

In Lemma \[71.6.5\] the above expression was shown to converge to 0 in probability. Therefore, by the usual appeal to the Borel Cantelli lemma, there is a subsequence still referred to as \( \{m\} \), such that it converges to 0 pointwise in \( \omega \) for all \( \omega \) off some set of measure 0 as \( m \to \infty \). It follows there is a set of measure 0 including the earlier one such that for \( \omega \) not in that set, \[71.7.38\] converges to 0 in \( \mathbb{R} \). Similar reasoning shows the first term on the right in the non stochastic integral of \[71.7.37\] is dominated by an expression of the form

\[
4 \int_{0}^{T} \left| \langle Y(s), X(s) - X_m^i(s) \rangle \right| ds
\]

which clearly converges to 0 thanks to Lemma \[71.6.4\]. Finally, it is obvious that

\[
\lim_{m \to \infty} \int_{t(m)}^{t(k)} \langle BZ, Z \rangle_{L^2} ds = 0 \text{ for a.e. } \omega
\]

due to the assumptions on \( Z \). For \( \{g_i\} \) an orthonormal basis of \( Q^{1/2}(U) \),

\[
\langle BZ, Z \rangle_{L^2} \equiv \sum_i \langle R^{-1}BZ(g_i), Z(g_i) \rangle = \sum_i \langle BZ(g_i), Z(g_i) \rangle
\]

\[
\leq \|B\| \sum_i \|Z(g_i)\|^2_{W} \in L^1(0,T) \text{ a.e.}
\]
This shows that for $\omega$ off a set of measure 0
\[
\lim_{m,k \to \infty} \langle B (X (t (k)) - X (t (m))) , X (t (k)) - X (t (m)) \rangle = 0
\]
Then for $x \in W$,
\[
| \langle B (X (t (k)) - X (t (m))) , x \rangle | 
\leq \langle B (X (t (k)) - X (t (m))) , X (t (k)) - X (t (m)) \rangle^{1/2} \langle B , x \rangle^{1/2} 
\leq \langle B (X (t (k)) - X (t (m))) , X (t (k)) - X (t (m)) \rangle^{1/2} \| B \|^{1/2} \| x \|_{W'}
\]
and so
\[
\lim_{m,k \to \infty} \| B (X (t (k)) - B (X (t (m))) \|_{W'} = 0
\]
Recall $t$ was arbitrary in $N'_w$ and $\{ t (k) \}$ is a sequence converging to $t$. Then the above has shown that $\{ B (X (t (k))) \}_{k=1}^\infty$ is a convergent sequence in $W'$. Does it converge to $B (X (t))$? Let $\xi (t) \in W'$ be what it converges to. Letting $v \in V$ then, since the integral equation shows that $t \to B (X (t))$ is continuous into $V'$,
\[
\langle \xi (t) , v \rangle = \lim_{k \to \infty} \langle B (X (t (k)) , v \rangle = \langle B (X (t) , v \rangle,
\]
and now, since $V$ is dense in $W$, this implies $\xi (t) = B (X (t) = B (X (t))$. Recall also that it was shown earlier that $B (X)$ is weakly continuous into $W'$. Hence the strong convergence of $\{ B (X (t (k))) \}_{k=1}^\infty$ in $W'$ implies that it converges to $B (X (t))$, this for any $t \in N'_w$.

For every $t \in D$ and for $\omega$ off the exceptional set of measure zero described earlier,
\[
\langle B (X (t)), X (t) \rangle = \langle B X_0 , X_0 \rangle + \int_0^t (2 \langle Y (s), X (s) \rangle + \langle B Z, Z \rangle_{\mathcal{L}_2} ds) ds
\]
\[+ 2 \int_0^t (Z \circ J^{-1})^* B X \circ J dW \quad (71.7.39)
\]
Does this formula hold for all $t \in [0, T]$? Maybe not. However, it will hold for $t \notin N_\omega$. So let $t \notin N_\omega$. Then using the Cauchy Schwarz inequality on each term,
\[
\quad \leq \langle B (X (t (k)) - X (t (k)), X (t (k)) - X (t) \rangle^{1/2} \times \left( \langle B (X (t (k)) , X (t (k)) \rangle^{1/2} + \langle B (X (t) , X (t) \rangle^{1/2} \right)^{1/2}
\]
As before, one can use the lower semicontinuity of
\[ t \to \langle B(X(t(k)) - X(t)), X(t(k)) - X(t) \rangle \]
on \mathcal{C} along with the boundedness of \( \langle BX(t), X(t) \rangle \) also shown earlier off \( N_\omega \) to conclude
\[
\left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right| \\
\leq C \left( \langle B(X(t(k)) - X(t)), X(t(k)) - X(t) \rangle \right)^{1/2} \\
\leq C \lim_{m \to \infty} \inf \langle B(X(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle^{1/2} < \varepsilon
\]
provided \( k \) is sufficiently large. Since \( \varepsilon \) is arbitrary,
\[
\lim_{k \to \infty} \langle BX(t(k)), X(t(k)) \rangle = \langle BX(t), X(t) \rangle.
\]
It follows that the formula (71.7.39) is valid for all \( t \notin N_\omega \). Now define the function \( \langle BX, X \rangle(t) \) as
\[
\langle BX, X \rangle(t) = \begin{cases} 
\langle B(X(t)), X(t) \rangle, t \notin N_\omega \\
\text{The right side of (71.7.39) if } t \in N_\omega
\end{cases}
\]
Then in short, \( \langle BX, X \rangle(t) \) equals the right side of (71.7.39) for all \( t \in [0,T] \) and is consequently progressively measurable and continuous. Furthermore, for a.e. \( t \), this function equals \( \langle B(X(t)), X(t) \rangle \). Since it is known on a dense subset, it must be unique.

This implies that \( t \to BX(t) \) is continuous with values in \( W' \) for \( t \notin N_\omega \). Here is why. The fact that the formula (71.7.39) holds for all \( t \notin N_\omega \) implies that \( t \to \langle BX(t), X(t) \rangle \) is continuous on \( \mathcal{C} \). Then for \( x \in W \),
\[
|\langle BX(t) - BX(s), x \rangle| \leq \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \|B\|^{1/2} \|x\|_W.
\]
Also
\[
\langle B(X(t) - X(s)), X(t) - X(s) \rangle = \langle BX(t), X(t) \rangle + \langle BX(s), X(s) \rangle - 2 \langle BX(t), X(s) \rangle
\]
By weak continuity of \( t \to BX(t) \) shown earlier,
\[
\lim_{t \to s} \langle BX(t), X(s) \rangle = \langle BX(s), X(s) \rangle.
\]
Therefore,
\[
\lim_{t \to s} \langle B(X(t) - X(s)), X(t) - X(s) \rangle = 0
\]
and so the inequality (71.7.40) implies the continuity of \( t \to BX(t) \) into \( W' \) for \( t \notin N_\omega \). Note that by assumption this function is continuous into \( V' \) for all \( t \).
It was also shown that it is weakly continuous into $W'$ on $[0, T]$ and hence it is bounded in $W'$.

Now consider the claim about the expectation. Since the stochastic integral

$$2 \int_0^t \left( Z \circ J^{-1} \right) X \circ J \, dW$$

is only a local martingale, it is necessary to employ a stopping time. We use the function $\langle BX, X \rangle$ to define this stopping time as

$$\tau_p = \inf \{ t > 0 : \langle BX, X \rangle (t) > p \}$$

This is the first hitting time of a continuous process and so it is a valid stopping time. Using this, leads to

$$\langle BX, X \rangle^{\tau_p} (t) = \langle BX_0, X_0 \rangle + \int_0^t X_{[0, \tau_p]} (s) \left( 2 \langle Y (s), X (s) \rangle + \langle BZ, Z \rangle_{L^2} \right) ds \, ds + 2 \int_0^t X_{[0, \tau_p]} (s) \left( Z \circ J^{-1} \right) X \circ J \, dW$$

By continuity of $\langle BX, X \rangle$, $\tau_p = \infty$ for all $p$ large enough. Take expectation of both sides of the above. In the integrand of the last term, $BX$ refers to the function $BX (t, \omega) \equiv B (X (t, \omega))$ and so it is progressively measurable because $X$ is assumed to be so. Hence $BX^{\tau_p}$ is also progressively measurable and for a.e. $s, \|BX (s \wedge \tau_p)\|_{W'} \leq \sqrt{\tau} \|B\|$. Therefore, one can take expectations and get

$$E \langle BX, X \rangle^{\tau_p} (t) = E \langle BX_0, X_0 \rangle + E \left( \int_0^t X_{[0, \tau_p]} (s) \left( 2 \langle Y (s), X (s) \rangle + \langle BZ, Z \rangle_{L^2} \right) ds \right)$$

Now let $p \to \infty$ and use the monotone convergence theorem on the left and the dominated convergence theorem on the right to obtain the desired result. The claim about the quadratic variation follows from Corollary 63.11.1. ■
Chapter 72

A More Attractive Version

The following lemma is convenient.

**Lemma 72.0.1** Let $f_n \to f$ in $L^p([0,T] \times \Omega, E)$. Then there exists a subsequence $n_k$ and a set of measure zero $N$ such that if $\omega \notin N$, then

$$f_{n_k}(\cdot, \omega) \to f(\cdot, \omega)$$

in $L^p([0,T], E)$ and for a.e. $t$.

**Proof:** We have

$$P \left( \left\| f_n - f \right\|_{L^p([0,T], E)} > \lambda \right) \leq \frac{1}{\lambda} \int_{\Omega} \| f_n - f \|_{L^p([0,T], E)} dP$$

$$\leq \frac{1}{\lambda} \| f_n - f \|_{L^p([0,T] \times \Omega, E)}$$

Hence there exists a subsequence $n_k$ such that

$$P \left( \left\| f_{n_k} - f \right\|_{L^p([0,T], E)} > 2^{-k} \right) \leq 2^{-k}$$

Then by the Borel Cantelli lemma, it follows that there exists a set of measure zero $N$ such that for all $k$ large enough and $\omega \notin N$,

$$\| f_{n_k} - f \|_{L^p([0,T], E)} \leq 2^{-k}$$

Now by the usual arguments used in proving completeness, $f_{n_k}(t) \to f(t)$ for a.e. $t$.

Also, we have the approximation lemma proved earlier, Lemma 63.3.1

**Lemma 72.0.2** Let $\Phi : [0,T] \times \Omega \to V$, be $B([0,T]) \times \mathcal{F}$ measurable and suppose

$$\Phi \in K \equiv L^p([0,T] \times \Omega; E), \ p \geq 1$$

...
Then there exists a sequence of nested partitions, \( \mathcal{P}_k \subseteq \mathcal{P}_{k+1} \),

\[
\mathcal{P}_k \equiv \{ t^{k}_0, \ldots, t^{k}_{m_k} \}
\]
such that the step functions given by

\[
\Phi^+_k (t) = \sum_{j=1}^{m_k} \Phi (t^k_j) \chi_{(t^k_{j-1}, t^k_j]} (t)
\]

\[
\Phi^-_k (t) = \sum_{j=1}^{m_k} \Phi (t^k_{j-1}) \chi_{(t^k_{j-1}, t^k_j]} (t)
\]

both converge to \( \Phi \) in \( K \) as \( k \to \infty \) and

\[
\lim_{k \to \infty} \max \{ |t^k_j - t^k_{j+1}| : j \in \{0, \ldots, m_k \} \} = 0.
\]

Also, each \( \Phi (t^k_j), \Phi (t^k_{j-1}) \) is in \( L^p (\Omega; E) \). One can also assume that \( \Phi (0) = 0 \).

The mesh points \( \{ t^k_j \}^{m_k}_{j=0} \) can be chosen to miss a given set of measure zero. In addition to this, we can assume that

\[
|t^k_j - t^k_{j-1}| = 2^{-n_k}
\]

except for the case where \( j = 1 \) or \( j = m_{n_k} \) when this might not be so. In the case of the last subinterval defined by the partition, we can assume

\[
|t^k_m - t^k_{m-1}| = |T - t^k_{m-1}| \geq 2^{-(n_k+1)}
\]

### 72.1 The Situation

Now consider the following situation. There are real separable Banach spaces \( V, W \) such that \( W \) is a Hilbert space and

\[
V \subseteq W \quad W' \subseteq V'
\]

where \( V \) is dense in \( W \). Also let \( B \in \mathcal{L} (W, W') \) satisfy

\[
\langle Bw, w \rangle \geq 0, \quad \langle Bu, v \rangle = \langle Bv, u \rangle
\]

Note that \( B \) does not need to be one to one. Also allowed is the case where \( B \) is the Riesz map. It could also happen that \( V = W \). Assume that \( B = B (\omega) \) where \( B \) is \( \mathcal{F}_0 \) measurable into \( \mathcal{L} (W, W') \). This dependence on \( \omega \) will be suppressed in the interest of simpler notation. For convenience, assume \( \| B (\omega) \| \) is bounded. This is assumed mainly so that an estimate can be made on \( \langle BX_0, X_0 \rangle \) for \( X_0 \) given in \( L^2 (\Omega) \). It probably suffices to simply give an estimate on \( \| \langle BX_0, X_0 \rangle \|_{L^1 (\Omega)} \) along with something else on the Ito integral. However, it seems at this time like this is more trouble than it is worth.
72.2. PRELIMINARY RESULTS

Situation 72.1.1 Let $X$ have values in $V$ and satisfy the following

$$BX(t) = BX_0 + \int_0^t Y(s) \, ds + BM(t),$$  \hspace{1cm} (72.1.1)

$X_0 \in L^2(\Omega; W)$ and is $\mathcal{F}_0$ measurable. Here $M(t)$ is a continuous $L^2$ martingale having values in $W$. By this is meant that $\lim_{t \to 0^+} \|M(t)\|_{L^2(\Omega)} = 0$ and for each $\omega$, $\lim_{t \to 0^+} M(t) = 0$, $\|M\|_W^2 \in L^2([0, T] \times \Omega)$. Assume that $d[M] = k dm$ for $k \in L^1([0, T] \times \Omega)$, that is, the measure determined by the quadratic variation for the martingale is absolutely continuous with respect to Lebesgue measure as just described.

Assume $Y$ satisfies

$$Y \in K' \equiv L^{p'}([0, T] \times \Omega; V'),$$

the $\sigma$ algebra of measurable sets defining $K'$ will be the progressively measurable sets. Here $1/p' + 1/p = 1$, $p > 1$.

Also the sense in which the equation holds is as follows. For a.e. $\omega$, the equation holds in $V'$ for all $t \in [0, T]$. Thus we are considering a particular representative $X$ for which this happens. Also it is only assumed that $BX(t) = B(X(t))$ for a.e. $t$. Thus $BX$ is the name of a function having values in $V'$ for which $BX(t) = B(X(t))$ for a.e. $t$. Assume that $X$ is progressively measurable also and $X \in L^p([0, T] \times \Omega, V)$.

The goal is to prove the following Itô formula valid for a.e. $t$ for each $\omega$ off a set of measure zero.

$$\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t \langle 2 \langle Y(s), X(s) \rangle \rangle \, ds$$

$$+ \left[ R^{-1}BM, M \right](t) + 2 \int_0^t \langle BX, dM \rangle$$  \hspace{1cm} (72.1.2)

where $R$ is the Riesz map from $W$ to $W'$. The most significant feature of the last term is that it is a local martingale. The third term on the right is the covariation of the two martingales $R^{-1}BM$ and $M$. It will follow from the argument that this will be nonnegative.

Note that the assumptions on $M$ imply that $[M] \in L^1([0, T] \times \Omega)$.

72.2 Preliminary Results

Here are discussed some preliminary results which will be needed. From the integral equation, if $\phi \in L^q(\Omega; V)$ and $\psi \in C_c(0, T)$ for $q = \max(p, 2)$,

$$\int_0^T \int_0^t (BX)(t) - BM(t) - BX_0 \psi' \phi dt dP$$

$$= \int_\Omega \int_0^T \int_0^t Y(s) \psi'(t) \, ds \phi dt dP$$
Then the term on the right equals
\[
\int_\Omega \int_0^T \int_s^T Y(s) \psi'(t) \, dt \, ds \, \phi(\omega) \, dP = \int_\Omega \left( - \int_0^T Y(s) \psi(s) \, ds \right) \phi(\omega) \, dP
\]
It follows that, since \( \phi \) is arbitrary,
\[
\int_0^T ((BX)(t) - BM(t) - BX_0) \psi'(t) \, dt = - \int_0^T Y(s) \psi(s) \, ds
\]
in \( L^\prime(\Omega; V) \) and so the weak time derivative of
\[
t \mapsto (BX)(t) - BM(t) - BX_0
\]
equals \( Y \) in \( L^\prime([0,T]; L^\prime(\Omega, V)) \). Thus, by Theorem 7.2.4, for a.e. \( t \),
\[
B(X(t) - M(t)) = BX_0 + \int_0^t Y(s) \, ds \text{ in } L^\prime(\Omega, V').
\]
That is,
\[
(BX)(t) = BX_0 + \int_0^t Y(s) \, ds + BM(t), \quad t \notin \check{N}, \ m\left(\check{N}\right) = 0
\]
holds in \( L^\prime(\Omega, V) \) where \( (BX)(t) = B(X(t)) \) a.e. \( t \) in this space, for all \( t \notin \check{N} \), a set of Lebesgue measure zero, in addition to holding for all \( t \) for each \( \omega \). Now let \( \{t^m_k\}_{k=1}^{\infty} \) be partitions for which, from Lemma 7.2.2, there are left and right step functions \( X^L_k, X^R_k \), which converge in \( L^p([0,T] \times \Omega; V) \) to \( X \) and such that each \( \{t^m_k\}_{k=1}^{\infty} \) has empty intersection with the set of measure zero \( \check{N} \) where, in \( L^\prime(\Omega, V') \),
\[
(BX)(t) \neq B(X(t)) \text{ in } L^\prime(\Omega, V').
\]
Thus for \( t_k \) a generic partition point,
\[
BX(t_k) = B(X(t_k)) \text{ in } L^\prime(\Omega, V')
\]
Hence there is an exceptional set of measure zero, \( N(t_k) \subseteq \Omega \) such that for \( \omega \notin N(t_k), BX(t_k)(\omega) = B(X(t_k, \omega)) \). Define an exceptional set \( N \subseteq \Omega \) to be the union of all these \( N(t_k) \). There are countably many and so \( N \) is also a set of measure zero. Then for \( \omega \notin N \), and \( t_k \) any mesh point at all, \( BX(t_k)(\omega) = B(X(t_k, \omega)) \). This will be important in what follows. In addition to this, from the integral equation, for each of these \( \omega \notin N \), \( BX(t)(\omega) = B(X(t, \omega)) \) for all \( t \notin N_\omega \subseteq [0,T] \) where \( N_\omega \) is a set of Lebesgue measure zero. Thus the \( t_k \) from the various partitions are always in \( N_\omega \). By Lemma 7.2.3, there exists a countable set \( \{e_i\} \) of vectors in \( V \) such that
\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]
and for each \( x \in W \),
\[
\langle Bx, x \rangle = \sum_{i=0}^\infty |\langle Bx, e_i \rangle|^2, \quad Bx = \sum_{i=1}^\infty \langle Bx, e_i \rangle Be_i
\]
72.2. PRELIMINARY RESULTS

By this lemma, if $B = B(\omega)$ where $B$ is $\mathcal{F}_0$ measurable into $\mathcal{L}(W,W')$, then the $e_i$ are also $\mathcal{F}_0$ measurable into $V$. Thus the conclusion of the above discussion is that at the mesh points, it is valid to write
\[
\langle (BX)(t_k), X(t_k) \rangle = \langle B(X(t_k)), X(t_k) \rangle = \sum_i \langle (BX)(t_k), e_i \rangle^2 = \sum_i \langle B(X(t_k)), e_i \rangle^2
\]
just as would be the case if $(BX)(t) = B(X(t))$ for every $t$. In all which follows, the mesh points will be like this and an appropriate set of measure zero which may be replaced with a larger set of measure zero finitely many times is being neglected. Obviously, one can take a subsequence of the sequence of partitions described above without disturbing the above observations. We will denote these partitions as $P_k$. Thus we obtain the following interesting lemma.

**Lemma 72.2.1** In the above situation, there exists a set of measure zero $N \subseteq \Omega$ and a dense subset of $[0,T]$, $D$ such that for $\omega \notin N$, $BX(t,\omega) = B(X(t,\omega))$ for all $t \in D$. This set $D$ is the union of nested partitions $\{P_k\} = \{t_k^j\}^m_{j=1,k=1}$ such that the left and right step functions $\{X_k^1\}, \{X_k^L\}$ converge to $X$ in $L^p([0,T] \times \Omega; V)$. There is also a set of Lebesgue measure zero $\hat{N} \subseteq [0,T]$ such that $BX(t) = B(X(t))$ in $L^q(\Omega; V')$ for all $t \notin \hat{N}$. Thus for such $t$, $BX(t)(\omega) = B(X(t,\omega))$ for a.e.$\omega$. In particular, for such $t \notin \hat{N}$,
\[
\langle BX(t)(\omega), X(t,\omega) \rangle = \sum_i \langle B(X(t)), e_i \rangle^2 \text{ a.e.} \omega.
\]

$D$ has empty intersection with $\hat{N}$. There is also a set of Lebesgue measure zero $N_\omega$ for each $\omega \notin N$ defined by $BX(t,\omega) = B(X(t,\omega))$ for all $t \notin N_\omega$.

Now define a stopping time.
\[
\sigma_q^n = \inf \left\{ t : \langle BX^n(t), X^n(t) \rangle > q \right\},  \quad (72.2.3)
\]

Thus this pertains to the $n^{th}$ partition. Since $X^n_k$ is right continuous, this will be a well defined stopping time. Thus, for $t$ one of the partition points,
\[
\left\langle BX\sigma^n_q(t,\omega), X\sigma^n_q(t,\omega) \right\rangle \leq q \quad (72.2.4)
\]

From the definition of $X^n_k$ and the observation that these partitions are nested,
\[
\lim_{n \to \infty} \sigma^n_q \equiv \sigma_q
\]
exists because this is a decreasing sequence. There are more available times to consider as $n$ gets larger and so when the inf is taken, it can only get smaller. Thus
\[
[\sigma_q \leq t] = \cap_{m=1}^\infty \cup_{k=1}^\infty \cap_{n \geq k} \left[ \sigma^n_q \leq t + \frac{1}{m} \right] \in \cap_{m=1}^\infty \mathcal{F}_{t+(1/m)} = \mathcal{F}_t
\]
since it is assumed that the filtration is normal. Thus this appears to be a stopping time. However, I don’t know how to use this.
Theorem 72.2.2 Let \( \{t^n_j\}_{j=0}^{m_n} \) be the above sequence of partitions of the sort in Lemma 72.0.2 such that if

\[
X^i_n(t) = \sum_{j=0}^{m_n-1} X(t^n_j) X(t^n_j, t^n_{j+1})(t)
\]

then \( X_n \to X \) in \( L^p([0,T] \times \Omega, V) \) with the other conditions holding which were discussed above. In particular, \( BX(t) = B(X(t)) \) for \( t \) one of these mesh points. Then the expression

\[
\sum_{j=0}^{m_n-1} \langle B(M(t^n_{j+1} + t) - M(t^n_j + t)), X(t^n_j) \rangle
\]

is a local martingale

\[
\int_0^t \langle BX^i_k, dM \rangle
\]

with \( \{\sigma^n_q\}_{q=1}^\infty \) being a localizing sequence.

**Proof:** This follows from Lemma 72.0.20. This can be seen because, thanks to the fact that \( BX^k_\sigma \) is bounded, the function \( BX^i_k \) is in the set \( G \) described there. This is a place where we use that \( d[M] = kdt \). \( \blacksquare \)

72.3 The Main Estimate

The argument will be based on a formula which follows in the next lemma.

**Lemma 72.3.1** In Situation 72.1.1 the following formula holds for a.e. \( \omega \) for 0 < \( s < t \). In the following, \( \langle \cdot, \cdot \rangle \) denotes the duality pairing between \( V, V' \).

\[
\langle BX(t), X(t) \rangle = \langle BX(s), X(s) \rangle +
\]

\[
+ 2 \int_s^t \langle Y(u), X(t) \rangle du + \langle B(M(t) - M(s)), M(t) - M(s) \rangle
\]

\[
- \langle BX(t) - BX(s) - (M(t) - M(s)), X(t) - X(s) - (M(t) - M(s)) \rangle
\]

\[
+ 2 \langle BX(s), M(t) - M(s) \rangle \quad (72.3.6)
\]

Also for \( t > 0 \)

\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + 2 \int_0^t \langle Y(u), X(t) \rangle du + 2 \langle BX_0, M(t) \rangle +
\]

\[
\langle BM(t), M(t) \rangle - \langle BX(t) - BX_0 - BM(t), X(t) - X_0 - M(t) \rangle \quad (72.3.7)
\]
72.3. THE MAIN ESTIMATE

Proof: From the formula which is assumed to hold,

\[ BX(t) = BX_0 + \int_0^t Y(u) \, du + BM(t) \]
\[ BX(s) = BX_0 + \int_0^s Y(u) \, du + BM(s) \]

Then

\[ BM(t) - BM(s) + \int_s^t Y(u) \, du = BX(t) - BX(s) \]

It follows that

\[ \langle B(M(t) - M(s)) , M(t) - M(s) \rangle - \langle BX(t) - BX(s) , X(t) - X(s) - (M(t) - M(s)) \rangle + 2 \langle BX(s) , M(t) - M(s) \rangle \]

\[ = \langle B(M(t) - M(s)) , M(t) - M(s) \rangle - \langle BX(t) - BX(s) , X(t) - X(s) \rangle + 2 \langle BX(t) - BX(s) , M(t) - M(s) \rangle - (B(M(t) - M(s))) , M(t) - M(s)) + 2 \langle BX(s) , M(t) - M(s) \rangle \]

Some terms cancel and this yields

\[ = - \langle BX(t) - BX(s) , X(t) - X(s) \rangle + 2 \langle BX(t) , M(t) - M(s) \rangle \]
\[ = - \langle BX(t) - BX(s) , X(t) - X(s) \rangle + 2 \langle B(M(t) - M(s)) , X(t) \rangle \]

\[ = - \langle B(X(t) - X(s)) , X(t) - X(s) \rangle + 2 \left( BX(t) - BX(s) - \int_s^t Y(u) \, du , X(t) \right) \]

\[ = - \langle BX(t) , X(t) \rangle - \langle BX(s) , X(s) \rangle + 2 \langle BX(t) , X(t) \rangle + 2 \langle BX(t) , X(t) \rangle - 2 \langle BX(s) , X(t) \rangle - 2 \int_s^t \langle Y(u) , X(t) \rangle \, du \]

\[ = \langle BX(t) , X(t) \rangle - \langle BX(s) , X(s) \rangle - 2 \int_s^t \langle Y(u) , X(t) \rangle \, du \]

Therefore,

\[ \langle BX(t) , X(t) \rangle - \langle BX(s) , X(s) \rangle \]
\[ = 2 \int_s^t \langle Y(u) , X(t) \rangle \, du + \langle B(M(t) - M(s)) , M(t) - M(s) \rangle \]
In the Situation \(72.1.1\), the continuity result is strengthened further to give strong continuity. \(H\) actually continuous a.e. with values in \(E\).

Now let \(C\) denote a point of \(K;K\) where \(K;K\) are defined earlier. In fact, \(C\) is lower semicontinuous on \(N\). Thus for a.e. \(\omega\),

\[
\sup_{t \in N_0} \langle BX (t, \omega) , X (t, \omega) \rangle \leq C (\omega) < \infty.
\]

Also for \(\omega\) off a set of measure zero described earlier, \(t \to BX (t) (\omega)\) is weakly continuous with values in \(W'\) on \([0,T]\). Also \(t \to \langle BX (t), X (t) \rangle\) is lower semicontinuous on \(N_0\).

**Proof:** Consider the formula in Lemma \(72.3.1\)

\[
\langle BX (t), X (t) \rangle = \langle BX (s), X (s) \rangle + 2 \int_s^t \langle Y (u), X (t) \rangle \, du + \langle B (M (t) - M (s)), M (t) - M (s) \rangle
\]

\[
- \langle B (X (t) - X (s) - (M (t) - M (s))), X (t) - X (s) - (M (t) - M (s)) \rangle
\]

\[
+ 2 \langle BX (s), M (t) - M (s) \rangle\] (72.3.9)

Now let \(t_j\) denote a point of \(P_k\) from Lemma \(72.3.1\). Then for \(t_j > 0, X (t_j)\) is just the value of \(X\) at \(t_j\) but when \(t = 0\), the definition of \(X (0)\) in this step function is \(X (0) \equiv 0\). Thus

\[
\sum_{j=1}^{m-1} \langle BX (t_{j+1}), X (t_{j+1}) \rangle - \langle BX (t_j), X (t_j) \rangle + \langle BX (t_1), X (t_1) \rangle - \langle BX_0, X_0 \rangle
\]
72.3. THE MAIN ESTIMATE

\[ = \langle BX (t_m) , X (t_m) \rangle - \langle BX_0, X_0 \rangle \]

Using the formula in Lemma 72.3.1, for \( t = t_m \) this yields

\[ \langle BX (t_m) , X (t_m) \rangle - \langle BX_0, X_0 \rangle = 2 \sum_{j=1}^{m-1} \int_{t_j}^{t_{j+1}} \langle Y (u) , X^r_k (u) \rangle \, du + \]

\[ + 2 \sum_{j=1}^{m-1} \langle BX (t_j) , M (t_{j+1}) - M (t_j) \rangle \]

\[ + \sum_{j=1}^{m-1} \langle B (M (t_{j+1}) - M (t_j)) , M (t_{j+1}) - M (t_j) \rangle \]

\[ - \sum_{j=1}^{m-1} \langle B (X (t_{j+1}) - X (t_j) - (M (t_{j+1}) - M (t_j))) , X (t_{j+1}) - X (t_j) - (M (t_{j+1}) - M (t_j)) \rangle \]

\[ + 2 \int_{0}^{t_1} \langle Y (u) , X (t_1) \rangle \, du + 2 \langle BX_0, M (t_1) \rangle + \langle BM (t_1) , M (t_1) \rangle \]

\[ - \langle B (X (t_1) - X_0 - M (t_1)) , X (t_1) - X_0 - M (t_1) \rangle \]  

(72.3.10)

First consider

\[ 2 \int_{0}^{t_1} \langle Y (u) , X (t_1) \rangle \, du + 2 \langle BX_0, M (t_1) \rangle + \langle BM (t_1) , M (t_1) \rangle . \]

Each term of the above converges to 0 for a.e. \( \omega \) as \( k \to \infty \) and in \( L^1 (\Omega) \). This follows right away for the second two terms from the assumptions on \( M \) given in the situation. Recall it was assumed that \( \| B (\omega) \| \) is bounded. This is where it is convenient to make this assumption. Consider the first term. This term is dominated by

\[ \left( \int_{0}^{t_1} \| Y (u) \|^{p'} \, du \right)^{1/p'} \left( \int_{0}^{t_1} \| X^r_k (u) \|^{p} \, du \right)^{1/p} \leq C (\omega) \left( \int_{0}^{t_1} \| Y (u) \|^{p'} \, du \right)^{1/p'} \left( \int_{\Omega} C (\omega)^p \, dP \right)^{1/p} < \infty \]

Hence this converges to 0 for a.e. \( \omega \) and also converges to 0 in \( L^1 (\Omega) \).

At this time, not much is known about the last term in (72.3.10), but it is negative and is about to be neglected anyway.

The second term on the right equals

\[ 2 \int_{t_1}^{t_m} \langle BX^r_k , dM \rangle = 2 \int_{0}^{t_m} \langle BX^r_k , dM \rangle + e (k) \]
where \( e(k) \to 0 \) for a.e. \( \omega \) and in \( L^1(\Omega) \). Also note that since \( \langle BM(t_1), M(t_1) \rangle \) converges to 0 in \( L^1(\Omega) \) and for a.e. \( \omega \), the sum involving

\[
\langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

can be started at 0 rather than 1 at the expense of adding in a term which converges to 0 a.e. and in \( L^1(\Omega) \). Thus (72.3.10) is of the form

\[
\langle BX(t_m), X(t_m) \rangle - \langle BX_0, X_0 \rangle = e(k) + 2 \int_0^{t_m} \langle Y(u), X_k(u) \rangle \, du + \\
+2 \int_0^{t_m} \langle BX_k, dM \rangle + \sum_{j=0}^{m-1} \langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

\[
- \sum_{j=1}^{m-1} \langle B(X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j))), X(t_{j+1}) - X(t_j) - (M(t_{j+1}) - M(t_j)) \rangle
\]

\[
- \langle B(X(t_1) - X_0 - M(t_1)), X(t_1) - X_0 - M(t_1) \rangle
\]

where \( e(k) \to 0 \) for a.e. \( \omega \) and also in \( L^1(\Omega) \).

Now it follows, on discarding the negative terms,

\[
\langle BX(t_m), X(t_m) \rangle - \langle BX_0, X_0 \rangle \leq e(k) + 2 \int_0^{t_m} \langle Y(u), X_k(u) \rangle \, du + \\
+2 \int_0^{t_m} \langle BX_k, dM \rangle + \sum_{j=0}^{m-1} \langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

Therefore,

\[
\sup_{t_m \in P_k} \langle BX(t_m), X(t_m) \rangle \leq \langle BX_0, X_0 \rangle + e(k) + 2 \int_0^{T} |\langle Y(u), X_k(u) \rangle| \, du + \\
+2 \sup_{t_m \in P_k} \left| \int_0^{t_m} \langle BX_k, dM \rangle \right| + \sum_{j=0}^{m-1} \langle B(M(t_{j+1}) - M(t_j)), M(t_{j+1}) - M(t_j) \rangle
\]

(72.3.12)
where there are $m_k + 1$ points in $\mathcal{P}_k$. Consider that last term. It is no larger than

$$
\|B\| \sum_{j=0}^{m-1} \| M(t_{j+1}) - M(t_j) \|^2
$$

Say the last point in the partition is $t_p = T$ and consider the sum

$$
\sum_{j=0}^{p-1} \| M(t_{j+1} \wedge t) - M(t_j \wedge t) \|^2 = \sum_{j=0}^{p-1} \| M^{t_{j+1}} - M^{t_j} \|^2(t)
$$

$$
= \sum_{j=0}^{p-1} \left[ M^{t_{j+1}}(t) - M^{t_j}(t) \right] + N_j(t) = \sum_{j=0}^{p-1} \left[ M^{t_{j+1}}(t) - M^{t_j}(t) + N_j(t) \right]
$$

for $N_j$ a martingale which equals 0 for $t \leq t_j$. Now when you put in $t = t_m$, this becomes

$$
\sum_{j=0}^{m-1} \left[ M^{t_{j+1}}(t_m) - M^{t_j}(t_m) \right] + N_j(t_m)
$$

Thus the expectation of that last term in $\text{72.3.12}$ is no larger than

$$
\|B\| E\left( \sum_{j=0}^{m-1} \left[ M^{t_{j+1}}(t_m) - M^{t_j}(t_m) \right] \right) = \|B\| E\left( [M](t_m) \right)
$$

The next task is to take the expectation of both sides of $\text{72.3.12}$. Of course there is a small problem with things not being in $L^1$. Hence it is appropriate to localize with the stopping time $\sigma^k_q$ defined in $\text{72.2.3}$. That is, we obtain all of the above with $X$ replaced with $X^{\sigma^k_q}$, stopping the original integral equation by introducing $X_{[0,\sigma^k_q]}$ in the integrals. Then carry out the following argument and pass to a limit as $q \to \infty$. In fact $\sigma^k_q = \infty$ if $q$ is large enough. Then carry out everything with $X^{\sigma^k_q}$. We don’t write it, but this is what is being done in the following argument.

$$
E\left( \sup_{t_m \in \mathcal{P}_k} \langle BX(t_m), X(t_m) \rangle \right) \leq E\left( \langle BX_0, X_0 \rangle \right) + E\left( \|e(k)\| \right) + 2 \|Y\|_{K'} \|X \|_{K}
$$

$$
+ 2E\left( \sup_{t_m \in \mathcal{P}_k} \left| \int_0^{t_m} \langle BX_k, dM \rangle \right| \right) + \|B\| E\left( [M](T) \right)
$$

Now using the Burkholder Davis Gundy inequality and the inequality for the quadratic variation of that funny integral involving $\langle BX_k, dM \rangle$,

$$
\leq E\left( \langle BX_0, X_0 \rangle \right) + E\left( \|e(k)\| \right) + 2 \|Y\|_{K'} \|X \|_{K}
$$

$$
+ CE\left( \left( \int_0^T \|BX_k\|^2 \, d[M] \right)^{1/2} \right) + \|B\| E\left( [M](T) \right)
$$
Now \( \|Bv\|_{W'}^2 \leq \|B\| \langle Bv, v \rangle \). Hence the above reduces to the following after adjusting the constant \( C \),
\[
\begin{aligned}
&\leq E (\langle B X_0, X_0 \rangle) + E (|e(k)|) + 2 \|Y\|_{K'} \|X_k^r\|_K \\
&\quad + CE \left( \left( \int_0^T \langle B X_k^r, X_k^l \rangle \, d[M] \right)^{1/2} \right) + \|B\| E ([M] (T))
\end{aligned}
\]
\[
\leq \frac{1}{2} \sup_{t_m \in P_k} \langle B X (t_m), X (t_m) \rangle + (C + \|B\|) E ([M] (T)) \\
&\quad + C (E (\langle B X_0, X_0 \rangle), \|Y\|_{K'}, \|X_k^r\|_K) + E (|e(k)|)
\]
It follows on subtracting the first term on the right and adjusting constants again,
\[
E \left( \sup_{t_m \in P_k} \langle B X (t_m), X (t_m) \rangle \right)
\]
\[
\leq (C + \|B\|) E ([M] (T)) + C (E (\langle B X_0, X_0 \rangle), \|Y\|_{K'}, \|X_k^r\|_K) + E (|e(k)|)
\]
Now let \( q \to \infty \) and use the monotone convergence theorem which yields the above for un-modified \( X \).
Observe that these partitions are nested and that the constant \( C (\cdots) \) is continuous and increasing in each argument with \( C (\mathbf{0}) = 0, C (\cdots) \) not depending on \( T \). Thus the left side is increasing and for given \( \varepsilon > 0 \), there exists \( N \) such that \( k \geq N \) implies the right side is no larger than
\[
C (E (\langle B X_0, X_0 \rangle), \|Y\|_{K'}, \|X_k^r\|_K) + C (C + \|B\|) E ([M] (T)) + \varepsilon \tag{72.3.13}
\]
Now let \( D \) denote the union of these nested partitions. Then from the monotone convergence theorem,
\[
E \left( \sup_{t \in D} \langle B X (t), X (t) \rangle \right)
\]
is no larger than the right side of (72.3.13). Since this is true for all \( \varepsilon > 0 \), it follows
\[
E \left( \sup_{t \in D} \langle B X (t), X (t) \rangle \right) \leq C (E (\langle B X_0, X_0 \rangle), \|Y\|_{K'}, \|X_k^r\|_K, E ([M] (T))) \tag{72.3.14}
\]
where \( C (\cdots) \) is increasing in each argument, continuous, and \( C (\mathbf{0}) = 0 \). Thus, enlarging \( N \), for \( \omega \notin N \),
\[
\sup_{t \in D} \langle B X (t), X (t) \rangle = C (\omega) < \infty \tag{72.3.15}
\]
where \( \int_\Omega C (\omega) \, dP < \infty \). By Lemma 76.3.1, there exists a countable set \( \{e_i\} \) of vectors in \( V \) such that
\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]
and for each $x \in W$, 

$$\langle Bx, x \rangle = \sum_{i=0}^{\infty} \langle Bx, e_i \rangle^2, \quad Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle B e_i$$

Thus for $t$ not in a set of measure zero off which $BX(t) = B(X(t))$, 

$$\langle BX(t), X(t) \rangle = \sum_{i=0}^{\infty} \langle BX(t), e_i \rangle^2 = \sup_m \sum_{k=1}^{m} \langle BX(t), e_i \rangle^2$$

Now from the formula for $BX(t)$, it follows that $BX$ is continuous into $V'$. For any $t \not\in N$ so that $(BX)(t) = B(X(t))$ in $L' (\Omega; V')$ and letting $t_k \to t$ where $t_k \in D$, Fatou’s lemma implies 

$$E (\langle BX(t), X(t) \rangle) = \sum_i E (\langle BX(t), e_i \rangle^2) = \sum_i \liminf_{k \to \infty} E (\langle BX(t_k), e_i \rangle^2) 
\leq \liminf_{k \to \infty} \sum_i E (\langle BX(t_k), e_i \rangle^2) = \liminf_{k \to \infty} E (\langle BX(t_k), X(t_k) \rangle) 
\leq C \left( \|Y\|_{K'}, \|X\|_{K}, \|Z\|_{J}, \|BX_0, X_0\|_{L^1(\Omega)} \right)$$

In addition to this, for arbitrary $t \in [0, T]$, and $t_k \to t$ from $D$, 

$$\sum_i \langle BX(t), e_i \rangle^2 \leq \liminf_{k \to \infty} \sum_i \langle BX(t_k), e_i \rangle^2 \leq \sup_{s \in D} \langle BX(s), X(s) \rangle$$

Hence 

$$\sup_{t \in [0, T]} \sum_i \langle BX(t), e_i \rangle^2 \leq \sup_{s \in D} \langle BX(s), X(s) \rangle = \sup_{s \in D} \sum_i \langle BX(s), e_i \rangle^2 \leq \sup_{t \in [0, T]} \sum_i \langle BX(t), e_i \rangle^2$$

It follows that $\sup_{t \in [0, T]} \sum_i \langle BX(t), e_i \rangle^2$ is measurable and 

$$E \left( \sup_{t \in [0, T]} \sum_i \langle BX(t), e_i \rangle^2 \right) \leq E \left( \sup_{s \in D} \langle BX(s), X(s) \rangle \right) 
\leq C \left( \|Y\|_{K'}, \|X\|_{K}, \|Z\|_{J}, \|BX_0, X_0\|_{L^1(\Omega)} \right)$$

And so, for $\omega$ off a set of measure zero, $\sup_{t \in [0, T]} \sum_i \langle BX(t), e_i \rangle^2$ is bounded above. Include this exceptional set in $N$.

Also for $t \not\in N_\omega$ and a given $\omega \not\in N$, letting $t_k \to t$ for $t_k \in D$, 

$$\langle BX(t), X(t) \rangle = \sum_i \langle BX(t), e_i \rangle^2 \leq \liminf_{k \to \infty} \sum_i \langle BX(t_k), e_i \rangle^2 
= \liminf_{k \to \infty} \langle BX(t_k), X(t_k) \rangle \leq \sup_{t \in D} \langle BX(t), X(t) \rangle$$
and so

\[
\sup_{t \in \mathcal{N}_\omega} \langle BX(t), X(t) \rangle \leq \sup_{t \in \mathcal{D}} \langle BX(t), X(t) \rangle \leq \sup_{t \in \mathcal{N}_\omega} \langle BX(t), X(t) \rangle
\]

From (72.3.15),

\[
\sup_{t \in \mathcal{N}_\omega} \langle BX(t), X(t) \rangle = C(\omega) \quad \text{a.e.}\omega
\]

where \( \int_{\Omega} C(\omega) \, dP < \infty \). In particular, \( \sup_{t \in \mathcal{N}_\omega} \langle BX(t), X(t) \rangle \) is bounded for a.e. \( \omega \) say for \( \omega \not\in N \) where \( N \) includes the earlier sets of measure zero. This shows that \( BX(t) \) is bounded in \( W' \) for \( t \in \mathcal{N}_\omega \).

If \( v \in V \), then for \( \omega \not\in N \),

\[
\lim_{t \to s} \langle BX(t), v \rangle = \langle BX(s), v \rangle, \quad t, s
\]

Therefore, since for such \( \omega \), \( \|BX(t)\|_{W'} \) is bounded for \( t \not\in \mathcal{N}_\omega \), the above holds for all \( v \in W \) also. Therefore, for a.e. \( \omega \), \( t \to BX(t, \omega) \) is weakly continuous with values in \( W' \) for \( t \not\in \mathcal{N}_\omega \).

Note also that

\[
\int_T^0 \int_{\Omega} \|BX(t)\|^2 \, dP \, dt \leq \int_T^0 \int_{\Omega} \|B\|^{1/2} \langle BX(t), X(t) \rangle \, dP \, dt
\]

\[
\leq C \left( \|Y\|_{K'}, \|X\|_{K}, \|Z\|_{K'}, \|\langle BX_0, X_0 \rangle\|_{L^1(\Omega)} \right) \|B\|^{1/2} T \tag{72.3.16}
\]

Eventually, it is shown that in fact, the function \( t \to BX(t, \omega) \) is continuous with values in \( W' \). The above shows that \( BX \in L^2([0, T] \times \Omega, W') \).

Finally consider the claim of weak continuity of \( BX \) into \( W' \). From the integral equation, \( BX \) is continuous into \( V' \). Also \( t \to BX(t) \) is bounded in \( W' \) on \( \mathcal{N}'_\omega \). Let \( s \in [0, T] \) be arbitrary. I claim that if \( t_n \to s, t_n \in \mathcal{D} \), it follows that \( BX(t_n) \to BX(s) \) weakly in \( W' \). If not, then there is a subsequence, still denoted as \( t_n \), such that \( BX(t_n) \to Y \) weakly in \( W' \) but \( Y \not= BX(s) \). However, the continuity into \( V' \) means that for all \( v \in V \),

\[
\langle Y, v \rangle = \lim_{n \to \infty} \langle BX(t_n), v \rangle = \langle BX(s), v \rangle
\]

which is a contradiction since \( V \) is dense in \( W \). This establishes the claim. Also this shows that \( BX(s) \) is bounded in \( W' \).

\[
|\langle BX(s), w \rangle| = \lim_{n \to \infty} |\langle BX(t_n), w \rangle| \leq \lim_{n \to \infty} \inf \|BX(t_n)\|_{W'}, \|w\|_{W'} \leq C(\omega) \|w\|_{W'}
\]

Now a repeat of the above argument shows that \( s \to BX(s) \) is weakly continuous into \( W' \).
72.4 A SIMPLIFICATION OF THE FORMULA

This estimate in Lemma 72.3.2 also provides a way to simplify one of the formulas derived earlier in the case that \(X_0 \in L^p(\Omega, V)\) so that \(X - X_0 \in L^p([0,T] \times \Omega, V)\). Refer to 72.3.11. One term there is

\[
\langle B (X(t_1) - X_0 - M(t_1)) , X(t_1) - X_0 - M(t_1) \rangle
\]

Also,

\[
\langle B (X(t_1) - X_0 - M(t_1)) , X(t_1) - X_0 - M(t_1) \rangle \\
\leq 2 \langle B (X(t_1) - X_0) , X(t_1) - X_0 \rangle + 2 \langle BM(t_1) , M(t_1) \rangle
\]

It was observed above that \(2 \langle BM(t_1) , M(t_1) \rangle \to 0\) a.e. and also in \(L^1(\Omega)\) as \(k \to \infty\). Apply the above lemma to \(\langle B (X(t_1) - X_0) , X(t_1) - X_0 \rangle\) using \([0,t_1]\) instead of \([0,T]\). The new \(X_0\) equals 0. Then from the estimate 72.3.8 it follows that

\[
E \left( \langle B (X(t_1) - X_0) , X(t_1) - X_0 \rangle \right) \to 0
\]
as \(k \to \infty\). Taking a subsequence, we could also assume that

\[
\langle B (X(t_1) - X_0) , X(t_1) - X_0 \rangle \to 0
\]
a.e. \(\omega\) as \(k \to \infty\). Then, using this subsequence, it would follow from 72.3.10,

\[
\langle BX(t_m) , X(t_m) \rangle - \langle BX_0 , X_0 \rangle = e(k) +
\]

\[
2 \int_0^{t_m} \langle Y(u) , X_k(u) \rangle du + 2 \int_0^{t_m} \langle BX_k^j , dM \rangle
\]

\[
+ \sum_{j=0}^{m-1} \langle B (M(t_{j+1}) - M(t_j)) , M(t_{j+1}) - M(t_j) \rangle
\]

\[
- \sum_{j=1}^{m-1} \langle B (\Delta X(t_j) - \Delta M(t_j)) , \Delta X(t_j) - \Delta M(t_j) \rangle
\]

(72.4.17)

where \(e(k) \to 0\) in \(L^1(\Omega)\) and a.e. \(\omega\) and

\[
\Delta X(t_j) \equiv X(t_{j+1}) - X(t_j)
\]

\(\Delta M(t_j)\) being defined similarly. Note how this eliminated the need to consider the term

\[
\langle B (X(t_1) - X_0 - M(t_1)) , X(t_1) - X_0 - M(t_1) \rangle
\]
in passing to a limit. This is a very desirable thing to be able to conclude.

Can you obtain something similar even in case \(X_0\) is not assumed to be in \(L^p(\Omega, V)\)? Let \(X_{0k} \in L^p(\Omega, V) \cap L^2(\Omega, W)\), \(X_{0k} \to X_0\) in \(L^2(\Omega, W)\). Then from the usual arguments involving the Cauchy Schwarz inequality,

\[
\langle B (X(t_1) - X_0) , X(t_1) - X_0 \rangle^{1/2} \leq \langle B (X(t_1) - X_{0k}) , X(t_1) - X_{0k} \rangle^{1/2}
\]

\[
+ \langle B (X_{0k} - X_0) , X_{0k} - X_0 \rangle^{1/2}
\]
Also, restoring the superscript to identify the partition,
\[
B \left( X (t_1^n) - X_{0k} \right) = B (X_0 - X_{0k}) + \int_0^{t_1^n} Y (s) \, ds + BM \left( t_1^n \right).
\]

Of course \( \| X - X_{0k} \|_{\mathcal{K}} \) is not bounded, but for each \( k \) it is finite. There is a sequence of partitions \( \mathcal{P}_k, \| \mathcal{P}_k \| \to 0 \) such that all the above holds. In the definitions of \( K, K', E \left( [M] (T) \right) \) replace \([0, T] \) with \([0, t]\) and let the resulting spaces be denoted by \( K_t, K'_t \). Let \( n_k \) denote a subsequence of \( \{ k \} \) such that
\[
\| X - X_{0k} \|_{K_t'_{n_k}} < 1/k.
\]

Then from the above lemma,
\[
E \left( \langle B \left( X \left( t_1^n \right) - X_{0k} \right), X \left( t_1^n \right) - X_{0k} \rangle \right)
\leq C \left( \langle B \left( X_0 - X_{0k} \right), X_0 - X_{0k} \rangle_{L^1 (\Omega)} : \| Y \|_{K_t'_{n_k}}, \| X - X_{0k} \|_{K_t'_{n_k}}, E \left( [M] \left( t_1^n \right) \right) \right)
\leq C \left( \langle B \left( X_0 - X_{0k} \right), X_0 - X_{0k} \rangle_{L^1 (\Omega)} : \| Y \|_{K_t'_{n_k}}, 1/k, E \left( [M] \left( t_1^n \right) \right) \right)
\]

Hence
\[
E \left( \langle B \left( X \left( t_1^n \right) - X_0 \right), X \left( t_1^n \right) - X_0 \rangle \right)
\leq 2 E \left( \langle B \left( X \left( t_1^n \right) - X_{0k} \right), X \left( t_1^n \right) - X_{0k} \rangle \right) + 2 E \left( \langle B \left( X_{0k} - X_0 \right), X_{0k} - X_0 \rangle \right)
\leq 2 C \left( \langle B \left( X_0 - X_{0k} \right), X_0 - X_{0k} \rangle_{L^1 (\Omega)} : \| Y \|_{K_t'_{n_k}}, 1/k, E \left( [M] \left( t_1^n \right) \right) \right)
+ 2 \| B \|_{L^2 (\Omega, W)} \| X_{0k} - X_0 \|_{L^2 (\Omega, W)}^2
\]

which converges to 0 as \( k \to \infty \). It follows that there exists a suitable subsequence such that (72.4.18) holds even in the case that \( X_0 \) is only known to be in \( L^2 (\Omega, W) \). From now on, assume this subsequence for the partitions \( \mathcal{P}_k \). Thus \( k \) will really be \( n_k \) and it suffices to consider the limit as \( k \to \infty \) of the equation of (72.4.18). To emphasize this point again, the reason for the above observations is to argue that, even when \( X_0 \) is only in \( L^2 (\Omega, W) \), one can neglect \( \langle B \left( X \left( t_1 \right) - X_0 - M \left( t_1 \right) \right), X \left( t_1 \right) - X_0 - M \left( t_1 \right) \rangle \) in passing to the limit as \( k \to \infty \) provided a suitable subsequence is used.

### 72.5 Convergence

Convergence will be shown for a subsequence and from now on every sequence will be a subsequence of this one. Since \( B X \in L^2 ([0, T] \times \Omega; W') \) which was shown
above, there exists a sequence of partitions of the sort described above such that also, in addition to the other claims

\[ BX^k \rightarrow BX, BX^l_k \rightarrow BX \]

in \( L^2 ([0, T] \times \Omega, W') \). Then the next lemma improves on this.

**Lemma 72.5.1** There exists a subsequence still denoted with the subscript \( k \) and an enlarged set of measure zero \( N \) including the earlier one such that \( BX^k(t), BX^l_k(t) \) also converge pointwise a.e. \( t \) to \( BX(t) \) in \( W' \) and \( X^l_k(t), X^r_k(t) \) converge pointwise a.e. in \( V \) to \( X(t) \) for \( \omega \notin N \) as well as having convergence of \( X^k(\cdot, \omega) \) to \( X(\cdot, \omega) \) in \( L^p ([0, T]; V) \) and \( BX^l_k(\cdot, \omega) \) to \( BX(\cdot, \omega) \) in \( L^2 ([0, T]; W') \).

**Proof:** To see that such a sequence exists, let \( a \) be such that

\[
\int_\Omega \int_0^T \| BX^l_{nk} (t) - BX (t) \|^2_{W'} dt dP + \int_\Omega \int_0^T \| X^r_{nk} (t) - X (t) \|^p_{V'} dt dP < 4^{-k}.
\]

Then

\[
P \left( \int_0^T \| BX^l_{nk} (t) - BX (t) \|^2_{W'} dt + \int_0^T \| X^r_{nk} (t) - X (t) \|^p_{V'} dt > 2^{-k} \right)
\]

\[
\leq 2^k (4^{-k}) = 2^{-k}
\]

and so by Borel Cantelli lemma, there is a set of measure zero \( N \) such that if \( \omega \notin N \),

\[
\int_0^T \| BX^l_{nk} (t) - BX (t) \|^2_{W'} dt + \int_0^T \| X^r_{nk} (t) - X (t) \|^p_{V'} dt + \int_0^T \| BX^l_{nk} (t) - BX (t) \|^2_{W'} dt + \int_0^T \| X^r_{nk} (t) - X (t) \|^p_{V'} dt \leq 2^{-k}
\]

for all \( k \) large enough. By the usual proof of completeness of \( L^p \), it follows that \( X^l_{nk} (t) \rightarrow X(t) \) for a.e. \( t \), this for each \( \omega \notin N \), a similar assertion holding for \( X^r_{nk} \). Also \( BX^l_{nk} (t) \rightarrow BX(t) \) for a.e. \( t \), similar for \( BX^r_{nk}(t) \). We denote these subsequences as \( \{X^l_k\}_{k=1}^{\infty}, \{X^r_k\}_{k=1}^{\infty} \).

Define the following stopping time.

\[ \tau_p \equiv \inf \left\{ t : \sum_i \langle BX(t), e_i \rangle^2 > p \right\} \]

By Lemma \( 72.5.2 \), \( \tau_p = \infty \) for all \( p \) large enough off some set of measure zero. Also, \( BX(t)(\omega) = B(X(t, \omega)) \) for a.e. \( t \) and so for a.e.t, \( \langle BX(t), X(t) \rangle = \sum_i \langle BX(t), e_i \rangle^2 \) and so \( \|BX^r(t)\|_{W'} \leq \|B\| \sqrt{p} \) for a.e.t. Hence \( BX^r \in L^\infty ([0, T] \times \Omega, W') \).
Lemma 72.5.2  The process $\int_0^t \langle BX_k, dM \rangle$ converges in probability as $k \to \infty$ to $\int_0^t \langle BX, dM \rangle$ which is a local martingale. Also, there is a subsequence and an enlarged set of measure zero $N$ such that for $\omega$ not in this set, the convergence is uniform on $[0, T]$.

Proof: By assumption, $d[M] = kdt$ for some $k \in L^1([0, T] \times \Omega)$ and so $BX^{\tau_p} \in \mathcal{G}$ where $\mathcal{G}$ was the class of functions for which one can write $\int_0^t \langle BX, dM \rangle$. By the Burkholder Davis Gundy inequality,

$$P \left( \sup_t \left| \int_0^{t \wedge \tau_p} \langle B(X_k), BX, dM \rangle \right| > \varepsilon \right) \leq \frac{C}{\varepsilon} \int \left( \int_0^{T \wedge \tau_p} \| B(X_k) - BX \|^2_W \, dt \right)^{1/2} \, dP$$

Let

$$A_k = \left( \sup_t \left| \int_0^t \langle BX_k, BX, dM \rangle \right| > \varepsilon \right)$$

Then, since $\tau_p = \infty$ for all $p$ large enough,

$$A_k = \bigcup_{n=0}^\infty A_k \cap ([\tau_p = \infty] \setminus [\tau_p-1 \neq \infty])$$

Consider $BX^{\tau_p}_k$. If $t > \tau_p$, what of the values of $BX^{\tau_p}_k$? It equals $BX(s)$ where $s$ is one of the mesh points $s \leq \tau_p$ because this is a left step function. Therefore,

$$\langle BX^{\tau_p}_k(s), X^{\tau_p}_k(s) \rangle = \langle B(X^{\tau_p}_k(s)), X^{\tau_p}_k(s) \rangle = \sum_i \langle BX(s), e_i \rangle^2 \leq p$$

As to $X_{[0,\tau_p]}BX$, it follows that for all $t \leq \tau_p$ you have $\sum_i \langle BX(t), e_i \rangle^2 \leq p$ and so, since this equals $\langle B(X(t)), X(t) \rangle$ a.e. $t$, it follows that $\|X_{[0,\tau_p]}BX(t)\|_W$, is bounded by a constant depending on $p$ for a.e.$t$. It follows that $BX$ and $BX^l_k$ are bounded. Now by Lemma 72.5.1, $BX^l_k(t) \to BX(t)$ a.e. $t$ and the term $\|B(X^l_k) - BX\|^2_W$ is essentially bounded. Therefore, in (72.5.19), the integral converges to 0. From this formula,

$$P \left( A_k \cap ([\tau_p = \infty] \setminus [\tau_p-1 \neq \infty]) \right) \leq P \left( A_k \cap ([\tau_p = \infty]) \right) \leq \frac{C}{\varepsilon} \int \left( \int_0^{T \wedge \tau_p} \| B(X_k) - BX \|^2_W \, dt \right)^{1/2} \, dP$$
Thus
\[
\lim_{k \to \infty} P(A_k \cap (\tau_p = \infty) \setminus [\tau_{p-1} \neq \infty]) = 0
\]
Then
\[
P(A_k) = \sum_{p=1}^{\infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} \neq \infty]))
\]
and taking limits using the dominated convergence theorem on the sum on the right,
\[
\lim_{k \to \infty} P(A_k) = \sum_{p=1}^{\infty} \lim_{k \to \infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} \neq \infty])) = 0
\]
This proves convergence in probability.
\[
\lim_{k \to \infty} P \left( \sup_t \left| \int_0^t \langle B(X_k^t) - BX, dM \rangle \right| > \varepsilon \right) = 0
\]
Then selecting a subsequence, still denoted with $k$, we can obtain
\[
P \left( \sup_t \left| \int_0^t \langle B(X_k^t) - BX, dM \rangle \right| > \frac{1}{k} \right) < 2^{-k}
\]
and so, by the Borel Cantelli lemma, there is a set of measure zero $N$ such that for this subsequence, for all $\omega \notin N$,
\[
\sup_t \left| \int_0^t \langle B(X_k^t) - BX, dM \rangle \right| \leq \frac{1}{k}
\]
for all $k$ large enough. Thus convergence is uniform. ■

From now on, include $N$ in the exceptional set and every subsequence will be a subsequence of this one.

### 72.6 The Ito Formula

Now at long last, here is the first version of the Ito formula valid on the partition points.

**Lemma 72.6.1** In Situation [Situation 72.1.4], let $D$ be as above, the union of all the positive mesh points for all the $P_k$. Also assume $X_0 \in L^2(\Omega; W)$. Then for $\omega \notin N$ the exceptional set of measure zero in $\Omega$ and every $t \in D$,
\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t 2 \langle Y(s), X(s) \rangle \, ds
\]
\[
+ [R^{-1}BM, M](t) + 2 \int_0^t \langle BX, dM \rangle
\]
for $R$ the Riesz map from $W$ to $W'$. The covariation term $[R^{-1}BM, M](t)$ is nonnegative.
CHAPTER 72. A MORE ATTRACTIVE VERSION

**Proof:** Let \( t \in D \). Then \( t \in \mathcal{P}_k \) for all \( k \) large enough. Consider \( t_{q_k} = t \).

\[
\langle BX (t), X (t) \rangle - \langle BX_0, X_0 \rangle = e (k) + 2 \int_0^t \langle Y (u), X^*_k (u) \rangle \, du
\]

\[
+ 2 \int_0^t \langle BX^*_k, dM \rangle + \sum_{j=0}^{q_k-1} \langle B (M (t_{j+1}) - M (t_j)), M (t_{j+1}) - M (t_j) \rangle
\]

\[
- \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), \Delta X (t_j) - \Delta M (t_j) \rangle
\]

(72.6.21)

where \( t_{q_k} = t \), \( \Delta X (t_j) = X (t_{j+1}) - X (t_j) \) and \( e (k) \to 0 \) in probability. By Lemma \( 72.5.2 \), the stochastic integral on the right converges uniformly for \( t \in [0, T] \) to

\[
2 \int_0^t \langle BX, dM \rangle
\]

for \( \omega \) off a set of measure zero. The deterministic integral on the right converges uniformly for \( t \in [0, T] \) to

\[
2 \int_0^t \langle Y (u), X (u) \rangle \, du
\]

Thanks to Lemma \( 72.5.1 \).

\[
\left| \int_0^t \langle Y (u), X (u) \rangle \, du - \int_0^t \langle Y (u), X^*_k (u) \rangle \, du \right|
\]

\[
\leq \int_0^T \| Y (u) \|_{V'} \| X (u) - X^*_k (u) \|_V
\]

\[
\leq \| Y \|_{L^p ([0, T])} (2^{-k})^{1/p}
\]

for all \( k \) large enough. Consider the fourth term. It equals

\[
\sum_{j=0}^{q_k-1} \left( R^{-1} B (M (t_{j+1}) - M (t_j)), M (t_{j+1}) - M (t_j) \right)
\]

(72.6.22)

where \( R^{-1} \) is the Riesz map from \( W \) to \( W' \). This equals

\[
\frac{1}{4} \left( \sum_{j=0}^{q_k-1} \| R^{-1} BM (t_{j+1}) + M (t_{j+1}) - (R^{-1} BM (t_j) + M (t_j)) \|^2
\]

\[
- \sum_{j=0}^{q_k-1} \| R^{-1} BM (t_{j+1}) - M (t_{j+1}) - (R^{-1} BM (t_j) - M (t_j)) \|^2 \right)
\]

From Theorem \( 72.4.17 \), as \( k \to \infty \), the above converges in probability to \( (t_{q_k} = t) \)

\[
\frac{1}{4} \left( [R^{-1} BM + M] (t) - [R^{-1} BM - M] (t) \right) \equiv [R^{-1} BM, M] (t)
\]
Also note that from 72.6.22, this term must be nonnegative since it is a limit of nonnegative quantities. This is what was desired.

Thus all the terms in 72.6.21 converge in probability except for the last term which also must converge in probability because it equals the sum of terms which do. It remains to find what this last term converges to. Thus

\[
\langle BX(t), X(t) \rangle - \langle BX_0, X_0 \rangle = 2 \int_0^t \langle Y(u), X(u) \rangle \, du \\
+ 2 \int_0^t \langle BX, dM \rangle + \left[ R^{-1} BM, M \right](t) - a
\]

where \( a \) is the limit in probability of the term

\[
\sum_{j=1}^{q_k-1} \langle B(\Delta X(t_j) - \Delta M(t_j)), \Delta X(t_j) - \Delta M(t_j) \rangle \quad (72.6.23)
\]

Let \( P_n \) be the projection onto span \( \{e_1, \ldots, e_n\} \) where \( \{e_k\} \) is an orthonormal basis for \( W \) with each \( e_k \in V \). Then using

\[
BX(t_{j+1}) - BX(t_j) - (BM(t_{j+1}) - BM(t_j)) = \int_{t_j}^{t_{j+1}} Y(s) \, ds
\]

the troublesome term of 72.6.23 above is of the form

\[
\sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), \Delta X(t_j) - \Delta M(t_j) \rangle \, ds
\]

\[
= \sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), \Delta X(t_j) - P_n \Delta M(t_j) \rangle \, ds \\
+ \sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), -(I - P_n) \Delta M(t_j) \rangle \, ds
\]

which equals

\[
\sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X(t_{j+1}) - X(t_j) - P_n(M(t_{j+1}) - M(t_j)) \rangle \, ds \quad (72.6.24)
\]

\[
+ \sum_{j=1}^{q_k-1} \langle B(\Delta X(t_j) - \Delta M(t_j)), -(I - P_n)(M(t_{j+1}) - M(t_j)) \rangle \quad (72.6.25)
\]

The reason for the \( P_n \) is to get \( P_n(M(t_{j+1}) - M(t_j)) \) in \( V \). The sum in 72.6.24 is dominated by

\[
\left( \sum_{j=1}^{q_k-1} \langle B(\Delta X(t_j) - \Delta M(t_j)), (\Delta X(t_j) - \Delta M(t_j)) \rangle \right)^{1/2}.
\]
(72.6.26)

\[
\left( \sum_{j=1}^{q_k^{-1}} \langle (B(I-P_n) \Delta M(t_j), (I-P_n) \Delta M(t_j)) \rangle \right)^{1/2}
\]

Now it is known from the above that

\[
\sum_{j=1}^{q_k^{-1}} \langle B(\Delta X(t_j) - \Delta M(t_j)), (\Delta X(t_j) - \Delta M(t_j)) \rangle
\]

converges in probability to \( a \geq 0 \). If you take the expectation of the square of the other factor, it is no larger than

\[
\|B\| E \left( \sum_{j=1}^{q_k^{-1}} \| (I-P_n) \Delta M(t_j) \|^2_{\mathbb{W}} \right)
\]

\[
= \|B\| E \left( \sum_{j=1}^{q_k^{-1}} \| (I-P_n) (M(t_{j+1}) - M(t_j)) \|^2_{\mathbb{W}} \right)
\]

\[
= \|B\| \sum_{j=1}^{q_k^{-1}} E \left( \| (I-P_n) (M(t_{j+1}) - M(t_j)) \|^2_{\mathbb{W}} \right)
\]

Then

\[
\| (I-P_n) (M(t_{j+1}) - M(t_j)) \|^2_{\mathbb{W}} = [\| (1-P_n) M(t_j) \|^2_{\mathbb{W}}] (t) + N(t)
\]

\[
= [(1-P_n) M(t_j)] (t) + N(t)
\]

for \( N(t) \) a martingale. In particular, taking \( t = t_{q_k} \), the above reduces to

\[
\|B\| \sum_{j=1}^{q_k^{-1}} E \left( \| (I-P_n) (M(t_{j+1}) - M(t_j)) \|^2_{\mathbb{W}} \right)
\]

\[
= \|B\| \sum_{j=1}^{q_k^{-1}} E \left( [(1-P_n) M(t_{j+1})] - [(1-P_n) M(t_j)] \right)
\]

\[
= \|B\| E \left( [(1-P_n) M(t_{q_k})] \right) = \|B\| E \left( \| (1-P_n) M(t_{q_k}) \|^2_{\mathbb{W}} \right)
\]

From maximal theorems, Theorem 60.9.4,

\[
\|B\| E \left( \sup_{t_{q_k}} \| (1-P_n) M(t_{q_k}) \|^2_{\mathbb{W}} \right) \leq 2 \|B\| E \left( \| (1-P_n) M(T) \|^2_{\mathbb{W}} \right)
\]

and this on the right converges to zero as \( n \to \infty \) by assumption that \( M(t) \) is in \( L^2 \) and the dominated convergence theorem. In particular, this shows that

\[
\left( \sum_{j=1}^{q_k^{-1}} \langle B(I-P_n) \Delta M(t_j), (I-P_n) \Delta M(t_j) \rangle \right)^{1/2}
\]
converges to 0 in $L^2(\Omega)$ independent of $k$ as $n \to \infty$.

Thus the expression in (72.6.24) is of the form $f_k g_{nk}$ where $f_k$ converges in probability to $a^{1/2}$ as $k \to \infty$ and $g_{nk}$ converges in probability to 0 as $n \to \infty$ independent of $k$. Now this implies $f_k g_{nk}$ converges in probability to 0. Here is why.

$$P \left( \left| f_k g_{nk} \right| > \varepsilon \right) \leq P \left( 2\delta \left| f_k \right| > \varepsilon \right) + P \left( 2C_\delta \left| g_{nk} \right| > \varepsilon \right) \leq P \left( 2\delta \left| f_k - a^{1/2} \right| + 2\delta \left| a^{1/2} \right| > \varepsilon \right) + P \left( 2C_\delta \left| g_{nk} \right| > \varepsilon \right)$$

where $\delta \left| f_k \right| + C_\delta \left| g_{nk} \right| > |f_k g_{nk}|$ and $\lim_{\delta \to 0} C_\delta = \infty$. Pick $\delta$ small enough that $\varepsilon - 2\delta a^{1/2} > \varepsilon/2$. Then this is dominated by

$$\leq P \left( 2\delta \left| f_k - a^{1/2} \right| > \varepsilon/2 \right) + P \left( 2C_\delta \left| g_{nk} \right| > \varepsilon \right)$$

Fix $n$ large enough that the second term is less than $\eta$ for all $k$. Now taking $k$ large enough, the above is less than $\eta$. It follows the expression in (72.6.24) and consequently in (72.6.23) converges to 0 in probability.

Now consider the other term (72.6.22) using the $n$ just determined. This term is of the form

$$\sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X(t_{j+1}) - X(t_j) - P_n(M(t_{j+1}) - M(t_j)) \rangle \, ds =$$

$$= \sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X_k^r(s) - X_k^l(s) - P_n(M_k^r(s) - M_k^l(s)) \rangle \, ds$$

$$= \sum_{j=1}^{q_k-1} \int_{t_j}^{t_{j+1}} \langle Y(s), X_k^r(s) - X_k^l(s) - P_n(M_k^r(s) - M_k^l(s)) \rangle \, ds$$

where $M_k^r$ denotes the step function

$$M_k^r(t) = \sum_{i=0}^{m_k-1} M(t_{i+1}) \delta_{(t_i, t_{i+1}]}(t)$$

and $M_k^l$ is defined similarly. The term

$$\int_{t_{i_1}}^{t} \langle Y(s), P_n(M_k^r(s) - M_k^l(s)) \rangle \, ds$$

converges to 0 for a.e. $\omega$ as $k \to \infty$ thanks to continuity of $t \to M(t)$. However, more is needed than this. Define the stopping time

$$\tau_p = \inf \{ t > 0 : \| M(t) \|_W > p \}.$$ 

Then $\tau_p = \infty$ for all $p$ large enough, this for a.e. $\omega$. Let

$$A_k = \left[ \int_{t_{i_1}}^{t} \langle Y(s), P_n(M_k^r(s) - M_k^l(s)) \rangle \, ds \right]$$

$$> \varepsilon$$

\[ P(A_k) = \sum_{p=0}^{\infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) \quad (72.6.27) \]

Now
\[ P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) \leq P\left(\left\| \int_{t_1}^{t} \langle Y(s), P_n \left((M^{\tau_p})_{k}^r (s) - (M^{\tau_p})_{k}^l (s)\right) \rangle ds \right\|_W > \varepsilon \right) \]

This is so because if \( p = 1 \), then it has no effect but also it could happen that the defining inequality may hold even if \( p < 1 \) hence the inequality. This is no larger than an expression of the form
\[ \frac{C_n}{\varepsilon} \int_{\Omega} \int_{0}^{T} \| Y(s) \|_{V}, \| (M^{\tau_p})_{k}^r (s) - (M^{\tau_p})_{k}^l (s) \|_W d\sigma dP \quad (72.6.28) \]

The inside integral converges to 0 by continuity of \( M \). Also, thanks to the stopping time, the inside integral is dominated by an expression of the form
\[ \int_{0}^{T} \| Y(s) \|_{V}, 2pds \]
and this is a function in \( L^1(\Omega) \) by assumption on \( Y \). It follows that the integral in \( \text{(72.6.27)} \) converges to 0 as \( k \to \infty \) by the dominated convergence theorem. Hence
\[ \lim_{k \to \infty} P(A_k \cap ([\tau_p = \infty])) = 0. \]

Since the sets \( [\tau_p = \infty] \setminus [\tau_{p-1} < \infty] \) are disjoint, the sum of their probabilities is finite. Hence there is a dominating function in \( \text{(72.6.27)} \) and so, by the dominated convergence theorem applied to the sum,
\[ \lim_{k \to \infty} P(A_k) = \sum_{p=0}^{\infty} \lim_{k \to \infty} P(A_k \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) = 0 \]

Thus \( \int_{t_1}^{t} \langle Y(s), P_n (M_{k}^r (s) - M_{k}^l (s)) \rangle ds \) converges to 0 in probability as \( k \to \infty \).

Now consider
\[ \left| \int_{t_1}^{t} \langle Y(s), X_{k}^r (s) - X_{k}^l (s) \rangle ds \right| \leq \int_{0}^{T} \| \langle Y(s), X_{k}^r (s) - X (s) \rangle \|_W ds \]
\[ + \int_{0}^{T} \| \langle Y(s), X_{k}^l (s) - X (s) \rangle \|_W ds \]
\[ \leq 2 \| Y(\cdot, \omega) \|_{L^p(0,T)} (2^{-k})^{1/p} \]
for all \( k \) large enough, this by Lemma \( \text{(24.6.24)} \). Therefore,
\[ \sum_{j=1}^{q_k-1} \langle B (\Delta X (t_j) - \Delta M (t_j)), \Delta X (t_j) - \Delta M (t_j) \rangle \]
converges to 0 in probability. This establishes the desired formula for \( t \in D. \)

In fact, the formula \( \text{(72.6.24)} \) is valid for all \( t \in N_\omega^C \).
Theorem 72.6.2 In Situation 72.1.1, for \( \omega \) off a set of measure zero, it follows that for every \( t \in N^C_\omega \),

\[
\langle B_X (t), X (t) \rangle = \langle B_X_0, X_0 \rangle + \int_0^t 2 \langle Y(s), X(s) \rangle \, ds
\]

\[
[R^{-1}BM, M] (t) + 2 \int_0^t \langle BX, dM \rangle
\]  

(72.6.29)

Also, there exists a unique continuous, progressively measurable function denoted as \( \langle BX, X \rangle \) such that it equals \( \langle B_X(t), X(t) \rangle \) for a.e. \( t \) and \( \langle BX, X \rangle (t) \) equals the right side of the above for all \( t \). In addition to this,

\[
E (\langle BX, X \rangle (t)) = E (\langle B_X_0, X_0 \rangle) + E \left( \int_0^t 2 \langle Y(s), X(s) \rangle \, ds + [R^{-1}BM, M] (t) \right)
\]  

(72.6.30)

Also the quadratic variation of the stochastic integral in 72.6.29 is dominated by

\[
\int_0^t \|BX\|_{W'}^2 \, d[M]
\]  

(72.6.31)

Also \( t \to BX(t) \) is continuous with values in \( W' \) for \( t \in N^C_\omega \).

Proof: Let \( t \in N^C_\omega \setminus D \). For \( t > 0 \), let \( t(k) \) denote the largest point of \( P_k \) which is less than \( t \). Hence \( m \leq k \). Then

\[
BX(t(m)) = B_X_0 + \int_0^{t(m)} Y(s) \, ds + BM(t(m)),
\]

a similar formula holding for \( X(t(k)) \). Thus for \( t > t(m), t \in N^C_\omega \),

\[
B(X(t) - X(t(m))) = \int_{t(m)}^t Y(s) \, ds + B(M(t) - M(t(m)))
\]

which is the same sort of thing studied so far except that it starts at \( t(m) \) rather than at 0 and \( B_X_0 = 0 \). Therefore, from Lemma 72.6.1 it follows

\[
\langle B(X(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle
\]

\[
= \int_{t(m)}^{t(k)} 2 \langle Y(s), X(s) - X(t(m)) \rangle \, ds
\]

\[
+ [R^{-1}BM, M] (t(k)) - [R^{-1}BM, M] (t(m))
\]

\[
+ 2 \int_{t(m)}^{t(k)} \langle B(X - X(t(m)), dM \rangle
\]  

(72.6.32)
Consider that last term. It equals

$$2 \int_{t(m)}^{t(k)} \langle B \left( X - X_{m}^{l} \right) , dM \rangle$$  \hspace{1cm} (72.6.33)$$

This is dominated by

$$2 \left| \int_{0}^{t(k)} \langle B \left( X - X_{m}^{l} \right) , dM \rangle - \int_{0}^{t(m)} \langle B \left( X - X_{m}^{l} \right) , dM \rangle \right|$$

$$\leq 4 \sup_{t \in [0,T]} \left| \int_{0}^{t} \langle B \left( X - X_{m}^{l} \right) , dM \rangle \right|$$

In Lemma 72.5.2 the above expression converges to 0. It follows there is a set of measure 0 including the earlier one such that for \( \omega \) not in that set, the integral of (72.6.33) converges to 0 in \( \mathbb{R} \). Similar reasoning shows the first term on the right in the non stochastic integral of (72.6.32) is dominated by an expression of the form

$$4 \int_{0}^{T} \left| \langle Y (s) , X (s) - X_{m}^{l} (s) \rangle \right| ds$$

which clearly converges to 0 thanks to Lemma 72.5.1. Finally, it is obvious that

$$\lim_{m,k \to \infty} \left[ R^{-1}BM, M \right] (t(k)) - \left[ R^{-1}BM, M \right] (t(m)) = 0 \text{ for a.e. } \omega$$

due to the continuity of the quadratic variation.

This shows that for \( \omega \) off a set of measure 0

$$\lim_{m,k \to \infty} \langle B (X (t(k)) - X (t(m))) , X (t(k)) - X (t(m)) \rangle = 0$$

Then for \( x \in W \),

$$\left| \langle B (X (t(k)) - X (t(m))) , x \rangle \right|$$

$$\leq \langle B (X (t(k)) - X (t(m))) , X (t(k)) - X (t(m)) \rangle^{1/2} \langle Bx, x \rangle^{1/2}$$

$$\leq \langle B (X (t(k)) - X (t(m))) , X (t(k)) - X (t(m)) \rangle^{1/2} \|B\|^{1/2} \|x\|_{W}$$

and so

$$\lim_{m,k \to \infty} \|BX (t(k)) - BX (t(m))\|_{W'} = 0$$

Recall \( t \) was arbitrary and \( \{t(k)\} \) is a sequence converging to \( t \). Then the above has shown that \( \{BX (t(k))\}_{k=1}^{\infty} \) is a convergent sequence in \( W' \). Does it converge to \( BX (t) \)? Let \( \xi (t) \in W' \) be what it converges to. Letting \( v \in V \) then, since the integral equation shows that \( t \to BX (t) \) is continuous into \( V' \),

$$\langle \xi (t) , v \rangle = \lim_{k \to \infty} \langle BX (t(k)) , v \rangle = \langle BX (t) , v \rangle,$$
and now, since $V$ is dense in $W$, this implies $\xi(t) = BX(t) = B(X(t))$ since $t \notin N_\omega$.

Recall also that it was shown earlier that $BX$ is weakly continuous into $W'$ on $[0, T]$ hence the strong convergence of $\{BX(t(k))\}_{k=1}^\infty$ in $W'$ implies that it converges to $BX(t)$, this for any $t \in N_\omega'$. For every $t \in D$ and for $\omega$ off the exceptional set of measure zero described earlier,

$$\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t 2 \langle Y(s), X(s) \rangle ds + \left[ R^{-1}BM, M \right](t) + 2 \int_0^t \langle BX, dM \rangle$$

(72.6.34)

Does this formula hold for all $t \in [0, T]$? Maybe not. However, it will hold for $t \notin N_\omega$. So let $t \notin N_\omega$.

$$\left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right|$$

$$\leq \left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t(k)) \rangle \right|$$

$$+ \left| \langle BX(t), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right|$$

$$= \left| \langle BX(t(k)) - X(t), X(t(k)) \rangle + \langle BX(t(k)) - X(t), X(t) \rangle \right|$$

Then using the Cauchy Schwarz inequality on each term,

$$\leq \langle BX(t(k)) - X(t), X(t(k)) \rangle^{1/2}$$

$$\cdot \left( \langle BX(t(k)), X(t(k)) \rangle^{1/2} + \langle BX(t), X(t) \rangle^{1/2} \right)$$

As before, one can use the lower semicontinuity of

$$t \rightarrow \langle BX(t(k)) - X(t), X(t(k)) - X(t) \rangle$$

on $N_\omega'$ along with the boundedness of $\langle BX(t), X(t) \rangle$ also shown earlier off $N_\omega$ to conclude

$$\left| \langle BX(t(k)), X(t(k)) \rangle - \langle BX(t), X(t) \rangle \right|$$

$$\leq C \left| \langle BX(t(k)) - X(t), X(t(k)) - X(t) \rangle^{1/2} \right|$$

$$\leq C \lim_{m \to \infty} \inf \langle BX(t(k)) - X(t(m)), X(t(k)) - X(t(m)) \rangle^{1/2} < \varepsilon$$

provided $k$ is sufficiently large. Since $\varepsilon$ is arbitrary,

$$\lim_{k \to \infty} \langle BX(t(k)), X(t(k)) \rangle = \langle BX(t), X(t) \rangle.$$ 

It follows that the formula in (72.6.34) is valid for all $t \in N_\omega'$. Now define the function $\langle BX, X \rangle(t)$ as

$$\langle BX, X \rangle(t) \equiv \begin{cases} \langle BX(t), X(t) \rangle, t \notin N_\omega, \\
\text{The right side of (72.6.34) if } t \in N_\omega. \end{cases}$$
Then in short, \( \langle BX, X \rangle(t) \) equals the right side of (72.6.34) for all \( t \in [0,T] \) and is consequently progressively measurable and continuous. Furthermore, for a.e. \( t \), this function equals \( \langle B(X(t)), X(t) \rangle \). Since it is known on a dense subset, it must be unique.

This implies that \( t \to BX(t) \) is continuous with values in \( W' \) for \( t \in N_\omega \). Here is why. The fact that the formula (72.6.34) holds for all \( t \in N_\omega \) implies that \( \langle BX(t), X(t) \rangle \) is continuous on \( N_\omega \). Then for \( x \in W, t, s \in N_\omega \)

\[
||\langle BX(t) - BX(s), x \rangle| \leq \langle B(X(t) - X(s)), X(t) - X(s) \rangle^{1/2} \|B\|^{1/2} \|x\|_W .
\]

Also,

\[
\langle B(X(t) - X(s)), X(t) - X(s) \rangle = \langle BX(t), X(t) \rangle + \langle BX(s), X(s) \rangle - 2 \langle BX(t), X(s) \rangle
\]

By weak continuity of \( t \to BX(t) \) shown earlier,

\[
\lim_{t \to s} \langle BX(t), X(s) \rangle = \langle BX(s), X(s) \rangle .
\]

Therefore,

\[
\lim_{t \to s} \langle B(X(t) - X(s)), X(t) - X(s) \rangle = 0
\]

and so the inequality (72.6.34) implies the continuity of \( t \to BX(t) \) into \( W' \) for \( t \not\in N_\omega \). Note that by assumption this function is continuous into \( V' \) for all \( t \).

Now consider the claim about the expectation. Use the function \( \langle BX, X \rangle \) to define a stopping time as

\[
\tau_p \equiv \inf \{ t > 0 : \langle BX, X \rangle(t) > p \}
\]

This is the first hitting time of a continuous process and so it is a valid stopping time. Using this, leads to

\[
\langle BX, X \rangle^{\tau_p}(t) = \langle BX_0, X_0 \rangle + \int_0^t \mathcal{X}_{[0,\tau_p]} 2 \langle Y(s), X(s) \rangle ds + [R^{-1}BM, M]_{\tau_p}(t) + 2 \int_0^t \mathcal{X}_{[0,\tau_p]} \langle BX, dM \rangle
\]

The term at the end is now a martingale because \( \mathcal{X}_{[0,\tau_p]}BX \) is bounded. Hence the expectation of the martingale at the end equals 0. Thus you obtain

\[
E(\langle BX, X \rangle^{\tau_p}(t)) = E(\langle BX_0, X_0 \rangle)
\]

\[
+ E \left( \int_0^t \mathcal{X}_{[0,\tau_p]} 2 \langle Y(s), X(s) \rangle ds \right) + E \left( [R^{-1}BM, M]^{\tau_p}(t) \right)
\]

Now use the monotone convergence theorem and the dominated convergence theorem to pass to a limit as \( p \to \infty \) and obtain (72.6.30). The claim about the quadratic variation follows from Theorem (72.6.22).
What of the special case where $W = H = H'$ and you are in the context of a Gelfand triple

$$V \subseteq H = H' \subseteq V'$$

and $B$ is simply the identity. Then we obtain the following theorem as a special case.

**Theorem 72.6.3** In Situation [72.1.1] in which $W = H = H'$ and $B = I$, it follows that off a set of measure zero, for every $t \in [0, T]$, there is a set of measure zero $N$ such that for $\omega \notin N$, there is a continuous function $\langle X, X \rangle$ which equals $|X(t)|_H^2$ for a.e. $t$ such that

$$\langle X, X \rangle(t) = |X_0|_H^2 + \int_0^t 2 \langle Y(s), X(s) \rangle \, ds + [M](t) + 2 \int_0^t \langle X, dM \rangle$$

(72.6.37)

Furthermore, off a set of measure zero, $t \to X(t)$ is continuous as a map into $H$ for a.e. $\omega$. In addition to this,

$$E(\langle X, X \rangle(t)) = E(|X_0|^2) + E \left( \int_0^t 2 \langle Y(s), X(s) \rangle \, ds \right) + E([M](t))$$

(72.6.38)

The quadratic variation of the stochastic integral satisfies

$$\left[ \int_0^{(} (X, dM) \right](t) \leq \int_0^t \|X\|_H^2 \, d[M]$$

It is more attractive to write $|X(t)|_H^2$ in place of $\langle X, X \rangle(t)$. However, I guess this is not strictly right although the discrepancy is only on a set of measure zero so it seems fairly harmless to indulge in this sloppiness. However, for $t \notin N_\omega$,

$$|X(t)|_H^2 = \sum_i \langle X(t), e_i \rangle^2$$

where the orthonormal basis $\{e_i\}$ is in $V$. Then for $s \in N_\omega$, you can get the following. Let $t_n \to s$ where $t_n \in N_\omega$. Then in the above notation,

$$\sum_i \langle X(s), e_i \rangle^2 \leq \lim \inf \sum_i \langle X(t_n), e_i \rangle_H^2 = \lim \inf \sum_i |X(t_n)|_H^2 \leq C(\omega)$$

It follows that in fact $X(s) \in H$ and you can take $X(s) = \sum_i \langle X(s), e_i \rangle e_i \in H$ because $\sum_i \langle X(s), e_i \rangle^2 < \infty$. Hence

$$|X(s)|^2 = \sum_i \langle X(s), e_i \rangle^2 \leq \lim \inf \sum_i |X(t_n)|_H^2$$

so $X$ has values in $H$ and is lower semicontinuous on $[0, T]$.
Chapter 73

Some Nonlinear Operators

In this chapter is a description and properties of some standard nonlinear maps.

73.1 An Assortment Of Nonlinear Operators

Definition 73.1.1 For $V$ a real Banach space, $A : V \to V'$ is a pseudomonotone map if whenever

$$u_n \rightharpoonup u$$

and

$$\lim \sup_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0$$

it follows that for all $v \in V$,

$$\lim \inf_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle.$$

The half arrows denote weak convergence.

Definition 73.1.2 $A : V \to V'$ is monotone if for all $v, u \in V$,

$$\langle Au - Av, u - v \rangle \geq 0,$$

and $A$ is Hemicontinuous if for all $v, u \in V$,

$$\lim_{t \to 0^+} \langle A(u + t(v - u)), u - v \rangle = \langle Au, u - v \rangle.$$

Theorem 73.1.3 Let $V$ be a Banach space and let $A : V \to V'$ be monotone and hemicontinuous. Then $A$ is pseudomonotone.

Proof: Let $A$ be monotone and Hemicontinuous. First here is a claim.

Claim: If $[\text{1}]$ and $[\text{2}]$ hold, then $\lim_{n \to \infty} \langle Au_n, u_n - u \rangle = 0$.

Proof of the claim: Since $A$ is monotone,

$$\langle Au_n - Au, u_n - u \rangle \geq 0$$
CHAPTER 73. SOME NONLINEAR OPERATORS

so

\[ \langle Au_n, u_n - u \rangle \geq \langle Au, u_n - u \rangle. \]

Therefore,

\[
0 = \liminf_{n \to \infty} \langle Au, u_n - u \rangle \leq \liminf_{n \to \infty} \langle Au_n, u_n - u \rangle \leq \limsup_{n \to \infty} \langle Au_n, u_n - u \rangle \leq 0.
\]

Now using that \( A \) is monotone again, then letting \( t > 0 \),

\[
\langle Au_n - A(u + t(v - u)), u_n - u + t(u - v) \rangle \geq 0
\]

and so

\[
\langle Au_n, u_n - u + t(u - v) \rangle \geq \langle A(u + t(v - u)), u_n - u + t(u - v) \rangle.
\]

Taking the \( \liminf \) on both sides and using the claim and \( t > 0 \),

\[
t \liminf_{n \to \infty} \langle Au_n, u - v \rangle \geq t \langle A(u + t(v - u)), (u - v) \rangle.
\]

Next divide by \( t \) and use the Hemicontinuity of \( A \) to conclude that

\[
\liminf_{n \to \infty} \langle Au_n, u - v \rangle \geq \langle Au, u - v \rangle.
\]

From the claim,

\[
\liminf_{n \to \infty} \langle Au_n, u - v \rangle = \liminf_{n \to \infty} \left( \langle Au_n, u_n - v \rangle + \langle Au_n, u - u_n \rangle \right)
= \liminf_{n \to \infty} \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle. \]

Monotonicity is very important in the above proof. The next example shows that even if the operator is linear and bounded, it is not necessarily pseudomonotone.

**Example 73.1.4** Let \( H \) be any Hilbert space and let \( A : H \to H' \) be given by

\[
\langle Ax, y \rangle \equiv \langle -x, y \rangle_H.
\]

Then \( A \) fails to be pseudomonotone.

**Proof:** Let \( \{ x_n \}_{n=1}^\infty \) be an orthonormal set of vectors in \( H \). Then Parsevall’s inequality implies

\[
\|x\|^2 \geq \sum_{n=1}^{\infty} |(x_n, x)|^2
\]

and so for any \( x \in H \), \( \lim_{n \to \infty} (x_n, x) = 0 \). Thus \( x_n \to 0 \equiv x \). Also

\[
\limsup_{n \to \infty} \langle Ax_n, x_n - x \rangle =
\]

\[
\limsup_{n \to \infty} \langle Ax_n, x_n - 0 \rangle = \limsup_{n \to \infty} \left(-\|x_n\|^2\right) = -1 \leq 0.
\]
73.1. AN ASSORTMENT OF NONLINEAR OPERATORS

If $A$ were pseudomonotone, we would need to be able to conclude that for all $y \in H$,

$$\lim_{n \to \infty} \inf \langle Ax_n, x_n - y \rangle \geq \langle Ax, x - y \rangle = 0.$$ 

However,

$$\lim_{n \to \infty} \inf \langle Ax_n, x_n - 0 \rangle = -1 < 0 = \langle A0, 0 - 0 \rangle.$$ 

Now the following proposition is useful.

**Proposition 73.1.5** Suppose $A : V \to V'$ is pseudomonotone and bounded where $V$ is separable. Then it must be demicontinuous. This means that if $u_n \to u$, then $Au_n \to Au$.

**Proof:** Since $u_n \to u$ is strong convergence and since $Au_n$ is bounded, it follows

$$\lim_{n \to \infty} \sup \langle Au_n, u_n - u \rangle = \lim_{n \to \infty} \langle Au_n, u_n - u \rangle = 0.$$ 

Suppose this is not so that $Au_n$ converges weakly to $Au$. Since $A$ is bounded, there exists a subsequence, still denoted by $n$ such that $Au_n \to \xi$ weak*. I need to verify $\xi = Au$. From the above, it follows that for all $v \in V$

$$\langle Au, u - v \rangle \leq \lim_{n \to \infty} \inf \langle Au_n, u_n - v \rangle$$

$$= \lim_{n \to \infty} \inf \langle Au_n, u - v \rangle = \langle \xi, u - v \rangle$$

Hence $\xi = Au$. ■

There is another type of operator which is more general than pseudomonotone.

**Definition 73.1.6** Let $A : V \to V'$ be an operator. Then $A$ is called type $M$ if whenever $u_n \to u$ and $Au_n \to \xi$, and

$$\lim_{n \to \infty} \sup \langle Au_n, u_n \rangle \leq \langle \xi, u \rangle$$

it follows that $Au = \xi$.

**Proposition 73.1.7** If $A$ is pseudomonotone, then $A$ is type $M$.

**Proof:** Suppose $A$ is pseudomonotone and $u_n \to u$ and $Au_n \to \xi$, and

$$\lim_{n \to \infty} \sup \langle Au_n, u_n \rangle \leq \langle \xi, u \rangle$$

Then

$$\lim_{n \to \infty} \sup \langle Au_n, u_n - u \rangle = \lim_{n \to \infty} \sup \langle Au_n, u_n \rangle - \langle \xi, u \rangle \leq 0$$

Hence

$$\lim_{n \to \infty} \inf \langle Au_n, u_n - v \rangle \geq \langle Au, u - v \rangle$$
for all \( v \in V \). Consequently, for all \( v \in V \),
\[
\langle Au, u - v \rangle \leq \lim \inf_{n \to \infty} \langle Au_n, u_n - v \rangle
\]
\[
= \lim \inf_{n \to \infty} \left( \langle Au_n, u - v \rangle + \langle Au_n, u_n - u \rangle \right)
\]
\[
= \langle \xi, u - v \rangle + \lim \inf_{n \to \infty} \langle Au_n, u_n - u \rangle \leq \langle \xi, u - v \rangle
\]
and so \( Au = \xi \). \( \Box \)

An interesting result is the following which states that a monotone linear function added to a type M is also type M.

**Proposition 73.1.8** Suppose \( A : V \to V' \) is type M and suppose \( L : V \to V' \) is monotone, bounded and linear. Then \( L + A \) is type M. Let \( V \) be separable or reflexive so that the weak convergences in the following argument are valid.

**Proof:** Suppose \( u_n \rightharpoonup u \) and \( Au_n + Lu_n \rightharpoonup \xi \) and also that
\[
\lim \sup_{n \to \infty} \langle Au_n + Lu_n, u_n \rangle \leq \langle \xi, u \rangle
\]
Does it follow that \( \xi = Au + Lu \)? Suppose not. There exists a further subsequence, still called \( n \) such that \( Lu_n \rightharpoonup Lu \). This follows because \( L \) is linear and bounded. Then from monotonicity,
\[
\langle Lu_n, u_n \rangle \geq \langle Lu_n, u \rangle + \langle (L(u), u_n - u) \rangle
\]
Hence with this further subsequence, the lim sup is no larger and so
\[
\lim \sup_{n \to \infty} \langle Au_n, u_n \rangle + \lim \inf_{n \to \infty} \langle Lu_n, u_n - u \rangle \leq \langle \xi, u \rangle
\]
and so
\[
\lim \sup_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi - Lu, u \rangle
\]
It follows since \( A \) is type M that \( Au = \xi - Lu \), which contradicts the assumption that \( \xi \neq Au + Lu \). \( \Box \)

There is also the following useful generalization of the above proposition.

**Corollary 73.1.9** Suppose \( A : V \to V' \) is type M and suppose \( L : V \to V' \) is monotone, bounded and linear. Then for \( u_0 \in V \) define \( M(u) \equiv L(u - u_0) \). Then \( M + A \) is type M. Let \( V \) be separable or reflexive so that the weak convergences in the following argument are valid.

**Proof:** Suppose \( u_n \rightharpoonup u \) and \( Au_n + Mu_n \rightharpoonup \xi \) and also that
\[
\lim \sup_{n \to \infty} \langle Au_n + Mu_n, u_n \rangle \leq \langle \xi, u \rangle
\]
Does it follow that \( \xi = Au + Mu \)? Suppose not. By assumption, \( u_n - u_0 \rightharpoonup u - u_0 \) and so, since \( L \) is bounded, there is a further subsequence, still called \( n \) such that
\[
Mu_n = L(u_n - u_0) \to L(u - u_0) = Mu.
\]
Since $M$ is monotone,
\[ \langle Mu_n - Mu, u_n - u \rangle \geq 0 \]
Thus
\[ \langle Mu_n, u_n \rangle - \langle Mu_n, u \rangle - \langle Mu, u_n \rangle + \langle Mu, u \rangle \geq 0 \]
and so
\[ \langle Mu_n, u_n \rangle \geq \langle Mu_n, u \rangle + \langle Mu, u_n - u \rangle \]
Hence with this further subsequence, the lim sup is no larger and so
\[ \limsup_{n \to \infty} \langle Au_n, u_n \rangle + \lim_{n \to \infty} (\langle Mu_n, u \rangle + \langle M(u), u_n - u \rangle) \leq \langle \xi, u \rangle \]
and so
\[ \limsup_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi - Mu, u \rangle \]
It follows since $A$ is type $M$ that $Au = \xi - Mu$, which contradicts the assumption that $\xi \neq Au + Mu$. \(\blacksquare\)

The following is Browder's lemma. It is a very interesting application of the Brouwer fixed point theorem.

**Lemma 73.1.10 (Browder)** Let $K$ be a convex closed and bounded set in $\mathbb{R}^n$ and let $A : K \to \mathbb{R}^n$ be continuous and $f \in \mathbb{R}^n$. Then there exists $x \in K$ such that for all $y \in K$,
\[ (f - Ax, y - x) \leq 0 \]

**Proof:** Let $P_K$ denote the projection onto $K$. Thus $P_K$ is Lipschitz continuous.
\[ x \to P_K (f - Ax + x) \]
is a continuous map from $K$ to $K$. By the Brouwer fixed point theorem, it has a fixed point $x \in K$. Therefore, for all $y \in K$,
\[ (f - Ax + x - x, y - x) = (f - Ax, y - x) \leq 0 \]
From this lemma, there is an interesting theorem on surjectivity.

**Proposition 73.1.11** Let $A : \mathbb{R}^n \to \mathbb{R}^n$ be continuous and coercive,
\[ \lim_{|x| \to \infty} \frac{\langle A(x + x_0), x \rangle}{|x|} = \infty \]
for some $x_0$. Then for all $f \in \mathbb{R}^n$, there exists $x \in \mathbb{R}^n$ such that $Ax = f$.

**Proof:** Define the closed convex sets $B_n \equiv \overline{B(x_0, n)}$. By Browder's lemma, there exists $x_n$ such that
\[ (f - Ax_n, y - x_n) \leq 0 \]
for all $y \in B_n$. Then taking $y = x_0$, it follows from the coercivity condition that the $x_n - x_0$ are bounded. It follows that for large $n$, $x_n$ is an interior point of $B_n$. Therefore,
\[ (f - Ax_n, z) \leq 0 \]
for all $z$ in some open ball centered at $x_0$. Hence $f = Ax_n$. \(\blacksquare\)
Lemma 73.1.12 Let $A : V \to V'$ be type $M$ and bounded and suppose $V$ is reflexive or $V$ is separable. Then $A$ is demicontinuous.

**Proof:** Suppose $u_n \to u$ and $Au_n$ fails to converge weakly to $Au$. Then there is a further subsequence, still denoted as $u_n$ such that $Au_n \not\to \zeta = Au$. Then thanks to the strong convergence, you have

$$\lim_{n \to \infty} \sup\langle Au_n, u_n \rangle = \langle \zeta, u_n \rangle$$

which implies $\zeta = Au$ after all. $\blacksquare$

With these lemmas and the above proposition, there is a very interesting surjectivity result.

**Theorem 73.1.13** Let $A : V \to V'$ be type $M$, bounded, and coercive

$$\lim_{\|u\| \to \infty} \frac{\langle A(u + u_0), u \rangle}{\|u\|} = \infty,$$  (73.1.4)

for some $u_0$, where $V$ is a separable reflexive Banach space. Then $A$ is surjective.

**Proof:** Since $V$ is separable, there exists an increasing sequence of finite dimensional subspaces \{\(V_n\)} such that $\bigcup_n V_n = V$. Say span \(\{v_1, \ldots, v_n\} = V_n\). Then consider the following diagram.

$$\begin{array}{ccc}
\mathbb{R}^n & \overset{\theta^*}{\to} & V' \\
\mathbb{R}^n & \overset{\theta}{\to} & V_n & \overset{i}{\to} & V
\end{array}$$

Here the map $\theta$ is the one which does the following.

$$\theta(x) = \sum_{i=1}^{n} x_i v_i.$$  

The map $i$ is the inclusion map. Consider the map $\theta^* i^* A i \theta$. By Lemma 73.1.11, this map is continuous. The map $\theta$ is continuous, one to one, and onto. Thus its inverse is also continuous. Let $x_0$ correspond to $u_0$. Then for some constant $C$,

$$\frac{(\theta^* i^* A i \theta (x + x_0), x)}{|x|} \geq \frac{\langle A i \theta (x + x_0), i \theta x \rangle}{C \|i \theta x\|_V}$$

and to say $|x| \to \infty$ is the same as saying that $\|i \theta x\|_V \to \infty$. Hence $\theta^* i^* A i \theta$ is coercive. Let $f \in V'$. Then from Proposition 73.1.11, there exists $x_n$ such that

$$\theta^* i^* A i \theta x_n = \theta^* i^* f$$

Thus, $i^* A i \theta x_n = i^* f$ and this implies that for $v_n = \theta x_n$,

$$i^* A i v_n = i^* f$$
In other words, 
\[ (A v_n, y) = \langle f, y \rangle \]  \hspace{1cm} (73.1.5)

for all \( y \in V_n \). Then from the coercivity condition \([3.1.4]\), the \( v_n \) are bounded independent of \( n \). Since \( V \) is reflexive, there is a subsequence, still called \( \{v_n\} \) which converges weakly to \( v \in V \). Since \( A \) is bounded, it can also be assumed that \( A v_n \rightharpoonup \zeta \in V' \). Then

\[ \limsup_{n \to \infty} \langle A v_n, v_n \rangle = \limsup_{n \to \infty} \langle f, v_n \rangle = \langle f, v \rangle \]

Also, passing to the limit in \([3.1.3]\),

\[ \langle \zeta, y \rangle = \langle f, y \rangle \]

for any \( y \in V_n \), this for any \( n \). Since the union of these \( V_n \) is dense, it follows that the above equation holds for all \( y \in V \). Therefore, \( f = \zeta \) and so

\[ \limsup_{n \to \infty} \langle A v_n, v_n \rangle = \limsup_{n \to \infty} \langle f, v_n \rangle = \langle f, v \rangle = \langle \zeta, v \rangle \]

Since \( A \) is type \( M \),

\[ A v = \zeta = f \]

### 73.2 Duality Maps

The duality map is an attempt to duplicate some of the features of the Riesz map in Hilbert space which is discussed in the chapter on Hilbert space.

**Definition 73.2.1** A Banach space is said to be strictly convex if whenever \( \|x\| = \|y\| \) and \( x \neq y \), then

\[ \left\| \frac{x + y}{2} \right\| < \|x\| \]

\( F : X \to X' \) is said to be a duality map if it satisfies the following: a.) \( \|F(x)\| = \|x\|^{p-1} \). b.) \( F(x)(x) = \|x\|^p \), where \( p > 1 \).

Duality maps exist. Here is why. Let

\[ F(x) = \left\{ x^* : \|x^*\| \leq \|x\|^{p-1} \text{ and } x^*(x) = \|x\|^p \right\} \]

Then \( F(x) \) is not empty because you can let \( f(\alpha x) = \alpha \|x\|^p \). Then \( f \) is linear and defined on a subspace of \( X \). Also

\[ \sup_{\|\alpha x\| \leq 1} |f(\alpha x)| = \sup_{\|\alpha x\| \leq 1} |\alpha| \|x\|^p \leq \|x\|^{p-1} \]

Also from the definition,

\[ f(x) = \|x\|^p \]
and so, letting $x^*$ be a Hahn Banach extension, it follows $x^* \in F(x)$. Also, $F(x)$ is closed and convex. It is clearly closed because if $x^*_n \to x^*$, the condition on the norm clearly holds and also the other one does too. It is convex because

$$
\|x^* \lambda + (1 - \lambda) y^*\| \leq \lambda \|x^*\| + (1 - \lambda) \|y^*\| \leq \lambda \|x\|^{p-1} + (1 - \lambda) \|x\|^{p-1}
$$

If the conditions hold for $x^*$, then we can show that in fact $\|x^*\| = \|x\|^{p-1}$. This is because

$$
\|x^*\| \geq \left| x^* \left( \frac{x}{\|x\|} \right) \right| = \frac{1}{\|x\|} \|x^* (x)\| = \|x\|^{p-1}.
$$

Now how many things are in $F(x)$ assuming the norm on $X'$ is strictly convex? Suppose $x_1^*$ and $x_2^*$ are two things in $F(x)$. Then by convexity, so is $(x_1^* + x_2^*)/2$. Hence by strict convexity, if the two are different, then

$$
\left\| \frac{x_1^* + x_2^*}{2} \right\| = \|x\|^{p-1} < \frac{1}{2} \|x_1^*\| + \frac{1}{2} \|x_2^*\| = \|x\|^{p-1}
$$

which is a contradiction. Therefore, $F$ is an actual mapping.

What are some of its properties? First is one which is similar to the Cauchy Schwarz inequality. Since $p - 1 = p/p'$,

$$
\sup_{\|y\| \leq 1} |\langle Fx, y \rangle| = \|x\|^{p/p'}
$$

and so for arbitrary $y \neq 0$,

$$
|\langle Fx, y \rangle| = \|y\| \left| \langle Fx, \frac{y}{\|y\|} \rangle \right| \leq \|y\| \|x\|^{p/p'} = \|F(y, y)^{1/p} \langle Fx, x \rangle \|^{1/p'}
$$

Next we can show that $F$ is monotone.

$$
\langle Fx - Fy, x - y \rangle = \langle Fx, x \rangle - \langle Fx, y \rangle - \langle Fy, x \rangle + \langle Fy, y \rangle \\
\geq \|x\|^p + \|y\|^p - \|y\| \|x\|^{p/p'} - \|y\|^{p/p'} \|x\| \\
\geq \|x\|^p + \|y\|^p - \left( \frac{\|y\|^p}{p} + \frac{|x|^p}{p'} \right) - \left( \frac{\|y\|^p}{p'} + \frac{|x|^p}{p} \right) = 0
$$

Next it can be shown that $F$ is hemicontinuous. By the construction, $F'(x + ty)$ is bounded as $t \to 0$. Let $t \to 0$ be a subsequence such that

$$
F(x + ty) \to \xi \text{ weak *}
$$

Then we ask: Does $\xi$ do what it needs to do in order to be $F(x)$? The answer is yes. First of all $\|F(x + ty)\| = \|x + ty\|^{p-1} \to \|x\|^{p-1}$. The set

$$
\left\{ x^* : \|x^*\| \leq \|x\|^{p-1} + \varepsilon \right\}
$$
73.2. DUALITY MAPS

is closed and convex and so it is weak * closed as well. For all small enough \( t \), it follows \( F(x + ty) \) is in this set. Therefore, the weak limit is also in this set and it follows \( ||\xi|| \leq ||x||^{p-1} + \varepsilon \). Since \( \varepsilon \) is arbitrary, it follows \( ||\xi|| \leq ||x||^{p-1} \). Is \( \xi(x) = ||x||^p \)? We have

\[
||x||^p = \lim_{t \to 0} ||x + ty||^p = \lim_{t \to 0} \langle F(x + ty), x + ty \rangle \\
= \lim_{t \to 0} \langle F(x + ty), x \rangle = \langle \xi, x \rangle
\]

and so, \( \xi \) does what it needs to do to be \( F(x) \). This would be clear if \( ||\xi|| = ||x||^{p-1} \).

However, \( ||\xi, x|| = ||x||^p \) and so \( ||\xi|| \geq \left( \langle \xi, \frac{x}{||x||} \rangle \right) = ||x||^{p-1} \). Thus \( ||\xi|| = ||x||^{p-1} \) which shows \( \xi \) does everything it needs to do to equal \( F(x) \) and so it is \( F(x) \).

Since this conclusion follows for any convergent sequence, it follows that \( F(x + ty) \) converges to \( F(x) \) weakly as \( t \to 0 \). This is what it means to be hemicontinuous.

This proves the following theorem. One can show also that \( F \) is demicontinuous which means strongly convergent sequences go to weakly convergent sequences. Here is a proof for the case where \( p = 2 \). You can clearly do the same thing for arbitrary \( p \).

**Lemma 73.2.2** Let \( F \) be a duality map for \( p = 2 \) where \( X, X' \) are reflexive and have strictly convex norms. (If \( X \) is reflexive, there is always an equivalent strictly convex norm \( [7] \).) Then \( F \) is demicontinuous.

**Proof:** Say \( x_n \to x \). Then does it follow that \( Fx_n \to Fx \)? Suppose not. Then there is a subsequence, still denoted as \( x_n \) such that \( x_n \to x \) but \( Fx_n \to y \neq Fx \) where here \( \to \) denotes weak convergence. This follows from the Eberlein Smulian theorem. Then

\[
\langle y, x \rangle = \lim_{n \to \infty} \langle Fx_n, x_n \rangle = \lim_{n \to \infty} ||x_n||^2 = ||x||^2
\]

Also, there exists \( z, ||z|| = 1 \) and \( \langle y, z \rangle \geq ||y|| - \varepsilon \). Then

\[
||y|| - \varepsilon \leq \langle y, z \rangle = \lim_{n \to \infty} \langle Fx_n, z \rangle \leq \liminf_{n \to \infty} ||F x_n|| = \liminf_{n \to \infty} ||x_n|| = ||x||
\]

and since \( \varepsilon \) is arbitrary, \( ||y|| \leq ||x|| \). It follows from the above construction of \( Fx \), that \( y = Fx \) after all, a contradiction.

**Theorem 73.2.3** Let \( X \) be a reflexive Banach space with \( X' \) having strictly convex norm\(^1\). Then for \( p > 1 \), there exists a mapping \( F : X \to X' \) which is bounded, monotone, hemicontinuous, coercive in the sense that \( \lim_{||x|| \to \infty} \langle Fx, x \rangle / ||x|| = \infty \), which also satisfies the inequalities

\[
||\langle Fx, y \rangle|| \leq ||\langle Fx, x \rangle||^{1/p} ||\langle Fy, y \rangle||^{1/p}
\]

\(^1\)It is known that if the space is reflexive, then there is an equivalent norm which is strictly convex. However, in most examples, this strict convexity is obvious.
Note that these conclusions about duality maps show that they map onto the dual space.

The duality map was onto and it was monotone. This was shown above. Consider the form of a duality map for the $L^p$ spaces. Let $F : L^p \rightarrow (L^p)'$ be the one which satisfies

$$
\|Ff\| = \|f\|^{p-1}, \quad \langle Ff, f \rangle = \|f\|^p
$$

Then in this case,

$$
Ff = |f|^{p-2} \mathcal{J}
$$

This is because it does what it needs to do.

$$
\|Ff\|_{L^p} = \left( \int_{\Omega} \left( |f|^{p-1} \right)^{p'} d\mu \right)^{1/p'} = \left( \int_{\Omega} \left( |f|^{p/p'} \right)^{p'} d\mu \right)^{1/p'}
$$

$$
= \left( \int_{\Omega} |f|^p d\mu \right)^{1-1/p} = \left( \left( \int_{\Omega} |f|^p d\mu \right)^{1/p} \right)^{p-1} = \|f\|_{L^p}^{p-1}
$$

while it is obvious that

$$
\langle Ff, f \rangle = \int_{\Omega} |f|^p d\mu = \|f\|_{L^p(\Omega)}^p.
$$

Now here is an interesting inequality which I will only consider in the case where the quantities are real valued.

**Lemma 73.2.4** Let $p > 2$. Then for $a, b$ real numbers, \( (|a|^{p-2} a - |b|^{p-2} b) (a - b) \geq C |a - b|^p \) for some constant $C$ independent of $a, b$.

**Proof:** There is nothing to show if $a = b$. Without loss of generality, assume $a > b$. Also assume $p \geq 2$. There is nothing to show if $p = 2$. I want to show that there exists a constant $C$ such that for $a > b$,

$$
\frac{|a|^{p-2} a - |b|^{p-2} b}{|a - b|^{p-1}} \geq C \quad (73.2.6)
$$

First assume also that $b \geq 0$. Now it is clear that as $a \to \infty$, the quotient above converges to 1. Take the derivative of this quotient. This yields

$$
(p - 1) |a - b|^{p-2} \frac{|a|^{p-2} |a - b| - (|a|^{p-2} a - |b|^{p-2} b)}{|a - b|^{2p-2}}
$$

Now remember $a > b$. Then the above reduces to

$$
(p - 1) |a - b|^{p-2} b \frac{|b|^{p-2} - |a|^{p-2}}{|a - b|^{2p-2}}
$$

Since $b \geq 0$, this is negative and so 1 would be a lower bound. Now suppose $b < 0$. Then the above derivative is negative for $b < a \leq -b$ and then it is positive for
73.2. **DUALITY MAPS**

$a > -b$. It equals 0 when $a = -b$. Therefore the quotient in (73.2.6) achieves its minimum value when $a = -b$. This value is

$$\frac{|-b|^{p-2}(-b) - |b|^{p-2} b}{|b|^{p-1}} = |b|^{p-2} \frac{-2b}{2b|b|^{p-2}} = \frac{1}{2}.$$ 

Therefore, the conclusion holds whenever $p \geq 2$. That is

$$\left(|a|^{p-2} a - |b|^{p-2} b \right) (a - b) \geq \frac{1}{2^{p-2}} |a - b|^p.$$ 

This proves the lemma.

This holds for $p > 1$ also, but I don’t remember how to show this at this time.

However, in the context of strictly convex norms on the reflexive Banach space $X$, the following important result holds. I will give it for the case where $p = 2$ since this is the case of most interest.

**Theorem 73.2.5** Let $X$ be a reflexive Banach space and $X, X'$ have strictly convex norms as discussed above. Let $F$ be the duality map with $p = 2$. Then $F$ is strictly monotone. This means

$$\langle Fu - Fv, u - v \rangle \geq 0$$

and it equals 0 if and only if $u = v$.

**Proof:** First why is it monotone? By definition of $F$, $\langle F(u), u \rangle = \|u\|^2$ and $\|F(u)\| = \|u\|$. Then

$$\|\langle Fu, v \rangle\| = \left| \left\langle Fu, \frac{v}{\|v\|} \right\rangle \right| \|v\| \leq \|Fu\| \|v\| = \|u\| \|v\|$$

Hence

$$\langle Fu - Fv, u - v \rangle = \|u\|^2 + \|v\|^2 - \langle Fu, v \rangle - \langle Fv, u \rangle \geq \|u\|^2 + \|v\|^2 - 2 \|u\| \|v\| \geq 0$$

Now suppose $\|x\| = \|y\| = 1$ but $x \neq y$. Then

$$\left\langle Fx, \frac{x + y}{2} \right\rangle \leq \left\| \frac{x + y}{2} \right\| = \frac{\|x\| + \|y\|}{2} = 1$$

It follows that

$$\frac{1}{2} \langle Fx, x \rangle + \frac{1}{2} \langle Fx, y \rangle = \frac{1}{2} + \frac{1}{2} \langle Fx, y \rangle < 1$$

and so

$$\langle Fx, y \rangle < 1$$

For arbitrary $x, y, x/\|x\| \neq y/\|y\|$,

$$\langle Fx, y \rangle = \|x\| \|y\| \langle \bar{F} \left( \frac{x}{\|x\|} \right), \left( \frac{y}{\|y\|} \right) \rangle$$
It is easy to check that \( F(x) = F(x) \). Therefore,
\[
|\langle Fx, y \rangle| = \|x\| \|y\| \left\langle F \left( \frac{x}{\|x\|} \right), \left( \frac{y}{\|y\|} \right) \right\rangle < \|x\| \|y\|
\]

Now say that \( x \neq y \) and consider
\[
\langle Fx - Fy, x - y \rangle
\]
First suppose \( x = \alpha y \). Then the above is
\[
\langle F(\alpha y) - Fy, (\alpha - 1) y \rangle = (\alpha - 1) \left( \langle F(\alpha y), y \rangle - \|y\|^2 \right)
\]
\[
= (\alpha - 1) \left( \langle \alpha F(y), y \rangle - \|y\|^2 \right)
\]
\[
= (\alpha - 1)^2 \|y\|^2 > 0
\]
The other case is that \( x/\|x\| \neq y/\|y\| \) and in this case,
\[
\langle Fx - Fy, x - y \rangle = \|x\|^2 + \|y\|^2 - \langle Fx, y \rangle - \langle Fy, x \rangle
\]
\[
> \|x\|^2 + \|y\|^2 - 2\|x\|\|y\| \geq 0
\]
Thus \( F \) is strictly monotone as claimed.

Another useful observation about duality maps for \( p = 2 \) is that \( \|F^{-1}y^*\|_V = \|y^*\|_{V'} \). This is because
\[\|y^*\|_{V'} = \|FF^{-1}y^*\|_{V'} = \|F^{-1}y^*\|_V \]
also from similar reasoning,
\[\langle y^*, F^{-1}y^* \rangle = \langle FF^{-1}y^*, F^{-1}y^* \rangle = \|F^{-1}y^*\|_V^2 = \|y^*\|_{V'}^2 \]
Chapter 74

Implicit Stochastic Equations

74.1 Introduction

In this chapter, implicit evolution equations are considered. These are of the form

\[ Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(t, \omega), \omega) \, ds = \int_0^t f(s) \, ds + B \int_0^t \Phi \, dW \]

the term on the end being a stochastic integral. The novelty is in allowing \( B \) to be an operator which could vanish or have other interesting features. Thus the integral equation could degenerate to a non stochastic elliptic equation. This generalization of evolution equations has proven useful in the study of deterministic evolution equations and we give some interesting examples which indicate that this may be true in the case of stochastic equations also. In any case, it is an interesting generalization and equations of the usual form are recovered by using a Gelfand triple in which \( B = I \).

Like deterministic equations, there are many ways to consider stochastic equations. Here it is based on an approach due to Bardos and Brezis \[13\] which avoids the consideration of finite dimensional problems. A generalized Ito formula is summarized in the next section. It is Theorem \[14\].

74.2 Preliminary Results

Let \( X \) have values in \( W \) and satisfy the following

\[ BX(t) = BX_0 + \int_0^t Y(s) \, ds + B \int_0^t Z(s) \, dW(s), \quad (74.2.1) \]

\( X_0 \in L^2(\Omega;W) \) and is \( \mathcal{F}_0 \) measurable, where \( Z \) is \( \mathcal{L}_2(Q^{1/2}U,W) \) progressively measurable and

\[ \| Z \|_{L^2([0,T] \times \Omega, \mathcal{L}_2(Q^{1/2}U,W))} < \infty. \]
This is what is needed to define the stochastic integral in the above formula. Here \( Q \) is a nonnegative self-adjoint operator defined on a separable real Hilbert space \( U \). In what follows, \( J \) will denote a one to one Hilbert Schmidt operator mapping \( Q^{1/2}U \) into another separable Hilbert space \( U_1 \). For more explanation on this situation see [15].

Assume \( X, Y \) satisfy

\[
X \in K \equiv L^p ([0, T] \times \Omega; V), \quad Y \in K' = L^{p'} ([0, T] \times \Omega; V')
\]

where \( 1/p' + 1/p = 1, p > 1 \), and \( X, Y \) are progressively measurable into \( V \) and \( V' \) respectively.

The sense in which the equation (74.2.1) holds is as follows. For a.e. \( \omega \), the equation holds in \( V' \) for all \( t \in [0, T] \). Assume that

\[
X \in L^2 ([0, T] \times \Omega, W), \quad BX \in L^2 ([0, T] \times \Omega, B([0, T]) \times \mathcal{F}, W'), \quad X \in L^p ([0, T] \times \Omega, B([0, T]) \times \mathcal{F}, V)
\]

Note that, since \( X \) is progressively measurable into \( V \), this implies that \( BX \) is progressively measurable into \( W' \). Also \( W(t) \) is a \( JJ^* \) Wiener process on \( U_1 \) in the following diagram. (\( W \) is a cylindrical Wiener process.)

\[
\begin{array}{c}
U \\
\downarrow \\
\cdots \\
1 \\
\downarrow \\
\Phi \\
W
\end{array}
\]

We will also make use of the following generalization of familiar concepts from Hilbert space.

**Lemma 74.2.1** Suppose \( V, W \) are separable Banach spaces, \( W \) also a Hilbert space such that \( V \) is dense in \( W \) and \( B \in \mathcal{L}(W, W') \) satisfies

\[
\langle Bx, x \rangle \geq 0, \quad \langle Bx, y \rangle = \langle By, x \rangle, \quad B \neq 0.
\]

Then there exists a countable set \( \{e_i\} \) of vectors in \( V \) such that

\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]

and for each \( x \in W \),

\[
\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,
\]

and also

\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i,
\]

the series converging in \( W' \).
Then in the above situation, we have the following fundamental estimate.

**Lemma 74.2.2** In the above situation where, off a set of measure zero, \[74.2.1\] holds for all \( t \in [0, T] \), and \( X \) is progressively measurable into \( V \),

\[
E \left( \sup_{t \in [0,T]} \langle BX, X \rangle (t) \right) < C \left( \|Y\|_{K'}, \|X\|_{K'}, \|Z\|_J, \|\langle BX_0, X_0 \rangle\|_{L^1(\Omega)} \right) < \infty.
\]

where \( \langle BX, X \rangle (t) = \langle B (X (t)) , X (t) \rangle \) a.e. and \( \langle BX, X \rangle \) is progressively measurable and continuous in \( t \).

\[
J = L^2 \left( \left[ 0, T \right] \times \Omega; L_2 \left( Q^{1/2} U; W \right) \right),
\]

\[
K = L^p \left( \left[ 0, T \right] \times \Omega; V \right),
\]

\[
K' = L^p' \left( \left[ 0, T \right] \times \Omega; V' \right).
\]

Also, \( C \) is a continuous function of its arguments and \( C (0, 0, 0, 0) = 0 \). Thus for a.e. \( \omega \),

\[
\sup_{t \in [0,T]} \langle BX, X \rangle (t) \leq C (\omega) < \infty.
\]

For a.e. \( \omega, t \to BX (t, \omega) \) is weakly continuous with values in \( W' \) for \( t \) off a set of measure zero. Also \( t \to \langle BX (t) , X (t) \rangle \) is lower semicontinuous off a set of measure zero.

Then from this fundamental lemma, the following Ito formula is valid. The proof of this theorem follows the same methods used for a similar result in [98].

**Theorem 74.2.3** Off a set of measure zero, for every \( t \in [0, T] \),

\[
\langle BX, X \rangle (t) = \langle BX_0, X_0 \rangle + \int_0^t \left( 2 \langle Y (s) , X (s) \rangle + \langle BZ, Z \rangle_{L_2} \right) ds
\]

\[
+ 2 \int_0^t (Z \circ J^{-1})^* BX \circ J dW
\]

(74.2.2)

Also

\[
E (\langle BX, X \rangle (t)) = E (\langle BX_0, X_0 \rangle) + E \left( \int_0^t \left( 2 \langle Y (s) , X (s) \rangle + \langle BZ, Z \rangle_{L_2} \right) ds \right)
\]

(74.2.3)

The quadratic variation of the stochastic integral is dominated by

\[
C \int_0^t \|Z\|^2_{L_2} \|BX\|^2_{W'} ds
\]

(74.2.4)

for a suitable constant \( C \). Also \( t \to BX (t) \) is continuous with values in \( W' \) for \( t \in N_\omega^C \).
We will often abuse the notation and write \( \langle BX(t), X(t) \rangle \) instead of the more precise \( \langle BX, X \rangle(t) \). No harm is done because these two are equal a.e.

In addition to the above, we will use the following basic theorems about nonlinear operators. This is Proposition 73.1.8 above.

**Proposition 74.2.4** Suppose \( A : V \to V' \) is type \( M \), see 82, and suppose \( L : V \to V' \) is monotone, bounded and linear. Here \( V \) is a separable reflexive Banach space. Then \( L + A \) is type \( M \):

As an important example, we give the following definition.

**Definition 74.2.5** Let \( f : [0,T] \times \Omega \to V \)

\[
\tau_h f(t, \omega) \equiv \begin{cases}
  f(t-h, \omega) & \text{if } t \geq h \\
  0 & \text{if } t < h
\end{cases}
\]

Then letting \( B \) be a monotone nonnegative, self adjoint operator, \( B : W \to W' \) for \( W \) a separable Hilbert space, consider the linear operator \( L : L^2(0,T,W) \equiv W \to L^2(0,T,W') \equiv W' \) given as

\[
Lu = \left( \frac{I - \tau_h}{h} \right) Bu.
\]

Is it the case that \( L \) is monotone? Clearly it is linear and so it suffices to consider \( \langle Lu, w \rangle_{W', W} \) which equals

\[
\begin{align*}
& \frac{1}{h} \int_0^T \langle Bu(t), u(t) \rangle \, dt - \frac{1}{h} \int_h^T \langle Bu(t-h), u(t) \rangle \, dt \\
= & \frac{1}{h} \int_0^T \langle Bu(t), u(t) \rangle \, dt - \frac{1}{h} \int_0^{T-h} \langle Bu(t), u(t+h) \rangle \, dt \\
\geq & \frac{1}{h} \int_0^T \langle Bu(t), u(t) \rangle \, dt \\
& - \frac{1}{h} \int_0^{T-h} \left( \frac{1}{2} \langle Bu(t), u(t) \rangle + \frac{1}{2} \langle Bu(t+h), u(t+h) \rangle \right) \, dt \\
= & \frac{1}{2h} \int_0^{T-h} \langle Bu(t), u(t) \rangle \, dt + \frac{1}{h} \int_{T-h}^T \langle Bu(t), u(t) \rangle \, dt \\
& - \frac{1}{2h} \int_0^{T-h} \langle Bu(t+h), u(t+h) \rangle \, dt \\
= & \frac{1}{2h} \int_0^{T-h} \langle Bu(t), u(t) \rangle \, dt + \frac{1}{h} \int_{T-h}^T \langle Bu(t), u(t) \rangle \, dt \\
& - \frac{1}{2h} \int_h^T \langle Bu(t), u(t) \rangle \, dt
\end{align*}
\]
74.2. PRELIMINARY RESULTS

\[
\begin{align*}
&= \frac{1}{2h} \int_{T-h}^{T} \langle Bu(t), u(t) \rangle \, dt + \frac{1}{2h} \int_{0}^{h} \langle Bu(t), u(t) \rangle \, dt \\
&+ \frac{1}{h} \int_{T-h}^{T} \langle Bu(t), u(t) \rangle \, dt - \frac{1}{2h} \int_{h}^{T} \langle Bu(t), u(t) \rangle \, dt \\
&= \frac{1}{2h} \int_{h}^{T} \langle Bu(t), u(t) \rangle \, dt + \frac{1}{2h} \int_{h}^{T} \langle Bu(t), u(t) \rangle \, dt \\
&\quad - \frac{1}{2h} \int_{0}^{T} \langle Bu(t), u(t) \rangle \, dt \\
&\quad + \frac{1}{h} \int_{0}^{h} \langle Bu(t), u(t) \rangle \, dt - \frac{1}{2h} \int_{h}^{T} \langle Bu(t), u(t) \rangle \, dt \\
&= \frac{1}{2h} \int_{T-h}^{T} \langle Bu(t), u(t) \rangle \, dt + \frac{1}{2h} \int_{0}^{h} \langle Bu(t), u(t) \rangle \, dt \geq 0 \quad (74.2.5)
\end{align*}
\]

The following is a restatement of Theorem 74.1.13.

**Theorem 74.2.6** Let \( A : V \to V' \) be type \( M \), bounded, and coercive

\[
\lim_{\|u\| \to \infty} \frac{\langle A(u + u_0), u \rangle}{\|u\|} = \infty, \quad (74.2.6)
\]

for some \( u_0 \in V \), where \( V \) is a separable reflexive Banach space. Then \( A \) is surjective.

In addition, there is a fundamental definition and theorem about weak derivatives which will be used.

**Definition 74.2.7** Let \( f \in L^1(a,b,V') \) where \( V' \) is the dual of a Banach space \( V \). Let \( \mathcal{D}^* (a,b) \) be the linear mappings from \( C_c^\infty (a,b) \) to \( V' \). Then we can consider \( f \in \mathcal{D}^* (a,b) \), the linear transformations defined on \( C_c^\infty (a,b) \) as follows.

\[
f(\phi) \equiv \int_{a}^{b} f \phi \, ds
\]

This is well defined due to regularity considerations for Lebesgue measure. Then define \( Df \in \mathcal{D}^* (a,b) \) by

\[
Df(\phi) \equiv - \int_{a}^{b} f \phi' \, ds
\]

To say that \( Df \in L^1(a,b,V') \) is to say that there exists \( g \in L^1(a,b,V') \) such that

\[
Df(\phi) \equiv - \int_{a}^{b} f \phi' \, ds = \int_{a}^{b} g \phi \, ds
\]

for all \( \phi \in C_c^\infty (a,b) \). Note that regularity considerations imply that \( g \) is unique if it exists.
The following is Theorem 67.2.9.

**Theorem 74.2.8** Suppose that \( f \) and \( Df \) are both in \( L^1(a,b,V') \). Then \( f \) is equal to a continuous function a.e., still denoted by \( f \) and

\[
f(x) = f(a) + \int_a^x Df(t) \, dt.
\]

In the next section are theorems about how shifts in time relate to progressive measurability.

### 74.3 The Existence Of Approximate Solutions

The situation is as follows. There are spaces \( V \subseteq W \) where \( V \) is a reflexive separable Banach space and \( W \) is a separable Hilbert space. It is assumed that \( V \) is dense in \( W \). Define the spaces

\[
V \equiv L^p([0,T] \times \Omega, V), \quad W \equiv L^2([0,T] \times \Omega, W)
\]

where in each case, the \( \sigma \) algebra of measurable sets will be the progressively measurable sets. Thus, from the Riesz representation theorem,

\[
V' = L^p([0,T] \times \Omega, V'), \quad W' = L^2([0,T] \times \Omega, W')
\]

It will be assumed for the sake of convenience that \( p \geq 2 \). It follows that

\[
V \subseteq W, \quad W' \subseteq V'
\]

The entire presentation will be based on the following lemma.

**Lemma 74.3.1** Let \( V \equiv L^p([0,T] \times \Omega, V) \) where \( V \) is a separable Banach space and the \( \sigma \) algebra of measurable sets consists of those which are progressively measurable. Then for \( h \in (0,T), \tau_h : V \to V \).

**Proof:** First consider \( Q \) which is a progressively measurable set. Is it the case that \( \tau_h X_Q \) is also progressively measurable? Define \( Q + h \) as

\[
Q + h \equiv \{(t+h,\omega) : (t,\omega) \in Q\}
\]

Then

\[
\tau_h X_Q (t,\omega) = \begin{cases} X_{Q+h} (t,\omega) & \text{if } t \geq h \\ 0 & \text{if } t < h \end{cases}
\]

Is this function progressively measurable? For \( (s,\omega) \in [0,t] \times \Omega \), we have the following

\[
0 < \alpha \leq 1, [(s,\omega) : \tau_h X_Q (s,\omega) \geq \alpha] = [h,t] \times \Omega \cap (Q + h)
\]

\[
\alpha > 1, [(s,\omega) : \tau_h X_Q (s,\omega) \geq \alpha] = \emptyset \in \mathcal{B}([0,t]) \times \mathcal{F}_t
\]
74.3. THE EXISTENCE OF APPROXIMATE SOLUTIONS

\[ \alpha \leq 0, [(s, \omega) : \tau_h X_Q (s, \omega) \geq \alpha] = [0, t] \times \Omega \in B ([0, t]) \times F_t \]

It suffices to show that for \( t \geq h, [h, t] \times \Omega \cap (Q + h) \) is \( B ([0, t]) \times F_t \) measurable. It is known that \( [0, t] \times \Omega \cap Q \) is \( B ([0, t]) \times F_t \) measurable and also that \( [0, t - h] \times \Omega \cap Q \) is \( B ([0, t - h]) \times F_{t - h} \) measurable. Let

\[ \mathcal{G} \equiv \{ Q \in B ([0, t - h]) \times F_{t - h} : [h, t] \times \Omega \cap Q + h \in B ([0, t]) \times F_t \} \]

First consider \( I \times B \) where \( I \) is an interval in \( B ([0, t]) \) and \( B \in F_{t - h} \). Then

\[ [h, t] \times \Omega \cap (I + h) \times B = I' \times B \]

where \( I' \) is in \( B ([0, t]) \) and of course \( B \in F_{t - h} \subseteq F_t \). Thus the sets of this form, are in \( \mathcal{G} \). Next suppose \( Q \in \mathcal{G} \). Is \( Q^C \in \mathcal{G} \)?

\[ ([h, t] \times \Omega \cap (Q^C + h)) \cup [h, t] \times \Omega \cap (Q + h) \cup [0, h) \times \Omega = [0, t] \times \Omega \]

Then all of these disjoint sets but the first are in \( B ([0, t]) \times F_t \). It follows that the first is also in \( B ([0, t]) \times F_t \). It is clear that \( \mathcal{G} \) is also closed with respect to countable disjoint unions. Therefore, \( \mathcal{G} \) contains the \( \pi \) system of sets of the form \( I \times B \) just described. It follows that \( \mathcal{G} = B ([0, t - h]) \times F_{t - h} \).

Now if \( Q \) is progressively measurable, then \( [0, t - h] \times \Omega \cap Q \) is \( B ([0, t - h]) \times F_{t - h} \) measurable and so from what was just shown, \( [h, t] \times \Omega \cap Q + h \in B ([0, t]) \times F_t \). Thus \( \tau_h X_Q \) is progressively measurable. It follows that if \( f \in \mathcal{V} \), you could consider \( \phi (f) \) for \( \phi \in \mathcal{V}' \) and the positive and negative parts of this function. Each of these is the limit of a sequence of simple functions involving combinations of indicator functions of the form \( X_Q \). Thus \( \tau_h \phi (f) = \phi (\tau_h f) \) is the limit of simple functions involving combinations of functions \( \tau_h X_Q \) and, as just shown, these simple functions are progressively measurable. Thus \( \tau_h f \) is also progressively measurable by the Pettis theorem. \( \blacksquare \)

This Lemma states that you can do \( \tau_h \) to progressively measurable functions and end up with one which is progressively measurable. Let

\[ B \in \mathcal{L}(W, W') \]

satisfy

\[ (Bx, y) = (By, x), \quad (Bx, x) \geq 0 \quad (74.3.7) \]

Also suppose that

\[ A \text{ is monotone and hemicontinuous from } \mathcal{V} \text{ to } \mathcal{V}' \quad (74.3.8) \]

This means the operator is monotone:

\[ \langle Au - Au, u - v \rangle_{\mathcal{V}', \mathcal{V}} \geq 0 \]

and hemicontinuous:

\[ \lim_{t \to 0} \langle A(u + tv), w \rangle_{\mathcal{V}', \mathcal{V}} = \langle Au, w \rangle_{\mathcal{V}', \mathcal{V}} \]
Also we assume that $A$ is bounded and takes the form

$$Au(t, \omega) = A(t, u(t, \omega), \omega)$$

for $u \in V$. Such an operator is type $M$ and this is what we use. Such an operator is defined by:

If $u_n \to u$ weakly in $V$ and $Au_n \to \xi$ weakly in $V'$ and $\limsup_{n \to \infty} \langle Au_n, u_n \rangle \leq \langle \xi, u \rangle$

Then the above implies

$$Au = \xi.$$

We define $V_\omega$ as $L^p(0,T,V)$ with the definition of $V'_\omega$ similar, the subscript denoting that $\omega$ is fixed, the $\sigma$ algebra of measurable sets being the Borel sets, $\mathcal{B}([0,T])$. Also,

$$(t,u,\omega) \to A(t,u,\omega)$$

is progressively measurable.

Suppose $A(\omega)$ is monotone and hemicontinuous and bounded from $V_\omega$ to $V'_\omega$. Thus

$$A(\omega) \text{ is type } M \text{ from } V_\omega \text{ to } V'_\omega$$

where

$$A(\omega) u \equiv A(t,u,\omega)$$

We assume the estimates found in the next lemma.

**Lemma 74.3.2** If $p \geq 2$ and

$$\langle A(t,u,\omega), u \rangle_V \geq \delta \|u\|_V^p - c(t,\omega)$$

$$\|A(t,u,\omega)\|_{V'} \leq k \|u\|_V^{p-1} + c^{1/p'}(t,\omega)$$

where $c \geq 0$, $c \in L^1([0,T] \times \Omega)$, then if $(t,\omega) \to q(t,\omega)$ is in $V_\omega$, it follows that for a.e. $\omega$, similar inequalities hold for $A$ given by

$$\tilde{A}(t,u,\omega) \equiv A(t,u + q(t,\omega),\omega)$$

**Proof:** Letting $q$ be progressively measurable, $q(t,\omega) \in V$ only consider $\omega$ such that $t \to q(t,\omega)$ is in $L^p(0,T,V)$.

$$\langle \tilde{A}(t,u,\omega), u \rangle =$$

$$\langle A(t,u + q(t,\omega),\omega), u \rangle = \langle A(t,u + q(t,\omega),\omega), u + q(t,\omega) \rangle - \langle A(t,u + q(t,\omega),\omega), q(t,\omega) \rangle$$

$$\geq \delta \|u + q(t,\omega)\|_V^p - k \|u + q(t,\omega)\|_V^{p-1} \|q(t,\omega)\|_V - c^{1/p'}(t,\omega) \|q(t,\omega)\|_V - c(t,\omega)$$

$$\geq \delta \|u + q(t,\omega)\|_V^p - k \|u + q(t,\omega)\|_V^{p-1} \|q(t,\omega)\|_V - \|q(t,\omega)\|_V^p - 2c(t,\omega)$$
\[ \geq \frac{\delta}{2} \| u + q(t,\omega) \|_{V^p}^p - C(k,\delta,T) \| q(t,\omega) \|_{V^p}^p - 2c(t,\omega) \]

Now
\[ \| u + q(t,\omega) \| \geq \| u \| - \| q(t,\omega) \| \]

and so by convexity,
\[ \frac{\| u + q(t,\omega) \|^{2p} + \| q(t,\omega) \|^{2p}}{2} \geq \left( \frac{\| u + q(t,\omega) \| + \| q(t,\omega) \|}{2} \right)^p \geq \left( \frac{\| u \|}{2} \right)^p \]

This implies
\[ \| u + q(t,\omega) \|^p \geq 2 \left( \frac{\| u \|^{2p} - \| q(t,\omega) \|^{2p}}{2} \right) \]

Therefore,
\[ \langle A(t,u,\omega), u \rangle = \]
\[ \langle A(t,u+q(t,\omega),\omega), u \rangle \geq \frac{\delta}{2} \left( 2 \left( \frac{\| u \|^{2p} - \| q(t,\omega) \|^{2p}}{2} \right) \right) - C(k,\delta,T) \| q(t,\omega) \|_{V^p}^p - 2c(t,\omega) \]
\[ \geq \frac{\delta}{2p} \| u \|^{2p} - c'(t,\omega) \]

where \( c' \in L^1([0,T] \times \Omega) \).

Consider the other inequality. Let \( \| z \|_{V^p} \leq 1 \). Then
\[ |\langle A(t,u+q(t,\omega),\omega), z \rangle| \leq k \| u + q(t,\omega) \|^{p-1} + c^{1/p'}(t,\omega) \]

Since \( p \geq 2 \), a convexity argument shows that
\[ \langle A(t,u+q(t,\omega),\omega), z \rangle \leq k \left( 2^{p-2} \| u \|^{p-1} + 2^{p-2} \| q(t,\omega) \|^{p-1} \right) + c^{1/p'}(t,\omega) \]
\[ = 2^{p-2}k \| u \|^{p-1} + (\bar{c}(t,\omega))^{1/p'} \]

where \( \bar{c} \in L^1([0,T] \times \Omega) \). Thus the same two inequalities continue to hold. \[ \square \]

In what follows, \( c \geq 0 \) and is in \( L^1([0,T] \times \Omega) \), the \( \sigma \) algebra being \( \mathcal{B}([0,T]) \times \mathcal{F}_T \).

\[ \langle A(t,u,\omega), u \rangle_{V^p} \geq \delta \| u \|_{V^p} - c(t,\omega) \quad (74.3.14) \]
\[ \| A(t,u,\omega) \|_{V^p} \leq k \| u \|_{V^p}^{p-1} + c^{1/p'}(t,\omega) \quad (74.3.15) \]

Letting \( \bar{A} \) be defined above in \( \mathbb{F} \times \mathbb{R} \),
\[ \bar{A}(t,u,\omega) \equiv A(t,u+q,\omega) \equiv \bar{A}(\omega)(t,u) \]

Assume the following pathwise uniqueness condition which is the hypothesis of the following lemma.
Lemma 74.3.3 Suppose it is true that whenever \( u, v \in V \) and
\[
B u (t) - B v (t) + \int_0^t A (u) - A (v) \, ds = 0
\]  
(74.3.16)
it follows that \( u = v \). Then if
\[
(B u)' + A (\omega) u = f \text{ in } V', \quad B u (0) = B u_0 \\
(B v)' + A (\omega) v = f \text{ in } V', \quad B v (0) = B v_0
\]  
(74.3.17)
it follows that \( u = v \) in \( V \). Here \( u_0 \in W \).

**Proof:** If \( (B u)' + A (\omega) u = f \) and \( (B v)' + A (\omega) v = f \), then
\[
B u (t) - B v (t) + \int_0^t A (u + q) - A (v + q) \, ds = 0
\]
Hence
\[
B (u (t) + q (t)) - B (v (t) + q (t)) + \int_0^t A (u + q) - A (v + q) \, ds = 0
\]
and so \( u + q = v + q \) showing that \( u = v \). \( \blacksquare \)

We give the following measurability lemma.

Lemma 74.3.4 Suppose \( f_n \) is progressively measurable and converges weakly to \( \bar{f} \) in
\[
L^\alpha ([0,T] \times \Omega, X, \mathcal{B}([0,T]) \times \mathcal{F}_T), \quad \alpha > 1
\]
where \( X \) is a reflexive separable Banach space. Also suppose that for each \( \omega \notin N \) a set of measure zero,
\[
f_n (\cdot, \omega) \to f (\cdot, \omega) \text{ weakly in } L^\alpha (0,T,X)
\]
Then there is an enlarged set of measure zero, still denoted as \( N \) such that for \( \omega \notin N \),
\[
\bar{f} (\cdot, \omega) = f (\cdot, \omega) \text{ in } L^\alpha (0,T,X).
\]
Also \( \bar{f} \) is progressively measurable.

**Proof:** By the Pettis theorem, \( \bar{f} \) is progressively measurable. Letting \( \phi \in L^{\alpha'} ([0,T] \times \Omega, X', \mathcal{B}([0,T]) \times \mathcal{F}_T) \), it is known that for a.e. \( \omega \),
\[
\int_0^T \langle \phi (t, \omega), f_n (t, \omega) \rangle \, dt \to \int_0^T \langle \phi (t, \omega), f (t, \omega) \rangle \, dt
\]
Therefore, the function of $\omega$ on the right is at least $F_T$ measurable. Now let $g \in L^\infty(\Omega, X', F_T)$ and let $\psi \in C([0, T])$. Then for $1 < p \leq \alpha$,

$$
\left| \int_\Omega \int_0^T \langle g(\omega) \psi(t), f_n(t, \omega) \rangle \, dt \right|^p \, dP \\
\leq C(T) \int_\Omega \|g\|^p_{L^\infty(\Omega, X')} \int_0^T |\psi(t)|^p \|f_n(t, \omega)\|^p_X \, dt \, dP \\
\leq C(T, g, \psi) \int_\Omega \int_0^T \|f_n(t, \omega)\|^p_X \, dt \, dP \leq C < \infty
$$

for some $C$. Since $\int_0^T \langle g(\omega) \psi(t), f_n(t, \omega) \rangle \, dt$ is bounded in $L^p(\Omega)$ independent of $n$ because $\int_\Omega \int_0^T \|f_n(t, \omega)\|^p_X \, dt \, dP$ is given to be bounded, it follows that the functions

$$
\omega \rightarrow \int_0^T \langle g(\omega) \psi(t), f_n(t, \omega) \rangle \, dt
$$

are uniformly integrable and so it follows from the Vitali convergence theorem that

$$
\int_\Omega \int_0^T \langle g(\omega) \psi(t), f_n(t, \omega) \rangle \, dt \, dP \rightarrow \int_\Omega \int_0^T \langle g(\omega) \psi(t), f(t, \omega) \rangle \, dt \, dP
$$

But also from the assumed weak convergence to $\bar{f}$

$$
\int_\Omega \int_0^T \langle g(\omega) \psi(t), f_n(t, \omega) \rangle \, dt \, dP \rightarrow \int_\Omega \int_0^T \langle g(\omega) \psi(t), \bar{f}(t, \omega) \rangle \, dt \, dP
$$

It follows that

$$
\int_\Omega \left\langle g(\omega), \int_0^T (f - \bar{f}) \psi(t) \, dt \right\rangle \, dP = 0
$$

This is true for every such $g \in L^\infty(\Omega, X')$, and so for a fixed $\psi \in C([0, T])$ and the Riesz representation theorem,

$$
\int_\Omega \left\| \int_0^T (f - \bar{f}) \psi(t) \, dt \right\|_X \, dP = 0
$$

Therefore, there exists $N_\psi$ such that if $\omega \notin N_\psi$, then

$$
\int_0^T (f - \bar{f}) \psi(t) \, dt = 0
$$

Enlarge $N$, the exceptional set to also include $\cup_{\psi \in D} N_\psi$ where $D$ is a countable dense subset of $C([0, T])$. Therefore, if $\omega \notin N$, then the above holds for all $\psi \in C([0, T])$. It follows that for such $\omega$, $f(t, \omega) = \bar{f}(t, \omega)$ for a.e. $t$. Therefore, $f(\cdot, \omega) = \bar{f}(\cdot, \omega)$ in $L^\alpha(0, T, X)$ for all $\omega \notin N$. ■

Then one can obtain the following existence theorem using a technique of Bardos and Brezis [13].
Lemma 74.3.5 Let \( q \in V \) and let the conditions \( 74.3.14 \) - \( 74.3.17 \) be valid. Let \( f \in V' \) be given. Then for each \( \omega \) off a set of measure zero, there exists \( u (\cdot, \omega) \in V_\omega \) such that \( (Bu)' (\cdot, \omega) \in V_\omega' \) and

\[
Bu (0, \omega) = 0
\]

and also the following equation holds in \( V_\omega' \) for a.e. \( \omega \)

\[
(Bu)' (\cdot, \omega) + \tilde{A} (\omega) (\cdot, u (\cdot, \omega)) = f (\cdot, \omega)
\]

In addition to this, it can be assumed that \( (t, \omega) \to u (t, \omega) \) is progressively measurable into \( V \). That is, for each \( \omega \) off a set of measure zero, \( t \to u (t, \omega) \) can be modified on a set of measure zero in \([0, T]\) such that the resulting \( u \) is progressively measurable.

**Proof:** Consider the equation

\[
L_h Bu + \tilde{A} u = \frac{1}{h} (I - \tau_h) (Bu) + \tilde{A} u = f \text{ in } V'
\]  

(74.3.18)

By Proposition \( 74.2.4 \) and Theorem \( 74.2.6 \), there exists a solution to the above equation if the left side is coercive. However, it was shown above in the computations leading to \( 74.2.5 \) that \( L_h \circ B \) is monotone. Hence the coercivity follows right away from Lemma \( 74.3.2 \).

Thus \( 74.3.18 \) holds in \( V' \). It follows that, indexing the solution by \( h \),

\[
\int_\Omega \int_0^T \frac{1}{h} (I - \tau_h) (Bu_h) + \tilde{A} u_h - f \biggvert_{V'}^p dtdP = 0
\]

and so there exists a set of measure zero \( N_h \) such that for \( \omega \notin N_h \), the following equation holds in \( V_\omega' \)

\[
\frac{1}{h} (I - \tau_h) (Bu_h (\cdot, \omega)) + \tilde{A} (\omega) (u_h (\cdot, \omega)) = f (\cdot, \omega)
\]

Let \( h \) denote a sequence converging to 0 and let \( N \) be a set of measure zero which includes \( \cup_h N_h \).

Letting \( u_h \in V \) be the above solution to \( 74.3.18 \), it also follows from the above estimates \( 74.3.14 \) - \( 74.3.17 \) that for \( \omega \) off \( N \), \( \| u_h (\cdot, \omega) \|_{V_\omega} \) is bounded independent of \( h \). Thus, for such \( \omega \) off this set, there exists a subsequence still called \( u_h \) such that the following convergences hold.

\[
u_h \rightharpoonup u \text{ in } V_\omega
\]

\[
\tilde{A} (\omega) u_h \rightharpoonup \xi \text{ in } V_\omega'
\]

\[
\frac{1}{h} (I - \tau_h) (Bu_h) \rightharpoonup \zeta \text{ in } V_\omega'
\]
First we need to identify $\zeta$. Let $\phi \in C^\infty ([0,T])$ where $\phi = 0$ near $T$ and let $w \in V$. Then
\[
\left\langle \int_0^T \zeta \phi, w \right\rangle = \lim_{h \to 0} \left\langle \int_0^T \frac{1}{h} (I - \tau_h) (Bu_h), w \phi \right\rangle
\]
\[
= \lim_{h \to 0} \left\langle \int_0^T \frac{Bu_h (t)}{h} \phi (t) - \int_h^T \frac{Bu_h (t - h)}{h} \phi (t), w \right\rangle
\]
\[
= \lim_{h \to 0} \left\langle \int_0^T \frac{Bu_h (t)}{h} \phi (t) - \int_0^{T-h} \frac{Bu_h (t)}{h} \phi (t + h), w \right\rangle
\]
\[
= \lim_{h \to 0} \left( \left\langle \int_0^{T-h} \frac{Bu_h (t)}{h} \phi (t) - \frac{\phi (t + h)}{h}, w \right\rangle + \int_0^{T-h} \frac{Bu_h (t)}{h} \phi (t) \right)
\]
\[
= \left\langle - \int_0^T Bu \phi' (t), w \right\rangle
\]
Since this holds for all $\phi \in C^\infty_c (0,T)$, it follows that $\zeta = (Bu)'$. Hence letting $\phi$ be an arbitrary function in $C^\infty ([0,T])$ which equals zero near $T$, this implies from the above that
\[
\left\langle - \int_0^T \zeta \phi, w \right\rangle = \left\langle \int_0^T Bu (t) \phi' (t), w \right\rangle
\]
\[
= \left\langle \int_0^T (Bu (0) + \int_0^t (Bu)' (s) ds) \phi' (t), w \right\rangle
\]
\[
= \int_0^T (Bu (0), w) \phi' (t) dt + \left\langle \int_0^T \int_0^t (Bu)' (s) d\phi' (t), w \right\rangle
\]
\[
= - (Bu (0), w) \phi (0) + \left\langle \int_0^T (Bu)' (s) \int_s^T \phi' (t) dtds, w \right\rangle
\]
\[
= - (Bu (0), w) \phi (0) - \left\langle \int_0^T (Bu)' (s) \phi (s) ds, w \right\rangle
\]
Hence, since $\zeta = (Bu)'$, \[0 = - (Bu (0), w) \phi (0)\] Then it follows that, $(Bu (0), w) = 0$. Since $w$ was arbitrary, $Bu (0) = 0$ and $\zeta = (Bu)'$.

Thus, passing to a limit in $\mathcal{V}'$, \[(Bu)' + \xi = f \text{ in } \mathcal{V}'_w, \quad Bu (0) = 0\]
It is desired to identify $\xi$ with $\tilde{A}(\omega) u$. First let

$$L_h \equiv \frac{I - \tau_h}{h}$$

Then

$$L_h (Bu)(t) = \begin{cases} \frac{1}{h} \int_{t-h}^t (Bu)' \, ds & \text{if } t \geq h \\ \frac{1}{h} \int_0^t (Bu)' \, ds & \text{if } t < h \end{cases}$$

Then from standard considerations involving approximate identities,

$$\lim_{h \to 0} L_h (Bu) = (Bu)' \text{ strongly in } V_\omega' \quad (74.3.19)$$

Thus

$$\langle L_h (Bu) - (Bu)', u_h - u \rangle =$$

$$\langle L_h (Bu) - L_h (Bu), u_h - u \rangle + \langle L_h (Bu) - (Bu)', u_h - u \rangle$$

$$\geq \langle L_h (Bu) - (Bu)', u_h - u \rangle$$

and the above strong convergence implies that this converges to 0. Therefore, from

$$L_h Bu_h + \tilde{A} u_h = f \text{ in } V_\omega'$$

and so

$$\langle L_h Bu_h, u_h - u \rangle + \langle \tilde{A} u_h, u_h - u \rangle = \langle f, u_h - u \rangle$$

From the above,

$$\langle (Bu)', u_h - u \rangle + \langle L_h (Bu) - (Bu)', u_h - u \rangle + \langle \tilde{A} u_h, u_h - u \rangle \leq \langle f, u_h - u \rangle$$

and so, taking $\limsup_{h \to 0}$ of both sides, it follows from [74.3.18] that

$$\limsup_{h \to 0} \langle \tilde{A} u_h, u_h - u \rangle \leq 0, \quad \limsup_{h \to 0} \langle \tilde{A} u_h, u_h \rangle \leq \langle \xi, u \rangle$$

Since $A$ is monotone and hemicontinuous, the same is true of $\tilde{A}$ and so

$$\tilde{A} u = \xi$$

Thus

$$((Bu)'(\cdot, \omega)) + \tilde{A}(\omega) u(\cdot, \omega) = f(\cdot, \omega) \text{ in } V_\omega', \quad Bu(0, \omega) = 0 \quad (74.3.20)$$

It follows from the uniqueness assumption [74.3.17] that for each $\omega$ off a set of measure zero, there exists a unique solution to

$$(Bu)'(\cdot, \omega) + \tilde{A}(\cdot, u(\cdot, \omega), \omega) = f(\cdot, \omega) \text{ in } V_\omega', \quad B(u(\cdot, \omega))(0) = 0$$
You can consider the function of two variables $u(t, \omega)$. Is this function progressively measurable? Right now, this is not clear because we have done nothing more than solve a problem for each $\omega$.

However, we can at least say that $u_h$ is progressively measurable because $u_h \in \mathcal{V}$. Recall also that

$$\frac{1}{h} (I - \tau_h) B u_h + \bar{A}(\omega) u_h = f, \ u_h \in \mathcal{V}$$

Next we show that because of uniqueness, one can assume that $u$ is progressively measurable. To do this, we show that the sequence for which convergence holds in the above can be chosen independent of $\omega$.

Claim: A single sequence $h \to 0$ works for all $\omega$ off a set of measure zero.

Proof: Since there is only one solution to the above initial value problem for $\omega \notin N$, then letting $h \to 0$ be a single sequence, one can conclude that $u_h (\cdot, \omega) \to u (\cdot, \omega)$ in $\mathcal{V}_\omega = L^p(0, T, \mathcal{V})$. Otherwise, from the above argument, one could obtain another subsequence which converges to a solution different than $u (\cdot, \omega)$ which would violate uniqueness.

From the coercivity condition, it follows that there exists a constant $C (f)$ depending on $f$ such that for all $h$,

$$\|u_h\|_\mathcal{V} \leq C (f)$$

Therefore, there is a further subsequence still denoted by $h$ such that

$$u_h \rightharpoonup \bar{u} \text{ in } L^p ([0, T] \times \Omega; \mathcal{V})$$

where the measurable sets are just the product measurable sets $\mathcal{B}([0, T]) \times \mathcal{F}_T$. Then it follows from Lemma 74.3.2 that $u (\cdot, \omega) = \bar{u} (\cdot, \omega)$ in $\mathcal{V}_\omega$ for all $\omega$ off a set of measure zero. It follows that in all of the above, we could substitute $\bar{u}$ for $u$ at least for $\omega$ off a single set of measure zero. Thus $u$ can be assumed progressively measurable.

Note the importance of path uniqueness in obtaining the result on progressive measurability of the solutions.

We will write $u$ rather than $\bar{u}$ to save notation. Now with this lemma, it is easy to obtain the following proposition.

**Proposition 74.3.6** Let $q \in \mathcal{V}$ such that $t \to q(t, \omega)$ is continuous and $q(0, \omega) = 0$, and let the conditions [74.3.14] - [74.3.17] be valid. Also let $u_0 \in L^2 (\Omega, \mathcal{V})$ such that $u_0$ is $\mathcal{F}_0$ measurable. Let $f \in \mathcal{V}'$ be given. Then for each $\omega$ off a set of measure zero, there exists $u (\cdot, \omega) \in \mathcal{V}_\omega$ such that $(Bu) (\cdot, \omega) \in \mathcal{V}_\omega'$ and

$$Bu(0, \omega) = Bu_0$$

and also the following equation holds in $\mathcal{V}_\omega'$ for a.e. $\omega$

$$(Bu - Bq)'(\cdot, \omega) + A (\cdot, u (\cdot, \omega), \omega) = f (\cdot, \omega)$$

In addition to this, it can be assumed that $(t, \omega) \to u(t, \omega)$ is progressively measurable into $\mathcal{V}$. That is, for each $\omega$ off a set of measure zero, $t \to u(t, \omega)$ can be modified
CHAPTER 74. IMPLICIT STOCHASTIC EQUATIONS

on a set of measure zero in \([0, T]\) such that the resulting \(u\) is progressively measurable. Then one also obtains that \(u\) is the unique solution to the integral equation which holds for a.e. \(\omega\)

\[
Bu(t, \omega) - Bu_0 + \int_0^t A(s, u(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bq(t, \omega) \tag{74.3.22}
\]

**Proof:** Recall

\[
\bar{A}(\omega)(t, u) \equiv A(t, u + q(t, \omega), \omega)
\]
where \(q\) was in \(V\). Therefore, replace this definition of \(A\) with

\[
\bar{A}(\omega)(t, u) \equiv A(t, u + q(t, \omega) + u_0, \omega)
\]
Then from Lemma \[74.3.5\] there exists \(w \in V\) such that

\[
(Bw)\prime(\cdot, \omega) + A(\cdot, w(\cdot, \omega) + q(\cdot, \omega) + u_0(\omega), \omega) = f(\cdot, \omega), \quad Bw(0) = 0
\]
Let \(u(t, \omega) = w(t, \omega) + q(t, \omega) + u_0(\omega)\). Then for fixed \(\omega\), \(Bu(0) = Bw(0) + Bu_0 = Bu_0\). Also

\[
(B(u-q))\prime + A(\cdot, u, \omega) = f(\cdot, \omega), \quad Bu(0) = Bu_0
\]
Then an integration yields \[74.3.22\]. Uniqueness follows from the above uniqueness assumption.

One can easily generalize this using an exponential shift argument.

**Corollary 74.3.7** Suppose the situation of the above proposition but that all that is known is that \(\lambda B + A\) is monotone and hemicontinuous on \(V\) for all \(\lambda\) sufficiently large. Then defining

\[
(A(\lambda(t, w, \omega), v)_{V', V} \equiv \langle e^{-\lambda t} A(t, e^{\lambda t} w, \omega), v \rangle_{V', V}
\]
for such \(\lambda\), it follows that \(\lambda B + A_\lambda\) is also monotone and hemicontinuous. Then replace the coercivity, and boundedness conditions above with the following weaker conditions

\[
\lambda \langle Bu, u \rangle + \langle A(t, u, \omega), u \rangle_V \geq \delta \|u\|_V^p - c(t, \omega) \tag{74.3.23}
\]
for all \(\lambda\) large enough.

\[
\|A(t, u, \omega)\|_V \leq k\|u\|_V^{p-1} + e^{1/p'}(t, \omega) \tag{74.3.24}
\]
where \(c \in L^1([0,T] \times \Omega), c \geq 0\). Then the conclusion of Proposition \[74.3.6\] is still valid. There exists a unique \(u \in V\) such that for a.e. \(\omega\),

\[
(Bu - Bq)'(\cdot, \omega) + A(\cdot, u(\cdot, \omega)) = f(\cdot, \omega), \quad B(u-q)(0) = Bu_0 \tag{74.3.25}
\]

**Proof:** That \(\lambda B + A_\lambda\) is monotone and hemicontinuous follows from the definition. Also, from the above estimates,

\[
\lambda \langle Bu, u \rangle + \langle A_\lambda(t, u, \omega), u \rangle_V \geq e^{-2\lambda t}(\lambda \langle B(e^{\lambda t} u), e^{\lambda t} u \rangle + \langle A(t, e^{\lambda t} u, \omega), e^{\lambda t} u \rangle)
\]
74.3. THE EXISTENCE OF APPROXIMATE SOLUTIONS

\[ \geq e^{-2\lambda t} \left( \delta \| e^{\lambda t} u \|^p_V - c(t, \omega) \right) \geq e^{-2\lambda t} \left( \delta \| e^{\lambda t} u \|^p_V - e^{\lambda p t} e^{-\lambda p t} c(t, \omega) \right) \]

\[ \geq e^{-2\lambda t} e^{\lambda p t} (\delta \| u \|^p_V - e^{-\lambda p t} c(t, \omega)) \geq \delta \| u \|^p_V - e^{-\lambda p t} c(t, \omega) \]

which is of the right form.

Similarly

\[
\| \lambda Bw + A \left( t, w, \omega \right) \|_V \leq \| \lambda Bw \|_V + \| e^{-\lambda t} A \left( t, e^{\lambda t} w, \omega \right) \|_V,
\]

\[
\leq \lambda \| B \| \| w \|_V + e^{-\lambda t} \| A \left( t, e^{\lambda t} w, \omega \right) \|_V,
\]

\[
\leq \lambda \| B \| \| w \|_V + e^{-\lambda t} \| k \|_V + e^{\lambda t} e^{\lambda t} \| w \|_V = p^{-1} + e^{-\lambda t} e^{\lambda t} \| w \|_V
\]

Since \( p \geq 2 \), this is no larger than

\[
\leq (\lambda \| B \|)^{p/(p-p')} + \| w \|_V^{p-1} + e^{(p-1)p} e^{\lambda t} \| w \|_V^{p-1} + e^{-\lambda t} e^{\lambda t} \| w \|_V
\]

\[
\leq (e^{p-2})^{\lambda t} + 1 \| w \|_V^{p-1} + e^{-\lambda t} e^{\lambda t} \| w \|_V + (\lambda \| B \|)^{p/(p-p')}\]

\[\equiv \bar{k} \| w \|_V^{p-1} + \bar{c}(t, \omega)^{1/p'} \]

Now note that \( w \) is a solution to

\[
B \left( w - e^{-\lambda(t)} q \right)' + \lambda B w + e^{-\lambda(t)} A \left( t, e^{\lambda(t)} w, \omega \right) = e^{-\lambda(t)} f \left( \cdot, \omega \right) + \lambda B e^{-\lambda(t)} q \left( \cdot, \omega \right) \quad \text{in } V \omega
\]

\[
B \left( w - e^{-\lambda(t)} q \right) (0) = Bu_0
\]

if and only if \( u(t) \equiv e^{\lambda t} w(t) \) is a solution to

\[
B \left( u - q \right)' + A \left( t, u, \omega \right) = f \left( \cdot, \omega \right), \quad B \left( u - q \right) (0) = Bu_0
\]

Thus the necessary uniqueness condition holds for the initial value problem for \( w \) and hence it follows from Proposition 74.3.1 that there exists a unique progressively measurable solution to the initial value problem for \( w \) and hence a unique progressively measurable solution to the above one for \( u \).

Now suppose the situation of the above corollary and let \( E \) be a separable Hilbert space which is dense in \( V \) and let

\[
\Phi \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, E \right) \right), \quad \Phi \text{ being progressively measurable},
\]

so that one can consider the stochastic integral \( \int_0^t \Phi dW \). Let

\[
\tau_n \equiv \inf \left\{ t : \left\| \int_0^t \Phi dW \right\|_E > 2^n \right\}
\]
Thus
\[ \left\| \int_0^{t \wedge \tau_n} \Phi dW \right\|_E \leq 2^n \]

Then you could pick \( u_0 \in L^p(\Omega, V), u_0 \) being \( \mathcal{F}_0 \) measurable, and let
\[ q(t, \omega) = \int_0^{t \wedge \tau_n} \Phi dW. \]

The result is clearly in \( V \) and is continuous in \( t \). Therefore, from Corollary 74.3.7, there exists a unique solution \( u \in V \) to the initial value problem
\[ (Bu - B \int_0^{t \wedge \tau_n} \Phi dW)'(\cdot, \omega) + A(\omega)(u(\cdot, \omega)) = f(\cdot, \omega), \quad Bu(0) = Bu_0. \]

Integrating, one obtains a unique solution \( u_n \in V \) to the integral equation
\[ Bu_n(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u_n, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^{t \wedge \tau_n} \Phi dW. \]

This holds in \( V'_\omega \) and is so for all \( \omega \) off a set of measure zero \( N_n \). Let \( N = \cup_n N_n \). For \( \omega \notin N, t \to \int_0^t \Phi dW \) is continuous and so for all \( n \) large enough, \( \tau_n = \infty \). Thus for a fixed \( \omega \), it follows that for all \( n \) large enough \( \tau_n = \infty \) and so one obtains
\[ Bu_n(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u_n, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi dW. \]

Then for \( k \) some other index sufficiently large, the same holds for \( u_k \). By the uniqueness assumption 74.3.17, \( u_k(t, \omega) = u_n(t, \omega) \) and so it follows that \( \lim_{n \to \infty} u_n(t, \omega) \) exists because for each \( \omega \) off a set of measure zero, there is eventually no change in \( u_n \). Defining \( u(t, \omega) = \lim_{n \to \infty} u_n(t, \omega) \equiv u_n(t, \omega) \) for all \( n \) large enough, it follows that \( u \) is progressively measurable since it is the pointwise limit of progressively measurable functions and
\[ Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi dW. \]

This has shown the following lemma.

**Lemma 74.3.8** Let \( (t, u, \omega) \to A(t, u, \omega) \) be progressively measurable into \( V' \) and suppose for some \( \lambda \),
\[ \lambda B + A(\omega) : V_\omega \to V'_\omega, \]
\[ \lambda B + A : V \to V' \]
are both monotone bounded and hemicontinuous. Also suppose the two estimates giving boundedness and coercivity 74.3.23 - 74.3.24 of Corollary 74.3.7 above. Here \( V, W \) are as described above \( V \subseteq W, W' \subseteq V' \), \( V \) is a separable Hilbert space and
74.4. THE GENERAL CASE

\( V \) is a separable reflexive Banach space. \( B : W \to W' \) is nonnegative and self adjoint. Let \( f \in V' \) and let \( u_0 \in L^p(\Omega, V) \) where \( u_0 \) is \( \mathcal{F}_0 \) measurable. Then if \( \Phi \in L^2\left([0,T] \times \Omega, \mathcal{L}_2\left(Q^{1/2}U, E\right)\right) \), \( \Phi \) being progressively measurable, into \( E \), where \( E \) is a Hilbert space dense in \( V \) with \( \|u\|_E \geq \|u\|_V \), then there exists a unique solution to the integral equation

\[
Bu(t) - Bu_0 + \int_0^t A(s, u, \omega) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \Phi \, dW
\]

in the sense that \( u \) is in \( V \) and there exists a set of measure zero \( N \) such that if \( \omega \notin N \), then the above integral equation holds for all \( t \).

74.4 The General Case

Suppose \( \lambda B + A(\omega), \lambda B + A \) are both monotone bounded and hemicontinuous on \( V \) respectively for \( \lambda \) sufficiently large. Also suppose the two estimates giving boundedness and coercivity above. We strengthen the assumption that \( \lambda B + A(\omega) \) is monotone as follows. In the usual case where \( B \) is the identity, this conclusion is obvious, but here we need to assume it.

\[
((\lambda B + A(\omega)) (u) - (\lambda B + A(\omega)) (v), u - v) \geq \delta \| u - v \|_U^\alpha, \quad \alpha \geq 1 \quad (74.4.26)
\]

where here \( U \) is a reflexive Banach space such that \( V \subseteq U \) and the inclusion map is continuous, \( V \) being dense in \( U \). In regards to this monotonicity condition, here is a simple lemma which will be used later.

**Lemma 74.4.1** Suppose \( u_n \to w \) weakly in \( V \) and that for a.e.t, \( u_n(t) \to u(t) \) in \( U \). Then \( w(t) = u(t) \) a.e.

**Proof:** You know that \( \|u_n\|_{L^p([0,T], V)} \) is bounded. Now consider \( \phi \in U' \) and \( \psi \in C\left([0,T]\right) \). Then the weak convergence implies

\[
\lim_{n \to \infty} \int_0^T \left\langle \phi, u_n \right\rangle_{U', U} \psi \, dt = \int_0^T \left\langle \phi, w \right\rangle_{U', U} \psi \, dt
\]

because it is also the case that \( u_n \to w \) weakly in \( L^p\left([0,T], U\right) \). However, the fact that \( \|u_n\|_{L^p([0,T], V)} \) is bounded means that, by the assumed pointwise convergence,

\[
\lim_{n \to \infty} \int_0^T \left\langle \phi, u_n \right\rangle_{U', U} \psi \, dt = \int_0^T \left\langle \phi, u \right\rangle_{U', U} \psi \, dt
\]

It follows that

\[
\int_0^T \left\langle \phi, u - w \right\rangle \psi \, dt = 0
\]
Since this is true for all \( \psi \in C ([0, T]) \), there exists a set of measure zero \( Q_\phi \) such that for \( t \notin Q_\phi \),

\[
\langle \phi, u(t) - w(t) \rangle = 0
\]

Letting \( Q = \bigcup_{\phi \in D} Q_\phi \), where \( D \) is a countable dense subset of \( U' \), it follows that for \( t \notin Q \), the above holds for all \( \phi \in U' \). Hence \( u(t) = w(t) \) for \( t \notin Q \) and \( m(Q) = 0 \).

Typically \( \alpha = 2 \) and \( U = W \).

Recall that \( V \subseteq W \), \( W' \subseteq V' \)

each space dense in the one to its right and the inclusion maps are continuous.

Assume only

\[
\Phi \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, W \right) \right).
\]

By density of \( E \) into \( W \), there exists a sequence

\[
\Phi_n \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, E \right) \right)
\]

such that

\[
\| \Phi_n - \Phi \|_{L^2 ([0, T] \times \Omega, \mathcal{L}_2 (Q^{1/2} U, W))} \to 0,
\]

\[
\| \Phi_n \|_{\mathcal{L}_2 (Q^{1/2} U, W)} \leq \| \Phi \|_{\mathcal{L}_2 (Q^{1/2} U, W)}.
\]

Also let \( u_{0n} \in L^p (\Omega, V) \) where \( u_{0n} \) is \( F_0 \) measurable and such that \( u_{0n} \in L^p (\Omega, V) \) and

\[
\| u_{0n} (\omega) - u_0 (\omega) \|_W \to 0, \quad \langle Bu_{0n}, u_{0n} \rangle \leq 2 \langle Bu_0, u_0 \rangle
\]

for each \( \omega \). The existence of such an approximating sequence follows from density considerations of \( E \) into \( V \) and of \( V \) into \( W \).

By Lemma 74.3.8 there is a solution \( u_n \) to the integral equation

\[
Bu_n (t) - Bu_0 + \int_0^t A(s, u_n, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi_n dW \quad (74.4.27)
\]

Then by the Implicit Ito formula there is a set of measure zero such that for all \( n, m \)

\[
\frac{1}{2} \langle B(u_n - u_m), u_n - u_m \rangle (t) - \frac{1}{2} \langle Bu_0, u_{0n} - u_{0m} \rangle + \delta \int_0^t \| u_n - u_m \|^2_U ds
\]

\[
\leq \lambda \int_0^t \langle B(u_n - u_m), u_n - u_m \rangle (s) ds
\]

\[
+ \frac{1}{2} \int_0^t \langle B(\Phi_n - \Phi_m), \Phi_n - \Phi_m \rangle \mathcal{L}_2 ds + M_{mn} (t)
\]
Also the last term is a martingale whose quadratic variation satisfies
\[
\mathbb{M}_{mn}(t) \leq C \int_0^t \|\Phi_n - \Phi_m\|^2_{L^2(Q^{1/2};W)} \|B(u_n - u_m)\|^2_W \, ds
\]
\[
\leq C \int_0^t \|\Phi_n - \Phi_m\|^2_{L^2(Q^{1/2};W)} \langle Bu_n - Bu_m, u_n - u_m \rangle \, ds
\]
Then from Gronwall’s inequality, and adjusting the constants,
\[
\langle Bu_n - Bu_m, u_n - u_m \rangle(t) + \int_0^t \|u_n - u_m\|_U^\alpha \, ds
\]
\[
\leq C (u_{0n} - u_{0m}, \Phi_n - \Phi_m) + C(T) M^*_{mn}(t)
\]
where the expectation of the first constant on the right converges to 0 as \(m,n \to \infty\).
Here
\[
M^*_{nm}(t) = \sup_{s \in [0,t]} |M_{nm}(s)|
\]
Since \(M^*\) is increasing, this implies that after adjusting constants,
\[
\sup_{s \in [0,t]} \left( \langle Bu_n - Bu_m, u_n - u_m \rangle(s) + \int_0^t \|u_n - u_m\|_U^\alpha \, ds \right)
\]
\[
\leq C (u_{0n} - u_{0m}, \Phi_n - \Phi_m) + C(T) M^*_{mn}(t)
\]
Then taking expectations and using the Burkholder Davis Gundy inequality,
\[
E \left( \sup_{s \in [0,t]} \left( \langle Bu_n - Bu_m, u_n - u_m \rangle(s) + \int_0^t \|u_n - u_m\|_U^\alpha \, ds \right) \right)
\]
\[
\leq C (u_{0n} - u_{0m}, \Phi_n - \Phi_m) +
\]
\[
C(T) \int_{\Omega} \left( \int_0^t \|\Phi_n - \Phi_m\|^2_{L^2(Q^{1/2};W)} \langle Bu_n - Bu_m, u_n - u_m \rangle \, ds \right)^{1/2} \, dP
\]
\[
\leq C_{n,m} + 2C \int_{\Omega} \sup_{s \in [0,t]} \langle Bu_n - Bu_m, u_n - u_m \rangle^{1/2}(s) \cdot
\]
\[
\left( \int_0^t \|\Phi_n - \Phi_m\|^2_{L^2(Q^{1/2};W)} \right)^{1/2} \, dP
\]
Then adjusting the constants,
\[
E \left( \sup_{s \in [0,t]} \left( \langle Bu_n - Bu_m, u_n - u_m \rangle(s) + \int_0^t \|u_n - u_m\|_U^\alpha \, ds \right) \right)
\]
\[
\leq C_{n,m} + C \int_{\Omega} \int_0^T \|\Phi_n - \Phi_m\|^2_{L^2(Q^{1/2};W)} \, dt \, dP \equiv C_{n,m}
\]
where \( C_{n,m} \to 0 \) as \( n, m \to \infty \). In particular, it is true for \( t = T \)

\[
E \left( \sup_{s \in [0,T]} \langle B(u_n - u_m), u_n - u_m \rangle (s) + \int_0^T \| u_n - u_m \|_U^\alpha \, ds \right) \leq C_{n,m}
\]

Then

\[
P \left( \sup_{s \in [0,T]} \langle B(u_n - u_m), u_n - u_m \rangle (s) + \int_0^T \| u_n - u_m \|_U^\alpha \, ds \geq \lambda \right) \leq \frac{C_{n,m}}{\lambda}
\]

Now take a subsequence such that if \( m > n_k, C_{n_k,m} < 4^{-k} \). Then the above inequality implies that

\[
P \left( \sup_{s \in [0,T]} \langle B(u_n - u_m), u_n - u_m \rangle (s) + \int_0^T \| u_{n_k} - u_{n_{k+1}} \|_U^\alpha \, ds \geq 2^{-k} \right) \leq \frac{4^{-k}}{2^{-k}} = 2^{-k}
\]

and so, by the Borel Cantelli lemma, there is a set of measure zero \( N \) including all earlier exceptional sets of measure zero such that for \( \omega \notin N \),

\[
\sup_{s \in [0,T]} \langle B(u_n - u_m), u_n - u_m \rangle (s) + \int_0^T \| u_{n_k} - u_{n_{k+1}} \|_U^\alpha \, ds < 2^{-k}
\]

for all \( k \) large enough. We will denote this new subsequence by \( \{u_n\} \). Thus for such \( \omega \), it follows that \( Bu_n \) is a Cauchy sequence in \( C(N^C, W') \) for \( N_\omega \), an exceptional set of measure zero where \( B(u_n - u_m) (t) \neq B(u_n (t) - u_m (t)) \) and also \( \{u_n\} \) is a Cauchy sequence in \( L^\alpha (0, T, U) \). It follows

\[
Bu_n \to z \text{ strongly in } C(N^C, W') \text{ with uniform norm} \tag{74.4.28}
\]

\[
\lim_{m,n \to \infty} \sup_{s \in [0,T]} \langle B(u_n - u_m), u_n - u_m \rangle (s) = 0 \tag{74.4.29}
\]

There exists \( u \in L^\alpha (0, T, U) \) such that for \( \omega \notin N \),

\[
\| u_n - u \|_{L^\alpha (0,T,U)} \to 0, \ u_n (t, \omega) \to u(t, \omega) \text{ for a.e.t in } U \tag{74.4.30}
\]

Of course a technical issue is the fact that \( B \) is a degenerate operator which might not be invertible. In the above limit, we do not know that \( z = Bu \) for some \( u \). We resolve this issue by obtaining pointwise estimates for a given \( \omega \) and then pass to a limit. After this, a time integration will give the desired result. There are easier ways to do this if \( B \) is not degenerate.

From now on, this or a subsequence of this one will be the sequence of interest. Return to \( [\text{previous section}] \) and use the Itô formula again. Thus using the estimates,

\[
\frac{1}{2} \langle Bu_n, u_n \rangle (t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \delta \int_0^t \| u_n \|_{V'}^p \, ds - \lambda \int_0^t \langle Bu_n, u_n \rangle \, ds
\]

\[
= \frac{1}{2} \int_0^t \langle B \Phi_n, \Phi_n \rangle \, ds + \int_0^t c(s, \omega) \, ds + \int_0^t \langle f, u_n \rangle \, ds + M_n (t)
\]
where $M_n(t)$ is a local martingale whose quadratic variation satisfies

$$[M_n](t) \leq C \int_0^t \|\Phi_n\|_{L^2}^2 \|B u_n\|_W^2 \, ds$$

Then adjusting the constants,

$$\langle B u_n, u_n \rangle(t) + \int_0^t \|u_n\|_V^p \, ds \leq C (u_{0n}, \Phi_n, f, c) + CM_n^*(t)$$

where the expectation of the first constant on the right is no larger than a constant $C$ which is independent of $n$. Since the right term is increasing in $t$,

$$\sup_{s \in [0,t]} \langle B u_n, u_n \rangle(s) + \int_0^t \|u_n\|_V^p \, ds \leq C (u_{0n}, \Phi_n, f, c) + CM_n^*(t) \quad (74.4.31)$$

Now using the Burkholder Davis Gundy inequality as before and taking the expectation,

$$E \left( \sup_{s \in [0,t]} \langle B u_n, u_n \rangle(s) \right) + E \int_0^t \|u_n\|_V^p \, ds \leq C + C \int_0^t \left( \int_0^t \|\Phi_n\|_{L^2} \|B u_n\|_W^2 \, ds \right)^{1/2} \, dP$$

Then adjusting the constants and using the approximation properties of $\Phi_n$ given above, there is a constant $C$ independent of $n, t \leq T$ such that

$$E \left( \sup_{s \in [0,t]} \langle B u_n, u_n \rangle(s) \right) + E \int_0^t \|u_n\|_V^p \, ds \leq C \quad (74.4.32)$$

In particular

$$E \left( \sup_{s \in [0,T]} \langle B u_n, u_n \rangle(s) \right) + E \int_0^T \|u_n\|_V^p \, ds \leq C$$

Next use monotonicity to obtain

$$\frac{1}{2} \langle B u_r - B u_q, u_r - u_q \rangle(t) \leq \frac{1}{2} \int_0^t \left( (\Phi_r - \Phi_q) \circ J^{-1} \right)^* B (u_r - u_q) \circ J \, dW$$

$$+ C \int_0^t \langle B u_r - B u_q, u_r - u_q \rangle \, ds + \int_0^t \|\Phi_r - \Phi_q\|_2^2 \, ds$$
and so, from Gronwall’s inequality, there is a constant $C$ which is independent of $r, q$ such that

$$\langle Bu_r - Bu_q, u_r - u_q \rangle (t) \leq CM_{rq} (t) \leq CM^*_{rq} (T) + C \int_0^t \| \Phi_r - \Phi_q \|^2 ds$$

where $M_{rq}$ refers to that local martingale on the right. Thus also

$$\sup_{t \in [0,T]} \langle Bu_r - Bu_q, u_r - u_q \rangle (t) \leq CM_{rq} (t) \leq CM^*_{rq} (T) + C \int_0^T \| \Phi_r - \Phi_q \|^2 ds$$

Taking the expectation and using the Burkholder Davis Gundy inequality again, and similar estimates to the above, using appropriate stopping times as needed, we obtain

$$E \left( \sup_{t \in [0,T]} \langle Bu_r - Bu_q, u_r - u_q \rangle (t) \right) \leq C \int \int_0^T \| \Phi_r - \Phi_q \|^2 dt dP$$

Now the right side converges to 0 as $r, q \to \infty$ and so there is a subsequence, denoted with the index $k$ such that if $p > k$,

$$E \left( \sup_{t \in [0,T]} \langle Bu_k - Bu_p, u_k - u_p \rangle (t) \right) \leq \frac{1}{2^k} \quad \text{(74.4.34)}$$

Then consider the earlier local martingales. One of these is of the form

$$M_k = \int_0^t (\Phi_k \circ J^{-1})^* Bu_k \circ J dW$$

Then by the Burkholder Davis Gundy inequality and modifying constants as appropriate,

$$E \left( (M_k - M_{k+1})^* \right) \leq C \int \int_0^T \left( \| (\Phi_k \circ J^{-1})^* Bu_k - (\Phi_{k+1} \circ J^{-1})^* Bu_{k+1} \|^2 dt \right)^{1/2} dP$$

$$\leq C \int \left( \int_0^T \| \Phi_k - \Phi_{k+1} \|^2 \langle Bu_k, u_k \rangle + \| \Phi_{k+1} \|^2 \langle Bu_k - Bu_{k+1}, u_k - u_{k+1} \rangle dt \right)^{1/2} dP$$

$$\leq C \int \left( \int_0^T \| \Phi_k - \Phi_{k+1} \|^2 \langle Bu_k, u_k \rangle dt \right)^{1/2}$$

$$+ C \int \left( \int_0^T \| \Phi_{k+1} \|^2 \langle Bu_k - Bu_{k+1}, u_k - u_{k+1} \rangle dt \right)^{1/2} dP$$
\[
\leq C \int \sup_t \langle Bu_k, u_k \rangle^{1/2} \left( \int_0^T \| \Phi_k - \Phi_{k+1} \|^2 dt \right)^{1/2} dP
\]
\add\geq C \int \sup_t \langle Bu_k - Bu_{k+1}, u_k - u_{k+1} \rangle^{1/2} \left( \int_0^T \| \Phi_{k+1} \|^2 dt \right)^{1/2} dP
\leq C \left( \int \sup_t \langle Bu_k, u_k \rangle dP \right)^{1/2} \left( \int \int_0^T \| \Phi_k - \Phi_{k+1} \|^2 dt dP \right)^{1/2}
\add\geq C \left( \int \sup_t \langle Bu_k - Bu_{k+1}, u_k - u_{k+1} \rangle dP \right)^{1/2} \left( \int \int_0^T \| \Phi_{k+1} \|^2 dt dP \right)^{1/2}
\]
From the above inequalities, after adjusting the constants, the above is no larger than an expression of the form \( C \left( \frac{1}{2} \right)^{k/2} \) which is a summable sequence. Then
\[
\sum_k \int \sup_{t \in [0,T]} \left| M_k(t) - M_{k+1}(t) \right| dP < \infty
\]

Then \( \{ M_k \} \) is a Cauchy sequence in \( M_T \) and so there is a continuous martingale \( M \) such that
\[
\lim_{k \to \infty} E \left( \sup_t |M_k(t) - M(t)| \right) = 0 \quad (74.4.35)
\]
Taking a further subsequence if needed, one can also have
\[
P \left( \sup_t |M_k(t) - M(t)| > \frac{1}{2^k} \right) \leq \frac{1}{2^k}
\]
and so by the Borel Cantelli lemma, there is a set of measure zero such that off this set, \( \sup_t |M_k(t) - M(t)| \) converges to 0. Hence for such \( \omega \), \( M^\omega_T(t) \) is bounded independent of \( k \). Thus for \( \omega \) off a set of measure zero, (74.4.35) implies that for such \( \omega \),
\[
\sup_{s \in [0,T]} \langle Bu_r, u_r \rangle (s) + \int_0^T \| u_r (s) \|^p_V ds \leq C(\omega)
\]
where \( C(\omega) \) does not depend on the index \( r \), this for the subsequence just described which will be the sequence of interest in what follows. Using the boundedness assumption for \( A \), one also obtains an estimate of the form
\[
\sup_{s \in [0,T]} \langle Bu_n, u_n \rangle (s) + \int_0^T \| u_n (s) \|^p_V ds + \int_0^T \| z_r \|^p_V, \leq C(\omega) \quad (74.4.36)
\]

**Lemma 74.4.2** There is a subsequence, still indexed by \( n \) and a set of measure zero \( N \), containing all the preceding sets of measure zero such that for \( \omega \notin N \),
\[
\sup_{s \in [0,T]} \langle Bu_n, u_n \rangle (s) + \int_0^T \| u_n \|^p_V ds \leq C(\omega) < \infty
\]
From the theory of the stochastic integral, there is a further subsequence of the above such that
\[ \int_0^t \Phi_n dW \to \int_0^t \Phi dW \text{ strongly in } C([0, T], W) \]
for all \( \omega \) off a set of measure zero. Enlarge the exceptional set \( N \) and only use subsequences of this one so that both the above estimate in the lemma and the above convergence hold for \( \omega \notin N \). Recall the integral equation solved,
\[
Bu_n(t) - Bu_0 + \int_0^t A(s, u_n, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi_n dW \quad (74.4.37)
\]
Thus
\[
\left( Bu_n - B \int_0^t \Phi_n dW - Bu_0 \right)' + Au_n = f
\]
Then for \( \omega \notin N \), a subsequence of the one for which the above lemma holds, still denoted as \( \{u_n\} \), yields the following convergences,
\[
u_n \to u \text{ weakly in } V_\omega \quad (74.4.38)
\]
\[
Au_n \rightharpoonup \xi \text{ weakly in } V'_\omega \quad (74.4.39)
\]
\[
\left( Bu_n - B \int_0^t \Phi_n dW - Bu_0 \right)' \rightharpoonup \zeta \text{ weakly in } V'_\omega \quad (74.4.40)
\]
By the earlier convergence \[74.4.30\], this \( u \) is the same as the one in \[74.4.39\].
Consider \( \zeta \). Let \( \psi \) be infinitely differentiable and equal to 0 near \( T \) and let \( g \in V \). Then since \( Bu_n(0) = Bu_0 \),
\[
\int_0^T \langle \zeta, \psi g \rangle dt = \lim_{n \to \infty} \int_0^T \left\langle \left( Bu_n - B \int_0^t \Phi_n dW - Bu_0 \right)', \psi g \right\rangle dt
\]
\[
= -\lim_{n \to \infty} \int_0^T \left\langle \left( Bu_n - B \int_0^t \Phi_n dW - Bu_0 \right)', \psi' g \right\rangle dt
\]
\[
= -\int_0^T \left\langle \psi' B g, \left( u - \int_0^t \Phi dW - u_0 \right) \right\rangle dt
\]
\[
= -\int_0^T \left\langle B \left( u - \int_0^t \Phi dW - u_0 \right), \psi' g \right\rangle dt
\]
which shows that
\[
\zeta = \left( B \left( u - \int_0^t \Phi dW - u_0 \right) \right)'
\]
74.4. THE GENERAL CASE

in the sense of \( V' \) valued distributions. Also from the above,

\[
\int_0^T \langle \zeta, \psi g \rangle \, dt = \langle Bu(0) - Bu_0, \psi(0) g \rangle + \int_0^T \left( \langle Bu - B \int_0^t \Phi dW - Bu_0, \psi' g \rangle \right) \, dt
\]

\[
= \langle Bu(0) - Bu_0, \psi(0) g \rangle + \int_0^T \langle \zeta, \psi g \rangle \, dt
\]

Hence \( B(u(0, \omega)) = Bu_0 \). Thus this has shown that

\[
\left( B \left( u - \int_0^t \Phi dW - u_0 \right) \right)' + \xi(\cdot, \omega) = f(\cdot, \omega) \text{ in } V'_\omega, \ Bu(0) = Bu_0.
\]

Thus integrating this, we get

\[
Bu(t, \omega) - Bu_0(\omega) + \int_0^t \xi(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \Phi dW \quad (74.4.41)
\]

**Lemma 74.4.3** The above sequence does not depend on \( \omega \notin N \). In fact, it is not necessary to take a further subsequence.

**Proof:** In fact, it is not necessary to take a subsequence to get the convergences \( 74.4.38 - 74.4.40 \). This is because of the pointwise convergence of \( 74.4.30 \) and Lemma \( 74.4.1 \). If the original sequence did not converge, then there would be two subsequences converging weakly to two different functions in \( V'_\omega \) \( v, w \) which is impossible because of \( 74.4.30 \) and this lemma since it would require \( v(\cdot) = w(\cdot) \) \( a.e. \).

The question at this point is whether \( u \) is progressively measurable. From the assumed estimates, the Ito formula, and \( 74.4.27 \), the same kind of estimates used earlier show that there exists an estimate of the form

\[
\|u_n\|_V \leq C
\]

Therefore, there exists a further subsequence such that

\[
u_n \to \bar{u} \text{ weakly in } V
\]

It follows from Lemma \( 74.4.2 \) that off an enlarged exceptional set of measure zero, still denoted as \( N \),

\[
\bar{u}(\cdot, \omega) = u(\cdot, \omega) \text{ in } V'_\omega
\]

Hence we can assume that \( u \) is progressively measurable into \( V \). It follows that \( Bu \) is progressively measurable into \( W' \).

Thus also

\[
(t, \omega) \to \int_0^t \xi(s, \omega) \, ds
\]
is progressively measurable into $V'$.

Of course the next task is to identify $\xi$. This is always a problem even in the non stochastic case. Here it is especially difficult because in order to identify $\xi$ we need to use the implicit Ito formula which only holds if $\xi$ is sufficiently measurable. However, we have obtained $\xi$ as a weak limit for fixed $\omega$. Therefore, this is a significant issue. In stochastic evolution problems where $B = I$ this is not as difficult because one gets $\xi$ as a weak limit in $\mathcal{V}$ and then $\xi$ is progressively measurable. We cannot do it this way and still get the best results in which there is a solution to the integral equation which holds for all $t$ off a set of measure zero because of the degenerate nature of the operator $B$. However, $\xi$ is only an equivalence class of functions. We show in the next lemma that there exists a representative of this equivalence class for each $\omega$ off an exceptional set of measure zero such that the resulting $\xi$ is progressively measurable. This will enable us to use the implicit Ito formula and indentify $\xi$.

The following lemma will allow the use of the Ito formula and eventually identify $\xi$.

**Lemma 74.4.4** \textit{Enlarging the exceptional set, one can assume that $\xi$ is also progressively measurable. In fact, if}

$$
\xi_n \equiv \int_{t-(1/n)}^{t} \xi ds
$$

\textit{is known to be progressively measurable, $\xi(t, \omega) \equiv 0$ for $t < 0$, then there exists a set of measure zero $N$ such that for $\omega \notin N, \xi(t, \omega) = \hat{\xi}(t, \omega)$ for all $t$ off a set of measure zero and $\hat{\xi}$ is progressively measurable.}

**Proof:** Define

$$
\xi_n \equiv n \int_{t-(1/n)}^{t} \xi ds
$$

where $\xi$ is defined to be zero for $t \leq 0$. Then by what was just shown, this is progressively measurable. Also, standard approximate identity arguments verify that for each $\omega, \xi_n \to \xi$ in $\mathcal{V}_\omega$. Next note that the set where $\xi_n$ is not a Cauchy sequence is a progressively measurable set. It equals

$$
\{ (t, \omega) : \| \xi_i(t, \omega) - \xi_k(t, \omega) \| > \frac{1}{n} \}
$$

Now for $p > 0$

$$
\lim_{m \to \infty} P \left( \sup_{p > 0} \| \xi_{m+p} - \xi_m \|_{\mathcal{V}_\omega} > \varepsilon \right) = 0
$$

This is because of the convergence of $\xi_n$ to $\xi$ in $\mathcal{V}_\omega$. Therefore, there is a subsequence still called $\xi_n$ such that

$$
P \left( \sup_{p > 0} \| \xi_{n+p} - \xi_n \|_{\mathcal{V}_\omega} > 2^{-n} \right) < 2^{-n}$$
and so there is an enlarged set of measure zero, still denoted as $N$ such that all of the above considerations hold for $\omega \notin N$ and also for $\omega \notin N$,

$$
\sup_{p>0} \left\| \xi_{n+p} - \xi_n \right\|_{V_\omega} \leq 2^{-n}
$$

for all $n$ large enough. Now let $S$ defined above, correspond to this particular subsequence. Let $S(\omega)$ be those $t$ such that $(t, \omega) \in S$. Then $S(\omega)$ is a set of measure zero for each $\omega \notin N$ because the above inequality implies that $t \rightarrow \xi_n (t, \omega)$ is a Cauchy sequence off a set of measure zero which by definition is $S(\omega)$. Then consider $\{\xi_n (t, \omega) X(t, \omega)\}$. For each $\omega$ off $N$, this converges for all $t$. Thus it converges pointwise to a function $\xi$ which must be progressively measurable. However, $t \rightarrow \xi (t, \omega)$ must also equal $t \rightarrow \xi(t, \omega)$ in $V_\omega$ by the above construction. Therefore, we can assume without loss of generality that $\xi$ is itself progressively measurable. ■

From the weak convergence of $u_n$ to $u$ in $V_\omega$,

$$
Bu_n \rightarrow Bu \text{ weakly in } V_\omega
$$

and so

$$
(\lambda B + A(\omega)) u_n \rightarrow \lambda Bu + \xi \text{ weakly in } V_\omega'
$$

Now the above convergences and the integral equation imply that off the exceptional set $N$, for each $t$

$$
Bu_n (t) \rightarrow Bu (t) \text{ weakly in } V'
$$

From a generalization of standard theorems in Hilbert space, stated in Lemma 74.2.1 there exist vectors $\{e_i\} \subseteq V$ such that

$$
\langle Bu_n (t), u_n (t) \rangle = \sum_{i=1}^{\infty} |\langle Bu_n (t), e_i \rangle|^2
$$

Hence

$$
\lim_{n \rightarrow \infty} \inf_{t \in [0, T]} \langle Bu_n (t), u_n (t) \rangle \geq \sum_{i=1}^{\infty} \lim_{n \rightarrow \infty} \inf_{t \in [0, T]} |\langle Bu_n (t), e_i \rangle|^2
$$

$$
= \sum_{i=1}^{\infty} |\langle Bu (t), e_i \rangle|^2 = \langle Bu (t), u (t) \rangle
$$

Thus the above inequalities and formulas hold for a.e. $t$.

Return to the equation (74.4.41). Define the stopping time

$$
\tau_p \equiv \inf \left\{ t \in [0, T] : \langle Bu, u \rangle (t) + \int_0^t \| \xi \|^2_{V_\omega'} ds > p \right\}
$$
From Section 74.4.28 and the fact that $\xi \in \mathcal{V}_\omega'$, it follows that $\tau_p = \infty$ for all $p$ large enough. Then stop the equation using this stopping time.

$$Bu^{\tau_p}(t, \omega) - Bu_0(\omega) + \int_0^t \mathcal{X}_{[0, \tau_p]} \xi^{\tau_p}(s, \omega) \, ds$$

$$= \int_0^t \mathcal{X}_{[0, \tau_p]} f(s, \omega) \, ds + B \int_0^t \mathcal{X}_{[0, \tau_p]} \Phi \, dW$$

From the implicit Itô formula Theorem 74.2.3, for a.e. $t$,

$$\frac{1}{2} \langle Bu^{\tau_p}(t), u^{\tau_p}(t) \rangle - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \mathcal{X}_{[0, \tau_p]} \langle \xi^{\tau_p}, u^{\tau_p} \rangle \, ds$$

$$= \frac{1}{2} \int_0^t \mathcal{X}_{[0, \tau_p]} \langle B\Phi, \Phi \rangle \, ds$$

$$+ \int_0^t \mathcal{X}_{[0, \tau_p]} \langle f, u^{\tau_p} \rangle \, ds + \int_0^t \mathcal{X}_{[0, \tau_p]} \langle \Phi \circ J^{-1}, Bu^{\tau_p} \circ J \rangle dW$$

Then letting $p \to \infty$ this yields the following formula for a.e. $t$

$$\frac{1}{2} \langle Bu(t), u(t) \rangle - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle \lambda Bu + \xi, u \rangle \, ds = \frac{1}{2} \int_0^t \langle B\Phi, \Phi \rangle \, ds$$

$$+ \int_0^t \langle f, u \rangle \, ds + \int_0^t \langle \Phi \circ J^{-1}, Bu \circ J \rangle dW + \int_0^t \langle \lambda Bu, u \rangle \, ds \quad (74.4.43)$$

**Lemma 74.4.5** It is true that

$$\lim_{n \to \infty} \int_0^T \langle Bu_n, u_n \rangle \, dt = \int_0^T \langle Bu, u \rangle \, dt$$

**Proof:** From Section 74.4.28 $Bu_n \to z$ strongly in $C(N_C, W').$ But also, for each $t, Bu_n(t) \to Bu(t)$ weakly in $V'$ and so $z(t) = Bu(t).$ This strong convergence in $C(N_C, W')$ along with the uniform norm with the weak convergence of $u_n$ to $u$ in $\mathcal{V}_\omega$ is sufficient to obtain the above limit.

You might think that

$$\int_0^T (\Phi_n \circ J^{-1})^* Bu_n \circ J dW \to \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW$$

but this is not entirely clear. It will be true in the case that in Section 74.4.6 $\alpha = 2$ and $U = W$ and this is shown later. However, it is not clearly true here unless it is also the case that $\Phi \in L^2(\Omega, L^\infty([0, T], \mathcal{L}_2(Q^{1/2}U, W))).$

**Lemma 74.4.6** If $\Phi \in L^2(\Omega, L^\infty([0, T], \mathcal{L}_2(Q^{1/2}U, W)))$ then

$$\int_0^T (\Phi_n \circ J^{-1})^* Bu_n \circ J dW \to \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW$$
74.4. THE GENERAL CASE

Proof:

\[
E \left( \left| \int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW - \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW \right| \right)
\]

\[
\leq E \left( \left| \int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW - \int_0^T (\Phi \circ J^{-1})^* B u_n \circ J dW \right| \right)
\]

\[
+ E \left( \left| \int_0^T (\Phi \circ J^{-1})^* B u_n \circ J dW - \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW \right| \right)
\]

\[
\leq \int_\Omega \left( \int_0^T \|\Phi_n - \Phi\|^2 \langle B u_n, u_n \rangle \right)^{1/2} dP
\]

\[
+ \int_\Omega \left( \int_0^T \|B u_n - B u, u_n - u\| dt \right)^{1/2} dP
\]

(74.4.44)

Consider that second term. It is no larger than

\[
\int_\Omega \left( \int_0^T \|B u_n - B u, u_n - u\| dt \right)^{1/2} dP
\]

\[
\leq \left( \int_\Omega \|\Phi\|^2 \langle B u_n, u_n \rangle \right)^{1/2} \left( \int_\Omega \int_0^T \langle B u_n - B u, u_n - u\rangle dtdP \right)^{1/2}
\]

Now consider the following. Letting the \(e_i\) be the special vectors of Lemma 74.4.3, it follows,

\[
\int_\Omega \int_0^T \langle B u_n - B u, u_n - u\rangle dtdP = \int_\Omega \int_0^T \sum_{i=1}^{\infty} \langle B u_n - B u, e_i \rangle^2 dtdP
\]

\[
= \int_\Omega \int_0^T \sum_{i=1}^{\infty} \lim_{p \to \infty} \langle B u_n - B u_p, e_i \rangle^2 dtdP
\]

\[
\leq \lim_{p \to \infty} \int_\Omega \int_0^T \sum_{i=1}^{\infty} \langle B u_n - B u_p, e_i \rangle^2 dtdP
\]

\[
= \lim_{p \to \infty} \int_\Omega \int_0^T \langle B u_n - B u_p, u_n - u_p \rangle dtdP \leq \frac{T}{2^n}
\]

The last inequality follows from 74.4.34. Therefore, the second term in 74.4.44 is no larger than \((C(T, \Phi) / 2^n)^{1/2}\) which converges to 0 as \(n \to \infty\). Now consider the
CHAPTER 74. IMPLICIT STOCHASTIC EQUATIONS

The first term in (74.4.44) is

\[ \int_\Omega \left( \int_0^T \| \Phi_n - \Phi \|_{L^2}^2 (Bu_n, u_n) \right)^{1/2} dP \]

\[ \leq \int_\Omega \sup_{t \in [0,T]} (Bu_n, u_n)^{1/2} \left( \int_0^T \| \Phi_n - \Phi \|_{L^2} dt \right)^{1/2} dP \]

\[ \leq \left( \int_\Omega \sup_{t \in [0,T]} (Bu_n, u_n) (t) \right)^{1/2} \left( \int_\Omega \int_0^T \| \Phi_n - \Phi \|_{L^2} dt \right)^{1/2} \]

From (74.4.32)

\[ \leq C \left( \int_\Omega \int_0^T \| \Phi_n - \Phi \|_{L^2} dt \right)^{1/2} \]

which converges to 0. □

Return now to the equation solved by \( u_n \) in (74.4.37). Apply the Ito formula to this one. This yields for a.e. \( t \),

\[ \frac{1}{2} \langle Bu_n (t), u_n (t) \rangle - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle A(\omega) u_n, u_n \rangle \, ds = \frac{1}{2} \int_0^t \langle B\Phi_n, \Phi_n \rangle \, ds \]

\[ + \int_0^t \langle f, u_n \rangle \, ds + \int_0^t (\Phi_n \circ J^{-1})^* Bu_n \circ J dW \quad (74.4.45) \]

Assume without loss of generality that \( T \) is not in the exceptional set. If not, consider all \( T' \) close to \( T \) such that \( T' \) is not in the exceptional set.

\[ \int_0^T \langle (\lambda B + A(\omega)) u_n, u_n \rangle \, ds \]

\[ = \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu_n (T), u_n (T) \rangle + \int_0^T \langle f, u_n \rangle \, ds \]

\[ + \int_0^T (\Phi_n \circ J^{-1})^* Bu_n \circ J dW + \frac{1}{2} \int_0^T \langle B\Phi_n, \Phi_n \rangle \, ds + \int_0^T \langle \lambda Bu_n, u_n \rangle \, ds \]

Now it follows from (74.4.38) applied to \( t = T \) and the above lemma that

\[ \lim_{n \to \infty} \sup \int_0^T \langle (\lambda B + A(\omega)) u_n, u_n \rangle \, ds \]

\[ \leq \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu (T), u (T) \rangle + \int_0^T \langle f, u \rangle \, ds \]

\[ + \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW + \frac{1}{2} \int_0^T \langle B\Phi, \Phi \rangle \, ds + \int_0^T \langle \lambda Bu, u \rangle \, ds \]
from (74.4.43), the expression on the right equals \( \int_0^T \langle \lambda Bu + \xi, u \rangle \, ds \). Hence
\[
\lim \sup_{n \to \infty} \int_0^T \langle (\lambda B + A(\omega)) u_n, u_n \rangle \, ds \leq \int_0^T \langle \lambda Bu + \xi, u \rangle \, ds
\]
Then since \( \lambda B + A(\omega) \) is monotone and hemicontinuous, it is type \( M \) and so this requires \( A(\omega) u = \xi \).

Hence we obtain
\[
Bu(t) - Bu_0(\omega) + \int_0^t A(\omega)(u) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \Phi \, dW
\]
This is a solution for a given \( \omega \notin N \). Also, a stopping time argument like the above and the coercivity estimates for \( A \) along with the implicit Ito formula show that \( u \in V \). This yields the existence part of the following existence and uniqueness theorem.

**Theorem 74.4.7** Suppose \( V \equiv L^p([0,T] \times \Omega, V) \) where \( p \geq 2 \), with the \( \sigma \) algebra of progressively measurable sets and \( V_\omega = L^p([0,T], V) \).

\[\Phi \in L^2([0,T] \times \Omega, \mathcal{L}_2(Q^{1/2}U, W)) \cap L^2(\Omega, L^\infty([0,T], \mathcal{L}_2(Q^{1/2}U, W))) \]
\[f \in V' \equiv L^p'(([0,T] \times \Omega, V'))\]
and both are progressively measurable. Suppose that
\[\lambda B + A(\omega) : V_\omega \to V_\omega, \lambda B + A : V \to V'\]
are monotone hemicontinuous and bounded where
\[A(\omega) u(t) \equiv A(t, u(t), \omega)\]
and \((t, u, \omega) \to A(t, u, \omega)\) is progressively measurable. Also, suppose for \( p \geq 2 \), the coercivity, and the boundedness conditions
\[\lambda (Bu, u) + (A(t, u, \omega), u)_V \geq \delta \|u\|_V^p - c(t, \omega) \quad (74.4.46)\]
where \( c \in L^1([0,T] \times \Omega) \) for all \( \lambda \) large enough. Also,
\[\|A(t, u, \omega)\|_V \leq k \|u\|_V^{p-1} + c^{1/p'}(t, \omega) \quad (74.4.47)\]
also suppose the monotonicity condition for all \( \lambda \) large enough.
\[\langle (\lambda B + A(\omega))(u) - (\lambda B + A(\omega))(v), u - v \rangle \geq \delta \|u - v\|_U^2 \quad (74.4.48)\]
Then if \( u_0 \in L^2(\Omega, W) \) with \( u_0 \mathcal{F}_0 \) measurable, there exists a unique solution \( u(\cdot, \omega) \in V_\omega \) with \( u \in V \) \((L^p([0,T] \times \Omega, V) \) and progressively measurable\) such that for \( \omega \) off a set of measure zero,
\[Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(s, \omega), \omega) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \Phi \, dW.\]
It is also assumed that \( V \) is a reflexive separable real Banach space.
Proof: The uniqueness assertion follows easily from the monotonicity condition.

Now we remove the assumption that $\Phi \in L^2(\Omega, L^\infty([0, T], L^2(Q^{1/2}U, W)))$.

Everything is the same except for the need for a different argument to show that

$$\int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW \to \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW.$$ 

In this case we assume

$$((\lambda B + A (\omega)) (u) - (\lambda B + A (\omega)) (v), u - v) \geq \delta \|u - v\|^2_W$$

Then repeating the above argument with this change yields set of measure zero, still denoted as $N$ such that for $\omega \notin N$

$$\int_0^T \|u_n - u_{n+1}\|^2_W \, ds \leq 2^{-n} \quad (74.4.49)$$

for all $n$ large enough. Hence for such $\omega$, $u_n (\cdot, \omega)$ is Cauchy in $L^2([0, T], W)$ and in fact $u_n (t, \omega)$ is a Cauchy sequence in $W$. This $\{u_n (\cdot, \omega)\}$ converges in $L^2([0, T], W)$ to $u (\cdot, \omega) \in L^2([0, T], W)$ and by the above considerations involving continuous dependence of $V$ into $W$, it follows that $u (\cdot, \omega)$ will be the same as the $u$ from the above convergences. Now this convergence implies that in addition, for a.e. $t$,

$$\lim_{n \to \infty} \langle Bu_n (t, \omega) - Bu (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle = 0 \quad (74.4.50)$$

$$\lim_{n \to \infty} \int_0^T \langle Bu_n (t, \omega) - Bu (t, \omega), u_n (t, \omega) - u (t, \omega) \rangle \, dt = 0$$

What is known from is that for

$$M_n (t) = \int_0^t (\Phi_n \circ J^{-1})^* B u_n \circ J dW$$

there is a continuous martingale $M \in M_T^1$ such that

$$\lim_{n \to \infty} E \left( \sup_{t \in [0, T]} |M_n (t) - M (t)| \right) = 0 \quad (74.4.51)$$

Define a stopping time

$$\tau_p \equiv \inf \left\{ t : \langle Bu, u \rangle (t) + \sup_n \langle Bu_n, u_n \rangle (t) > p \right\}$$

This is a good enough stopping time because the function used to define it as a hitting time is lower semicontinuous.

**Lemma 74.4.8** $\int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW \to \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW$ in probability. Also there is a further subsequence and set of measure zero such that off this set,

$$\lim_{n \to \infty} \left( \sup_{t \in [0, T]} \left| \int_0^t (\Phi \circ J^{-1})^* B u \circ J dW - \int_0^t (\Phi_n \circ J^{-1})^* B u_n \circ J dW \right| \right) = 0.$$
In particular, what is needed here is valid,

\[ \lim_{n \to \infty} \int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW = \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW \]

Proof: Let \( \varepsilon > 0 \). Then define

\[ A_n = \left\{ \omega : \left| \int_0^T (\Phi_n \circ J^{-1})^* B u_n \circ J dW - \int_0^T (\Phi \circ J^{-1})^* B u \circ J dW \right| > \varepsilon \right\} \]

Then \( A_n = \bigcup_{p=1}^\infty A_n \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty]), [\tau_0 < \infty] \equiv \emptyset \)

the sets in the union being disjoint. Then \( A \cap ([\tau_p = \infty]) \subseteq \)

\[ \left\{ \omega : \left| \int_0^T \mathcal{X}_{[0,\tau_p]} (\Phi_n \circ J^{-1})^* B u_n \circ J dW - \int_0^T \mathcal{X}_{[0,\tau_p]} (\Phi \circ J^{-1})^* B u \circ J dW \right| > \varepsilon \right\} \]

Then as before,

\( E \left( \left| \int_0^T \mathcal{X}_{[0,\tau_p]} (\Phi_n \circ J^{-1})^* B u_n \circ J dW - \int_0^T \mathcal{X}_{[0,\tau_p]} (\Phi \circ J^{-1})^* B u \circ J dW \right| \right) \)

\[ \leq \int_{\Omega} \left( \left( \int_0^T \|\Phi_n - \Phi\|^2_{L^2} \mathcal{X}_{[0,\tau_p]} \langle B u_n, u_n \rangle \right)^{1/2} \right) dP 
+ \int_{\Omega} \left( \int_0^T \mathcal{X}_{[0,\tau_p]} \|\Phi\|^2_{L^2} \langle B u_n - B u, u_n - u \rangle dt \right)^{1/2} dP \quad (74.4.52) \]

Consider the second term. It is no larger than

\[ \left( \int_{\Omega} \int_0^T \mathcal{X}_{[0,\tau_p]} \|\Phi\|^2_{L^2} \langle B u_n - B u, u_n - u \rangle dt dP \right)^{1/2} \]

Now \( t \to \langle B u_n, u_n \rangle \) is continuous and so \( \mathcal{X}_{[0,\tau_p]} \langle B u_n, u_n \rangle \leq p \). If not, then you would have \( \langle B u_n, u_n \rangle (t) > p \) for some \( t \leq \tau_p \), and so, by continuity, there would be \( s < t \leq \tau_p \) for which \( \langle B u_n, u_n \rangle (s) > p \) contrary to the definition of \( \tau_p \). Then \( \mathcal{X}_{[0,\tau_p]} \|B u_n - B u, u_n - u\| \) is bounded a.e. and also converges to 0 for a.e. \( t \leq \tau_p \) as \( n \to \infty \). Therefore, off a set of measure zero, including the set where \( t \to \|\Phi\|^2_{L^2} \) is not in \( L^1 \), the double integral converges to 0 by the dominated convergence theorem. As to the first integral in (74.4.52), it is dominated by

\[ \int_{\Omega} \mathcal{X}_{[0,\tau_p]} \sup_{t \in [0, \tau_p]} \langle B u_n, u_n \rangle^{1/2} (t) \left( \int_0^T \|\Phi_n - \Phi\|^2_{L^2} \right)^{1/2} dP \]
\begin{align*}
&
\leq \left( \int_{\Omega} \sup_{t \in [0,T]} \langle Bu_n, u_n \rangle \, dP \right)^{1/2} \left( \int_{\Omega} \int_0^T \| \Phi_n - \Phi \|^2_{L^2} \, dt \, dP \right)^{1/2}.
\end{align*}

From the estimate

\begin{align*}
\leq C \left( \int_{\Omega} \int_0^T \| \Phi_n - \Phi \|^2_{L^2} \, dt \, dP \right)^{1/2}
\end{align*}

for a constant \( C \) independent of \( n \). Therefore,

\begin{align*}
\lim_{n \to \infty} E \left( \sup_{t \in [0,T]} \left( \int_0^T \mathcal{L}_{[0,\tau_p]} \left( \Phi_n \circ J^{-1} \right)^* Bu_n \circ JdW - \int_0^T \mathcal{L}_{[0,\tau_p]} \left( \Phi \circ J^{-1} \right)^* Bu \circ JdW \right) \right) = 0.
\end{align*}

Hence

\begin{align*}
P ( A_n \cap [\tau_p = \infty]) \leq \frac{1}{\varepsilon} E \left( \left| \int_0^T \mathcal{L}_{[0,\tau_p]} \left( \Phi_n \circ J^{-1} \right)^* Bu_n \circ JdW - \int_0^T \mathcal{L}_{[0,\tau_p]} \left( \Phi \circ J^{-1} \right)^* Bu \circ JdW \right| \right)
\end{align*}

and so

\begin{align*}
\lim_{n \to \infty} P ( A_n \cap [\tau_p = \infty]) = 0.
\end{align*}

Then

\begin{align*}
P ( A_n) = \sum_{p=1}^\infty P ( A_n \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty]))
\end{align*}

and so from the dominated convergence theorem,

\begin{align*}
\lim_{n \to \infty} P ( A_n) = \sum_{p=1}^\infty \lim_{n \to \infty} P ( A_n \cap ([\tau_p = \infty] \setminus [\tau_{p-1} < \infty])) = \sum_p 0 = 0.
\end{align*}

There was nothing special about \( T \). The same argument holds for all \( t \) and so \( M (t) \) mentioned above has been identified as \( \int_0^t \left( \Phi \circ J^{-1} \right)^* Bu \circ JdW \). Then from

\begin{align*}
\lim_{n \to \infty} \mathbb{E} \left( \sup_{t \in [0,T]} \left| \int_0^t \left( \Phi \circ J^{-1} \right)^* Bu \circ JdW - \int_0^t \left( \Phi_n \circ J^{-1} \right)^* Bu_n \circ JdW \right| \right) = 0.
\end{align*}

It follows from the usual Borel Cantelli argument that there is a set of measure zero and a further subsequence such that off this set, all the above convergences happen and also

\begin{align*}
\int_0^t \left( \Phi_n \circ J^{-1} \right)^* Bu_n \circ JdW \rightarrow \int_0^t \left( \Phi \circ J^{-1} \right)^* Bu \circ JdW
\end{align*}

uniformly on \([0,T]\). \( \blacksquare \)

The rest of the argument is identical. This yields the following theorem.
74.5. REPLACING $\Phi$ WITH $\sigma (u)$

**Theorem 74.4.9** Suppose $V \equiv L^p ([0, T] \times \Omega, V)$ where $p \geq 2$, with the $\sigma$ algebra of progressively measurable sets and $V_\omega = L^p ([0, T], V)$. 

$$
\Phi \in L^2 \left( [0, T] \times \Omega, L_2 (Q^{1/2} U, W) \right),
$$

$$
f \in V' \equiv L^p' ([0, T] \times \Omega, V')
$$

and both are progressively measurable. Suppose that $\lambda B + A (\omega) : V_\omega \rightarrow V'_\omega$, $\lambda B + A : V \rightarrow V'$ are monotone hemicontinuous and bounded where

$$
A (\omega) u (t) \equiv A (t, u (t), \omega)
$$

and $(t, u, \omega) \rightarrow A (t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$
\lambda \langle Bu, u \rangle + \langle A (t, u, \omega), u \rangle_V \geq \delta \| u \|_V^p - c (t, \omega) 
$$

(74.4.53)

where $c \in L^1 ([0, T] \times \Omega)$ for all $\lambda$ large enough. Also,

$$
\| A (t, u, \omega) \|_V \leq k \| u \|_V^{p-1} + c^{1/p'} (t, \omega) 
$$

(74.4.54)

also suppose the monotonicity condition for all $\lambda$ large enough.

$$
\langle (\lambda B + A (\omega)) (u) - (\lambda B + A (\omega)) (v), u - v \rangle \geq \delta \| u - v \|_W^2 
$$

(74.4.55)

Then if $u_0 \in L^2 (\Omega, W)$ with $u_0 \mathcal{F}_0$ measurable, there exists a unique solution $u (\cdot, \omega) \in V_\omega$ with $u \in V (L^p ([0, T] \times \Omega, V)$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$
Bu (t, \omega) - Bu_0 (\omega) + \int_0^t A (s, u (s, \omega), \omega) ds = \int_0^t f ds + B \int_0^t \Phi dW.
$$

It is also assumed that $V$ is a reflexive separable real Banach space.

74.5 Replacing $\Phi$ With $\sigma (u)$

It is not hard to include the case where $\Phi$ is replaced with a function $\sigma (u)$. We make the following assumptions. **For each** $r > 0$ there exists $\lambda$ large enough that

$$
\langle \lambda B (u) + A (u) - \lambda B (\hat{u}) + A (\hat{u}), u - \hat{u} \rangle \geq r \| u - \hat{u} \|_W^2
$$

Note that in the case where $B = I$ and there is a conventional Gelfand triple, $V, H, V'$, this kind of condition is obvious if $\lambda I + A$ is monotone for some $\lambda$. Thus this is not an unreasonable assumption to make although it is stronger than some of the assumptions used above with the integral given by $\int_0^t \Phi dW$. 

As to \( \sigma \) we make the following assumptions.

\[(t, u, \omega) \in [0, T] \times W \times \Omega \rightarrow \sigma (t, u, \omega) \text{ is progressively measurable into } W\]

\[
\|\sigma (t, u, \omega)\|_W \leq C + C \|u\|_W
\]

\[
\|\sigma (t, u, \omega) - \sigma (t, \hat{u}, \omega)\|_{\mathcal{L}_2(Q; zU, W)} \leq K \|u - \hat{u}\|_W
\]

That is, it has linear growth and is Lipschitz.

Let \( \lambda \) correspond to \( r \) where \( r - \|B\| K^2 > 4 \). Also let \( T \) be such that

\[
\dot{C}e^{\lambda T} K^2 < 3
\]

where \( \dot{C} \) is a constant used in the Burkholder Davis Gundy inequality. This is a restriction on the size of \( K \). Thus we only give a solution if \( K \) is small enough. Later, this will be removed in the most interesting case. This will give a local solution valid for a fixed \( T > 0 \) and then the global solution can be obtained by applying this result on the succession of intervals \([0, T], [T, 2T], [3T, 4T], \) and so forth.

From Theorem 74.4.9, if \( w \in \mathcal{W} \), there exists a unique solution \( u \) to

\[
Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(s, \omega), \omega) \, ds = \int_0^t f ds + B \int_0^t \sigma(w) \, dW.
\]

holding in the sense described there. Let \( u_1 \) result from \( w_1 \). Then from the implicit Itô formula and the above monotonicity estimate,

\[
\frac{1}{2} \langle B(u_1 - u_2), u_1 - u_2 \rangle (t) + r \int_0^t \|u_1 - u_2\|_W^2 \, ds - \lambda \int_0^t \langle B(u_1 - u_2), u_1 - u_2 \rangle \, ds - \int_0^t \langle B\sigma(u_1) - B\sigma(u_2), \sigma(u_1) - \sigma(u_2) \rangle \, ds \leq M^*(t)
\]

where the right side is of the form \( \sup_{s \in [0, t]} |M(s)| \) where \( M(t) \) is a local martingale having quadratic variation dominated by

\[
C \int_0^t \|\sigma(u_1) - \sigma(u_2)\|^2 \langle B(u_1 - u_2), u_1 - u_2 \rangle \, ds
\]

(74.5.56)

Therefore, since \( M^* \) is increasing in \( t \), it follows from the Lipschitz condition on \( \sigma \) that

\[
\frac{1}{2} \langle B(u_1 - u_2), u_1 - u_2 \rangle (t) + r \int_0^t \|u_1 - u_2\|_W^2 \, ds - \lambda \int_0^t \langle B(u_1 - u_2), u_1 - u_2 \rangle \, ds - \|B\| K^2 \int_0^t \|u_1 - u_2\|_W^2 \, ds \leq M^*(t)
\]
Thus, from the assumption about $r$,

$$
\sup_{s \in [0, t]} \langle B (u_1 - u_2) , u_1 - u_2 \rangle (s) + 4 \int_0^t \| u_1 - u_2 \|^2_W \ ds \\
\leq \lambda \int_0^t \langle B (u_1 - u_2) , u_1 - u_2 \rangle \ ds + 2M^* (t)
$$

Then applying Gronwall’s inequality,

$$
\sup_{s \in [0, t]} \langle B (u_1 - u_2) , u_1 - u_2 \rangle (s) + 4 \int_0^t \| u_1 - u_2 \|^2_W \ ds \leq 2e^{\lambda T} M^* (t)
$$

Now take expectations and use the Burkholder Davis Gundy inequality. The expectation of the right side is then dominated by

$$
2 \hat{C} e^{\lambda T} \int \left( \int_0^t \| \sigma (w_1) - \sigma (w_2) \|^2_{L^2} \langle B (u_1 - u_2) , u_1 - u_2 \rangle \ ds \right)^{1/2} \ dP
$$

$$
\leq \left[ \int \sup_{s \in [0, t]} \langle B (u_1 - u_2) , u_1 - u_2 \rangle^{1/2} \right] \cdot 2 \hat{C} e^{\lambda T} \left( \int_0^t K^2 \| w_1 - w_2 \|^2_W \ dt \right)^{1/2} \ dP
$$

$$
\leq E \left( \frac{1}{2} \sup_{s \in [0, t]} \langle B (u_1 - u_2) , u_1 - u_2 \rangle (s) \right)
$$

$$
+ \hat{C} e^{\lambda T} E \left( \int_0^t K^2 \| w_1 - w_2 \|^2_W \ dt \right)
$$

It follows that, after adjusting constants as needed, one gets an inequality of the following form.

$$
\frac{1}{2} E \left( \sup_{s \in [0, t]} \langle B (u_1 - u_2) , u_1 - u_2 \rangle (s) \right) + 4 \int \int_0^t \| u_1 - u_2 \|^2_W \ ds \ dP \\
\leq \hat{C} e^{\lambda T} E \left( \int_0^t K^2 \| w_1 - w_2 \|^2_W \ dt \right)
$$

This holds for every $t \leq T$ and so, from the estimate on the size of $T$, it follows that

$$
\int_0^T \int \| u_1 - u_2 \|^2_W \ dsdP \leq \frac{3}{4} \int_0^T \int \| w_1 - w_2 \|^2_W \ dt \ dP
$$

Therefore, there is a unique fixed point to this mapping which takes $w \in \mathcal{W}$ to $u$ the solution to the integral equation. We denote it as $u$. Thus $u$ is progressively
measurable and for $\omega$ off a set of measure zero, we have a solution to the integral equation

$$Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(s, \omega), \omega) \, ds$$

$$= \int_0^t f \, ds + B \int_0^t \sigma(u) \, dW, \quad t \in [0, T]$$

Now the same argument can be repeated for the succession of intervals mentioned above. However, you need to be careful that at $T$, you have $Bu(T, \omega) = B(u(T, \omega))$ for $\omega$ off a set of measure zero. If this is not so, you locate $T'$ close to $T$ for which it is so as in Lemma 71.3.1 and use this $T'$ instead, but these are mainly technical issues. This proves the following existence and uniqueness theorem.

**Theorem 74.5.1** Suppose $f \in V'$ is progressively measurable and that $(t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega))$ is progressively measurable whenever $u$ is. Suppose that

$$\lambda B + A(\omega) : V_\omega \rightarrow V'_\omega, \quad \lambda B + A : V \rightarrow V'$$

are monotone hemicontinuous and bounded where

$$A(\omega) u(t) \equiv A(t, u(t), \omega)$$

and $(t, u, \omega) \rightarrow A(t, u, \omega)$ is progressively measurable. Also suppose for $p \geq 2$, the coercivity, and the boundedness conditions

$$\lambda \langle Bu, u \rangle + \langle A(t, u, \omega), u \rangle_V \geq \delta \|u\|_V^p - c(t, \omega) \quad (74.5.57)$$

for all $\lambda$ large enough.

$$\|A(t, u, \omega)\|_{V'} \leq k \|u\|_{V}^{p-1} + c^{1/p'}(t, \omega) \quad (74.5.58)$$

where $c \in L^1([0, T] \times \Omega)$. Also suppose the monotonicity condition that for all $r > 0$

$$(\lambda B + A(\omega))(u) - (\lambda B + A(\omega))(v), u - v \geq r \|u - v\|_W^2$$

Also suppose that

$$(t, u, \omega) \in [0, T] \times W \times \Omega \rightarrow \sigma(t, u, \omega)$$

is progressively measurable into $W$

$$\|\sigma(t, u, \omega)\|_W \leq C + C \|u\|_W$$

$$\|\sigma(t, u, \omega) - \sigma(t, \hat{u}, \omega)\|_{L_2(Q_1/2U, W)} \leq K \|u - \hat{u}\|_W$$

Then if $u_0 \in L^2(\Omega, W)$ with $u_0 F_0$ measurable, there exists a unique solution $u(\cdot, \omega) \in V_\omega$ with $u \in V (L^p([0, T] \times \Omega, V)$ and progressively measurable) such that for $\omega$ off a set of measure zero,

$$Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(s, \omega), \omega) \, ds = \int_0^t f \, ds + B \int_0^t \sigma(u) \, dW.$$
In case $B$ is the Riesz map, you do not have to make any assumption on the size of $K$. Thus
\[
\langle Bu, u \rangle = \|u\|_W^2
\]
The case of most interest is the usual one where $V \subseteq W = W' \subseteq V'$, the case of a Gelfand triple in which $B$ is the identity. As to $\sigma$, the assumption is made that
\[
\|\sigma (t, \omega, u_1) - \sigma (t, \omega, u_2)\|_{L^2(Q^{1/2}U, W')} \leq K \|u_1 - u_2\|_W
\]
Of course it is also assumed that whenever $u$ has values in $W$ and is progressively measurable, $(t, \omega) \to \sigma (t, \omega, u(t, \omega))$ is also progressively measurable into $L^2(Q^{1/2}U, W)$.

Letting $w_i \in L^2([0, T] \times \Omega, W)$ each $w_i$ being progressively measurable, the above assumptions imply that there exists a solution $u_i$ to the integral equation
\[
Bu_i (t, \omega) - Bu_0 (\omega) + \int_0^t A(u_i) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \sigma (w_i) \, dW
\]
here we write $\sigma (w_i)$ for short instead of $\sigma (t, \omega, w_i)$. First, consider
\[
w \in L^2 ([0, T] \times \Omega, W) \cap L^\infty ([0, T], L^2 (\Omega, W))
\]
and let $u$ be the solution which results from placing $w$ in $\sigma$. Then from the estimates,
\[
\langle Bu, u \rangle (t) - \langle Bu_0, u_0 \rangle + \delta \int_0^t \|u\|_{V'}^2 \, ds = 2 \int_0^t \langle f, u \rangle \, ds + C (b_3, b_4, b_5)
\]
\[+ \lambda \int_0^t \langle Bu, u \rangle \, ds + \int_0^t \langle B \sigma (w) , \sigma (w) \rangle_{L^2} \, ds + 2M^* (t)
\]
\[\leq 2 \int_0^t \langle f, u \rangle \, ds + C (b_3, b_4, b_5) + \lambda \int_0^t \langle Bu, u \rangle \, ds + \int_0^t \left( C + C \|w\|_W^2 \right) \, ds + 2M^* (t)
\]
where $M^* (t) = \sup_{s \in [0, t]} |M (s)|$ and the quadratic variation of $M$ is no larger than
\[
\int_0^t \|\sigma (w)\|^2 \langle B(u), u \rangle \, ds
\]
Then using Gronwall’s inequality, one obtains an inequality of the form
\[
\sup_{s \in [0, T]} \langle Bu, u \rangle (s) \leq C + C \left( M^* (t) + \int_0^t \|w\|_W^2 \, ds \right)
\]
where $C = C(u_0, f, \delta, \lambda, b_3, b_4, b_5, T)$ and is integrable. Then take expectation. By Burkholder Davis Gundy inequality and adjusting constants as needed,

$$E \left( \sup_{s \in [0,T]} \langle Bu, u \rangle (s) \right) \leq C + C \int_\Omega \int_0^T \|w\|_W^2 \ dP + C \int_\Omega \left( \int_0^T \|\sigma(w)\|^2 \langle B(u), u \rangle \ ds \right)^{1/2} \ dP$$

$$\leq C + C \int_\Omega \int_0^T \|w\|_W^2 \ dP + C \int_\Omega \sup_{s \in [0,T]} \langle Bu, u \rangle^{1/2} \left( \int_0^T \|\sigma(w)\|^2 \ ds \right)^{1/2} \ dP$$

$$\leq C + C \int_\Omega \int_0^T \|w\|_W^2 \ dP + \frac{1}{2} E \left( \sup_{s \in [0,T]} \langle Bu, u \rangle (s) \right) + C \int_0^T \left( C + C \|w\|_W^2 \right)$$

Thus

$$E \left( \langle Bu, u \rangle (t) \right) \leq E \left( \sup_{s \in [0,T]} \langle Bu, u \rangle (s) \right) \leq C + C \int_\Omega \int_0^T \|w\|_W^2 \ dP$$

and so

$$\|w\|_{L^\infty([0,T], L^2(\Omega, W))} \leq C + C \int_\Omega \int_0^T \|w\|_W^2 \ dP$$

which implies $u \in L^\infty ([0, T], L^2 (\Omega, W))$ and is progressively measurable.

Using the monotonicity assumption, there is a suitable $\lambda$ such that

$$\frac{1}{2} \langle B (u_1 - u_2), u_1 - u_2 \rangle (t) + r \int_0^t \|u_1 - u_2\|_W^2 \ ds$$

$$- \lambda \int_0^t \langle B (u_1 - u_2), u_1 - u_2 \rangle \ ds$$

$$- \int_0^t \langle B \sigma (u_1) - B \sigma (u_2), \sigma (u_1) - \sigma (u_2) \rangle_{L^2} \ ds \leq M^* (t)$$

where the right side is of the form $\sup_{s \in [0,t]} |M(s)|$ where $M(t)$ is a local martingale having quadratic variation dominated by

$$C \int_0^t \|\sigma (w_1) - \sigma (w_2)\|^2 \langle B (u_1 - u_2), u_1 - u_2 \rangle \ ds$$

(74.5.59)

Then by assumption and using Gronwall’s inequality, there is a constant $C = C(\lambda, K, T)$ such that

$$\langle B (u_1 - u_2), u_1 - u_2 \rangle (t) \leq C M^* (t)$$

Then also, since $M^*$ is increasing,

$$\sup_{s \in [0,t]} \langle B (u_1 - u_2), u_1 - u_2 \rangle (s) \leq C M^* (t)$$
Taking expectations and from the Burkholder Davis Gundy inequality,

\[ E \left( \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle(s) \right) \leq C \int_\Omega \left( \int_0^t \|\sigma(w_1) - \sigma(w_2)\|^2 \langle B(u_1 - u_2), u_1 - u_2 \rangle \right)^{1/2} dP \]

\[ \leq C \int_\Omega \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle^{1/2}(s) \left( \int_0^t \|\sigma(w_1) - \sigma(w_2)\|^2 \right)^{1/2} dP \]

Then it follows after adjusting constants that there exists an inequality of the form

\[ E \left( \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle(s) \right) \leq CE \left( \int_0^t \|\sigma(w_1) - \sigma(w_2)\|^2 \right) ds \]

Hence

\[ E \left( \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle(t) \right) \leq CK^2E \left( \int_0^t \|w_1 - w_2\|^2_W ds \right) \]

Thus, for each \( t \leq T \)

\[ \int_\Omega \langle B(u_1 - u_2), u_1 - u_2 \rangle(t) dP \leq CK^2E \left( \int_0^t \|w_1 - w_2\|^2_W ds \right) \]

one can consider the map \( \psi(w) \equiv u \) as described above. Then the above inequality implies

\[ E (\langle B(\psi^n w_1 - \psi^n w_2), \psi^n w_1 - \psi^n w_2 \rangle(t)) \leq CK^2E \left( \int_0^t \|\psi^{n-1} w_1 - \psi^{n-1} w_2\|^2_W dt_1 \right) \]

\[ = CK^2E \left( \int_0^t \langle B(\psi^{n-1} w_1 - \psi^{n-1} w_2), \psi^{n-1} w_1 - \psi^{n-1} w_2 \rangle(t_1) dt_1 \right) \]

\[ \leq (CK^2)^n \left( \int_0^t \int_0^{t_1} \langle B(\psi^{n-2} w_1 - \psi^{n-2} w_2), \psi^{n-2} w_1 - \psi^{n-2} w_2 \rangle(t_2) dt_2 dt_1 \right) \]

\[ \cdots \leq (CK^2)^n \left( \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} \langle B(w_1 - w_2), w_1 - w_2 \rangle(t_n) dt_n \cdots dt_2 dt_1 \right) \]

\[ = (CK^2)^n \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} E (\langle B(w_1 - w_2), w_1 - w_2 \rangle(t_n)) dt_n \cdots dt_2 dt_1 \]

\[ \leq (CK^2)^n \sup_t E (\langle B(w_1 - w_2), w_1 - w_2 \rangle(t)) \frac{T^n}{n!} \leq \frac{1}{2} \|w_1 - w_2\|^2_{L^\infty([0,T], L^2(\Omega,W))} \]
provided \( n \) is sufficiently large. It follows that
\[
\|\psi^n w_1 - \psi^n w_2\|_{L^\infty([0,T],L^2(\Omega,W))}^2 \leq \frac{1}{2} \|w_1 - w_2\|_{L^\infty([0,T],L^2(\Omega,W))}^2
\]
for all \( n \) sufficiently large. Hence, if one begins with \( w_2 \in L^1([0,T];L^2(\Omega,W)) \cap L^2([0,T] \times \Omega, W) \), the sequence of iterates \( \{\psi^n w\}_{n=1}^\infty \) must converge to some fixed point \( u \in L^\infty([0,T],L^2(\Omega,W)) \). This \( u \) is automatically in \( L^2([0,T] \times \Omega, W) \) and is progressively measurable since each of the iterates is progressively measurable.

This proves the following theorem.

**Theorem 74.5.2** Suppose \( f \in \mathcal{Y}' \) is progressively measurable and that \( (t,\omega) \to \sigma(t,u,\omega) \) is progressively measurable whenever \( u \) is. Suppose that \( B : W \to W' \) is a Riesz map.

\[
\lambda B + A(\omega) : \mathcal{Y}_w \to \mathcal{Y}_w', \quad \lambda B + A : \mathcal{Y} \to \mathcal{Y}'
\]
are monotone hemicontinuous and bounded where
\[
A(\omega) u(t) \equiv A(t, u(t), \omega)
\]
and \( (t, u, \omega) \to A(t, u, \omega) \) is progressively measurable. Also suppose for \( p \geq 2 \), the coercivity, and the boundedness conditions
\[
\lambda (Bu, u) + (A(t, u, \omega), u)_{\mathcal{Y}} \geq \delta \|u\|_{\mathcal{Y}}^p - c(t, \omega) \tag{74.5.60}
\]
for all \( \lambda \) large enough.
\[
\|A(t, u, \omega)\|_{\mathcal{Y}'_w} \leq k \|u\|_{\mathcal{Y}}^{p-1} + c^{1/p'}(t, \omega) \tag{74.5.61}
\]
where \( c \in L^1([0,T] \times \Omega) \). Also suppose that
\[
\|\sigma(t, u, \omega)\|_W \leq C \|u\|_W
\]
\[
\|\sigma(t, u, \omega) - \sigma(t, \tilde{u}, \omega)\|_{L^q(\Omega \times [0,T], W)} \leq K \|u - \tilde{u}\|_W
\]
Then if \( u_0 \in L^2(\Omega,W) \) with \( u_0 \mathcal{F}_0 \) measurable, there exists a unique solution \( u(t, \omega) \) with \( u \in \mathcal{Y} \) \((L^p([0,T] \times \Omega, \mathcal{Y}) \) and progressively measurable\) such that for \( \omega \) off a set of measure zero,
\[
Bu(t, \omega) - Bu_0(\omega) + \int_0^t A(s, u(s, \omega), \omega) ds = \int_0^t f ds + B \int_0^t \sigma(u) dW.
\]

### 74.6 Examples

Here we give some examples. The first is a standard example, the porous media equation, which is discussed well in [105]. For stochastic versions of this example, see [98]. The generalization to stochastic equations does not require the theory developed here. We will show, however, that it can be considered in terms of the theory of this paper without much difficulty using an approach proposed in [22]. These examples involve operators which are not monotone, in the usual way but they can be transformed into equations which do fit the above theory.
Example 74.6.1 The stochastic porous media equation is
\[ u_t - \Delta \left( u |u|^{p-2} \right) = f, \quad u(0) = u_0, \quad u = 0 \text{ on } \partial U \]
where here \( U \) is a bounded open set in \( \mathbb{R}^n, \ n \leq 3 \) having Lipschitz boundary. One can consider a stochastic version of this as a solution to the following integral equation
\[ u(t) - u_0 + \int_0^t (-\Delta) \left( u |u|^{p-2} \right) ds = \int_0^t \Phi dW + \int_0^t f ds \quad (74.6.62) \]
where here
\[ \Phi \in L^2 \left( [0, T] \times \Omega, L_2 \left( Q^{1/2} U, H \right) \right) \cap L^2 \left( \Omega, L^\infty \left( [0, T], L_2 \left( Q^{1/2} U, H \right) \right) \right), \]
\[ H = L^2 (U) \text{ and the equation holds in the manner described above in } H^{-1} (U). \]
Assume \( p \geq 2 \) and \( f \in L^2 ((0,T) \times \Omega, H). \)

One can consider this as an implicit integral equation of the form
\[ (-\Delta)^{-1} u(t) - (-\Delta)^{-1} u_0 + \int_0^t u |u|^{p-2} ds = (-\Delta)^{-1} \int_0^t \Phi dW + (-\Delta)^{-1} \int_0^t f ds \quad (74.6.63) \]
where \(-\Delta\) is the Riesz map of \( H^1_0 (U) \) to \( H^{-1} (U) \). Then we can also consider \((-\Delta)^{-1}\) as a map from \( L^2 (U) \) to \( L^2 (U) \) as follows.
\[ (-\Delta)^{-1} f = u \text{ where } -\Delta u = f, \quad u = 0 \text{ on } \partial U. \]
Thus we let \( W = L^2 (U) = H \) and \( V = L^p (U) \). Let \( B \equiv (-\Delta)^{-1} \) on \( L^2 (U) \) as just described. Let \( A(u) = u |u|^{p-2} \). It is obvious that the necessary coercivity condition holds. In addition, there is a strong monotonicity condition which holds. Therefore, if \( u_0 \in L^2 (\Omega, L^2 (U)) \) and \( F_0 \) measurable, Theorem \[ \text{Theorem 74.6.4} \]
applies and we can conclude that there exists a unique solution to the integral equation \[ \text{in the sense described in this theorem.} \]
Here \( u \in L^p ((0,T] \times \Omega, L^p (U)) \) and is progressively measurable, the integral equation holding for all \( t \) for \( \omega \) off a set of measure zero. Since \( A \) satisfies for some \( \delta > 0 \) an inequality of the form
\[ \langle Au - Av, u - v \rangle \geq \delta \| u - v \|_{L^p(U)}^p \]
it follows easily from the above methods that the solution is also unique. In fact, this follows right away from Theorem \[ \text{Theorem 74.6.4} \]
because \((-\Delta)^{-1} u, u = \| u \|_{H^{-1}}^2. \)
Also note that from the integral equation,
\[ (-\Delta)^{-1} \left( u(t) - u_0 - \int_0^t \Phi dW \right) + \int_0^t u |u|^{p-2} ds = (-\Delta)^{-1} \int_0^t f ds \]
and so, since \((-\Delta)\) is the Riesz map on \( H^1_0 (U) \), the integral equation above shows that off a set of measure zero,
\[ \int_0^t u |u|^{p-2} ds = (-\Delta)^{-1} \left( \int_0^t f ds - \left( u(t) - u_0 - \int_0^t \Phi dW \right) \right) \in L^2 (0,T, H^1_0 (U) \cap H^2 (U)) \]
by elliptic regularity results. If it were not for that stochastic integral, one could assert that $|u|^\frac{p}{2-2} \in L^2(0,T, H^1_0(U))$. This is shown in [22]. However, it appears that no such condition can be obtained here because of the nowhere differentiability of the stochastic integral, even if more is assumed on $u_0$ and $\Phi$.

Also in this reference is a treatment of the Stefan problem. The Stefan problem involves a partial differential equation

$$u_t - \sum_i \frac{\partial}{\partial x_i} \left( k(u) \frac{\partial u}{\partial x_i} \right) = f, \text{ on } U \times [0,T] \equiv Q$$

for $(x,t) \notin S$ where $u$ is the temperature and $k(u)$ has a jump at $\sigma$ and $S$ is given by $u(x,t) = \sigma$. It is assumed that $0 < k_1 \leq k(r) \leq k_2 < \infty$ for all $r \in \mathbb{R}$. For example, its graph could be of the form

$$\begin{array}{c}
\begin{array}{cc}
0 & k(u) \\
\sigma & u
\end{array}
\end{array}$$

On $S$ there is a jump condition which is assumed to hold. Namely

$$bn_t - (k(u^+) u_i (+) - k(u^-) u_i (-)) n_i = 0$$

where the sum is taken over repeated indices and $b$ is the “limit” as $(x',t') \to (x,t) \in S$ where $(x',t') \in S_+$, $u (-)$ defined similarly. Also $n$ will denote the unit normal which goes from $S_+ \equiv \{(x,t) : u(x,t) > \sigma\}$ toward $S_- \equiv \{(x,t) : u(x,t) < \sigma\}$.

$$n = (n_t, n_{x_1}, \cdots, n_{x_n})$$

In addition, there is an initial condition and boundary conditions

$$u(x,0) = u_0(x) \notin S, \ u(x,t) = 0 \text{ on } \partial U.$$ 

The idea is to obtain a variational formulation of this thing. To do this, let $K(r) \equiv \int_0^r k(s) \, ds$. Thus in the case of the above picture, the graph of $K(r)$ would look like

$$\begin{array}{c}
\begin{array}{c}
K(u) \\
\sigma
\end{array}
\end{array}$$

Now let $\beta(t)$ be a function which satisfies

$$\beta'(t) = \frac{1}{k(K^{-1}(t))} \text{ for } t \neq \tau \equiv K(\sigma)$$

and it has a jump equal to $b$ at $\tau$. 

$$\begin{array}{c}
\begin{array}{c}
\beta(v) \\
\tau
\end{array}
\end{array}$$
Let \( v = K(u) \). Then for \( u \neq \sigma \), equivalently \( v \neq \tau \),

\[
v_t = K'(u) u_t = k(K^{-1}(v)) u_t
\]

and so

\[
u_t = \frac{1}{k(K^{-1}(v))} v_t = \frac{d}{dt}(\beta(v))
\]

Also,

\[
v_i = K'(u) u_i = k(u) u_i
\]

and so

\[
u_i = \frac{1}{k(u)} v_i
\]

Hence

\[
(k(u) u_i)_i = \left( k(u) \frac{1}{k(u)} v_i \right)_i = \Delta v
\]

Thus, off the set \( S \),

\[
\beta(v)_t - \Delta v = f
\]

Now let \( \phi \in L^2(0, T, H^1_0(U)) \) with \( \phi(x, T) = 0 \). Then assume \( S \) is sufficiently smooth that things like divergence theorem apply. Also note that \( u = \sigma \) is the same as \( v = \tau \).

\[
\int_Q (\beta(v)_t - \Delta v) \phi = \int_{S_+} (\beta(v)_t - \Delta v) \phi + \int_{S_-} (\beta(v)_t - \Delta v) \phi
\]

\[
= \int_{S_+} (\beta(v) \phi)_t - (v)_i \phi - (v, \phi)_i + v_i \phi_i
\]

\[
+ \int_{S_-} (\beta(v) \phi)_t - (v)_i \phi - (v, \phi)_i + v_i \phi_i
\]

Now using the divergence theorem, and continuing these formal manipulations, the above reduces to

\[
\int_S \beta(v(+)) \phi n_t - (v, +) \phi n_t + \int_{S_+} -\beta(v) \phi_t + v_i \phi_i - \int_{U \cap S_+} \beta(v(x, 0)) \phi(x, 0)
\]

\[
+ \int_S -\beta(v(-)) \phi n_t + (v, -) \phi n_t + \int_{S_-} -\beta(v) \phi_t + v_i \phi_i - \int_{U \cap S_-} \beta(v(x, 0)) \phi(x, 0)
\]

Combining the two integrals over \( S \) yields

\[
\int_S (b_1 - (v, +) - v(-)) n_i \phi = \int_S (b_1 - (k(u) u_i(+)) - k(u) u_i(-)) n_i \phi = 0
\]

by assumption. Therefore, including \( f \), we obtain

\[
\int_Q -\beta(v) \phi_t + v_i \phi_i - \int_U \beta(v(x, 0)) \phi(x, 0) = \int_Q f \phi
\]
which implies, using the initial condition
\[
\int_U \beta(v_0) \phi(x,0) + \int_Q ((\beta(v))' \phi + v_i \phi_i) - \int_U \beta(v(x,0)) \phi(x,0) = \int_Q f \phi
\]

Regard $\beta$ as a maximal monotone graph and let $\alpha(t) \equiv \beta^{-1}(t)$. Thus $\alpha$ is single valued. It just has a horizontal place corresponding to the jump in $\beta$. Then let

\[
w = \beta(v)
\]

so that
\[
v = \alpha(w)
\]

Then in terms of $w$, the above equals
\[
\int_U w_0 \phi(x,0) + \int_Q (w' \phi + \alpha(w)_i \phi_i) - \int_U w(x,0) \phi(x,0) = \int_Q f \phi
\]

and so this simplifies to
\[
w' - \Delta (\alpha(w)) = f, \ w(0) = w_0
\]

where $\alpha$ maps onto $\mathbb{R}$ and is monotone and satisfies
\[
\alpha(r_1) - \alpha(r_2) \geq 0, \ |\alpha(r)| \leq m |r| , \ |\alpha(r_1) - \alpha(r_2)| \leq m |r_1 - r_2| , \ \alpha(r) r \geq \delta |r|^2
\]

for some $\delta, m > 0$. Then $K^{-1}(\alpha(w)) = u$ where $u$ is the original dependent variable. Obviously, the original function $k$ could have had more than one jump and you would handle it the same way by defining $\beta$ to be like $K^{-1}$ except for having appropriate jumps at the values of $K(u)$ corresponding to the jumps in $k$. This explains the following example.

**Example 74.6.2** It can be shown that the Stefan problem can be reduced to the consideration of an equation of the form

\[
w_t - \Delta (\alpha(w)) = f, \ w(0) = w_0
\]

where $\alpha : L^2(0,T;L^2(U)) \rightarrow L^2(0,T;L^2(U))$ is monotone hemicontinuous and coercive, $\alpha$ being a single valued function. Here $f$ is the same which occurred in the original partial differential equation

\[
u_t - \sum_i \frac{\partial}{\partial x_i} \left( k(u) \frac{\partial u}{\partial x_i} \right) = f
\]

Thus a stochastic Stefan problem could be considered in the form

\[
(-\Delta^{-1}) w(t) - (-\Delta)^{-1} w_0 + \int_0^t \alpha(w) ds = (-\Delta^{-1}) \int_0^t f ds + (-\Delta^{-1}) \int_0^t \Phi dW
\]
This example can be included in the above general theory because

\[
((-\Delta^{-1}) u - (-\Delta^{-1}) v, u - v) \geq \|u - v\|_{V'}^2, \quad V' = H^{-1}, V = H^1_0(U)
\]

This is seen as follows. \( V, L^2(U), V' \) is a Gelfand triple. Then \(-\Delta\) is the Riesz map \( R \) from \( H^1_0(U) \) to \( H^{-1}(U) \). Then you have

\[
(y, R^{-1}y)_{L^2(U)} = \langle RR^{-1}y, R^{-1}y \rangle_{V', V} = \|R^{-1}y\|_{V'}^2 = \|y\|_{V'}^2.
\]

Next we give a simple example which is a singular and degenerate equation. This is a model problem which illustrates how the theory can be used. This problem is mixed parabolic and stochastic and nonlinear elliptic. It is a singular equation because the coefficient \( b \) can be unbounded. The existence of a solution is easy to obtain from the above theory but it does not follow readily from other methods. If \( p = 2 \) it is an abstract version of stochastic heat equation which could model a material in which the density becomes vanishingly small in some regions and very large in other regions.

**Example 74.6.3** Suppose \( U \) is a bounded open set in \( \mathbb{R}^3 \) and \( b(x) \geq 0, b \in L^p(U), \) \( p \geq 4 \) for simplicity. Consider the degenerate stochastic initial boundary value problem

\[
\begin{align*}
b(\cdot) u(t, \cdot) - b(\cdot) u_0(\cdot) - \int_0^t \nabla \cdot \left( |\nabla u|^{p-2} \nabla u \right) &= b \int_0^t \Phi dW \\
u &= 0 \text{ on } \partial U
\end{align*}
\]

where \( \Phi \in L^2([0, T] \times \Omega, \mathcal{L}_2(Q^{1/2}U, W)) \) for \( W = H^1_0(U) \).

To consider this equation and initial condition, it suffices to let \( W = H^1_0(U), V = W^1_p(U) \),

\[
A : V \rightarrow V', \quad \langle Au, v \rangle = \int_U |\nabla u|^{p-2} \nabla u : \nabla v dx,
\]

\[
B : W \rightarrow W', \quad \langle Bu, v \rangle = \int_U b(x) u(x) v(x) dx
\]

Then by the Sobolev embedding theorem, \( B \) is obviously self adjoint, bounded and nonnegative. This follows from a short computation:

\[
\left| \int_U b(x) u(x) v(x) dx \right| \leq \|v\|_{L^4(U)} \left( \int_U |b(x)|^{4/3} |u(x)|^{4/3} dx \right)^{3/4}
\]

\[
\leq \|v\|_{H^1_0(U)} \left( \left( \int_U |b(x)|^4 dx \right)^{1/3} \left( \int \left( |u(x)|^{4/3} \right)^{2/3} dx \right)^{2/3} \right)^{3/4}
\]

\[
= \|v\|_{H^1_0(U)} \|b\|_{L^4(U)} \|u\|_{L^2(U)} \leq \|b\|_{L^4} \|u\|_{H^1_0} \|v\|_{H^1_0}
\]
Also for some $\delta > 0$

$$\langle Au - Av, u - v \rangle \geq \delta \|u - v\|^p_V$$

The nonlinear operator is obviously monotone and hemi-continuous. As for $u_0$, it is only necessary to assume $u_0 \in L^2(\Omega, W)$ and $\mathcal{F}_0$ measurable. Then Theorem 74.4.7 gives the existence of a solution in the sense that for a.e. $\omega$ the integral equation holds for all $t$. Note that $b$ can be unbounded and may also vanish. Thus the equation can degenerate to the case of a non stochastic nonlinear elliptic equation.

The existence theorems can easily be extended to include the situation where $\Phi$ is replaced with a function of the unknown function $u$. This is done by splitting the time interval into small sub intervals of length $h$ and retarding the function in the stochastic integral, like a standard proof of the Peano existence theorem. Then the Itô formula is applied to obtain estimates and a limit is taken.

Other examples of the usefulness of this theory will result when one considers stochastic versions of systems of partial differential equations in which there is a nonlinear coupling between a parabolic equation and a nonlinear elliptic equation. These kinds of problems occur, for example as quasistatic damage problems in which the damage parameter satisfies a parabolic equation and the balance of momentum is a nonlinear elliptic equation and the two equations are coupled in a nonlinear way.

### 74.7 Other Examples, Inclusions

The above general result can also be used as a starting point for evolution inclusions or other situations where one does not have hemi-continuous operators. Assume here that

$$\Phi \in L^\infty ([0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, H \right) ) .$$

We will use the following simple observation. Let $\alpha > 2$. Let $\|\Phi\|_\infty$ denote the norm in $L^\infty ([0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, H \right) )$. By the Burkholder–Davis–Gundy inequality,

$$\int_\Omega \left( \int_s^t \Phi dW \right)^\alpha \, dP \leq C \int_\Omega \left( \int_s^t \|\Phi\|^2 \, d\tau \right)^{\alpha/2} \, dP$$

$$\int_\Omega \left( \sup_{r \in [s, t]} \left| \int_s^r \Phi dW \right| \right)^\alpha \, dP \leq C \int_\Omega \left( \int_s^t \|\Phi\|^2 \, d\tau \right)^{\alpha/2} \, dP$$

$$\leq C \|\Phi\|_\infty^\alpha \int_\Omega \left( \int_s^t \, d\tau \right)^{\alpha/2} \, dP = C \|\Phi\|_\infty^\alpha |t - s|^\alpha/2$$

By the Kolmogorov–Cenkov theorem, this shows that $t \to \int_0^t \Phi dW$ is Hölder continuous with exponent

$$\gamma < \frac{(\alpha/2) - 1}{\alpha} = \frac{1}{2} - \frac{1}{\alpha}.$$
Since \( \alpha > 2 \) is arbitrary, this shows that for any \( \gamma < 1/2 \), the stochastic integral is Holder continuous with exponent \( \gamma \). This is exactly the same kind of continuity possessed by the Wiener process. We state this as the following lemma.

**Lemma 74.7.1** Let \( \Phi \in L^\infty ([0,T] \times \Omega, L_2 (Q^{1/2} U, H)) \) then for any \( \gamma < 1/2 \), the stochastic integral \( \int_0^T \Phi dW \) is Holder continuous with exponent \( \gamma \).

To begin with, we consider a stochastic inclusion. Suppose, in the context of Theorem 74.4.7, that \( V \) is a closed subspace of \( W^{\sigma,p} (U) \), \( \sigma > 1 \) which contains \( C^\infty (U) \) where \( U \) is an open bounded set in \( \mathbb{R}^n \), different than the Hilbert space \( U \).

(In case the matrix \( A \) which follows equals 0, it suffices to take \( \sigma \) equal \( \geq 1 \).) Let

\[
\sum_{i,j} a_{i,j} (x) \xi_i \xi_j \geq 0, \quad a_{ij} = a_{ji}
\]

where the \( a_{i,j} \in C^1 (\bar{U}) \). Denoting by \( A \) the matrix whose \( ij^{th} \) entry is \( a_{ij} \), let

\[
W \equiv \left\{ u \in L^2 (U) : ( u, A^{1/2} \nabla u ) \in L^2 (U)^{n+1} \right\}
\]

with a norm given by

\[
\| u \|_W \equiv \left( \int_U \left( uv + \sum_{i,j} a_{i,j} (x) \partial_i u \partial_j v \right) dx \right)^{1/2}
\]

\( B : W \to W' \) be given by

\[
(Bu, v) = \int_U \left( uv + \sum_{i,j} a_{i,j} (x) \partial_i u \partial_j v \right) dx
\]

so that \( B \) is the Riesz map for this space. The case where the \( a_{ij} \) could vanish is allowed. Thus \( B \) is a positive self adjoint operator and is therefore, included in the above discussion. In this example, it will be significant that \( B \) is one to one and does not vanish.

This operator maps onto \( L^2 (U) \) because of basic considerations concerning maximal monotone operators. This is because

\[
(Du, v) = \int_U \sum_{i,j} a_{i,j} (x) \partial_i u \partial_j v dx
\]

can be obtained as a subgradient of a convex lower semicontinuous and proper functional defined on \( L^2 (U) \). Therefore, the operator is maximal monotone on \( L^2 (U) \) which means that \( I + D \) is onto. The domain of \( D \) consists of all \( u \in L^2 (U) \) such that

\[
Du = - \sum_{i,j} \partial_j (a_{ij} (x) \partial_i u) \in L^2 (U)
\]
along with suitable boundary conditions determined by the choice of \( V \). It follows that if 
\[
 u + Du = Bu = f \in H = L^2(U), 
\]
then
\[
 u - \sum_{i,j} \partial_j (a_{ij} \partial_i u) = f 
\]
Therefore,
\[
 \|u\|^2_{L^2(U)} + \int U \sum_{i,j} a_{ij} (x) \partial_i u \partial_j u = \|u\|^2_W = 
\]
\[
 = (f, u) \leq \|f\|_{L^2(U)} \|u\|_{L^2(U)} \leq \|f\|_{L^2(U)} \|u\|_W 
\]
which shows that the map \( B^{-1} : H = L^2(U) \to W \) is continuous.

Next suppose that \( \Phi \in L^\infty ([0,T] \times \Omega; L^2 (Q^{1/2}U, H)) \). Then by continuity of
the mapping \( B^{-1} \), it follows that \( \Psi \equiv B^{-1} \Phi \) satisfies \( \Psi \in L^\infty ([0,T] \times \Omega; L^2 (Q^{1/2}U, W)) \).
Thus \( \Phi = B\Psi \). In addition to this, to simplify the presentation, assume in addition that
\[
 \langle A(t, u, \omega) - A(t, v, \omega), u - v \rangle \geq \delta^2 \|u - v\|_V^p, 
\]
\[
 \langle A(t, u, \omega), u \rangle \geq \delta^2 \|u\|_V^p 
\]
Also assume the uniqueness condition of Lemma \( \text{Lemma 74.3.16} \) is satisfied. Consider the
following graph.

There is a monotone Lipschitz function \( J_n \) which is approximating a function
with the indicated jump. For a convex function \( \phi \), we denote by \( \partial \phi \) its subgradient. Thus for \( y \in \partial \phi (x) \)
\[
 (y, u) \leq \phi (x + u) - \phi (x). 
\]
Denote the Lipschitz function as \( J_n \) and the maximal monotone graph which it is
approximating as \( J \). Thus \( J \) denotes the ordered pairs \((x, y)\) which are of the form
\( (0, y) \) for \( |y| \leq 1 \) along with ordered pairs \( (x, 1), x > 0 \) and ordered pairs \( (x, -1) \)
for \( x < 0 \). The graph of \( J \) is illustrated in the above picture and is a maximal
monotone graph. Thus \( J = \partial \phi \) where \( \phi (r) = |r| \). As illustrated in the graph, \( J_n \) is
piecewise linear.

Let \( \phi_n (r) \equiv \int_0^r J_n (s) \, ds \). It follows easily that \( \phi_n (r) \to \phi (r) \) uniformly on \( \mathbb{R} \).
Also let \( h \geq 0 \) be progressively measurable and uniformly bounded by \( M \) and let
\( u_0 \in L^2 (\Omega, W), u_0 \mathcal{F}_0 \) measurable. Then from the above theorems, there exists a
unique solution to the integral equation
\[
 Bu_n (t) - Bu_0 + \int_0^t A(s, u_n, \omega) \, ds + \int_0^t h(s, \omega) J_n (u_n) \, ds = B \int_0^t \Psi dW, 
\]
the last term equaling $\int_0^t \Phi \, dW$. The integral equation holds off a set of measure zero and is progressively measurable.

Then from the Ito formula, one obtains, using the monotonicity of $J_n$ an estimate in which $C$ does not depend on $n$

$$\frac{1}{2} E \langle Bu_n (t), u_n (t) \rangle - \frac{1}{2} E \langle Bu_0, u_0 \rangle + E \int_0^t \langle Au_n, u_n \rangle_V \, ds \leq C$$

In particular, this holds for $n = 1$. Therefore, adjusting the constant, it follows that

$$\int_\Omega \langle Bu_1 (t), u_1 (t) \rangle + \int_0^T \| u_1 \|^p_V \, dt ds \leq C$$

Consequently, there exists a set of measure zero $N$ such that for $\omega \notin N$,

$$\langle Bu_1 (t), u_1 (t) \rangle + \int_0^T \| u_1 \|^p_V \, dt \leq C (\omega) \quad (74.7.64)$$

From the integral equation, it follows that, enlarging $N$ by including countably many sets of measure zero, for $\omega \notin N$

$$Bu_n (t) - Bu_1 (t) + \int_0^t A (s, u_n, \omega) - A (s, u_1, \omega) \, ds$$

$$+ \int_0^t h (s, \omega) J_n (u_n) - h (s, \omega) J_1 (u_1) \, ds = 0$$

Now it is certainly true that $|J_n (u_n) - J_1 (u_n)| \leq 2$. Thus

$$\int_0^t \langle h (s, \omega) J_n (u_n) - h (s, \omega) J_1 (u_1), u_n - u_1 \rangle \, ds$$

$$= \int_0^t \langle h (s, \omega) J_n (u_n) - h (s, \omega) J_1 (u_n), u_n - u_1 \rangle \, ds$$

$$+ \int_0^t \langle h (s, \omega) (J_1 (u_n) - J_1 (u_1)), u_n - u_1 \rangle \, ds$$

$$\geq -2M \int_0^t |u_n - u_1| \, ds$$

Therefore, from the Ito formula and for $\omega \notin N$,

$$\frac{1}{2} \langle Bu_n (t) - Bu_1 (t), u_n (t) - u_1 (t) \rangle + \delta^2 \int_0^t \| u_n - u_1 \|^p_V \, ds$$

$$\leq \int_0^t 2M |u_n - u_1| \, ds \leq \left( 2 + \frac{1}{2} \int_0^t |u_n - u_1|^2 \, ds \right) M$$

$$\leq \left( 2 + \frac{1}{2} \int_0^t \langle Bu_n - Bu_1, u_n - u_1 \rangle \, ds \right) M$$
where $M$ is an upper bound to $h$. Then by Gronwall’s inequality
\[
\frac{1}{2} \langle Bu_n(t) - Bu_1(t), u_n(t) - u_1(t) \rangle \leq 2Me^{MT}
\]
Hence
\[
\frac{1}{2} \langle Bu_n(t) - Bu_1(t), u_n(t) - u_1(t) \rangle + \delta^2 \int_0^t \|u_n - u_1\|^p_V \, ds \leq 2M + TM2e^{TM}
\]
It follows from (74.7.64) that for all $\omega \notin N$ and adjusting the constant,
\[
\langle Bu_n(t), u_n(t) \rangle + \int_0^T \|u_n\|^p_V \, ds \leq C(\omega) \quad (74.7.65)
\]
for all $n$, where $C(\omega)$ depends only on $\omega$.

For $\omega \notin N$, the above estimate implies there exists a further subsequence, still called $n$ such that
\[
Bu_n \to Bu \text{ weak * in } L^\infty(0,T,W')
\]
\[
u_n \to u \text{ weak * in } L^\infty(0,T,H)
\]
\[
u_n \to u \text{ weakly in } V_\omega
\]
From the integral equation solved and the assumption that $A$ is bounded, it can also be assumed that
\[
\left(B\left(u_n - \int_0^t \Psi dW\right)\right)' \to \left(B\left(u - \int_0^t \Psi dW\right)\right)' \quad \text{weakly in } V'_\omega \quad (74.7.66)
\]
\[
Bu(0) = Bu_0
\]
\[
Au_n \to \xi \text{ weakly in } V'_\omega
\]
It is known that $u_n$ is bounded in $V_\omega$. Also it is known that $\left(B\left(u_n - \int_0^t \Psi dW\right)\right)'$ is bounded in $V'_\omega$. Therefore, $B\left(u_n - \int_0^t \Psi dW\right)$ satisfies a Holder condition into $V'$. Since $\Psi$ is in $L^\infty$, $\int_0^t \Psi dW$ satisfies a Holder condition, and so $Bu_n$ satisfies a Holder condition into $V'$ while $Bu_n$ is bounded in $W'$. By compactness of the embedding of $V$ into $W$, it follows that $W'$ embeds compactly into $V'$. This is sufficient to conclude that $\{Bu_n\}$ is precompact in $W'$. The proof is similar to one given by Lions. See Theorem 76.5.6. Since $B$ is the Riesz map, this implies that $\{u_n\}$ is precompact in $W_\omega$ and hence in $H_\omega$.

Therefore, one can take a further subsequence and conclude that
\[
u_n \to u \text{ strongly in } H_\omega \equiv L^2([0,T], L^2(U))
\]
Therefore, a further subsequence, still denoted by $n$ satisfies
\[
u_n(t) \to u(t) \text{ in } L^2(U) \text{ for a.e. } t
\]
We can also assume that
\[ J_n(u_n) \to \zeta \text{ weak * in } L^\infty(0,T,L^\infty(U)) \]

From the integral equation solved,
\[ \left\langle \left( B \left( u_n - \int_0^t \Psi dW \right) \right)', u_n - u \right\rangle_{V_\omega} \]
\[ + \langle A(t,u_n) + h(t,\omega) J_n(u_n), u_n - u \rangle = 0 \] (74.7.67)

We claim that
\[ \int_0^t \left\langle \left( B \left( u_n - \int_0^s \Psi dW \right) \right)', u_n - u \right\rangle \, ds \geq 0 \] (74.7.68)

The difficulty is that \( \int_0^t \Psi dW \) is only in \( W \). To see that the conclusion is so, note that it is clear from a computation that
\[ \int_0^t \left\langle \left( B \left( u_n - \int_0^s \Psi dW \right) \right)', \left( u_n - \int_0^s \Psi dW \right) \right\rangle ds \geq 0 \]

**Claim:** The above is indeed nonnegative.

**Proof:** Denote by \( q(t) \) the stochastic integral, \( u_n \) as \( u \) and \( u \) as \( v \) to save notation. Then the left side of the above equals
\[ \frac{1}{h} \int_0^t \langle B(u-q) - B(v-q) , u-v \rangle \, ds \]
\[ - \frac{1}{h} \int_h^t \langle B(u(s-h) - q(s-h)) - B(v(s-h) - q(s-h)) , u(s) - v(s) \rangle \, ds \]
\[ \geq \frac{1}{h} \int_0^t \langle B(u-q) - B(v-q) , u-v \rangle \, ds \]
\[ - \frac{1}{2h} \int_h^t \left\langle B(u(s-h) - q(s-h)) - B(v(s-h) - q(s-h)) , (u(s-h) - v(s-h)) \right\rangle \, ds \]
\[ - \frac{1}{2h} \int_h^t \langle B(u-q) - B(v-q) , u-v \rangle \, ds \]
\[ \geq \frac{1}{h} \int_0^t \langle B(u-q) - B(v-q) , u-v \rangle \, ds \]
\[ - \frac{1}{2h} \int_0^{t-h} \langle B(u(s) - q(s)) - B(v(s) - q(s)) , (u(s) - v(s)) \rangle \, ds \]
\[ - \frac{1}{2h} \int_h^t \langle B(u-q) - B(v-q) , u-v \rangle \, ds \]
\[ \begin{align*}
&= \frac{1}{h} \int_{t-h}^{t} \langle B(u - q) - B(v - q), u - v \rangle \, ds \\
&\quad + \frac{1}{h} \int_{t-h}^{t} \langle B(u - q) - B(v - q), u - v \rangle \, ds \\
&\quad - \frac{1}{2h} \int_{t}^{t-h} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
&\quad - \frac{1}{2h} \int_{h}^{t} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
&\quad = \frac{1}{h} \int_{t-h}^{t} \langle B(u - q) - B(v - q), u - v \rangle \, ds \\
&\quad + \frac{1}{h} \int_{t-h}^{t} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
&\quad - \frac{1}{2h} \int_{t}^{t-h} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
&\quad - \frac{1}{2h} \int_{h}^{t} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
&\quad = \frac{1}{2h} \int_{t-h}^{t} \langle B(u - q) - B(v - q), u - v \rangle \, ds \\
&\quad + \frac{1}{2h} \int_{t}^{h} \langle B(u - q) - B(v - q), (u - v) \rangle \, ds \\
\end{align*} \]

which is nonnegative as can be seen by replacing \( u - v \) with \( (u - q) - (v - q) \) and using monotonicity of \( B \).

Now pass to a limit in $\text{(74.7.68)}$ as $h \to 0$ to get the desired inequality. Therefore, from $\text{(74.7.67)}$,

\[ \lim sup_{n \to \infty} \int_{0}^{T} \langle A(t, u_n) + h(t, \omega) J_n (u_n), u_n - u \rangle \, dt \leq 0 \]

From the above strong convergence, the left side equals

\[ \lim sup_{n \to \infty} \int_{0}^{T} \langle A(t, u_n), u_n - u \rangle \, dt \leq 0 \]
It follows that for all \( v \in \mathcal{V}_\omega \),
\[
\int_0^T \langle A(t, u), u - v \rangle dt \\
\quad \leq \liminf_{n \to \infty} \int_0^T \langle A(t, u_n), u_n - v \rangle dt \\
\quad = \limsup_{n \to \infty} \left[ \int_0^T \langle A(t, u_n), u_n - u \rangle dt + \int_0^T \langle A(t, u_n), u - v \rangle dt \right] \\
\quad \leq \int_0^T \langle \xi, u - v \rangle dt
\]

Since \( v \) is arbitrary, \( A(\cdot, u) = \xi \in \mathcal{V}_\omega' \). Passing to the limit in the integral equation yields
\[
Bu(t) - Bu_0 + \int_0^t A(s, u) ds + \int_0^t h(s, \omega) \zeta(s, \omega) ds = \int_0^t \Phi dW
\]

What is \( h(s, \omega) \zeta(s, \omega) \)?
\[
\int_0^T \langle h(s, \omega) J_n(u_n(s)), v(s) - u_n(s) \rangle ds \leq \int_0^T h(s, \omega) (\phi_n(v) - \phi_n(u_n)) ds
\]
Passing to the limit and using the strong convergence described above along with the uniform convergence of \( \phi_n \) to \( \phi \),
\[
\int_0^T (h(s, \omega) \zeta(s), v(s) - u(s))_H ds \leq \int_0^T h(s, \omega) (\phi(v(s)) - \phi(u(s))) ds
\]
Hence,
\[
\int_0^T (h(s, \omega) \phi(v(s)) - h(s, \omega) \phi(u(s))) - (h(s, \omega) \zeta(s), v(s) - u(s))_H ds \geq 0
\]
for any choice of \( v \in \mathcal{H}_\omega \). It follows that for a.e. \( s, h(s, \omega) \zeta(s) \in \partial_{\mathcal{H}} (h(s, \omega) \phi(u(s))) \).

This has shown that for each \( \omega \notin N \), there exists a solution to the integral equation
\[
Bu(t) - Bu_0 + \int_0^t A(s, u) ds + \int_0^t h(s, \omega) \zeta(s, \omega) ds = \int_0^t \Phi dW \quad (74.7.69)
\]
where for a.e. \( s, h(s, \omega) \zeta(s, \omega) \in \partial_{\mathcal{H}} (h(s, \omega) \phi(u(s))) \). Suppose you have two such solutions \((u_1, \zeta_1)\) and \((u_2, \zeta_2)\). Then
\[
Bu_1(t) - Bu_2(t) + \int_0^t A(s, u_1) - A(s, u_2) ds + \int_0^t h(s, \omega) (\zeta_1(s, \omega) - \zeta_2(s, \omega)) ds = 0
\]
CHAPTER 74. IMPLICIT STOCHASTIC EQUATIONS

Then from monotonicity of the subgradient it follows that \( u_1 = u_2 \). Then the two integral equations yield that for a.e. \( t \)

\[
\left( B \left( u_1 - \int_0^t \Psi dW \right) \right)'(t) + A(s, u_1(t)) + h(t, \omega) \zeta_1(t, \omega) = \]

\[
= \left( B \left( u_2 - \int_0^t \Psi dW \right) \right)'(t) + A(s, u_2(t)) + h(t, \omega) \zeta_2(t, \omega) = 0
\]

Therefore, for a.e. \( t, h(t, \omega) \zeta_1(t, \omega) = h(t, \omega) \zeta_2(t, \omega) \). Thus the solution to the integral equation for each \( \omega \) off a set of measure zero is unique.

At this point it is not clear that \( (t, \omega) \mapsto u(t, \omega) \) is progressively measurable. We claim that for \( \omega \in \mathcal{N} \) it is not necessary to take a subsequence in the above. This is because the above argument shows that if \( u_n \) fails to converge weakly, then there would exist two subsequences converging weakly to two different solutions to the integral equation which would contradict uniqueness.

Therefore, for \( \omega \notin \mathcal{N} \), \( u_n(\cdot, \omega) \to u(\cdot, \omega) \) weakly in \( \mathcal{Y}_\omega \) for a single sequence. Using the estimate \( \Xi \), it also follows that for a further subsequence still denoted as \( u_n \),

\[ u_n \rightharpoonup \bar{u} \text{ in } L^p([0, T] \times \Omega; V) \]

where the measurable sets are just the product measurable sets \( \mathcal{B}([0, T]) \times \mathcal{F}_T \). By Lemma \( \Xi \) for \( \omega \) off a set of measure zero, \( u(\cdot, \omega) = \bar{u}(\cdot, \omega) \) in \( \mathcal{Y}_\omega \) where \( \bar{u} \) is progressively measurable. It follows that in all of the above, we could substitute \( \bar{u} \) for \( u \) at least for \( \omega \) off a single set of measure zero. Thus \( u \) can be assumed progressively measurable. The above argument along with technical details related to exponential shift considerations proves the following theorem.

**Theorem 74.7.2** In the situation of Corollary \( \Xi \), where \( V \) is a closed subspace of \( W^{\sigma, p}(U), \sigma > 1 \) and \( W \) is as described above for \( U \) a bounded open set, \( u_0 \in L^2(\Omega, W), u_0 \mathcal{F}_0 \) measurable. Suppose \( \lambda I + A(t, u, \omega) \) satisfies

\[
\langle \lambda I + A(t, u, \omega) - (\lambda I + A(t, v, \omega)), u - v \rangle \geq \delta^2 \| u - v \|^p_V
\]

for all \( \lambda \) large enough. Also assume \( \Phi \in L^\infty([0, T] \times \Omega, \mathcal{L}_2(Q^{1/2}U, H)) \) with \( \Phi = B\Psi \) where

\[
\Psi \in L^\infty([0, T] \times \Omega, \mathcal{L}_2(Q^{1/2}U, W))
\]

and progressively measurable. Then there exists a unique solution to the integral equation

\[
Bu(t) - Bu_0 + \int_0^t A(s, u) ds + \int_0^t h(s, \omega) \zeta(s, \omega) ds = \int_0^\phi \Phi dW \tag{74.7.70}
\]

where for a.e. \( s, h(s, \omega) \zeta(s, \omega) \in \partial_\alpha h(s, \omega) \phi(u(s)) \) where \( \phi(r) \equiv |r| \). The symbol \( \partial_\alpha \) is the subgradient of \( \phi(u) \). Written in terms of inclusions, there exists a
set of measure zero such that off this set,

\[
\left( B\left( u - \int_0^t \Phi dW \right) \right)’ + A(t, u) \in \partial_u (h(t, \omega) \phi(u(s))) \text{ a.e. } \quad u(0) = u_0
\]

Note that one can replace

\[
\phi \in L^\infty \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right)
\]

with \( \phi \in L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2}U, H \right) \right) \) along with an assumption that \( t \to \phi(t, \omega) \) is continuous. This can be done by defining a stopping time

\[
\tau_n \equiv \inf \{ t : \| \phi(t) \| > n \}
\]

Then from the above example, there exists a solution to the integral equation off a set of measure zero

\[
Bu_n(t) - Bu_0 + \int_0^t A(s, u_n) ds + \int_0^t h(s, \omega) \zeta_n(s, \omega) ds = \int_0^{t \wedge \tau_n} \Phi dW
\]

Since \( \Phi \) is a continuous process, \( \tau_n \to \infty \) for all \( n \) large enough. Hence, one can replace the above with the desired integral equation. Of course the size of \( n \) depends on \( \omega \), but we can define

\[
u(t, \omega) = \lim_{n \to \infty} u_n(t, \omega)
\]

because by uniqueness which comes from monotonicity, if for a particular \( \omega \), both \( n, k \) are sufficiently large, then \( u_n = u_k \). Thus \( \nu \) is progressively measurable and is the desired solution.

Next we show that the above theory can also be used as a starting point for some second order in time problems. Consider a beam which has a point mass of mass \( m \) attached to one end. Suppose for sake of illustration that the left end is clamped, \( u(0, t) = u_x(0, t) = 0 \), while the right end which has the attached mass is free to move, \( u_x(1, t) = 0 \), and the beam occupies the interval \([0, 1]\) in material coordinates. Then the stress is \( \sigma = -u_{xxx} \) and balance of momentum is

\[
u_{tt} = \sigma_x + f
\]

where \( f \) is a body force. Thus, letting

\[
w \in V \equiv \{ w \in H^2(0, 1) : w(0) = w_x(0) = 0, w_x(1) = 0 \}
\]

be a test function,

\[
\int_0^1 u_{tt} w dx = \sigma w_x^1 + \int_0^1 (-\sigma) w_x dx + \int_0^1 f w dx
\]

\[
= -mu_{tt}(1, t) w(1, t) + \int_0^1 u_{xxx} w_x dx + \int_0^1 f w dx
\]
Doing another integration by parts and using the boundary conditions, it follows that an appropriate variational formulation for this problem is

\[ \int_0^1 u_{tt} w \, dx + m \gamma_1 u_{tt} \gamma_1 w + \int_0^1 u_{xx} w_{xx} \, dx = \int_0^1 f w \, dx \]

where here \( \gamma_1 \) is the trace map on the right end.

Letting

\[ u(t) = u_0 + \int_0^t v(s) \, ds, \]

where \( u(0, t) = u_0 \), we can write the above variational equation in the form

\[ (Bv)' + Au = f, \quad Bv(0) = Bv_0 \]

where we assume that \( v_0 \in W \) where \( W \) is the closure of \( V \) in \( H^1(0, 1) \) and the operators are given by

\[ B : W \to W', \quad \langle Bu, w \rangle = \int_0^1 u w \, dx + m \gamma_1 u \gamma_1 w \]

\[ A : V \to V', \quad \langle Au, w \rangle = \int_0^1 u_{xx} w_{xx} \, dx \]

Thus in terms of an integral equation, this would be of the form

\[ Bv(t) - Bv_0 + \int_0^t A(u) \, ds = \int_0^t f \, ds \]

This suggests a stochastic version of the form

\[ Bv(t) - Bv_0 + \int_0^t A(u) \, ds = \int_0^t f \, ds + \int_0^t \Phi dW \]

where \( \Phi \in L^\infty((0, T) \times \Omega, L_2(Q^{1/2}U, H)) \) for \( H = L^2(0, 1) \). As in the previous example, simple considerations involving maximal monotone operators imply that there exists \( \Psi \in L^\infty((0, T) \times \Omega, L_2(Q^{1/2}U, W)) \) such that \( \Phi = B \Psi \). We also assume that \( f \in V' \) and \( u_0, v_0 \) are in \( L^2(\Omega, V) \) and \( L^2(\Omega, W) \) respectively, both being \( \mathcal{F}_0 \) measurable. The above equation does not fit the general theory developed earlier because it is second order in time and is a stochastic version of a hyperbolic equation rather than a parabolic one. We consider it using a parabolic regularization which can be studied with the above general theory along with a simple fixed point argument.

Consider the approximate problem which is to find a solution to

\[ Bv(t) - Bv_0 + \varepsilon \int_0^t A\varepsilon \, ds + \int_0^t A(u) \, ds = \int_0^t f \, ds + \int_0^t \Phi dW \quad (74.7.71) \]

where \( u \) is given above as an integral of \( v \). First we argue that there exists a unique solution to the above integral equation and then we pass to a limit as \( \varepsilon \to 0 \). Let \( u \in \mathcal{V} \) be given.
From Corollary 2669.9 there exists a unique solution \( v \) to (47.7.71). Now suppose \( u_1, u_2 \) are two given in \( \mathcal{V} \) and denote by \( v_i \) the corresponding \( v \) which solves the above. Then from the Ito formula or standard considerations,

\[
\frac{1}{2} E \langle B (v_1 (t) - v_2 (t)), v_1 (t) - v_2 (t) \rangle + \varepsilon E \int_0^t \| v_1 - v_2 \|^2_{\mathcal{V}} \, ds \\
\leq \varepsilon E \int_0^t \| v_1 - v_2 \|^2 \, ds + C \varepsilon E \int_0^t \| u_1 - u_2 \|^2 \, ds
\]

Now define a mapping \( \theta \) from \( \mathcal{V} \) to \( \mathcal{V} \) as follows. Begin with \( v \) then obtain \( u(t) = u_0 + \int_0^t v (s) \, ds \) (74.7.72).

Use this \( u \) in (74.7.71). Then \( v \) is the solution to (74.7.71) which corresponds to \( u \).

Then the above inequality shows that

\[
\int_0^t \int_\Omega \| \theta v_1 (s) - \theta v_2 (s) \|^2 dP ds \leq \frac{C \varepsilon}{\varepsilon} \int_0^t \int_\Omega \| u_1 - u_2 \|^2_{\mathcal{V}} dP ds \leq \frac{C \varepsilon}{\varepsilon} C T \int_0^t \int_0^s \int_\Omega \| v_1 (r) - v_2 (r) \|^2 \, dP dr ds
\]

It follows that a high enough power of \( \theta \) is a contraction map on \( L^2 (0, T; L^2 (\Omega, \mathcal{V})) \) and so there exists a unique fixed point. This yields a unique solution to the above approximate problem in which \( u, v \) are related by (74.7.72).

Next we let \( \varepsilon \to 0 \). Index the above solution with \( \varepsilon \). By the Ito formula again,

\[
\frac{1}{2} E \langle B v_\varepsilon (t), v_\varepsilon (t) \rangle - \frac{1}{2} E \langle B v_0, v_0 \rangle + \varepsilon \int_0^t E \| v_\varepsilon \|^2_{\mathcal{V}} \, ds \\
\geq \frac{1}{2} E \| u_\varepsilon (t) \|^2_{\mathcal{V}} - \frac{1}{2} E \| u_0 \|^2_{\mathcal{V}} = \int_0^t E \langle f, v_\varepsilon \rangle \, ds
\]

Then one can obtain an estimate and pass to a limit as \( \varepsilon \to 0 \) obtaining the following convergences.

\( \varepsilon v_\varepsilon \to v \) strongly in \( \mathcal{V} \)

\( B v_\varepsilon \to B v \) weak \( \ast \) in \( L^\infty (0, T; L^2 (\Omega, W')) \)

\( u_\varepsilon (t) \to u (t) \) weak \( \ast \) in \( L^\infty (0, T; L^2 (\Omega, V)) \)

Then one can simply pass to a limit in the approximate integral equation and obtain, thanks to linearity considerations, that

\[
B v (t) - B v_0 + \int_0^t A (u) \, ds = \int_0^t f \, ds + \int_0^t \Phi dW; \ u (t) = u_0 + \int_0^t v (s) \, ds \quad (74.7.73)
\]

the equation holding in \( \mathcal{V}' \). Thus for a.e. \( \omega \), the above holds for a.e. \( t \). It is possible to work harder and have the equation holding for all \( t \). This involves using the other form of the Ito formula, estimating for a fixed \( \omega \) as done above and then arguing that by uniqueness one can use a single subsequence which works independent of \( \omega \).
Example 74.7.3 Let $u_0 \in L^2(\Omega, V)$ where $V$ is described above and let $v_0 \in L^2(\Omega, W)$ for $W$ described above. Let both of these initial conditions be progressively measurable. Also let $f \in V'$ and $\Phi \in L^\infty((0,T) \times \Omega, L_2(Q^{1/2}U, H))$. Then there exists a unique solution to the integral equation which can be written in the form

$$Bu_t(t) - Bv_0 + \int_0^t A \left( u_0 + \int_0^t u_t(r) \, dr \right) \, ds = \int_0^t f \, ds + \int_0^t \Phi dW$$

Note that a more standard model involves no point mass at the tip of the beam. This would be done the same way but it would not require the generalized Ito formula presented earlier. A more standard version would work.

One can find many other examples where this generalized Ito formula is a useful tool to study various kinds of stochastic partial differential equations. We have presented five examples above in which it was helpful to have the extra generality.
Chapter 75

Stochastic Inclusions

75.1 The General Context

The situation is as follows. There are spaces \( V \subseteq W \) where \( V, W \) are reflexive separable Banach spaces. It is assumed that \( V \) is dense in \( W \). Define the space for \( p > 1 \)

\[
V = L^p ([0, T]; V)
\]

where in each case, the \( \sigma \) algebra of measurable sets will be \( B ([0, T]) \) the Borel measurable sets. Thus, from the Riesz representation theorem,

\[
V' = L^{p'} ([0, T]; V'),
\]

We also assume \((\Omega, \mathcal{F}, P)\) is a complete probability space. That is, if \( P (E) = 0 \) and \( F \subseteq E \), then \( F \in \mathcal{F} \). Also

\[
V \subseteq W, \ W' \subseteq V'
\]

\( B (\omega) \) will be a linear operator, \( B (\omega) : W \to W' \) which satisfies

1. \( \langle B (\omega) x, y \rangle = \langle B (\omega) y, x \rangle \)
2. \( \langle B (\omega) x, x \rangle \geq 0 \) and equals 0 if and only if \( x = 0 \).
3. \( \omega \to B (\omega) \) is a measurable \( \mathcal{L} (W, W') \) valued function.

In the above formulae, \( \langle \cdot, \cdot \rangle \) denotes the duality pairing of the Banach space \( W \), with its dual space. We will use this notation in the present paper, the exact specification of which Banach space being determined by the context in which this notation occurs.

For example, you could simply take \( W = H = H' \) and \( B \) the identity and consider a standard Gelfand triple where \( H \) is a Hilbert space and \( B \) equal to the identity. An interesting feature is the requirement that \( B (\omega) \) be one to one. It would be interesting to include the case of degenerate \( B \), but \( B \) one to one includes
the case of most interest just mentioned. Also a more general set of assumptions will allow the inclusion of this case of degenerate $B(\omega)$ also.

We assume always that the norm on the various reflexive Banach spaces is strictly convex.

### 75.2 Some Fundamental Theorems

The following fundamental result will be very useful. It says essentially that if $(Bu)' \in L^{p'}(0, T; V')$ and $u \in L^p(0, T; V)$ then the map $u \to Bu(t)$ is continuous as a map from

$$X \equiv \left\{ u \in L^p([0, T]; V) : (Bu)' \in L^{p'}([0, T]; V') \right\}$$

having norm equal to

$$\|u\|_X \equiv \|u\|_{L^p(0, T; V)} + \|(Bu)\|_{L^{p'}(0, T; V')}$$

to $W'$. There is also a convenient integration by parts formula, Theorem 31.4.3. For convenience, the dependence of $B$ on $\omega$ is often suppressed. This is not a problem because the entire approach will be to consider the situation for fixed $\omega$.

**Theorem 75.2.1** Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, and let $Y \in L^{p'}(0, T; V')$ and

$$Bu(t) = Bu_0 + \int_0^t Y(s) \, ds \text{ in } V', \quad u_0 \in W, \quad Bu(t) = B(u(t)) \text{ for a.e. } t \quad (75.2.1)$$

Thus $Y = (Bu)'$ as a weak derivative in the sense of $V'$ valued distributions. It is known that $u \in L^p(0, T, V)$ for $p > 1$. Then $t \to Bu(t)$ is continuous into $W'$ for $t$ off a set of measure zero $N$ and also there exists a continuous function $t \to \langle Bu, u \rangle(t)$ such that for all $t \notin N, \langle Bu, u \rangle(t) = \langle B(u(t)), u(t) \rangle, Bu(t) = B(u(t))$, and for all $t$,

$$\frac{1}{2} \langle Bu, u \rangle(t) = \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle Y(s), u(s) \rangle \, ds$$

Note that the formula shows that $Bu_0 = Bu(0)$. Also it shows that $t \to \langle Bu, u \rangle(t)$ is continuous. To emphasize this a little more, $Bu$ is the name of a function. $Bu(t) = B(u(t))$ for a.e. $t$ and $t \to Bu(t)$ is continuous into $V'$ on $[0, T]$ because of the integral equation.

**Theorem 75.2.2** In the above corollary, the map $u \to Bu(t)$ is continuous as a map from $X$ to $V'$. Also if $Y$ denotes those $f \in L^p([0, T]; V)$ for which $f' \in L^p([0, T]; V)$, so that $f$ has a representative such that $f(t) = f(0) + \int_0^t f'(s) \, ds$, then if $\|f\|_Y \equiv \|f\|_{L^p([0, T]; V)} + \|f'\|_{L^p([0, T]; V)}$ the map $f \to f(t)$ is continuous.
Proof: First, why is $u \to Bu(0)$ continuous? Say $u, v \in X$ and say $p \geq 2$ first.

$$Bu(t) - Bv(t) = Bu(0) - Bv(0) + \int_0^t (Bu)'(s) - (Bv)'(s) \, ds$$

and so,

$$\left(\int_0^T \|Bu(0) - Bv(0)\|_{V'}^{p'} \, dt\right)^{1/p'} \leq \left(\int_0^T \|Bu(t) - Bv(t)\|_{V'}^{p'} \, dt\right)^{1/p'}$$

and so

$$\|Bu(0) - Bv(0)\|_{V'}, T^{1/p'} \leq \left(\|B\| \|u - v\|_{L^{p'}([0,T];V')} + T^{1/p'} \|(Bu)' - (Bv)\|_{L^{p'}([0,T];V')}\right)$$

$$\leq C (\|B\|, T) \|u - v\|_X$$

Thus $u \to Bu(0)$ is continuous into $V'$. If $p < 2$, then you do something similar.

$$\left(\int_0^T \|Bu(0) - Bv(0)\|_{V'}^p \, dt\right)^{1/p} \leq \left(\int_0^T \|Bu(t) - Bv(t)\|_{V'}^p \, dt\right)^{1/p}$$

$$\|Bu(0) - Bv(0)\|_{V'}, T^{1/p} \leq \|B\| \|u - v\|_{L^p} + C (T) \|(Bu)' - (Bv)'\|_{L^{p'}([0,T];V')}$$

$$\leq C (\|B\|, T) \|u - v\|_X.$$

However, one could just as easily have done this for an arbitrary $s < T$ by repeating the argument for

$$Bu(t) = Bu(s) + \int_s^t (Bu)'(r) \, dr$$

Thus this mapping is certainly continuous into $V'$. The last assertion is similar.

Also of use will be the following generalization of the Ascoli Arzela theorem. [Ku], Theorem 17.2.3.

**Theorem 75.2.3** Let $q > 1$ and let $E \subseteq W \subseteq X$ where the injection map is continuous from $W$ to $X$ and compact from $E$ to $W$. Let $S$ be defined by

$$\left\{ u \text{ such that } \|u(t)|_E \leq R \text{ for all } t \in [a,b], \text{ and } \|u(s) - u(t)\|_X \leq R|t - s|^{1/q} \right\}.$$
Thus $S$ is bounded in $L^\infty (0,T;E)$ and in addition, the functions are uniformly Holder continuous into $X$. Then $S \subseteq C ([a,b];W)$ and if $\{u_n\} \subseteq S$, there exists a subsequence, $\{u_{nk}\}$ which converges to a function $u \in C ([a,b];W)$ in the following way.

$$\lim_{k \to \infty} \|u_{nk} - u\|_{\infty, W} = 0.$$ 

Next is a major measurable selection theorem which forms an essential part of showing the existence of measurable solutions. See Theorem 75.2.4. The following is not dependent on there being a measure but in the applications there is typically a probability measure and often a set of measure zero which occurs in a natural way so an exceptional set of measure zero is included in the statement of the theorem but it has absolutely nothing to do with a set of measure zero as will be seen by just letting the exceptional set be $\emptyset$.

**Theorem 75.2.4** Let $V$ be a reflexive separable Banach space with dual $V'$, and let $p, p'$ be such that $p > 1$ and $\frac{1}{p} + \frac{1}{p'} = 1$. Let the functions $t \to u_n (t, \omega)$, for $n \in \mathbb{N}$, be in $L^p (\mathbb{R} \times [0,T], V')$ and $(t, \omega) \to u_n (t, \omega)$ be $B ([0,T]) \times \mathcal{F} \equiv \mathcal{P}$ measurable into $V'$. Suppose there is a set of measure zero $\mathcal{N} \subseteq \Omega$ such that if $\omega \notin \mathcal{N}$, then

$$\sup_{t \in [0,T]} \|u_n (t, \omega)\|_{V'} \leq C (\omega),$$

for all $n$. Also, suppose for each $\omega \notin \mathcal{N}$, each subsequence of $\{u_n\}$ has a further subsequence that converges weakly in $L^p (\mathbb{R} \times [0,T], V')$ to $v (\cdot, \omega) \in L^{p'} (\mathbb{R} \times [0,T]; V')$ such that the function $t \to v (t, \omega)$ is weakly continuous into $V'$.

Then, there exists a product measurable function $u$ such that $t \to u (t, \omega)$ is weakly continuous into $V'$ and for each $\omega \notin \mathcal{N}$, a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)} (\cdot, \omega) \to u (\cdot, \omega)$ weakly in $L^{p'} (\mathbb{R} \times [0,T]; V')$.

We prove the theorem in steps given below. Let $X = \prod_{k=1}^{\infty} C ([0,T])$ and note that when it is equipped with the product topology, then one can consider $X$ as a metric space using the metric

$$d (f, g) = \sum_{k=1}^{\infty} 2^{-k} \frac{\|f_k - g_k\|}{1 + \|f_k - g_k\|},$$

where $f = (f_1, f_2, \ldots), g = (g_1, g_2, \ldots) \in X$, and the norm is the maximum norm in $C ([0,T])$. With this metric, $X$ is complete and separable.

**Lemma 75.2.5** Let $\{f_n\}$ be a sequence in $X$ and suppose that each one of the components $f_{nk}$ is bounded by $C = C (k)$ in $C^{0,1} ([0,T])$. Then, there exists a subsequence $\{f_{nk}\}$ that converges to some $f \in X$ as $n_j \to \infty$. Thus, $\{f_n\}$ is pre-compact in $X$.

**Proof:** By the Ascoli–Arzelà theorem, there exists a subsequence $\{f_{nk}\}$ such that the sequence of the first components $f_{nk1}$ converges in $C ([0,T])$. Then, taking
75.2. SOME FUNDAMENTAL THEOREMS 2675

a subsequence, one can obtain \( \{n_k\} \) a subsequence of \( \{n_1\} \) such that both the first and second components of \( f_{n_1} \) converge. Continuing in this way one obtains a sequence of subsequences, each a subsequence of the previous one such that \( f_{n_1} \) has the first \( j \) components converging to functions in \( C([0,T]) \). Therefore, the diagonal subsequence has the property that it has every component converging to a function in \( C([0,T]) \). The resulting function is \( f \in \prod_k C([0,T]) \).

Now, for \( m \in \mathbb{N} \) and \( \phi \in V \), define \( l_m(t) \equiv \max(0, t - (1/m)) \) and \( \psi_{m,\phi} : L^p([0,T];V') \rightarrow C([0,T]) \) by

\[
\psi_{m,\phi} u(t) \equiv \int_0^T \langle m\phi \chi_{[l_m(t),t)}(s), u(s) \rangle_V \, ds = m \int_{l_m(t)}^t \langle \phi, u(s) \rangle_V \, ds.
\]

Here, \( \chi_{[l_m(t),t]}(\cdot) \) is the indicator function of the interval \([l_m(t),t)\) and \( \langle \cdot, \cdot \rangle_V = \langle \cdot, \cdot \rangle_V \) is the duality pairing between \( V \) and \( V' \).

Let \( D = \{ \phi, r \}_{r=1}^{\infty} \) denote a countable dense subset of \( V \). Then the pairs \((\phi, m)\) for \( \phi \in D \) and \( m \in \mathbb{N} \) form a countable set. Let \((m_k, \phi_{r_k})\) denote an enumeration of the pairs \((m, \phi) \in \mathbb{N} \times D \). To simplify the notation, we set

\[
f_k(u)(t) \equiv \psi_{m_k,\phi_{r_k}} u(t) = m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u(s) \rangle_V \, ds.
\]

For fixed \( \omega \notin N \) and \( k \), the functions \( \{ t \mapsto f_k(u_j(\cdot, \omega))(t) \}_{j=1}^{\infty} \) are uniformly bounded and equicontinuous because they are in \( C^{0,1}([0,T]) \). Indeed, we have for \( \omega \notin N \),

\[
|f_k(u_j(\cdot, \omega))(t)| = \left| m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds \right| \leq C(\omega) \| \phi_{r_k} \|_V
\]

and for \( t \leq t' \)

\[
|f_k(u_j(\cdot, \omega))(t) - f_k(u_j(\cdot, \omega))(t')| \leq m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds - m_k \int_{l_{m_k}(t')}^t \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds
\]

\[
\leq 2m_k |t' - t| C(\omega) \| \phi_{r_k} \|_V.
\]

By Lemma \ref{Lemma}, the set of functions \( \{ X_{N,C}(\omega) f(u_j(\cdot, \omega)) \}_{j=1}^{\infty} \) is pre-compact in \( X = \prod_k C([0,T]) \). We now define a set valued map \( \Gamma^n : \Omega \rightarrow X \) by

\[
\Gamma^n(\omega) \equiv \bigcup_{j \geq n} \{ X_{N,C}(\omega) f(u_j(\cdot, \omega)) \},
\]

where the closure is taken in \( X \). Then \( \Gamma^n(\omega) \) is the closure of a pre-compact set in \( X \) and so \( \Gamma^n(\omega) \) is compact in \( X \). From the definition, a function \( f \) is in \( \Gamma^n(\omega) \) if and only if \( d(f, X_{N,C}(\omega) f(w_l)) \rightarrow 0 \) as \( l \rightarrow \infty \), where each \( w_l \) is one of the \( u_j(\cdot, \omega) \) for \( j \geq n \). In the topology on \( X \), this happens iff for every \( k \),

\[
f_k(t) = \lim_{l \rightarrow \infty} m_k \int_{l_{m_k}(t)}^t \langle \phi_{r_k}, X_{N,C}(\omega) w_l(s, \omega) \rangle_V \, ds,
\]
CHAPTER 75. STOCHASTIC INCLUSIONS

where the limit is the uniform limit in \( t \).

**Lemma 75.2.6** The mapping \( \omega \rightarrow \Gamma^n (\omega) \) is an \( \mathcal{F} \) measurable set-valued map with values in \( X \). If \( \sigma \) is a measurable selection, then for each \( t, \omega \rightarrow \sigma (t, \omega) \) is \( \mathcal{F} \) measurable and \( (t, \omega) \rightarrow \sigma (t, \omega) \) is \( B ([0, T]) \times \mathcal{F} \) measurable.

We note that if \( \sigma \) is a measurable selection then \( \sigma (\omega) \in \Gamma^n (\omega) \), so \( \sigma = \sigma (\cdot, \omega) \) is a continuous function. To have \( \sigma \) measurable would mean that \( \sigma_k^{-1} (\text{open}) \in \mathcal{F} \), where the open set is in \( C ([0, T]) \).

**Proof:** Let \( O \) be a basic open set in \( X \). Then \( O = \prod_{k=1}^{\infty} O_k \), where \( O_k \) is a proper open set of \( C ([0, T]) \) only for \( k \in \{ k_1, \ldots, k_r \} \). Thus there is a proper open set in these positions and in every other position the open set is the whole space \( C ([0, T]) \). We need to show that

\[
\Gamma^n (O) = \{ \omega : \Gamma^n (\omega) \cap O \neq \emptyset \} \in \mathcal{F}.
\]

Now, \( \Gamma^n (O) = \cap_{k=1}^{\infty} \{ \omega : \Gamma^n (\omega)_{k_i} \cap O_{k_i} \neq \emptyset \} \), so we consider whether

\[
\{ \omega : \Gamma^n (\omega)_{k_i} \cap O_{k_i} \neq \emptyset \} \in \mathcal{F}. \tag{75.2.2}
\]

From the definition of \( \Gamma^n (\omega) \), this is equivalent to the condition that

\[
f_{k_i} (X_{NC} (\omega) u_j (\cdot, \omega)) = (f (X_{NC} (\omega) u_j (\cdot, \omega)))_{k_i} \in O_{k_i},
\]

for some \( j \geq n \), and so the set in (75.2.2) is of the form

\[
\bigcup_{j=n}^{\infty} \{ \omega : (f (X_{NC} (\omega) u_j (\cdot, \omega)))_{k_i} \in O_{k_i} \}.
\]

Now \( \omega \rightarrow (f (X_{NC} (\omega) u_j (\cdot, \omega)))_{k_i} \) is \( \mathcal{F} \) measurable into \( C ([0, T]) \) and so the above set is in \( \mathcal{F} \). To see this, let \( g \in C ([0, T]) \) and consider the inverse image of the ball with radius \( r \) and center \( g \),

\[
B (g, r) = \{ \omega : \| (X_{NC} (\omega) f (u_j (\cdot, \omega)))_{k_i} - g \|_{C([0,T])} < r \}.
\]

By continuity considerations,

\[
\| (X_{NC} (\omega) f (u_j (\cdot, \omega)))_{k_i} - g \|_{C([0,T])} = \sup_{t \in [0,T]} | (X_{NC} (\omega) f (u_j (t, \omega)))_{k_i} - g (t) |,
\]

which is the sup over countably many \( \mathcal{F} \) measurable functions. Thus, it is \( \mathcal{F} \) measurable. Since every open set is the countable union of such balls, it follows that the claim about \( \mathcal{F} \) measurability is valid. Hence, \( \Gamma^n (O) \) is \( \mathcal{F} \) measurable whenever \( O \) is a basic open set.
Now, $X$ is a separable metric space and so every open set is a countable union of these basic sets. Let $U \subseteq X$ be open with $U = \bigcup_{i=1}^{\infty}O_i$ where $O_i$ is a basic open set as above. Then,
\[ \Gamma^n (U) = \bigcup_{i=1}^{\infty} \Gamma^n (O_i) \in \mathcal{F}. \]

The existence of a measurable selection follows from the standard theory of measurable multi-functions. See Proposition 46.1, Section 46.3, starting on Page 141 for all the necessary stuff on measurable multifunctions or Section 46.4. If $\sigma$ is one of these measurable selections, the evaluation at $t$ is $\mathcal{F}$ measurable. Thus, $\omega \to \sigma(t, \omega)$ is $\mathcal{F}$ measurable with values in $\mathbb{R}^\infty$. Also, $t \to \sigma(t, \omega)$ is continuous, and so it follows that in fact $\sigma$ is product measurable as claimed. 

**Definition 75.2.7** Let $\Gamma(\omega) \equiv \cap_{n=1}^{\infty} \Gamma^n(\omega)$.

**Lemma 75.2.8** $\Gamma$ is a nonempty $\mathcal{F}$ measurable set-valued function with values in compact subsets of $X$. There exists a measurable selection $\gamma$ such that $(t, \omega) \to \gamma(t, \omega)$ is $\mathcal{P}$ measurable. Also, for each $\omega$, there exists a subsequence, $u_{n(\omega)}(\cdot, \omega)$ such that for each $k$,
\[ \gamma_k (t, \omega) = \lim_{n(\omega) \to \infty} f \left( \mathcal{X}_{N^C} (\omega) u_{n(\omega)} (t, \omega) \right)_k \]
\[ = \lim_{n(\omega) \to \infty} m_k \int_{t_m(t)}^t \langle \phi_{r_k}, \mathcal{X}_{N^C} (\omega) u_{n(\omega)} (s, \omega) \rangle_{U^*} \, ds. \]

**Proof:** From the definition of $\Gamma(\omega) = \cap_{n=1}^{\infty} \Gamma^n(\omega)$ it follows that $\omega \to \Gamma(\omega)$ is a compact set-valued map in $X$ and is nonempty because each $\Gamma^n(\omega)$ is nonempty and compact, and the $\Gamma^n(\omega)$ are nested. We next show that $\omega \to \Gamma(\omega)$ is $\mathcal{F}$ measurable. Indeed, each $\Gamma^n$ is compact valued and $\mathcal{F}$ measurable so, if $F$ is closed,
\[ \Gamma(\omega) \cap F = \cap_{n=1}^{\infty} \Gamma^n(\omega) \cap F, \]
and the left-hand side is not empty if and only if each $\Gamma^n(\omega) \cap F \neq \emptyset$. Thus, for $F$ closed,
\[ \{ \omega : \Gamma(\omega) \cap F \neq \emptyset \} = \cap_n \{ \omega : \Gamma^n(\omega) \cap F \neq \emptyset \}, \]
and so
\[ \Gamma^{-}(F) = \cap_n \Gamma^{-}(F) \in \mathcal{F}. \]

The last claim follows from the theory of multi-functions, see, e.g., Section 46.3. The fact that $\Gamma^n(\omega)$ is compact, $\Gamma^n$ is measurable and $\Gamma^n(U) \in \mathcal{F}$, for $U$ open, imply the strong measurability of $\Gamma^n$. See also Section 46.4 and also that $\Gamma^{-}(F) \in \mathcal{F}$. Thus, $\omega \to \Gamma(\omega)$ is a nonempty compact valued in $X$ and $\mathcal{F}$ measurable. We are using the theorem which says that when $\Gamma$ has compact values, then one can conclude that strong measurability and measurability coincide. This is why we can say that $\Gamma^{-}(F) \in \mathcal{F}$.

The standard theory also guarantees the existence of an $\mathcal{F}$ measurable selection $\omega \to \gamma(\omega)$ with $\gamma(\omega) \in \Gamma(\omega)$, for each $\omega$, and also that $t \to \gamma_k(t, \omega)$ (the $k^{th}$ component of $\gamma$) is continuous. Next, we consider the product
measurability of $\gamma_k$. We know that $\omega \to \gamma_k (\omega)$ is $F$ measurable into $C ([0, T])$ and since pointwise evaluation is continuous, $\omega \to \gamma_k (t, \omega)$ is $F$ measurable. (This is nothing more than a case of the general result that a continuous function of a measurable function is measurable.) Then, since $t \to \gamma_k (t, \omega)$ is continuous, it follows that $\gamma_k$ is a $P$ measurable real valued function and that $\gamma$ is a $P$ measurable $\mathbb{R}^\infty$ valued function. Since $\gamma (\omega) \in \Gamma (\omega)$, it follows that for each $n$, $\gamma (\omega) \in \Gamma_n (\omega)$.

Therefore, there exists $f_n \geq n$ such that for each $\omega$,

$$d (f (\mathcal{X}_{NC} (\omega) u_{j_n} (\cdot, \omega)), \gamma (\omega)) < 2^{-n}.$$  

Therefore, for a suitable subsequence $\{u_{n(\omega)} (\cdot, \omega)\}$, we have

$$\gamma (\omega) = \lim_{n(\omega) \to \infty} f (\mathcal{X}_{NC} (\omega) u_{n(\omega)} (\cdot, \omega)),$$

for each $\omega$. In particular, for each $k$

$$\gamma_k (t, \omega) = \lim_{n(\omega) \to \infty} f (\mathcal{X}_{NC} (\omega) u_{n(\omega)} (t, \omega))_k$$

$$= \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k} (t)}^t \langle \phi_{r_k}, \mathcal{X}_{NC} (\omega) u_{n(\omega)} (s, \omega) \rangle \, ds, \quad (75.2.3)$$

for each $t$. ■

Note that it is not clear that $(t, \omega) \to f (\mathcal{X}_{NC} (\omega) u_{n(\omega)} (t, \omega))$ is $P$ measurable, although $(t, \omega) \to \gamma (t, \omega)$ is $P$ measurable.

Now here is the proof of the theorem.

**Proof of Theorem**

By assumption, there exists a further subsequence, still denoted by $n (\omega)$, such that, in addition to $\{u_{n(\omega)} (\cdot, \omega)\}$, the weak limit

$$\lim_{n(\omega) \to \infty} \mathcal{X}_{NC} (\omega) u_{n(\omega)} (\cdot, \omega) = u (\cdot, \omega)$$

exists in $L^{V'} ([0, T]; V')$ such that $t \to u (t, \omega)$ is weakly continuous into $V'$. Then, $\{u_{n(\omega)} (\cdot, \omega)\}$ also holds for this further subsequence and in addition,

$$m_k \int_{l_{m_k} (t)}^t \langle \phi_{r_k}, u (s, \omega) \rangle \, ds$$

$$= \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k} (t)}^t \langle \phi_{r_k}, \mathcal{X}_{NC} (\omega) u_{n(\omega)} (s, \omega) \rangle \, ds$$

$$= \gamma_k (t, \omega).$$

Letting $\phi \in D$ be given, there exists a subsequence, denoted by $k$, such that $m_k \to \infty$ and $\phi_{r_k} = \phi$. Recall $\{m_k, \phi_{r_k}\}$ denoted an enumeration of the pairs $(m, \phi) \in \mathbb{N} \times D$. Then, passing to the limit and using the assumed continuity of $s \to u (s, \omega)$, the left-hand side of this equality converges to $\langle \phi, u (s, \omega) \rangle$ and so the right-hand side, $\gamma_k (t, \omega)$, must also converge and for each $\omega$. Since the right-hand side is a product measurable function of $(t, \omega)$, it follows that the pointwise limit is also product.
measurable. Hence, \((t, \omega) \mapsto \langle \phi, u(t, \omega) \rangle_V\) is product measurable for each \(\phi \in D\). Since \(D\) is a dense set, it follows that \((t, \omega) \mapsto \langle \phi, u(t, \omega) \rangle_V\) is \(P\) measurable for all \(\phi \in V\) and so by the Pettis theorem, \((t, \omega) \mapsto u(t, \omega)\) is \(P\) measurable into \(V'\).

Actually, one can say more about the measurability of the approximating sequence and in fact, we can obtain one for which \(\omega \mapsto u_{n(\omega)}(t, \omega)\) is also \(F\) measurable.

**Lemma 75.2.9** Suppose that \(u_{n(\omega)} \rightarrow u\) weakly in \(L^p([0, T]; V')\), where \(u\) is product measurable, and \(\{ u_{n(\omega)} \}\) is a subsequence of \(\{ u_n \}\), such that there exists a set of measure zero \(N \subseteq \Omega\) and

\[
\sup_{t \in [0, T]} \| u_n(t, \omega) \|_{V'}, < C(\omega) , \quad \text{for } \omega \notin N.
\]

Then, there exists a subsequence of \(\{ u_n \}\), denoted as \(\{ u_{k(\omega)} \}\), such that \(u_{k(\omega)} \rightarrow u\) weakly in \(L^p([0, T]; V')\), \(\omega \mapsto k(\omega)\) is \(F\) measurable, and \(\omega \mapsto u_{k(\omega)}(t, \omega)\) is also \(F\) measurable, for each \(\omega \notin N\).

**Proof:** Assume that \(f, g \in L^p([0, T]; V')\) and let \(\{ \phi_k \}\) be a countable dense subset of \(L^p([0, T]; V)\). Then, a bounded set in \(L^p([0, T]; V')\) with the weak topology can be considered a complete metric space using the metric

\[
d(f, g) = \sum_{j=1}^{\infty} 2^{-j} \frac{|\langle \phi_k, f - g \rangle|}{1 + |\langle \phi_k, f - g \rangle|}.
\]

Now, let \(k(\omega)\) be the first index of \(\{ u_n \}\) that is at least as large as \(k\) and such that

\[
d(\mathcal{X}_{N^c}(\omega) u_{k(\omega)}, u) \leq 2^{-k}.
\]

Such an index exists because there exists a convergent sequence \(\mathcal{X}_{N^c}(\omega) u_{n(\omega)}\) that converge weakly to \(u\). In fact,

\[
\{ \omega : k(\omega) = l \} = \{ \omega : d(u_l, u) \leq 2^{-k} \} \cap \bigcap_{j=1}^{l-1} \{ \omega : d(u_j, u) > 2^{-k} \}.
\]

Since \(u\) is product measurable and each \(u_l\) is also product measurable, these are all measurable sets with respect to \(F\) and so \(\omega \mapsto k(\omega)\) is \(F\) measurable. Now, we have that \(\mathcal{X}_{N^c}(\omega) u_{k(\omega)} \rightarrow u\) weakly in \(L^p([0, T]; V')\), for each \(\omega\), and each function is \(F\) measurable because

\[
u_{k(\omega)}(t, \omega) = \sum_{j=1}^{\infty} \mathcal{X}_{[k(\omega) = j]} u_j(t, \omega),
\]

and every term in the sum is \(F\) measurable. ■

Theorem 75.2.4 can be generalized in a very nice way. It is a better result because you don’t need to assume anything so strong as to have the functions bounded. One does not need any assumption that the limit is weakly continuous.
into $V'$. You can also have the functions take values in either $V$ or $V'$. The following is not dependent on there being a measure but in the applications there is typically a probability measure and often a set of measure zero which occurs in a natural way so an exceptional set of measure zero is included in the statement of the theorem.

**Theorem 75.2.10** Let $V$ be a reflexive separable Banach space with dual $V'$, and let $p,p'$ be such that $p > 1$ and $\frac{1}{p} + \frac{1}{p'} = 1$. Let the functions $t \to u_n (t,\omega)$, for $n \in \mathbb{N}$, be in $L^p ([0,T] ; V) \equiv V$ and $(t,\omega) \to u_n (t,\omega)$ be $B ([0,T]) \times \mathcal{F} \equiv \mathcal{P}$ measurable into $V$. Suppose there is a set of measure zero $\Omega \subseteq \Omega$ such that if $\omega \notin \Omega$, then

$$\| u_n (\cdot,\omega) \|_V \leq C (\omega),$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\{ u_n \}$ has a further subsequence that converges weakly in $V$ to $v (\cdot,\omega) \in V$. $v$ not known to be $\mathcal{P}$ measurable)

Then, there exists a product measurable function $u$ such that $t \to u (t,\omega)$ is in $V$ and for each $\omega \notin \Omega$, a subsequence $u_n(\omega)$ such that $u_n(\omega)(\cdot,\omega) \to u (\cdot,\omega)$ weakly in $V$.

We prove the theorem in steps given below. Let $X = \prod_{k=1}^{\infty} C ([0,T])$ and note that when it is equipped with the product topology, then one can consider $X$ as a metric space using the metric

$$d (f,g) = \sum_{k=1}^{\infty} 2^{-k} \frac{\| f_k - g_k \|}{1 + \| f_k - g_k \|},$$

where $f = (f_1, f_2, \ldots), g = (g_1, g_2, \ldots) \in X$, and the norm is the maximum norm in $C ([0,T])$. With this metric, $X$ is complete and separable.

**Lemma 75.2.11** Let $\{ f_n \}$ be a sequence in $X$ and suppose that each one of the components $f_{nk}$ is bounded by $C = C (k)$ in $C^0 (1/p') ([0,T])$. Then, there exists a subsequence $\{ f_{n_j} \}$ that converges to some $f \in X$ as $n_j \to \infty$. Thus, $\{ f_n \}$ is pre-compact in $X$.

**Proof:** This follows right away from Tychonoff’s theorem and the compactness of the embedding of the Holder space into $C ([0,1])$. ■

Now, for $m \in \mathbb{N}$ and $\phi \in V'$, define $l_m(t) = \max (0, t - (1/m))$ and $\psi_{m,\phi} : V \to C ([0,T])$ by

$$\psi_{m,\phi} u (t) = \int_0^T \langle m \phi \chi_{[l_m(t),t]} (s), u (s) \rangle_V ds = m \int_{l_m(t)}^d \langle \phi, u (s) \rangle_V ds.$$

Here, $\chi_{[l_m(t),t]} (\cdot)$ is the characteristic function of the interval $[l_m(t),t]$ and $\langle \cdot, \cdot \rangle_V = \langle \cdot, \cdot \rangle_V$ is the duality pairing between $V$ and $V'$. 
75.2. SOME FUNDAMENTAL THEOREMS

Let \( D = \{ \phi_r \}_{r=1}^{\infty} \) denote a countable subset of \( V' \). Then the pairs \((\phi, m)\) for \( \phi \in D \) and \( m \in \mathbb{N} \) form a countable set. Let \((m_k, \phi_{r_k})\) denote an enumeration of the pairs \((m, \phi) \in \mathbb{N} \times D\). To simplify the notation, we set

\[
f_k(u)(t) = \psi_{m_k, \phi_{r_k}}(u)(t) = m_k \int_{t_m(t)}^{t} \langle \phi_{r_k}, u(s) \rangle_V \, ds.
\]

For fixed \( \omega \notin N \) and \( k \), the functions \( \{t \mapsto f_k(u_j(\cdot, \omega))(t)\}_j \) are uniformly bounded and equicontinuous because they are in \( C^{0,1/p'}([0,T]) \). Indeed, we have for \( \omega \notin N \),

\[
|f_k(u_j(\cdot, \omega))(t)| = \left| m_k \int_{t_m(t)}^{t} \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds \right|
\]

\[
\leq m \|\phi_{r_k}\| T^{1/p'} \left| \int_{0}^{T} \|u_j(s, \omega)\|_V^p \, ds \right|^{1/p} \leq C(\omega) m \|\phi_{r_k}\| V, T^{1/p'}
\]

and for \( t \leq t' \)

\[
|f_k(u_j(\cdot, \omega))(t) - f_k(u_j(\cdot, \omega))(t')| 
\]

\[
\leq m_k \left| \int_{t_m(t)}^{t} \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds - m_k \int_{t_m(t')}^{t'} \langle \phi_{r_k}, u_j(s, \omega) \rangle_V \, ds \right| 
\]

\[
\leq 2m_k |t' - t|^{1/p'} C(\omega) \|\phi_{r_k}\| V.
\]

By Lemma 75.2.11, the set of functions \( \{\chi_{NC}(\omega)f(u_j(\cdot, \omega))\}_{j=1}^{\infty} \) is pre-compact in \( X = \prod_{k} C([0,T]) \). We now define a set valued map \( \Gamma^n : \Omega \rightarrow X \) by

\[
\Gamma^n(\omega) \equiv \bigcup_{j \geq n} \{\chi_{NC}(\omega)f(u_j(\cdot, \omega))\},
\]

where the closure is taken in \( X \). Then \( \Gamma^n(\omega) \) is the closure of a pre-compact set in \( X \) and so \( \Gamma^n(\omega) \) is compact in \( X \). From the definition, a function \( f \) is in \( \Gamma^n(\omega) \) if and only if \( d(f, \chi_{NC}(\omega)f(w_j)) \rightarrow 0 \) as \( l \rightarrow \infty \), where each \( w_j \) is one of the \( u_j(\cdot, \omega) \) for \( j \geq n \). In the topology on \( X \), this happens iff for every \( k \),

\[
f_k(t) = \lim_{l \rightarrow \infty} m_k \int_{t_m(t)}^{t} \langle \phi_{r_k}, \chi_{NC}(\omega)w_l(s, \omega) \rangle_V \, ds,
\]

where the limit is the uniform limit in \( t \).

**Lemma 75.2.12** The mapping \( \omega \mapsto \Gamma^n(\omega) \) is an \( F \) measurable set-valued map with values in \( X \). If \( \sigma \) is a measurable selection, then for each \( t, \omega \rightarrow \sigma(t, \omega) \) is \( F \) measurable and \( (t, \omega) \rightarrow \sigma(t, \omega) \) is \( B([0,T]) \times F \) measurable.

We note that if \( \sigma \) is a measurable selection then \( \sigma(\omega) \in \Gamma^n(\omega) \), so \( \sigma = \sigma(\cdot, \omega) \) is a continuous function. To have \( \sigma \) measurable would mean that \( \sigma^{-1}(\text{open}) \in F \), where the open set is in \( C([0,T]) \).

CHAPTER 75. STOCHASTIC INCLUSIONS

Proof: Let $O$ be a basic open set in $X$. Then $O = \prod_{k=1}^{\infty} O_k$, where $O_k$ is a proper open set of $C([0,T])$ only for $k \in \{k_1, \ldots, k_r\}$. Thus there is a proper open set in these positions and in every other position the open set is the whole space $C([0,T])$. We need to show that

$$\Gamma^n (O) \equiv \{ \omega : \Gamma^n (\omega) \cap O \neq \emptyset \} \in \mathcal{F}.$$  

Now, $\Gamma^n (O) = \cap_{i=1}^{\infty} \{ \omega : \Gamma^n (\omega)_{k_i} \cap O_{k_i} \neq \emptyset \}$, so we consider whether

$$\{ \omega : \Gamma^n (\omega)_{k_i} \cap O_{k_i} \neq \emptyset \} \in \mathcal{F}. \quad (75.2.4)$$

From the definition of $\Gamma^n (\omega)$, this is equivalent to the condition that

$$f_{k_i} (\mathcal{X}_{NC} (\omega) u_j (\cdot, \omega)) = (f (\mathcal{X}_{NC} (\omega) u_j (\cdot, \omega)))_{k_i} \in O_{k_i}$$

for some $j \geq n$, and so the set in (75.2.4) is of the form

$$\cup_{j=n}^{\infty} \{ \omega : (f (\mathcal{X}_{NC} (\omega) u_j (\cdot, \omega)))_{k_i} \in O_{k_i} \}.$$ 

Now $\omega \rightarrow (f (\mathcal{X}_{NC} (\omega) u_j (\cdot, \omega)))_{k_i}$ is $\mathcal{F}$ measurable into $C([0,T])$ and so the above set is in $\mathcal{F}$. To see this, let $g \in C([0,T])$ and consider the inverse image of the ball with radius $r$ and center $g$,

$$B(g, r) = \left\{ \omega : \| (\mathcal{X}_{NC} (\omega) f (u_j (\cdot, \omega)))_{k_i} - g \|_{C([0,T])} < r \right\}.$$ 

By continuity considerations,

$$\left\| (\mathcal{X}_{NC} (\omega) f (u_j (\cdot, \omega)))_{k_i} - g \right\|_{C([0,T])} = \sup_{t \in [0,T]} \left\| (\mathcal{X}_{NC} (\omega) f (u_j (t, \omega)))_{k_i} - g(t) \right\|,$$

which is the sup over countably many $\mathcal{F}$ measurable functions. Thus, it is $\mathcal{F}$ measurable. Since every open set is the countable union of such balls, it follows that the claim about $\mathcal{F}$ measurability is valid. Hence, $\Gamma^n (O) \in \mathcal{F}$ measurable whenever $O$ is a basic open set.

Now, $X$ is a separable metric space and so every open set is a countable union of these basic sets. Let $U \subseteq X$ be open with $U = \cup_{i=1}^{\infty} O_i$ where $O_i$ is a basic open set as above. Then,

$$\Gamma^n (U) = \cup_{i=1}^{\infty} \Gamma^n (O_i) \in \mathcal{F}.$$ 

The existence of a measurable selection follows from the standard theory of measurable multi-functions [1, 2] see [3] starting on Page 141 for all the necessary stuff on measurable multifunctions or Section 46. If $\sigma$ is one of these measurable selections, the evaluation at $t$ is $\mathcal{F}$ measurable. Thus, $\omega \rightarrow \sigma (t, \omega)$ is $\mathcal{F}$ measurable with values in $\mathbb{R}^\infty$. Also, $t \rightarrow \sigma (t, \omega)$ is continuous, and so it follows that in fact $\sigma$ is product measurable as claimed.
Definition 75.2.13 Let $\Gamma (\omega ) \equiv \cap_{n=1}^{\infty } \Gamma^n (\omega )$.

Lemma 75.2.14 $\Gamma$ is a nonempty $\mathcal{F}$ measurable set-valued function with values in compact subsets of $X$. There exists a measurable selection $\gamma$ such that $(t, \omega ) \rightarrow \gamma (t, \omega )$ is $\mathcal{P}$ measurable. Also, for each $\omega$, there exists a subsequence, $u_{n(\omega )} (\cdot , \omega )$ such that for each $k$,

$$
\gamma_k (t, \omega ) = \lim_{n(\omega ) \rightarrow \infty } f \left( X_{N^C} (\omega ) u_{n(\omega )} (t, \omega ) \right)_k
$$

$$
= \lim_{n(\omega ) \rightarrow \infty } m_k \int_{l_{mk}(t)}^t \phi_{rk}, X_{N^C} (\omega ) u_{n(\omega )} (s, \omega ) \psi ds.
$$

Proof: From the definition of $\Gamma (\omega ) = \cap_{n=1}^{\infty } \Gamma^n (\omega )$ it follows that $\omega \rightarrow \Gamma (\omega )$ is a compact set-valued map in $X$ and is nonempty because each $\Gamma^n (\omega )$ is nonempty and compact, and the $\Gamma^n (\omega )$ are nested. We next show that $\omega \rightarrow \Gamma (\omega )$ is $\mathcal{F}$ measurable. Indeed, each $\Gamma^n$ is compact valued and $\mathcal{F}$ measurable so, if $F$ is closed,

$$
\Gamma (\omega ) \cap F = \cap_{n=1}^{\infty } \Gamma^n (\omega ) \cap F,
$$

and the left-hand side is not empty if and only if each $\Gamma^n (\omega ) \cap F \neq \emptyset$. Thus, for $F$ closed,

$$
\{ \omega : \Gamma (\omega ) \cap F \neq \emptyset \} = \cap_n \{ \omega : \Gamma^n (\omega ) \cap F \neq \emptyset \},
$$

and so

$$
\Gamma^- (F) = \cap_n \Gamma'^- (F) \in \mathcal{F}.
$$

The last claim follows from the theory of multi-functions, see, e.g., [4, 5] or Section 13. The fact that $\Gamma^n (\omega )$ is compact, $\Gamma^n$ is measurable and $\Gamma'^- (U) \in \mathcal{F}$, for $U$ open, imply the strong measurability of $\Gamma^n$ [4, 5] see also Section 13, and also that $\Gamma'^- (F) \in \mathcal{F}$. Thus, $\omega \rightarrow \Gamma (\omega )$ is nonempty compact valued in $X$ and $\mathcal{F}$ measurable. We are using the theorem which says that when $\Gamma$ has compact values, then one can conclude that strong measurability and measurability coincide. See Proposition 13.1.13. This is why we can say that $\Gamma'^- (F) \in \mathcal{F}$.

The standard theory [4, 5], Section 13, also guarantees the existence of an $\mathcal{F}$ measurable selection $\omega \rightarrow \gamma (\omega )$ with $\gamma (\omega ) \in \Gamma (\omega )$, for each $\omega$, and also that $t \rightarrow \gamma_k (t, \omega )$ (the $k^{th}$ component of $\gamma$) is continuous. Next, we consider the product measurability of $\gamma_k$. We know that $\omega \rightarrow \gamma_k (\omega )$ is $\mathcal{F}$ measurable into $C([0, T])$ and since pointwise evaluation is continuous, $\omega \rightarrow \gamma_k (t, \omega )$ is $\mathcal{F}$ measurable. (This is nothing more than a case of the general result that a continuous function of a measurable function is measurable.) Then, since $t \rightarrow \gamma_k (t, \omega )$ is continuous, it follows that $\gamma_k$ is a $\mathcal{P}$ measurable real valued function and that $\gamma$ is a $\mathcal{P}$ measurable $\mathbb{R}^\infty$ valued function. Since $\gamma (\omega ) \in \Gamma (\omega )$, it follows that for each $n$, $\gamma (\omega ) \in \Gamma^n (\omega )$. Therefore, there exists $j_n \geq n$ such that for each $\omega$,

$$
d (f (X_{N^C} (\omega ) u_{j_n} (\cdot , \omega )), \gamma (\omega )) < 2^{-n}.
$$

Therefore, for a suitable subsequence $\{ u_{n(\omega )} (\cdot , \omega ) \}$, we have

$$
\gamma (\omega ) = \lim_{n(\omega ) \rightarrow \infty } f (X_{N^C} (\omega ) u_{n(\omega )} (\cdot , \omega )).
$$
for each \( \omega \). In particular, for each \( k \)

\[
\gamma_k (t, \omega) = \lim_{n(\omega) \to \infty} f \left( X_{NC} (\omega) u_n(\omega) (t, \omega) \right)_k
\]

\[
= \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k}(t)}^{t} \langle \phi_{r_k}, X_{NC} (\omega) u_n(\omega) (s, \omega) \rangle_V ds,
\]

(75.2.5)

for each \( t \).

Note that it is not clear that \( (t, \omega) \to f \left( X_{NC} (\omega) u_n(\omega) (t, \omega) \right) \) is \( \mathcal{P} \) measurable, although \( (t, \omega) \to \gamma (t, \omega) \) is \( \mathcal{P} \) measurable.

Now here is the proof of the theorem.

**Proof of Theorem 75.2.10** By assumption, there exists a further subsequence, still denoted by \( n (\omega) \), such that the weak limit

\[
\lim_{n(\omega) \to \infty} X_{NC} (\omega) u_n(\omega) (\cdot, \omega) = v (\cdot, \omega)
\]

exists in \( V \). Then,

\[
m_k \int_{l_{m_k}(t)}^{t} \langle \phi_{r_k}, v (s, \omega) \rangle_V ds
\]

\[
= \lim_{n(\omega) \to \infty} m_k \int_{l_{m_k}(t)}^{t} \langle \phi_{r_k}, X_{NC} (\omega) u_n(\omega) (s, \omega) \rangle_V ds
\]

\[
= \gamma_k (t, \omega), \text{ product measurable.}
\]

Letting \( \phi \in \mathcal{D} \) be given, there exists a subsequence, denoted by \( k \), such that \( m_k \to \infty \) and \( \phi_{r_k} = \phi \). Recall \( (m_k, \phi_{r_k}) \) denoted an enumeration of the pairs \( (m, \phi) \in \mathbb{N} \times \mathcal{D} \). For a given \( \phi \in \mathcal{D} \) denote this sequence by \( m_{\phi} \). Thus we have measurability of

\[
(t, \omega) \to m_{\phi} \int_{l_{m_{\phi}}(t)}^{t} \langle \phi, v (s, \omega) \rangle_V ds
\]

for each \( \phi \in \mathcal{D} \).

Now we will be a little more careful about the countable set \( \mathcal{D} \). Iterate the following. Let \( \phi_1 \neq 0 \). Let \( \mathcal{F} \) denote linearly independent subsets of \( V' \) which contain \( \phi_1 \) such that the elements are further apart than \( 1/5 \). Let \( \mathcal{C} \) denote a maximal chain. Thus \( \mathcal{C} \cup \mathcal{F} \) is also in \( \mathcal{F} \). If \( W := \text{span} \mathcal{C} \) fails to be all of \( V' \), then there would exist \( \psi \notin W \) such that the distance of \( \psi \) to the closed subspace \( W \) is at least \( 1/5 \). Now \( \mathcal{C}, \cup \{ \mathcal{C} \cup \{ \psi \} \} \) would violate maximality of \( \mathcal{C} \). Hence \( W = V' \). Now it follows that \( \mathcal{C} \) must be countable since otherwise, \( V' \) would fail to be separable.

Let \( M \) be the rational linear combinations of \( \mathcal{D} \). It must be dense in \( V' \). Note that linear combinations of the \( \phi_i \) are uniquely determined because none is a linear combination of the others. Now define a linear mapping on \( M \) which makes sense for \( (t, \omega) \) on a certain set.
Definition 75.2.15 Let $E$ be those points $(t, \omega)$ such that the following limit exists for each $\phi \in \mathcal{D}$

$$
\Lambda (t, \omega) \phi \equiv \lim_{m_\phi \to \infty} m_\phi \int_{l_{m_\phi}(t)}^{t} \langle \phi, v(s, \omega) \rangle \, ds
$$

The set of points where the limit of measurable functions exists is always measurable so $E$ is a measurable set. Extend this mapping linearly. That is, for $\psi \in M, \psi \equiv \sum_i a_i \phi_i$,

$$
\Lambda (t, \omega) \psi \equiv \sum_i a_i \Lambda (t, \omega) \phi_i = \sum_i a_i \left( \lim_{m_{\phi_i} \to \infty} m_{\phi_i} \int_{l_{m_{\phi_i}}(t)}^{t} \langle \phi_i, v(s, \omega) \rangle \, ds \right)
$$

Thus $(t, \omega) \to \Lambda (t, \omega) \psi$ is product measurable, being the sum of limits of product measurable functions. Let $G$ denote those $(t, \omega)$ in $E$ such that there exists a constant $C(t, \omega)$ such that for all $\psi \in M$,

$$
|\Lambda (t, \omega) \psi| \leq C(t, \omega) \|\psi\|
$$

Lemma 75.2.16 $G$ is product measurable.

Proof: This follows from the formula

$$
E \cap G^C = \cap_{n \in \mathbb{N}} \bigcup_{\psi \in M} \{ (t, \omega) \in E : |\Lambda (t, \omega) \psi| > n \|\psi\| \}
$$

which is clearly product measurable because $(t, \omega) \to \Lambda (t, \omega) \psi$ is. Thus, since $E$ is measurable, it follows that $E \cap G = G$ is also. \(\square\)

For $(t, \omega) \in G, \Lambda (t, \omega)$ has a unique extension to all of $V$, the dual space of $V'$, still denoted as $\Lambda (t, \omega)$. By the Riesz representation theorem, for $(t, \omega) \in G$, there exists $u(t, \omega) \in V$,

$$
\Lambda (t, \omega) \psi = \langle \psi, u(t, \omega) \rangle_{V', V}
$$

Thus $(t, \omega) \to \chi_G (t, \omega) u(t, \omega)$ is product measurable by the Pettis theorem. Let $u = 0$ off $G$. We know $G$ is product measurable. Now we want to show that for each $\omega, \{ t : (t, \omega) \in G \}$ has full measure. This involves the fundamental theorem of calculus.

Fix $\omega$. By the fundamental theorem of calculus,

$$
\lim_{m \to \infty} m \int_{l_m(t)}^{t} v(s, \omega) \, ds = v(t, \omega) \text{ in } V
$$

for a.e. $t$ say for all $t \notin N(\omega) \subseteq [0, T]$. Of course we do not know that $\omega \to v(t, \omega)$ is measurable. However, the existence of this limit for $t \notin N(\omega)$ implies that for every $\phi \in V'$,

$$
\lim_{m \to \infty} m \int_{l_m(t)}^{t} \langle \phi, v(s, \omega) \rangle \, ds \leq C(t, \omega) \|\phi\|
$$
for some \( C(t, \omega) \). Here \( m \) does not depend on \( \phi \). Thus, in particular, this holds for a subsequence and so for each \( t \notin N(\omega), (t, \omega) \in G \) because for each \( \phi \in D \),

\[
\lim_{m_\phi \to \infty} m_\phi \int_{l_{m_\phi}(t)}^t \langle \phi, v(s, \omega) \rangle \, ds \text{ exists and satisfies the above inequality.}
\]

Hence, for all \( \psi \in M \),

\[
\Lambda(t, \omega) \psi = \langle \psi, u(t, \omega) \rangle_{V', V},
\]

where \( u \) is product measurable.

Also, for \( t \notin N(\omega) \) and \( \phi \in D \),

\[
\langle \phi, u(t, \omega) \rangle_{V', V} = \Lambda(t, \omega) \phi \equiv \lim_{m_\phi \to \infty} m_\phi \int_{l_{m_\phi}(t)}^t \langle \phi, v(s, \omega) \rangle \, ds = \langle \phi, v(t, \omega) \rangle_{V', V}
\]

therefore, for all \( \phi \in M \)

\[
\langle \phi, u(t, \omega) \rangle_{V', V} = \langle \phi, v(t, \omega) \rangle_{V', V}
\]

and hence \( u(t, \omega) = v(t, \omega) \). Thus, for each \( \omega \), the product measurable function \( u \) satisfies \( u(t, \omega) = v(t, \omega) \) for a.e. \( t \). Hence \( u(\cdot, \omega) = v(\cdot, \omega) \) in \( V' \).

Of course a similar theorem will hold with essentially the identical proof if the functions take values in \( V' \).

One can also combine the two theorems to obtain a useful result for limits of functions in \( V' \) and \( V \). You just let

\[
X = \prod_{k=1}^{\infty} C([0, T]) \times C([0, T])
\]

and let \( \{\phi_k\} \) be a dense subset of \( V' \) while \( \{\eta_k\} \) is a dense subset of \( V \). Then the mappings are given by

\[
\psi_{m, \phi} u(t) = m \int_{l_{m}(t)}^t \langle \phi, u(s) \rangle_{V', V} \, ds, \quad \psi_{m, \eta} y(t) = m \int_{l_{m}(t)}^t \langle \eta, y(s) \rangle_{V', V} \, ds
\]

and one considers for each \( \phi_k, \eta_k \),

\[
\left( m_k \int_{l_{m_k}(t)}^t \langle \phi_k, u(s) \rangle_{V', V} \, ds, \ m_k \int_{l_{m_k}(t)}^t \langle \eta_k, y(s) \rangle_{V', V} \, ds \right)
\]

This time you need to use an enumeration of \( \mathbb{N} \times V' \times V \) and in the last step, you must use a subsequence still denoted with \( k \) such that \( m_k \to \infty \) but \( \phi_k = \phi \) and \( \eta_k = \eta \) for \( \phi, \eta \) two given elements of \( V' \) and \( V \) respectively. Then repeating the above argument, one obtains the following generalization.

**Theorem 75.2.17** Let \( V \) be a reflexive separable Banach space with dual \( V' \), and let \( p, p' \) be such that \( p > 1 \) and \( \frac{1}{p} + \frac{1}{p'} = 1 \). Let the functions \( t \to u_n(t, \omega) \), for \( n \in \mathbb{N} \),
be in $L^p ([0, T]; V)$ and $(t, \omega) \to u_n (t, \omega)$ be $B ([0, T]) \times F \equiv \mathcal{P}$ measurable into $V$. Also let the functions $t \to y_n (t, \omega)$ be in $V'$ and $(t, \omega) \to y_n (t, \omega)$ is $\mathcal{P}$ measurable into $V'$. Suppose there is a set of measure zero $N \subseteq \Omega$ such that if $\omega \notin N$, then

$$\sup_{t \in [0, T]} \| y_n (t, \omega) \|_{V'} + \| u_n (\cdot, \omega) \|_V \leq C (\omega),$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\{ u_n \}$ has a further subsequence that converges weakly in $V$ to $v (\cdot, \omega) \in V$. (v not known to be $\mathcal{P}$ measurable)) Suppose that each subsequence of $\{ y_n (\cdot, \omega) \}$ has a subsequence which converges weakly in $V'$ to $z (\cdot, \omega) \in V'$ such that the function $t \to z (t, \omega)$ is weakly continuous into $V'$.

Then, there exist product measurable functions $u, y$ such that $t \to u (t, \omega)$ is in $V$, $t \to y (t, \omega)$ is weakly continuous into $V'$ and for each $\omega \notin N$, a subsequence of $\mathbb{N}$ denoted by $\{ n (\omega) \}$ such that $u_{n(\omega)} (\cdot, \omega) \to u (\cdot, \omega)$ weakly in $V$ and $y_{n(\omega)} (\cdot, \omega)$ converges weakly to $y (\cdot, \omega)$ in $V'$.

Note that the conclusion of the proposition holds if $p = 1$ and $V = L^1 ([0, T], V)$. Here is something else about being measurable into $V$ or $V'$. Such functions have representatives which are product measurable.

**Lemma 75.2.18** Let $f (\cdot, \omega) \in V'$. Then if $f (\cdot, \omega)$ is measurable into $V'$, it follows that for each $\omega$, there exists a representative $\hat{f} (\cdot, \omega) \in V'$ such that $f (t, \omega) \to \hat{f} (t, \omega)$ is product measurable. If $f (\cdot, \omega) \in V'$ and $f (t, \omega) \to \hat{f} (t, \omega)$ is product measurable, then $\omega \to f (\cdot, \omega)$ is measurable into $V'$. The same holds replacing $V'$ with $V$.

**Proof:** If a function $f$ is measurable into $V'$, then there exist simple functions $f_n$

$$\lim_{n \to \infty} \| f_n (\omega) - f (\omega) \|_{V'} = 0, \quad \| f_n (\omega) \| \leq 2 \| f (\omega) \|_{V'} \equiv C (\omega)$$

Now one of these simple functions is of the form

$$\sum_{i=1}^{M} c_i \mathcal{X}_{E_i} (\omega)$$

where $c_i \in V'$. Therefore, there is no loss of generality in assuming that $c_i (t) = \sum_{j=1}^{N} d_{ij} \mathcal{X}_{F_j} (t)$ where $d_{ij} \in V'$. Hence we can assume each $f_n$ is product measurable into $\mathcal{B} (V') \times F$. Then by Theorem [75.2.11], there exists $\hat{f} (\cdot, \omega) \in V'$ such that $\hat{f}$ is product measurable and a subsequence $f_n(\omega)$ converging weakly in $V'$ to $\hat{f} (\cdot, \omega)$ for each $\omega$. Thus $f_n(\omega) (\omega) \to \hat{f} (\omega)$ strongly in $V'$ and $f_n(\omega) (\omega) \to \hat{f} (\omega)$ weakly in $V'$. Therefore, $\hat{f} (\omega) = f (\omega)$ in $V'$ and so it can be assumed that if $f$ is measurable into $V'$ then for each $\omega$, it has a representative $\hat{f} (\omega)$ such that $(t, \omega) \to \hat{f} (t, \omega)$ is product measurable.

If $f$ is product measurable into $V'$ and each $f (\cdot, \omega) \in V'$, does it follow that $f$ is measurable into $V'$? By measurability, $f (t, \omega) = \lim_{n \to \infty} \sum_{i=1}^{m_n} c_{ni} \mathcal{X}_{E_{ni}} (t, \omega) =$
\[ \lim_{n \to \infty} f_n(t, \omega) \] where \( E^n_i \) is product measurable and we can assume \( \| f_n(t, \omega) \|_{\mathcal{V}'} \leq 2 \| f(t, \omega) \| \). Then by product measurability, \( \omega \to f_n(\cdot, \omega) \) is measurable into \( \mathcal{V}' \) because if \( g \in \mathcal{V} \) then
\[ \omega \to \langle f_n(\cdot, \omega), g \rangle \]
is of the form
\[ \omega \to \sum_{i=1}^{m_n} \int_0^T \langle c_i^n, X_{E^n_i}(t, \omega), g(t) \rangle dt \]
which is \( \omega \to \sum_{i=1}^{m_n} \int_0^T \langle c_i^n, g(t) \rangle X_{E^n_i}(t, \omega) dt \)
and this is \( \mathcal{F} \) measurable since \( E^n_i \) is product measurable. Thus, it is measurable into \( \mathcal{V}' \) as desired and
\[ \langle f(\cdot, \omega), g \rangle = \lim_{n \to \infty} \langle f_n(\cdot, \omega), g \rangle, \omega \to \langle f_n(\cdot, \omega), g \rangle \text{ is } \mathcal{F} \text{ measurable.} \]

By the Pettis theorem, \( \omega \to \langle f(\cdot, \omega), g \rangle \) is measurable into \( \mathcal{V}' \). Obviously, the conclusion is the same for these two conditions if \( \mathcal{V}' \) is replaced with \( \mathcal{V} \).

The following theorem is also useful. It is really a generalization of the familiar Gram Schmidt process. It is Lemma 31.4.2.

\textbf{Theorem 75.2.19} Suppose \( V, W \) are separable Banach spaces, such that \( V \) is dense in \( W \) and \( B \in \mathcal{L}(W, W') \) satisfies
\[ \langle Bx, x \rangle \geq 0, \langle Bx, y \rangle = \langle By, x \rangle, B \neq 0. \]
Then there exists a countable set \( \{ e_i \} \) of vectors in \( V \) such that
\[ \langle Be_i, e_j \rangle = \delta_{ij} \]
and for each \( x \in W \),
\[ \langle Bx, x \rangle = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle^2, \]
and also
\[ Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i, \]
the series converging in \( W' \). In case \( B = B(\omega) \) where \( \omega \to B(\omega) \) is measurable into \( \mathcal{L}(W, W') \), these vectors \( e_i \) will also depend on \( \omega \) and will be measurable functions of \( \omega \).

\textbf{75.3 Preliminary Results}

We use the following well known theorem [82]. It is Theorem 31.7.6.
Theorem 75.3.1 Let $E \subseteq F \subseteq G$ where the injection map is continuous from $F$ to $G$ and compact from $E$ to $F$. Let $p \geq 1$, let $q > 1$, and define

$$S = \{ u \in L^p ([a, b], E) : \text{for some } C, \| u(t) - u(s) \|_G \leq C |t - s|^{1/q} \}$$

and $\| u \|_{L^p([a, b], E)} \leq R$.

Thus $S$ is bounded in $L^p ([a, b], E)$ and Holder continuous into $G$. Then $S$ is precompact in $L^p ([a, b], F)$. This means that if $\{ u_n \}_{n=1}^\infty \subseteq S$, it has a subsequence $\{ u_{n_k} \}$ which converges in $L^p ([a, b], F)$.

We recall the following theorem which is proved in [30] and earlier, Theorem 23.5.2 for what will suffice here.

Theorem 75.3.2 If $A$ and $B$ are pseudo monotone and bounded then $A + B$ is also pseudo monotone and bounded.

Also the following result, found in [32] is well known.

Theorem 75.3.3 If a single valued map, $A : X \to X'$ is monotone, hemicontinuous, and bounded, then $A$ is pseudo monotone. Furthermore, the duality map, $J^{-1} : X \to X'$ which satisfies $\langle J^{-1} f, f \rangle = \| f \|^2, \| J^{-1} f \|_{X'} = \| f \|_X$ is strictly monotone hemicontinuous and bounded. So is the duality map $F : X \to X'$ which satisfies $\| F f \|_{X'} = \| f \|_{X}^{p-1}, \langle F f, f \rangle = \| f \|_X^p$ for $p > 1$.

The following fundamental result will be of use in what follows. There is somewhat more in this than will be needed. In this paper, $B$ is a possibly degenerate operator satisfying only the following:

$$B \in \mathcal{L} (W, W'), \langle Bu, u \rangle \geq 0, \langle Bu, v \rangle = \langle Bv, u \rangle \quad (75.3.6)$$

where here $V \subseteq W$ and $V$ is dense in $W$. In the case where $B = B(\omega)$, we will assume for the sake of simplicity that

$$B(\omega) = k(\omega) B, \ k(\omega) \geq 0, \ k \text{ being } \mathcal{F} \text{ measurable}$$

Allowing $B$ to depend on $\omega$ introduces some technical considerations so if there is no interest in this, simply assume $B$ is independent of $\omega$. This includes all cases of most interest.

Lemma 75.3.4 Suppose $V, W$ are separable Banach spaces such that $V$ is dense in $W$ and $B \in \mathcal{L} (W, W')$ satisfies

$$\langle B x, x \rangle \geq 0, \langle B x, y \rangle = \langle B y, x \rangle, B \neq 0.$$

Then there exists a countable set $\{ e_i \}$ of vectors in $V$ such that

$$\langle B e_i, e_j \rangle = \delta_{ij}$$
and for each $x \in W$,

$$
\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,
$$

and also

$$
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i,
$$

the series converging in $W'$. If $B = B(\omega)$ and $B$ is $F$ measurable into $\mathcal{L}(W, W')$ and if the $e_i = e_i(\omega)$ are as described above, then these $e_i$ are measurable into $V$. If $t \to B(t, \omega)$ is $C^1([0, T], \mathcal{L}(W, W'))$ and if for each $w \in W$,

$$
\langle B'(t, \omega) w, w \rangle \leq k_{w,\omega}(t) \langle B(t, \omega) w, w \rangle
$$

Where $k_{w,\omega} \in L^1([0, T])$, then the vectors $e_i(t)$ can be chosen to also be right continuous functions of $t$.

The following has to do with the values of $Bu$ and gives an integration by parts formula.

**Corollary 75.3.5** Let $V \subseteq W, W' \subseteq V'$ be separable Banach spaces, and $B \in \mathcal{L}(W, W')$ is nonnegative and self adjoint. Also suppose $t \to B(u(t))$ has a weak derivative $(Bu)' \in L^p(0, T, V')$ for $u \in L^p(0, T, V)$. Then there is a continuous function denoted as $t \to Bu(t)$ which equals $B(u(t))$ a.e. $t$. Say for $t \notin N$. Suppose $Bu(0) = Bu_0$, $u_0 \in W$. Then

$$
Bu(t) = Bu_0 + \int_0^t (Bu)'(s) \, ds \text{ in } V' \tag{75.3.7}
$$

Then $t \to Bu(t)$ is in $C(N^C, W')$ and also for such $t$,

$$
\frac{1}{2} (Bu(t), u(t)) = \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle (Bu)'(s), u(s) \rangle \, ds
$$

There exists a continuous function $t \to \langle Bu, u \rangle(t)$ which equals the right side of the above for all $t$ and equals $\langle B(u(t)), u(t) \rangle$ off $N$. This also satisfies

$$
\sup_{t \in [0, T]} \langle Bu, u \rangle(t) \leq C \left( \|Bu\|_{L^p(0, T, V')}, \|u\|_{L^p(0, T, V)} \right)
$$

This also makes it easy to verify continuity of pointwise evaluation of $Bu$. Let $Lu = (Bu)'$.

$$
u \in D(L) \equiv X \equiv \left\{ u \in L^p(0, T, V) : Lu \equiv (Bu)' \in L^p(0, T, V') \right\}
$$

$$
\|u\|_X \equiv \max \left( \|u\|_{L^p(0, T, V)}, \|Lu\|_{L^p(0, T, V')} \right) \tag{75.3.8}
$$

Since $L$ is closed, this $X$ is a Banach space.

Then the following theorem is obtained.
Theorem 75.3.6 Say \((Bu)' \in L^{p'}(0, T, V')\) so
\[
Bu(t) = Bu(0) + \int_0^t (Bu)'(s) \, ds \text{ in } V'
\]
the map \(u \mapsto Bu(t)\) is continuous as a map from \(X\) to \(V'\). Also, if \(Y\) denotes those \(f \in L^p([0, T], V)\) for which \(f' \in L^p([0, T], V')\), so that \(f\) has a representative such that \(f(t) = f(0) + \int_0^t f'(s) \, ds\), then if \(\|f\|_Y \equiv \|f\|_{L^p([0, T], V)} + \|f'\|_{L^p([0, T], V')}\), the map \(f \mapsto f(t)\) is continuous.

Also one can obtain the following for \(p > 1\).

Proposition 75.3.7 Let
\[
X = \left\{ u \in L^p(0, T, V) : Lu \equiv (Bu)' \in L^{p'}(0, T, V') \right\}
\]
where \(V\) is a reflexive Banach space. Let a norm on \(X\) be given by
\[
\|u\|_X \equiv \max (\|u\|_V, \|Lu\|_{V'})
\]
Then there is a continuous function \(t \mapsto \langle Bu, v \rangle(t)\) such that
\[
\langle Bu, v \rangle(t) = \langle B(u(t)), v(t) \rangle
\]
a.e. \(t\) such that
\[
\sup_{t \in [0, T]} |\langle Bu, v \rangle(t)| \leq C \|u\|_X \|v\|_X
\]
and if \(K : X \to X'\)
\[
\langle Ku, v \rangle \equiv \int_0^T \langle Lu, v \rangle \, ds + \langle Bu, v \rangle(0)
\]
Then \(K\) is continuous and linear and
\[
\langle Ku, u \rangle = \frac{1}{2} [\langle Bu, u \rangle(T) + \langle Bu, u \rangle(0)]
\]
If \(u \in X\) and \(Bu(0) = 0\) then there exists a sequence \(\{u_n\}\) such that \(\|u_n - u\|_X \to 0\) but \(u_n(t) = 0\) for all \(t\) close to 0.

75.4 Measurable Approximate Solutions

The main result in this section is the following theorem. Its proof follows a method due to Brezis and Lions [82] adapted to the case considered here where the operator is set valued. In this theorem, we let \(F : V \to V'\) be the duality map \(\langle Fu, u \rangle = \|u\|^p, \|Fu\| = \|u\|^{p-1}\) for \(p > 1\).
As above, \( Lu = (Bu)' \). In addition to this, define \( \Lambda \) to be the restriction of \( L \) to those \( u \in X \) which have \( Bu(0) = 0 \). Thus

\[
D(\Lambda) = \{ u \in X : Bu(0) = 0 \}
\]

Then one can show that \( \Lambda^* \) is monotone. It is not hard to see that this should be the case. Let \( v \in D(\Lambda^*) \) and suppose it is smooth. Then

\[
\int_0^T \langle \Lambda u, v \rangle \, dt = \langle Bu(T), v(T) \rangle - \int_0^T \langle Bu, v' \rangle \, dt
\]

and so, if \( \left| \int_0^T \langle \Lambda u, v \rangle \, dt \right| \leq C \| u \|_{Y'} \), then we need to have \( v(T) = 0 \) and \( \Lambda^* v = -Bv' \). Now it is just a matter of doing the computations to verify that

\[
\langle \Lambda^* v, v \rangle \geq 0.
\]

**Lemma 75.4.1** Let \( K \) and \( L \) be as in Proposition 75.3.7. Then for each \( f \in V' \) and \( u_0 \in W \), there exists a unique \( u \in X \) such that

\[
(Ku, v) + Fu = \langle f, v \rangle + \langle Bu(0), u_0 \rangle
\]

for all \( v \in X \). Also, the mapping which takes \( (f, u_0) \) to this solution is demicontinuous in the sense that if \( f_n \to f \) strongly in \( V' \) and \( u_{0n} \to u_0 \) in \( W \), then \( u_n \to u \) weakly in \( V \).

**Proof:** Let \( J^{-1} \) be the duality map mentioned above and define \( H_\varepsilon : X \to X' \) by

\[
\langle H_\varepsilon (u), v \rangle = \varepsilon \langle Lv, J^{-1} Lu \rangle + \langle Fu, v \rangle + \langle Ku, v \rangle
\]

for all \( v \in X \). Then \( H_\varepsilon \) is pseudo monotone because it is monotone, bounded, and hemicontinuous. This follows from Theorem 75.4.3 and 75.4.4. It is also easy to see that \( H_\varepsilon \) is coercive.

\[
\frac{\langle H_\varepsilon (u), u \rangle}{\| u \|_X} = \varepsilon \frac{\| Lu \|_{Y'}}{\| u \|_X} + \frac{\| u \|_Y^p}{\| u \|_X} + \frac{1}{2} \frac{\langle Bu(T), u(T) \rangle + \langle Bu, u \rangle(0)}{\| u \|_X} \leq \frac{1}{\| u \|_X}
\]

If not, then there is \( \| u_n \|_X \to \infty \) but for some \( M \),

\[
\varepsilon \frac{\| Lu_n \|_{Y'}}{\| u_n \|_X} + \frac{\| u_n \|_Y^p}{\| u_n \|_X} + \frac{1}{2} \frac{\langle Bu_n(T), u_n(T) \rangle + \langle Bu_n, u_n \rangle(0)}{\| u_n \|_X} \leq M
\]

Then one of \( \| u_n \|_Y \) or \( \| Lu_n \|_{Y'} \) is unbounded. Either way, a contradiction is obtained. Thus \( H_\varepsilon \) is coercive bounded, and pseudomonotone. It follows that it maps onto \( X' \).

There exists \( u_\varepsilon \in X \) such that for all \( v \in X \),

\[
\varepsilon \langle Lv, J^{-1} Lu_\varepsilon \rangle + \langle Fu_\varepsilon, v \rangle + \langle Ku_\varepsilon, v \rangle = \langle f, v \rangle + \langle Bu(0), u_0 \rangle
\] (75.4.10)
In (75.4.10), let $v = u'_\varepsilon$. Using the inequality,

$$\langle Bu_\varepsilon (0), u_0 \rangle \leq \langle Bu_\varepsilon, v \rangle^{1/2} (0) \langle Bu_0, u_0 \rangle^{1/2} \leq \frac{1}{2} \langle Bu_\varepsilon, v \rangle (0) + \frac{1}{2} \langle Bu_0, u_0 \rangle,$$

it follows that

$$\langle Fu_\varepsilon, u_\varepsilon \rangle + \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (T) + \langle Bu_\varepsilon, u_\varepsilon \rangle (0) \leq \|f\|_{V'} \|u_\varepsilon\|_{V} + \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (0) + \frac{1}{2} \langle Bu_0, u_0 \rangle$$

Thus

$$\|u_\varepsilon\|_{V}^{p} + \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (T) \leq \frac{1}{2} \langle Bu_0, u_0 \rangle + \|f\|_{V'} \|u_\varepsilon\|_{V},$$

which implies that there exists a constant $C$ independent of $\varepsilon$ such that

$$\|u_\varepsilon\|_{V} \leq C. \quad (75.4.11)$$

Now let $v \in D(\Lambda)$. Thus $v \in X$ and $Bv (0) = 0$ so the last term of (75.4.10) equals 0. The term, $\langle Bu_\varepsilon, v \rangle (0)$ found in the definition of $\langle Ku_\varepsilon, v \rangle$ also equals 0. This follows from $\langle Bu_\varepsilon, v \rangle (0) = \lim_{n \to \infty} \langle Bu_\varepsilon, v_n \rangle (0) = 0$.

where $v_n = 0$ near 0 and converges to $v$ in $X$ by Proposition 75.3.7. Therefore, for $v \in D(\Lambda)$, a dense subset of $V$,

$$\varepsilon \langle \Lambda v, J^{-1} L u_\varepsilon \rangle + \langle Fu_\varepsilon, v \rangle + \langle Lu_\varepsilon, v \rangle = \langle f, v \rangle.$$  

It follows that $J^{-1} L u_\varepsilon \in D(\Lambda^*)$ and so for all $v \in D(\Lambda)$,

$$\varepsilon \langle \Lambda^* J^{-1} L u_\varepsilon, v \rangle + \langle Fu_\varepsilon, v \rangle + \langle Lu_\varepsilon, v \rangle = \langle f, v \rangle. \quad (75.4.12)$$

Since $D(\Lambda)$ is dense in $V$, this equation holds for all $v \in V$ and so in particular, it holds for $v = J^{-1} L u_\varepsilon$. Therefore,

$$- \|Fu_\varepsilon\|_{V'} \|L u_\varepsilon\|_{V'} + \|L u_\varepsilon\|_{V'}^{2} \leq \|f\|_{V'} \|L u_\varepsilon\|_{V'} \cdot \quad (75.4.13)$$

It follows from (75.4.13), (75.4.14) that $\|L u_\varepsilon\|_{V'}$ is bounded independent of $\varepsilon$. Therefore, there exists a sequence $\varepsilon \to 0$ such that

$$u_\varepsilon \rightharpoonup u \text{ in } V,$$

$$K u_\varepsilon \rightharpoonup K u \text{ in } X',$$

$$F u_\varepsilon \rightharpoonup u^* \text{ in } V',$$

$$B u_\varepsilon (0) \to B u (0) \text{ in } W'.$$  

(75.4.14, 75.4.15, 75.4.16, 75.4.17)
replace \( v \) with \( u \):

\[
\langle Lu, J_1 \rangle \leq \langle f, u_\varepsilon - u \rangle + \langle B (u_\varepsilon - u) (0), u_0 \rangle
\]

By pseudomonotonicity,

\[
\liminf_{\varepsilon \to 0} \langle Fu_\varepsilon + Ku_\varepsilon, u_\varepsilon - u \rangle = 0
\]

so \( u^* = Fu \) and from (75.4.10),

\[
\langle Ku, u \rangle + \langle Fu, v \rangle = \langle f, v \rangle + \langle Bv (0), u \rangle
\]

Thus for every \( v \in X \),

\[
\int_0^T \langle (Bu)' , v \rangle ds + \langle Bu, v \rangle (0) + \int_0^T \langle Fu, v \rangle ds = \int_0^T \langle f, v \rangle ds + \langle Bv (0) , u_0 \rangle
\]

So let \( v \) be smooth and equal to 0 except for \( t \in [0, \delta] \) and equals \( v_0 \) at 0. Then as \( \delta \to 0 \), the integrals become increasingly small and so

\[
\langle Bu (0), v_0 \rangle = \langle Bv_0, u_0 \rangle = \langle Bu_0, v_0 \rangle
\]

and since \( v_0 \) is arbitrary in \( V \), then it follows that \( Bu (0) = Bu_0 \). Thus this has provided a solution \( u \) to the system

\[
(Bu)' + Fu = f, \quad Bu (0) = Bu_0, \quad u \in X
\]

It remains to consider the assertion about continuity. First note that the solution to the above initial value problem is unique due to the strict monotonicity of \( F \). In fact, if there are two solutions, \( u, w \), then

\[
\frac{1}{2} \|Bu (t) - Bw (t)\|^2_W + \int_0^t \langle Fu - Fw, u - w \rangle ds = 0
\]

and so, in particular, \( \langle Fu - Fw, u - w \rangle_{\mathcal{V}', \mathcal{V}} = 0 \) which implies \( u = w \) in \( \mathcal{V} \).
Let \( u \) be the solution which goes with \((f,u_0)\) and let \( u_n \) denote the solution which goes with \((f_n,u_{0n})\) where it is assumed that \( f_n \to f \) in \( V' \) and \( u_{0n} \to u_0 \) in \( W \). It is desired to show that \( u_n \to u \) weakly in \( V \). First note that the \( u_n \) are bounded in \( V \) because
\[
\frac{1}{2} \langle Bu_n, u_n \rangle (T) - \frac{1}{2} \langle Bu_{0n}, u_{0n} \rangle + \int_0^T \|u_n\|^2 \, ds = \int_0^T \langle f_n, u_n \rangle \, ds \leq \|f_n\|_{V'} \|u_n\|_V
\]
and this clearly implies that \( \|u_n\|_V \) is indeed bounded. Thus if this sequence fails to converge weakly to \( u \), it must be the case that there is a subsequence, still denoted as \( u_n \) which converges weakly to \( w \neq u \) in \( V \). Then by the fact that \( F \) is bounded, there is an estimate of the form
\[
\|u_n\|_V + \|Lu_n\|_{V'} \leq C
\]
Thus, a further subsequence satisfies
\[
\begin{align*}
&u_n \to w \text{ weakly in } V \\
&Lu_n \to Lw \text{ weakly in } V' \\
&Fu_n \to \xi \text{ weakly in } V'
\end{align*}
\]
then
\[
\int_0^T \langle (B(u_n - w))', u_n - w \rangle \, dt = \frac{1}{2} \langle B(u_n - w), (u_n - w) \rangle (T) - \frac{1}{2} \langle B(u_n - w), (u_n - w) \rangle (0) \geq -\frac{1}{2} \langle B(u_{0n} - u_0), u_{0n} - u_0 \rangle
\]
It follows
\[
\langle Lu, u_n - w \rangle_{V'} + \langle Fu_n, u_n - w \rangle_{V'} - \frac{1}{2} \langle B(u_{0n} - u_0), u_{0n} - u_0 \rangle \leq \langle f_n, u_n - w \rangle
\]
and so \( \limsup_{n \to \infty} \langle Fu_n, u_n - w \rangle \leq 0 \). Then as before, \( \xi = Fw \) and one obtains
\[
(Bw)' + Fw = f, \quad Bw(0) = Bu_0, \quad w \in X
\]
contradicting uniqueness. Hence \( u_n \to u \) weakly as claimed. \( \blacksquare \)

Now suppose \((\Omega,\mathcal{F})\) is a measurable space and \( B = B(\omega) \) and is measurable into \( L(W,W') \) and \( f : [0,T] \times \Omega \to V' \) is product measurable, \( B([0,T]) \times \mathcal{F} \) measurable where \( \mathcal{B}([0,T]) \) denotes the Borel sets. Also, it is assumed that for each \( \omega, f(\cdot,\omega) \in V' \). The following lemma ties together these ideas. It is Lemma 75.4.1 proved above. It is stated here for convenience.

**Lemma 75.4.2** Let \( f(\cdot,\omega) \in V' \). Then if \( \omega \to f(\cdot,\omega) \) is measurable into \( V' \), it follows that for each \( \omega \), there exists a representative \( \tilde{f}(\cdot,\omega) \in V' \), \( \tilde{f}(\cdot,\omega) = f(\cdot,\omega) \) in \( V' \) such that \( (t,\omega) \to \tilde{f}(t,\omega) \) is product measurable. If \( f(\cdot,\omega) \in V' \) and \( (t,\omega) \to f(t,\omega) \) is product measurable, then \( \omega \to f(\cdot,\omega) \) is measurable into \( V' \). The same holds replacing \( V' \) with \( V \).
Now consider the initial value problem
\[
(B(\omega)u(\cdot,\omega))' + Fu(\cdot,\omega) = f(\cdot,\omega), \\
B(\omega)u(0,\omega) = B(\omega)u_0(\omega), \ u(\cdot,\omega) \in X
\]
(75.4.21)
where we also assume \(u_0\) is \(F\) measurable into \(W\). From Lemma 75.4.2, \(\omega \to (f(\cdot,\omega), u_0(\omega))\) is measurable into \(V' \times W\). That is,
\[
(f, u_0)^{-1}(U) = \{ \omega : (f(\cdot,\omega), u_0(\omega)) \in U \} \in \mathcal{F}
\]
for \(U\) an open set in \(V' \times W\). From Lemma 75.4.1, the map \(\Phi_\omega\) which takes \((f, u_0)\) to the solution \(u\) is demicontinuous. We desire to argue that \(u\) is measurable into \(V\).

In doing so, it is easiest to assume that \(B\) does not depend on \(\omega\). However, the dependence on \(\omega\) can be included using the approximation assumption for \(B(\omega)\) mentioned earlier.

Letting \(f_n(\cdot,\omega) \to f(\cdot,\omega)\) where \(f_n\) is a simple function and \(u_{0n}(\omega) \to u_0(\omega)\) where \(u_{0n}\) is also a simple function, it follows that
\[
\Phi_\omega(f_n(\cdot,\omega), u_{0n}(\omega)) \to \Phi_\omega(f(\cdot,\omega), u_0(\omega)) = u
\]
weakly.

**Lemma 75.4.3** Suppose \(f(\cdot,\omega) \in V'\) for each \(\omega\) and that \((t, \omega) \to f(t, \omega)\) is product measurable into \(V'\). Also \(u_0\) is \(F\) measurable into \(W\) and
\[
B(\omega) = k(\omega)B, \ k(\omega) \geq 0, \ k \text{ measurable}
\]
Then for each \(\omega \in \Omega\), there exists a unique solution \(u(\cdot, \omega)\) in \(V\) satisfying
\[
(B(\omega)u(\cdot,\omega))' + Fu(\cdot,\omega) = f(\cdot,\omega), \\
B(\omega)u(0,\omega) = B(\omega)u_0(\omega), \ u(\cdot,\omega) \in X
\]
This solution has a representative which satisfies \((t, \omega) \to u(t, \omega)\) is product measurable into \(V\).

**Proof:** Let \(B_n(\omega) \equiv k_n(\omega)B\) where \(\{k_n(\omega)\}\) is an increasing sequence of simple functions converging pointwise to \(k(\omega)\). Replace \(B(\omega)\) with \(B_n(\omega)\). Then define
\[
\langle K_nu, v \rangle = \int_0^T \langle L_nu, v \rangle \, ds + \langle Bu, v \rangle(0)
\]
where \(L_n\) is defined as
\[
L_nu = (B_n(\omega)u)'
\]
for \(B_n\) having values in \(\mathcal{L}(W, W')\) such that \(B_n(\omega) \to B(\omega)\) and each of these is self adjoint and nonnegative. Let \(u_n\) be the solution to the above initial value problem
\[
\langle K_nu_n, v \rangle + F(u_n) = \langle f_n, v \rangle + \langle Bv(0), u_{0n} \rangle
\]
in which \( u_{0n} \) and \( f_n \) are simple functions converging to \( u_0 \) and \( f \) in \( W \) and \( V' \) respectively for each \( \omega \). Thus these have constant values in \( V' \) or \( W \) on finitely many measurable subsets of \( \Omega \). Since \( B_n \) is constant on measurable sets, it follows that \( u_n (\cdot, \omega) \) is also a constant element of \( V \) on each of finitely many measurable sets. Hence \( u_n (\cdot, \omega) \) is measurable into \( V \). Then fixing \( \omega \), and letting \( v = u_n \),

\[
\frac{1}{2} \langle Bu_n, u_n \rangle (T) + \langle Bu_n, u_n \rangle (0) + \int_0^T \|u_n\|^p_V ds = \int_0^T (f_n, u_n) ds + \langle Bv (0), u_0 \rangle
\]

Thus, since \( F \) is bounded, one obtains an inequality of the form

\[
\|u_n\|_V + \|(B_n (\omega) u_n)\|_{V'} \leq C
\]

Then there is a subsequence such that

\[
u_n \to u \text{ weakly in } V
\]

\[
B_n (\omega) u_n \to B (\omega) u \text{ weak * in } L^\infty (\Omega, T; V')
\]

\[
B_n (\omega) u_n \to B (\omega) u \text{ weakly in } V'
\]

\[
Fu_n \to \xi \text{ weakly in } V'
\]

\[
(B_n (\omega) u_n)' \to (B (\omega) u)' \text{ weakly in } V'
\]

Also, suppressing the dependence on \( \omega \),

\[
(B_n u_n) (t) = B_n u_{0n} + \int_0^t (B_n u)' (s) ds
\]

and so in fact,

\[
(B_n u_n) (t) \to (Bu) (t) \text{ in } V' \text{ for each } t
\]

Also,

\[
\langle (B_n u)' , u_n - u \rangle_{V', V} + \langle Fu_n, u_n - u \rangle_{V', V} = \langle f_n, u_n - u \rangle_{V', V}
\]

\[
\langle k_n (\omega) (Bu_n)' , u_n - u \rangle_{V', V} + \langle Fu_n, u_n - u \rangle_{V', V} = \langle f_n, u_n - u \rangle_{V', V}
\]

Thus, by monotonicity,

\[
\langle k_n (\omega) (Bu_n)' , u_n - u \rangle_{V', V} = \langle k (\omega) (Bu_n)' , u_n - u \rangle_{V', V}
\]

\[
+ \langle (k_n (\omega) - k (\omega)) (Bu_n)' , u_n - u \rangle_{V', V}
\]

\[
\geq \langle k (\omega) (Bu)' , u_n - u \rangle_{V', V} + \langle (k_n (\omega) - k (\omega)) (Bu_n)' , u_n - u \rangle_{V', V}
\]

The last term in the above expression converges to 0 due to the convergence of \( k_n (\omega) \) to \( k (\omega) \). Thus

\[
\langle (B (\omega) u)' , u_n - u \rangle_{V', V} + \langle Fu_n, u_n - u \rangle_{V', V} \leq \langle f_n, u_n - u \rangle_{V', V}
\]
and so
\[ \lim_{n \to \infty} \sup_{n} \langle F u_n, u_n - u \rangle_{V', V} \leq 0. \]
Then as before, one can conclude that \( F u = \xi \). Then passing to the limit gives the desired solution to the equation, this for each \( \omega \). However, by uniqueness, it follows that if \( \bar{u} \) is the solution to the evolution equation of Lemma 75.4, then for each \( \omega, u = \bar{u} \) in \( V \). Also this \( u \) just obtained is measurable into \( V \) thanks to the Pettis theorem. Therefore, \( u \) can be modified on a set of measure zero for each fixed \( \omega \) to equal \( u \) a function measurable into \( V \). Hence there exists a solution to the evolution equation of this lemma \( u \) which is measurable into \( V \). By the Lemma 75.4.2, it follows that there is a representative for \( u \) which is product measurable into \( V \). \( \blacksquare \)

### 75.5 The Main Result

The main result is an existence theorem for product measurable solutions to the system
\[
\begin{align*}
(B(\omega) u(\cdot, \omega))' + u^*(\cdot, \omega) &= f(\cdot, \omega) \text{ in } V', \\
B(\omega) u(0, \omega) &= B(\omega) u_0(\omega)
\end{align*}
\]
where \( u^*(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \). It is Theorem 75.5.6 below. First are some assumptions.

Here \( I \) will denote a subinterval of \([0, T]\), of the form \( I = [0, \hat{T}], \hat{T} \leq T \), and \( V_I \equiv L^p(I, V) \) with similar things defined analogously. We assume only that \( p > 1 \).

**Definition 75.5.1** For \( X \) a reflexive Banach space, we say \( A : X \to \mathcal{P}(X') \) is pseudomonotone and bounded if the following hold.

1. The set \( Au \) is nonempty, closed and convex for all \( u \in X \). \( A \) takes bounded sets to bounded sets.
2. If \( u_i \to u \) weakly in \( X \) and \( u_i^* \in Au_i \) is such that
\[ \lim_{i \to \infty} \sup_{i} \langle u_i^*, u_i - u \rangle \leq 0, \] (75.5.23)
then, for each \( v \in X \), there exists \( u^*(v) \in Au \) such that
\[ \lim_{i \to \infty} \inf_{i} \langle u_i^*, u_i - v \rangle \geq \langle u^*(v), u - v \rangle. \] (75.5.24)

Now suppose the following for the operator \( A(\cdot, \omega) : A(\cdot, \omega) : \mathcal{V}_I \to \mathcal{V}'_I \) for each \( I \) a subinterval of \([0, T]\) and
\[ A(\cdot, \omega) : \mathcal{V}_I \to \mathcal{P}(\mathcal{V}'_I) \text{ is bounded}, \] (75.5.25)
75.5. THE MAIN RESULT

If, for \( u \in \mathcal{V} \),
\[
 u^* \mathcal{X}_{[0, \bar{T}]} \in A \left( u \mathcal{X}_{[0, \bar{T}]} : \omega \right)
\]
for each \( \bar{T} \) in an increasing sequence converging to \( T \), then
\[
u^* \in A (u, \omega)
\]  
(75.5.26)

Assume the specific estimate
\[
\sup \left\{ \| u^* \|_{V'_I} : u^* \in A (u, \omega) \right\} \leq a(\omega) + b(\omega) \| u \|_{V'_{\bar{I}}}^{-1}
\]  
(75.5.27)

where \( a(\omega), b(\omega) \) are nonnegative. Also assume the coercivity condition:
\[
\lim_{\| u \|_{V} \to \infty} \inf_{u \in X_r} \left\{ 2(u^*, u)_{V', V} + \{Bu, u\} (T) : u^* \in A(u, \omega) \right\} = \infty,
\]  
(75.5.28)

or alternatively the following specific estimate valid for each \( t \leq T \) and for some \( \lambda(\omega) \geq 0 \),
\[
\inf \left( \int_0^t \langle u^* , u \rangle + \lambda(\omega) \langle Bu, u \rangle \, dt : u^* \in A(u, \omega) \right) \geq \delta(\omega) \int_0^t \| u \|^p_{V'} \, ds - m(\omega)
\]  
(75.5.29)

where \( m(\omega) \) is some nonnegative constant, \( \delta(\omega) > 0 \). Note that the estimate is a coercivity condition on \( \lambda B + A \) rather than on \( A \) but is more specific than (75.5.28).

Let \( U \) be a Banach space dense in \( V \) and that if \( u_i \rightharpoonup u \in \mathcal{V}_I \) and \( u_i^* \in A(u_i) \) with \( u_i^* \rightharpoonup u^* \) in \( \mathcal{V}_I' \) and \( (Bu_i)' \rightharpoonup (Bu)' \) in \( U_{I'} \), \( \rightharpoonup \) denoting weak convergence, then if
\[
\limsup_{i \to \infty} \langle u_i^* , u_i - u \rangle_{V_I', V_I} \leq 0
\]

it follows that for all \( v \in \mathcal{V}_I \), there exists \( u^*(v) \in Au \) such that
\[
\liminf_{i \to \infty} \langle u_i^* , u_i - v \rangle_{V_I', V_I} \geq \langle u^*(v) , u - v \rangle_{V_I', V_I}
\]  
(75.5.30)

where \( r > \max (p, 2) \), and we replace \( p \) with \( r \) and \( I \) an arbitrary subinterval of the form \([0, \bar{T}]\), \( \bar{T} < T \), for \([0, T]\), and \( U \) for \( V \) where indicated. Here
\[
U_{I'} \equiv L' (I; U)
\]

Note that we are not assuming \( A \) is pseudomonotone, just that it satisfies a similar limit condition. Typically, this limit condition holds because of a use of the compact embedding of theorem 75.3.1 or similar result and it does not matter whether \( U \) is a small subset of \( V \) as long as it is dense in \( V \).

Here is an alternate limit condition. Let \( U \) be a Banach space dense in \( V \) and that if \( u_i \rightharpoonup u \) in \( \mathcal{V}_I \) and \( u_i^* \in A(u_i) \) with \( u_i^* \rightharpoonup u^* \) in \( \mathcal{V}_I' \) and \( t \rightarrow Bu_i(t) \) is continuous and
\[
\sup_i \sup_{t \neq s} \frac{\| Bu_i (t) - Bu_i (s) \|_{U'}}{|t - s|^r} \leq C
\]  
(75.5.31)
then if
\[ \lim \sup_{i \to \infty} \langle u^*_i, u_i - u \rangle_{V'_i, V_i} \leq 0 \] (75.5.32)

it follows that for all \( v \in V_i \), there exists \( u^*(v) \in Au \) such that
\[ \lim \inf_{i \to \infty} \langle u^*_i, u_i - v \rangle_{V'_i, V_i} \geq \langle u^*(v), u - v \rangle_{V'_i, V_i} \] (75.5.33)

This alternate condition is implied by (75.5.30) but the conditions under which either condition holds are likely to depend on some sort of compactness which will be useable for either limit condition. Technically if you assume this alternate condition, you are assuming more, but I don’t have any examples to show that it would be actually assuming more.

For \( \omega \to u(\cdot, \omega) \) measurable into \( V \),
\[ \omega \to A(u(\cdot, \omega), \omega) \] has a measurable selection into \( V' \). (75.5.34)

This last condition means there is a function \( \omega \to u^*(\omega) \) which is measurable into \( V' \) such that \( u^*(\omega) \in A(u(\cdot, \omega), \omega) \). This is assured to take place if the following standard measurability condition is satisfied for all \( O \) open in \( V' \):
\[ \{ \omega : A(u(\cdot, \omega), \omega) \cap O \neq \emptyset \} \in \mathcal{F} \] (75.5.35)

See for example [3], [4]. Our assumption is implied by this one but they are not equivalent. Thus what is considered here is more general than an assumption that \( \omega \to A(u(\cdot, \omega), \omega) \) is set valued measurable.

Note that this condition would hold if \( u \to A(t, u, \omega) \) is bounded and pseudomonotone as a single valued map from \( V \) to \( V' \) and \( (t, \omega) \to A(t, u, \omega) \) is product measurable into \( V' \). One would use the demicontinuity of \( u \to A(\cdot, u, \omega) \) which comes from the pseudo monotone and bounded assumption and consider a sequence of simple functions \( u_n(t, \omega) \to u(t, \omega) \) in \( V \) for \( u \) measurable, each \( u(\cdot, \omega) \) being in \( V \), Then the measurability of \( A(t, u_n, \omega) \) would attach to \( A(t, u, \omega) \) in the limit. More generally, here is a useful lemma. It is about preserving the existence of a measurable representative under the assumption that the values are closed and convex.

**Lemma 75.5.2** Suppose \( \omega \to A(u(\cdot, \omega)) \) has a measurable selection in \( V' \) for \( u \) a given element of \( V \) not dependent on \( \omega \) and for each \( \omega \), \( A(u, \omega) \) is a closed bounded, convex set in \( V' \). Also suppose \( u \to A(u(\cdot, \omega)) \) is upper semicontinuous from the strong topology of \( V \) to the weak topology of \( V' \). That is, if \( u_n \to u \) in \( V \) strongly, then if \( O \) is a weakly open set containing \( A(u(\cdot, \omega)) \), it follows that \( A(u_n, \omega) \in O \) for all \( n \) large enough. Then whenever \( u \) is measurable into \( V \), it follows that there is a measurable selection for \( \omega \to A(u(\cdot, \omega), \omega) \) into \( V' \).

**Proof:** Let \( \omega \to u(\omega) \) be measurable into \( V \) and let \( u_n(\omega) \to u(\omega) \) in \( V \) where \( u_n \) is a simple function
\[ u_n(\omega) = \sum_{k=1}^{m_n} c_k^n A_{E_k^n}(\omega), \] the \( E_k^n \) disjoint, \( \Omega = \cup_k E_k^n \),
each \( c_k^n \) being in \( V \). Then by assumption, there is a measurable selection for \( \omega \mapsto A(c_k^n, \omega) \) denoted as \( \omega \mapsto y_k^n(\omega) \). Thus \( \omega \mapsto y_k^n(\omega) \) is measurable into \( V' \) and \( y_k^n(\omega) \in A(c_k^n, \omega) \) for all \( \omega \in \Omega \). Then consider
\[
y^n(\omega) = \sum_{k=1}^{m_n} y_k^n(\omega) X_{E_k^n}(\omega)
\]
It is measurable and for \( \omega \in E_k^n \) it equals \( y_k^n(\omega) \in A(c_k^n, \omega) = A(u_n(\omega), \omega) \). Thus \( y^n \) is a measurable selection of \( \omega \mapsto A(u_n(\omega), \omega) \). By the estimates, for each \( \omega \) these \( y^n(\omega) \) lie in a bounded subset of \( V' \). The bound might depend on \( \omega \) of course. By Theorem 75.5.3 and Lemma 75.5.2 there is a measurable into \( V' \) function \( \omega \mapsto y(\omega) \) and a subsequence for each \( \omega, y^n(\omega) \) such that \( y_n(\omega) \to y(\omega) \) weakly in \( V' \). By the Pettis theorem, \( y \) is measurable into \( V' \). Where is \( y(\omega) \)? If \( y(\omega) \notin A(u(\omega), \omega) \), then there would exist \( z(\omega) \in V \) such that \( \langle y(\omega), z \rangle > r > \langle w, z \rangle \) for all \( w \in A(u(\omega), \omega) \). Let \( O = \{ w \in V' \text{ such that } r > \langle w, z \rangle \} \). Then \( O \) contains \( A(u(\omega), \omega) \) and is a weakly open set. It follows from the upper semicontinuity assumption that \( y^n(\omega) \in O \) for all \( n(\omega) \) large enough. Thus \( r > \langle y^n(\omega), z \rangle \). But by weak convergence,
\[
\langle y(\omega), z \rangle > r \geq \lim_{n(\omega) \to \infty} \langle y^n(\omega), z \rangle = \langle y(\omega), z \rangle
\]
contradicting \( y(\omega) \notin A(u(\omega), \omega) \). Hence \( y(\omega) \in A(u(\omega), \omega) \) and \( \omega \mapsto y(\omega) \) is a measurable selection. ■

In fact, this is just a special case of a general result in the next theorem. It says essentially that having a measurable selection is preserved when going from constant to measurable functions. In this theorem, \( V \) is a reflexive separable Banach space. This is difficult to show for measurable multifunctions. It is Theorem 75.5.3 and was proved earlier. A proof is given here also.

**Theorem 75.5.3** Suppose \( \omega \mapsto A(u, \omega) \) has a measurable selection in \( V' \) for \( u \) a given element of \( V \) not dependent on \( \omega \) and for each \( \omega, A(u, \omega) \) is a closed, convex set in \( V' \) and \( A(\cdot, \omega) \) is bounded. Also suppose \( u \mapsto A(u, \omega) \) is upper semicontinuous from the strong topology of \( V \) to the weak topology of \( V' \). That is, if \( u_n \to u \) in \( V \) strongly, then if \( O \) is a weakly open set containing \( A(u, \omega) \), it follows that \( A(u_n, \omega) \in O \) for all \( n \) large enough. Then whenever \( \omega \mapsto A(u(\omega), \omega) \) is measurable into \( V' \), it follows that there is a measurable selection for \( \omega \mapsto A(u(\omega), \omega) \) into \( V' \).

**Proof:** Let \( \omega \mapsto u(\omega) \) be measurable into \( V \) and let \( u_n(\omega) \to u(\omega) \) in \( V \) where \( u_n \) is a simple function
\[
u_n(\omega) = \sum_{k=1}^{m_n} c_k^n X_{E_k^n}(\omega), \text{ the } E_k^n \text{ disjoint}, \Omega = \cup_k E_k^n,
\]
each \( c_k^n \) being in \( V \). We can assume that \( \|u_n(\omega)\| \leq 2\|u(\omega)\| \) for all \( \omega \). Then by assumption, there is a measurable selection for \( \omega \mapsto A(c_k^n, \omega) \) denoted as \( \omega \mapsto
Claim: \( \Gamma_n (\omega) \) is measurable into \( X \).

Proof of claim: It is necessary to show that \( \Gamma_n^{-1} (U) \equiv \{ \omega : \Gamma_n (U) \cap U \neq \emptyset \} \) is measurable whenever \( U \) is open. It suffices to verify this for \( U \) a basic open set in the topology of \( X \). Thus let \( U = \bigcap_{i=1}^{\infty} O_i \) where \( O_i \) is a proper open subset of \( \mathbb{R} \) only for \( i \in \{ j_1, \cdots, j_n \} \). Then

\[
\Gamma_n^{-1} (U) = \bigcup_{j \geq n} \cap_{i=1}^{\infty} \{ \omega : \langle y^j (\omega), z_i \rangle \in O_j \}
\]

which is a measurable set thanks to \( y^j \) being measurable.

In addition to this, \( \Gamma_n (\omega) \) is compact, as explained above. Therefore, \( \Gamma_n \) is also strongly measurable meaning \( \Gamma_n^{-1} (F) \) is measurable for all \( F \) closed. Now let \( \Gamma^{-1} (\omega) \equiv \bigcap_{n=1}^{\infty} \Gamma_n^{-1} (\omega) \). It is a nonempty closed subset of \( X \) and if \( F \) is closed in \( X \),

\[
\Gamma^{-1} (F) = \bigcap_{n=1}^{\infty} \Gamma_n^{-1} (F)
\]

a measurable set since each \( \Gamma_n^{-1} (F) \) is measurable. Thus \( \Gamma \) is a measurable multifunction and so it has a measurable selection \( \omega \to z (\omega) \). Thus by definition, for each \( i, z_i (\omega) = \lim_{n(\omega) \to \infty} \langle y^{n(\omega)} (\omega), z_i \rangle \) for some subsequence indexed by \( n(\omega) \). The sequence \( \{ y^{n(\omega)} (\omega) \} \) is bounded in \( V' \) and so there is a subsequence still denoted as \( \{ y^{n(\omega)} \} \) which converges weakly to \( y (\omega) \). Thus \( z_i (\omega) = \langle y (\omega), z_i \rangle \) for each \( i \). Since \( \omega \to z_i (\omega) \) is measurable, it follows from density of the \( \{ z_i \} \) that \( y \) is weakly, hence strongly measurable, this by the Pettis theorem. Now \( y (\omega) = \lim_{n(\omega) \to \infty} y^{n(\omega)} (\omega) \). But

\[
y^{n(\omega)} (\omega) \in A (u_{n(\omega)} (\omega), \omega)
\]

which is a convex closed set for which \( u \to A (u, \omega) \) is upper semicontinuous and \( u_{n(\omega)} \to u \) so in fact, \( y (\omega) \in A (u (\omega), \omega) \). This is the claimed measurable selection.
75.5. THE MAIN RESULT

Note that we are not assuming that \( \omega \rightarrow A(u, \omega) \) is measurable, only that it has a measurable selection and of course the upper semicontinuity and that the values are closed and convex. Also note that \( \omega \rightarrow \Gamma(\omega) \) is measurable so there is a dense subset of measurable functions \( \{z_k(\omega)\} \) each being measurable into \( X \). However, we don’t know much about \( \Gamma(\omega) \) other than it is measurable into \( X \).

Also \( V \) could be replaced with \( L^p(I, V) \) where \( I \) is any interval and nothing changes.

The condition leading to 75.5.26 will typically be satisfied. For example, suppose \( u^* \in A(u, \omega) \) means that

\[
u^*(t) = A \left( t, u(t), \int_0^t u(s) \, ds, \omega \right)\]

for a.e. \( t \) where \( A \) has values in \( P(V') \). Then to say that \( u^*\mathcal{X}[0,T] \in A \left( u\mathcal{X}[0,T], \omega \right) \) for each \( \hat{T} \) in an increasing sequence converging to \( T \) would imply the above holding for a.e. \( t \). While the above is the typical situation one would expect to see, the following proposition is also interesting.

**Proposition 75.5.4** Suppose \( A(\cdot, \omega) : V \rightarrow P(V') \) is upper semicontinuous from the strong topology of \( V \) to the weak topology of \( V' \) and has closed convex values. Then if

\[
u^*\mathcal{X}[0,T] \in A \left( u\mathcal{X}[0,T], \omega \right)
\]

for each \( \hat{T} \) in an increasing sequence converging to \( T \), then \( u^* \in A(u, \omega) \).

**Proof:** Let \( \hat{T}_n \uparrow T \) such that \( u^*\mathcal{X}[0,\hat{t}_n] \in A \left( u\mathcal{X}[0,\hat{t}_n], \omega \right) \). Then if \( u^* \notin A(u, \omega) \), there exists \( z \in V \) such that

\[
\langle u^*, z \rangle > r > \langle u^*, z \rangle
\]

for all \( u^* \in A(u, \omega) \). Now \( u^*\mathcal{X}[0,\hat{t}_n] \rightarrow u^* \) in \( V' \) and \( u\mathcal{X}[0,\hat{t}_n] \rightarrow u \) in \( V \). Letting \( O \) be the weakly open set, \( \{z^* : \langle z^*, z \rangle < r\} \), it follows that this \( O \) is a weakly open set which contains \( A(u, \omega) \). Hence, by upper semicontinuity, \( \langle u^*\mathcal{X}[0,\hat{t}_n], z \rangle < r \) for all \( n \) large enough. Hence, passing to a limit, one obtains \( \langle u^*, z \rangle > r \geq \langle u^*, z \rangle \), a contradiction. Thus \( u^* \in A(u, \omega) \).

Let \( r > \max(p, 2) \). Let \( \mathcal{U} \) and \( \mathcal{U}_t \) be defined by analogy with \( V \) and \( V_t \) where \( \mathcal{U} \equiv L^p([0,T], U) \). Here \( U \) is a Hilbert space which is dense in \( V \) and embeds compactly into \( V \), \( \|u\|_U \geq \|u\|_V \). Also let \( F : U \rightarrow U' \) be the duality map for \( r \). Thus

\[
\|Fu\|_{V'} = \|u\|_{V'}^{r-1}, \quad \langle Fu, u \rangle = \|u\|_V^r
\]

Also define the following notation for small positive \( h \).

\[
\tau_h g(t) = \begin{cases} g(t-h) & \text{if } t > h \\ 0 & \text{if } t \leq h \end{cases}
\]
Let $\omega \to u_0(\omega)$ be $\mathcal{F}$ measurable into $W$. Also let $\omega \to f(\cdot, \omega)$ be $\mathcal{F}$ measurable into $\mathcal{V}'$, $\omega \to B(\omega)$ measurable into $\mathcal{L}(W, W')$. Now let $u_h$ for $h > 0$ and small, be the unique solution to the initial value problem

$$(B(\omega) u_h(\cdot, \omega))' + \varepsilon F u_h(\cdot, \omega) = f(\cdot, \omega) - u_h(\cdot, \omega) \quad \text{in } \mathcal{U}', \quad Bu_h(0, \omega) = Bu_0(\omega)$$

where $u_h^* \in A(\tau_h u, \omega)$ is a $\mathcal{F}$ measurable selection into $\mathcal{V}'$. Since $F$ is monotone bounded and hemicontinuous, there is no problem with it being pseudomonotone from $X_T$ to $X_T'$. Such a solution exists on $[0, h]$ by the above reasoning. Let this solution be denoted by $u_1$. Then use it to define a solution to the evolution equation on $[0, 2h]$ called $u_2$. By uniqueness, these coincide on $[0, h]$. Then use $u_2$ to extend to a solution on $[0, 3h]$ called $u_3$. Then $u_3 = u_2$ on $[0, 2h]$. Continue this way to obtain a solution valid on $[0, T]$. By Lemma 75.3, this solution may be assumed to be measurable into $\mathcal{U}'$. One gets this by using the lemma on a succession of intervals $[0, h], [0, 2h], \ldots$, and so forth.

Now acting on $u_h$ and suppressing the dependence on $\omega$ in most places, it follows from the assumed estimates that

$$\frac{1}{2} \left( Bu_h, u_h \right)(T) - \frac{1}{2} \left( Bu_0, u_0 \right) + \varepsilon \int_0^T \| u_h \|^p_{\mathcal{V}} \, ds$$

$$\leq \left( \int_0^T \| f \|^p_{\mathcal{V}'} \, ds \right)^{1/p'} \left( \int_0^T \| u_h \|^p_{\mathcal{V}} \, ds \right)^{1/p}$$

$$+ \int_0^T (a + b \| \tau_k u_h \|^{p-1}_{\mathcal{V}}) \| u_h \|^p_{\mathcal{V}} \, ds$$

$$\leq \| f \|^p_{\mathcal{V}'} + \| u_h \|^p_{\mathcal{V}} + \| u_h \|^p_{\mathcal{V}} + aT^{1/p'} + b \| u_h \|^p_{\mathcal{V}}$$

which is of the form

$$\leq C \left( \| f \|^p_{\mathcal{V}'} , a(\omega) T \right) + (2 + b) \| u_h \|^p_{\mathcal{V}}$$

Now here is where it is good that $p < r$.

$$\| u_h \|^p_{\mathcal{V}} \leq \int_0^T \frac{1}{\delta} \| u_h \|^p_{\mathcal{U}} \, ds$$

$$\leq \left( \int_0^T \delta^{r/p} \| u_h \|^p_{\mathcal{U}} \, ds \right)^{p/r} \left( \int_0^T \frac{1}{\delta^{(r-p)/r}} 1^{r/(r-p)} \right)^{(r-p)/r}$$

$$\leq \frac{1}{\delta^{r/(r-p)}} \frac{T^{(r-p)/r}}{r} (r-p) + \frac{p \delta^{r/p}}{r} \| u_h \|^p_{\mathcal{U}}$$

Thus this has shown

$$\frac{1}{2} \left( Bu_h, u_h \right)(T) - \frac{1}{2} \left( Bu_0, u_0 \right) + \varepsilon \| u_h \|^p_{\mathcal{U}}$$

$$\leq C \left( \| f \|^p_{\mathcal{V}'} , a(\omega) T \right) + \frac{1}{\delta^{r/(r-p)}} \frac{T^{(r-p)/r}}{r} (r-p) + \frac{p \delta^{r/p}}{r} \| u_h \|^p_{\mathcal{U}}$$
Then for $\delta$ small enough, depending on $\varepsilon$,

$$\frac{p^r}{r} < \frac{\varepsilon}{2}$$

And so the inequality ending at (75.5.38) yields

$$\langle Bu_h, u_h \rangle (T) + \varepsilon \|u_h\|_{\mathcal{U}}^r \leq C \left( \|f\|_{\mathcal{V}'}^r, (a(\omega) + 1) T, \varepsilon \right) + \langle Bu_0, u_0 \rangle$$

From (75.5.37) and the boundedness of the various operators, $(B(\omega) u_h (\cdot, \omega))^\prime$ is bounded in $\mathcal{U}'$. Thus, summarizing these estimates yields

$$\|(B(\omega) u_h (\cdot, \omega))^\prime\|_{\mathcal{U}'} + \|u_h\|_{\mathcal{U}} + \|u_h^*\|_{\mathcal{V}'} \leq C \quad (75.5.39)$$

where $C$ does not depend on $h$ although it does depend on $\varepsilon$ and of course on $\omega$. Then one can get a subsequence, still denoted with $h$ such that as $h \to 0$,

$$u_h \to u \text{ weakly in } \mathcal{U} \quad (75.5.40)$$

$$\tau_h u_h \to u \text{ weakly in } \mathcal{U} \quad (75.5.41)$$

$$(B(\omega) u_h (\cdot, \omega))^\prime \to (B(\omega) u)^\prime \text{ weakly in } \mathcal{U}' \quad (75.5.42)$$

$$u_h \to u \text{ strongly in } \mathcal{V} \quad (75.5.43)$$

$$u_h^* \to u^* \text{ weakly in } \mathcal{V}' \quad (75.5.44)$$

$$F u_h \to \xi \in \mathcal{U}' \quad (75.5.45)$$

$$Bu(0, \omega) = Bu_0(\omega) \quad (75.5.46)$$

The fourth of these comes from a use of Theorem (75.3.1). We need to argue that $u^* \in A(u, \omega)$. From the equation and initial conditions of (75.5.37) it follows from monotonicity conditions and the observation that $\mathcal{V}'$ is contained in $\mathcal{U}'$ that

$$\langle (B(\omega) u_h (\cdot, \omega))^\prime, u_h - u \rangle + \langle \varepsilon Fu_h (\cdot, \omega), u_h - u \rangle = \langle f (\cdot, \omega), u_h - u \rangle$$

and so

$$\langle (B(\omega) u (\cdot, \omega))^\prime, u_h - u \rangle + \langle \varepsilon Fu_h (\cdot, \omega), u_h - u \rangle_{\mathcal{U}', \mathcal{U}} + \langle u_h^*(\cdot, \omega), u_h - u \rangle_{\mathcal{V}', \mathcal{V}} \leq \langle f (\cdot, \omega), u_h - u \rangle$$

by the strong convergence of (75.5.43), it follows that the third term converges to 0 as $h \to 0$. This is because the estimate (75.5.47) implies that the $u_h^*$ are bounded, and then the strong convergence gives the desired result. Hence

$$\limsup_{h \to 0} \langle \varepsilon Fu_h (\cdot, \omega), u_h - u \rangle_{\mathcal{U}', \mathcal{U}} \leq 0$$

and since $F$ is monotone and hemicontinuous, it follows that in fact,

$$\lim_{h \to 0} \langle \varepsilon Fu_h (\cdot, \omega), u_h - u \rangle_{\mathcal{U}', \mathcal{U}} = 0$$
so for \( v \in U \) arbitrary,
\[
\langle \xi, u - v \rangle = \liminf_{h \to 0} \left( \langle \varepsilon F u_h (\cdot), u - u_h \rangle_{U', U} + \langle \varepsilon F u_h (\cdot), u_h - v \rangle_{U', U} \right)
\]
\[
= \liminf_{h \to 0} \langle \varepsilon F u_h (\cdot), u_h - v \rangle_{U', U} \geq \langle \varepsilon F u, u - v \rangle
\]
and so, since \( v \) is an arbitrary element of \( U \), it follows that \( \xi = F(u) \).

Now consider the other term involving \( u^*_h \). Recall that \( u^*_h \in A (\tau_h u_h, \omega) \).
\[
\| \tau_h u_h - u \|_V \leq \| \tau_h u_h - \tau_h u \|_V + \| \tau_h u - u \|_V
\]
and both of these on the right converge to 0 thanks to continuity of translation and \( \text{[A5.5.40]} \). Therefore,
\[
\lim_{h \to 0} \langle u^*_h (\cdot), \tau_h u_h - u \rangle_{V', V} = 0.
\]
It follows that
\[
\langle u^*, u - v \rangle_{V', V} = \liminf_{h \to 0} \left( \langle u^*_h (\cdot), u - \tau_h u_h \rangle_{V', V} + \langle u^*_h (\cdot), \tau_h u_h - v \rangle_{V', V} \right)
\]
\[
\geq \liminf_{h \to 0} \langle u^*_h (\cdot), \tau_h u_h - v \rangle \geq \langle u^* (v), u - v \rangle
\]
where \( u^* (v) \in A (u, \omega) \). Then it follows that \( u^* \in A (u, \omega) \) because if not, then by separation theorems, there would exist \( v \) such that
\[
\langle u^*, u - v \rangle_{V', V} < \langle w^*, u - v \rangle_{V', V}
\]
for all \( w^* \in A (u, \omega) \) which contradicts the above inequality. Thus, passing to the limit in \( \text{[A5.5.41]} \),
\[
(B \omega (u (\cdot, \omega)))' + \varepsilon F u (\cdot, \omega) + u^* = f(\cdot, \omega) \text{ in } U', \quad (75.5.47)
\]
\[
Bu(0,\omega) = B u_0(\omega)
\]
Here \( u^* \in A (u, \omega) \). Of course nothing is known about the measurability of \( u^*, u \). All that has been obtained in the above is a solution for each fixed \( \omega \). However, each of the functions \( u_h, u^*_h \) is measurable. Also we have the estimate \( \text{[A5.5.43]} \). By Theorem \( \text{[A5.5.14]} \), there are functions \( \hat{u} (\cdot, \omega), \hat{u}^* (\cdot, \omega) \) and a subsequence with subscript \( h (\omega) \) such that the following weak convergences in \( V \) and \( V' \) take place
\[
u_h (\omega) \rightharpoonup \hat{u} (\cdot, \omega), \quad u^*_h (\omega) \rightharpoonup \hat{u}^* (\cdot, \omega)
\]
such that the functions \( (t, \omega) \to \hat{u} (t, \omega), (t, \omega) \to \hat{u}^* (t, \omega) \) are product measurable into \( V \) and \( V' \) respectively. The above argument shows that for each \( \omega \), there is a further subsequence, still denoted with subscript \( h (\omega) \) such that \( u_h (\omega) \rightharpoonup u (\cdot, \omega) \) weakly in \( V \) and \( u^*_h (\omega) \rightharpoonup u^* (\cdot, \omega) \) weakly in \( V' \) such that \( (u (\cdot, \omega), u^* (\cdot, \omega)) \) is a solution to the evolution equation for each \( \omega \). By uniqueness of limits, \( u (\cdot, \omega) = \hat{u} (\cdot, \omega) \), similar for \( \hat{u}^* \). Thus this solution which is defined for each \( \omega \) has a representative for each \( \omega \) such that the resulting functions of \( t, \omega \) are product measurable into \( V, V' \) respectively. This proves the following lemma.
Lemma 75.5.5 For each \( \varepsilon > 0 \) there exists a solution to
\[
(B(\omega)u(\cdot,\omega))' + \varepsilon Fu(\cdot,\omega) + u^*(\cdot,\omega) = f(\cdot,\omega) \quad \text{in } \mathcal{U}',
\]
\[
Bu(0,\omega) = Bu_0(\omega)
\]
\[
u^*(\cdot,\omega) \in A(u(\cdot,\omega),\omega)
\]
this solution satisfies \((t,\omega) \rightarrow u(t,\omega)\) is product measurable into \(V\). Also \((t,\omega) \rightarrow u^*(t,\omega)\), and \((t,\omega) \rightarrow B(\omega)u(t,\omega)\) are product measurable into \(V'\) and \(W'\) respectively.

Next it is desired to remove the regularizing term \(\varepsilon Fu\). This will involve another use of Theorem 75.2.10. Denote by \(u_\varepsilon\) the solution to the above lemma. Then act on \(u_\varepsilon\) on both sides. This yields
\[
\frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle(T) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \varepsilon \int_0^T \langle Fu_\varepsilon, u_\varepsilon \rangle ds
\]
\[
+ \int_0^T \langle u^*_\varepsilon, u_\varepsilon \rangle ds = \int_0^T \langle f, u_\varepsilon \rangle ds
\]
(75.5.50)

Then by the coercivity assumption,
\[
\lim_{\|u\|_V \rightarrow \infty} \frac{\inf \left\{ \right\}}{\|u\|_V} = \infty
\]
it follows that
\[
\varepsilon \langle Fu_\varepsilon, u_\varepsilon \rangle_{\mathcal{U}',\mathcal{U}} + \|u_\varepsilon\|_V \leq C(u_0,f)
\]
(75.5.51)
where the constant on the right does not depend on \(\varepsilon\). Then
\[
\varepsilon Fu_\varepsilon \rightarrow 0 \quad \text{strongly in } \mathcal{U}'
\]
this follows because from properties of the duality map,
\[
\langle \varepsilon Fu_\varepsilon, v \rangle \leq \varepsilon \langle Fu_\varepsilon, u_\varepsilon \rangle^{1/r'} \langle Fv, v \rangle^{1/r}
\]
\[
= \varepsilon^{1/r'} \langle Fu_\varepsilon, u_\varepsilon \rangle^{1/r'} \varepsilon^{1/r} \|v\|_\mathcal{U} \leq C\varepsilon^{1/r} \|v\|_\mathcal{U}
\]
Then since \(A\) is bounded, there is a constant \(C\) independent of \(\varepsilon\) such that
\[
\|u_\varepsilon^*\|_V + \|(Bu_\varepsilon)'\|_{\mathcal{U}'} + \|u_\varepsilon\|_V \leq C
\]
(75.5.52)
It follows there is a subsequence, still denoted with \(\varepsilon\) such that
\[
u_\varepsilon^* \rightarrow u^* \quad \text{weakly in } V',
\]
(75.5.53)
\[(Bu_\varepsilon)' \rightarrow (Bu)' \quad \text{weakly in } \mathcal{U}',
\]
(75.5.54)
\[u_\varepsilon \rightarrow u \quad \text{weakly in } V.
\]
(75.5.55)
Also

\[ \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (T) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \langle u_\varepsilon^*, u_\varepsilon \rangle + \varepsilon \langle Fu_\varepsilon, u_\varepsilon \rangle = \langle f, u_\varepsilon \rangle \]

Assume \( T \) is such that

\[ \langle Bu_\varepsilon, u_\varepsilon \rangle (T) = \langle B (u_\varepsilon (T)), u_\varepsilon (T) \rangle, \quad Bu_\varepsilon (T) = B (u_\varepsilon (T)) \]

for all \( \varepsilon \) in the sequence converging to 0 and also \( Bu_\varepsilon (T) = B (u_\varepsilon (T)), \langle Bu, u \rangle (T) = \langle B (u (T)), u (T) \rangle \). If not, carry out the argument for \( \tilde{T} \) close to \( T \) for which this condition does hold. We have the integral equation

\[ Bu_\varepsilon (t) - Bu_0 + \int_0^t u_\varepsilon^* ds + \int_0^t \varepsilon Fu_\varepsilon ds = \int_0^t f ds \]

and so \( Bu_\varepsilon (t) \) converges to \( Bu(t) \) in \( U' \) weakly. This follows right away from the convergence of \( (Bu_\varepsilon)' \) in the above. Also from the above equation,

\[ Bu (t) - Bu_0 + \int_0^t u^* ds = \int_0^t f ds \]

Thus

\[ Bu (0) = Bu_0 \]

\[ (Bu)' + u^* = f \text{ in } U' \]

Since \( V' \subseteq U' \),

\[ \frac{1}{2} \langle Bu, u \rangle (t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle u^*, u \rangle_{V', V} ds = \int_0^t \langle f, u \rangle ds \]

Also

\[ \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^t \langle u_\varepsilon^*, u_\varepsilon \rangle_{V', V} ds \]

\[ + \int_0^t \langle \varepsilon Fu_\varepsilon, u_\varepsilon \rangle ds = \int_0^t \langle f, u_\varepsilon \rangle ds \] \quad (75.5.56)

Now let \( \{e_i\} \) be the vectors of Lemma 75.3.4 where these are in \( U \). Thus

\[ \langle Bu_\varepsilon, u_\varepsilon \rangle (T) = \sum_{i=1}^{\infty} \langle B (u_\varepsilon (T)), e_i \rangle^2 \]
Hence, by Fatou’s lemma,

$$\liminf_{\varepsilon \to 0} \langle Bu_\varepsilon, u_\varepsilon \rangle (T) = \liminf_{\varepsilon \to 0} \sum_{i=1}^{\infty} \langle B(u_\varepsilon(T)), e_i \rangle^2$$

$$\geq \sum_{i=1}^{\infty} \liminf_{\varepsilon \to 0} \langle B(u_\varepsilon(T)), e_i \rangle^2$$

$$= \sum_{i=1}^{\infty} \liminf_{\varepsilon \to 0} \langle Bu_\varepsilon(T), e_i \rangle^2$$

$$= \sum_{i=1}^{\infty} \langle Bu(T), e_i \rangle^2$$

$$= \langle B(u(T)), u(T) \rangle = \langle Bu, u \rangle (T)$$

From 75.5.56, letting $t = T$,

$$\limsup_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon \rangle_{V^*, V} \leq \limsup_{\varepsilon \to 0} \left( \langle f, u_\varepsilon \rangle + \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle (T) \right)$$

$$\leq \langle f, u \rangle_{V^*, V} + \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu, u \rangle (T) = \langle u^*, u \rangle_{V^*, V}$$

It follows that

$$\limsup_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - u \rangle \leq \langle u^*, u \rangle_{V^*, V} - \langle u^*, u \rangle_{V^*, V} = 0$$

and so

$$\liminf_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - v \rangle \geq \langle u^*(v), u - v \rangle$$

for any $v \in V$ where $u^*(v) \in A(u, \omega)$. In particular for $v = u$. Hence

$$\liminf_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - u \rangle \geq \langle u^*(v), u - u \rangle = 0 \geq \limsup_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - u \rangle$$

showing that $\lim_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - u \rangle = 0$. Thus

$$\langle u^*, u - v \rangle \geq \liminf_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - u \rangle + \langle u_\varepsilon^*, u_\varepsilon - v \rangle$$

$$= \liminf_{\varepsilon \to 0} \langle u_\varepsilon^*, u_\varepsilon - v \rangle \geq \langle u^*(v), u - v \rangle$$

This implies $u^* \in A(u, \omega)$ because if not, then by separation theorems, there exists $v \in V$ such that for all $w^* \in A(u, \omega)$,

$$\langle u^*, u - v \rangle < \langle w^*, u - v \rangle$$

contrary to what was shown above. Thus this obtains

$$Bu(t) - Bu_0 + \int_0^t u^* ds = \int_0^t f ds$$
where \( u^* \in A(u, \omega) \). In case \( Bu_\varepsilon(T) \neq B(u_\varepsilon(T)) \), you do the same argument for \( \tilde{T} < T \) where \( Bu_\varepsilon(\tilde{T}) = B(u_\varepsilon(\tilde{T})) \) for all \( \varepsilon \) and for \( u \). Then the above argument shows that \( u^*X^{[0,T]} \in A(X^{[0,T]}u, \omega) \). This being true for every such \( \tilde{T} < T \) implies that it holds on \([0,T]\) and shows part of the following theorem which is the main result.

**Theorem 75.5.6** Let the conditions on \( A \) hold\( 75.3.29 - 75.3.28, 75.3.34 - 75.3.34 \). Also let \( B \) satisfy \( 75.3.34 \) and assume, if it depends on \( \omega \), it is of the form

\[
B(\omega) = k(\omega)B, \quad k(\omega) \geq 0, \quad k \text{ measurable}
\]

Let \( u_0 \) be \( \mathcal{F} \) measurable into \( W \), and let \( f(\cdot, \omega) \in \mathcal{V}' \). Then there exists a solution to the following evolution inclusion

\[
(B(\omega)u(\cdot, \omega))^t + u^*(\cdot, \omega) = f(\cdot, \omega) \quad \text{in} \ \mathcal{V}'
\]

\[
B(\omega)u(0, \omega) = B(\omega)u_0(\omega)
\]

\[
(75.5.57)
\]

where \( u^*(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \). In addition to this, \((t, \omega) \rightarrow u(t, \omega)\) is product measurable into \( V \) and \((t, \omega) \rightarrow u^*(t, \omega)\) is product measurable into \( V' \).

In place of the coercivity condition \( 75.5.29 \) assume the coercivity condition involving both \( B \) and \( A \) given in \( 75.5.29 \). Then

\[
(B(\omega)u(\cdot, \omega))^t + u^*(\cdot, \omega) = f(\cdot, \omega) \quad \text{in} \ \mathcal{U}'
\]

\[
B(\omega)u(0, \omega) = B(\omega)u_0(\omega)
\]

\[
(75.5.58)
\]

\[
(75.5.59)
\]

Thus the following holds in \( V' \)

\[
(B(\omega)u(\cdot, \omega))(t) - B(\omega)u_0(\omega) + \int_0^t u^*(\cdot, \omega) ds = \int_0^t f(s, \omega) ds \quad Bu^t \in \mathcal{V}
\]

**Proof of Theorem 75.5.6**: First consider the claim about replacing the coercivity condition. Returning to \( 75.5.34 \), one obtains by integrating up to \( t \) and adding \( \lambda \int_0^t \langle Bu_\varepsilon, u_\varepsilon \rangle ds \) to both sides,

\[
\frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle(t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \varepsilon \int_0^t \langle Fu_\varepsilon, u_\varepsilon \rangle ds
\]

\[
+ \int_0^t \langle u_\varepsilon^*, u_\varepsilon \rangle ds + \lambda \int_0^t \langle Bu_\varepsilon, u_\varepsilon \rangle ds = \int_0^t \langle f, u_\varepsilon \rangle ds + \lambda \int_0^t \langle Bu_\varepsilon, u_\varepsilon \rangle ds \quad (75.5.60)
\]

Then from the estimate \( 75.5.74 \),

\[
\frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle(t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \varepsilon \int_0^t \langle Fu_\varepsilon, u_\varepsilon \rangle ds
\]
75.5. THE MAIN RESULT

\[ + \delta(\omega) \int_0^t \|u_\varepsilon\|_{V'}^p \, ds - m(\omega) = \int_0^t \langle f, u_\varepsilon \rangle \, ds + \lambda \int_0^t \langle Bu_\varepsilon, u_\varepsilon \rangle \, ds \quad (75.5.61) \]

From this, it is a routine use of Gronwall’s inequality to obtain the estimate

\[ \varepsilon \langle Fu_\varepsilon, u_\varepsilon \rangle_{V', V} + \|u_\varepsilon\|_V \leq C(u_0, f, \lambda, \omega) \quad (75.5.62) \]

Then the rest of the argument is the same. You obtain the following in \( U' \).

\[ B(\omega) u(t, \omega) - B(\omega) u_0(\omega) + \int_0^t u^*(\cdot, \omega) \, ds = \int_0^t f(s, \omega) \, ds \]

Since all terms but the first are in \( V' \), the equation holds in \( V' \). Also, the equation in \( 75.5.68 \) shows that \( (B(\omega) u(\cdot, \omega))' \in V' \).

It only remains to show that there is a product measurable solution. The above argument has shown that there exists a solution for each \( \omega \). This is another application of Theorem 75.2.10. For the sequence defined in the convergences \( 75.5.53 - 75.5.55 \), there is an estimate \( 75.5.52 \). Therefore, the conditions of this theorem hold and there exists a subsequence denoted with \( \varepsilon(\omega) \) such that

\[ u_\varepsilon(\omega)(\cdot, \omega) \rightharpoonup \hat{u}(\cdot, \omega) \text{ weakly in } V, \]

\[ u_\varepsilon(\omega)(\cdot, \omega) \rightharpoonup \hat{u}^*(\cdot, \omega) \text{ weakly in } V' \]

where the \( \hat{u} \) and \( \hat{u}^* \) are product measurable. Now the above argument shows that for each \( \omega \) there exists a further subsequence, still denoted with \( \varepsilon(\omega) \) such that convergence to a solution to the evolution inclusion is obtained \( (u(\cdot, \omega), u^*(\cdot, \omega)) \).

Then by uniqueness of limits, \( \hat{u}(\cdot, \omega) = u(\cdot, \omega) \in V \), similar for \( u^* \) and \( \hat{u}^* \). Hence there is a solution to the above evolution problem which satisfies the claimed product measurability.

One can give a very interesting generalization of the above theorem.

**Theorem 75.5.7** In the context of Theorem 75.5.6, let \( q(t, \omega) \) be a product measurable function into \( V \) such that \( t \to q(t, \omega) \) is continuous, \( q(0, \omega) = 0 \).

Then, there exists a solution \( u \) of the integral equation

\[ Bu(t, \omega) + \int_0^t z(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) + Bq(t, \omega), \]

where \( (t, \omega) \to u(t, \omega) \) is product measurable. Moreover, for each \( \omega \), \( Bu(t, \omega) = B(u(t, \omega)) \) for a.e. \( t \) and \( z(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \) for a.e. \( t \), \( z \) is product measurable into \( V' \). Also, for each \( a \in [0, T] \),

\[ Bu(t, \omega) + \int_a^t z(s, \omega) \, ds = \int_a^t f(s, \omega) \, ds + Bu(a, \omega) + Bq(t, \omega) - Bq(a, \omega) \]

**Proof:** Define a stopping time

\[ \tau_r \equiv \inf \{ t : |q(t, \omega)| > r \} \]
Then this is the first hitting time of an open set by a continuous random variable and so it is a valid stopping time. Then for each \( r \), let

\[
A_r (\omega, w) \equiv A (\omega, w + q^r (\cdot, \omega)),
\]

where the notation means \( q^r (t) \equiv q (t \wedge \tau_r) \). Then, since \( q^r \) is uniformly bounded, all of the necessary estimates and measurability for the solution to the above corollary hold for \( A_r \) replacing \( A \). Therefore, there exists a solution \( w_r \) to the inclusion

\[
(Bw_r)' (\cdot, \omega) + A_r (w_r (\cdot, \omega), \omega) \ni f (\cdot, \omega), \quad Bw_r (0, \omega) = Bu_0 (\omega)
\]

Now for fixed \( \omega, q^r (t, \omega) \) does not change for all \( r \) large enough. This is because it is a continuous function of \( t \) and so is bounded on the interval \([0, T]\). Thus, for \( r \) large enough and fixed \( \omega \), \( q^r (t; \omega) = q (t; \omega) \). Thus, we obtain

\[
\langle Bw_r (t, \omega), w_r (t, \omega) \rangle + \int_0^t ||w_r (s, \omega)||_V^p \, ds \leq C (\omega) \quad (75.5.63)
\]

Now, as before one can pass to a limit involving a subsequence, as \( r \to \infty \) and obtain a solution to the integral equation

\[
Bw (t, \omega) - Bu_0 (\omega) + \int_0^t z (s, \omega) \, ds = \int_0^t f (s, \omega) \, ds
\]

where \( z (s, \omega) \in A (s, \omega, w (s, \omega) + q (s, \omega)) \) for a.e. \( s \) and \( z \) is product measurable. Then an application of Theorem 75.2.10 shows that there exists a solution \( w \) to this integral equation for each \( \omega \) which also has \((t, \omega) \to w (t, \omega)\) product measurable and \((t, \omega) \to z (t, \omega)\) product measurable. Now just let \( u (t, \omega) = w (t, \omega) + q (t, \omega) \).

The last claim follows from letting \( t = a \) in the top equation and then subtracting this from the top equation with \( t > a \). ■

75.6 Variational Inequalities

We have some good theorems above in the context of 75.5.25 - 75.5.28, 75.5.30 - 75.5.34 and \( B \) satisfies 75.3.6 and assume, if it depends on \( \omega \), it is of the form

\[
B (\omega) = k (\omega) B, \quad k (\omega) \geq 0, \quad k \text{ measurable}
\]

Now this will be used to consider variational inequalities. Let \( \mathcal{K} \) be a closed convex subset of \( \mathcal{V} \) containing 0. Let \( P : \mathcal{V} \to \mathcal{V}' \) be an operator of penalization. Thus \( P = 0 \) on \( \mathcal{K} \) and is monotone and demicontinuous and nonzero off \( \mathcal{K} \).

\[
P = F (u - \text{proj}_\mathcal{K} (u))
\]

where \( F \) is the duality map such that \( \langle Fu, u \rangle = ||u||^2, ||Fu|| = ||u|| \). Then \( A (\cdot, \omega) + nP \) satisfies the conditions for Theorem 75.3.4 assuming \( A (\cdot, \omega) \) satisfies the conditions of this theorem. Then by Theorem 75.5.4 there exists a solution \( u_n \) such
that \((t, \omega) \rightarrow u_n (t, \omega), (t, \omega) \rightarrow u_n^* (t, \omega)\) are product measurable, and for each \(\omega\),

\[
(Bu_n)' + u_n^* (\cdot, \omega) + nP (u_n (\cdot, \omega)) = f (\cdot, \omega) \quad \text{in } V',
Bu_n (0, \omega) = 0
\]

Here \(B\) is as described in that theorem. Using \(0 \in K\) and monotonicity of \(P\), the estimates for \(A\) lead to an estimate of the form

\[
\|u_n (\cdot, \omega)\|_V + \|u_n^* (\cdot, \omega)\|_{V'} \leq C (\omega)
\]

Then there is a subsequence

\[
\begin{align*}
&u_n \rightarrow u \text{ weakly in } V, \\
&u_n^* \rightarrow u^* \text{ weakly in } V', \\
&P u_n \rightarrow \xi \text{ weakly in } V'
\end{align*}
\]

Let \(\Lambda\) denote those \(v \in V\) such that \((Bv)' \in V'\) and \(Bv (0) = 0\). Then for \(v \in \Lambda\),

\[
\langle (Bu_n)', u_n - v \rangle + \langle u_n^* (\cdot, \omega), u_n - v \rangle + n \langle P (u_n (\cdot, \omega)) , u_n - v \rangle = \langle f (\cdot, \omega), u_n - v \rangle
\]

Thus by monotonicity considerations,

\[
\langle (Bv)', u_n - v \rangle + \langle u_n^* (\cdot, \omega), u_n - v \rangle + n \langle P (u_n (\cdot, \omega)) , u_n - v \rangle \leq \langle f (\cdot, \omega), u_n - v \rangle
\]

It follows that

\[
\limsup_{n \to \infty} \langle P (u_n (\cdot, \omega)) , u_n - v \rangle \leq 0
\]

Now, since \(\Lambda\) is dense, \(v\) can be chosen as close as desired to \(u\) and hence

\[
\limsup_{n \to \infty} \langle P (u_n (\cdot, \omega)) , u_n - u \rangle \leq 0
\]

Since \(P\) is monotone, in fact the limit exists in the above. Therefore, for any \(v \in \Lambda\) and \(*\),

\[
\liminf_{n \to \infty} \langle (P (u_n (\cdot, \omega)) , u_n - v) \rangle \geq \langle Pu, u - v \rangle
\]

and so

\[
\langle Pu, u - v \rangle \leq 0
\]

for all \(v \in \Lambda\). It follows that \(Pu = 0\) and so \(u \in K\).

Now for \(v \in \Lambda \cap K\), monotonicity considerations imply

\[
\langle (Bv)', u_n - v \rangle + \langle u_n^* (\cdot, \omega), u_n - u \rangle + \langle u_n^* (\cdot, \omega), u - v \rangle \leq \langle f (\cdot, \omega), u_n - v \rangle
\]
Then
\[
\langle u_n^* (\cdot, \omega), u_n - u \rangle \leq \langle f (\cdot, \omega), u_n - v \rangle - \langle (Bv)', u_n - v \rangle - \langle u_n^* (\cdot, \omega), u - v \rangle
\]
\[(75.6.65)\]
Then
\[
\limsup_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - u \rangle \leq \langle f (\cdot, \omega), u - v \rangle + \langle (Bv)', v - u \rangle + \langle u^* (\cdot, \omega), v - u \rangle
\]
We assume the existence of a regularizing sequence. If \( u_i \to u \) weakly in \( V \) such that
\[
\limsup_{i \to \infty} \langle (Bu_i)', u_i - u \rangle \leq 0
\]
In the above inequality, let \( v = u_i \)
\[
\limsup_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - u \rangle \leq \langle f (\cdot, \omega), u_i - u \rangle + \langle (Bu_i)', u_i - u \rangle + \langle u^* (\cdot, \omega), u_i - u \rangle
\]
Then take \( \limsup_{i \to 0} \) of both sides to obtain
\[
\limsup_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - u \rangle \leq 0.
\]
Now assume the usual limit condition holds for \( A (\cdot, \omega) \). In practice, this typically means \( A (\cdot, \omega) \) will be single valued, monotone and hemicontinuous because there is no control on the time derivative. However, we will go ahead and assume just that the limit condition holds. This would also take place if \( A (\cdot, \omega) \) were defined on \( V \) and maximal monotone, for example. Then for every \( v \in V \),
\[
\liminf_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - v \rangle \geq \langle u^* (v), u - v \rangle
\]
where \( u^* (v) \in A (u, \omega) \). In particular, this holds for \( v = u \) and so
\[
\liminf_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - u \rangle \geq 0 \geq \limsup_{n \to \infty} \langle u_n^* (\cdot, \omega), u_n - u \rangle
\]
showing the the limit exists. Then
\[
\langle u^* (v), u - v \rangle \leq \liminf_{n \to \infty} (\langle u_n^* (\cdot, \omega), u_n - v \rangle)
\]
\[
= \liminf_{n \to \infty} (\langle u_n^* (\cdot, \omega), u_n - u \rangle + \langle u_n^* (\cdot, \omega), u - v \rangle)
\]
\[
= \langle u^*, u - v \rangle
\]
and since this is true for all \( v \in V \) it follows that \( u^* \in A (u (\cdot, \omega), \omega) \) since otherwise, separation theorems would give a contradiction. If \( u^* \) were not in \( A (u (\cdot, \omega), \omega) \) there would exist \( v \) such that for all \( z^* \in A (u, \omega), \)
\[
\langle z^*, u - v \rangle > \langle u^*, u - v \rangle
contrary to the above. Therefore, in this section we can take the limit of both sides and conclude that for every \( v \in \mathcal{K} \) such that \((Bv)' \in \mathcal{V}'\), \( Bv(0) = 0 \),

\[
\langle (Bv)', u - v \rangle + \langle u^*, u - v \rangle \leq \langle f (\cdot, \omega), u - v \rangle
\]

where \( u^* \in A(u, \omega) \)

This has proved the first part of the following theorem which gives measurable solutions to a variational inequality.

**Theorem 75.6.1** Suppose \( A(\cdot, \omega) \) is monotone hemi-continuous and bounded and single valued and coercive as a map from \( \mathcal{V} \to \mathcal{V}' \). Suppose also that for \( \omega \to u(\omega) \) measurable into \( \mathcal{V} \), it follows that \( \omega \to A(u(\omega), \omega) \) is measurable into \( \mathcal{V}' \). Let \( \mathcal{K} \) be a closed convex subset of \( \mathcal{V} \) containing 0 and let \( B \in \mathcal{L}(\mathcal{W}, \mathcal{W}') \) be self adjoint and nonnegative as above. Let there be a regularizing sequence \( \{u_i\} \) for each \( u \in \mathcal{K} \) satisfying \( Bu_i(0) = 0 \), \((Bu_i)' \in \mathcal{V}'\), \( u_i \in \mathcal{K} \),

\[
\lim \sup_{i \to \infty} \langle (Bu_i)', u_i - u \rangle \leq 0
\]

Then for each \( \omega \), there exists a solution to

\[
\langle (Bv)', u - v \rangle + \langle A(u(\cdot, \omega), \omega), u(\cdot, \omega) - v \rangle \leq \langle f(\cdot, \omega), u - v \rangle
\]

valid for all \( v \in \mathcal{K} \) such that \((Bv)' \in \mathcal{V}', Bv(0) = 0 \), and \((t, \omega) \to u(t, \omega), \) is \( \mathcal{B}([0, T]) \times \mathcal{F} \) measurable.

**Proof:** This follows from Theorem 75.2.10. This is because there is an estimate of the right sort for the measurable functions \( u_n(\cdot, \omega) \) and \( u_n^*(\cdot, \omega) \) and the above argument which shows that a subsequence has a convergent subsequence which converges appropriately to a solution.

You can have \( \mathcal{K} = \mathcal{K}(\omega) \). There would be absolutely no change in the above theorem. You just need to have the operator of penalization satisfy \( \omega \to P(u(\omega), \omega) = F\left(u(\omega) - \text{proj}_{\mathcal{K}(\omega)} u(\omega)\right) \) is measurable into \( \mathcal{V}' \) provided \( \omega \to u(\omega) \) is measurable into \( \mathcal{V} \). What are the conditions on the set valued \( \omega \to \mathcal{K}(\omega) \) which will cause this to take place?

**Lemma 75.6.2** Let \( \omega \to \mathcal{K}(\omega) \) be measurable into \( \mathcal{V} \). Then \( \omega \to \text{proj}_{\mathcal{K}(\omega)} u(\omega) \) is also measurable into \( \mathcal{V} \) if \( \omega \to u(\omega) \) is measurable.

**Proof:** It follows from standard results on measurable multi-functions that there is a countable collection \( \{w_n(\omega)\} \), \( \omega \to w_n(\omega) \) being measurable and \( w_n(\omega) \in \mathcal{K}(\omega) \) for each \( \omega \) such that for each \( \omega, \mathcal{K}(\omega) = \bigcup_n w_n(\omega) \). Let

\[
d_n(\omega) \equiv \min \left\{ \| u(\omega) - w_k(\omega) \|, k \leq n \right\}
\]

Let \( u_1(\omega) \equiv w_1(\omega) \). Let

\[
u_2(\omega) = u_1(\omega)
\]
on the set
\[ \{ \omega : \| u(\omega) - w_1(\omega) \| < \| u(\omega) - w_2(\omega) \| \} \]
and
\[ u_2(\omega) \equiv w_2(\omega) \text{ off the above set.} \]
Thus \( \| u_2(\omega) - u(\omega) \| = d_2 \). Let

\[
\begin{align*}
u_3(\omega) &= w_1(\omega) \text{ on } \left\{ \omega : \| u(\omega) - w_1(\omega) \| < \| u(\omega) - w_j(\omega) \|, j = 2, 3 \right\} \equiv S_1 \\
u_3(\omega) &= w_2(\omega) \text{ on } S_1 \cap \left\{ \omega : \| u(\omega) - w_1(\omega) \| < \| u(\omega) - w_j(\omega) \|, j = 3 \right\} \\
u_3(\omega) &= w_3(\omega) \text{ on the remainder of } \Omega
\end{align*}
\]
Thus \( \| u_3(\omega) - u(\omega) \| = d_3 \). Continue this way, obtaining \( u_n(\omega) \) such that \( \| u_n(\omega) - u(\omega) \| = d_n(\omega) \) and \( u_n(\omega) \in K(\omega) \) with \( u_n \) measurable. Thus, in effect one picks the closest of all the \( u_k(\omega) \) for \( k \leq n \) as the value of \( u_n(\omega) \) and \( u_n \) is measurable and by density in \( K(\omega) \) of \( \{ u_n(\omega) \} \) for each \( \omega \), \( \{ u_n(\omega) \} \) must be a minimizing sequence for

\[ \lambda(\omega) \equiv \inf \{ \| u(\omega) - z \| : z \in K(\omega) \} \]
Then it follows that \( u_n(\omega) \to \text{proj}_{K(\omega)} u(\omega) \) weakly in \( V \). Here is why: Suppose it fails to converge to \( \text{proj}_{K(\omega)} u(\omega) \). Since it is minimizing, it is a bounded sequence. Thus there would be a subsequence, still denoted as \( u_n(\omega) \) which converges to some \( q(\omega) \neq \text{proj}_{K(\omega)} u(\omega) \). Then

\[ \lambda(\omega) = \lim_{n \to \infty} \| u(\omega) - u_n(\omega) \| \geq \| u(\omega) - q(\omega) \| \]
because convex and lower semicontinuous is weakly lower semicontinuous. But this implies \( q(\omega) = \text{proj}_{K(\omega)} (u(\omega)) \) because the projection map is well defined thanks to strict convexity of the norm used. This is a contradiction. Hence \( \text{proj}_{K(\omega)} u(\omega) = \lim_{n \to \infty} u_n(\omega) \) and so is a measurable function. It follows that \( \omega \to P(u(\omega), \omega) \) is measurable into \( V \).

The following corollary is now immediate.

**Corollary 75.6.3** Suppose \( A(\cdot, \omega) \) is monotone hemicontinuous bounded, single valued, and coercive as a map from \( V \) to \( V' \). Suppose also that for \( \omega \to u(\omega) \) measurable into \( V \), it follows that \( \omega \to A(u(\omega), \omega) \) is measurable into \( V' \). Let \( K(\omega) \) be a closed convex subset of \( V \) containing \( 0 \) and \( \omega \to K(\omega) \) is a set valued measurable multifunction. Let \( \mathcal{B} \in \mathcal{L}(W, W') \) be self adjoint and nonnegative as above. Let there be a regularizing sequence \( \{ u_i \} \) for each \( u \in K \) satisfying \( Bu_i(0) = 0 \), \( (Bu_i)' \in V', u_i \in K \),

\[ \limsup_{i \to \infty} \langle (Bu_i)', u_i - u \rangle \leq 0 \]
Then for each \( \omega \), there exists a solution to

\[ \langle (Bv)', u - v \rangle + \langle A(u(\cdot, \omega), \omega), u(\cdot, \omega) - v \rangle \leq \langle f(\cdot, \omega), u(\cdot, \omega) - v \rangle \]
valid for all \( v \in K(\omega) \) such that \( (Bv)' \in V', Bv(0) = 0 \), and \( t, \omega \to u(t, \omega) \), is \( \mathcal{B}([0, T]) \times \mathcal{F} \) measurable.
Proof: The proof is identical to the above. One obtains a measurable solution to \(75.6.64\) in which \(P\) is replaced with \(P(\cdot, \omega)\). Then one proceeds in exactly the same steps as before and finally uses Theorem \(75.2.10\) to obtain the measurability of a solution to the variational inequality.

What does it mean for \(u(\cdot, \omega) \in \mathcal{K}(\omega)\) for each \(\omega\)? It means that there is a sequence of the \(w_n\) \(\{w_n(\omega)\}\) such that each \(w_n\) is measurable into \(V\) implying that for each \(\omega\) there is a representative \(t \rightarrow w_n(t, \omega)\) such that the resulting \((t, \omega) \rightarrow w_n(t, \omega)\) is product measurable and \(\|u(\cdot, \omega) - w_n(\cdot, \omega)\|_V \rightarrow 0\). Thus there is no reason to think that \((t, \omega) \rightarrow u(t, \omega)\) is product measurable. The message of the above corollary says that nevertheless, there is a measurable solution to the variational inequality.

### 75.7 Progressively Measurable Solutions

In the context of uniqueness of the evolution initial value problem for fixed \(\omega\), one can prove theorems about progressively measurable solutions fairly easily. First is a definition of the term progressively measurable.

**Definition 75.7.1** Let \(F_t\) be an increasing in \(t\) set of \(\sigma\) algebras of sets of \(\mathcal{F}\). Thus each \(F_t\) is a \(\sigma\) algebra and if \(s \leq t\), then \(F_s \subseteq F_t\). This set of \(\sigma\) algebras is called a filtration. A set \(S \subseteq [0, T] \times \Omega\) is called progressively measurable if for every \(t \in [0, T]\),

\[
S \cap [0, t] \times \Omega \in \mathcal{B}([0, t]) \times \mathcal{F}_t
\]

Denote by \(P\) the progressively measurable sets. This is a \(\sigma\) algebra of subsets of \([0, T] \times \Omega\). A function \(g\) is progressively measurable if \(X_{[0, t]} g\) is \(\mathcal{B}([0, t]) \times \mathcal{F}_t\) measurable for each \(t\).

Let \(A\) satisfy the bounded condition \(75.5.25\), the condition on subintervals \(75.5.26\), the specific boundedness estimate \(75.5.27\), the specific coercivity estimate involving \(B\) and \(A\) in \(75.5.29\), and the limit condition \(75.5.30\). In place of the condition on the existence of a measurable selection \(75.5.34\), we will assume the following condition.

**Condition 75.7.2** For each \(t \leq T\), if \(\omega \rightarrow u(\cdot, \omega)\) is \(F_t\) measurable into \(V_{[0, t]}\), then there exists a \(F_t\) measurable selection of \(A(u(\cdot, \omega), \omega)\) into \(V_{[0, t]}\).

Note that \(u(\cdot, \omega)\) is in \(V_{[0, t]}\) so \(u(t, \omega) \in V\).

In this section, we assume that \(\omega \rightarrow B(\omega)\) is \(F_0\) measurable into \(\mathcal{L}(W, W')\).

The theorem to be shown is the following.

**Theorem 75.7.3** Assume the above conditions, \(75.5.24\), \(75.5.24\), \(75.5.24\), \(75.5.24\), \(75.5.30\), and the Condition \(75.7.2\). Let \(u_0\) be \(F_0\) measurable and \(\omega \rightarrow B(\omega)\) also \(F_0\) measurable and \((t, \omega) \rightarrow X_{[0, t]}(t) f(t, \omega)\) is \(\mathcal{B}([0, t]) \times \mathcal{F}_t\) product measurable into
CHAPTER 75. STOCHASTIC INCLUSIONS

V' for each t. Also assume that for each \( \omega \), there is at most one solution to the evolution equation

\[
(B(\omega)u(t,\omega))(t) - B(\omega)u_0(\omega) + \int_0^t u^*(\cdot,\omega) \, ds = \int_0^t f(s,\omega) \, ds,
\]

for \( t \in [0,T] \) for each \( T \leq T \). Then there exists a solution to the integral equation on \([0,1]\) for each \( T \). Thus there is at most one solution to the integral equation on \([0,1]\) for each \( T \). This solution satisfies \( (t,\omega) \rightarrow (u(t,\omega),u^*(t,\omega)) \) is progressively measurable into \( V \times V' \).

**Proof:** Let \( T \) denote subsets of \((0,T]\) which contain \( T \) such that for \( S \in T \), there exists a solution \( u_S \) for each \( \omega \) to the above integral equation on \([0,1]\) such that \( (t,\omega) \rightarrow X_{[0,1]}(t)u_S(t,\omega) \) is \( B([0,1]) \times F_s \) measurable for each \( s \in S \). Then \( \{T\} \in T \). If \( S, S' \) are in \( T \), then \( S \subset S' \) will mean that \( S \subset S' \) and also \( u_S(t,\omega) = u_{S'}(t,\omega) \) in \( V \) for all \( t \in S \), similar for \( u^*_S \) and \( u^*_{S'} \). Note that equality must hold in \( V \) by uniqueness. Now let \( C \) denote a maximal chain. Is \( \cup C \equiv S_\infty \) all of \((0,T]\)? What is \( u_{S_\infty} \)? Define \( u_{S_\infty}(t,\omega) \) the common value of \( u_S(t,\omega) \) for all \( S \in C \), which contain \( t \in S_\infty \). If \( s \in S_\infty \), then it is in some \( S \in C \) and so the product measurability condition holds for this \( s \). Thus \( S_\infty \) is a maximal element of the partially ordered set. Is \( S_\infty \) all of \((0,T]\)? Suppose \( s \notin S_\infty, T > s > 0 \).

From Theorem 75.7.3 there exists a solution to the integral equation on \([0,1]\) called \( u_1 \) such that \( (t,\omega) \rightarrow u_1(t,\omega) \) is \( B([0,1]) \times F_s \) measurable, similar for \( u^*_1 \). By the same theorem, there is a solution on \([0,1], u_2 \) which is \( B([0,1]) \times F_T \) measurable. Now by uniqueness, \( u_2(\cdot,\omega) = u_1(\cdot,\omega) \) in \( V_{[0,1]} \), similar for \( u^*_2 \). Therefore, no harm is done in re-defining \( u_2 \) on \([0,1]\) so that \( u_2(t,\omega) = u_1(t,\omega) \) for all \( t \in [0,1] \), similar for \( u^* \). Denote these functions as \( \hat{u}, \hat{u}^* \). By uniqueness, \( u_{S_\infty}(\cdot,\omega) = \hat{u}(\cdot,\omega) \) in \( L^p([0,1], V) \). Thus no harm is done by re-defining \( \hat{u}(s,\omega) \) to equal \( u_{S_\infty}(s,\omega) \) for \( s < s \) and \( \hat{u}(s,\omega) \) at \( s \). As to \( s > s \) also re define \( \hat{u}(s,\omega) \equiv u_{S_\infty}(s,\omega) \) for such \( s \). By uniqueness, the two are equal in \( V_{[s,T]} \) and so no change occurs in the solution of the integral equation. Now \( S_\infty \) was not maximal after all. \( S_\infty \cup \{s\} \) is larger. This contradiction shows that in fact, \( S_\infty = (0,1] \). ■

**Theorem 75.7.4** Assume the above conditions, 75.5.24, 75.5.29, 75.5.30, and the Condition 75.7.2. Let \( u_0 \) be \( F_0 \) measurable and \( \omega \rightarrow B(\omega) \) also \( F_0 \) measurable and \( (t,\omega) \rightarrow X_{[0,1]}(t) f(t,\omega) \) is \( B([0,1]) \times F_t \) product measurable into \( V' \) for each \( t \).

\[
B(\omega) = k(\omega) B, \ k(\omega) \geq 0, k \text{ measurable}.
\]

Also let \( t \rightarrow q(t,\omega) \) be continuous and \( q \) is progressively measurable into \( V \). Suppose there is at most one solution to

\[
Bu(t,\omega) + \int_0^t z(s,\omega) \, ds = \int_0^t f(s,\omega) \, ds + Bu_0(\omega) + Bq(t,\omega), \quad (75.7.66)
\]

for each \( \omega \). Then the solution \( u \) to the above integral equation is progressively measurable and so is \( z \). Moreover, for each \( \omega \), both \( Bu(t,\omega) = B(u(t,\omega)) \) a.e. \( t \)
and \( z(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \). Also, for each \( a \in [0, T] \),

\[
Bu(t, \omega) + \int_a^t z(s, \omega) \, ds = \int_a^t f(s, \omega) \, ds + Bu(a, \omega) + Bq(t, \omega) - Bq(a, \omega)
\]

**Proof:** By Theorem 75.5.7 there exists a solution to 75.7.66 which is \( \mathcal{B}([0, T]) \times \mathcal{F}_T \)-measurable. Now, as in the proof of Theorem 75.5.7 one can define a new operator

\[
A_r(w, \omega) \equiv A(\omega, w + q^r(\cdot, \omega))
\]

where \( r \) is the stopping time defined there. Then, since \( q \) is progressively measurable, the progressively measurable condition is satisfied for this new operator. Hence by Theorem 75.7.3 there exists a unique solution \( w_r \) which is progressively measurable to the integral equation

\[
Bu_r(t, \omega) + \int_0^t z_r(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega)
\]

where \( z_r(\cdot, \omega) \in A_r(w(\cdot, \omega), \omega) \). Then as in Theorem 75.7.3 you can let \( r \to \infty \) and eventually \( q^{r^\tau}(\cdot, \omega) = q(\cdot, \omega) \). Then, passing to a limit, it follows that for a given \( \omega \), there is a solution to

\[
Bu(t, \omega) + \int_0^t z(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega)
\]

where \( z(\cdot, \omega) \in A(w(\cdot, \omega), \omega) \). Then as in Theorem 75.7.3 you can let \( r \to \infty \) and eventually \( q^r(\cdot, \omega) = q(\cdot, \omega) \). Then, passing to a limit, it follows that for a given \( \omega \), there is a solution to

\[
Bu(t, \omega) + \int_0^t z(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega)
\]

which is progressively measurable because \( w(\cdot, \omega) = \lim_{r \to \infty} w_r(\cdot, \omega) \) in \( \mathcal{V} \) each \( w_r \) being progressively measurable. Note how uniqueness for fixed \( \omega \) is important in this argument. Recall that

\[
\tau_\omega \equiv \inf \{ t : |q(t, \omega)| > r \}
\]

By continuity, eventually, for a given \( \omega, \tau_\omega = \infty \) and so no further change takes place in \( q^{r^\tau}(\cdot, \omega) \) for that \( \omega \). By uniqueness, the same is true of the solution \( w_r(\cdot, \omega) \) and so pointwise convergence takes place for the \( w_r \). Without uniqueness holding, this becomes very unclear. Thus for each \( T < T, \omega \to w(\cdot, \omega) \) is measurable into \( \mathcal{V}_{[0, T]} \).

Then by Lemma 75.4.2, \( w \) has a representative in \( \mathcal{V} \) for each \( \omega \) such that the resulting function satisfies \( (t, \omega) \to X_{[0, T]}(t) \, w(t, \omega) \) is \( \mathcal{B}([0, T]) \times \mathcal{F}_T \)-measurable into \( \mathcal{V} \). Thus one can assume that \( w \) is progressively measurable. Now as in Theorem 75.5.7. Define \( u = w + q \).

The last claim follows from letting \( t = a \) in the top equation and then subtracting this from the top equation with \( t > a \).

### 75.8 Adding A Quasi-bounded Operator

Recall the following conditions for the various operators.
CHAPTER 75. STOCHASTIC INCLUSIONS

Bounded and coercive conditions

\( A (\cdot, \omega) : \mathcal{V}_I \rightarrow \mathcal{V}'_I \) for each \( I \) a subinterval of \([0, T] \) \( I = [0, \hat{T}] \), \( \hat{T} \leq T \)

\[ A (\cdot, \omega) : \mathcal{V}_I \rightarrow \mathcal{P}(\mathcal{V}'_I) \] is bounded, \( (75.8.67) \)

If, for \( u \in \mathcal{V} \),

\[ u^* x_{[0,\hat{T}]} \in A \left( u x_{[0,\hat{T}]}, \omega \right) \]

for each \( \hat{T} \) in an increasing sequence converging to \( T \), then

\[ u^* \in A (u, \omega) \] \( (75.8.68) \)

Assume the specific estimate

\[ \sup \left\{ \| u^* \|_{\mathcal{V}'_I} : u^* \in A (u, \omega) \right\} \leq a (\omega) + b (\omega) \| u \|_{\mathcal{V}_I}^{p-1} \] \( (75.8.69) \)

where \( a (\omega) \), \( b (\omega) \) are nonnegative. Also assume the following coercivity estimate valid for each \( t \leq T \) and for some \( \lambda (\omega) \geq 0 \),

\[ \inf \left( \int_0^t \langle u^*, u \rangle + \lambda (\omega) \langle Bu, u \rangle \, dt : u^* \in A (u, \omega) \right) \geq \delta (\omega) \int_0^t \| u \|_{\mathcal{V}_I}^p \, ds - m (\omega) \] \( (75.8.70) \)

where \( m (\omega) \) is some nonnegative constant, \( \delta (\omega) > 0 \).

Limit condition

Let \( U \) be a Banach space dense in \( \mathcal{V} \) and that if \( u_i \rightharpoonup u \) in \( \mathcal{V}_I \) and \( u^*_i \in A (u_i) \) with \( u^*_i \rightharpoonup u^* \) in \( \mathcal{V}'_I \) and \( (Bu_i)' \rightharpoonup (Bu)' \) in \( \mathcal{U}'_I \), \( \rightharpoonup \) denoting weak convergence, then if

\[ \lim \sup_{i \to \infty} \langle u^*_i, u_i - u \rangle_{\mathcal{V}'_I, \mathcal{V}_I} \leq 0 \]

it follows that for all \( v \in \mathcal{V}_I \), there exists \( u^*(v) \in Au \) such that

\[ \lim_{i \to \infty} \inf \langle u^*_i, u_i - v \rangle_{\mathcal{V}'_I, \mathcal{V}_I} \geq \langle u^* (v), u - v \rangle_{\mathcal{V}'_I, \mathcal{V}_I} \] \( (75.8.71) \)

where \( r > \max (p, 2) \), and we replace \( p \) with \( r \) and \( I \) an arbitrary subinterval of the form \([0, \hat{T}] \), \( \hat{T} < T \), for \([0, T] \), and \( U \) for \( V \) where indicated. Here

\[ \mathcal{U}_I \equiv L^r (I; U) \]

Typically, \( U \) is compactly embedded in \( \mathcal{V} \).

Measurability condition
For \( \omega \rightarrow u(\cdot, \omega) \) measurable into \( \mathcal{V} \),

\[
\omega \rightarrow A(u(\cdot, \omega), \omega) \text{ has a measurable selection into } \mathcal{V}'.
\]  

(75.8.72)

This last condition means there is a function \( \omega \rightarrow u^*(\omega) \) which is measurable into \( \mathcal{V}' \) such that \( u^*(\omega) \in A(u(\cdot, \omega), \omega) \).

As for the operator \( B \) it is either independent of \( \omega \) and is a nonnegative self adjoint operator mapping \( \mathcal{W} \) to \( \mathcal{W}' \) or else it is of the form \( k(\omega)B \) where \( k \geq 0 \) and is measurable.

We will assume here that \( p > 1 \). Then the following main result was obtained above. It is Theorem [75.5.7].

**Theorem 75.8.1** If [75.8.01 - 75.8.72] and \( B \) as described above, let \( q(t, \omega) \) be a product measurable function into \( \mathcal{V} \) such that \( t \rightarrow q(t, \omega) \) is continuous, \( q(0, \omega) = 0 \).

Then, there exists a solution \( u \) of the integral equation

\[
Bu(t, \omega) + \int_0^t z(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) + Bq(t, \omega),
\]

where \( (t, \omega) \rightarrow u(t, \omega) \) is measurable. Moreover, for each \( \omega \), \( Bu(t, \omega) = B(u(t, \omega)) \) for a.e. \( t \) and \( z(\cdot, \omega) \in A(\omega, u(\cdot, \omega)) \) for a.e. \( t \). Also, for each \( a \in [0, T] \),

\[
Bu(t, \omega) + \int_a^t z(s, \omega) \, ds = \int_a^t f(s, \omega) \, ds + Bu(a, \omega) + Bq(t, \omega) - Bq(a, \omega)
\]

The idea here is to show that everything works as well if a suitable unbounded maximal monotone operator is added in. The result is interesting but not as interesting as it might be. This is because the maximal monotone operator must be quasi bounded. Still it is interesting to note that the above holds for some unbounded operators. This has been pointed out in the case where there are no stochastic effects in a recent paper [51]. This generalizes this result by considering the measurability of solutions and allowing for possibly degenerate leading operator \( B \).

To begin with assume \( q = 0 \).

Now let \( G : D(G) \subseteq \mathcal{V} \rightarrow \mathcal{P}(\mathcal{V}') \) be maximal monotone. Also assume that \( 0 \in D(G) \). Then you have

\[
\langle u^*, u \rangle \geq \langle g^*, u \rangle \text{ if } u^* \in Gu
\]

for every \( g^* \in G(0) \). Hence

\[
\langle u^*, u \rangle \geq -|G(0)| \|u\|_{\mathcal{V}'} \text{ if } u^* \in Gu
\]

(75.8.73)

where \( |G(0)| \equiv \inf \{ \|y^*\|_{\mathcal{V}'} : y^* \in G(0) \} \).

There is a standard way of approximating \( G \) with bounded demicontinuous operators which is reviewed next. It is all in Barbu [12]. See Section 46.7.3. Since \( G \) is maximal monotone,

\[
0 \in F(x_\mu - x) + \mu^{p-1}G(x_\mu)
\]
CHAPTER 75. STOCHASTIC INCLUSIONS

where \( F \) is a duality map for \( p \), the one used in the above theorem. Barbu uses only \( p = 2 \) but it works just as well for arbitrary \( p > 1 \) with the minor modifications used here. To see this, you consider \( \hat{G}(y) \equiv G(x + y) \). Then \( \hat{G} \) is also maximal monotone and so there exists a solution to

\[
0 \in F(\hat{x}) + \mu^{p-1}\hat{G}(\hat{x}) = F(\hat{x}) + \mu^{p-1}G(x + \hat{x})
\]

Now let \( x_\mu = x + \hat{x} \) so \( \hat{x} = x_\mu - x \). Hence

\[
0 \in F(x_\mu - x) + \mu^{p-1}Gx_\mu
\]

The symbol \( \limsup_{n,n \to \infty} a_{mn} \) means \( \lim_{N \to \infty} (\sup_{m \geq N, n \geq N} a_{mn}) \).

**Lemma 75.8.2** Suppose \( \limsup_{n,n \to \infty} a_{mn} \leq 0 \). Then \( \limsup_{m \to \infty} (\limsup_{n \to \infty} a_{mn}) \leq 0 \).

**Proof:** Suppose the first inequality. Then for \( \varepsilon > 0 \), there exists \( N \) such that if \( n, m \) are both as large as \( N \), then \( a_{mn} \leq \varepsilon \). Thus \( \sup_{n \geq N} a_{mn} \leq \varepsilon \) provided \( m \geq N \) also. Hence for such \( m \),

\[
\lim_{n \to \infty} \left( \sup_{n \geq N} a_{mn} \right) \leq \varepsilon
\]

for each \( m \geq N \). It follows \( \limsup_{m \to \infty} (\limsup_{n \to \infty} a_{mn}) \leq \varepsilon \). Since \( \varepsilon \) is arbitrary, this proves the lemma. \( \blacksquare \)

Then here is a simple observation.

**Lemma 75.8.3** Let \( G : D(G) \subseteq X \to \mathcal{P}(X') \) where \( X \) is a Banach space be maximal monotone and let \( v_n \in Gu_n \) and

\[
u_n \to u, \ v_n \to v \text{ weakly.}
\]

Also suppose that

\[
\lim sup_{m,n \to \infty} (v_n - v_m, u_n - u_m) \leq 0
\]

or

\[
\lim sup_{n \to \infty} (v_n - v, u_n - u) \leq 0
\]

Then \( [u,v] \in G(G) \) and \( \langle v_n, u_n \rangle \to \langle v, u \rangle \).

**Proof:** By monotonicity,

\[
0 \geq \lim sup_{m,n \to \infty} (v_n - v_m, u_n - u_m)
\]

and so

\[
\lim_{m,n \to \infty} (v_n - v_m, u_n - u_m) = 0
\]
Suppose then that \( \langle v_n, u_n \rangle \) fails to converge to \( \langle v, u \rangle \). Then there is a subsequence, still denoted with subscript \( n \) such that \( \langle v_n, u_n \rangle \to \mu \neq \langle v, u \rangle \). Let \( \epsilon > 0 \). Then there exists \( M \) such that if \( n, m > M \), then
\[
|\langle v_n, u_n \rangle - \mu| < \epsilon, |\langle v_n - v_m, u_n - u_m \rangle| < \epsilon
\]
Then if \( m, n > M \),
\[
|\langle v_n - v_m, u_n - u_m \rangle| = |\langle v_n, u_n \rangle + \langle v_m, u_m \rangle - \langle v_n, u_m \rangle - \langle v_m, u_n \rangle| < \epsilon
\]
Hence it is also true that
\[
|\langle v_n, u_n \rangle + \langle v_m, u_m \rangle - \langle v_n, u_m \rangle - \langle v_m, u_n \rangle| = |2\mu - (\langle v_n, u_m \rangle + \langle v_m, u_n \rangle)| < 3\epsilon
\]
Now take a limit first with respect to \( n \) and then with respect to \( m \) to obtain
\[
|2\mu - (\langle v, u \rangle + \langle v, u \rangle)| < 3\epsilon
\]
Since \( \epsilon \) is arbitrary, \( \mu = \langle v, u \rangle \) after all. Hence the claim that \( \langle v_n, u_m \rangle \to \langle v, u \rangle \) is verified. Next suppose \( [x, y] \in \mathcal{G}(G) \) and consider
\[
\langle v - y, u - x \rangle = \langle v, u \rangle - \langle v, x \rangle - \langle y, u \rangle + \langle y, x \rangle
\]
\[
= \lim_{n \to \infty} (\langle v_n, u_n \rangle - \langle v_n, x \rangle - \langle y, u_n \rangle + \langle y, x \rangle)
\]
\[
= \lim_{n \to \infty} \langle v_n - y, u_n - x \rangle \geq 0
\]
and since \( [x, y] \) is arbitrary, it follows that \( v \in Gu \).

Next suppose \( \limsup_{n \to \infty} \langle v_n - v, u_n - u \rangle \leq 0 \). It is not known that \( [u, v] \in \mathcal{G}(G) \).
\[
\limsup_{n \to \infty} \langle v_n - v, u_n - u \rangle \leq 0
\]
the second coming from monotonicity and the fact that \( v \in Gu \). Therefore,
\[
\lim_{n \to \infty} \langle v_n - v, u_n - u \rangle = 0
\]
which shows that \( \lim_{n \to \infty} \langle v_n, u_n \rangle = \langle v, u \rangle \). ■

Similar reasoning implies
Lemma 75.8.4 Suppose $A$ is a set valued operator, $A : X \rightarrow \mathcal{P}(X)$ and $u_n^* \in Au_n$. Suppose also that $u_n \rightharpoonup u$ weakly and $u_n^* \rightharpoonup u^*$ weakly. Suppose also that

$$\lim \sup_{m,n \rightarrow \infty} \langle u_n^* - u_m^*, u_n - u_m \rangle \leq 0$$

Then one can conclude that

$$\lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n - u \rangle \leq 0$$

Proof: It is assumed that

$$\lim \sup_{m,n \rightarrow \infty} (\langle u_n^*, u_n \rangle + \langle u_m^*, u_m \rangle - (\langle u_n^*, u_n \rangle + \langle u_m^*, u_m \rangle)) \leq 0$$

Then is it the case that $\lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n \rangle \leq \langle u^*, u \rangle$? Let $\mu = \lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n \rangle$. Then in the above, it implies

$$(2\mu - (\langle u_n^*, u_n \rangle + \langle u_n^*, u_n \rangle)) < \varepsilon$$

whenever $m,n$ large enough. Thus taking $\lim \sup_{n \rightarrow \infty} \lim \sup_{m \rightarrow \infty}$ of the above, you get

$$(2\mu - (\langle u^*, u \rangle + \langle u^*, u \rangle)) < \varepsilon$$

Thus you at least need $\mu \leq \langle u^*, u \rangle$. That is, $\lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n \rangle \leq \langle u^*, u \rangle$. Hence

$$\lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n - u \rangle = \lim \sup_{n \rightarrow \infty} \langle u_n^*, u_n \rangle - \langle u^*, u \rangle \leq \langle u^*, u \rangle - \langle u^*, u \rangle = 0$$

Definition 75.8.5 Let $x_\mu$ just defined be denoted by $J_\mu x$ and define also

$$G_\mu (x) = -\mu^{-(p-1)} F (x_\mu - x).$$

This $x_\mu$ is defined as follows.

$$0 \in F (x_\mu - x) + \mu^{p-1} Gx_\mu$$

Later, we will write $J_\mu u$ for $u_\mu$. Thus

$$0 = F (J_\mu u - u) + \mu^{p-1} z_\mu, \quad z_\mu \in G (J_\mu u)$$

Also from this definition,

$$G_\mu (u) = -\mu^{-(p-1)} F (J_\mu u - u) = z_\mu \in G (J_\mu u)$$

Then there are some things which can be said about these operators.

Theorem 75.8.6 The following hold. Here $V$ is a reflexive Banach space with strictly convex norm. $G : D(G) \rightarrow \mathcal{P}(V')$ is maximal monotone. Then

1. $J_\mu$ and $G_\mu$ are bounded single valued operators defined on $V$. Bounded means they take bounded sets to bounded sets. Also $G_\mu$ is a monotone operator.
2. \(G_\mu, J_\mu\) are demicontinuous. That is, strongly convergent sequences are mapped to weakly convergent sequences.

3. For every \(x \in D(G)\), \(|| G_\mu (x) || \leq |Gx| \equiv \inf \{ \| y^* \| : y^* \in Gx \}\). For every \(x \in \text{conv}(D(G))\), it follows that \(\lim_{\mu \to 0} J_\mu (x) = x\). The new symbol means the closure of the convex hull. It is the closure of the set of all convex combinations of points of \(D(G)\).

Then \(A (\cdot , \omega) + G_\mu\) will be bounded and have the same limit properties as \(A (\cdot , \omega)\). As to measurability, \(G\) and hence \(G_\mu\) do not depend on \(\omega\) and so the measurability condition will hold.

What about the estimates? We need to consider the estimates. Recall what these were:

\[
\sup \left\{ \| u^* \|_{V'} : u^* \in A(u, \omega) \right\} \leq a(\omega) + b(\omega) \||u||_V^{p-1} \tag{75.8.74}
\]

where \(a(\omega), b(\omega)\) are nonnegative. Also assume the following coercivity estimate valid for each \(t \leq T\) and for some \(\lambda(\omega) \geq 0\),

\[
\inf \left( \int_0^t \langle u^* , u \rangle + \lambda(\omega) \langle Bu, u \rangle \, dt : u^* \in A(u, \omega) \right) \geq \delta(\omega) \int_0^t \| u \|_V^p \, ds - m(\omega) \tag{75.8.75}
\]

where \(m(\omega)\) is some nonnegative constant, \(\delta(\omega) > 0\).

The coercivity is not too bad. This is because \(G_\mu\) is monotone and \(0 \in D(G)\). Therefore,

\[
\langle G_\mu u, u \rangle = \langle G_\mu u - G_\mu (0), u \rangle \geq 0
\]

so

\[
\langle G_\mu u, u \rangle \geq -|G(0)| \| u \| \geq \frac{\delta(\omega)}{2} \| u \|_V^p - m(\omega)
\]

so the coercivity condition will end up holding for \(A + G_\mu\). However, more needs to be considered for the growth condition.

From the definition of \(u_\mu\), there exists \(z_\mu \in GU_\mu\)

\[
0 = F(u_\mu - u) + \mu^{p-1}z_\mu
\]

Then from the choice of \(F\), it is also the duality map from \(V\) to \(V'\) corresponding to \(p > 2\).
Thus
\[ 0 \geq \|u\| - \|u\|^{p} - p\mu \|G(0)\| \|u\| \]
This requires that there is some constant \(C\) such that \(\|u\| \leq C\|u\| + C\). The details follow.

Let \(a = \|u\|, b = \|u\|\). Then they are both positive and
\[ 0 \geq |a - b|^{p} - b^{p} - \alpha a \]
where \(\alpha = p\mu \|G(0)\|\). Want to say \(a \leq Cb + C\) for some \(C\). This is the conclusion of the following lemma.

**Lemma 75.8.7** Suppose \(0 \geq |a - b|^{p} - b^{p} - \alpha a\) for \(a, b \geq 0\) and \(\alpha > 0\). Then there exists a constant \(C\) such that
\[ a \leq Cb + C \]

**Proof:** If \(b \geq a\), then there is nothing to show. Therefore, it suffices to show that the desired inequality holds for \(a > b\). Thus from now on, \(a > b\).

\[ 0 \geq (a - b)^{p} - b^{p} - \alpha a \]

Suppose \(a > nb + n\). Let \(x = b/a\). Then for \(x \in [0, 1]\),
\[
0 \geq (1 - x)^{p} - x^{p} - \alpha \frac{1}{ap^{1}} \\
\geq (1 - x)^{p} - x^{p} - \alpha \frac{1}{nb + n}^{p-1} \\
\geq (1 - x)^{p} - x^{p} - \alpha \frac{1}{n}^{p-1}
\]

Now for all \(n\) large enough, the right side is a decreasing function of \(x\) which is positive at \(x = 0\) and negative at \(x = 1\). Thus \(x\) corresponds to the place where this function is negative. Taking a limit as \(n \to \infty\), it follows that we must have
\[ x \geq \delta, \delta \in (0, 1) \]

It is where \((1 - x)^{p} - x^{p} = 0\). Thus \(x = \frac{a}{b} \geq \delta\). Then, since \(a > nb + n\),
\[ \frac{1}{\delta} b \geq a > nb + n \]

Now this is a contradiction when \(n\) is taken increasingly large. Hence, for large enough \(n, a \leq nb + n\). 

It follows that \(\|u\| \leq C\|u\| + C\) for some \(C\). Hence,
\[
\|G_{u}u\| \leq \frac{1}{\mu^{p-1}} \|u\| - \|u\|^{p} \leq \frac{1}{\mu^{p-1}} (\|u\|^{p-1} + \|u\|)^{p-1} \\
\leq \frac{2^{p-2}}{\mu^{p-1}} (\|u\|^{p-1} + \|u\|^{p-1})
\]
implies that by acting on that estimates valid for \( u \) is, both so it is clear that there is an inequality of the form

\[
\frac{1}{\mu^{p-1}} (\|u\|^{p} + \|u\|) \leq \frac{1}{\mu^{p-1}} \left( C_{\mu} \|u\|^{p} + C_{\mu} \right)
\]

This is the case that \( p \geq 2 \). The case that \( p > 1 \) but \( p < 2 \) is easier. In this case,

\[
\frac{1}{\mu^{p-1}} (\|u\|^{p} + \|u\|) \leq \frac{1}{\mu^{p-1}} \left( C_{\mu} \|u\|^{p} + C_{\mu} \right)
\]

A similar inequality holds. Thus the necessary growth condition is obtained for \( G_{\mu} \) and consequently, the necessary growth condition remains valid for \( G_{\mu} + A \). It was noted earlier that the coercivity estimate continues to hold.

It follows that there exists a solution to the integral equation

\[
Bu(t, \omega) + \int_{0}^{t} z(s, \omega) \, ds + \int_{0}^{t} G_{\mu}(u(s, \omega)) \, ds = \int_{0}^{t} f(s, \omega) \, ds + Bu_{0}(\omega)
\]

where \( z(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \) which has the measurability described above. That is, both \( u \) and \( z \) are product measurable. Then acting on \( u_{\lambda}[0,t] \) and using the estimates valid for \( \lambda \) large enough, one can get an estimate of the form

\[
\frac{1}{2} \langle Bu, u \rangle(t) - \frac{1}{2} \langle Bu_{0}, u_{0} \rangle + \int_{0}^{t} \|u(s)\|_{V}^{p} \, ds + \int_{0}^{t} \langle G_{\mu}u, u \rangle \, ds \leq \lambda \int_{0}^{t} \langle Bu, u \rangle \, ds + C(f)
\]

(75.8.76)

Now \( G_{\mu} \) is monotone and so,

\[
\langle G_{\mu}u, u \rangle = \langle G_{\mu}u - G_{\mu}0, u \rangle + \langle G_{\mu}(0), u \rangle \geq \langle G_{\mu}(0), u \rangle \geq -\|G(0)\| \|u\|
\]

It follows easily from standard manipulations and (75.8.77) that \( \|u\|_{V} \) is bounded independent of \( \mu \). That is, there is a constant \( C \) independent of \( \mu \) such that

\[
\|u\|_{V} \leq C
\]

(75.8.77)

The details follow. The above inequality \( 75.8.77 \) implies that by acting on \( u_{\lambda}[0,t] \),

\[
\frac{1}{2} \langle Bu, u \rangle(t) - \frac{1}{2} \langle Bu_{0}, u_{0} \rangle + \int_{0}^{t} \|u(s)\|_{V}^{p} \, ds - \int_{0}^{t} |G(0)| \|u\|_{V} \, ds \leq \lambda \int_{0}^{t} \langle Bu, u \rangle \, ds + C(f)
\]

Then by Gronwall’s inequality and adjusting constants,

\[
\langle Bu, u \rangle(t) + \int_{0}^{t} \|u(s)\|_{V}^{p} \, ds \leq C(\mu_{0}, f, \lambda) + C(\lambda) \int_{0}^{t} |G(0)| \|u\|_{V} \, ds
\]

(75.8.78)

so it is clear that there is an inequality of the form

\[
\sup_{t \in [0,T]} \langle Bu, u \rangle(t) + \int_{0}^{T} \|u(s)\|_{V}^{p} \, ds \leq C(\mu_{0}, f, \lambda)
\]
Then returning to (75.8.76), all terms are bounded except \( \int_0^T \langle G_\mu u, u \rangle \, dt \), so this term must also be bounded for \( t = T \) also. Thus
\[
\left| \int_0^T \langle G_\mu u, u \rangle \, dt \right| \leq C
\]
where \( C \) is independent of \( \mu \). We denote by \( u_\mu \) the solution to the above equation.

Here is the definition of quasi-bounded.

**Definition 75.8.8** A set valued operator \( G \) is quasi-bounded if whenever \( x \in D(G) \) and \( x^* \in Gx \) are such that
\[
|x^*, x|, \|x\| \leq M,
\]
it follows that \( \|x^*\| \leq K_M \). Bounded would mean that if \( \|x\| \leq M \), then \( \|x^*\| \leq K_M \). Here you only know this if there is another condition.

**Assumption 75.8.9** \( G : D(G) \to \mathcal{P}(V') \) is quasi-bounded and maximal monotone.

By Proposition 23.7.23, an example of a quasi-bounded operator is a maximal monotone operator \( G \) for which \( 0 \notin \text{int}(D(G)) \).

Now \( G_\mu u_\mu \in GJ_\mu u_\mu \) as noted above. Therefore, there exists \( g_\mu \in G(J_\mu u_\mu) \) such that
\[
C \geq \langle G_\mu u_\mu, u_\mu \rangle_{V', V} = \langle g_\mu, u_\mu \rangle_{V', V} = \langle g_\mu, J_\mu u_\mu \rangle_{V', V} + \langle g_\mu, u_\mu - J_\mu u_\mu \rangle_{V', V} \quad (75.8.79)
\]
\[
\geq -|G(0)| \|J_\mu u_\mu\|_V + \left\langle -\frac{1}{\mu^{p-1}} F(J_\mu u_\mu - u_\mu), u_\mu - J_\mu u_\mu \right\rangle_{V', V}
\]
\[
= -|G(0)| \|J_\mu u_\mu\|_V + \frac{1}{\mu^{p-1}} \|J_\mu u_\mu - u_\mu\|_V^p \quad (75.8.80)
\]
Thus the fact that \( \|u_\mu\| \) is bounded independent of \( \mu \) implies that \( \|J_\mu u_\mu\| \) is also bounded and that in fact \( \|u_\mu - J_\mu u_\mu\|_V \to 0 \) as \( \mu \to 0 \). This follows from consideration of the last line of the above formula. Note also that
\[
\langle g_\mu, u_\mu - J_\mu u_\mu \rangle_{V', V} = \frac{1}{\mu^{p-1}} \|J_\mu u_\mu - u_\mu\|_V^p \text{ is bounded.} \quad (75.8.81)
\]
Then from (75.8.76), it follows that \( \langle g_\mu, J_\mu u_\mu \rangle_{V', V} \) is bounded. By the assumption that \( G \) is quasi-bounded, \( g_\mu \) must also be bounded.

Then we have shown
\[
Bu_\mu(t, \omega) + \int_0^t z_\mu(s, \omega) \, ds + \int_0^t g_\mu(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) \quad (75.8.82)
\]
where
\[
\|g_\mu\|_{V'} + \|z_\mu\|_{V'} + \sup_{t \in [0, T]} \langle Bu_\mu, u_\mu \rangle(t) + \|J_\mu u_\mu\|_V + \|u_\mu\|_V + \|(B_\mu')\|_{V'} \leq C \quad (75.8.83)
\]
75.8. ADDING A QUASI-BOUNDED OPERATOR

The last term in the sum being bounded follows from the integral equation and the fundamental theorem of calculus along with the boundedness \( f, g, z \). In addition to this, the estimate \( 75.8.80 \) implies

\[
\lim_{\mu \to 0} \| J_\mu u - u \|_V = 0. \tag{75.8.84}
\]

There is a subsequence, \( \mu \to 0 \) still denoted as \( \mu \) such that

\[
g_\mu \to g \text{ weakly in } V'
\]

\[
z_\mu \to z \text{ weakly in } V'
\]

\[
u_\mu \to u \text{ weakly in } V
\]

\[
J_\mu u_\mu \to u \text{ weakly in } V
\]

\[
(Bu_\mu)' \to (Bu)' \text{ weakly in } V'
\]

\[
Bu_\mu(t) \to Bu(t) \text{ weakly in } V'
\]

Now consider two of these for \( \mu \) and \( \nu \). Subtract and act on \( u_\mu - u_\nu \). Then one obtains

\[
\langle Bu_\mu - Bu_\nu, u_\mu - u_\nu \rangle(t) + \int_0^t \langle z_\mu - z_\nu, u_\mu - u_\nu \rangle + \int_0^t \langle g_\mu - g_\nu, u_\mu - u_\nu \rangle = 0
\]

Consider that last term for \( t = T \). It equals

\[
\int_0^T \langle G_\mu u_\mu - G_\nu u_\nu, u_\mu - u_\nu \rangle = \int_0^T \langle G_\mu u_\mu - G_\nu u_\nu, J_\mu u_\mu - J_\nu u_\nu \rangle
\]

\[
+ \int_0^T \langle g_\mu - g_\nu, u_\mu - J_\mu u_\mu - (u_\nu - J_\nu u_\nu) \rangle
\]

\[
= \int_0^T \langle g_\mu - g_\nu, J_\mu u_\mu - J_\nu u_\nu \rangle + \varepsilon(\mu, \nu)
\]

where

\[
|\varepsilon(\mu, \nu)| \leq \left( \int_0^T (\|g_\mu\| + \|g_\nu\|)^p \right)^{1/p} \left( \int_0^T (\|u_\mu - J_\mu u_\mu\| + \|u_\nu - J_\nu u_\nu\|)^p \right)^{1/p}
\]

\[
\leq 2C (\|u_\mu - J_\mu u_\mu\|_V + \|u_\nu - J_\nu u_\nu\|_V)
\]

Adjusting constants and using \( 75.8.81 \)

\[
\leq C \left( \mu^{1-1/p} + \nu^{1-1/p} \right)
\]
Thus
\[
\int_0^T \langle G_\mu u_\mu - G_\nu u_\nu, u_\mu - u_\nu \rangle = \int_0^T \langle g_\mu - g_\nu, J_\mu u_\mu - J_\nu u_\nu \rangle + \varepsilon(\mu, \nu)
\]
where \(\lim_{\mu, \nu \to 0} \varepsilon(\mu, \nu) = 0\). It follows from (75.8.91)
\[
\limsup_{\mu, \nu \to 0} \left( \int_0^T \langle z_\mu - z_\nu, u_\mu - u_\nu \rangle \, ds + \varepsilon(\mu, \nu) \right) \leq 0
\]
From Lemma (75.8.3),
\[
\limsup_{\mu \to 0} \langle z_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} \leq 0
\]
By the limit condition for \(A(\cdot, \omega)\), for each \(v \in \mathcal{V}\), there exists \(z(v) \in Au\) such that
\[
\liminf_{\mu \to 0} \langle z_\mu, u_\mu - v \rangle = \liminf_{\mu \to 0} (\langle z_\mu, u_\mu - u \rangle + \langle z_\mu, u - v \rangle) = \langle z, u - v \rangle \geq \langle z(v), u - v \rangle
\]
Since \(A(u, \omega)\) is convex and closed, separation theorems imply that \(z \in Au\). Return to the equation solved.
\[
(Bu_\mu)' + z_\mu + g_\mu = f
\]
Then act on \(u_\mu - u\) and use monotonicity arguments to write
\[
\langle (Bu)'_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} + \langle z_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} + \langle g_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} \leq \langle f, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}}
\]
Then it was shown above that
\[
0 \geq \limsup_{\mu \to 0} \langle z_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} \geq \liminf_{\mu \to 0} \langle z_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} \geq \langle z(u), u - u \rangle_{\mathcal{V}', \mathcal{V}} = 0
\]
and so, from (75.8.92)
\[
\lim_{\mu \to 0} \langle g_\mu, u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} = \lim_{\mu \to 0} \langle g_\mu, J_\mu u_\mu - u \rangle_{\mathcal{V}', \mathcal{V}} = 0
\]
and so
\[
\lim_{\mu \to 0} \langle g_\mu, J_\mu u_\mu \rangle_{\mathcal{V}', \mathcal{V}} = \langle g, u \rangle_{\mathcal{V}', \mathcal{V}}
\]
Now let \([a, b] \in \mathcal{G}(G)\). Then
\[
\langle b - g, a - u \rangle = \lim_{\mu \to 0} \langle b - g_\mu, a - J_\mu u_\mu \rangle \geq 0
\]
because \(g_\mu \in G(J_\mu u_\mu)\). Since \(G\) is maximal monotone, it follows that \([u, g] \in \mathcal{G}(G)\).
This has shown that for each \(\omega\) fixed, and every sequence of solutions to the integral equation \(\{u_\mu\}\), each function \(\{Bu_\mu\}\) being product measurable by Theorem
there exists a subsequence which converges to a solution \( u \) to the integral equation. In particular, \( t \rightarrow Bu(t) \) is weakly continuous into \( V' \). Then by the fundamental measurable selection theorem, Theorem 75.8.10, there exists a product measurable function \( \bar{u}(t, \omega) \) with values in \( V \) weakly continuous in \( t \) and a sequence depending on \( \omega \), \( \{ u_{\mu(\omega)} \} \) such that for each \( \omega \), \( \lim_{\mu(\omega) \rightarrow 0} u_{\mu(\omega)}(\cdot, \omega) = \bar{u}(\cdot, \omega) \) weakly in \( V \). However, from the above argument, for each \( \omega \), there is a further subsequence, still denoted with subscript \( \mu(\omega) \) such that in \( V' \),

\[
\lim_{\mu(\omega) \rightarrow 0} u_{\mu(\omega)}(\cdot, \omega) = u(\cdot, \omega)
\]

where \( u \) is a solution to the integral equation. Since \( u(\cdot, \omega) = \bar{u}(\cdot, \omega) \) in \( V \) it follows that these must be equal a.e. and hence \( (t, \omega) \rightarrow u(t, \omega) \) is product measurable. This proves the following theorem.

**Theorem 75.8.10** Suppose 75.8.10 - 75.8.12 and \( B \) as described above and \( u_0 \) is \( F \) measurable. Also let \( G : D(G) \subseteq V \rightarrow P(V') \) be maximal monotone and quasi-bounded.

Then, there exists a solution \( u \) of the integral equation

\[
Bu(t, \omega) + \int_0^t z(s, \omega) \, ds + \int_0^t g(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega),
\]

where \( (t, \omega) \rightarrow u(t, \omega) \) is product measurable \( (t, \omega) \rightarrow z(t, \omega) \) also. Moreover, for each \( \omega \), \( Bu(t, \omega) = B(u(t, \omega)) \) a.e. \( t \) and \( z(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \), and \( g(\cdot, \omega) \in G(u(\cdot, \omega)) \) for each \( \omega \).

Note that in the case of most interest where you have a Gelfand triple and \( B \) is the identity, the fundamental theorem of calculus implies easily that \( \omega \rightarrow z(s, \omega) + g(s, \omega) \) is measurable for a.e. \( s \). One can also generalize to the following in which a measurable \( q(t, \omega) \) is added.

**Corollary 75.8.11** Suppose 75.8.11 - 75.8.12 and \( B \) as described above and \( u_0 \) is \( F \) measurable. Also let \( G : D(G) \subseteq V \rightarrow P(V') \) be maximal monotone and quasi-bounded. Let \( (t, \omega) \rightarrow q(t, \omega) \) be product measurable into \( V \) and let \( t \rightarrow q(t, \omega) \) be continuous, \( q(0, \omega) = 0 \). Then, there exists a solution \( u \) of the integral equation

\[
Bu(t, \omega) + \int_0^t z(s, \omega) \, ds + \int_0^t g(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) + Bq(t, \omega),
\]

where \( (t, \omega) \rightarrow u(t, \omega), (t, \omega) \rightarrow z(t, \omega), g(t, \omega) \) are product measurable. Moreover, for each \( \omega \), \( Bu(t, \omega) = B(u(t, \omega)) \) a.e. \( t \) and \( z(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \) for a.e. \( t \), and \( g(\cdot, \omega) \in G(u(\cdot, \omega)) \) for each \( \omega \).

**Proof:** Define a stopping time

\[
\tau_n(\omega) \equiv \inf \{ t : q(t, \omega) > n \}
\]
Then let \( \tilde{A} (\cdot, \omega) \equiv A \left( q^n (\cdot, \omega) + w, \omega \right) \). Then \( \tilde{A} \) satisfies the same properties as \( A \) and so there exists a solution to the integral equation

\[
Bw_n (t, \omega) + \int_0^t z_n (s, \omega) \, ds + \int_0^t g_n (s, \omega) \, ds = \int_0^t f (s, \omega) \, ds + Bu_0 (\omega)
\]

where \( w_n, z_n, g_n \) are product measurable, \( z_n (\cdot, \omega) \in \tilde{A} (w_n (\cdot, \omega), \omega) \) a.e. \( t \). By continuity of \( t \to q (t, \omega), \tau_n = \infty \) for all \( n \) sufficiently large and so \( q (t, \omega) = q^n (t, \omega) \). As before, for each \( \omega, z (\cdot, \omega) \in \tilde{A} (w (\cdot, \omega), \omega) \) a.e. where \( t \to w (t, \omega) \) is the function to which \( w_n (\cdot, \omega) \) converges weakly. Note that the estimates allowing this to happen are dependent on \( \omega \). However, one can apply Theorem 75.2.10 as before and obtain a solution to

\[
Bw (t, \omega) + \int_0^t z (s, \omega) \, ds + \int_0^t g (s, \omega) \, ds = \int_0^t f (s, \omega) \, ds + Bu_0 (\omega)
\]

such that \( w, z, g \) are product measurable into \( V \) or \( V' \) and \( z (\cdot, \omega) \in \tilde{A} (w (\cdot, \omega), \omega) \).

Now let \( u (t, \omega) = w (t, \omega) + q (t, \omega) \) to obtain the existence of the desired solution in the corollary. \( \blacksquare \)
Chapter 76

A Different Approach

76.1 Summary Of The Problem

The situation is as follows. There are spaces $V \subseteq W$ where $V, W$ are reflexive separable Banach spaces. It is assumed that $V$ is dense in $W$. Define the space for $p > 1$

$$V \equiv L^p([0, T] ; V)$$

where in each case, the $\sigma$ algebra of measurable sets will be $B([0, T])$ the Borel measurable sets. Thus, from the Riesz representation theorem,

$$V' = L^{p'}([0, T] ; V'),$$

We also assume $(\Omega, F)$ is a measurable space. No measure is needed. Also

$$V \subseteq W, \quad W' \subseteq V', \quad V \text{ dense in } W,$$

$B(t)$ will be a linear operator, $B(t) : W \rightarrow W'$ which satisfies

1. $\langle B(t)x, y \rangle = \langle B(t)y, x \rangle$
2. $\langle B(t)x, x \rangle \geq 0$
3. $B \in C^1([0, T] ; \mathcal{L}(W, W'))$ so in particular, the time derivative is bounded.

In the above formulae, $\langle \cdot, \cdot \rangle$ denotes the duality pairing of the Banach space $W$, with its dual space. We will use this notation in the present paper, the exact specification of which Banach space being determined, by the context in which this notation occurs.

For example, you could simply take $W = H = H'$ and $B$ the identity and consider a standard Gelfand triple where $H$ is a Hilbert space and $B$ equal to the identity.

2733
The product measurable sets are those in the smallest $\sigma$ algebra which contains the measurable rectangles $B \times A$ where $B \in \mathcal{B}([0,T]), A \in \mathcal{F}$. The paper is about the existence of product measurable solutions to the system

\[
( Bu (\cdot, \omega) )' + u^* (\cdot, \omega) = f (\cdot, \omega) \quad \text{in } V',
\]

\[
Bu (0, \omega) = Bu_0 (\omega), \quad \text{(76.1.1)}
\]

\[
u^* (\cdot, \omega) \in A ( u (\cdot, \omega), \omega). \quad \text{(76.1.2)}
\]

The evolution inclusion is well understood for fixed $\omega$. However, we will show the existence of a solution $u, u^*$ such that $(t; \omega) \to u(t, \omega)$ and $(t, \omega) \to u^*(t, \omega)$ are product measurable in this solution. Essentially, we show the existence of a measurable selection in the set of solutions. There are no assumptions made on the measurable space. It is just a set with a $\sigma$ algebra of subsets. Essentially this involves showing that the usual limit processes preserve measurability in some sense. The main theorems in this paper are essentially measurable selection theorems for the set of solutions to these implicit inclusions.

To begin with, we will assume $p \geq 2$. The reason for this is that we want to consider

\[
\int_0^T \langle B' u, u \rangle \, dt
\]

and this won’t make sense unless $p \geq 2$. However, this restriction is not necessary if $B$ is a constant operator, as we show in the succeeding section.

### 76.1.1 General Assumptions On $A$

The case $A(u, \omega)$ for $u \in V$ given by $A(u, \omega)(t) = A(u(t), \omega)$ is included as a special case. In addition to this commonly used situation, we are including the case where $A(u, \omega)(t)$ depends on past values of $u(s)$ for $s \leq t$. This makes our theory useful in situations where the problem is second order in $t$. The following definition is the standard one [III].

**Definition 76.1.1** For $X$ a reflexive Banach space, we say $A : X \to \mathcal{P}(X')$ is pseudomonotone and bounded if the following hold.

1. The set $Au$ is nonempty, closed and convex for all $u \in X$. $A$ takes bounded sets to bounded sets.

2. If $u_i \to u$ weakly in $X$ and $u_i^* \in Au_i$ is such that

\[
\limsup_{i \to \infty} \langle u_i^*, u_i - u \rangle \leq 0, \quad \text{(76.1.3)}
\]

then, for each $v \in X$, there exists $u^* (v) \in Au$ such that

\[
\liminf_{i \to \infty} \langle u_i^*, u_i - v \rangle \geq \langle u^*(v), u - v \rangle. \quad \text{(76.1.4)}
\]

We will assume in this section in which $B$ is time dependent that $p \geq 2$. The specific assumptions on $A (\cdot, \omega)$ are described next.
76.1. SUMMARY OF THE PROBLEM

- **growth estimate**
  Assume the specific estimate
  \[ \sup \{ \| u^* \|_{V'} : u^* \in A(u, \omega) \} \leq a(\omega) + b(\omega) \| u \|_{V'}^{p-1} \]  
  (76.1.5)
  where \( a(\omega), b(\omega) \) are nonnegative.

- **coercivity estimate**
  Also assume the coercivity condition: valid for each \( t \leq T \),
  \[ \inf \left( \int_0^t \langle u^*, u \rangle ds : u^* \in A(u, \omega) \right) \]
  \[ + \frac{1}{2} \int_0^t \langle B' u, u \rangle ds \geq \delta(\omega) \int_0^t \| u \|_V^p ds - m(\omega) \]  
  (76.1.6)
  where \( m(\omega) \) is some nonnegative constant, \( \delta(\omega) > 0 \). In fact, it is often enough to assume the left side is given by
  \[ \inf \left( \int_0^t \langle u^*, u \rangle + \lambda(\omega) \langle B u, u \rangle ds : u^* \in A(u, \omega) \right) \]
  for some \( \lambda(\omega) \) by using a suitable exponential shift argument and changing the dependent variable. We will sometimes denote weak convergence by \( \rightharpoonup \).

- **limit condition**
  If \( u_i \rightharpoonup u \) in \( V \) and \( (B u_i)' \rightharpoonup (B u)' \) in \( V' \), \( u^*_i \in A(u_i) \), \( \rightharpoonup \) denoting weak convergence, then if
  \[ \limsup_{i \to \infty} \langle u^*_i, u_i - u \rangle_{V', V} \leq 0 \]
  it follows that for all \( v \in V \), there exists \( u^*(v) \in Au \) such that
  \[ \lim inf_{i \to \infty} \langle u^*_i, u_i - v \rangle_{V', V} \geq \langle u^*(v), u - v \rangle_{V', V} \]  
  (76.1.7)

- **measurability condition**
  For \( \omega \rightharpoonup u(\cdot, \omega) \) measurable into \( V \),
  \[ \omega \rightharpoonup A(u(\cdot, \omega), \omega) \]  
  has a measurable selection into \( V' \).  
  (76.1.8)
  This last condition means there is a function \( \omega \rightharpoonup u^*(\omega) \) which is measurable into \( V' \) such that \( u^*(\omega) \in A(u(\cdot, \omega), \omega) \). This is assured to take place if the following standard measurability condition is satisfied for all \( O \) open in \( V' \):
  \[ \{ \omega : A(u(\cdot, \omega), \omega) \cap O \neq \emptyset \} \in \mathcal{F} \]  
  (76.1.9)
  See for example [63], [9] or the chapter on measurable multifunctions Chapter 46. Our assumption is implied by this one but they are not equivalent. Thus what is
considered here is more general than an assumption that \( \omega \rightarrow A(u(\cdot,\omega),\omega) \) is set valued measurable.

Note that this condition would hold if \( u \rightarrow A(t,u,\omega) \) is bounded and pseudo-monotone as a single valued map from \( V \) to \( V' \) and \( (t,\omega) \rightarrow A(t,u,\omega) \) is product measurable into \( V' \) for each \( u \). One would use the demicontinuity of \( u \rightarrow A(t,u,\omega) \) which comes from a pseudo monotone and bounded assumption and consider a sequence of simple functions \( u_n(t,\omega) \rightarrow u(t,\omega) \) in \( V \) for \( u \) measurable, each \( u_n(\cdot,\omega) \) being in \( V \). Then the measurability of \( A(t,u_n,\omega) \) would attach to \( A(t,u,\omega) \) in the limit. In the situation where \( A(\cdot,\omega) \) satisfies a suitable upper semicontinuity condition, it is enough to assume only that \( \omega \rightarrow A(u,\omega) \) has a measurable selection for each \( u \in V \). This is a straightforward exercise in approximating with simple functions and then using upper semicontinuity instead of continuity.

We assume always that the norm on the various reflexive Banach spaces is strictly convex.

### 76.1.2 Preliminary Results

We use the following well known theorem \([82] \). It is stated here for the situation in which a Holder condition is given rather than a bound on weak derivatives. See Theorem \([31.7.6] \) on Page \([1211] \).

**Theorem 76.1.2** Let \( E \subseteq F \subseteq G \) where the injection map is continuous from \( F \) to \( G \) and compact from \( E \) to \( F \). Let \( p \geq 1 \), let \( q > 1 \), and define

\[
S \equiv \{ u \in L^p([a,b],E) : \text{for some } C, \|u(t) - u(s)\|_C \leq C|t-s|^{1/q} \}
\]

and \( \|u\|_{L^p([a,b],E)} \leq R \).

Thus \( S \) is bounded in \( L^p([a,b],E) \) and Holder continuous into \( G \). Then \( S \) is precompact in \( L^p([a,b],F) \). This means that if \( \{u_n\}_{n=1}^\infty \subseteq S \), it has a subsequence \( \{u_{n_k}\} \) which converges in \( L^p([a,b],F) \). The same conclusion can be drawn if it is known instead of the Holder condition that \( \|u\|_{L^1([a,b],X)} \) is bounded.

Next are some measurable selection theorems which form an essential part of showing the existence of measurable solutions. They are not dependent on there being a measure but in the applications of most interest to us, there is typically a probability measure. First is a basic selection theorem for a set of limits. See Lemma \([46.2.2] \) on Page \([1578] \).

**Theorem 76.1.3** Let \( E \) be a separable reflexive Banach space. Suppose there is a sequence \( \{u_j(\omega)\}_{j=1}^\infty \) in \( U \), where \( \omega \rightarrow u_j(\omega) \) is measurable and for each \( \omega \),

\[
\sup_j \|u_j(\omega)\|_U < \infty.
\]

Then there exists a function \( \omega \rightarrow u(\omega) \) with values in \( U \) such that \( \omega \rightarrow u(\omega) \) is measurable, and a subsequence \( u_{n_j}(\omega) \), depending on \( \omega \), such that

\[
\lim_{n(\omega) \rightarrow \infty} u_{n(\omega)}(\omega) = u(\omega) \text{ weakly in } U.
\]
Next is a specialization to the situation where the Banach space is a function space. The proof is in [22]. This gives a result on product measurability. It is Theorem 76.1.4 on Page 2737.

**Theorem 76.1.4** Let $V$ be a reflexive separable Banach space with dual $V'$, and let $p,p'$ be such that $p > 1$ and $\frac{1}{p} + \frac{1}{p'} = 1$. Let the functions $t \rightarrow u_n(t,\omega)$, for $n \in \mathbb{N}$, be in $L^p([0,T];V) \equiv V$ and $(t,\omega) \rightarrow u_n(t,\omega)$ be $\mathcal{B}([0,T]) \times \mathcal{F} \equiv \mathcal{P}$ measurable into $V$. Suppose

$$\|u_n(\cdot,\omega)\|_V \leq C(\omega),$$

for all $n$. (Thus, by weak compactness, for each $\omega$, each subsequence of $\{u_n\}$ has a further subsequence that converges weakly in $V$ to $v(\cdot,\omega) \in V$. ($v$ not known to be $\mathcal{P}$ measurable))

Then, there exists a product measurable function $u$ such that $t \rightarrow u(t,\omega)$ is in $V$ and for each $\omega$ a subsequence $u_{n(\omega)}$ such that $u_{n(\omega)}(\cdot,\omega) \rightarrow u(\cdot,\omega)$ weakly in $V$.

Next is what it means to be measurable into $V$ or $V'$. Such functions have representatives which are product measurable.

**Lemma 76.1.5** Let $f(\cdot,\omega) \in V'$. Then if $\omega \rightarrow f(\cdot,\omega)$ is measurable into $V'$, it follows that for each $\omega$, there exists a representative $\hat{f}(\cdot,\omega) \in V'$, $\hat{f}(\cdot,\omega) = f(\cdot,\omega)$ in $V'$ such that $(t,\omega) \rightarrow \hat{f}(t,\omega)$ is product measurable. If $f(\cdot,\omega) \in V'$ and $(t,\omega) \rightarrow f(t,\omega)$ is product measurable, then $\omega \rightarrow f(\cdot,\omega)$ is measurable into $V'$. The same holds replacing $V'$ with $V$.

**Proof:** If a function $f$ is measurable into $V'$, then there exist simple functions $f_n$

$$\lim_{n \rightarrow \infty} \|f_n(\omega) - f(\omega)\|_{V'} = 0, \quad \|f_n(\omega)\| \leq 2\|f(\omega)\|_{V'} \equiv C(\omega)$$

Now one of these simple functions is of the form

$$\sum_{i=1}^{M} c_i \mathcal{X}_{E_i}(\omega)$$

where $c_i \in V'$. Therefore, there is no loss of generality in assuming that $c_i(t) = \sum_{j=1}^{N} d_{ij} \mathcal{X}_{F_j}(t)$ where $d_{ij} \in V'$. Hence we can assume each $f_n$ is product measurable into $\mathcal{B}(V') \times \mathcal{F}$. Then by Theorem 76.1.4, there exists $\hat{f}(\cdot,\omega) \in V'$ such that $\hat{f}$ is product measurable and a subsequence $f_{n(\omega)}$ converging weakly in $V'$ to $\hat{f}(\cdot,\omega)$ for each $\omega$. Thus $f_{n(\omega)}(\omega) \rightarrow f(\omega)$ strongly in $V'$ and $f_{n(\omega)}(\omega) \rightarrow \hat{f}(\omega)$ weakly in $V'$. Therefore, $\hat{f}(\omega) = f(\omega)$ in $V'$ and so it can be assumed that if $f$ is measurable into $V'$ then for each $\omega$, it has a representative $\hat{f}(\omega)$ such that $(t,\omega) \rightarrow \hat{f}(t,\omega)$ is product measurable.

If $f$ is product measurable into $V'$ and each $f(\cdot,\omega) \in V'$, does it follow that $f$ is measurable into $V''$? By measurability, $f(t,\omega) = \lim_{n \rightarrow \infty} \sum_{i=1}^{m_n} c_{i} \mathcal{X}_{E_i}(t,\omega) = \lim_{n \rightarrow \infty} f_n(t,\omega)$ where $E_{i}^{n}$ is product measurable and we can assume $\|f_n(t,\omega)\|_{V''} \leq $
2 \| f (t, \omega) \|. Then by product measurability, \( \omega \rightarrow f_n (\cdot, \omega) \) is measurable into \( V' \) because if \( g \in V \) then
\[
\omega \rightarrow \langle f_n (\cdot, \omega), g \rangle
\]
is of the form
\[
\omega \rightarrow \sum_{i=1}^{m_n} \int_0^T \langle c_i^n X_{E_i^n} (t, \omega), g(t) \rangle dt \text{ which is } \omega \rightarrow \sum_{i=1}^{m_n} \int_0^T \langle c_i^n, g(t) \rangle X_{E_i^n} (t, \omega) dt
\]
and this is \( \mathcal{F} \) measurable since \( E_i^n \) is product measurable. Thus, it is measurable into \( V' \) as desired and
\[
\langle f (\cdot, \omega), g \rangle = \lim_{n \rightarrow \infty} \langle f_n (\cdot, \omega), g \rangle, \ \omega \rightarrow (f_n (\cdot, \omega), g) \text{ is } \mathcal{F} \text{ measurable.}
\]

By the Pettis theorem, \( \omega \rightarrow \langle f (\cdot, \omega), g \rangle \) is measurable into \( V' \). Obviously, the conclusion is the same for these two conditions if \( V' \) is replaced with \( V \).

The following theorem is also useful. It is really a generalization of the familiar Gram Schmidt process. See Lemma 31.4.2 on Page 1169.

**Theorem 76.1.6** Suppose \( V, W \) are separable Banach spaces, such that \( V \) is dense in \( W \) and \( B \in \mathcal{L} (W, W') \) satisfies
\[
\langle Bx, x \rangle \geq 0, \ \langle Bx, y \rangle = \langle By, x \rangle, B \neq 0.
\]
Then there exists a countable set \( \{ e_i \} \) of vectors in \( V \) such that
\[
\langle Be_i, e_j \rangle = \delta_{ij}
\]
and for each \( x \in W \),
\[
\langle Bx, x \rangle = \sum_{i=1}^{\infty} |\langle Bx, e_i \rangle|^2,
\]
and also
\[
Bx = \sum_{i=1}^{\infty} \langle Bx, e_i \rangle Be_i,
\]
the series converging in \( W' \). In case \( B = B (\omega) \) where \( \omega \rightarrow B (\omega) \) is measurable into \( \mathcal{L} (W, W') \), these vectors \( e_i \) will also depend on \( \omega \) and will be measurable functions of \( \omega \). In particular, we could let \( \omega = t \) with the Lebesgue measurable sets.

The following result, found in [24] is well known. See Section 23.2 on Page 511.

**Theorem 76.1.7** If a single valued map, \( A : X \rightarrow X' \) is monotone, hemicontinuous, and bounded, then \( A \) is pseudo monotone. Furthermore, the duality map, \( J^{-1} : X \rightarrow X' \) which satisfies \( (J^{-1} f, f) = \| f \|^2, \| J^{-1} f \|_X = \| f \|_X \) is strictly monotone hemicontinuous and bounded. So is the duality map \( F : X \rightarrow X' \) which satisfies \( \| Ff \|_{X'} = \| f \|_{X}^{p-1}, \langle Ff, f \rangle = \| f \|_{X}^p \text{ for } p > 1 \).
The following fundamental result will be of use in what follows. There is somewhat more in this than will be needed. \( B \) is a possibly degenerate operator satisfying only the following:

\[
B \in \mathcal{L}(W, W'), \quad \langle Bu, u \rangle \geq 0, \langle Bu, v \rangle = \langle Bv, u \rangle
\]  

(76.1.10)

where here \( V \subseteq W \) and \( V \) is dense in \( W \).

Also one can obtain the following for \( p \geq 2 \). It is an integration by parts formula. See Theorem 31.6.4 on Page 1202.

**Proposition 76.1.8** Let \( p \geq 2 \) in what follows. For \( u, v \in X \), the following hold.

1. \( t \to \langle B(t)u(t), v(t) \rangle_{W', W} \) equals an absolutely continuous function a.e., denoted by \( \langle Bu, v \rangle (\cdot) \).
2. \( \langle Lu(t), u(t) \rangle = \frac{1}{2} [(Bu, u)'(t) + \langle B'(t)u(t), u(t) \rangle] \) a.e. \( t \)
3. \( |\langle Bu, v \rangle(t)| \leq C \|u\|_X \|v\|_X \) for some \( C > 0 \) and for all \( t \in [0, T] \).
4. \( t \to B(t)u(t) \) equals a function in \( C(0, T; W') \) a.e., denoted by \( Bu(\cdot) \).
5. \( \sup \{ \|Bu(t)\|_{W'}, t \in [0, T] \} \leq C \|u\|_X \) for some \( C > 0 \).
6. \( K \) is linear, continuous and weakly continuous.
7. \( \langle Ku, u \rangle = \frac{1}{2} [(Bu, u)(T) + \langle Bu, u \rangle(0)] + \frac{1}{2} \int_0^T \langle B'(t)u(t), u(t) \rangle dt. \)
8. If \( Bu(0) = 0 \), for \( u \in X \), there exists \( u_n \to u \) in \( X \) such that \( u_n(t) \) is \( 0 \) near \( 0 \). A similar conclusion could be deduced at \( T \) if \( Bu(T) = 0 \).

Fussing with \( p \geq 2 \) is necessary only because of the consideration of

\[
\int_0^T \langle B'(t)u(t), u(t) \rangle dt.
\]

If \( p < 2 \), this term might not make sense. The last assertion about approximation makes possible the following corollary.

**Corollary 76.1.9** If \( Bu(0) = 0 \) for \( u \in X \), then \( \langle Bu, u \rangle(0) = 0 \). The converse is also true. An analogous result will hold with \( 0 \) replaced with \( T \).
Proof: Let $u_n \to u$ in $X$ with $u_n(t) = 0$ for all $t$ close enough to 0. For $t$ off a set of measure zero consisting of the union of sets of measure zero corresponding to $u_n$ and $u$,

$$\langle Bu_n, u_n \rangle(t) = \langle B(t) u_n(t), u_n(t) \rangle, \langle Bu, u \rangle(t) = \langle B(t) u(t), u(t) \rangle,$$

$$\langle B(u - u_n), u \rangle(t) = \langle B(t)(u(t) - u_n(t)), u(t) \rangle$$

$$\langle Bu_n, u - u_n \rangle(t) = \langle B(t) u_n(t), u(t) - u_n(t) \rangle$$

Then, considering such $t$,

$$\langle B(t) u(t), u(t) \rangle - \langle B(t) u_n(t), u_n(t) \rangle = \langle B(t)(u(t) - u_n(t)), u(t) \rangle$$

$$+ \langle B(t) u_n(t), u(t) - u_n(t) \rangle$$

Hence from Theorem 46.14.5

$$|\langle B(t) u(t), u(t) \rangle - \langle B(t) u_n(t), u_n(t) \rangle| \leq C \|u - u_n\|_X (\|u\|_X + \|u_n\|_X)$$

Thus if $n$ is sufficiently large,

$$|\langle B(t) u(t), u(t) \rangle - \langle B(t) u_n(t), u_n(t) \rangle| < \varepsilon$$

So let $n$ be fixed and this large and now let $t_k \to 0$ to obtain

$$\langle B(t_k) u_n(t_k), u_n(t_k) \rangle = 0$$

for $k$ large enough. Hence

$$\langle Bu, u \rangle(0) = \lim_{k \to \infty} \langle B(t_k) u(t_k), u(t_k) \rangle < \varepsilon$$

Since $\varepsilon$ is arbitrary, $\langle Bu, u \rangle(0) = 0$.

Next suppose $\langle Bu, u \rangle(0) = 0$. Then letting $v \in X$, with $v$ smooth,

$$\langle Bu(0), v(0) \rangle = \langle Bu, v \rangle(0) = \langle Bu, u \rangle^{1/2}(0) \langle Bu, v \rangle^{1/2}(0) = 0$$

and it follows that $Bu(0) = 0$.\[\blacksquare\]

Note also that this shows that if $(Bv)' \in L^{p'}(0, T; V')$ as well as $(Bu)'$, then there is a continuous function

$$t \to \langle B(u + v), u + v \rangle(t)$$

which equals $\langle B(u(t) + v(t)), u(t) + v(t) \rangle$ for a.e. $t$ and so, defining

$$\langle Bu, v \rangle(t) \equiv (\langle Bu, u \rangle(t) + \langle Bv, u \rangle(t) - \langle B(u + v), u + v \rangle(t)) \frac{1}{2}.$$

It follows that $t \to \langle Bu, v \rangle(t)$ is continuous and equals $\langle B(u(t)), v(t) \rangle$ a.e. $t$.

This also makes it easy to verify continuity of pointwise evaluation of $Bu$.\[\blacksquare\]
76.1. SUMMARY OF THE PROBLEM

Let $Lu = (Bu)'$.

$$u \in D(L) \equiv X \equiv \left\{ u \in L^p(0,T,V) : Lu \equiv (Bu)' \in L^{p'}(0,T,V') \right\}$$

$$\|u\|_X \equiv \max \left( \|u\|_{L^p(0,T,V)}, \|Lu\|_{L^{p'}(0,T,V')} \right) \quad (76.1.11)$$

Since $L$ is closed, this $X$ is a Banach space. To see that $L$ is closed, suppose $u_n \to u$ in $V$ and $(Bu_n)' \to \xi$ in $V'$. Is $\xi = (Bu)'$? Letting $\phi \in C^\infty_c([0,T])$ and $v \in V$,

$$\int_0^T \langle \xi, \phi v \rangle_{V',V} = \lim_{n \to \infty} \int_0^T \langle (Bu_n)', \phi v \rangle = \lim_{n \to \infty} -\int_0^T \langle Bu_n, \phi' v \rangle \quad (76.1.12)$$

We can take a subsequence, still denoted with $n$ such that $u_n(t) \to u(t)$ pointwise a.e. Also

$$\int_0^T |\langle Bu_n, \phi' v \rangle|^p \leq \int_0^T \|u_n\|^p dC \langle \phi', v \rangle$$

and these terms on the right are uniformly bounded by the assumption that $u_n$ is bounded in $V$. Therefore, by the Vitali convergence theorem, and using the subsequence just described, we can pass to the limit in $76.1.12$.

$$\left\langle \int_0^T \xi \phi dt, v \right\rangle = \left\langle -\int_0^T (Bu) \phi' dt, v \right\rangle$$

Since $v$ is arbitrary, this shows that

$$\int_0^T \xi \phi dt = -\int_0^T (Bu) \phi' dt \text{ in } V'$$

and so $\xi = (Bu)'$ because this is what is meant by $(Bu)'$. Hence $L$ is indeed closed and $X$ is a Banach space. It is also a reflexive Banach space because it is isometric to a closed subspace of the reflexive Banach space $V \times V'$. Also, the following is useful. See Theorem 31.4.7 on Page 1183.

**Theorem 76.1.10** If $Y$ denotes those $f \in L^p([0,T];V)$ for which $f' \in L^p([0,T];V)$, so that $f$ has a representative such that $f(t) = f(0) + \int_0^t f'(s) ds$ a.e. $t$, then if $\|f\|_Y \equiv \|f\|_{L^p([0,T];V)} + \|f'\|_{L^p([0,T];V)}$ the map $f \to f(t)$ is continuous in the sense that $\|f(t)\| \leq C(\|f\|_Y)$.

We also have the following general theory about existence of measurable solutions to elliptic problems. First are conditions which a nonlinear set valued map should satisfy. In what follows, $X$ denotes a reflexive separable Banach space with dual $X'$, $(\Omega, \mathcal{F})$ is a measurable space, and $A(\cdot, \omega) : X \to \mathcal{P}(X')$, for $\omega \in \Omega$, denotes a set valued operator. We make the following assumptions on such an operator:

- **H1 Measurability condition.** For each $u \in X$, there is a measurable selection $z(\omega)$ such that $z(\omega) \in A(u, \omega).$
CHAPTER 76. A DIFFERENT APPROACH

- **H₂ Values of \( A \).** \( A(\cdot, \omega) : X \to \mathcal{P}(X') \) has bounded, closed, nonempty, and convex values. \( A(\cdot, \omega) \) maps bounded sets to bounded sets.

- **H₃ Limit conditions, \( A(\cdot, \omega) \) is pseudomonotone:**

  If \( u_n \to u \) and \( \limsup_{n \to \infty} \langle z_n, u_n - u \rangle \leq 0 \), for \( z_n \in A(u_n, \omega) \),

  then for each \( v \), there exists \( z(v) \in A(u, \omega) \) such that

  \[
  \liminf_{k \to \infty} \langle z_n, u_n - v \rangle \geq \langle z(v), u - v \rangle.
  \]

  In our use of the above, the space \( X \) will be a space of functions defined on \([0, T]\) to be described more later.

  We note that for a fixed \( \omega \), the operator \( A(\cdot, \omega) \) described earlier is set-valued, bounded and pseudomonotone as a map from \( X \) to \( \mathcal{P}(X) \). Moreover, the sum of two of such operators is set-valued, bounded and pseudomonotone, Theorem 76.1.12 below. The limit condition \( H₃ \) implies that \( A(\cdot, \omega) \) is upper-semicontinuous from the strong topology to the weak topology. This can be used to show that when \( \omega \to u(\omega) \) is measurable, then \( A(u(\omega), \omega) \) has a measurable selection assuming only that \( \omega \to A(u, \omega) \) has a measurable selection for fixed \( u \in X \). Here is a well known result on the sum of pseudomonotone operators. See Theorem 76.1.1 on Page 2743.

**Theorem 76.1.11** Assume that \( A \) and \( B \) are set-valued, bounded and pseudomonotone operators. Then, their sum is also a set-valued, bounded and pseudomonotone operator. Moreover, if \( u_n \to u \) weakly, \( z_n \to z \), \( z_n \in A(u_n) \), \( w_n \to w \) weakly with \( w_n \in A(u_n) \), and

\[
\limsup_{n \to \infty} (z_n + w_n, u_n - u) \leq 0,
\]

then,

\[
\liminf_{n \to \infty} (z_n + w_n, u_n - v) \geq \langle z(v) + w(v), u - v \rangle,
\]

for \( z(v) \in A(u) \), \( w(v) \in B(u) \) and in fact, \( z \in A(u) \) and \( w \in B(u) \).

We now state our result on measurable solutions to general elliptic variational inequalities that may contain sums of set-valued, bounded and pseudomonotone operators. Then the following is proved in [?]. See also Theorem 76.1.12 on Page 2744.

**Theorem 76.1.12** Let \( \omega \to K(\omega) \) be a measurable set-valued function, where \( K(\omega) \subseteq V \) is convex, closed and bounded. Let the operators \( A(\cdot, \cdot) \) and \( B(\cdot, \cdot) \) satisfy assumptions \( H₁ - H₃ \). Finally, let \( \omega \to f(\omega) \) be measurable with values in \( V' \).

Then, there exists a measurable function \( \omega \to u(\omega) \in K(\omega) \) such that \( \omega \to w^A(\omega) \), and \( \omega \to w^B(\omega) \) with \( w^A(\omega) \in A(u(\omega), \omega) \) and \( w^B(\omega) \in B(u(\omega), \omega) \), and

\[
\langle f(\omega) - (w^A(\omega) + w^B(\omega)), z - u(\omega) \rangle \leq 0,
\]
for all \( z \in K(\omega) \).

If it is only known that \( K(\omega) \) is closed and convex, the same conclusion holds true if it is also known that for some \( z(\omega) \in K(\omega) \), \( A(\cdot, \omega) + B(\cdot, \omega) \) is coercive, that is

\[
\lim_{\|v\| \to \infty} \inf \left\{ \frac{(z^*, v - z)}{\|v\|} : z^* \in (A(v, \omega) + B(v, \omega)) \right\} = \infty.
\]

Instead of two operators, one could have the sum of finitely many with the same conclusions.

### 76.2 Measurable Solutions To Evolution Inclusions

The main result in this section is Theorem 76.2.2 below. It gives an existence theorem for many evolution inclusions. We are assuming that \( A(\cdot, \omega) : V \to \mathcal{P}(V') \) satisfies some conditions presented earlier: These are 76.1.1-76.1.1. Then we can regard \( A(\cdot, \omega) \) as a set valued pseudomonotone map from \( X \) to \( \mathcal{P}(X') \). It is clear that \( A(u, \omega) \) is a closed convex set in \( X' \) because if \( z_n^* \to z^* \) in \( X' \), \( z_n^* \in A(u, \omega) \), then \( z^* \in A(u, \omega) \) because a subsequence, still denoted as \( z_n^* \) converges weakly to some \( w^* \in A(u, \omega) \) in \( V' \). Since \( X \) is dense in \( V \), this requires \( w^* = z^* \). The necessary limit conditions for pseudomonotone are nothing more than the assumed conditions in 76.1.1. Also, we will assume in this section that \( p \geq 2 \). This restriction is necessary because of the desire to consider time dependent \( B \) and the assumption 76.1.6 which involves a term \( \int_0^T \langle B' u, u \rangle \) which might not make sense if \( p \) were only larger than 1. If \( B \) were not time dependent, this assumption would not be necessary and the argument given here would continue to be valid. We essentially show this is the case in the following section in which we also consider a more general coercivity condition than 76.1.1, but one can see that there is no change in the argument and it is in fact simpler if we assume \( B \) is constant.

As above, \( K : X \to X' \) can be defined as

\[
\langle Ku, v \rangle \equiv \int_0^T \langle Lu, v \rangle \, ds + \langle Bu, v \rangle (0)
\]

Note that from Proposition 76.1.8 if \( v \in X \) and \( Bv(0) = 0 \), then

\[
\langle Ku, v \rangle = \int_0^T \langle Lu, v \rangle \, ds \quad (76.2.13)
\]

This is because, from the Cauchy Schwarz inequality and continuity of \( \langle Bu, u \rangle (\cdot) \),

\[
\langle Bu, v \rangle (0) \leq \langle Bu, u \rangle^{1/2} (0) \, \langle Bv, v \rangle^{1/2} (0)
\]

and if \( Bv(0) = 0 \), then from Corollary 76.1.9, \( \langle Bv, v \rangle^{1/2} (0) = 0 \). From the above Proposition 76.1.8, this operator \( K \) is hemicontinuous and bounded and monotone as a map from \( X \) to \( X' \). Thus \( K + A (\cdot, \omega) \) is a set valued pseudomonotone map for
which we can apply Theorem 76.1.12 and obtain existence theorems for measurable solutions to variational inequalities right away, but we want to obtain solutions to an evolution equation in which \( K(\omega) = V \) and the above theorem does not apply because the sum of these two operators is not coercive. Therefore, we consider another operator which, when added, will result in coercivity. Let \( J : V \to V' \) be the duality map for 2. Thus \( \|Ju\|_V = \|u\|_V \) and \( \langle Ju, u \rangle = \|u\|_V^2 \). Then \( J^{-1} : V' \to V \) also satisfies \( \langle f, J^{-1}f \rangle = \|f\|_{V'}^2 \).

The main result in this section is based on methods due to Brezis \([21]\) and Lions \([82]\) adapted to the case considered here where the operator is set valued, and we consider measurability. We define the operator \( M : X \to X' \) by

\[
\langle Mu, v \rangle = \langle Lu, J_1 Lu \rangle_{V', V}
\]

where as above, \( Lu = (Bu)' \):

Then let \( f \) be measurable into \( V' \). Thus, in particular, \( f(\omega) \in V' \) for each \( \omega \). Consider the approximate problem and a solution \( u_\varepsilon \) to

\[
\varepsilon Mu_\varepsilon(\omega) + Ku_\varepsilon(\omega) + w_\varepsilon^*(\omega) = f(\omega) + g(\omega), \quad w_\varepsilon^*(\omega) \in A(u_\varepsilon(\omega), \omega). \quad (76.2.14)
\]

Where \( g(\omega) \in X' \) is given by

\[
(g(\omega), v) = (Bv(0), u_0(\omega))
\]

where \( u_0(\omega) \) is a given function measurable into \( W \). Now for \( u \in X \), we let

\[
A(u, \omega) = \varepsilon Mu + Ku + A(u, \omega)
\]

Then by the assumptions on \( A(\cdot, \omega) \), there is \( u^*(\omega) \) for which \( \omega \to u^*(\omega) \) is measurable into \( V' \), hence measurable into \( X' \). Therefore, \( \omega \to A(u, \omega) \) has a measurable selection, namely \( \varepsilon Mu + Ku + u^*(\omega) \) and so condition 76.1.1 is verified.

By Theorem 76.1.12, a solution to (76.2.14) will exist with both \( u_\varepsilon \) and \( w_\varepsilon^* \) measurable if we can argue that the sum of the operators \( \varepsilon M + K + A(\cdot, \omega) \) is coercive, since this is the sum of pseudomonotone operators. From 76.1.14

\[
\inf \left( \int_0^T \langle u, u \rangle \, ds : u^* \in A(u, \omega) \right) + \frac{1}{2} \int_0^T \langle B'u, u \rangle \geq \delta(\omega) \int_0^T \|u\|_{V'}^2 \, ds - m(\omega)
\]

and so routine considerations show that \( \varepsilon M + K + A(\cdot, \omega) \) does indeed satisfy a suitable coercivity estimate for each positive \( \varepsilon \). Thus we have the following existence theorem for approximate solutions.

**Lemma 76.2.1** Let \( f \) be measurable into \( V' \) and let \( A \) satisfy the conditions 76.1.7 - 76.1.10. Then for \( K \) and \( M \) defined as above, it follows there exist measurable \( u_\varepsilon \) and \( w_\varepsilon^* \) satisfying 76.2.14.

Note this implies that, suppressing dependence on \( \omega \),

\[
\langle Bu_\varepsilon, v \rangle (0) = \langle Bv(0), u_0 \rangle
\]
for all \( v \in X \). Thus, letting \( v \) be a smooth function with values in \( V \)
\[
\langle Bu_x(0), v(0) \rangle = \langle Bu_0, v(0) \rangle
\]
Since \( V \) is dense in \( W \), this requires \( Bu_x(0) = Bu_0 \).

Now define \( \Lambda \) to be the restriction of \( L \) to those \( u \in X \) which have \( Bu(0) = 0 \).

Thus by Corollary 76.1.9,
\[
D(\Lambda) = \{ u \in X : Bu(0) = 0 \} = \{ u \in X : \langle Bu, u \rangle(0) = 0 \}
\]
and if \( v \in D(\Lambda), u \in X \), then as noted earlier,
\[
\langle Ku, v \rangle = \int_0^T \langle Lu, v \rangle \, ds
\]
Also, one can show an estimate for \( \Lambda^* \).

You can define \( D(T) \equiv \{ u \in V : u' \in V, u(T) = 0 \} \) and let \( Tu = -Bu' \). Then
\[
\langle Tu, u \rangle = -\int_0^T \langle Bu', u \rangle = -\langle Bu, u \rangle|_0^T + \int_0^T \langle (Bu)' , u \rangle
\]
\[
= \langle Bu, u \rangle(0) + \int_0^T \langle B'u, u \rangle + \int_0^T \langle Bu', u \rangle
\]
and so we obtain
\[
2 \langle Tu, u \rangle \geq \int_0^T \langle B'u, u \rangle \tag{76.2.15}
\]
Then one shows that \( T^* = \Lambda \) and that the graph of \( \Lambda^* \) is the closure of the graph of \( T \) thus showing that \( \Lambda^* \) also satisfies an inequality like (76.2.15) for \( u \in D(\Lambda^*) \).

From (76.2.14),
\[
\varepsilon \langle Lv, J^{-1}Lu_x \rangle_{V',V} + \langle Ku_x(\omega), v \rangle_{X',X} + \langle w_x^*(\omega), v \rangle_{V',V} = \langle f(\omega), v \rangle_{V',V}
\]
If we restrict to \( v \in D(\Lambda) \) so \( Bv(0) = 0 \), then it reduces to
\[
\varepsilon \langle Lv, J^{-1}Lu_x \rangle_{V',V} + \langle Lu_x(\omega), v \rangle_{V',V} + \langle w_x^*(\omega), v \rangle_{V',V} = \langle f(\omega), v \rangle_{V',V}
\]
and so \( J^{-1}Lu_x \in D(\Lambda^*) \). Thus, since \( D(\Lambda) \) is dense in \( V \), it follows that
\[
\varepsilon \Lambda^* J^{-1}Lu_x + Lu_x + w_x^* = f \text{ in } V'
\]
Then act on \( J^{-1}Lu_x \) on both sides in the above. This yields for some \( C \) dependent on \( B' \) an inequality of the following form.
\[
-\varepsilon C ||Lu_x||^2 + ||Lu_x||^2 + \langle w_x^*, J^{-1}Lu_x \rangle \leq \langle f, J^{-1}Lu_x \rangle \tag{76.2.16}
\]
Also, acting on both sides of (76.2.14) with \( u_x \) and using the formula for \( \langle Ku, u \rangle \),
\[
\varepsilon \langle Lu_x, J^{-1}Lu_x \rangle + \frac{1}{2} [ \langle Bu_x, u_x \rangle(T) + \langle Bu_x, u_x \rangle(0) ]
\]
It follows easily from the coercivity condition \((6.1.4)\) that \(u_\varepsilon\) is bounded in \(V\) and consequently \(w_\varepsilon^*\) is bounded in \(V^*\), this from the growth estimate \((6.1.1)\). Now from \((6.2.13)\), it also follows that \(\|Lu_\varepsilon\|_{V^*}\) is bounded for small \(\varepsilon\). Thus

\[
\|Lu_\varepsilon (\omega)\|_{V^*} + \|u_\varepsilon (\omega)\|_V + \|w_\varepsilon^* (\omega)\|_{V^*} \leq C (\omega) < \infty,
\]

\(C (\omega)\) independent of small \(\varepsilon\). By Theorem \((6.1.3)\), there is a subsequence \(\varepsilon (\omega) \to 0\) such that

\[
\left( Lu_{\varepsilon (\omega)} (\omega), u_{\varepsilon (\omega)} (\omega), w_{\varepsilon (\omega)}^* (\omega), Bu_{\varepsilon (\omega)} (\omega) (0) \right) \to (Lu (\omega), u (\omega), \xi (\omega), Bu (\omega) (0))
\]

in \(V' \times V \times V' \times V'\) weakly and \(\omega \to (Lu (\omega), u (\omega), \xi (\omega))\) is measurable into \(V' \times V \times V'\). It follows that \(Bu (\omega) (0) = Bu_0 (\omega)\) because each \(Bu_{\varepsilon (\omega)} (\omega) (0) = Bu_0 (\omega)\). Note that this also shows that \(Ku_\varepsilon \to Ku\) in \(X'\). Thus, suppressing the dependence on \(\omega\), use \((6.2.13)\) to act on \(u_\varepsilon - u\) and obtain

\[
\varepsilon \langle Lu_\varepsilon - Lu, J^{-1} Lu_\varepsilon \rangle + \langle Ku_\varepsilon, u_\varepsilon - u \rangle + \langle w_\varepsilon^*, u_\varepsilon - u \rangle = \langle f, u_\varepsilon - u \rangle + \langle g, u_\varepsilon - u \rangle
\]

Using monotonicity of \(J^{-1}\),

\[
\varepsilon \langle Lu_\varepsilon - Lu, J^{-1} Lu \rangle + \langle Ku_\varepsilon, u_\varepsilon - u \rangle + \langle w_\varepsilon^*, u_\varepsilon - u \rangle \leq \langle f, u_\varepsilon - u \rangle + \langle g, u_\varepsilon - u \rangle
\]

Now \((Bu_\varepsilon - Bu) (0) = 0\). Therefore, \(u_\varepsilon - u \in D (A)\) and so

\[
\varepsilon \langle \Lambda^* J^{-1} Lu, u_\varepsilon - u \rangle + \langle Ku_\varepsilon, u_\varepsilon - u \rangle + \langle w_\varepsilon^*, u_\varepsilon - u \rangle \leq \langle f, u_\varepsilon - u \rangle + \langle g, u_\varepsilon - u \rangle
\]

Recall that \(K\) is monotone, bounded and hemicontinuous. In fact, it is monotone and linear. Hence, \(K + A\) is pseudomonotone. Then from the above,

\[
\lim \sup_{\varepsilon \to 0} \langle Ku_\varepsilon + w_\varepsilon^*, u_\varepsilon - u \rangle \leq 0
\]

Now these weak convergences in \((6.2.14)\) include the weak convergence of \(u_\varepsilon\) to \(u\) in \(X\). Thus, since \(K + A (\cdot, \omega)\) is pseudomonotone as a map from \(X\) to \(P (X')\), for every \(v \in X\), there exists \(w^*(v) \in K (u) + A (u, \omega)\) such that

\[
\lim \inf_{\varepsilon \to 0} \langle Ku_\varepsilon + w_\varepsilon^*, u_\varepsilon - v \rangle \geq \langle w^*(v), u - v \rangle
\]

In particular, this holds if \(v = u\) which shows that

\[
\lim_{\varepsilon \to 0} \langle Ku_\varepsilon + w_\varepsilon^*, u_\varepsilon - u \rangle = 0.
\]

It follows then that for \(v \in X\),

\[
\langle \xi + Ku, u - v \rangle = \lim_{\varepsilon \to 0} \langle w_\varepsilon^* + Ku_\varepsilon, u - v \rangle
\]

\[
= \lim_{\varepsilon \to 0} \left[ \langle w_\varepsilon^* + Ku_\varepsilon, u - u_\varepsilon \rangle + \langle w_\varepsilon^* + Ku_\varepsilon, u_\varepsilon - v \rangle \right]
\]

\[
\geq \lim \inf_{\varepsilon \to 0} \langle w_\varepsilon^* + Ku_\varepsilon, u_\varepsilon - v \rangle \geq \langle w^*(v), u - v \rangle
\]

\[
\langle \xi + Ku, u - v \rangle \leq \langle w^*(v), u - v \rangle.
\]
Since \( v \) is arbitrary, separation theorems imply that
\[
\xi (\omega) + Ku (\omega) \equiv w^* (\omega) + Ku (\omega) \in A (u (\omega), \omega) + Ku (\omega).
\]
Then passing to the limit in (76.2.14), we have
\[
Ku (\omega) + w^* (\omega) = f (\omega) + g (\omega) \quad \text{in } X',
\]
and \( Lu, w^*, u \) are all measurable into the appropriate spaces. This implies for each \( v \in X \),
\[
\int_0^T \langle Lu, v \rangle + \langle Bu, v \rangle (0) + \int_0^T \langle w^*, v \rangle = \int_0^T \langle f, v \rangle + \langle Bu (0), u_0 \rangle
\]
In particular, letting \( v = u \),
\[
\int_0^T \langle Lu, u \rangle + \langle Bu, u \rangle (0) + \int_0^T \langle w^*, u \rangle = \int_0^T \langle f, v \rangle + \langle Bu (0), u_0 \rangle
\]
Thanks to (76.2.18), this shows that \( \langle Bu, u \rangle (0) = \langle Bu_0, u_0 \rangle \). Also it follows from Theorem 76.1.8.

This has proved the following theorem.

**Theorem 76.2.2** Let \( p \geq 2 \) and let \( A \) satisfy 76.1.1-76.1.4 and let \( f \) be measurable into \( V' \) and let \( u_0 \) be measurable into \( W \). Then there exists a solution to (76.2.18) such that \( Lu, w^*, u \) are all measurable. We also have for \( u \) this solution that for fixed \( \omega \), \( \langle Bu_0, u_0 \rangle = \langle Bu, u \rangle (0) \).

We also have the following corollary which gives measurable solutions to periodic problems. Of course there is no uniqueness for such periodic problems so this is another place where our theory is applicable. In this corollary, we assume for the sake of simplicity that \( B (t) = B \) a constant. Thus, it is not necessary to assume \( p \geq 2 \) in the following corollary.

**Corollary 76.2.3** Let \( A \) satisfy 76.1.1-76.1.4, \( p > 1 \), and let \( f \) be measurable into \( V' \). Then there exists a solution to
\[
Lu (\omega) + w^* (\omega) = f (\omega), Bu (0, \omega) = Bu (T, \omega),
\]
\[
w^* (\omega) \in A (u (\omega), \omega)
\]
such that \( Lu, w^*, u \) are all measurable.
CHAPTER 76. A DIFFERENT APPROACH

**Proof:** Define \( \Lambda \) as the restriction of \( L \) to the space \( \{ u \in D (L) : Bu (0) = Bu (T) \} \). This enables periodic conditions. Let

\[
D (T) \equiv \{ v \in V : v' \in V \text{ and } v (T) = v (0) \} , \quad Tv = -Bv'
\]

Then consider \( T^* \). If \( u \in D (\Lambda) , v \in D (T) , \)

\[
- \int_0^T \langle Bu', u \rangle = - \langle Bu, v \rangle |_0^T + \int_0^T \langle (Bu)', v \rangle
\]

and so, since the boundary term vanishes, this shows that \( D (\Lambda) \subseteq D (T^*) \) and that \( T^* = \Lambda \) on \( D (\Lambda) \).

Next let \( u \in D (T^*) \). By definition, this means that

\[
|\langle Tv, u \rangle| \leq C_u \| v \| V (\star)
\]

So let \( v \in C_c^\infty ([0, T] ; V) \).

\[
(Tv, u) = - \int_0^T \langle Bu', u \rangle = - \int_0^T \langle Bu, v' \rangle
\]

From the Riesz representation theorem, there exists a unique \( (Bu)' \) such that the above equals \( \int_0^T \langle (Bu)', v \rangle \) and by density of \( C_c^\infty ([0, T] ; V) \) this shows \( T^* u = (Bu)' = Lu \). Thus \( T^* = L \) on \( D (T^*) \) and in particular \( (Bu)' \in V' \). It remains to consider the boundary conditions. For \( u \in D (T^*) \) and \( v \in D (T) \),

\[
(Tv, u) = - \int_0^T \langle Bu', u \rangle = - \langle Bu, v \rangle |_0^T + \int_0^T \langle (Bu)', v \rangle
\]

The boundary term is of the form

\[
\langle Bu (0) - Bu (T), v (0) \rangle
\]

If \( * \) is to hold for all \( v \in D (T) \) we must have \( Bu (0) = Bu (T) \). If the difference is \( \xi \neq 0 \), you would need to have

\[
|\langle \xi, v (0) \rangle| \leq C_u \| v \| V
\]

for all \( v \in D (T) \). So pick \( v \in D (T) \) such that \( |\langle \xi, v (0) \rangle| = \delta > 0 \) and consider a piecewise linear function \( \psi_n \), which is one at 0 and \( T \) but zero on \([1/n, T - (1/n)]\). Then if \( v_n = \psi_n v \), the left side is \( \delta \) for all \( n \) but the right converges to 0.

This shows that \( D (T^*) = D (\Lambda) \) and \( T^* = \Lambda \). Now it follows that \( T^{**} = \Lambda^* \) and so \( \Lambda^* \) is monotone because \( T \) is and the graph of \( \Lambda^* \) is the closure of the graph of \( T \). Indeed,

\[
\int_0^T \langle -Bv', v \rangle = \int_0^T \langle Bv', v \rangle
\]

so \( \langle Tv, v \rangle = 0 \). The same is true of \( \Lambda^* \).
Now in this case we let \( X \) be the same as before. Then we consider the approximate problem for \( u \) given by

\[
\varepsilon \langle Lv, J^{-1}(Lu) \rangle + \langle Lu(\omega), v \rangle_{V',V} + \frac{1}{2} \langle Bu, v \rangle (0) - \frac{1}{2} \langle Bu, v \rangle (T) + \langle w^*_\varepsilon(\omega), v \rangle = \langle f(\omega), v \rangle,
\]

Then using monotonicity of \( \Lambda^* \) and \( \Lambda \) as before, one obtains the existence of a measurable solution. To see that the necessary monotonicity holds, note that

\[
\langle Lu, u \rangle_{V',V} + \frac{1}{2} \langle Bu, u \rangle (0) - \frac{1}{2} \langle Bu, u \rangle (T) = 0
\]

This follows from \( \mathbf{1} \) and \( \mathbf{2} \). Indeed, these imply that

\[
\langle Lu, u \rangle_{V',V} + \langle Bu, u \rangle (0) = \frac{1}{2} \left| \langle Bu, u \rangle (T) + \langle Bu, u \rangle (0) \right|
\]

and so the above follows. The rest of the argument is similar to that used to prove Theorem 76.3.2. At the end you will obtain that

\[
\frac{1}{2} \langle Bu, v \rangle (0) - \frac{1}{2} \langle Bu, v \rangle (T) = 0
\]

which will require that \( Bu(T) = Bu(0) \) since \( v \) is arbitrary.

### 76.3 Relaxed Coercivity Condition

This section is devoted to proving Theorem 76.3.2 below. It includes a more general coercivity condition and uses a slightly modified limit condition. Also, it removes the restriction that \( p \geq 2 \), which was made because of the terms involving \( B' \). However, we will specialize to the case where \( B \) does not depend on \( t \). It seems that this will be necessary because if one is required to consider \( \langle B'u, u \rangle \) then this won’t make sense unless \( p \geq 2 \). In what follows \( p > 1 \).

Let \( U \) be dense in \( V \) with the embedding compact, \( U \) being a separable reflexive Banach space. It is always possible to get such a space, (In fact, it can be assumed a Hilbert space.) but in applications of most interest to us, it can be obtained by Sobolev embedding theorems. We will let \( r > \max(2,p) \) and \( \mathcal{U}_r = L^r([0,T];U) \). Also, for \( I = [0,\tilde{T}] \), \( \tilde{T} < T \), we will denote as \( \mathcal{V}_I \) the space \( L^p(I;V) \) with a similar usage of this notation in other situations. If \( u \in \mathcal{V} \), then we will always consider \( u \in \mathcal{V}_I \) also by simply considering its restriction to \( I \). With this convention, it is clear that if \( u \) is measurable into \( \mathcal{V} \) then it is also measurable into \( \mathcal{V}_I \).

Then the modified conditions on \( A : \mathcal{V}_I \to \mathcal{P}(\mathcal{V}'_I) \) are as follows for \( A(u,\omega) \) a convex closed set in \( \mathcal{V}'_I \) whenever \( u \in \mathcal{V}_I \).
growth estimate
Assume the specific estimate for $u \in \mathcal{V}_I$.

$$\sup \left\{ \|u^*\|_{\mathcal{V}_I'} : u^* \in A(u, \omega) \right\} \leq a(\omega) + b(\omega) \|u\|_{\mathcal{V}_I}^{p-1} \quad (76.3.19)$$

where $a(\omega), b(\omega)$ are nonnegative.

coercivity estimate
Also assume the coercivity condition: valid for each $t \leq T$ and for some $\lambda(\omega) \geq 0$,

$$\inf \left( \int_0^t \langle u^*, u \rangle + \lambda(\omega) \langle Bu, u \rangle \, ds : u^* \in A(u, \omega) \right) \geq \delta(\omega) \int_0^t \|u\|_{\mathcal{V}_I'}^p \, ds - m(\omega) \quad (76.3.20)$$

where $m(\omega)$ is some nonnegative constant for fixed $\omega$, and $\delta(\omega) > 0$. No uniformity in $\omega$ is necessary.

Limit conditions
Let $U$ be a Banach space dense and compact in $V$ and that if $u_i \rightharpoonup u$ in $\mathcal{V}_I$ and $u_i^* \in A(u_i, \omega)$ with $(Bu_i) \rightharpoonup (Bu)'$ weakly in $\mathcal{U}_I'$, then if

$$\limsup_{i \to \infty} \langle u_i^*, u_i - u \rangle_{\mathcal{V}_I', \mathcal{V}_I} \leq 0 \quad (76.3.21)$$

it follows that for all $v \in \mathcal{V}_I$, there exists $u^*(v) \in Au$ such that

$$\liminf_{i \to \infty} \langle u_i^*, u_i - v \rangle_{\mathcal{V}_I', \mathcal{V}_I} \geq \langle u^*(v), u - v \rangle_{\mathcal{V}_I', \mathcal{V}_I} \quad (76.3.22)$$

You typically obtain this kind of thing from Theorem 76.1.2 applied to lower order terms along with some sort of compactness of the embedding of $V$ into $W$.

measurability condition
For $\omega \to u(\cdot, \omega)$ measurable into $\mathcal{V}$,

$$\omega \to A(X_I u(\cdot, \omega), \omega) \text{ has a measurable selection into } \mathcal{V}_I'. \quad (76.3.23)$$

This condition means there is a function $\omega \to u^*(\omega)$ which is measurable into $\mathcal{V}_I'$ such that $u^*(\omega) \in A(X_I u(\cdot, \omega), \omega)$. This is assured to take place if the following standard measurability condition is satisfied for all $O$ open in $\mathcal{V}_I'$:

$$\{ \omega : A(X_I u(\cdot, \omega), \omega) \cap O \neq \emptyset \} \in \mathcal{F} \quad (76.3.24)$$

A sufficient condition for this condition is that $\omega \to A(u(\cdot, \omega), \omega)$ has a measurable selection into $\mathcal{V}$ for any $\omega \to u(\cdot, \omega)$ measurable into $\mathcal{V}$ and if $u^* \in A(u(\cdot, \omega), \omega)$, then $X_I u^* \in A(X_I u(\cdot, \omega), \omega)$, and this is typical of what we will always consider, in which the values of $u^*$ are dependent on the earlier values of $u$ only.
Let $F$ be the duality map for $r$. Thus
\[ \langle Fu, u \rangle = \|u\|^r, \quad \|Fu\| = \|u\|^{r-1} \]
and is a demicontinuous map. Let $X$ be those $u \in \mathcal{U}_r$ such that $(Bu)' \in \mathcal{U}_r'$ with a convenient norm given by $\max \left( \|u\|_{\mathcal{U}_r}, \| (Bu)' \|_{\mathcal{U}_r'} \right)$. Then if we let $\mathcal{U}_r I$ play the role of $\mathcal{V}_I$ in Theorem 76.2.2, we obtain the following lemma as a corollary of this theorem.

**Lemma 76.3.1** Let $A$ satisfy [76.3.76.3] and let $f$ be measurable into $\mathcal{V}'$ and let $u_0$ be measurable into $W$. Then for $\varepsilon > 0$, there exists a solution to
\[ Lu + \varepsilon Fu + u^* = f, \quad Bu(0, \omega) = Bu_0(\omega) \quad (76.3.25) \]
such that $Lu, u^*, u$ are all measurable into $\mathcal{U}_r, \mathcal{U}_r^r$, and $\mathcal{U}_r$ respectively, $u^*(\omega) \in A(u, \omega)$. In other terms, for $v \in X = \{ u \in \mathcal{U}_r : Lu \in \mathcal{U}_r' \}$
\[ \int_0^T \langle Lu, v \rangle + \varepsilon \int_0^T \langle Fu, v \rangle + \int_0^T \langle u^*, v \rangle + \langle Bu, v \rangle(0) = \int_0^T \langle f, v \rangle + \langle Bv(0), u_0 \rangle \quad (76.3.26) \]

**Proof:** Using easy estimates and the definition that $r > \max(p, 2)$, it is routine to show that the earlier coercivity condition holds for $\varepsilon F + A(\cdot, \omega)$. Indeed, we have the following from the above assumptions.
\[
\inf \left( \int_0^t \langle u^*, u \rangle + \lambda(\omega) \langle Bu, u \rangle \ ds : u^* \in A(u, \omega) \right) \\
\geq \delta(\omega) \int_0^t \|u\|^p_{\mathcal{V}} \ ds - m(\omega)
\]
Thus,
\[
\inf \left( \int_0^t \langle u^*, u \rangle : u^* \in A(u, \omega) \right) \geq \delta(\omega) \int_0^t \|u\|^p_{\mathcal{V}} \ ds \\
- C_B \lambda(\omega) \int_0^t \eta \left( \frac{1}{\eta} \right) \|u\|^2_{\mathcal{V}} - m(\omega)
\]
Then the right side is no smaller than
\[
- C_B \lambda(\omega) \int_0^t \left( \frac{1}{\eta} \right) \eta \|u\|^2_{\mathcal{V}} - m(\omega) \\
\geq - C_B \lambda(\omega) \eta^{r/2} \int_0^t \|u\|^r_{\mathcal{V}} - C_B \lambda(\omega) T \left( \frac{1}{\eta} \right)^{r/(r-2)} - m(\omega)
\]
Then picking $\eta$ small enough, we obtain $C_B \lambda(\omega) \eta^{r/2} < \varepsilon/2$. 
Both operators $\varepsilon F$ and $A(\cdot, \omega)$ are pseudomonotone as maps from $X$ to $\mathcal{P}(X')$ where $X$ is defined in terms of $U_{\epsilon_1}$ as before. Therefore, the existence of the measurable solution is obtained.

Denoting with $u_\varepsilon$ the above solution, suppose $L u_\varepsilon \to L u$ weakly in $U'$ with $L u = (B u)' \in V'$ and $u_\varepsilon \to u$ weakly in $V$ and $u_\varepsilon^* \to u^*$ in $V'$, $\varepsilon F u_\varepsilon \to 0$ strongly in $U'$. Thus, passing to the limit in (76.3.24) we obtain $L u \in V'$ because it equals something in $V'$. We will show this below by an argument that $\varepsilon F u_\varepsilon \to 0$ strongly in $U'$.

Written differently, the $u_\varepsilon$ satisfy the following for all $v \in X$.

$$
\int_0^T \langle L u_\varepsilon, v \rangle + \langle B u_\varepsilon, v \rangle(0) + \int_0^T \langle u_\varepsilon^*, v \rangle
+ \varepsilon \int_0^T \langle F u_\varepsilon, u_\varepsilon \rangle = \int_0^T \langle f, v \rangle + \langle B v(0), u_0 \rangle
$$

and

$$
B u_\varepsilon(t) = B u_0 + \int_0^t L u_\varepsilon(s) \, ds
$$

The weak convergence of $L u_\varepsilon$ implies that $B u_\varepsilon(t) \to B u(t)$ in $U'$. Thus

$$
B u(t) = B u_0 + \int_0^t L u(s) \, ds
$$

and so $B u(0) = B u_0$. We will show that there exist suitable subsequences such that the kind of convergence just described will hold.

Using the equation to act on $u$ in (76.3.24) or in (76.3.27) we obtain from the assumed coercivity condition the following for fixed $\omega$,

$$
\frac{1}{2} \langle B u, u \rangle(t) - \frac{1}{2} \langle B u, u \rangle(0) + \varepsilon \int_0^t \|u\|_{U'}^p \, ds + \delta(\omega) \int_0^t \|u\|_V^p \, ds - m(\omega)
\leq \lambda(\omega) \int_0^t \langle B u, u \rangle(s) \, ds + \int_0^t \langle f, u \rangle(s) \, ds
$$

From Gronwall’s inequality, one obtains an estimate of the form

$$
\langle B u, u \rangle(t) + \varepsilon \int_0^T \|u\|_{U'}^p \, ds + \int_0^T \|u\|_V^p \, ds \leq C(f, \omega)
$$

where the constant depends only on the indicated quantities. It follows from this and the definition of the duality map $F$ that if $u_\varepsilon$ is the solution to Lemma 76.3.1, then $\varepsilon F u_\varepsilon \to 0$ strongly in $U'$. Also, the estimates for $A$ and the above estimate implies that $L u_\varepsilon$ is bounded in $U'$. Thus we have an inequality of the form

$$
\langle B u_\varepsilon, u_\varepsilon \rangle(t) + \varepsilon \int_0^T \|u_\varepsilon\|_{U'}^p \, ds + \|u_\varepsilon\|_V^p + \|L u_\varepsilon\|_{U'} + \|u_\varepsilon^*\|_{V'} \leq C(f, \omega)
$$
Of course each of these \( u_\varepsilon, u_\varepsilon^* \) are measurable into \( V \) and \( U' \) respectively. By density considerations, \( u_\varepsilon^* \) is also measurable into \( V' \). It follows from Theorem 76.1.3 that there exists \((u, u^*)\) which is measurable into \( V \times V' \) and a sequence with \( \varepsilon(\omega) \) such that as \( \varepsilon(\omega) \to 0 \), \( (u_\varepsilon(\omega), u_\varepsilon^*(\omega)) \to (u(\omega), u^*(\omega)) \) in \( V \times V' \). Then, taking a further subsequence, we can obtain the following convergences for fixed \( \omega \).

\[
\begin{align*}
  u_\varepsilon(\omega) &\to u(\omega) \text{ weakly in } V \\
u_\varepsilon^*(\omega) &\to u^*(\omega) \text{ weakly in } V' \\
  Lu_\varepsilon(\omega) &\to Lu \text{ weakly in } U'.
\end{align*}
\]

These convergences continue to hold for \( V \) and \( U' \) replaced with \( V_I \) and \( U'_I \) and we simply consider the restrictions of the functions to \( I \). The problem here is that we do not know that \( u \) is in \( U \). This is why it is necessary to take a little different approach.

Letting \( \sigma > 0 \), there exists \( \tilde{T}(\omega) > T - \sigma \) such that for each \( \varepsilon(\omega) \) in that sequence,

\[
\langle Bu_\varepsilon(\omega), u_\varepsilon(\omega) \rangle \left( \tilde{T} \right) = \langle B \left( u_\varepsilon(\omega) \left( \tilde{T} \right) \right), u_\varepsilon(\omega) \left( \tilde{T} \right) \rangle, \quad Bu_\varepsilon \left( \tilde{T} \right) = B \left( u_\varepsilon \left( \tilde{T} \right) \right)
\]

for all \( \varepsilon(\omega) \) in the sequence converging to 0 and also

\[
Bu \left( \tilde{T} \right) = B \left( u \left( \tilde{T} \right) \right), \quad \langle Bu, u \rangle \left( \tilde{T} \right) = \langle B \left( u \left( \tilde{T} \right) \right), u \left( \tilde{T} \right) \rangle.
\]

Now let \( \{e_i\} \) be the vectors of Theorem 76.1.4 where these are in \( U \). Thus for \( \tilde{T} \),

\[
\langle Bu_\varepsilon, u_\varepsilon \rangle \left( \tilde{T} \right) = \langle Bu_\varepsilon \left( \tilde{T} \right), u_\varepsilon \left( \tilde{T} \right) \rangle = \sum_{i=1}^{\infty} \left\langle B \left( u_\varepsilon \left( \tilde{T} \right) \right), e_i \right\rangle^2
\]

Hence, by Fatou’s lemma,

\[
\liminf_{\varepsilon \to 0} \langle Bu_\varepsilon, u_\varepsilon \rangle \left( \tilde{T} \right) = \liminf_{\varepsilon \to 0} \sum_{i=1}^{\infty} \left\langle B \left( u_\varepsilon \left( \tilde{T} \right) \right), e_i \right\rangle^2 \geq \sum_{i=1}^{\infty} \liminf_{\varepsilon \to 0} \left\langle B \left( u_\varepsilon \left( \tilde{T} \right) \right), e_i \right\rangle^2 = \sum_{i=1}^{\infty} \langle Bu_\varepsilon \left( \tilde{T} \right), e_i \rangle^2 \geq \sum_{i=1}^{\infty} \left\langle Bu \left( \tilde{T} \right), e_i \right\rangle^2 \geq \langle B \left( u \left( \tilde{T} \right) \right), u \left( \tilde{T} \right) \rangle = \langle Bu, u \rangle \left( \tilde{T} \right) \tag{76.3.29}
\]
Then by (76.3.29), we can obtain
\[
\frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle \left( \hat{T} \right) - \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle \left( 0 \right) + \int_0^\hat{T} \varepsilon \langle Fu_\varepsilon, u_\varepsilon \rangle \, dt + \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon \rangle = \int_0^\hat{T} \langle f, u_\varepsilon \rangle
\]
(76.3.30)

From what was shown above, \( \langle Bu_\varepsilon, u_\varepsilon \rangle \left( 0 \right) = \langle Bu_0, u_0 \rangle \). Now passing to the limit as \( \varepsilon \to 0 \),

\[ Lu + u^* = f \]
in \( \mathcal{U}' \). But every term is in \( \mathcal{V}' \) except the first and so it is also in \( \mathcal{V}' \). Also, we know that \( \langle Bu_\varepsilon, u_\varepsilon \rangle \left( 0 \right) = \langle Bu_0, u_0 \rangle \) and by Theorem (76.1.29) \( \langle Bu, u \rangle \left( 0 \right) = \langle Bu_0, u_0 \rangle \) also. Then the integration by parts formula yields

\[
\frac{1}{2} \langle Bu, u \rangle \left( \hat{T} \right) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \int_0^\hat{T} \langle u^*, u \rangle \, dt = \int_0^\hat{T} \langle f, u \rangle \, dt
\]
which shows

\[
\int_0^\hat{T} \langle u^*, u \rangle \, dt = \int_0^\hat{T} \langle f, u \rangle \, dt - \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu, u \rangle \left( \hat{T} \right)
\]

Then from (76.3.31) and the lower semicontinuity shown in (76.3.34) it follows that

\[
\limsup_{\varepsilon \to 0} \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon \rangle \leq \int_0^\hat{T} \langle f, u \rangle \, dt + \frac{1}{2} \langle Bu_0, u_0 \rangle - \liminf_{\varepsilon \to 0} \frac{1}{2} \langle Bu_\varepsilon, u_\varepsilon \rangle \left( \hat{T} \right)
\]

\[
\leq \int_0^\hat{T} \langle f, u \rangle \, dt + \frac{1}{2} \langle Bu_0, u_0 \rangle - \frac{1}{2} \langle Bu, u \rangle \left( \hat{T} \right) - \int_0^\hat{T} \langle u^*, u \rangle \, dt
\]

Thus we have \( u_\varepsilon \to u \) weakly in \( \mathcal{V} \) and \( (Bu_\varepsilon)' \to (Bu)' \) weakly in \( \mathcal{U}_I' \),

\[
\limsup_{\varepsilon \to 0} \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon - u \rangle \leq \int_0^\hat{T} \langle u^*, u \rangle - \int_0^\hat{T} \langle u^*, u \rangle = 0
\]

Therefore, by the limit condition (76.3), for any \( v \in \mathcal{V} \)

\[
\liminf_{\varepsilon \to 0} \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon - v \rangle \geq \int_0^\hat{T} \langle u^* \left( v \right), u - v \rangle, \text{ some } u^* \left( v \right) \in A \left( u, \omega \right)
\]

In particular, this holds for \( u \) and so, in fact, \( \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon - u \rangle \) converges to 0. Therefore,

\[
\int_0^\hat{T} \langle u^*, u - v \rangle = \lim_{\varepsilon \to 0} \int_0^\hat{T} \langle u_\varepsilon^*, u - v \rangle
\]

\[
\geq \liminf_{\varepsilon \to 0} \left( \int_0^\hat{T} \langle u_\varepsilon^*, u - u_\varepsilon \rangle + \int_0^\hat{T} \langle u_\varepsilon^*, u_\varepsilon - v \rangle \right)
\]

\[
\geq \int_0^\hat{T} \langle u^* \left( v \right), u - v \rangle, \text{ some } u^* \left( v \right) \in A \left( u, \omega \right)
\]
since \( v \) is arbitrary, this shows from separation theorems that \( u^* (\omega) \in A(u(\omega), \omega) \) in \( V'_0 \).

This has proved the following theorem in which a more general coercivity condition is used.

**Theorem 76.3.2** Suppose the conditions on \( A \) and \( f \) of Theorem 76.3.1 are satisfied. Also let \( u_0 \) be measurable into \( W \) and \( f \) measurable into \( V' \). Let \( B \in L(W, W') \) be nonnegative and self adjoint as described above. Let \( \sigma > 0 \) be small. Then there exist functions \( u, u^* \) measurable into \( V_{[0,T-\sigma]} \times V'_{[0,T-\sigma]} \) such that \( u^* (\omega) \in A(X_{[0,T-\sigma]} u(\omega), \omega) \) for each \( \omega \) and for \( t \leq T - \sigma \), for each \( \omega \),

\[
Bu(t) - Bu_0 + \int_0^t u^*(s) \, ds = \int_0^t f(s) \, ds
\]

Note that if for a given \( \omega \) there is a unique solution to the evolution equation, then we can obtain the solution on \((0, T)\). However, \( \sigma \) was totally arbitrary so it seems like there is not much difference between the above and the optimum solution. However, one could also index the above solutions relative to \( \sigma \), take an appropriate extension of each on \((T - \sigma, T)\) and get similar estimates and pass to a limit as above as \( \sigma \to 0 \) and thereby obtain a measurable solution valid on \((0, T)\).

This time, it will be clear that \( Lu, Lu^* \) are both in \( V' \) so a monotonicity condition will hold for \( L \) without the delicate argument given above which caused a smaller interval to be considered. Thus the following corollary will hold if enough additional details are considered. The issue does not seem sufficiently significant to justify the consideration of these details.

**Corollary 76.3.3** In the situation of Theorem 76.3.2 there exists the same kind of measurable solution valid on \((0, T)\). This time, \( u^*, u \) are measurable into \( V \) and \( V' \) respectively.

One can give a very interesting generalization of Theorem 76.3.2.

**Theorem 76.3.4** In the context of Theorem 76.3.2 let \( q(t, \omega) \) be a product measurable function into \( V \) such that \( t \to q(t, \omega) \) is continuous, \( q(0, \omega) = 0 \).

Then for each small \( \sigma \), there exists a solution \( u \) of the integral equation

\[
Bu(t, \omega) + \int_0^t u^*(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) + Bq(t, \omega), \quad t \leq T - \sigma
\]

where \((t, \omega) \to u(t, \omega)\) is product measurable. Moreover, for each \( \omega \), \( Bu(t, \omega) = B(u(t, \omega)) \) for a.e. \( t \) and \( u^*(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \) for a.e. \( t \), \( u^* \) is product measurable into \( V' \). Also, for each \( a \in [0, T - \sigma] \),

\[
Bu(t, \omega) + \int_a^t u^*(s, \omega) \, ds = \int_a^t f(s, \omega) \, ds + Bu(a, \omega) + Bq(t, \omega) - Bq(a, \omega)
\]
**Proof:** Define a stopping time
\[ \tau_r(\omega) \equiv \inf \{ t : |q(t, \omega)| > r \} \]
Then this is the first hitting time of an open set by a continuous random variable and so it is a valid stopping time. Then for each \( r \), let
\[ A_r(\omega, w) \equiv A(\omega, w + q^{\tau_r}(\cdot, \omega)) , \]
where the notation means \( q^{\tau_r}(t) \equiv q(t \wedge \tau_r) \). Then, since \( q^{\tau_r} \) is uniformly bounded, all of the necessary estimates and measurability for the solution to the above corollary hold for \( A_r \) replacing \( A \). Therefore, there exists a solution \( w_r \) to the inclusion
\[ (Bw_r)'(\omega, \omega) + A_r(w_r(\cdot, \omega), \omega) \ni f(\cdot, \omega), \ Bw_r(0, \omega) = Bu_0(\omega), \ t \in [0, T - \sigma/2] \]
Now for fixed \( \omega \), \( q^{\tau_r}(t, \omega) \) does not change for all \( r \) large enough. This is because it is a continuous function of \( t \) and so is bounded on the interval \([0, T - \sigma/2]\). Thus, for \( r \) large enough and fixed \( \omega \), \( q^{\tau_r}(t, \omega) = q(t, \omega) \). Thus, we obtain
\[ \langle Bw_r(t, \omega), w_r(t, \omega) \rangle + \int_0^t \| w_r(s, \omega) \|_V^p \, ds \leq C(\omega) \quad (76.3.31) \]
Now, as before in the proof of Theorem [76.3.2], one can pass to a limit involving a subsequence, as \( r(\omega) \to \infty \) and obtain a solution to the integral equation
\[ Bw(t, \omega) - Bu_0(\omega) + \int_0^t u^*(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds, \ t \in [0, T - \sigma] \]
where \( u^*(\omega) \in A(w(s, \omega) + q(s, \omega), \omega) \) and \( u^*, w \) are measurable into \( V'_{[0, T - \sigma]} \).
Now let \( u(t, \omega) = w(t, \omega) + q(t, \omega) \).
The last claim follows from letting \( t = a \) in the top equation and then subtracting this from the top equation with \( t > a \). □

### 76.4 Progressively Measurable Solutions

In the context of uniqueness of the evolution initial value problem for fixed \( \omega \), one can prove theorems about progressively measurable solutions fairly easily.

First is a definition of the term progressively measurable.

**Definition 76.4.1** Let \( \mathcal{F}_t \) be an increasing in \( t \) set of \( \sigma \) algebras of sets of \( \Omega \) where \((\Omega, \mathcal{F})\) is a measurable space. Thus each \( \mathcal{F}_t \) is a \( \sigma \) algebra and if \( s \leq t \), then \( \mathcal{F}_s \leq \mathcal{F}_t \). This set of \( \sigma \) algebras is called a filtration. A set \( S \subseteq [0, T] \times \Omega \) is called progressively measurable if for every \( t \subseteq [0, T] \),
\[ S \cap [0, t] \times \Omega \in \mathcal{B}([0, t]) \times \mathcal{F}_t \]
Denote by \( \mathcal{P} \) the progressively measurable sets. This is a \( \sigma \) algebra of subsets of \([0, T] \times \Omega \). A function \( g \) is progressively measurable if \( \mathcal{X}_{[0, t]}g \) is \( \mathcal{B}([0, t]) \times \mathcal{F}_t \) measurable for each \( t \).
Let $A$ satisfy the conditions but the last condition will be modified as follows.

**Condition 76.4.2** For each $t \leq T$, if $\omega \rightarrow u(\cdot, \omega)$ is $\mathcal{F}_t$ measurable into $\mathcal{V}_{[0,t]}$, then there exists a $\mathcal{F}_t$ measurable selection of $A(X_{[0,t]}u(\cdot, \omega), \omega)$ into $\mathcal{V}'_{[0,t]}$.

Note that $u(\cdot, \omega)$ is in $\mathcal{V}_{[0,t]}$ so $u(t, \omega) \in V$.

The theorem to be shown is the following.

**Theorem 76.4.3** Assume the above conditions, and. Let $u_0$ be $\mathcal{F}_0$ measurable and $(t, \omega) \rightarrow X_{[0,t]}(t) f(t, \omega)$ is $B(\mathbb{R}^n) \times \mathcal{F}_t$ product measurable into $V'$ for each $t$. Also assume that for each $\omega$, there is at most one solution $(u, u^*)$ to the evolution equation

$$Bu(\omega)(t) - Bu_0(\omega) + \int_0^t u^*(\cdot, \omega) ds = \int_0^t f(s, \omega) ds,$$

for $t \in [0, T]$. Then there exists a unique solution $(u(\cdot, \omega), u^*(\cdot, \omega))$ in $\mathcal{V}_{[0,T]} \times \mathcal{V}'_{[0,T]}$ to the above integral equation for each $\omega, t \in (0, T)$. This solution satisfies $(t, \omega) \rightarrow (u(t, \omega), u^*(t, \omega))$ is progressively measurable into $V \times V'$.

**Proof:** First note that Theorem there exists a solution on $[0, T - \sigma]$ for each small $\sigma > 0$. Then by uniqueness, there exists a solution on $(0, T)$. Let $T$ denote subsets of $(0, T - \sigma)$ which contain $T - \sigma$ such that for $S \in T$, there exists a solution $u_S$ for each $\omega$ to the above integral equation on $[0, T - \sigma]$ such that $(t, \omega) \rightarrow X_{[0,s]}(t) u_S(t, \omega)$ is $B(\mathbb{R}^n) \times \mathcal{F}_s$ measurable for each $s \in S$. Then $\{T - \sigma\} \in \mathcal{T}$. If $S, S'$ are in $\mathcal{T}$, then $S \subseteq S'$ will mean that $S \subseteq S'$ and also $u_S(t, \omega) = u_{S'}(t, \omega)$ in $V$ for all $t \in S$, similar for $u_S^*$ and $u_{S'}^*$. Now note how we are considering a particular representation of a function in $\mathcal{V}_{[0,T-\sigma]}$ and $\mathcal{V}'_{[0,T-\sigma]}$ because of the pointwise condition. Now let $C$ denote a maximal chain. Is $\cup C \equiv S_\infty$ all of $(0, T - \sigma)$? What is $u_{S_\infty}$? Define $u_{S_\infty}(t, \omega)$ the common value of $u_S(t, \omega)$ for all $S$ in $C$, which contain $t \in S_\infty$. If $s \in S_\infty$, then it is in some $S \in C$ and so the product measurability condition holds for this $s$. Thus $S_\infty$ is a maximal element of the partially ordered set. Is $S_\infty$ all of $(0, T - \sigma)$? Suppose $\delta \notin S_\infty, T - \sigma > \delta > 0$.

From Theorem there exists a solution to the integral equation on $[0, \delta]$ called $u_1$ such that $(t, \omega) \rightarrow u_1(t, \omega)$ is $B([0, \delta]) \times \mathcal{F}_s$ measurable, similar for $u_1^*$. By the same theorem, there is a solution on $[0, T - \sigma]$, $u_2$ which is $B([0, T - \sigma]) \times \mathcal{F}_{[0,T-\sigma]}$ measurable. Now by uniqueness, $u_2(\cdot, \omega) = u_1(\cdot, \omega)$ in $\mathcal{V}_{[0,\delta]}$, similar for $u_2^*$. Therefore, no harm is done in re-defining $u_2, u_2^*$ on $[0, \delta]$ so that $u_2(t, \omega) = u_1(t, \omega)$, for all $t \in [0, s]$, similar for $u^*$. Denote these functions as $\hat{u}, \hat{u}^*$. By uniqueness, $u_{S_\infty}(\cdot, \omega) = \hat{u}(\cdot, \omega)$ in $L^p([0, \delta], V)$. Thus no harm is done by re-defining $\hat{u}(s, \omega)$ to equal $u_{S_\infty}(s, \omega)$ for $s < \delta$ and $u_1(\delta, \omega)$ at $\delta$. As to $s > \delta$ also re define $\hat{u}(s, \omega) \equiv u_{S_\infty}(s, \omega)$ for such $s$. By uniqueness, the two are equal in $\mathcal{V}_{[\delta,T-\sigma]}$ and so no change occurs in the solution of the integral equation. Now $S_\infty$ was not maximal after all. $S_\infty \cup \{\delta\}$ is larger. This contradiction shows that in fact, $S_\infty = (0, T - \sigma)$.
there exists a unique progressively measurable solution to \( t^* \) on \([0, T - \sigma]\) for each small \( \sigma \). Thus we can simply use uniqueness to conclude the existence of a unique progressively measurable solution on \([0, T]\).

**Theorem 76.4.4** Assume the above conditions, \(76.3.3\) and \(76.4.3\). Let \( u_0 \) be \( \mathcal{F}_0 \) measurable and \((t, \omega) \rightarrow X_{[0, 1]}(t) f(t, \omega) \) is \( \mathcal{B}(\{0, 1\}) \times \mathcal{F}_t \) product measurable into \( V' \) for each \( t \in [0, T - \sigma] \). Also let \( t \rightarrow q(t, \omega) \) be continuous and \( q \) is progressively measurable into \( V \). Suppose there is at most one solution to

\[
Bu(t, \omega) + \int_0^t u^*(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega) + Bq(t, \omega),
\]

for each \( \omega \). Then the solution \( u \) to the above integral equation is progressively measurable and so is \( u^* \). Moreover, for each \( \omega, u^*(\cdot, \omega) \in A(u(\cdot, \omega), \omega) \). Also, for each \( \delta \in [0, T] \),

\[
Bu(\omega)(t) + \int_\delta^t u^*(s, \omega) \, ds = \int_\delta^t f(s, \omega) \, ds + Bu(\omega)(\delta) + Bq(t, \omega) - Bq(\delta, \omega)
\]

**Proof:** By Theorem \(76.3.3\) there exists a solution to \(76.3.3\) which is \( \mathcal{B}(\{0, T - \sigma\}) \times \mathcal{F}_{T - \sigma} \) measurable. Since this is true for all \( \sigma > 0 \), there exists a unique \( \mathcal{B}\left([0, \hat{T}]\right) \times \mathcal{F}_{\hat{T}} \) measurable solution for each \( \hat{T} < T \). Now, as in the proof of Theorem \(76.3.3\) one can define a new operator

\[
A_r(\omega, w) \equiv A(\omega, w + q^{\tau_r}(\cdot, \omega))
\]

where \( \tau_r \) is the stopping time defined there. Then, since \( q \) is progressively measurable, the progressively measurable condition is satisfied for this new operator. Hence by Theorem \(76.3.3\) there exists a unique solution \( w \) which is progressively measurable to the integral equation

\[
Bw_r(t, \omega) + \int_0^t u_r^*(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega)
\]

where \( u_r^*(\cdot, \omega) \in A_r(w(\cdot, \omega), \omega) \). Then you can let \( r \to \infty \) and eventually \( q^{\tau_r}(\cdot, \omega) = q(\cdot, \omega) \). Thus there is a solution to

\[
Bw(t, \omega) + \int_0^t u^*(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + Bu_0(\omega)
\]

where \( u^*(\cdot, \omega) \in A(w(\cdot, \omega) + Bq(\cdot, \omega), \omega) \), which is progressively measurable because \( w(\cdot, \omega) = \lim_{r \to \infty} w_r(\cdot, \omega) \) in \( V \) each \( w_r \) being progressively measurable. Uniqueness is needed in passing to the limit. Thus for each \( \hat{T} < T, \omega \rightarrow w(\cdot, \omega) \) is measurable into \( V_{[0, \hat{T}]} \). Then by Lemma \(76.4.4\) \( w \) has a representative in \( V_{[0, \hat{T}]} \) for each \( \omega \) such that the resulting function satisfies \((t, \omega) \rightarrow X_{[0, \hat{T}]}(t) w(t, \omega) \) is \( \mathcal{B}\left([0, \hat{T}]\right) \times \mathcal{F}_{\hat{T}} \) measurable into \( V \). Thus
one can assume that $w$ is progressively measurable. Now as in Theorem 76.3.4, Define $u = w + q$. It follows by uniqueness that there exists a unique progressively measurable solution to (76.3.5) on $(0, T)$.

The last claim follows from letting $t = a$ in the top equation and then subtracting this from the top equation with $t > a$. ■
Chapter 77

Including Stochastic Integrals

You can include stochastic integrals in the above formulation. In this section and from now on, we will assume that $W$ is a Hilbert space because the stochastic integrals featured here will have values in $W$ and the version of the stochastic integral to be considered here will be the Ito integral. Here is a brief review of this integral.

Let $U$ be a separable real Hilbert space and let $Q : U \to U$ be self adjoint and nonnegative. Also $H$ will be a separable real Hilbert space. $L_2(Q^{1/2}U, H)$ will denote the Hilbert Schmidt operators which map $Q^{1/2}U$ to $H$. Here $Q^{1/2}U$ is the Hilbert space which has an inner product given by

$$(y, z) \equiv \left(Q^{-1/2}y, Q^{-1/2}z \right)$$

where $Q^{-1/2}y$ denotes $x$ such that $Q^{1/2}x = y$ and out of all such $x$, this is the one which has the smallest norm. It is like the Moore Penrose inverse in linear algebra. Then one can define a stochastic integral

$$\int_0^t \Phi dW$$

where $\Phi \in L^2 ([0, T] \times \Omega; L_2(Q^{1/2}U, H))$ where here $\Phi$ is progressively measurable with respect to the filtration $F_t$. This filtration will be

$$F_t = \cap_{p \geq t} \sigma \{ W (r) - W (s) : 0 \leq s \leq r \leq p \}$$

The horizontal line indicates completion. The symbol

$$\sigma \{ W (r) - W (s) : 0 \leq s \leq r \leq p \}$$

indicates the smallest $\sigma$ algebra for which all those increments are measurable. Here $W(t)$ is a Wiener process which has values in $U_1$, some other Hilbert space,
maybe $H$. There is a Hilbert Schmidt operator $J \in \mathcal{L}_2 \left( Q^{1/2} U, U_1 \right)$ such that

$$W (t) = \sum_{i=1}^\infty \psi_i (t) J e_i$$

where the $\psi_i$ are independent real Wiener processes. You could take $U, U_1$ to both be $H$. This is following [15]. Then the stochastic integral has the following properties.

1. $\int_0^t \Phi dW$ is a martingale with respect to $\mathcal{F}_t$ with values in $H$, equal to 0 when $t = 0$.

2. One has the Itô isometry

$$E \left( \left| \int_0^t \Phi dW \right|^2 \right) = \int_0^t \| \Phi \|^2_{\mathcal{L}_2} d s$$

3. One can localize as follows. For $\tau$ a stopping time,

$$\int_0^{t \wedge \tau} \Phi dW = \int_0^t \chi_{[0, \tau]} \Phi dW$$

4. One can also generalize to the case where $\Phi$ is only progressively measurable and instead of being in $L^2 \left( [0, T] \times \Omega, \mathcal{L}_2 \left( Q^{1/2} U, H \right) \right)$, you have only that

$$P \left( \int_0^T \| \Phi (t) \|_{\mathcal{L}_2}^2 dt < \infty \right) = 1$$

This is done by using an appropriate sequence of stopping times called a localizing sequence. More generally a local martingale is a stochastic process $M (t)$ adapted to the filtration for which there is a localizing sequence of stopping times $\{ \tau_n \}$ such that $\lim_{n \to \infty} \tau_n = \infty$ and $M^{\tau_n}$ is a martingale. Local martingales will occur in the estimates which are encountered in what follows.

5. Denoting by $M (t)$ the stochastic integral, $M (t) = \int_0^t \Phi dW$, the quadratic variation is given by

$$[M] (t) = \int_0^t \| \Phi \|^2_{\mathcal{L}_2} d s$$

6. We will also need a part of the Burkholder Davis Gundy inequality [70], Theorem 6.14.4 which in terms of this stochastic integral is of the form

$$\int_\Omega M^* d P \leq C E \left( \left( \int_0^T \| \Phi \|^2_{\mathcal{L}_2} d s \right)^{1/2} \right), \ C \text{ some constant}$$

where $M (t)$ is the above stochastic integral and

$$M^* = \sup \{ \| M (t) \|_H : t \in [0, T] \}$$
Now let $\Phi \in L^2 \left( \left[0, T\right] \times \Omega; L^2 \left( Q^{1/2}U, W\right) \right)$. Let an orthonormal basis for $Q^{1/2}U$ be $\{g_i\}$ and an orthonormal basis for $W$ be $\{f_i\}$. Then $\{f_i \otimes g_i\}$ is an orthonormal basis for $L^2 \left( Q^{1/2}U, W\right)$. Hence,

$$
\Phi = \sum_i \sum_j \Phi_{ij} f_i \otimes g_j
$$

where $f_i \otimes g_j \equiv (g_j, y)_{Q^{1/2}U} f_i$. Let $E$ be a separable real Hilbert space which is dense in $V$. Then without loss of generality, one can assume that the orthonormal basis for $W$ are all vectors in $E$. Thus the orthogonal projection of $\Phi$ onto the closed subspace span $\{(f_i \otimes g_i), i, j \leq n\}$ given by

$$
\Phi_n = \sum_{i=1}^n \sum_{j=1}^n \Phi_{ij} f_i \otimes g_j
$$

Then $\Phi_n \in L^2 \left( \left[0, T\right] \times \Omega; L^2 \left( Q^{1/2}U, E\right) \right)$ and also

$$
\lim_{n \to \infty} \|\Phi_n - \Phi\|_{L^2 \left( \left[0, T\right] \times \Omega; L^2 \left( Q^{1/2}U, W\right) \right)} = 0
$$

and $\int_0^t \Phi_n dW$ is continuous and progressively measurable into $E$ hence into $V$. We can take a subsequence such that $\|\Phi_n - \Phi\|_{L^2 \left( \left[0, T\right] \times \Omega; L^2 \left( Q^{1/2}U, W\right) \right)} < 2^{-n}$ and this will be assumed whenever convenient.

Note that if $P_n$ is the orthogonal projection onto span $\{f_1, \cdots, f_n\}$, then

$$
|P_n \Phi (y)|_W = \left| \sum_{i=1}^n \sum_{j=1}^n \Phi_{ij} f_i \otimes g_j (y) \right|_W = \left| \sum_{i=1}^n \sum_{j=1}^n \Phi_{ij} f_i (y, g_j) \right|_W = \left| \sum_{i=1}^n \sum_{j=1}^n \Phi_{ij} f_i (y, g_j) \right|_W = |\Phi_n (y)|_W
$$

Thus

$$
\left| \int_s^t \Phi_n dW \right|_W \leq \left| \int_s^t P_n \Phi dW \right|_W = \left| P_n \int_s^t \Phi dW \right|_W \leq \left| \int_s^t \Phi dW \right|_W.
$$

The following corollary will be useful.
Corollary 77.0.1 Let \( \Phi_n \) be as described above. Then

\[
\| \Phi_n(t, \omega) \|_{L_2(Q^{1/2}U,W)} \leq \| \Phi(t, \omega) \|_{L_2(Q^{1/2}U,W)}
\]

where \( \| \Phi_n(t, \omega) \|_{L_2(Q^{1/2}U,W)} \uparrow \| \Phi(t, \omega) \|_{L_2(Q^{1/2}U,W)} \)

\( \Phi \in L^\alpha \left( \Omega; L^\infty \left( [0, T], L_2 \left( Q^{1/2}U, W \right) \right) \right) \cap L^2 \left( [0, T] \times \Omega, L_2 \left( Q^{1/2}U, W \right) \right) \)

where \( \alpha > 2 \). Then off a set of measure zero, the stochastic integrals \( \int_0^t \Phi_n dW \) satisfy

\[
\sup_n \sup_{t \neq s} \frac{\left\| \int_s^t \Phi_n dW \right\|}{|t-s|^\gamma} < C(\omega), \gamma < 1/2, \gamma = \frac{\alpha/2 - 1}{\alpha}
\]

Proof: Let, \( \alpha > 2 \). As explained above, \( |\int_s^t \Phi_n dW| \leq |\int_s^t \Phi dW| \). Thus by the Burkholder Davis Gundy inequality,

\[
\sup_n \left| \int_s^t \Phi_n dW \right| \leq \left| \int_s^t \Phi dW \right|
\]

\[
\int_\Omega \left( \left| \int_s^t \Phi dW \right| \right)^\alpha dP \leq C \int_\Omega \left( \int_s^t \| \Phi \|_2^2 dt \right)^{\alpha/2} dP
\]

\[
\leq C \int_\Omega \| \Phi \|_{L^\infty([0,T], L_2(Q^{1/2}U,W))} \| \Phi \|_{L^2([0,T], L_2(Q^{1/2}U,W))} |t-s|^\alpha/2 dP
\]

\[
\leq C \| \Phi \|_{L^\alpha(\Omega; L^\infty([0,T], L_2(Q^{1/2}U,W))))} \| \Phi \|_{L^2([0,T], L_2(Q^{1/2}U,W))} |t-s|^\alpha/2 dP
\]

Then by the Kolmogorov Čentsov theorem, for \( \gamma \) as given,

\[
E \left( \sup_{0 \leq s < t \leq T} \sup_n \frac{\left| \int_s^t \Phi_n dW \right|}{(t-s)^\gamma} \right) \leq E \left( \sup_{0 \leq s < t \leq T} \frac{\left| \int_s^t \Phi dW \right|}{(t-s)^\gamma} \right) \leq C
\]

where \( \gamma < \beta/\alpha \) where, \( \beta + 1 = \alpha/2 \). Thus for \( \gamma < \frac{\alpha/2 - 1}{\alpha} \),

\[
\sup_n \sup_{0 \leq s < t \leq T} \frac{\left| \int_s^t \Phi_n dW \right|}{(t-s)^\gamma} \leq C(\omega)
\]

for all \( \omega \) off a set of measure zero. \( \blacksquare \)

Recall the following conditions for the various operators.

**Bounded and coercive conditions**
A (·, ω), A (·, ω) : \mathcal{V}_I \to \mathcal{V}'_I for each I a subinterval of [0, T] I = [0, \bar{T}], \bar{T} \leq T

A (·, ω) : \mathcal{V}_I \to \mathcal{P}(\mathcal{V}'_I) is bounded, \quad (77.0.1)

If, for u \in \mathcal{V},

\begin{align*}
u^* X_{[0, \bar{T}]} & \in A \left( u X_{[0, \bar{T}]} , \omega \right) \\
\end{align*}

for each \bar{T} in an increasing sequence converging to T, then

\begin{align*}u^* & \in A (u, \omega) \quad (77.0.2)\end{align*}

Assume the specific estimate

\begin{align*}
sup \left\{ \|u^*\|_{\mathcal{V}'_I} : u^* \in A (u, \omega) \right\} & \leq a (\omega) + b (\omega) \|u\|_{\mathcal{V}_I}^{p-1} \quad (77.0.3)\end{align*}

where a (\omega), b (\omega) are nonnegative. Also assume the following coercivity estimate valid for each t \leq T and for some \lambda (\omega) \geq 0,

\begin{align*}
inf \left( \int_0^t \langle u^* , u \rangle + \lambda (\omega) (Bu , u) dt : u^* \in A (u, \omega) \right) & \geq \delta (\omega) \int_0^t \|u\|_{\mathcal{V}_I}^p ds - m (\omega) \quad (77.0.4)\end{align*}

where m (\omega) is some nonnegative constant, \delta (\omega) > 0.

**Monotonicity**

It will also be assumed that \lambda (\omega) B + A is monotone in the sense that

\begin{align*}
\int_0^t \langle \lambda (\omega) Bu + u^* - \lambda (\omega) Bv + v^* , u - v \rangle ds \geq 0
\end{align*}

for a suitable choice of \lambda (\omega) whenever u^* \in A (u, \omega), v^* \in A (v, \omega).

**Limit condition**

Let U be a Banach space dense in V and that if u_i \rightharpoonup u in \mathcal{V}_I and u_i^* \in A (u_i) with u_i^* \rightharpoonup u^* in \mathcal{V}'_I and t \to Bu_i (t) is continuous and

\begin{align*}
\sup_i \sup_{t \neq s} \frac{\|Bu_i (t) - Bu_i (s)\|_{\mathcal{V}'_I}}{|t - s|^{\alpha}} & \leq C \quad (77.0.5)\end{align*}

then if

\begin{align*}
\limsup_{i \to \infty} \langle u_i^* , u_i - u \rangle_{\mathcal{V}'_I, \mathcal{V}_I} & \leq 0 \quad (77.0.6)\end{align*}

it follows that for all v \in \mathcal{V}_I, there exists u^* (v) \in Au such that

\begin{align*}
\liminf_{i \to \infty} \langle u_i^* , u_i - v \rangle_{\mathcal{V}'_I, \mathcal{V}_I} & \geq \langle u^* (v) , u - v \rangle_{\mathcal{V}'_I, \mathcal{V}_I} \quad (77.0.7)\end{align*}

As to B (\omega), it is k (\omega) B where B \in \mathcal{L} (W, W') and is self adjoint and nonnegative where k is \mathcal{F}_0 measurable.
Progressively measurable condition

**Condition 77.0.2** For each \( t \leq T \), if \( \omega \rightarrow u(\cdot, \omega) \) is \( \mathcal{F}_t \) measurable into \( \mathcal{V}_{[0,t]} \), then there exists a \( \mathcal{F}_t \) measurable selection of \( A(u(\cdot, \omega), \omega) \) into \( \mathcal{V}_{[0,t]} \).

Then there is a theorem. It was Theorem 75.7.4 which gave existence and uniqueness of progressively measurable solutions \( u \) to the integral equation.

**Theorem 77.0.3** Assume the above conditions, 77.0.1 - , 77.0.7 along with the progressive measurability condition 77.0.2. Let \( u_0 \) be \( \mathcal{F}_0 \) measurable and \( \omega \rightarrow B(\omega) \) also \( \mathcal{F}_0 \) measurable and \( (t, \omega) \rightarrow X_{[0,t]}(t) f(t, \omega) \) is \( B([0,t]) \times \mathcal{F}_t \) product measurable into \( V' \) for each \( t \).

\[
B(\omega) = k(\omega) B, \ k(\omega) \geq 0, \ k \text{ measurable.}
\]

Also let \( t \rightarrow q(t, \omega) \) be continuous and \( q \) is progressively measurable into \( V \). Suppose there is at most one solution to

\[
Bu(t, \omega) + \int_0^t z(s, \omega) ds = \int_0^t f(s, \omega) ds + Bu_0(\omega) + Bq(t, \omega), \quad (77.0.8)
\]

for each \( \omega \). Then the solution to the above integral equation \( u \) is progressively measurable. Moreover, for each \( \omega \), both \( Bu(t, \omega) = B(u(t, \omega)) \) for a.e. \( t \) and \( z(t, \omega) \in A(u(t, \omega), \omega) \) for a.e. \( t \). Also, for each \( a \in [0, T] \),

\[
Bu(t, \omega) + \int_a^t z(s, \omega) ds = \int_a^t f(s, \omega) ds + Bu(a, \omega) + Bq(t, \omega) - Bq(a, \omega)
\]

Letting \( q(t) = \int_0^t \Phi_n dW \) defined above with the filtration also being the one obtained from the Wiener process, this implies the following theorem. The \( \sigma \) algebra of progressively measurable sets will be denoted by \( \mathcal{P} \).

**Theorem 77.0.4** Assume the above conditions, 77.0.1 - , 77.0.7 along with the progressive measurability condition 77.0.2. Also assume there is at most one solution to 77.0.8 where

\[
q(t, \cdot) = \int_0^t \Phi_n dW
\]

Then there exists a \( \mathcal{P} \) measurable \( u_n \) such that also \( z_n \) is progressively measurable

\[
Bu_n(t, \omega) - Bu_0(\omega) + \int_0^t z_n(s, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi_n dW
\]

where for each \( \omega, \ z_n(\cdot, \omega) \in A(u_n(\cdot, \omega), \omega) \). The function \( Bu_n(t, \omega) = B(u_n(t, \omega)) \) for a.e. \( t \).

This gives an existence theorem for the inclusion of a stochastic integral. However, it is desired to get a similar result for \( \Phi \) rather than \( \Phi_n \). Next is the Ito formula which is useable because of the progressive measurability of \( u_n, z_n \). This formula applies to the following situation.
Situation 77.0.5 Let \( X \) have values in \( V \) and satisfy the following
\[
BX(t) = BX_0 + \int_0^t Y(s) \, ds + B \int_0^t Z(s) \, dW(s),
\]
(77.0.9)
\( X_0 \in L^2(\Omega;W) \) and is \( \mathcal{F}_0 \) measurable, where \( Z \) is \( L^2(Q^{1/2}U,W) \) progressively measurable and
\[
\|Z\|_{L^2([0,T] \times \Omega, L_2(Q^{1/2}U,W))} < \infty.
\]
This is what is needed to define the stochastic integral in the above formula.
Assume \( X, Y \) satisfy
\[
BX, Y \in K' \equiv L^{p'}([0,T] \times \Omega; V'),
\]
the \( \sigma \) algebra of measurable sets defining \( K' \) will be the progressively measurable sets. Here \( 1/p' + 1/p = 1, \ p > 1. \)

Also the sense in which the equation holds is as follows. For a.e. \( \omega \), the equation holds in \( V' \) for all \( t \in [0,T] \). Thus we are considering a particular representative \( X \) of \( K \) for which this happens. \textbf{Also it is only assumed that} \( BX(t) = B(X(t)) \) \textbf{for a.e.} \( t. \) \textbf{Thus \( BX \) is the name of a function having values in \( V' \) for which} \( BX(t) = B(X(t)) \) \textbf{for a.e.} \( t, \) all \( t \notin N_\omega \) \textbf{a set of measure zero. Assume that} \( X \) is progressively measurable also and \( X \in L^p([0,T] \times \Omega, V) \).

Then in the above situation, we obtain the following integration by parts formula which is called the Ito formula. This particular version is presented in Theorem 77.0.6 and is a generalization of work of Krylov. A proof of the case of a Gelfand triple in which \( B = I \) is in [98].

**Theorem 77.0.6** In Situation 77.0.5, for \( \omega \) off a set of measure zero, for every \( t \in N_\omega^C \), the measure of \( N_\omega \) equalling 0,
\[
\langle BX(t), X(t) \rangle = \langle BX_0, X_0 \rangle + \int_0^t 2 \langle Y(s), X(s) \rangle \, ds + \int_0^t \langle BZ, Z \rangle_{L_2} \, ds + 2M(t)
\]
(77.0.10)
where \( M(t) \) is a stochastic integral and a local martingale equal to 0 when \( t = 0. \) Also, there exists a unique continuous, progressively measurable function denoted as \( \langle BX, X \rangle \) such that it equals \( \langle BX(t), X(t) \rangle \) for a.e. \( t \) and \( \langle BX, X \rangle(t) \) equals the right side of the above for all \( t. \) In addition to this,
\[
E(\langle BX, X \rangle(t)) =
\]
\[
E(\langle BX_0, X_0 \rangle) + E\left( \int_0^t (2 \langle Y(s), X(s) \rangle + \langle BZ, Z \rangle_{L_2}) \, ds \right)
\]
(77.0.11)
Also the quadratic variation of \( M(t) \) in (77.0.14) is dominated by
\[
C \int_0^t \| Z \|^2_{L_2} \| BX \|^2_W \, ds
\]
for a suitable constant \( C \). Also \( t \to BX(t) \) is continuous with values in \( W' \) for \( t \in N'_\omega \). In fact, this martingale can be written as
\[
\int_0^t (Z \circ J^{-1})^* BX \circ JdW
\]
That ugly integral displayed above can be written in the form
\[
\int_0^t \langle BX, dN \rangle
\]
where \( N(t) = \int_0^t Z(s) \, dW \).

Now we consider the meaning of the symbol \( \langle BZ, Z \rangle_{L_2} \). You begin with a complete orthonormal set \( \{ g_i \} \) in \( Q^{1/2}U \). Then to say that \( Z \) has values in \( L_2(Q^{1/2}U;W) \) is to say that
\[
\sum_i (z(g_i), e_j)^2 = \sum_i \| Z(g_i) \|_{W}^2 < \infty
\]
where \( \{ e_j \} \) is an orthonormal basis in \( W \). You can let it be the one used earlier where each is actually in \( V \) or even in \( E \). Then the symbol means
\[
(R^{-1}BZ, Z)_{L_2}
\]
where \( R \) is the Riesz map from the Hilbert space \( W \) to its dual space. Thus it equals
\[
\sum_i (R^{-1}BZ(g_i), Z(g_i))_W = \sum_i (BZ(g_i), Z(g_i))
\]
so it is seen to be nonnegative.

Now apply this Ito formula to Theorem 77.0.4 in which we make the assumptions there on \( \| u_0 \| \in L^2(\Omega) \) and that \( f \in L^p([0,T] \times \Omega;V') \) where the \( \sigma \) algebra is \( \mathcal{P} \) the progressively measurable \( \sigma \) algebra, and
\[
\Phi \in L^2 \left( \Omega, L^2 \left( [0,T], L_2 \left( Q^{1/2}U, W \right) \right) \right)
\]
which implies the same is true of \( \Phi_n \). This yields, from the assumed estimates, an expression of the form where \( \delta > 0 \) is a suitable constant.
\[
\frac{1}{2} \langle Bu_n, u_n \rangle(t) - \frac{1}{2} \langle Bu_0, u_0 \rangle + \delta \int_0^t \| u_n(s) \|_V^p \, ds
\]
\[
\leq \lambda \int_0^t \langle Bu_n, u_n \rangle(s) \, ds + \int_0^t \langle f, u_n \rangle_{V',V} \, ds + \int_0^t c(s, \omega) \, ds
\]
\[
+ \int_0^t \langle B\Phi_n, \Phi_n \rangle_{L_2} \, ds + M_n(t)
\]
(77.0.13)
where \( c \in L^1([0,T] \times \Omega) \). Then taking expectations or using that part of the Itô formula,

\[
\frac{1}{2} E \left( \langle Bu_n, u_n \rangle (t) \right) + \delta E \left( \int_0^T \| u_n(s) \|^p_V \, ds \right) \\
\leq \lambda \int_0^t E \left( \langle Bu_n, u_n \rangle (s) \right) \, ds + \int_0^t E \left( \langle f, u_n \rangle_{V', V} \right) \, ds + C(\Phi, u_0)
\]

Then by Gronwall’s inequality and some simple manipulations,

\[
E \left( \langle Bu_n, u_n \rangle (t) \right) + E \left( \int_0^T \| u_n(s) \|^p_V \, ds \right) \leq C(T, f, u_0, \Phi)
\]

Then using obvious estimates and Gronwall’s inequality in (77.0.13), this yields an inequality of the form

\[
\langle Bu_n, u_n \rangle (t) \leq C(f, \lambda, c, u_0) + 2 \| B \| \int_0^t \| \Phi_n \|^2_{L_2} \, ds + M_n^* (t)
\]

where the random variable \( C(f, \lambda, c) \) is nonnegative and is integrable. Now \( t \to M_n^* (t) \) is increasing as is the integral on the right. Hence it follows that, modifying the constants,

\[
\sup_{s \leq t} \langle Bu_n, u_n \rangle (s) + \int_0^t \| u_n(s) \|^p_V \, ds \\
\leq C(f, \lambda, c, u_0) + 2 \| B \| \int_0^t \| \Phi_n \|^2_{L_2} \, ds + 2M_n^* (t) \quad (77.0.14)
\]

Next take the expectation of both sides and use the Burkholder Davis Gundy inequality along with the description of the quadratic variation of the martingale \( M_n (t) \). This yields

\[
E \left( \sup_{s \leq t} \langle Bu_n, u_n \rangle (s) \right) + E \left( \int_0^t \| u_n(s) \|^p_V \, ds \right) \\
\leq C + 2 \| B \| E \left( \int_0^t \| \Phi_n \|^2_{L_2} \, ds \right) \\
+ C \int_\Omega \left( \int_0^t \| Bu_n \|^2_{W'} \| \Phi_n \|^2_{L_2} \, ds \right)^{1/2} \, dP
\]

Now \( \| Bu \| = \sup_{\| v \| \leq 1} \langle Bu, v \rangle \leq \langle Bw, w \rangle^{1/2} \). Also \( \int_0^t \| \Phi_n \|^2_{L_2} \, ds \leq \int_0^T \| \Phi \|^2_{L_2} \, ds \) and so the above inequality implies

\[
E \left( \sup_{s \leq t} \langle Bu_n, u_n \rangle (s) \right) + E \left( \int_0^t \| u_n(s) \|^p_V \, ds \right) \\
\leq C(f, \lambda, c, \Phi) + C \int_\Omega \sup_{s \leq t} \langle Bu_n, u_n \rangle (s) \left( \int_0^t \| \Phi \|^2_{L_2} \right)^{1/2} \, dP
\]
Then adjusting the constants yields
\[
\frac{1}{2} E \left( \sup_{s \in [0,T]} \langle Bu_n, u_n \rangle (s) \right) + E \left( \int_0^T \| u_n (s) \|_{V'}^p \, ds \right)
\leq C + C \int_\Omega \int_0^T \| \Phi \|_{L^2}^2 \, dt \, dP \equiv C
\] (77.0.15)

If needed, you could use a stopping time to be sure that \( E \left( \sup_{s \in [0,T]} \langle Bu_n, u_n \rangle (s) \right) < \infty \) and then let it converge to \( \infty \).

From the integral equation,
\[
Bu_n (t) - Bu_m (t) + \int_0^t z_n - z_m \, ds = B \int_0^t (\Phi_n - \Phi_m) \, dW
\]

Then using the monotonicity assumption and the Ito formula,
\[
\frac{1}{2} \langle Bu_n - Bu_m, u_n - u_m \rangle (t) \leq \lambda \int_0^t \langle Bu_n - Bu_m, u_n - u_m \rangle \, ds
\]
\[
+ \int_0^t \langle B (\Phi_n - \Phi_m), \Phi_n - \Phi_m \rangle \, ds + \int_0^t (\Phi_n - \Phi_m) \circ J^{-1} B (u_n - u_m) \circ J \, dW
\]

and so, from Gronwall's inequality, there is a constant \( C \) which is independent of \( m, n \) such that
\[
\langle Bu_n - Bu_m, u_n - u_m \rangle (t) \leq CM_{nm} (t) \leq CM_{nm}^* (T) + C \int_0^t \| \Phi_n - \Phi_m \|_{L^2}^2 \, ds
\]
where \( M_{nm} \) refers to that local martingale on the right. Thus also
\[
\sup_{t \in [0, T]} \langle Bu_n - Bu_m, u_n - u_m \rangle (t) \leq CM_{nm} (t) \leq CM_{nm}^* (T) + C \int_0^T \| \Phi_n - \Phi_m \|_{L^2}^2 \, ds
\] (77.0.16)

Taking the expectation and using the Burkholder Davis Gundy inequality again in a similar manner to the above,
\[
E \left( \sup_{t \in [0, T]} \langle Bu_n - Bu_m, u_n - u_m \rangle (t) \right) \leq C \int_\Omega \int_0^T \| \Phi_n - \Phi_m \|_{L^2}^2 \, dt \, dP
\]

Now the right side converges to 0 as \( m, n \to \infty \) and so there is a subsequence, denoted with the index \( k \) such that whenever \( m > k \),
\[
E \left( \sup_{t \in [0, T]} \langle Bu_k - Bu_m, u_k - u_m \rangle (t) \right) \leq \frac{1}{2^k}
\]
Note how this implies
\[
\int_{\Omega} \int_0^T (B_{u_k} - B_{u_m}, u_k - u_m) \, dt \, dP \leq \frac{T}{2^k} \quad (77.0.17)
\]

Then consider the martingales \( M_k (t) \) considered earlier. One of these is of the form
\[
M_k = \int_0^t (\Phi_k \circ J^{-1})^* B_{u_k} \circ J dW
\]

Then by the Burkholder Davis Gundy inequality and modifying constants as appropriate,
\[
E \left( (M_k - M_{k+1})^* \right) \\
\leq C \int_{\Omega} \left( \int_0^T \left\| (\Phi_k \circ J^{-1})^* B_{u_k} - (\Phi_{k+1} \circ J^{-1})^* B_{u_{k+1}} \right\|^2 \, dt \right)^{1/2} \, dP \\
\leq C \int_{\Omega} \left( \int_0^T \left| (\Phi_k - \Phi_{k+1}) \right|^2 \langle B_{u_k}, u_k \rangle \, dt \right)^{1/2} \, dP \\
+ C \int_{\Omega} \left( \int_0^T \left| \Phi_{k+1} \right|^2 \langle B_{u_k} - B_{u_{k+1}}, u_k - u_{k+1} \rangle \, dt \right)^{1/2} \, dP \\
\leq C \int_{\Omega} \sup_t \left( \int_0^T \left| \Phi_k - \Phi_{k+1} \right|^2 \, dt \right)^{1/2} \, dP \\
+ C \int_{\Omega} \sup_t \left( \int_0^T \left| \Phi_{k+1} \right|^2 \langle B_{u_k} - B_{u_{k+1}}, u_k - u_{k+1} \rangle \, dt \right)^{1/2} \, dP \\
\leq C \left( \int_{\Omega} \sup_t \langle B_{u_k}, u_k \rangle \, dP \right)^{1/2} \left( \int_{\Omega} \int_0^T \left| \Phi_k - \Phi_{k+1} \right|^2 \, dt \, dP \right)^{1/2} \\
+ C \left( \int_{\Omega} \sup_t \langle B_{u_k} - B_{u_{k+1}}, u_k - u_{k+1} \rangle \, dP \right)^{1/2} \left( \int_{\Omega} \int_0^T \left| \Phi_{k+1} \right|^2 \, dt \, dP \right)^{1/2}
\]

From the above inequality, and after adjusting the constants, the above is no larger than an expression of the form \( C \left( \frac{1}{2} \right)^{k/2} \) which is a summable sequence. Then
\[
\sum_k \int_{\Omega} \sup_{t \in [0,T]} |M_k (t) - M_{k+1} (t)| \, dP < \infty
\]
Thus \( \{M_k\} \) is a Cauchy sequence in \( M^T_1 \) and so there is a continuous martingale \( M \) such that
\[
\lim_{k \to \infty} E \left( \sup_t |M_k(t) - M(t)| \right) = 0
\]
Taking a further subsequence if needed, one can also have
\[
P \left( \sup_t |M_k(t) - M(t)| > \frac{1}{k} \right) \leq \frac{1}{2^k}
\]
and so by the Borel Cantelli lemma, there is a set of measure zero such that off this set, \( \sup_t |M_k(t) - M(t)| \) converges to 0. Hence for such \( \omega \), \( M^T_\omega (T) \) is bounded independent of \( k \). Thus for \( \omega \) off a set of measure zero, \( E \left( \sup_s \|Bu_r(s)\|_{\hat{V}}^p \right) \leq C(\omega) \) implies that for such \( \omega \),
\[
\sup_{s \in [0,T]} \langle Bu_r, u_r \rangle (s) + \int_0^T \|u_r(s)\|_{\hat{V}}^p ds \leq C(\omega)
\]
where \( C(\omega) \) does not depend on the index \( r \), this for the subsequence just described which will be the sequence of interest in what follows. Using the boundedness assumption for \( A \), one also obtains an estimate of the form
\[
\sup_{s \in [0,T]} \langle Bu_r, u_r \rangle (s) + \int_0^T \|u_r(s)\|_{\hat{V}}^p ds + \int_0^T \|z_r\|_{\hat{V}'}^p \leq C(\omega) \quad (77.0.18)
\]
The idea here is to take weak limits converging to a function \( u \) and then identify \( z(\cdot,\omega) \) as being in \( A(u,\omega) \) but this will involve a difficulty. It will require a use of the above Ito formula and this will need \( u \) to be progressively measurable. By uniqueness, it would seem that this could be concluded by arguing that one does not need to take a subsequence due to uniqueness but the problem is that we won’t know the limit of the sequence is a solution unless we use the Ito formula. This is why we make the extra assumption that for \( z_i(\cdot,\omega) \in A(u_i,\omega) \) and for all \( \lambda \) large enough,
\[
\langle \lambda Bu_1 + z_1 - (\lambda Bu_2 + z_2), u_1 - u_2 \rangle \geq \delta \|u_1 - u_2\|_{\hat{V}}^q, \quad \alpha \geq 1 \quad (77.0.19)
\]
where here \( \hat{V} \) will be a Banach space such that \( V \) is dense in \( \hat{V} \) and the embedding is continuous. As mentioned, this is not surprising in the case of most interest where there is a Gelfand triple and \( B = I \). Then using the integral equation for \( r = p, q, p < q \) along with the conclusion of the Ito formula above,
\[
E \left( \int_0^T \|u_n - u_m\|_{\hat{V}}^p ds \right) \leq E \left( \int_0^T \|B\| \|\Phi_n - \Phi_m\|_{L_2}^2 ds \right) \equiv e(m,n)
\]
Hence, the right side converges to 0 as \( m, n \to \infty \) from the dominated convergence theorem. In particular,
\[
E \left( \int_0^T \|u_n - u_m\|_{\hat{V}}^p ds \right) \leq E \left( \int_0^T \|B\| \|\Phi_n - \Phi_m\|_{L_2}^2 ds \right) \equiv e(m,n) \quad (77.0.20)
\]
Then also
\[ P \left( \int_0^T ||u_n - u_m||_V^2 \, ds > \lambda \right) \leq \frac{e(m,n)}{\lambda} \]
and so there exists a subsequence, denoted by \( r \) such that
\[ P \left( \int_0^T ||u_r - u_{r+1}||_V^2 \, ds \leq 2^{-r} \right) < 2^{-r} \]
Thus, by the Borel Cantelli lemma, there is a further enlarged set of measure zero, still denoted as \( N \) such that for \( \omega \notin N \)
\[ \int_0^T ||u_r - u_{r+1}||_V^2 \, ds \leq 2^{-r} \]
for all \( r \) large enough. Hence, by the usual proof of completeness, for these \( \omega \),
\[ \{u_r(\cdot, \omega)\} \]
is Cauchy in \( L^\alpha \left([0,T];\hat{V}\right) \) and also \( u_r(t,\omega) \) converges to some \( u(t,\omega) \) pointwise in \( \hat{V} \) for a.e. \( t \). In addition, from \( \text{77.0.20} \) these functions are a Cauchy sequence in \( L^\alpha \left([0,T] \times \Omega;\hat{V}\right) \) with respect to the \( \sigma \) algebra of progressively measurable sets. Thus from Lemma \( \text{77.0.21} \) it can be assumed that for \( \omega \) off the set of measure zero, \( (t,\omega) \rightarrow u(t,\omega) \) is progressively measurable. From now on, this will be the sequence or a further subsequence. For \( \omega \notin N \), a set of measure zero and \( \text{77.0.18} \), there is a
further subsequence for which the following convergences occur as \( r \rightarrow \infty \).
\[ u_r \rightarrow u \text{ weakly in } V \quad (77.0.21) \]
\[ B(u_r) \rightarrow B(u) \text{ weakly in } V' \quad (77.0.22) \]
\[ z_r \rightarrow z \text{ weakly in } V' \quad (77.0.23) \]
\[ \left( B \left( u_r - \int_0^{(1)} \Phi_r dW \right) \right)' \rightarrow \left( B \left( u - \int_0^{(1)} \Phi dW \right) \right)' \text{ weakly in } V' \quad (77.0.24) \]
\[ \int_0^{(1)} \Phi_r dW \rightarrow \int_0^{(1)} \Phi dW \text{ uniformly in } C([0,T];W) \quad (77.0.25) \]
\[ Bu_r(t) \rightarrow Bu(t) \text{ weakly in } V' \quad (77.0.26) \]
\[ Bu(0) = Bu_0, \quad (77.0.27) \]
\[ Bu(t) = B(u(t)) \text{ a.e. } t \quad (77.0.28) \]
In addition to this, we can choose the subsequence such that
\[ \sup_r \sup_{t \neq s} \frac{||\int_s^t \Phi_r dW||}{|t-s|^{\gamma}} < C(\omega) < \infty \quad (77.0.29) \]
This is thanks to Corollary 77.0.1. The boundedness of the operator \( A \), in particular the given estimates, imply that \( z_r \) is bounded in \( L^p([0,T] \times \Omega, V') \). Thus a subsequence can be obtained which yields weak convergence of \( z_r \) in \( L^p([0,T] \times \Omega, V') \) and then Lemma 74.3.2 may be applied to conclude that off a set of measure zero, \( z \) is progressively measurable.

The claim 77.0.26 and 77.0.27 follow from the continuity of the evaluation map defined on \( X \), Theorem 75.2.2. The claim in 77.0.28 follows from 77.0.22 and the convergence 77.0.26. To see this, let \( \psi \in C_c^\infty(0,T) \).

\[
\int_0^T Bu(t) \psi(t) dt = \lim_{r \to \infty} \int_0^T B u_r(t) \psi(t) dt = \lim_{r \to \infty} \int_0^T B (u_r(t)) \psi(t) dt = \int_0^T B (u(t)) \psi(t) dt
\]

Since this is true for all such \( \psi \), it follows that \( Bu(t) = B (u(t)) \) for a.e. \( t \). Passing to a limit in the integral equation yields the following for \( \omega \) off a set of measure zero,

\[
Bu(t, \omega) - Bu_0(\omega) + \int_0^t z(s, \omega) ds = \int_0^t f(s, \omega) ds + B \int_0^t \Phi_n dW
\]

In the following claim, assume \( \Phi \in L^2 \left( \Omega, L^\infty \left( [0,T], \mathcal{L}_2 \left( Q^{1/2} \hat{V}, W \right) \right) \right) \)

**Claim:** \( \lim_{r \to \infty} \int_0^T (\Phi_r \circ J^{-1})^* Bu_r \circ J dW = \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW \) off a set of measure zero.

**Proof of claim:**

\[
E \left( \left| \int_0^T (\Phi_r \circ J^{-1})^* Bu_r \circ J dW - \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW \right|^2 \right) \\
\leq E \left( \left| \int_0^T (\Phi_r \circ J^{-1})^* Bu_r \circ J dW - \int_0^T (\Phi \circ J^{-1})^* Bu_r \circ J dW \right|^2 \right) \\
+ E \left( \left| \int_0^T (\Phi \circ J^{-1})^* Bu_r \circ J dW - \int_0^T (\Phi \circ J^{-1})^* Bu \circ J dW \right|^2 \right)
\]

Then, by the Burkholder Davis Gundy inequality,

\[
\leq \int_\Omega \left( \int_0^T \|\Phi_r - \Phi\|^2 \langle Bu_r, u_r \rangle \right)^{1/2} dP \\
+ \int_\Omega \left( \int_0^T \|\Phi\|^2 \langle Bu_r - Bu, u_r - u \rangle \right)^{1/2} dP \\
\leq \int_\Omega \sup_{t} \langle Bu_r(t), u_r(t) \rangle^{1/2} \left( \int_0^T \|\Phi_r - \Phi\|^2 dt \right)^{1/2} dP
\]
+ \int_{\Omega} \|\Phi_n\|_{L^\infty([0,T],L^2)} \left( \int_0^T (B_{u_r} - B_u, u_r - u) \right)^{1/2} dP \\
\leq \left( \int_{\Omega} \sup_t \langle B_{u_r}(t), u_r(t) \rangle dP \right)^{1/2} \left( \int_{\Omega} \int_0^T \|\Phi_r - \Phi\|^2 dt \right)^{1/2} \\
+ \left( \int_{\Omega} \|\Phi_n\|_{L^\infty([0,T],L^2)}^2 \right)^{1/2} \left( \int_{\Omega} \int_0^T (B_{u_r} - B_u, u_r - u) dt dP \right)^{1/2} \\
(77.0.30)

Letting the \(e_i\) be the special vectors of Theorem 75.2.19,

\[
\int_{\Omega} \int_0^T \langle B_{u_r} - B_u, u_r - u \rangle dt dP = \int_{\Omega} \int_0^T \sum_i \langle B_{u_r} - B_u, e_i \rangle^2 dt dP \\
= \int_{\Omega} \int_0^T \sum_i \liminf_{p \to \infty} \langle B_{u_r} - B_{u_p}, e_i \rangle^2 dt dP \\
\leq \liminf_{p \to \infty} \int_{\Omega} \int_0^T \sum_i \langle B_{u_r} - B_{u_p}, e_i \rangle^2 dt dP \\
= \liminf_{p \to \infty} \int_{\Omega} \int_0^T \langle B_{u_r} - B_{u_p}, u_r - u_p \rangle dt dP \\
\]

Now by 77.0.17, the last expression is no larger than \(T/2^r\) and so

\[
\int_{\Omega} \int_0^T \langle B_{u_r} - B_u, u_r - u \rangle dt dP \leq \frac{T}{2^r} \\

Then, from 77.0.18,

\[
E \left( \left\| \int_0^T (\Phi_r \circ J^{-1})^* B_{u_r} \circ JdW - \int_0^T (\Phi \circ J^{-1})^* B_u \circ JdW \right\| \right) \\
\leq \left( \int_{\Omega} \sup_t \langle B_{u_r}(t), u_r(t) \rangle dP \right)^{1/2} \left( \int_{\Omega} \int_0^T \|\Phi_r - \Phi\|^2 dt \right)^{1/2} + C \left( \frac{T}{2^r} \right)^{1/2} \\
\leq C \left( \int_{\Omega} \int_0^T \|\Phi_r - \Phi\|^2 dt \right)^{1/2} + C \left( \frac{T}{2^r} \right)^{1/2} < C2^{-r} + C \left( \frac{T}{2^r} \right)^{1/2}
\]

which clearly converges to 0 as \(r \to \infty\). Since the right side is summable, one obtains also pointwise convergence. This proves the claim.
From the above considerations using the space $\hat{V}$, it follows that this $u$ is the same as the one just obtained in the sense that for $\omega$ off $N$, the two are equal for a.e. $t$. Thus we take $u$ to be this common function. Hence there is a set of measure zero such that $(t, \omega) \to X_{N\cap u}(t, \omega)$ is progressively measurable in the above convergences. Also, this shows that we are taking $u \in L^p([0, T] \times \Omega; V)$. From the measurability of $u$, we can obtain a dense countable subset $\{t_k\}$ and an enlarged set of measure zero $N$ such that for $\omega \notin N, Bu_k(t_k, \omega) = B(u(t_k, \omega))$ and $Bu_r(t_k, \omega) = B(u_r(t_k, \omega))$ for all $t_k$ and $r$. This uses the same argument as in Lemma 77.0.31.

It remains to verify that $z(\cdot, \omega) \in A(u(\cdot, \omega), \omega)$. It follows from the above considerations that the Ito formula above can be used at will. Assume that for a given $\omega \notin N, Bu(T, \omega) = B(u(T, \omega))$, similar for $Bu_r$. If not, just do the following argument for all $T'$ close to $T$, letting $T'$ be in the dense subset just described. Then from the integral equation solved, and letting $\{e_i\}$ be the special set described in Theorem 77.0.14 and suppressing the dependence on $\omega$,

$$
\sum_{i=1}^{\infty} \langle Bu_r(T), e_i \rangle^2 - \sum_{i=1}^{\infty} \langle Bu_0, e_i \rangle + 2 \int_0^T \langle z_r, u_r \rangle \, ds
\]

$$

$$
= 2 \int_0^T \langle f, u_r \rangle \, ds + 2 \int_0^T (\Phi_r \circ J^{-1})^* Bu_r \circ JdW
$$

Thus also

$$
2 \int_0^T \langle z_r, u_r \rangle \, ds = - \sum_{i=1}^{\infty} \langle Bu_r(T), e_i \rangle^2 + \sum_{i=1}^{\infty} \langle Bu_0, e_i \rangle
\]

$$

$$
+ 2 \int_0^T \langle f, u_r \rangle \, ds + 2 \int_0^T (\Phi_r \circ J^{-1})^* Bu_r \circ JdW
$$

(77.0.31)

A similar formula to (77.0.31) holds for $u$. Thus

$$
2 \int_0^T \langle z, u \rangle \, ds = - \sum_{i=1}^{\infty} \langle Bu(T), e_i \rangle^2 + \sum_{i=1}^{\infty} \langle Bu_0, e_i \rangle
\]

$$

$$
+ 2 \int_0^T \langle f, u \rangle \, ds + 2 \int_0^T (\Phi \circ J^{-1})^* Bu \circ JdW
$$

It follows from (77.0.24) and the other convergences that

$$
\lim \sup_{r \to \infty} \int_0^T \langle z_r, u_r \rangle \, ds \leq \int_0^T \langle z, u \rangle \, ds
$$

Hence

$$
\lim \sup_{r \to \infty} \langle z_r, u_r - u \rangle_{\mathcal{V}', \mathcal{V}} \leq 0
$$

Now from the limit condition, for any $v \in \mathcal{V}$, there exists a $z(v) \in A(u(\cdot, \omega), \omega)$ such that

$$
\langle z, u - v \rangle_{\mathcal{V}', \mathcal{V}} \geq \lim \inf_{r \to \infty} \langle (z_r, u_r - u) + (z_r, u - v) \rangle
\]

$$

$$
\geq \lim \inf_{r \to \infty} \langle z_r, u_r - v \rangle \geq \langle z(v), u - v \rangle
$$
77.1. REPLACING $\Phi$ WITH $\sigma (u)$

The reason the limit condition applies is the estimate (77.0.29) and the convergence (77.0.24) which shows that

$$B \left( u_r - \int_0^{(r)} \Phi_r dW \right)$$

satisfy a Holder condition into $V'$. Then the estimate (77.0.29) implies that the $B \int_0^{(r)} \Phi_r dW$ are bounded in a Holder norm and so the same is true of the $Bu_r$.

Thus the situation of the limit condition (77.0.7) is obtained. Then it follows from separation theorems and the fact that $A (u (\cdot, \omega), \omega)$ is closed and convex that $z (\cdot, \omega) \in A (u (\cdot, \omega), \omega)$. This has proved the following Theorem.

**Theorem 77.0.7** Assume the above conditions, (77.0.1) - (77.0.7) along with the progressive measurability condition (77.0.2). Also assume there is at most one solution to (77.0.8) where

$$q (t, \cdot) \equiv \int_0^t \Phi dW$$

Then there exists a $\mathcal{P}$ measurable $u$ such that also $z$ is progressively measurable

$$Bu (t, \omega) - Bu_0 (\omega) + \int_0^t z (s, \omega) ds = \int_0^t f (s, \omega) ds + B \int_0^t \Phi dW$$

where for each $\omega$, $z (\cdot, \omega) \in A (u (\cdot, \omega), \omega)$. The function $Bu (t, \omega) = B (u (t, \omega))$ for a.e. $t$. Here

$$\Phi \in L^\alpha \left( [0, T] \times \Omega, L^2 \left( Q^{1/2} U, W \right) \right) \cap L^2 \left( \Omega, L^\infty \left( [0, T], L^2 \left( Q^{1/2} U, W \right) \right) \right), \alpha > 2$$

and $u_0 \in L^2 (\Omega, W)$, $f \in L^{p'} ([0, T] \times \Omega; V')$.

### 77.1 Replacing $\Phi$ With $\sigma (u)$

This has an easy generalization to the case where $\Phi (t, \omega)$ is replaced with $\sigma (t, \omega, u)$ for $u$ the solution to the integral equation. In this generalization, we assume that

$$(Bu, u) = \|u\|_W^2$$

For example, it could be $W = W'$ and $B = I$ which is the usual case of a Gelfand triple. We will strengthen the monotonicity assumption to for $z_i \in A (u_i, \omega)$, (77.1.32)

$$\lambda Bu_1 + z_1 - (\lambda Bu_2 + z_2), u_1 - u_2 \geq \delta \|u_1 - u_2\|_W^2$$

The case of most interest is the usual one where $V \subseteq W = W' \subseteq V'$, the case of a Gelfand triple in which $B$ is the identity. As to $\sigma$, the assumption is made that

$$\|\sigma (t, \omega, u)\|_W \leq C + C \|u\|_W$$

$$(\sigma (t, \omega, u_1) - \sigma (t, \omega, u_2))_{L^2 (Q^{1/2} U, W)} \leq K \|u_1 - u_2\|_W$$
CHAPTER 77. INCLUDING STOCHASTIC INTEGRALS

Of course it is also assumed that whenever \( u \) has values in \( W \) and is progressively measurable, \( (t, \omega) \rightarrow \sigma(t, \omega, u(t, \omega)) \) is also progressively measurable into \( \mathcal{L}_2\left(Q^{1/2}U, W\right) \).

Letting \( w_i \in L^2([0, T] \times \Omega, W) \cap L^2(\Omega, L^\infty([0, T], W)) \) each \( w_i \) being progressively measurable, the above assumptions and Theorem 77.0.7, there exists a solution \( u_i \) to the integral equation

\[
Bu_i(t, \omega) - Bu_0(\omega) + \int_0^t z_i(s, \omega) \, ds = \int_0^t f(s, \omega) \, ds + B \int_0^t \sigma(w_i) \, dW
\]

where we write \( (w_i) \) for short instead of \( (t; \omega, w_i) \). Then from the estimates,

\[
\langle Bu, u \rangle(t) - \langle Bu_0, u_0 \rangle + \delta \int_0^t \|u\|^2_W \, ds = 2 \int_0^t \langle f, u \rangle \, ds + C(b_3, b_4, b_5)
\]

\[
+ \lambda \int_0^t \langle Bu, u \rangle \, ds + \int_0^t \langle B\sigma(w), \sigma(w) \rangle_{\mathcal{L}_2} \, ds + 2M^*(t)
\]

\[
\leq 2 \int_0^t \langle f, u \rangle \, ds + C(b_3, b_4, b_5) + \lambda \int_0^t \langle Bu, u \rangle \, ds + \int_0^t \left( C + C\|w\|^2_W \right) \, ds + 2M^*(t)
\]

where \( M^*(t) = \sup_{s \leq t} |M(s)| \) and the quadratic variation of \( M \) is no larger than

\[
\int_0^t \|\sigma(w)\|^2 \langle B(u), u \rangle \, ds
\]

Then using Gronwall’s inequality, one obtains an inequality of the form

\[
\sup_{s \leq t} \langle Bu, u \rangle(s) \leq C + C \left( M^*(t) + \int_0^t \|w\|^2_W \right) \]

where \( C = C(u_0, f, \delta, \lambda, b_3, b_4, b_5, T) \) and is integrable. Then take expectation. By Burkholder Davis Gundy inequality and adjusting constants as needed,

\[
E \left( \sup_{s \leq t} \langle Bu, u \rangle(s) \right)
\]

\[
\leq C + C \int_\Omega \int_0^T \|w\|^2_W \, ds \, dP + C \int_\Omega \left( \int_0^T \|\sigma(w)\|^2 \langle B(u), u \rangle \, ds \right)^{1/2} \, dP
\]

\[
\leq C + C \int_\Omega \int_0^T \|w\|^2_W \, ds \, dP + C \int_\Omega \sup_{s \leq T} \langle Bu, u \rangle^{1/2} \left( \int_0^T \|\sigma(w)\|^2 \, ds \right)^{1/2} \, dP
\]

\[
\leq C + C \int_\Omega \int_0^T \|w\|^2_W \, ds \, dP + \frac{1}{2} \left( \sup_{s \leq T} \langle Bu, u \rangle(s) \right) + C \int_\Omega \int_0^T \left( C + C\|w\|^2_W \right)
\]
77.1. REPLACING $\Phi$ WITH $\sigma (U)$

Thus

$$E \left( \langle Bu, u \rangle (t) \right) \leq E \left( \sup_{s \in [0,T]} \langle Bu, u \rangle (s) \right) \leq C + C \int_0^T \|w\|_W^2 \, ds \, dP$$

and so

$$\|u\|_{L^2 ([0,T], L^\infty (\Omega, W))}^2 \leq C + C \int_0^T \|w\|_W^2 \, ds \, dP$$

which implies $u \in L^2 (\Omega, L^\infty ([0,T], W))$ and is progressively measurable.

Using the monotonicity assumption, there is a suitable $\lambda$ such that

$$\frac{1}{2} \langle B (u_1 - u_2), u_1 - u_2 \rangle (t) + r \int_0^t \|u_1 - u_2\|_W^2 \, ds$$

$$- \lambda \int_0^t \langle B (u_1 - u_2), u_1 - u_2 \rangle \, ds$$

$$- \int_0^t \langle B \sigma (u_1) - B \sigma (u_2), \sigma (u_1) - \sigma (u_2) \rangle_{L^2} \, ds \leq M^* (t)$$

where the right side is of the form $\sup_{s \in [0,t]} |M (s)|$ where $M (t)$ is a local martingale having quadratic variation dominated by

$$C \int_0^t \|\sigma (w_1) - \sigma (w_2)\|^2 \langle B (u_1 - u_2), u_1 - u_2 \rangle \, ds$$

(77.1.33)

Then by assumption and using Gronwall’s inequality, there is a constant $C = C (\lambda, K, T)$ such that

$$\langle B (u_1 - u_2), u_1 - u_2 \rangle (t) \leq CM^* (t)$$

Then also, since $M^*$ is increasing,

$$\sup_{s \in [0,t]} \langle B (u_1 - u_2), u_1 - u_2 \rangle (s) \leq CM^* (t)$$

Taking expectations and from the Burkholder Davis Gundy inequality,

$$E \left( \sup_{s \in [0,t]} \langle B (u_1 - u_2), u_1 - u_2 \rangle (s) \right)$$

$$\leq C \int_0^t \left( \int_0^t \|\sigma (w_1) - \sigma (w_2)\|^2 \langle B (u_1 - u_2), u_1 - u_2 \rangle \, ds \right)^{1/2} \, dP$$

$$\leq C \int_0^t \sup_{s \in [0,t]} \langle B (u_1 - u_2), u_1 - u_2 \rangle^{1/2} (s) \left( \int_0^t \|\sigma (w_1) - \sigma (w_2)\|^2 \, ds \right)^{1/2} \, dP$$
Then it follows after adjusting constants that there exists an inequality of the form

\[
E \left( \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle (s) \right) \leq CE \left( \int_0^t \| \sigma(w_1) - \sigma(w_2) \|^2 \, ds \right)
\]

Hence

\[
E \left( \sup_{s \in [0,t]} \langle B(u_1 - u_2), u_1 - u_2 \rangle (t) \right) \leq CK^2 E \left( \int_0^t \| w_1 - w_2 \|^2 \, ds \right)
\]

Thus, for each \( t \leq T \)

\[
\int \langle B(u_1 - u_2), u_1 - u_2 \rangle (t) \, dP \leq CK^2 E \left( \int_0^t \| w_1 - w_2 \|^2 \, ds \right)
\]

one can consider the map \( \psi(w) \equiv u \) as described above. The function \( t \to \langle B(\psi^n w_1 - \psi^n w_2), \psi^n w_1 - \psi^n w_2 \rangle (t) \) is continuous. So there exists \( t(\omega) \) where the maximum occurs. Then let \( t \) be this \( t(\omega) \). Then the above inequality implies

\[
E \left( \| \psi^n w_1 - \psi^n w_2 \|^2_{L^\infty([0,T],W)} \right)
= E \left( \langle B(\psi^n w_1 - \psi^n w_2), \psi^n w_1 - \psi^n w_2 \rangle (t) \right)
\leq CK^2 E \left( \int_0^t \| \psi^{n-1} w_1 - \psi^{n-1} w_2 \|^2 \, dt \right)
\]

\[
= CK^2 E \left( \int_0^t \langle B(\psi^{n-1} w_1 - \psi^{n-1} w_2), \psi^{n-1} w_1 - \psi^{n-1} w_2 \rangle (t_1) \, dt_1 \right)
\]

\[
\leq (CK^2)^2 E \left( \int_0^t \int_0^{t_1} \langle B(\psi^{n-2} w_1 - \psi^{n-2} w_2), \psi^{n-2} w_1 - \psi^{n-2} w_2 \rangle (t_2) \, dt_{2} \, dt_1 \right)
\]

\[
\cdots \leq (CK^2)^n E \left( \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} \langle B(w_1 - w_2), w_1 - w_2 \rangle (t_n) \, dt_n \cdots dt_1 \right)
\]

\[
\leq (CK^2)^n E \left( \sup_t \langle B(w_1 - w_2), w_1 - w_2 \rangle (t) \right) \frac{T^n}{n!} < \frac{1}{2} \| w_1 - w_2 \|^2_{L^2(\Omega, L^\infty([0,T],W))}
\]

provided \( n \) is sufficiently large. It follows that

\[
\| \psi^n w_1 - \psi^n w_2 \|^2_{L^2(\Omega, L^\infty([0,T],W))} \leq \frac{1}{2} \| w_1 - w_2 \|^2_{L^2(\Omega, L^\infty([0,T],W))}
\]

for all \( n \) sufficiently large. Hence, if one begins with \( w \in L^2(\Omega, L^\infty([0,T],W)) \cap L^2([0,T] \times \Omega, W) \), the sequence of iterates \( \{ \psi^n w \}_{n=1}^{\infty} \) must converge to some fixed point \( u \) in \( L^2(\Omega, L^\infty([0,T],W)) \). This \( u \) is automatically in \( L^2([0,T] \times \Omega, W) \) and is progressively measurable since each of the iterates is progressively measurable.
Appendix A

The Hausdorff Maximal Theorem

The purpose of this appendix is to prove the equivalence between the axiom of choice, the Hausdorff maximal theorem, and the well-ordering principle. The Hausdorff maximal theorem and the well-ordering principle are very useful but a little hard to believe; so, it may be surprising that they are equivalent to the axiom of choice. First it is shown that the axiom of choice implies the Hausdorff maximal theorem, a remarkable theorem about partially ordered sets.

A nonempty set is partially ordered if there exists a partial order, $\prec$, satisfying

$x \prec x$

and

if $x \prec y$ and $y \prec z$ then $x \prec z$.

An example of a partially ordered set is the set of all subsets of a given set and $\subseteq$. Note that two elements in a partially ordered sets may not be related. In other words, just because $x$, $y$ are in the partially ordered set, it does not follow that either $x \prec y$ or $y \prec x$. A subset of a partially ordered set, $\mathcal{C}$, is called a chain if $x$, $y \in \mathcal{C}$ implies that either $x \prec y$ or $y \prec x$. If either $x \prec y$ or $y \prec x$ then $x$ and $y$ are described as being comparable. A chain is also called a totally ordered set. $\mathcal{C}$ is a maximal chain if whenever $\mathcal{C}$ is a chain containing $\mathcal{C}$, it follows the two chains are equal. In other words $\mathcal{C}$ is a maximal chain if there is no strictly larger chain.

Lemma A.0.1 Let $\mathcal{F}$ be a nonempty partially ordered set with partial order $\prec$. Then assuming the axiom of choice, there exists a maximal chain in $\mathcal{F}$.

Proof: Let $\mathcal{X}$ be the set of all chains from $\mathcal{F}$. For $\mathcal{C} \in \mathcal{X}$, let

$S_{\mathcal{C}} = \{x \in \mathcal{F} \text{ such that } \mathcal{C} \cup \{x\} \text{ is a chain strictly larger than } \mathcal{C}\}$. 

2781
If $S_C = \emptyset$ for any $C$, then $C$ is maximal. Thus, assume $S_C \neq \emptyset$ for all $C \in \mathcal{X}$. Let $f(C) \in S_C$. (This is where the axiom of choice is being used.) Let

$$g(C) = C \cup \{f(C)\}.$$  

Thus $g(C) \supseteq C$ and $g(C) \setminus C = \{f(C)\}$ = a single element of $\mathcal{F}$. A subset $T$ of $\mathcal{X}$ is called a tower if

$$\emptyset \in T,$$

$$C \in T \text{ implies } g(C) \in T,$$

and if $S \subseteq T$ is totally ordered with respect to set inclusion, then

$$\cup S \in T.$$

Here $S$ is a chain with respect to set inclusion whose elements are chains.

Note that $\mathcal{X}$ is a tower. Let $\mathcal{T}_0$ be the intersection of all towers. Thus, $\mathcal{T}_0$ is a tower, the smallest tower. Are any two sets in $\mathcal{T}_0$ comparable in the sense of set inclusion so that $\mathcal{T}_0$ is actually a chain? Let $\mathcal{C}_0$ be a set of $\mathcal{T}_0$ which is comparable to every set of $\mathcal{T}_0$. Such sets exist, $\emptyset$ being an example. Let

$$\mathcal{B} \equiv \{D \in \mathcal{T}_0 : D \supseteq \mathcal{C}_0 \text{ and } f(C_0) \notin D\}.$$  

The picture represents sets of $\mathcal{B}$. As illustrated in the picture, $D$ is a set of $\mathcal{B}$ when $D$ is larger than $\mathcal{C}_0$ but fails to be comparable to $g(C_0)$. Thus there would be more than one chain ascending from $\mathcal{C}_0$ if $\mathcal{B} \neq \emptyset$, rather like a tree growing upward in more than one direction from a fork in the trunk. It will be shown this can't take place for any such $\mathcal{C}_0$ by showing $\mathcal{B} = \emptyset$.

This will be accomplished by showing $\mathcal{T}_0 \equiv \mathcal{T}_0 \setminus \mathcal{B}$ is a tower. Since $\mathcal{T}_0$ is the smallest tower, this will require that $\mathcal{T}_0 = \mathcal{T}_0$ and so $\mathcal{B} = \emptyset$.

**Claim:** $\mathcal{T}_0$ is a tower and so $\mathcal{B} = \emptyset$.

**Proof of the claim:** It is clear that $\emptyset \in \mathcal{T}_0$ because for $\emptyset$ to be contained in $\mathcal{B}$ it would be required to properly contain $\mathcal{C}_0$ which is not possible. Suppose $D \in \mathcal{T}_0$. The plan is to verify $g(D) \in \mathcal{T}_0$.

Case 1: $f(D) \in \mathcal{C}_0$. If $D \subseteq \mathcal{C}_0$, then since both $D$ and $\{f(D)\}$ are contained in $\mathcal{C}_0$, it follows $g(D) \subseteq \mathcal{C}_0$ and so $g(D) \notin \mathcal{B}$. On the other hand, if $D \supseteq \mathcal{C}_0$, then since $D \in \mathcal{T}_0$, $f(C_0) \in D$ and so $g(D)$ also contains $f(C_0)$ implying $g(D) \notin \mathcal{B}$. These are the only two cases to consider because $\mathcal{C}_0$ is comparable to every set of $\mathcal{T}_0$. 

Case 2: \( f(D) \notin C_0 \). If \( D \subseteq C_0 \) it can’t be the case that \( f(D) \notin C_0 \) because if this were so, \( g(D) \) would not compare to \( C_0 \).

\[
\begin{tikzpicture}
  \node (T) at (0,0) {f(D)};
  \node (C) at (0,-1.5) {f(C_0)};
  \node (D) at (0,-3) {f(D)};
  \draw[->] (T) to (C);
  \draw[->] (D) to (C);
\end{tikzpicture}
\]

Hence if \( f(D) \notin C_0 \), then \( D \supseteq C_0 \). If \( D = C_0 \), then \( f(D) = f(C_0) \in g(D) \) so \( g(D) \notin B \). Therefore, assume \( D \supseteq C_0 \). Then, since \( D \) is in \( T_0 \), \( f(C_0) \in D \) and so \( f(C_0) \in g(D) \). Therefore, \( g(D) \in T_0 \).

Now suppose \( S \) is a totally ordered subset of \( T_0 \) with respect to set inclusion. Then if every element of \( S \) is contained in \( C_0 \), so is \( \cup S \) and so \( \cup S \in T_0 \). If, on the other hand, some chain from \( S \), \( C \), contains \( C_0 \) properly, then since \( C \notin B \), \( f(C_0) \in C \subseteq \cup S \) showing that \( \cup S \notin B \) also. This has proved \( T_0 \) is a tower and since \( T_0 \) is the smallest tower, it follows \( T_0 = T_0 \). This has shown roughly that no splitting into more than one ascending chain can occur at any \( C_0 \) which is comparable to every set of \( T_0 \). Next it is shown that every element of \( T_0 \) has the property that it is comparable to all other elements of \( T_0 \). This is done by showing that these elements which possess this property form a tower.

Define \( T_1 \) to be the set of all elements of \( T_0 \) which are comparable to every element of \( T_0 \). (Recall the elements of \( T_0 \) are chains from the original partial order.)

Claim: \( T_1 \) is a tower.

Proof of the claim: It is clear that \( \emptyset \in T_1 \) because \( \emptyset \) is a subset of every set. Suppose \( C_0 \in T_1 \). It is necessary to verify that \( g(C_0) \in T_1 \). Let \( D \in T_0 \) (Thus \( D \subseteq C_0 \) or else \( D \supseteq C_0 \)) and consider \( g(C_0) = C_0 \cup \{ f(C_0) \} \). If \( D \subseteq C_0 \), then \( D \subseteq g(C_0) \) so \( g(C_0) \) is comparable to \( D \). If \( D \supseteq C_0 \), then \( D \supseteq g(C_0) \) by what was just shown (\( B = \emptyset \)). Hence \( g(C_0) \) is comparable to \( D \). Since \( D \) was arbitrary, it follows \( g(C_0) \) is comparable to every set of \( T_0 \). Now suppose \( S \) is a chain of elements of \( T_1 \) and let \( D \) be an element of \( T_0 \). If every element in the chain, \( S \), is contained in \( D \), then \( \cup S \) is also contained in \( D \). On the other hand, if some set, \( C \), from \( S \) contains \( D \) properly, then \( \cup S \) also contains \( D \). Thus \( \cup S \in T_1 \) since it is comparable to every \( D \in T_0 \).

This shows \( T_1 \) is a tower and proves therefore, that \( T_0 = T_1 \). Thus every set of \( T_0 \) compares with every other set of \( T_0 \) showing \( T_0 \) is a chain in addition to being a tower.

Now \( \cup T_0, g(\cup T_0) \in T_0 \). Hence, because \( g(\cup T_0) \) is an element of \( T_0 \), and \( T_0 \) is a chain of these, it follows \( g(\cup T_0) \subseteq \cup T_0 \). Thus

\[
\cup T_0 \supseteq g(\cup T_0) \supseteq \cup T_0,
\]

a contradiction. Hence there must exist a maximal chain after all. This proves the lemma.

If \( X \) is a nonempty set, \( \leq \) is an order on \( X \) if

\[
x \leq x,
\]
and if \( x, y \in X \), then

\[
\text{either } x \leq y \text{ or } y \leq x
\]

and

\[
\text{if } x \leq y \text{ and } y \leq z \text{ then } x \leq z.
\]

\( \leq \) is a well order and say that \((X, \leq)\) is a well-ordered set if every nonempty subset of \( X \) has a smallest element. More precisely, if \( S \neq \emptyset \) and \( S \subseteq X \) then there exists an \( x \in S \) such that \( x \leq y \) for all \( y \in S \). A familiar example of a well-ordered set is the natural numbers.

**Lemma A.0.2** The Hausdorff maximal principle implies every nonempty set can be well-ordered.

**Proof:** Let \( X \) be a nonempty set and let \( a \in X \). Then \( \{a\} \) is a well-ordered subset of \( X \). Let

\[
\mathcal{F} = \{ S \subseteq X : \text{there exists a well order for } S \}.
\]

Thus \( \mathcal{F} \neq \emptyset \). For \( S_1, S_2 \in \mathcal{F} \), define \( S_1 \prec S_2 \) if \( S_1 \subseteq S_2 \) and there exists a well order for \( S_2 \), \( \leq_2 \) such that

\[
(S_2, \leq_2) \text{ is well-ordered}
\]

and if

\[
y \in S_2 \setminus S_1 \text{ then } x \leq_2 y \text{ for all } x \in S_1,
\]

and if \( \leq_1 \) is the well order of \( S_1 \) then the two orders are consistent on \( S_1 \). Then observe that \( \prec \) is a partial order on \( \mathcal{F} \). By the Hausdorff maximal principle, let \( C \) be a maximal chain in \( \mathcal{F} \) and let

\[
X_\infty = \cup C.
\]

Define an order, \( \leq_1 \), on \( X_\infty \) as follows. If \( x, y \) are elements of \( X_\infty \), pick \( S \in C \) such that \( x, y \) are both in \( S \). Then if \( \leq_S \) is the order on \( S \), let \( x \leq y \) if and only if \( x \leq_S y \). This definition is well defined because of the definition of the order, \( \prec \). Now let \( U \) be any nonempty subset of \( X_\infty \). Then \( S \cap U \neq \emptyset \) for some \( S \in C \). Because of the definition of \( \leq \), if \( y \in S_2 \setminus S_1 \), \( S_1 \in C \), then \( x \leq y \) for all \( x \in S_1 \). Thus, if \( y \in X_\infty \setminus S \) then \( x \leq y \) for all \( x \in S \) and so the smallest element of \( S \cap U \) exists and is the smallest element in \( U \). Therefore \( X_\infty \) is well-ordered. Now suppose there exists \( z \in X \setminus X_\infty \). Define the following order, \( \leq_1 \), on \( X_\infty \cup \{z\} \).

\[
x \leq_1 y \text{ if and only if } x \leq y \text{ whenever } x, y \in X_\infty
\]

\[
x \leq_1 z \text{ whenever } x \in X_\infty.
\]

Then let

\[
\tilde{C} = \{ S \in C \text{ or } X_\infty \cup \{z\} \}.
\]

Then \( \tilde{C} \) is a strictly larger chain than \( C \) contradicting maximality of \( C \). Thus \( X \setminus X_\infty = \emptyset \) and this shows \( X \) is well-ordered by \( \leq \). This proves the lemma.

With these two lemmas the main result follows.
Theorem A.0.3 The following are equivalent.

The axiom of choice

The Hausdorff maximal principle

The well-ordering principle.

Proof: It only remains to prove that the well-ordering principle implies the axiom of choice. Let $I$ be a nonempty set and let $X_i$ be a nonempty set for each $i \in I$. Let $X = \bigcup\{X_i : i \in I\}$ and well order $X$. Let $f(i)$ be the smallest element of $X_i$. Then

$$f \in \prod_{i \in I} X_i.$$ 

A.1 The Hamel Basis

A Hamel basis is nothing more than the correct generalization of the notion of a basis for a finite dimensional vector space to vector spaces which are possibly not of finite dimension.

Definition A.1.1 Let $X$ be a vector space. A Hamel basis is a subset of $X$, $\Lambda$ such that every vector of $X$ can be written as a finite linear combination of vectors of $\Lambda$ and the vectors of $\Lambda$ are linearly independent in the sense that if $\{x_1, \ldots, x_n\} \subseteq \Lambda$ and

$$\sum_{k=1}^{n} c_k x_k = 0$$

then each $c_k = 0$.

The main result is the following theorem.

Theorem A.1.2 Let $X$ be a nonzero vector space. Then it has a Hamel basis.

Proof: Let $x_1 \in X$ and $x_1 \neq 0$. Let $\mathcal{F}$ denote the collection of subsets of $X$, $\Lambda$ containing $x_1$ with the property that the vectors of $\Lambda$ are linearly independent as described in Definition A.1.1 partially ordered by set inclusion. By the Hausdorff maximal theorem, there exists a maximal chain, $\mathcal{C}$ Let $\Lambda = \cup \mathcal{C}$. Since $\mathcal{C}$ is a chain, it follows that if $\{x_1, \ldots, x_n\} \subseteq \mathcal{C}$ then there exists a single $\Lambda' \in \mathcal{C}$ containing all these vectors. Therefore, if

$$\sum_{k=1}^{n} c_k x_k = 0$$

it follows each $c_k = 0$. Thus the vectors of $\Lambda$ are linearly independent. Is every vector of $X$ a finite linear combination of vectors of $\Lambda$?
Suppose not. Then there exists \( z \) which is not equal to a finite linear combination of vectors of \( \Lambda \). Consider \( \Lambda \cup \{ z \} \). If

\[
 cz + \sum_{k=1}^{m} c_k x_k = 0
\]

where the \( x_k \) are vectors of \( \Lambda \), then if \( c \neq 0 \) this contradicts the condition that \( z \) is not a finite linear combination of vectors of \( \Lambda \). Therefore, \( c = 0 \) and now all the \( c_k \) must equal zero because it was just shown \( \Lambda \) is linearly independent. It follows \( C \cup \{ \Lambda \cup \{ z \} \} \) is a strictly larger chain than \( C \) and this is a contradiction. Therefore, \( \Lambda \) is a Hamel basis as claimed. This proves the theorem.

A.2 Exercises

1. Zorn’s lemma states that in a nonempty partially ordered set, if every chain has an upper bound, there exists a maximal element, \( x \) in the partially ordered set. \( x \) is maximal, means that if \( x \prec y \), it follows \( y = x \). Show Zorn’s lemma is equivalent to the Hausdorff maximal theorem.

2. Show that if \( Y, Y_1 \) are two Hamel bases of \( X \), then there exists a one to one and onto map from \( Y \) to \( Y_1 \). Thus any two Hamel bases are of the same size.

3. Using the Baire category theorem of the chapter on Banach spaces show that any Hamel basis of a Banach space is either finite or uncountable.

4. Consider the vector space of all polynomials defined on \([0,1]\). Does there exist a norm, \( ||\cdot|| \) defined on these polynomials such that with this norm, the vector space of polynomials becomes a Banach space (complete normed vector space)?
